## 9. The convergence study: errors on a log-log plot

Now the main experiment. For each method we solve problem A from $t = 0$ to
$t = 1$ with $N = 2, 4, 8, \dots, 4096$ steps ($h = 1/N$) and record the error
$|y_N - e^{-1}|$ at the end time. The cell prints the table and fits a straight
line $\log e = \log C + p \log h$ through the points where the error is still
```

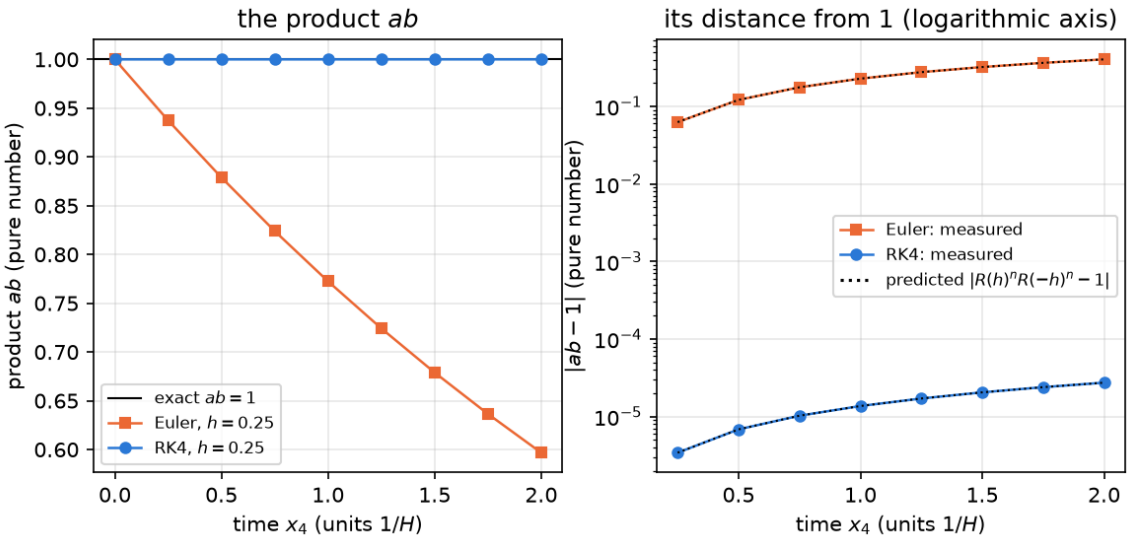

Figure 63: Left: the product ab of the 3-space factor and the extra-time factor of the previous figure, computed with the step $h = 0.25$; right: its distance $|ab - 1|$ from the exact value on a logarithmic axis. Horizontal axes the time x_4 in units of $1/H$; the product is a pure number. Exactly $ab = e^{x_4}e^{-x_4} = 1$ (black line). Euler (squares) multiplies the product by $1 - h^2 = 0.9375$ at every step and ends at $0.9375^8 = 0.597$; RK4 (circles) multiplies it by $1 + h^6/72 + h^8/576$ and ends within 3×10^{-5} of 1. The dotted lines are these predictions; the measured points lie on them. (Notebook 02a, figure 2.)

```
much larger than the rounding errors, with numpy's 'polyfit' (a least-squares
fit: the line with the smallest sum of squared vertical distances). The slope
$p$ is the measured order. The table also reproduces the classic numbers of
Euler's method, $(1 - h)^N$ = 0.250000, 0.316406, 0.343609, 0.356074 for
$h = 1/2, 1/4, 1/8, 1/16$.

## 11. Where rounding takes over

A smaller step is not always better. Every arithmetic operation rounds its result
to about 16 significant digits, and with $N$ steps about $N$ such rounding errors
add up. If they all had their largest size and the same sign, their total would
be about $N \epsilon$ times the size of the solution: a pessimistic bound. In
practice they have both signs and partly cancel, so the total stays far below
this bound, but it still grows with the number of steps $N = 1/h$, while the
truncation error of RK4 falls like $h^4$. The next cell runs RK4 for problem A
with up to $2^{18} = 262144$ steps (this takes about a second) and draws both
effects: the error falls along the slope-4 line until it reaches about
$10^{-16}$, then rises again, slowly and far below the bound.
```

In [10]:

```
N_LONG = [2 ** k for k in range(1, 19)]  # 2 ... 262144 steps

## 12. The step of the Revision Kohn-Sham solver, and the first missed term

The Rust program of the Revision record that solves the Kohn-Sham equations of
this book makes $G$ equal RK4 steps over an interval of length $L$ of the hidden
coordinate. The next cell reads $G$ and $L$ from the record
Revision/kohn_sham/results/parameters.json, together with the constants $A$ and
$H$ of the linear history $a_4 = A H x_4$ that section 8 used, and computes the
solver's step $h = L/G$. Here we use only this step, not the solver's equations.

How large is the error of a method of order $p$ at this step? For problem A we
can say it exactly to leading order. One step multiplies $y$ by $R(-h)$ instead
of the exact factor $e^{-h} = 1 - h + h^2/2 - h^3/6 + \dots$ Section 7 showed
that $R$ keeps the terms of this series up to the power $h^p$, so $R(-h)$
differs from $e^{-h}$ first by the missed term with the power $h^{p + 1}$:

$$R(-h) = e^{-h} - \frac{(-h)^{p+1}}{(p+1)!} + \dots$$

(the dots stand for terms with higher powers of $h$). Taking out the factor
$e^{-h}$ gives $R(-h) = e^{-h}(1 - q)$ with $q = e^{h}(-h)^{p+1}/(p+1)! + \dots
\approx (-h)^{p+1}/(p+1)!$, because $e^{h} = 1 + h + \dots$ changes only the
higher terms. After $N = 1/h$ steps (up to $t = 1$) the computed value is
$y_N = R(-h)^N = e^{-N h}(1 - q)^N = e^{-1}(1 - q)^N$. For a small $q$,
$(1 - q)^N \approx 1 - N q$ (the first two terms of the binomial theorem), and
$N q = (-1)^{p+1} h^{p}/(p+1)!$ (one factor $h$ cancels against $N = 1/h$). So

$$y_N - e^{-1} \approx e^{-1}\, \frac{(-1)^{p}\, h^{p}}{(p+1)!} .$$

Euler ($p = 1$) ends too LOW by $e^{-1} h/2$; the midpoint method ($p = 2$)
too HIGH by $e^{-1} h^2/6$; RK4 ($p = 4$) too high by $e^{-1} h^4/120$. The
cell solves problem A with the solver's step and compares the measured signed
errors with these predictions.

## 13. The oscillator: phase portrait and energy

Problem B as a system: the state is the vector $Y = (x, v)$ and the right-hand
side is $f(t, Y) = (v, -x)$. The exact solution goes round the circle
$x^2 + v^2 = 1$ in the $(x, v)$ plane, once every $2\pi$ time units. The next cell
solves it with the step $h = 0.2$ up to $t = 10$ (50 steps) with each method and
draws the three phase portraits. Section 7 predicts what happens to the energy
$E = (x^2 + v^2)/2$: each step multiplies it by $1 + h^2 = 1.04$ (Euler: the
point spirals outwards), by $1 + h^4/4 = 1.0004$ (midpoint) and by
$1 - h^6/72 + h^8/576 = 0.99999911$ (RK4).

The radius $\sqrt{x^2 + v^2} = \sqrt{2E}$ of the midpoint method grows only to
$\sqrt{1.0004^{50}} = 1.010$ in 50 steps, too little to be seen on the whole
circle. The right panel therefore zooms in on the last three points, at
$t = 9.6$, $9.8$ and $10$, where crosses mark the exact solution at the same
times. There a second error shows: each step
turns the point by a slightly wrong angle. With $w = x + i v$, one step
multiplies $w$ by $R(-ih)$, whose angle is $-\arg R(ih)$ (the angle of a complex
number is called its *argument*, $\arg$), while the exact factor $e^{-ih}$ turns
by $-h$. So after 50 steps the computed point runs ahead of the exact one,
clockwise, by the angle $50\,(\arg R(ih) - h)$; a negative value means that it
lags behind. The cell checks this prediction for the three methods.
```

```
The next cell follows the energy much longer, up to $t = 100$ (500 steps of
$h = 0.2$), and draws the relative energy error $|E_n/E_0 - 1|$ on a logarithmic
scale. After $n$ steps the energy is $E_0 q^n$, where $q$ is the factor per step,
so the relative error is $|q^n - 1|$. On a logarithmic vertical axis a straight
rising line means that the plotted quantity is multiplied by the same factor at
every step: that is Euler's $q^n$ once it is much larger than 1. For the midpoint
method and RK4, $q$ is so close to 1 that $q^n - 1 \approx n (q - 1)$: the error
grows in proportion to $n$, and on the logarithmic axis that is a curve that
bends over. The three methods differ by many powers of ten.

## 14. Richardson's rule: an error estimate without the exact answer

In real problems the exact answer is unknown. Suppose a method of order $p$ gives
$Y_h = Y + C h^p$ and $Y_{h/2} = Y + C h^p / 2^p$, where $Y$ is the exact value.
Subtracting the second from the first, $Y_h - Y_{h/2} = C h^p (1 - 2^{-p}) =
(C h^p / 2^p)(2^p - 1)$, so the error of the finer result is

$$Y_{h/2} - Y = \frac{C h^p}{2^p} = \frac{Y_h - Y_{h/2}}{2^p - 1},$$

which for RK4 ($p = 4$) is $(Y_h - Y_{h/2})/15$. Removing this estimated error
gives the *extrapolated* value $Y_{h/2} - (Y_h - Y_{h/2})/15 = (16 Y_{h/2} -
Y_h)/15$. The next cell tests both statements on problem A for $N = 2$ to 128
(finer run $2N$ steps). The rule assumes that the error is already close to
$C h^p$; the test shows from which $N$ on this is true.
```

## 16. What this notebook showed

- One step of size $h$ multiplies the solution of $y' = \lambda y$ by an
  amplification factor $R(\lambda h)$: $1 + z$ (Euler), $1 + z + z^2/2$
  (midpoint) and $1 + z + z^2/2 + z^3/6 + z^4/24$ (RK4), the first 2, 3 and 5
  terms of the series of $e^{z}$.
- Measured on a log-log plot, the error at a fixed end time is $C h^p$ with the
  orders $p = 1, 2, 4$; halving the step divides the error by 2, 4 and 16.
- RK4 reaches an error of about $10^{-16}$ with a few thousand steps; smaller
  steps make the result worse, because rounding errors add up, though they
  partly cancel and stay far below the pessimistic bound $N \epsilon$.
- The first term of the series of $e^{z}$ that a method misses predicts its
  error: for $y' = -y$ at $t = 1$ the error is $e^{-1}(-1)^p h^p/(p+1)!$. At the
  step $h = 1/300$ of the Revision Kohn-Sham solver (900 RK4 steps on an
  interval of length 3, read from its record) that is about $-6 \times 10^{-4}$
  for Euler, $7 \times 10^{-7}$ for the midpoint method and
  $4 \times 10^{-13}$ for RK4.
- The product of the inflating 3-space factor $e^{x_4}$ and the deflating
  extra-time factor $e^{-x_4}$ is exactly 1; Euler's method destroys this
  compensation (factor $1 - h^2$ per step), RK4 keeps it to $3 \times 10^{-5}$
  even with the coarse step $h = 0.25$ (factor $1 + h^6/72 + h^8/576$).
- For the oscillator the energy factors per step are exactly $1 + h^2$,
  $1 + h^4/4$ and $1 - h^6/72 + h^8/576$; the computed energies follow these
  predictions to 13 digits. The angle of $R(ih)$ predicts how far each method
  runs ahead of the exact solution (midpoint) or lags behind it (Euler, RK4).
- Richardson's rule $(Y_h - Y_{h/2})/(2^p - 1)$ estimates the error of the finer
  run $Y_{h/2}$ without the exact answer, and $(16 Y_{h/2} - Y_h)/15$ is a better
  value than either run.
```

2.11 Line-by-line walk-through of Notebook 02a

The notebook has fifteen code cells, In [1] to In [15]. This section explains every line of every one of them, in order. A line that starts with `#` is a **comment**: Python skips it; it is there for the reader. In the quoted code a line `...)` stands for the remaining lines of a long figure caption; every caption is printed in full under its figure in Section 2.10, and the paragraph "What Figure 02a.k shows" after the code says what to look for.

In [1], the set-up cell. Its first part is the complete run instructions of Section 2.9 again, as comment lines, so that the notebook file carries its own instructions. The code starts below the line of `=` signs that reads THE SET-UP. This part is the same in every notebook of the book except for one line (the notebook's name); we explain it here once, and the walk-throughs of Notebooks 02b, 02c and 02d refer back to this explanation.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it.

`json` reads and writes the text format JSON, in which the Revision record stores its results; `os` gives access to the computer's environment; `textwrap` breaks long text into lines; `from pathlib import Path` takes the single name `Path` out of the module `pathlib`. A `Path` is the address of a file or a folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell.

```
NOTEBOOK_ID = "02a"  # this notebook: chapter 02, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"02a"`. It is the only line of the set-up code that differs between notebooks.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description that Python stores but does not run. `Path.cwd()` is the folder in which the notebook runs and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with all of them. The `for` loop takes these folders one after the other; the operator `/` joins a folder and a name into a longer path; `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository and `return` hands it back. If none does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

REPO is the repository folder. os.environ holds the **environment variables** of the running program (named texts that the computer hands to it); .get(name, default) returns the value of TEXTBOOK_OUTPUT_ROOT if it is set and otherwise the default, the repository folder written as a string. When you run the notebook the variable is not set, so the notebook writes into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

repository_file("Revision/...") gives the full path of a repository file, for reading. output_file("Revision/...") gives the full path at which to write a file; path.parent.mkdir(parents=True, exist_ok=True) first creates the folder that will hold it (and any missing folder above it) and does nothing if it exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

say prints a text in lines of at most 89 characters; textwrap.fill breaks it at blanks, and every line after the first starts with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

matplotlib.rcdefaults() returns to matplotlib's built-in settings, so that a personal settings file cannot change the figures. plt.rcParams.update({...}) then sets, for every figure of the notebook, the size (7.0 by 4.2 inches), the size of the letters (10 points) and a faint grid (30 per cent opaque). The braces make a **dictionary**: pairs key: value.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with f is an **f-string**: every name in braces is replaced by its value, so CAPTION_FILE is "Revision/textbook/figures/02a.captions.json". FIGURE_NUMBERS and CAPTIONS

start as empty dictionaries. The last line writes an empty dictionary and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, ..., and a cell that is run twice keeps its numbers. The file name joins the notebook id, the number and the name, for example `02a_1_scale_factors.png`.

```
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`fig.savefig` writes the PNG file with 150 dots per inch, without an empty margin and without the program's name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory. The caption is stored, and the whole dictionary of captions is written into the captions file (`json.dumps` turns it into JSON text with sorted keys). `display(Image(...))` shows the saved picture below the cell; its `metadata` tells the book's tools which file it is. The last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order
```

```
def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
```

```
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection in square brackets). `check` is the function behind every check of the book. `condition` is either `True` or `False`; if it is false, `raise AssertionError(...)` stops the notebook with an error that names the check. Otherwise the name is appended to `PASSED` and the line PASS followed by the name is printed. `record=None` makes the third argument optional; a check that reproduces a Revision record passes the record's file and check name, and a second line names them.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a RESULT line; the expression in round brackets adds a blank and the unit when a unit is given and nothing otherwise. `all_checks_passed` prints the last line of the notebook; `len(PASSED)` is the number of checks that passed. The last statement prints the one output line of In [1].

In [2], the step rules and the solver.

```
import math  # exp, log10 and other functions of one number
from fractions import Fraction  # exact fractions such as 233/384

import numpy as np  # arrays (vectors) of numbers
import sympy as sp  # exact algebra with symbols
```

`math` holds the functions of single numbers (`math.exp`, `math.log2`, `math.factorial`). `Fraction` stores a fraction exactly as a numerator and a denominator, with no rounding. numpy (short name `np`) works with **arrays**, lists of numbers on which arithmetic acts entry by entry. sympy (short name `sp`) does exact algebra with symbols.

```
# One colour per method (a set that colour-blind readers can tell apart); every
# method also has its own line style and marker, so the plots read in grey too.
COLORS = {"euler": "#eb6834", "midpoint": "#1baf7a", "rk4": "#2a78d6",
          "exact": "#000000", "guide": "#8a8986"}
MARKERS = {"euler": "s", "midpoint": "^", "rk4": "o"}
LABELS = {"euler": "Euler", "midpoint": "midpoint", "rk4": "RK4"}
```

Three dictionaries fix, for each method, a colour (written as a hexadecimal code of red, green and blue: orange for Euler, green for the midpoint method, blue for RK4, black for exact curves, grey

for guide lines), a marker (`"s"` a square, `"^"` a triangle, `"o"` a circle) and the name printed in the legends.

```
def euler_step(f, t, y, h):
    """One Euler step: follow the slope at the start for the whole step."""
    return y + h * f(t, y)
```

This is Euler's rule $y_{n+1} = y_n + hf(t_n, y_n)$ of Section 2.4. The argument `f` is itself a function, the right-hand side; `f(t, y)` is its value, the slope.

```
def midpoint_step(f, t, y, h):
    """One midpoint step: use the slope at the estimated middle of the step."""
    k1 = f(t, y)  # the slope at the start
    k2 = f(t + h / 2, y + (h / 2) * k1)  # the slope at the estimated midpoint
    return y + h * k2
```

The midpoint rule, line for line as in Section 2.4.

```
def rk4_step(f, t, y, h):
    """One step of the classical fourth-order Runge-Kutta method (RK4)."""
    k1 = f(t, y)  # the slope at the start
    k2 = f(t + h / 2, y + (h / 2) * k1)  # at the midpoint, reached with k1
    k3 = f(t + h / 2, y + (h / 2) * k2)  # at the midpoint again, reached with k2
    k4 = f(t + h, y + h * k3)  # at the end, reached with k3
    return y + (h / 6) * (k1 + 2 * k2 + 2 * k3 + k4)  # weights 1 : 2 : 2 : 1
```

The RK4 rule of Section 2.4. Because these three functions use only `+`, `-`, `*` and `/`, they work unchanged with ordinary numbers, exact fractions, sympy symbols and numpy arrays (vectors); the notebook uses all four.

```
METHODS = {"euler": euler_step, "midpoint": midpoint_step, "rk4": rk4_step}
```

A dictionary from the name of each method to its step function, so that a loop can run all three.

```
def solve(step, f, y0, t_end, n):
    """n equal steps of the rule step from t = 0 to t = t_end.  Returns the list
    of the n + 1 times and the list of the n + 1 computed values."""
    h = t_end / n  # the step size
    times, values = [0 * h], [y0]
    y = y0
    for i in range(n):
        y = step(f, i * h, y, h)  # t_i = i h (no rounding drift of the time)
        times.append((i + 1) * h)
        values.append(y)
    return times, values
```

`solve` makes `n` steps of size $h = T/n$. The two lists start with the time 0 (written `0 * h`, so that it is a fraction when `h` is one) and the start value. `range(n)` counts $i = 0, 1, \ldots, n-1$; each pass makes one step from the time $t_i = ih$ and appends the new time and value. The time is computed as `i * h` rather than by adding `h` again and again, so that no rounding error piles up in the time.

```
def decay(t, y):
    """Problem A: y' = -y (an extra-time scale factor along the linear history)."""
    return -y

def growth(t, y):
    """y' = +y (the 3-space scale factor along the same history)."""
    return y

say("Three step rules and the solver are defined.")
```

The two right-hand sides of Section 2.2: `decay` for the deflating extra-time factor b and `growth` for the inflating 3-space factor a. The cell prints one line.

In [3], one step by hand.

```
h = Fraction(1, 2)  # the step size 1/2 as an exact fraction
one_step = {name: step(decay, 0, Fraction(1), h) for name, step in METHODS.items()}
```

`Fraction(1, 2)` is the exact fraction 1/2. The second line is a **dictionary comprehension**: for every pair (name, step function) of `METHODS.items()` it makes one step of Problem A from $y = 1$ and stores the result under the method's name. Because all numbers are fractions, the results are exact.

```
for name, value in one_step.items():
    say(f"{LABELS[name]:9} after one step: {str(value):8} = {float(value):.10f}")
say(f"exact     e^(-1/2)                 = {math.exp(-0.5):.10f}")
```

The loop prints each result as a fraction and as a decimal number; `{...:9}` pads the name to 9 characters so that the columns line up, and `{...:.10f}` writes 10 digits after the decimal point. The last line prints $e^{-1/2} = 0.6065306597$.

```
check(one_step["euler"] == Fraction(1, 2), "one Euler step of y' = -y gives 1/2")
check(one_step["midpoint"] == Fraction(5, 8), "one midpoint step gives 5/8")
check(one_step["rk4"] == Fraction(233, 384), "one RK4 step gives 233/384")
```

Three checks compare the exact results with the hand calculation of Section 2.4: 1/2, 5/8 and 233/384. The output shows 0.5, 0.625 and 0.6067708333 against the exact 0.6065306597.

In [4], the amplification factors.

```
z = sp.symbols("z")  # z = lambda h
hs = sp.symbols("h", positive=True)  # a positive step size, as a symbol
```

`sp.symbols` makes sympy symbols: letters that stand for any number. `z` is λh; `hs` is a step size h, declared positive.

```
def linear(t, y):
    """The test equation y' = z y."""
    return z * y

one = sp.Integer(1)  # sympy's exact 1 (so that 1/2 stays the exact fraction 1/2)
R = {name: sp.expand(step(linear, 0, one, one)) for name, step in METHODS.items()}
```

`linear` is the right-hand side of the test equation with $\lambda h = z$. With the step $h = 1$ (sympy's exact integer 1, so that `h / 2` is the exact fraction $1/2$ and not the rounded number 0.5) and the start value 1, one step of each method gives exactly $R(z)$; `sp.expand` multiplies out all brackets. This is the derivation of Section 2.5, done by the computer.

```
taylor = sp.series(sp.exp(z), z, 0, 6).removeO()  # 1 + z + ... + z^5/120
terms = sp.Poly(taylor, z).all_coeffs()[::-1]  # the coefficients 1, 1, 1/2, ...
```

`sp.series(sp.exp(z), z, 0, 6)` is the series of e^z around $z = 0$ up to the power z^5, followed by a symbol for the left-out terms, which `.removeO()` drops. `sp.Poly(...).all_coeffs()` lists the coefficients from the highest power down, and `[::-1]` reverses the list, so that `terms[k]` is the coefficient $1/k!$ of z^k.

```
for name, keep in (("euler", 2), ("midpoint", 3), ("rk4", 5)):
    partial = sum(terms[k] * z ** k for k in range(keep))  # the first keep terms
    say(f"R_{name}(z) = {sp.expand(R[name])}")
    check(sp.expand(R[name] - partial) == 0,
          f"R_{name}(z) equals the first {keep} terms of the series of e^z")
```

For each method, `partial` is the sum of the first `keep` terms of the series (z^k is written `z ** k` in Python). The cell prints $R(z)$ and checks that $R(z)$ minus that partial sum is exactly zero: Euler keeps 2 terms, the midpoint method 3, RK4 5. The output reads `z + 1`, `z**2/2 + z + 1` and `z**4/24 + z**3/6 + z**2/2 + z + 1`.

```
# The energy factor of one oscillator step, R(i h) R(-i h), as a polynomial in h.
ENERGY_FACTOR = {name: sp.expand(R[name].subs(z, sp.I * hs) *
                                 R[name].subs(z, -sp.I * hs))
                 for name in METHODS}
for name, factor in ENERGY_FACTOR.items():
    say(f"energy factor per step, {LABELS[name]:8}: {factor}")
check(ENERGY_FACTOR["euler"] == 1 + hs ** 2
      and ENERGY_FACTOR["midpoint"] == 1 + hs ** 4 / 4
      and ENERGY_FACTOR["rk4"] == 1 - hs ** 6 / 72 + hs ** 8 / 576,
      "energy factors 1 + h^2, 1 + h^4/4, 1 - h^6/72 + h^8/576")
```

`.subs(z, sp.I * hs)` replaces z by ih (`sp.I` is sympy's i). The product $R(ih)R(-ih)$, multiplied out, is the factor by which one step multiplies the oscillator's energy (Section 2.7). The check compares it with $1 + h^2$, $1 + h^4/4$ and $1 - h^6/72 + h^8/576$, the results of Section 2.7; the output prints the three polynomials.

In [5], the inflating and the deflating scale factor.

```
H_COARSE, STEPS = 0.25, 8  # step size and number of steps: t from 0 to 2
curves = {}
for name in ("euler", "rk4"):
    t_list, a_list = solve(METHODS[name], growth, 1.0, 2.0, STEPS)
    _, b_list = solve(METHODS[name], decay, 1.0, 2.0, STEPS)
    curves[name] = (np.array(t_list), np.array(a_list), np.array(b_list))
t_fine = np.linspace(0.0, 2.0, 201)  # many points for the exact curves
```

Two names are given two values at once: the step 0.25 and the number of steps 8 (so t runs from 0 to 2). For Euler and RK4 the loop solves $a' = a$ (`growth`) and $b' = -b$ (`decay`) from the value 1; `_` is the conventional name for a result that is not needed (the times, already known). The three lists are turned into numpy arrays and stored in `curves`. `np.linspace(0.0, 2.0, 201)` makes 201 equally spaced times for drawing the exact curves smoothly.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
left.plot(t_fine, np.exp(t_fine), color=COLORS["exact"], lw=1.0,
          label="exact $e^{t}$")
right.plot(t_fine, np.exp(-t_fine), color=COLORS["exact"], lw=1.0,
           label="exact $e^{-t}$")
```

`plt.subplots(1, 2, ...)` makes a figure with one row of two panels, named `left` and `right`. `.plot(xs, ys, ...)` draws a line through the points; `lw` is the line width and `label` the name in the legend (text between dollar signs is typeset as mathematics). The exact curves e^t and e^{-t} are drawn in black.

```
for name in ("euler", "rk4"):
    t_n, a_n, b_n = curves[name]
    style = dict(color=COLORS[name], marker=MARKERS[name], ms=5, lw=1.2)
    left.plot(t_n, a_n, **style, label=f"{LABELS[name]}, $h = 0.25$")
    right.plot(t_n, b_n, **style, label=f"{LABELS[name]}, $h = 0.25$")
```

For each method the three arrays are unpacked; `style` is a dictionary of drawing options (colour, marker, marker size `ms`, line width), and `**style` passes its entries as named arguments. The computed points of a go into the left panel, those of b into the right panel.

```
left.set_title("3-space factor $a$: $da/dx_4 = +a$ (inflates)")
right.set_title("extra-time factor $b$: $db/dx_4 = -b$ (deflates)")
for ax in (left, right):
    ax.set_xlabel("time $x_4$ (units $1/H$, $A = 1$)")
    ax.legend(fontsize=8)
left.set_ylabel("scale factor (pure number)")
save_figure(fig, "scale_factors",
            "Left: the 3-space scale factor $a = e^{x_4}$, which obeys "
            ...)
```

Titles, axis labels and legends; then `save_figure` saves the figure as `02a_1_scale_factors.png` with its caption (printed in full under Figure 02a.1 in Section 2.10; Python joins strings written next to each other into one). **What Figure 02a.1 shows:** in the left panel the Euler squares fall more and more below the growing exact curve, in the right panel they decay faster than the exact curve; the RK4 circles lie on both exact curves even with the coarse step 0.25.

```
a_euler, b_euler = curves["euler"][1][-1], curves["euler"][2][-1]
a_rk4, b_rk4 = curves["rk4"][1][-1], curves["rk4"][2][-1]
report("a(2): exact, Euler, RK4", f"{math.exp(2):.6f}, {a_euler:.6f}, {a_rk4:.6f}")
report("b(2): exact, Euler, RK4", f"{math.exp(-2):.6f}, {b_euler:.6f}, {b_rk4:.6f}")
```

`curves["euler"][1]` is the array of the Euler values of a, and `[-1]` its last entry (the value at $t = 2$). The two RESULT lines print $a(2)$: exact 7.389056, Euler 5.960464, RK4 7.388665, and $b(2)$: exact 0.135335, Euler 0.100113, RK4 0.135346.

```
check(abs(a_euler - 1.25 ** 8) < 1e-12 and abs(b_euler - 0.75 ** 8) < 1e-15,
      "Euler gives exactly 1.25^8 and 0.75^8 after 8 steps")
check(abs(a_rk4 / math.exp(2) - 1) < 1e-3 and abs(b_rk4 / math.exp(-2) - 1) < 1e-3,
      "RK4 with h = 0.25 is within 0.1 percent of e^2 and e^(-2)")
```

Euler multiplies by $R(0.25) = 1.25$ and $R(-0.25) = 0.75$ per step, so after 8 steps it must give $1.25^8 = 5.960464\ldots$ and $0.75^8 = 0.100113\ldots$; `abs` is the absolute value and `1e-12` means 10^{-12} (the allowed rounding). The second check confirms that RK4 is within 10^{-3}, that is 0.1 per cent, of the exact values.

In [6], the product of the two scale factors.

```
PRODUCT_FACTOR = {name: sp.expand(R[name].subs(z, hs) * R[name].subs(z, -hs))
                  for name in ("euler", "rk4")}
for name, factor in PRODUCT_FACTOR.items():
    say(f"factor of a b per step, {LABELS[name]:5}: {factor}")
check(PRODUCT_FACTOR["euler"] == 1 - hs ** 2
      and PRODUCT_FACTOR["rk4"] == 1 + hs ** 6 / 72 + hs ** 8 / 576,
      "R(h) R(-h) is 1 - h^2 (Euler) and 1 + h^6/72 + h^8/576 (RK4)")
```

sympy multiplies out $R(h)R(-h)$, the factor by which one step multiplies the product ab (Section 2.7), prints it and checks the two results of Section 2.7.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
left.axhline(1.0, color=COLORS["exact"], lw=1.0, label="exact $a b = 1$")
products = {}
```

A new figure with two panels; `axhline(1.0, ...)` draws a horizontal line at height 1, the exact product. `products` will hold the computed products.

```
for name in ("euler", "rk4"):
    t_n, a_n, b_n = curves[name]
    products[name] = a_n * b_n  # the computed product at every step
    factor = float(PRODUCT_FACTOR[name].subs(hs, sp.Rational(1, 4)))  # h = 1/4
    style = dict(color=COLORS[name], marker=MARKERS[name], ms=5, lw=1.2)
    left.plot(t_n, products[name], **style, label=f"{LABELS[name]}, $h = 0.25$")
    right.semilogy(t_n[1:], np.abs(products[name][1:] - 1.0), **style,
                   label=f"{LABELS[name]}: measured")
    predicted = np.abs(factor ** np.arange(1, STEPS + 1) - 1.0)
    right.semilogy(t_n[1:], predicted, ":", color=COLORS["exact"], lw=1.0)
```

For each method `a_n * b_n` multiplies the two arrays entry by entry. `factor` is the per-step factor at $h = 1/4$ (sympy's exact `Rational(1, 4)`), turned into an ordinary number by `float`. The left panel shows the product; the right panel shows its distance from 1, $|ab - 1|$, with `semilogy`, which draws the vertical axis logarithmically. `[1:]` leaves out the starting point, where the distance is exactly 0 and cannot be drawn on a logarithmic axis. `np.arange(1, STEPS + 1)` is the array $1, 2, \ldots, 8$, so `factor ** np.arange(...)` is the predicted product after n steps; the dotted black line (`":"`) draws its distance from 1.

```
right.plot([], [], ":", color=COLORS["exact"], label="predicted $|R(h)^n R(-h)^n - 1|$")
left.set_ylabel("product $a b$ (pure number)")
right.set_ylabel("$|a b - 1|$ (pure number)")
left.set_title("the product $a b$")
right.set_title("its distance from 1 (logarithmic axis)")
for ax in (left, right):
    ax.set_xlabel("time $x_4$ (units $1/H$)")
    ax.legend(fontsize=8)
save_figure(fig, "scale_factor_product",
            "Left: the product $a b$ of the 3-space factor and the extra-time "
            ...)
```

`right.plot([], [], ...)` draws nothing (two empty lists) but adds an entry for the dotted prediction to the legend. Then labels, titles, legends and the saved figure `02a_2_scale_factor_product.png`. **What Figure 02a.2 shows:** the Euler product falls step by step to $0.9375^8 = 0.597$; the RK4 product stays at 1 to within 3×10^{-5}; on the logarithmic right panel every measured point lies on its dotted prediction.

```
check(abs(products["euler"][-1] - (1 - H_COARSE ** 2) ** 8) < 1e-14,
      "Euler multiplies the product a b by 1 - h^2 per step")
rk4_factor = 1 + H_COARSE ** 6 / 72 + H_COARSE ** 8 / 576
check(abs(products["rk4"][-1] - rk4_factor ** 8) < 1e-14
      and abs(products["rk4"][-1] - 1) < 3e-5,
      "RK4 multiplies a b by 1 + h^6/72 + h^8/576 per step (within 3e-5 of 1)")
```

The final products must equal $(1 - h^2)^8$ (Euler) and $(1 + h^6/72 + h^8/576)^8$ (RK4) up to rounding, and the RK4 product must be within 3×10^{-5} of 1.

In [7], the convergence study.

```
EXACT_A = math.exp(-1.0)  # the exact value y(1) = e^(-1)
N_LIST = [2 ** k for k in range(1, 13)]  # 2, 4, ..., 4096 steps
ends = {name: [solve(step, decay, 1.0, 1.0, n)[1][-1] for n in N_LIST]
        for name, step in METHODS.items()}
errors = {name: np.abs(np.array(values) - EXACT_A) for name, values in ends.items()}
```

`EXACT_A` is $e^{-1} = 0.367879\ldots$. `N_LIST` is the list $2^1, 2^2, \ldots, 2^{12}$ (`range(1, 13)` counts 1 to 12). For each method and each N, `solve(...)[1][-1]` is the computed value at $t = 1$; `ends` stores the twelve end values of each method and `errors` their distances from e^{-1}.

```
say("     N        h     Euler y_N   error Euler  error midpoint     error RK4")
for i, n in enumerate(N_LIST):
```

```
    y_euler = ends["euler"][i]  # the Euler value y_N
    e_euler, e_mid, e_rk4 = (errors[name][i] for name in METHODS)  # three errors
    say(f"{n:6d} {1 / n:8.6f}  {y_euler:12.6f}  {e_euler:11.3e}  {e_mid:14.3e}  "
        f"{e_rk4:12.3e}")
```

`enumerate(N_LIST)` gives the position `i` together with each `n`. Each row prints N, $h = 1/N$, the Euler value and the three errors; `:6d` writes a whole number in 6 places, `:11.3e` a number in scientific notation with 3 digits after the point (for example `1.179e-01` means 1.179×10^{-1}). The table shows the Euler error halving and the midpoint error quartering from row to row, while the RK4 error falls 16-fold until it reaches about 10^{-16} at $N = 2048$.

```
h_array = 1.0 / np.array(N_LIST, dtype=float)
FIT = {"euler": slice(5, 12), "midpoint": slice(5, 12), "rk4": slice(1, 8)}
slopes = {}
for name, part in FIT.items():
    # polyfit(x, y, 1) returns (slope, intercept) of the best straight line.
    slope, _ = np.polyfit(np.log10(h_array[part]), np.log10(errors[name][part]), 1)
    slopes[name] = slope
    report(f"measured order of {LABELS[name]} (slope)", f"{slope:.4f}")
```

`h_array` holds the twelve step sizes. `FIT` chooses, for each method, the rows used for the straight-line fit: `slice(5, 12)` is the positions 5 to 11 ($N = 64$ to 4096), where the Euler and midpoint errors are already close to Ch^p; `slice(1, 8)` is the positions 1 to 7 ($N = 4$ to 256), where the RK4 error is not yet touched by rounding. `np.polyfit(x, y, 1)` fits the least-squares straight line through the points $(\log_{10} h, \log_{10} e)$ and returns its slope and its intercept. The measured orders are 1.0014, 2.0025 and 4.0439 (COMPUTED).

```
check([round(v, 6) for v in ends["euler"][:4]]
      == [0.25, 0.316406, 0.343609, 0.356074],
      "Euler values (1 - h)^N for h = 1/2, 1/4, 1/8, 1/16")
check(abs(slopes["euler"] - 1) < 0.02 and abs(slopes["midpoint"] - 2) < 0.02
      and abs(slopes["rk4"] - 4) < 0.1,
      "the measured orders are 1, 2 and 4")
```

The first check compares the first four Euler values, rounded to 6 digits, with $(1-h)^N$: $(1/2)^2 = 0.25$, $(3/4)^4 = 0.316406$, $(7/8)^8 = 0.343609$, $(15/16)^{16} = 0.356074$. The second requires the slopes to be within 0.02 of 1 and 2 and within 0.1 of 4.

In [8], the log-log plot.

```
fig, ax = plt.subplots(figsize=(7.0, 5.0))
for name in METHODS:
    ax.loglog(h_array, errors[name], color=COLORS[name], marker=MARKERS[name],
              ms=5, lw=1.2, label=f"{LABELS[name]} (measured slope "
              f"{slopes[name]:.2f})")
```

`ax.loglog` draws with both axes logarithmic. Each method's twelve errors are drawn against the step sizes, with the measured slope in the legend.

```
    order = {"euler": 1, "midpoint": 2, "rk4": 4}[name]
    anchor = FIT[name].stop - 1  # the last fitted point
    guide = errors[name][anchor] * (h_array / h_array[anchor]) ** order
    ax.loglog(h_array, guide, "--", color=COLORS["guide"], lw=0.9)
    ax.text(h_array[0] * 1.15, guide[0], f"slope {order}", fontsize=8,
            color=COLORS["guide"], va="center")
```

Still inside the loop: `order` is the expected order. `FIT[name].stop - 1` is the last position of the fitted rows. The guide line $\Delta_{\text{anchor}}(h/h_{\text{anchor}})^p$ (with Δ_{anchor} the error at that point) passes through that point with the exact slope p; it is drawn dashed (the line-style string of two hyphens) in grey, and `ax.text` writes "slope p" next to its right end (`va="center"` centres the text vertically).

```
ax.set_xlim(h_array[-1] / 1.5, h_array[0] * 3.0)
ax.set_ylim(1e-17, 1.0)
ax.set_xlabel("step size $h$ (time units)")
ax.set_ylabel("error $|y_N - e^{-1}|$ at $t = 1$")
ax.set_title("Problem A: error at the end time against the step size")
ax.legend(loc="lower right")
save_figure(fig, "convergence_loglog",
            "The error at the end time $t = 1$ of problem A, $y' = -y$, for the "
            ...)
check(errors["rk4"][7] < 1e-11 < errors["midpoint"][7] < errors["euler"][7],
      "at N = 256: RK4 error < 1e-11 < midpoint error < Euler error")
```

The axis ranges leave room for the slope labels; then labels, title, legend and the saved figure `02a_3_convergence_loglog.png`. The check is a chain of comparisons at position 7 ($N = 256$): the RK4 error 7.2×10^{-13} is below 10^{-11}, which is below the midpoint error 9.4×10^{-7}, which is below the Euler error 7.2×10^{-4}. **What Figure 02a.3 shows:** three straight lines of points, parallel to the guides of slopes 1, 2 and 4: the orders can be read off by eye. The RK4 line bends away at the bottom left, where rounding takes over.

In [9], what halving the step does.

```
ratios = {name: errors[name][:-1] / errors[name][1:] for name in METHODS}
```

`errors[name][:-1]` is the array without its last entry and `errors[name][1:]` without its first, so the quotient is $e(h)/e(h/2)$ for every pair of neighbouring rows.

```
fig, ax = plt.subplots()
for name in METHODS:
    shown = slice(0, 8) if name == "rk4" else slice(0, 11)  # RK4: before rounding
    ax.semilogx(N_LIST[1:][shown], ratios[name][shown], color=COLORS[name],
                marker=MARKERS[name], ms=5, lw=1.2, label=LABELS[name])
```

Each ratio is drawn against the N of the finer run (`N_LIST[1:]`), with a logarithmic horizontal axis (`semilogx`); for RK4 only the first 8 ratios (up to $N = 512$) are drawn, because later its errors are rounding noise.

```
for target in (2, 4, 16):
    # a dashed line from N = 3 to just beyond the data, its label to the right
    ax.hlines(target, 3.0, N_LIST[-1] * 1.4, ls="--", color=COLORS["guide"], lw=0.9)
    ax.text(N_LIST[-1] * 1.6, target, f"$2^{{{int(math.log2(target))}}}$ = "
            f"{target}", va="center", ha="left", fontsize=8, color=COLORS["guide"])
ax.set_xlim(3.0, N_LIST[-1] * 8.0)  # room on the right for the labels
```

Dashed horizontal guide lines at $2 = 2^1$, $4 = 2^2$ and $16 = 2^4$, each labelled; `math.log2(target)` is the power of 2, and in an f-string a doubled brace prints one brace, so the label reads $2^1 = 2$, and so on.

```
ax.set_xlabel("number of steps $N$ of the finer run ($h = 1/N$)")
ax.set_ylabel("error ratio $e(2h)/e(h)$")
ax.set_title("Halving the step divides the error by $2^p$")
ax.legend(loc="center left")
save_figure(fig, "error_ratios",
            "The factor by which the error of problem A at $t = 1$ shrinks when the "
            ...)
```

Labels, title, legend and the saved figure `02a_4_error_ratios.png`. **What Figure 02a.4 shows:** the three curves settle on the guide lines 2, 4 and 16, which is what order 1, 2 and 4 means.

```
ratio_euler = ratios["euler"][-1]  # the last ratio: N = 2048 -> 4096
ratio_midpoint = ratios["midpoint"][-1]
ratio_rk4 = ratios["rk4"][5]  # N = 64 -> 128, before rounding matters
report("ratio Euler at N = 4096", f"{ratio_euler:.5f}")
report("ratio midpoint at N = 4096", f"{ratio_midpoint:.5f}")
report("ratio RK4 at N = 128", f"{ratio_rk4:.4f}")
check(abs(ratio_euler - 2) < 0.001 and abs(ratio_midpoint - 4) < 0.001
      and abs(ratio_rk4 - 16) < 0.2,
      "halving h divides the errors by 2, 4 and 16")
```

The cell picks the last ratios of Euler and of the midpoint method and the RK4 ratio from $N = 64$ to 128, prints them (2.00020, 4.00073 and 16.1047; COMPUTED) and checks them against 2, 4 and 16.

In [10], where rounding takes over.

```
N_LONG = [2 ** k for k in range(1, 19)]  # 2 ... 262144 steps
rk4_long = np.array([abs(solve(rk4_step, decay, 1.0, 1.0, n)[1][-1] - EXACT_A)
                     for n in N_LONG])
h_long = 1.0 / np.array(N_LONG, dtype=float)
best = int(np.argmin(rk4_long))  # the position of the smallest error
EPS = 2.0 ** -52  # the machine epsilon
```

RK4 is run with $N = 2, 4, \ldots, 2^{18} = 262144$ steps and the eighteen errors at $t = 1$ are stored. `np.argmin` is the position of the smallest error. `EPS` is the machine epsilon 2^{-52} of Section 2.6.

```
fig, ax = plt.subplots()
shown = rk4_long > 0  # an error of exactly 0 cannot be drawn on a log axis
```

```
ax.loglog(h_long[shown], rk4_long[shown], color=COLORS["rk4"], marker="o", ms=5,
          lw=1.2, label="RK4: measured error")
ax.loglog(h_long, errors["rk4"][3] * (h_long / h_array[3]) ** 4, "--",
          color=COLORS["guide"], lw=0.9, label="truncation $C h^4$")
ax.loglog(h_long, EPS * EXACT_A / h_long, ":", color=COLORS["exact"], lw=1.0,
          label="rounding bound $N \\epsilon\\, e^{-1}$")
```

`rk4_long > 0` is an array of `True` and `False`; used as an index (`h_long[shown]`) it keeps only the entries where it is `True`. The measured errors are drawn as circles; the dashed line is the truncation error Ch^4 through the point $N = 16$; the dotted line is $N\epsilon e^{-1} = \epsilon e^{-1}/h$, the pessimistic bound of Section 2.6: the size that N rounding errors of relative size ϵ would reach only if all of them had their largest size and the same sign (in a Python string `\\` stands for one backslash, which matplotlib's mathematics needs).

```
ax.set_ylim(1e-18, 1e-2)
ax.set_xlabel("step size $h = 1/N$ (time units)")
ax.set_ylabel("error $|y_N - e^{-1}|$")
ax.set_title("RK4: truncation error against rounding error")
ax.legend(loc="upper center")
save_figure(fig, "rounding_floor",
            "The error of RK4 for problem A at $t = 1$ against the step size $h$ "
            ...)
report("smallest RK4 error", f"{rk4_long[best]:.3e} at N = {N_LONG[best]}")
report("RK4 error at N = 262144", f"{rk4_long[-1]:.3e}")
```

Axis range, labels, legend, the saved figure `02a_5_rounding_floor.png`, and two RESULT lines: the smallest error is 1.110×10^{-16} at $N = 4096$, and the error with 262144 steps is 5.773×10^{-15}, fifty times larger (COMPUTED).

```
bound = EPS * EXACT_A * np.array(N_LONG, dtype=float)  # the dotted line
below = bound[best + 1:] / rk4_long[best + 1:]  # past the minimum: bound / error
report("bound N eps e^-1 / measured error past the minimum (smallest, largest)",
       f"{below.min():.0f}, {below.max():.0f}")
```

`bound` holds the value $N\epsilon e^{-1}$ of the dotted line for each of the eighteen runs. `bound[best + 1:]` keeps the entries after the position of the smallest error (the runs with more steps than $N = 4096$); dividing them by the measured errors of the same runs gives, for each run, how many times its error lies below the bound. The RESULT line prints the smallest and the largest of these ratios, 524 and 3709 (COMPUTED). **What Figure 02a.5 shows:** coming from the right (large steps), the error falls along the slope-4 line; near 10^{-16} it stops; for smaller steps it grows again, but slowly and 524 to 3709 times below the dotted bound. The rounding errors partly cancel, so the bound gives only the scale of the worst case, not the error itself.

```
check(rk4_long[best] < 1e-15 and 256 <= N_LONG[best] <= 16384,
      "the smallest RK4 error is below 1e-15, reached at N between 256 and 16384")
check(rk4_long[-1] > 10 * max(rk4_long[best], EPS * EXACT_A)
      and rk4_long[-1] < 1e-11,
      "with 262144 steps rounding has made the error grow again")
check(np.all(below > 100),
      "past the minimum the error stays over 100 times below the bound N eps e^-1")
```

Three checks: the floor is below 10^{-15} and is reached at a moderate N; with the most steps the error is more than ten times the floor (so rounding has made it grow), yet still below 10^{-11}; and past the minimum every error lies more than 100 times below the bound $N\epsilon e^{-1}$. The checks use ranges rather than exact values, because rounding errors can differ in the last bits from one computer to another.

In [11], the step of the Revision solver and the first missed term.

```
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
parameters = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))
G_KS = parameters["numerics"]["rk4Steps"]  # the solver's number of RK4 steps
L_KS = parameters["physics"]["L_tipCutoff"]  # the length of its interval in y
A_KS = parameters["physics"]["historyA"]  # the constant A of a4 = A H x4
H_KS = parameters["physics"]["H"]  # the author's constant H
h_ks = L_KS / G_KS  # the solver's step
```

The cell reads the Revision record of the Kohn-Sham solver's parameters: `read_text` reads the file as text and `json.loads` turns the JSON text into nested dictionaries. `parameters["numerics"]["rk4Steps"]` is the entry `rk4Steps` inside the part `numerics`: the number $G = 900$ of RK4 steps. From the part `physics` come the length $L = 3$ of the interval in the hidden coordinate (the tip cut-off), the constant A of the history and the author's H. The solver's step is $h = L/G$.

```
report("solver: RK4 steps G, interval length L, step h = L/G",
       f"{G_KS}, {L_KS}, {h_ks:.10f}")
report("linear history a4 = A H x4 of the record: A, H", f"{A_KS}, {H_KS}")
check(G_KS == 900 and L_KS == 3.0 and A_KS == 1.0 and H_KS == 1.0,
      "the solver makes 900 RK4 steps on L = 3 (h = 1/300); the history has A = H = 1",
      record=f"{PARAMETERS}, keys rk4Steps, L_tipCutoff, historyA and H")
```

The two RESULT lines print 900, 3.0, 0.0033333333 and 1.0, 1.0; the check confirms the values and names the record and its keys in its second line (COMPUTED: reproduces `Revision/kohn_sham/results/parameters.json`, keys `rk4Steps`, `L_tipCutoff`, `historyA` and `H`).

```
N_KS = round(1.0 / h_ks)  # 300 steps of h = 1/300 reach t = 1
ORDER = {"euler": 1, "midpoint": 2, "rk4": 4}  # the orders measured in section 9
agreement = []
```

`round(1.0 / h_ks)` is the whole number 300: so many steps of the solver's size reach $t = 1$. `ORDER` holds the orders, and `agreement` will collect the ratios of measured to predicted errors.

```
for name, step in METHODS.items():
    p = ORDER[name]
    measured = solve(step, decay, 1.0, 1.0, N_KS)[1][-1] - EXACT_A  # signed error
    predicted = EXACT_A * (-1) ** p * h_ks ** p / math.factorial(p + 1)
    agreement.append(measured / predicted)
    say(f"{LABELS[name]:9} with h = 1/{N_KS}: error {measured:+.4e}, predicted "
        f"{predicted:+.4e}, ratio {measured / predicted:.5f}")
check(all(abs(ratio - 1) < 0.01 for ratio in agreement),
      "at the solver's step the errors are e^(-1) (-1)^p h^p/(p+1)! within 1 %")
```

For each method the signed error at $t = 1$ with 300 steps is measured (this time without `abs`, so that its sign is kept), and the prediction $e^{-1}(-1)^p h^p/(p+1)!$ of Section 2.6 is computed (`math.factorial(p + 1)` is $(p+1)!$, and `(-1) ** p` is $(-1)^p$). The quotient of the two is appended to `agreement`. The printed lines show Euler -6.1399×10^{-4} against the predicted -6.1313×10^{-4}, the midpoint method $+6.8296 \times 10^{-7}$ against $+6.8126 \times 10^{-7}$, and RK4 $+3.7920 \times 10^{-13}$ against $+3.7848 \times 10^{-13}$; the ratios are 1.00139, 1.00250 and 1.00190 (COMPUTED). `all(...)` is true when every entry of the sequence in its brackets is true, so the check requires every ratio to be within 1 per cent of 1. The predicted signs (Euler too low, the other two too high) and sizes are right, and at the Revision solver's step RK4 is about a billion times more accurate than Euler.

In [12], the oscillator: phase portrait and energy.

```
def oscillator(t, Y):
    """Problem B: x' = v, v' = -x for the state Y = (x, v)."""
    return np.array([Y[1], -Y[0]])

Y0 = np.array([1.0, 0.0])  # x(0) = 1, v(0) = 0
H_OSC = 0.2  # the step size
portraits = {name: np.array(solve(step, oscillator, Y0, 10.0, 50)[1])
             for name, step in METHODS.items()}
```

The state is a numpy array `Y` with `Y[0]` $= x$ and `Y[1]` $= v$ (positions are counted from 0), and the right-hand side returns the array $(v, -x)$. The start is $(1, 0)$. Each method makes 50 steps of $h = 0.2$ up to $t = 10$; the list of the 51 states becomes an array with 51 rows and 2 columns.

```
angle = np.linspace(0.0, 2 * np.pi, 400)
t_n = H_OSC * np.arange(51)  # the times 0, 0.2, ..., 10 of the 51 points
fig, (whole, zoom) = plt.subplots(1, 2, figsize=(10.0, 5.2))
```

400 angles from 0 to 2π will give the exact circle $x = \cos t$, $v = -\sin t$. `t_n` holds the 51 times $t_n = 0.2\,n$ of the computed points. The figure has two panels side by side: `whole` (left) for the whole portrait and `zoom` (right) for a close-up.

```
for name in METHODS:  # left panel: the whole portrait of each method
    whole.plot(portraits[name][:, 0], portraits[name][:, 1], color=COLORS[name],
               marker=MARKERS[name], ms=3, lw=0.9,
               label=f"{LABELS[name]}, $h = 0.2$, 50 steps")
for name in ("midpoint", "rk4"):  # right panel: the last three points only
    zoom.plot(portraits[name][48:, 0], portraits[name][48:, 1], ls="none",
              color=COLORS[name], marker=MARKERS[name], ms=8, label=LABELS[name])
```

`[:, 0]` is the first column of the array (all the positions) and `[:, 1]` the second (all the velocities). The left panel draws each method's whole path, points joined by lines. The right panel draws only the rows from position 48 on (`[48:, 0]`), the last three points at $t = 9.6$, 9.8 and 10, of the midpoint method and RK4, as large markers without lines (`ls="none"`); Euler's points are far outside the window of this panel.

```
for ax in (whole, zoom):  # the exact circle, dashed, drawn on top (zorder 5)
    ax.plot(np.cos(angle), -np.sin(angle), "--", color=COLORS["exact"], lw=0.9,
            zorder=5, label="exact circle $x^2 + v^2 = 1$")
    ax.set_aspect("equal")
    ax.set_xlabel("position $x$")
    ax.set_ylabel("velocity $v$")
whole.plot([1.0], [0.0], "o", color=COLORS["exact"], ms=6, zorder=6)  # the start
zoom.plot(np.cos(t_n[48:]), -np.sin(t_n[48:]), "x", color=COLORS["exact"], ms=9,
          zorder=6, label="exact solution, same times")
```

In both panels the exact circle is drawn as a thin dashed black line. `zorder=5` puts it on top of the coloured paths (a drawing with a larger `zorder` covers one with a smaller), so it stays visible where the RK4 path lies on it. `set_aspect("equal")` makes one unit equally long on both axes, so that the circle looks round. The black dot marks the start; in the right panel black crosses mark the exact solution $(\cos t_n, -\sin t_n)$ at the same three times.

```
zoom.set_xlim(-1.12, -0.74)  # a window round the points at t = 9.6, 9.8 and 10
zoom.set_ylim(0.12, 0.66)
whole.set_title("Phase portrait of $d^2x/dt^2 = -x$ up to $t = 10$")
zoom.set_title("Zoom: the points at $t = 9.6$, $9.8$, $10$")
whole.legend(loc="lower left", fontsize=8)
zoom.legend(loc="upper left", fontsize=8)
save_figure(fig, "phase_portrait",
            "Phase portrait of the oscillator $d^2x/dt^2 = -x$ started at $x = 1$, "
            ...)
```

The right panel shows only the window $-1.12 \le x \le -0.74$, $0.12 \le v \le 0.66$ around the last three points. Titles, legends, and the figure is saved as `02a_6_phase_portrait.png`. **What Figure 02a.6 shows:** on the left, Euler's path spirals outwards (each step multiplies the energy by 1.04), while the midpoint and RK4 paths stay close to the dashed circle; on this scale they are hard to tell apart, because the midpoint radius grows only to $\sqrt{1.0004^{50}} = 1.010$. The zoom on the right separates them: the RK4 circles sit on the exact crosses, while the midpoint triangles have run ahead along the circle and lie slightly outside it.

```
for name in METHODS:
    energy = 0.5 * (portraits[name][:, 0] ** 2 + portraits[name][:, 1] ** 2)
    factor = float(ENERGY_FACTOR[name].subs(hs, sp.Rational(1, 5)))  # at h = 0.2
    predicted = 0.5 * factor ** np.arange(51)  # E_0 times the factor n times
    report(f"energy after 50 steps, {LABELS[name]}", f"{energy[-1]:.10f}")
    check(np.max(np.abs(energy / predicted - 1)) < 1e-13,
          f"{LABELS[name]}: E_n = E_0 times the exact factor to the power n")
```

For each method the energy $E = (x^2 + v^2)/2$ is computed at all 51 points; the exact per-step factor of In [4] is evaluated at $h = 1/5$, and the prediction is $E_n = \frac{1}{2}q^n$ for $n = 0, \ldots, 50$. The energies after 50 steps are 3.5533416731 (Euler), 0.5100986302 (midpoint) and 0.4999778894 (RK4); the checks require every computed energy to equal its prediction to a relative 10^{-13}, and they pass: the energy drift of each method is exactly the one derived in Section 2.7.

```
angle_agrees = []
for name in METHODS:
```

```
    x_end, v_end = portraits[name][-1]  # the point at t = 10
    # the clockwise angle from the exact point e^(-10 i) to the computed one
    ahead = -np.angle(complex(x_end, v_end) * np.exp(10j))
```

The last part measures the angle error that the zoom shows. The **argument** $\arg w$ of a complex number w is its angle: the angle between the positive real axis and the arrow from 0 to w, counted anticlockwise; `np.angle` computes it, as a number between $-\pi$ and π. Write the computed point at $t = 10$ as $w = x + iv$ (`complex(x_end, v_end)`; `[-1]` is the last row). The exact solution is $x = \cos t$, $v = -\sin t$, that is $w = \cos t - i \sin t = e^{-it}$, so the exact point at $t = 10$ is e^{-10i}. In Python `10j` is the imaginary number $10i$, and `np.exp(10j)` is e^{10i}. Multiplying w by e^{10i} turns it back by the exact angle, so the argument of the product is the angle from the exact point to the computed one, counted anticlockwise; the minus sign counts it clockwise, the direction in which the point runs. So `ahead` is positive when the computed point has run ahead of the exact one and negative when it lags behind.

```
    R_ih = complex(R[name].subs(z, sp.I * sp.Rational(1, 5)))  # R(ih), h = 0.2
    predicted_ahead = 50 * (np.angle(R_ih) - 0.2)  # 50 (arg R(ih) - h)
```

The prediction. `R[name]` is the amplification factor of In [4], a polynomial in `z`; `.subs(z, sp.I * sp.Rational(1, 5))` puts in $z = ih$ with $h = 1/5$ (`sp.I` is sympy's i), and `complex(...)` turns the exact sympy number into an ordinary complex number. One step multiplies w by $R(-ih)$ (Section 2.7). Its argument is $-\arg R(ih)$, because $R(-ih)$ is the complex conjugate of $R(ih)$ (the coefficients of R are real) and conjugation reflects a point in the real axis, which reverses its angle. The exact factor e^{-ih} has the argument $-h$. The arguments of a product add up, so after 50 steps the computed point has turned by $-50 \arg R(ih)$ and the exact one by $-50h$; the computed point is ahead, clockwise, by $50\,(\arg R(ih) - h)$.

```
    report(f"t = 10, {LABELS[name]}: radius, angle ahead of the exact point",
           f"{math.hypot(x_end, v_end):.4f}, {ahead:+.3e} rad")
    angle_agrees.append(abs(ahead - predicted_ahead) < 1e-12)
check(all(angle_agrees),
      "at t = 10 each point is ahead of the exact one by 50 (arg R(ih) - h)")
```

`math.hypot(x_end, v_end)` is the radius $\sqrt{x^2 + v^2}$ of the end point. The three RESULT lines give the radius and the angle ahead: Euler 2.6658 and -1.302×10^{-1} rad (it lags behind by 0.13 rad); midpoint 1.0100 and $+6.586 \times 10^{-2}$ rad (ahead by 0.066 rad, the shift seen in the zoom); RK4 1.0000 and -1.314×10^{-4} rad (COMPUTED). The RK4 value agrees with the lag of $\omega^5/120$ per step derived in Section 2.24: $50 \cdot 0.2^5/120 = 1.33 \times 10^{-4}$ to leading order. The check requires each measured angle to equal its prediction within 10^{-12}, and it passes.

In [13], the energy over a long time.

```
long_runs = {name: np.array(solve(step, oscillator, Y0, 100.0, 500)[1])
             for name, step in METHODS.items()}
fig, ax = plt.subplots()
t_long = np.linspace(0.0, 100.0, 501)
drift = {}
for name in METHODS:
```

```
    energy = 0.5 * (long_runs[name][:, 0] ** 2 + long_runs[name][:, 1] ** 2)
    drift[name] = np.abs(energy / 0.5 - 1.0)
    ax.semilogy(t_long[1:], drift[name][1:], color=COLORS[name], lw=1.4,
                label=LABELS[name])
```

Now 500 steps of $h = 0.2$, up to $t = 100$. For each method the relative energy error $|E_n/E_0 - 1|$ (with $E_0 = 0.5$) is drawn on a logarithmic vertical axis against the 500 times after the start.

```
ax.set_xlabel("time $t$ (arbitrary units)")
ax.set_ylabel("relative energy error $|E_n/E_0 - 1|$")
ax.set_title("Energy drift of the oscillator, step $h = 0.2$")
ax.legend()
save_figure(fig, "energy_drift",
            "The relative error of the oscillator energy, $|E_n/E_0 - 1|$, on a "
            ...)
report("energy errors at t = 100 (Euler, midpoint, RK4)",
       ", ".join(f"{drift[name][-1]:.3e}" for name in METHODS))
check(drift["euler"][-1] > 1e8 and 0.1 < drift["midpoint"][-1] < 0.3
      and drift["rk4"][-1] < 5e-4,
      "after 500 steps: Euler energy off by > 1e8, midpoint by 10-30 %, RK4 < 5e-4")
```

Labels, title, legend and the saved figure `02a_7_energy_drift.png`. `", ".join(...)` writes the three final errors separated by commas: 3.286×10^8 (Euler: $1.04^{500} - 1$), 0.2214 (midpoint: $1.0004^{500} - 1$) and 4.421×10^{-4} (RK4: $1 - 0.99999911^{500}$). The check confirms these sizes. **What Figure 02a.7 shows:** the Euler curve is a straight rising line (the same factor at every step makes a straight line on a logarithmic axis); the midpoint and RK4 curves bend over, because their factors are so close to 1 that $q^n - 1 \approx n(q - 1)$ grows only in proportion to n; the three methods differ by many powers of ten.

In [14], Richardson's rule.

```
N_R = [2 ** k for k in range(1, 8)]  # the coarse runs: 2 ... 128 steps
coarse = np.array([solve(rk4_step, decay, 1.0, 1.0, n)[1][-1] for n in N_R])
fine = np.array([solve(rk4_step, decay, 1.0, 1.0, 2 * n)[1][-1] for n in N_R])
estimated = (coarse - fine) / 15.0  # Richardson's estimate of the error of fine
actual = fine - EXACT_A  # the true error of fine (we know the exact answer here)
extrapolated = (16.0 * fine - coarse) / 15.0
```

For $N = 2, 4, \ldots, 128$ the cell runs RK4 with N steps (`coarse`, the value Y_h) and with $2N$ steps (`fine`, the value $Y_{h/2}$). `estimated` is Richardson's estimate $(Y_h - Y_{h/2})/15$ of the error of the finer run, `actual` its true error, and `extrapolated` the value $(16Y_{h/2} - Y_h)/15$ of Section 2.6.

```
for n, e_est, e_act, e_ext in zip(N_R, estimated, actual, extrapolated - EXACT_A):
    say(f"N = {n:3d} -> {2 * n:3d}: estimated {e_est: .3e}, actual {e_act: .3e}, "
        f"extrapolated error {e_ext: .2e}")
```

`zip` walks through four sequences together. Each line prints the estimate, the true error and the error of the extrapolated value (the blank in `{e_est: .3e}` leaves room for a minus sign). From $N = 8$ on, the estimate agrees with the true error to within 6 per cent, and the extrapolated value is between 17 and 260 times more accurate than the finer run (COMPUTED).

```
fig, ax = plt.subplots(figsize=(6.0, 5.4))
ax.loglog(np.abs(actual), np.abs(estimated), "o", color=COLORS["rk4"], ms=6,
          label="RK4 runs with $2N = 4$ to $256$ steps")
for n, x_value, y_value in zip(N_R, np.abs(actual), np.abs(estimated)):
    ax.annotate(f"$N = {n}$", (x_value, y_value), textcoords="offset points",
                xytext=(6, -10), fontsize=7)
diagonal = np.array([1e-14, 1e-4])
ax.loglog(diagonal, diagonal, "--", color=COLORS["guide"], lw=0.9,
          label="estimate = actual")
```

Each run becomes one point (true error, estimate) on logarithmic axes; `ax.annotate` writes its N next to it, shifted by 6 points to the right and 10 points down. The dashed diagonal is the line on which estimate and true error are equal.

```
ax.set_xlabel("actual error of the finer run")
ax.set_ylabel("Richardson estimate $(Y_h - Y_{h/2})/15$")
ax.set_title("Richardson's estimate against the true error")
ax.legend(loc="upper left")
save_figure(fig, "richardson",
            "Richardson's error estimate $(Y_h - Y_{h/2})/15$ of RK4 for problem A "
            ...)
ratio = estimated[2:] / actual[2:]
check(np.all((ratio > 0.9) & (ratio < 1.1)),
      "Richardson's estimate is within 10 % of the actual error for N >= 8")
check(np.all(np.abs(extrapolated[2:6] - EXACT_A) < np.abs(actual[2:6]) / 10),
      "the extrapolated value is more than 10 times more accurate (N = 8 to 64)")
```

Labels, legend and the saved figure `02a_8_richardson.png`. `ratio` is the estimate divided by the true error for $N \geq 8$ (positions 2 and later); `&` combines two arrays of truth values entry by entry, and `np.all` requires every entry to be true: all ratios lie between 0.9 and 1.1. The second check requires the extrapolated values for $N = 8$ to 64 to be more than ten times more accurate than the finer runs. **What Figure 02a.8 shows:** the points lie on the diagonal: Richardson's estimate, made without the exact answer, is the error itself once the coarse run has at least 8 steps; for $N = 2$ and 4 the error is not yet close to Ch^4 and the estimate is off by up to 25 per cent.

In [15], the last check.

```
names = ["scale_factors", "scale_factor_product", "convergence_loglog",
         "error_ratios", "rounding_floor", "phase_portrait", "energy_drift",
         "richardson"]
present = [output_file(f"{FIGURE_FOLDER}/02a_{k}_{name}.png").is_file()
           for k, name in enumerate(names, 1)]
check(all(present), f"all {len(names)} figure files of notebook 02a exist")
all_checks_passed()
```

`enumerate(names, 1)` numbers the eight figure names from 1. For each, the cell asks whether the file `02a_<k>_<name>.png` exists; the check requires all eight to exist, and `all_checks_passed()` prints the last line, ALL 29 CHECKS PASSED (notebook 02a). The 29 checks are: 3 in In [3], 4 in In [4], 2 in In [5], 3 in In [6], 2 in In [7], 1 in In [8], 1 in In [9], 3 in In [10], 2 in In [11], 4 in In [12], 1 in In [13], 2 in In [14] and 1 in In [15].

2.12 Boundary-value problems and the shooting method

Conditions at both ends. So far every condition was given at the start: $y(0)$, or $x(0)$ and $x'(0)$. Many problems give one condition at each END of an interval instead. Such a problem is a **boundary-value problem**. Often it contains a number that is not known in advance, and it has a solution that is not zero everywhere only for special values of that number: these values are the **eigenvalues** and the solutions the **eigenfunctions**. The energy levels of quantum mechanics, and the Kohn-Sham levels of this book, are eigenvalues of this kind.

The vibrating string. The simplest example is

$$u''(x) = -\lambda\, u(x), \qquad u(0) = 0, \qquad u(1) = 0,$$

the shape $u(x)$ of a string fixed at $x = 0$ and $x = 1$ that vibrates in one of its natural modes; λ is the unknown number. For $\lambda > 0$ every solution of the equation has the form

$$u(x) = A\sin(\sqrt{\lambda}\,x) + B\cos(\sqrt{\lambda}\,x)$$

with two constants A and B. (Differentiating twice brings each term back multiplied by $-\lambda$: the derivative of $\sin(cx)$ is $c\cos(cx)$ and that of $\cos(cx)$ is $-c\sin(cx)$, with $c = \sqrt{\lambda}$ and $c^2 = \lambda$. That these are ALL the solutions follows from the uniqueness theorem of Section 2.2, because A and B can match any starting values $u(0)$, $u'(0)$.)

$$u(0) = A\sin 0 + B\cos 0 = B$$

($\sin 0 = 0$ and $\cos 0 = 1$), so the left condition $u(0) = 0$ forces $B = 0$. A multiple of a solution is again a solution, so we may fix the size by choosing the starting slope $u'(0) = 1$:

$$u'(0) = A\sqrt{\lambda}\cos 0 = A\sqrt{\lambda} = 1, \qquad A = \frac{1}{\sqrt{\lambda}}$$

(the derivative of $A\sin(\sqrt{\lambda}\,x)$ at $x = 0$). So the solution that starts with $u(0) = 0$ and $u'(0) = 1$ is

$$u(x;\lambda) = \frac{\sin(\sqrt{\lambda}\,x)}{\sqrt{\lambda}}.$$

The right condition $u(1) = 0$ holds when $\sin\sqrt{\lambda} = 0$, that is when $\sqrt{\lambda}$ is a whole multiple of π:

$$\sqrt{\lambda} = n\pi, \qquad \lambda_n = n^2\pi^2, \qquad n = 1, 2, 3, \ldots$$

(the zeros of the sine are the whole multiples of π; $n = 0$ gives $\lambda = 0$, where the solution is $u = x$, which is not zero at $x = 1$). So the eigenvalues of the string are $\pi^2 = 9.8696$, $4\pi^2 = 39.478$, $9\pi^2 = 88.826$, ... (PROVED).

The shooting method. The computer does not know this formula. It turns the boundary-value problem into a sequence of initial-value problems, like aiming a cannon:

1. guess a value of λ;
2. solve the initial-value problem from the left end with the conditions there ($u(0) = 0$, $u'(0) = 1$), for example with RK4;
3. see where the "shot" lands at the right end: the **mismatch** $F(\lambda) = u(1; \lambda)$;
4. change the guess until the mismatch is zero.

The function $F(\lambda)$ is the **shooting function**, and the eigenvalues are its zeros. For the string we know it exactly, $F(\lambda) = \sin\sqrt{\lambda}/\sqrt{\lambda}$, which lets Notebook 02b check every shot.

Brackets. Two guesses λ_{lo} and λ_{hi} at which F has opposite signs form a **bracket**. If F is continuous, it has a zero between them: this is the **intermediate value theorem** of calculus (ASSUMED: quoted without proof). For the string $F(5) = 0.35184 > 0$ and $F(15) = -0.17245 < 0$, so $5 < \lambda < 15$ brackets an eigenvalue (it is π^2).

Bisection. Take the midpoint $m = (\lambda_{\text{lo}} + \lambda_{\text{hi}})/2$ of the bracket and evaluate $F(m)$. If $F(m)$ has the same sign as $F(\lambda_{\text{lo}})$, the zero lies in the right half and m becomes the new λ_{lo}; otherwise it lies in the left half and m becomes the new λ_{hi}. Each step halves the bracket, so after k steps its width is

$$w_k = \frac{\lambda_{\text{hi}} - \lambda_{\text{lo}}}{2^k}$$

(the starting width halved k times). Bisection always works, but slowly: it gains one binary digit (a factor 2) per step; starting from the width 10, after 45 steps the width is $10/2^{45} = 2.8 \times 10^{-13}$. *Worked example.* From the bracket $(5, 15)$: $m = 10$, and $F(10) = \sin(3.1623)/3.1623 = -0.00654 < 0$ (because $\sqrt{10} = 3.1623$ is a little larger than π, where the sine turns negative), the opposite sign of $F(5)$, so the new bracket is $(5, 10)$; then $m = 7.5$ with $F > 0$, bracket $(7.5, 10)$; then 8.75, 9.375, 9.6875, 9.84375, ... (Notebook 02b, In [5], prints these midpoints and the signs of F).

The secant rule. Draw the straight line through the last two points $(x_0, F(x_0))$ and $(x_1, F(x_1))$ and take its zero as the next guess x_2. The line is

$$\ell(x) = F(x_1) + \frac{F(x_1) - F(x_0)}{x_1 - x_0}\,(x - x_1)$$

(the line through $(x_1, F(x_1))$ with the slope of the chord between the two points). Setting $\ell(x_2) = 0$:

$$\frac{F(x_1) - F(x_0)}{x_1 - x_0}\,(x_2 - x_1) = -F(x_1)$$

(subtract $F(x_1)$ from both sides);

$$x_2 = x_1 - F(x_1)\,\frac{x_1 - x_0}{F(x_1) - F(x_0)}$$

(divide by the slope and add x_1). Then repeat with the two newest points. *Worked example.* With $x_0 = 5$, $x_1 = 15$, $F(5) = 0.35184$, $F(15) = -0.17245$:

$$x_2 = 15 - (-0.17245)\cdot\frac{15-5}{-0.17245-0.35184} = 15 - \frac{1.7245}{0.52429} = 15 - 3.2892 = 11.7108$$

(the secant formula with these numbers). Notebook 02b prints 11.7107898. Close to a zero, the number of correct digits of the secant rule is multiplied by about 1.618 at every step (the golden ratio; ASSUMED: a standard result of numerical analysis, quoted without proof and only illustrated by the notebook), much faster than the one binary digit per step of bisection. Unlike bisection, the secant rule does not keep the root bracketed and can fail when the line is nearly flat; Section 2.24 shows how the Revision solver combines a fast rule with the safety of bisection.

2.13 The finite square well of quantum mechanics

The equation. In quantum mechanics the allowed energies E of a particle in one dimension, moving in a **potential** $V(x)$ (its potential energy at the position x), are the eigenvalues of the **Schrödinger equation**; in units in which Planck's constant divided by 2π (written $\hbar$) and the mass m are both 1, it reads

$$-\frac{1}{2}\,u''(x) + V(x)\,u(x) = E\,u(x).$$

We take this equation as given (ASSUMED here: it is the basic equation of quantum mechanics, used in this chapter only as an example of an eigenvalue problem). The function u is the **wave function**: $u(x)^2$ is the probability density of finding the particle at x, so u is **normalised**, $\int u^2\,dx = 1$. Multiplying the equation by -2 gives

$$u'' - 2Vu = -2Eu$$

(each term multiplied by -2), and adding $2Vu$ to both sides

$$u'' = 2\,(V(x) - E)\,u.$$

The well. We take $V(x) = -V_0$ inside $|x| < a$ and $V(x) = 0$ outside, with the depth $V_0 = 15$ and the half-width $a = 1$. A **bound state** is a solution with $-V_0 < E < 0$ that decays to zero far away on both sides; its energy is an eigenvalue. Write

$$k = \sqrt{2(E+V_0)}, \qquad \kappa = \sqrt{-2E}$$

(both are real and positive for $-V_0 < E < 0$).

Outside the well ($V = 0$): $u'' = -2Eu = \kappa^2 u$, solved by $e^{\kappa x}$ and $e^{-\kappa x}$ (differentiating twice brings back the factor κ^2). For $x < -a$ only $e^{\kappa x}$ goes to zero as $x \to -\infty$, so the solution on the left is a multiple of $e^{\kappa(x+a)}$; we choose the multiple 1. At $x = -a$ this gives the starting values

$$u(-a) = 1, \qquad u'(-a) = \kappa$$

(the value and the derivative of $e^{\kappa(x+a)}$ at $x=-a$, where the exponent is 0). So, unlike the string, here we know exactly how to start the shot.

Inside the well ($V=-V_0$): $u''=2(-V_0-E)u=-k^2u$, solved by $\cos(kx)$ and $\sin(kx)$.

The solution inside that continues the left tail is

$$u(x)=\cos\big(k(x+a)\big)+\frac{\kappa}{k}\sin\big(k(x+a)\big),$$

because at $x=-a$ it gives $u=\cos 0+0=1$ and $u'=-k\sin 0+\kappa\cos 0=\kappa$ (derivative term by term), the starting values above, and it solves $u''=-k^2u$.

Symmetry. The well is symmetric, $V(-x)=V(x)$. If $u(x)$ solves the equation, so does $u(-x)$ (the second derivative does not notice the change of sign of x, by the chain rule applied twice), and a bound-state energy of a one-dimensional problem belongs to only one wave function up to a factor (ASSUMED: a standard fact of one-dimensional quantum mechanics, quoted without proof). So $u(-x)=c\,u(x)$, and applying this twice gives $c^2=1$: every bound state is **even**, $u(-x)=u(x)$, or **odd**, $u(-x)=-u(x)$. An even smooth function has $u'(0)=0$ (its graph is flat at the centre) and an odd one has $u(0)=0$. These are the conditions at the far end of the shot from $x=-a$ to $x=0$:

$$F_{\text{even}}(E)=u'(0),\qquad F_{\text{odd}}(E)=u(0).$$

The exact conditions. At $x=0$ the inside solution gives

$$u(0)=\cos(ka)+\frac{\kappa}{k}\sin(ka),\qquad u'(0)=-k\sin(ka)+\kappa\cos(ka)$$

(insert $x=0$ into u and into its derivative). The even condition $u'(0)=0$ becomes

$$\kappa\cos(ka)=k\sin(ka),\qquad k\tan(ka)=\kappa$$

(move the sine term to the other side; then divide by $\cos(ka)$, using $\tan=\sin/\cos$). The odd condition $u(0)=0$ becomes

$$\cos(ka)=-\frac{\kappa}{k}\sin(ka),\qquad -k\cot(ka)=\kappa$$

(move the sine term; then multiply by k and divide by $\sin(ka)$, using $\cot=\cos/\sin$). Now put $z=ka$ and $z_0=a\sqrt{2V_0}$:

$$z^2+(\kappa a)^2=2(E+V_0)a^2-2Ea^2=2V_0a^2=z_0^2$$

(insert $k^2=2(E+V_0)$ and $\kappa^2=-2E$; the terms with E cancel), so $\kappa a=\sqrt{z_0^2-z^2}$. Multiplying the even and the odd condition by a and dividing by $z=ka$:

$$\text{even: }\tan z=\frac{\sqrt{z_0^2-z^2}}{z},\qquad \text{odd: }-\cot z=\frac{\sqrt{z_0^2-z^2}}{z},\qquad E=\frac{z^2}{2a^2}-V_0$$

(the last relation is $k^2 = 2(E + V_0)$ solved for E, with $k = z/a$). These are **transcendental equations**: no formula gives z, but a computer solves them to any number of digits. Here $z_0 = \sqrt{30} = 5.477$. The right side $\sqrt{z_0^2 - z^2}/z$ falls from $+\infty$ at $z = 0$ to 0 at $z = z_0$; on each interval of length $\pi/2$ one of the branches of $\tan z$ (on $(0, \pi/2)$, $(\pi, 3\pi/2)$, ...) or of $-\cot z$ (on $(\pi/2, \pi)$, ...) rises from 0 to $+\infty$ and crosses it exactly once. So the well has one bound state for every interval of length $\pi/2$ that begins below z_0: since $z_0/(\pi/2) = 3.487$, there are exactly 4 bound states, even, odd, even, odd. Their energies, computed with 30 digits by Notebook 02b (In [6]), are

$$E_0 = -14.1206, \quad E_1 = -11.5181, \quad E_2 = -7.3330, \quad E_3 = -2.0437$$

(COMPUTED from the exact equations).

Why shots miss. For an energy that is NOT an eigenvalue, the shot that starts with the decaying left tail arrives on the right side of the well as a mixture of $e^{-\kappa x}$ and the growing $e^{+\kappa x}$; the growing part takes over and the shot flies off to $+\infty$ or $-\infty$. Only at an eigenvalue is the growing part exactly absent. Just below and just above an eigenvalue the shot flies off to OPPOSITE infinities, which is what makes the shooting function change sign there (Figure 02b.6 shows it).

Normalisation and orthogonality. The tail on the left contributes to $\int u^2\,dx$ the amount

$$\int_{-\infty}^{-a} e^{2\kappa(x+a)}\,dx = \Big[\frac{e^{2\kappa(x+a)}}{2\kappa}\Big]_{-\infty}^{-a} = \frac{1}{2\kappa} - 0 = \frac{1}{2\kappa}$$

(an antiderivative of e^{cx} is e^{cx}/c; at $x = -a$ the exponential is $e^0 = 1$, and at $-\infty$ it is 0). Two wave functions u_m, u_n are **orthogonal** when $\int u_m u_n\,dx = 0$. For an even and an odd state the product $p(x) = u_m(x)u_n(x)$ is odd, $p(-x) = -p(x)$, and the integral of an odd function over the whole line is zero:

$$\int_{-\infty}^{\infty} p(x)\,dx = \int_{-\infty}^{0} p(x)\,dx + \int_{0}^{\infty} p(x)\,dx = -\int_{0}^{\infty} p(s)\,ds + \int_{0}^{\infty} p(x)\,dx = 0$$

(split at 0; in the first integral substitute $x = -s$, which turns dx into $-ds$, reverses the limits and turns $p(x)$ into $p(-s) = -p(s)$). Two states of the same parity with different energies are also orthogonal (ASSUMED here: a theorem of quantum mechanics, which Notebook 02b confirms numerically).

Simpson's rule. To integrate a function given at equally spaced points $x_0, x_1, \ldots, x_n$ (with n even and spacing h), Simpson's rule passes a parabola through every three neighbouring points and integrates it exactly. For three points at $-h$, 0, h with the values f_-, f_0, f_+, write the parabola as $p(x) = \alpha + \beta x + \gamma x^2$:

$$f_- = \alpha - \beta h + \gamma h^2, \qquad f_0 = \alpha, \qquad f_+ = \alpha + \beta h + \gamma h^2$$

(the parabola takes the three values);

$$\gamma h^2 = \frac{f_- + f_+}{2} - f_0$$

(add the first and the third equation, $f_- + f_+ = 2\alpha + 2\gamma h^2$, then use $\alpha = f_0$);

$$\int_{-h}^{h} p(x)\,dx = 2\alpha h + \frac{2\gamma h^3}{3}$$

(integrate term by term; the odd term βx gives zero);

$$\int_{-h}^{h} p(x)\,dx = 2f_0 h + \frac{2h}{3}\Big(\frac{f_- + f_+}{2} - f_0\Big) = \frac{h}{3}(f_- + 4f_0 + f_+)$$

(insert α and γh^2; collect: $2h - \frac{2h}{3} = \frac{4h}{3}$). Adding these pieces over the pairs of intervals gives Simpson's rule

$$\int_{x_0}^{x_n} f\,dx \approx \frac{h}{3}(f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 2f_{n-2} + 4f_{n-1} + f_n)$$

(every inner point with an even index belongs to two pieces and gets $1 + 1 = 2$). Its error is proportional to h^4 (ASSUMED: a standard result, quoted without proof), the same order as RK4.

The connection to this book. The Kohn-Sham equations of the book are solved in the same way. Two first-order equations along the hidden coordinate are shot from the tip of an interval to its other end, the brane, where, because of a mirror symmetry of the model that the Revision record labels ASSUMED, an even or an odd condition must hold, exactly like $u'(0) = 0$ or $u(0) = 0$ here (Section 2.24).

2.14 Example: shooting a string and a quantum well

Notebook 02b carries out Sections 2.12 and 2.13. Part A shoots the string with RK4 (200 steps), draws three shots and the whole shooting function, and finds $\lambda_1 = \pi^2$ both by bisection and by the secant rule, comparing how fast they converge. Part B solves the exact well equations with mpmath at 30 digits, shoots the well with RK4 from $x = -a$ with the even and the odd condition at the centre, refines all four levels at once by bisection, shows how a shot misses, draws the four normalised wave functions, checks their nodes, normalisation and orthogonality (for states of different parity also numerically), and measures the order 4 of the computed energies. It ends with ALL 16 CHECKS PASSED (notebook 02b).

2.15 How to run Notebook 02b

Step 1. What this notebook does and what it needs.

Notebook 02b (The shooting method: a vibrating string and a quantum well) is the file `Revision /textbook/notebooks/02b_shooting_quantum_well.ipynb` of the repository Dirac_claude. It finds the eigenvalues of two boundary-value problems by shooting: the string fixed at both ends, whose eigenvalues are n squared times pi squared, with bisection and the secant rule, and the finite square well of quantum mechanics (depth 15, half-width 1, in units with hbar = m = 1), whose four bound states it computes with RK4 and the even and odd conditions at the centre; it compares every energy with the exact transcendental equations solved with mpmath to 30 digits, counts the

nodes of the eigenfunctions, checks their orthogonality, and measures the order 4 of the eigenvalue error. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 02b_shooting_quantum_well.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02b_shooting_quantum_well.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 02b_shooting_quantum_well.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/02b.captions.json`
- `Revision/textbook/figures/02b_1_trial_solutions_string.png`
- `Revision/textbook/figures/02b_2_shooting_function_string.png`
- `Revision/textbook/figures/02b_3_bisection_vs_secant.png`
- `Revision/textbook/figures/02b_4_graphical_solution.png`
- `Revision/textbook/figures/02b_5_shooting_functions_well.png`
- `Revision/textbook/figures/02b_6_trial_solutions_well.png`
- `Revision/textbook/figures/02b_7_eigenfunctions.png`
- `Revision/textbook/figures/02b_8_eigenvalue_convergence.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02b exist
ALL 16 CHECKS PASSED (notebook 02b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 02b_shooting_quantum_well.ipynb
python -m nbconvert --execute --inplace 02b_shooting_quantum_well.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

2.16 Notebook 02b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Some differential equations have conditions at BOTH ends of an interval, and they
have solutions only for special values of a number in the equation, the
*eigenvalues*. The **shooting method** finds them: guess the number, solve the
equation from one end as an initial-value problem, see how badly the condition
at the other end fails, and correct the guess. This notebook

- Part A: shoots the equation of a string fixed at both ends,
  $u'' = -\lambda u$ with $u(0) = u(1) = 0$, whose eigenvalues are exactly
  $\lambda_n = n^2 \pi^2$; it finds $\lambda_1 = \pi^2$ by bisection and by the
  secant rule and compares how fast the two converge;
- Part B: shoots the Schroedinger equation of a particle in a finite square
  well (depth $V_0 = 15$, half-width $a = 1$), finds its four bound states with
  RK4 and the even and odd conditions at the centre, and compares every energy
  with the exact solution of the well's transcendental equations, computed with
  mpmath to 30 digits;
- draws the trial solutions that miss and the ones that hit, the shooting
  functions, the bound-state wave functions in the well, and the convergence of
  the computed energies (order 4, as for RK4 itself);
- checks the number of nodes and the orthogonality of the wave functions.

It draws 8 figures and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 02b (The shooting method: a vibrating string and a quantum well) is the file
`Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb` of the repository
Dirac_claude. It finds the eigenvalues of two boundary-value problems by shooting: the
string fixed at both ends, whose eigenvalues are n squared times pi squared, with
bisection and the secant rule, and the finite square well of quantum mechanics (depth 15,
half-width 1, in units with hbar = m = 1), whose four bound states it computes with RK4
and the even and odd conditions at the centre; it compares every energy with the exact
transcendental equations solved with mpmath to 30 digits, counts the nodes of the
eigenfunctions, checks their orthogonality, and measures the order 4 of the eigenvalue
error. It needs a computer with Windows 11, macOS or Linux, an internet connection for
the installation, the program Git, and Python 3.12 or newer (the notebooks were built
with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, mpmath
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.
```

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another

notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 02b_shooting_quantum_well.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 02b_shooting_quantum_well.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 02b_shooting_quantum_well.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/02b.captions.json‘
- ‘Revision/textbook/figures/02b_1_trial_solutions_string.png‘
- ‘Revision/textbook/figures/02b_2_shooting_function_string.png‘
- ‘Revision/textbook/figures/02b_3_bisection_vs_secant.png‘
- ‘Revision/textbook/figures/02b_4_graphical_solution.png‘
- ‘Revision/textbook/figures/02b_5_shooting_functions_well.png‘
- ‘Revision/textbook/figures/02b_6_trial_solutions_well.png‘
- ‘Revision/textbook/figures/02b_7_eigenfunctions.png‘
- ‘Revision/textbook/figures/02b_8_eigenvalue_convergence.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02b exist
ALL 16 CHECKS PASSED (notebook 02b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 02b_shooting_quantum_well.ipynb
  python -m nbconvert --execute --inplace 02b_shooting_quantum_well.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues

normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 02b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 02b (The shooting method: a vibrating string and a quantum well) is the file
# Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb of the repository
# Dirac_claude. It finds the eigenvalues of two boundary-value problems by shooting: the
# string fixed at both ends, whose eigenvalues are n squared times pi squared, with
# bisection and the secant rule, and the finite square well of quantum mechanics (depth
# 15, half-width 1, in units with hbar = m = 1), whose four bound states it computes with
# RK4 and the even and odd conditions at the centre; it compares every energy with the
# exact transcendental equations solved with mpmath to 30 digits, counts the nodes of the
# eigenfunctions, checks their orthogonality, and measures the order 4 of the eigenvalue
# error. It needs a computer with Windows 11, macOS or Linux, an internet connection for
# the installation, the program Git, and Python 3.12 or newer (the notebooks were built
# with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, mpmath
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
```

```
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
```

```
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 02b_shooting_quantum_well.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
```

```
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 02b_shooting_quantum_well.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 02b_shooting_quantum_well.ipynb (in the same folder, without running the cells again)
# to read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/02b.captions.json
# - Revision/textbook/figures/02b_1_trial_solutions_string.png
# - Revision/textbook/figures/02b_2_shooting_function_string.png
# - Revision/textbook/figures/02b_3_bisection_vs_secant.png
# - Revision/textbook/figures/02b_4_graphical_solution.png
# - Revision/textbook/figures/02b_5_shooting_functions_well.png
# - Revision/textbook/figures/02b_6_trial_solutions_well.png
# - Revision/textbook/figures/02b_7_eigenfunctions.png
# - Revision/textbook/figures/02b_8_eigenvalue_convergence.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 8 figure files of notebook 02b exist
#     ALL 16 CHECKS PASSED (notebook 02b)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
```

```
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/02b_shooting_quantum_well.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 02b_shooting_quantum_well.ipynb
#     python -m nbconvert --execute --inplace 02b_shooting_quantum_well.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================
import json  # reads and writes JSON files (text files that hold names and numbers)

## 3. The words used in this notebook

- **Boundary-value problem**: a differential equation with conditions at two
  different points (here at both ends of an interval), instead of all conditions
  at the start.
- **Eigenvalue, eigenfunction**: a value of the number $\lambda$ (or the energy
  $E$) for which the boundary-value problem has a solution that is not zero
  everywhere; that solution is an eigenfunction.
- **Shooting**: solve from one end with the conditions there and a guessed
  eigenvalue (like aiming a cannon), measure the *mismatch* at the other end
  (where the shot lands), and change the guess until the mismatch is zero.
- **Shooting function** $F$: the mismatch as a function of the guess; the
  eigenvalues are its zeros.
- **Bracket**: two guesses at which $F$ has opposite signs; a continuous $F$ has
  a zero between them.
- **Bisection**: replace the bracket by the half in which the sign changes; the
  bracket halves at every step.
- **Secant rule**: draw the straight line through the last two points
  $(\lambda, F(\lambda))$ and take its zero as the next guess.
- **Schroedinger equation**: the equation of quantum mechanics that gives the
  allowed energies $E$ of a particle in a potential $V(x)$; here, for one
  dimension and in units with $\hbar = m = 1$ ($\hbar$ is Planck's constant
  divided by $2\pi$, $m$ the mass), $-\frac{1}{2} u''(x) + V(x) u(x) = E u(x)$.
  We take it as given.
- **Potential well, bound state**: a region where $V$ is lower than outside; a
  bound state is a solution with $E$ below the outside value of $V$ that decays
  to zero far away. Its energy is an eigenvalue.
- **Wave function** $u(x)$: the eigenfunction of the Schroedinger equation;
  $u(x)^2$ is the probability density of finding the particle at $x$, so we
  *normalise* it: $\int u^2\,dx = 1$.
- **Even, odd (parity)**: $u$ is even if $u(-x) = u(x)$, odd if $u(-x) = -u(x)$.
  An even smooth function has $u'(0) = 0$, an odd one $u(0) = 0$.
- **Node**: a point where the eigenfunction changes sign.
- **Orthogonal**: two functions with $\int u_m u_n\,dx = 0$.
```

Text cell:

```
## 4. The physical and mathematical situation

**Part A: the string.** $u'' = -\lambda u$ on $0 \le x \le 1$ with $u(0) = 0$ and
$u(1) = 0$. For $\lambda > 0$ the solutions of the equation are
$A \sin(\sqrt{\lambda}\, x) + B \cos(\sqrt{\lambda}\, x)$ (differentiate twice:
each term comes back multiplied by $-\lambda$). The condition $u(0) = 0$ gives
$B = 0$. We may choose $A$ freely (a multiple of a solution is a solution), so
we start with $u(0) = 0$ and slope $u'(0) = 1$, which gives
$A = 1/\sqrt{\lambda}$:

$$u(x; \lambda) = \frac{\sin(\sqrt{\lambda}\, x)}{\sqrt{\lambda}}, \qquad
F(\lambda) = u(1; \lambda) = \frac{\sin\sqrt{\lambda}}{\sqrt{\lambda}}.$$
```

```
$F(\lambda) = 0$ when $\sqrt{\lambda} = n\pi$, that is $\lambda_n = n^2\pi^2$
for $n = 1, 2, 3, \dots$ The same equation describes a particle in a box with
infinitely high walls, with the energy $E = \lambda/2$ (units $\hbar = m = 1$).
The computer does not know the formula: it computes $F(\lambda)$ by solving the
initial-value problem with RK4, and we use the formula only to check it.

**Part B: the finite square well.** The potential is $V(x) = -V_0$ for
$|x| < a$ and $V(x) = 0$ for $|x| > a$, with $V_0 = 15$ and $a = 1$. The
Schroedinger equation $-\frac{1}{2} u'' + V u = E u$ multiplied by $-2$ reads

$$u'' = 2\,(V(x) - E)\, u .$$

A bound state has $-V_0 < E < 0$. Write $k = \sqrt{2(E + V_0)}$ and
$\kappa = \sqrt{-2E}$ (both positive).

- Outside the well ($V = 0$): $u'' = \kappa^2 u$, solved by $e^{\kappa x}$ and
  $e^{-\kappa x}$. For $x < -a$ only $e^{\kappa x}$ goes to zero as
  $x \to -\infty$. So we know exactly how to start: at $x = -a$ take $u = 1$
  and $u' = \kappa$ (the values of $e^{\kappa (x + a)}$ there).
- Inside ($V = -V_0$): $u'' = -k^2 u$, solved by $\cos$ and $\sin$ of $k x$.
- The well is symmetric, so every bound state is even or odd. An even state has
  $u'(0) = 0$, an odd state $u(0) = 0$. These are the conditions at the far end
  of the shot: we integrate from $x = -a$ to $x = 0$ and use the shooting
  functions $F_{\rm even}(E) = u'(0)$ and $F_{\rm odd}(E) = u(0)$.

**The exact answer.** Inside, the solution that starts with $u(-a) = 1$,
$u'(-a) = \kappa$ is $u = \cos(k(x + a)) + (\kappa/k) \sin(k(x + a))$ (check
the two start values by putting $x = -a$). At $x = 0$:
$F_{\rm even} = -k \sin(ka) + \kappa \cos(ka)$, which vanishes when
$k \tan(ka) = \kappa$, and $F_{\rm odd} = \cos(ka) + (\kappa/k) \sin(ka)$, which
vanishes when $-k \cot(ka) = \kappa$. With $z = ka$ and
$z_0 = a\sqrt{2V_0} = \sqrt{30}$ we have $\kappa a = \sqrt{z_0^2 - z^2}$, so

$$\text{even: } \tan z = \frac{\sqrt{z_0^2 - z^2}}{z}, \qquad
\text{odd: } -\cot z = \frac{\sqrt{z_0^2 - z^2}}{z}, \qquad
E = \frac{z^2}{2a^2} - V_0 .$$

These equations have no formula for $z$, but mpmath solves them to any number
of digits. The well has one bound state for each interval of length $\pi/2$
that begins below $z_0$. The intervals begin at $0$, $\pi/2 = 1.571$,
$\pi = 3.142$, $3\pi/2 = 4.712$, $2\pi = 6.283$, ...; with $z_0 = 5.477$
(so $z_0/(\pi/2) = 3.49$) the first four begin below $z_0$ and the fifth does
not, so the well has 4 bound states.

**The connection to this book.** The Kohn-Sham equations of the book are solved
in the same way: two first-order equations in the hidden coordinate are shot
from the tip of the interval to the brane, where (with the ASSUMED mirror
symmetry) an even or an odd condition must hold, exactly like $u'(0) = 0$ or
$u(0) = 0$ here.

## 5. The tools: RK4 for a system, bisection and the secant rule
```

The next cell defines one RK4 step for a system $Y' = f(x, Y)$ (the same rule as for one equation, applied to the vector $Y = (u, u')$), the bisection and the secant rule. Both root finders print nothing; they return the list of all the guesses they made, so that we can study how fast they approach the root.

In [2]:

```

## 8. Part B: the finite square well, solved exactly with mpmath
```

```
The next cell solves the even and odd equations of section 4 with mpmath at 30
significant digits. To avoid the infinities of $\tan$ and $\cot$ it multiplies
them out: even $g(z) = z \sin z - \sqrt{z_0^2 - z^2}\cos z = 0$, odd
$g(z) = z \cos z + \sqrt{z_0^2 - z^2}\sin z = 0$. Even roots lie between $n\pi$
and $n\pi + \pi/2$, odd ones between $n\pi + \pi/2$ and $(n + 1)\pi$ (but never
beyond $z_0$); mpmath's 'findroot' with the method "anderson" refines each
bracket. The figure shows the classic graphical solution: the curves $\tan z$
and $-\cot z$ cross the curve $\sqrt{z_0^2 - z^2}/z$ at the solutions.
```

## 9. Part B by shooting with RK4

The function ‘shoot_well(E, n)‘ starts at $x = -a$ with $u = 1$, $u’ = \kappa$
and makes $n$ RK4 steps to $x = 0$ with the inside equation $u’’ = -2(V_0 + E)
u$. It works for one energy or for a whole array of energies at once (numpy
computes elementwise), which makes the scan of the shooting functions fast. The
next cell draws $F_{\rm even}(E) = u’(0)$ and $F_{\rm odd}(E) = u(0)$ for 400
energies between $-V_0$ and 0 and marks the exact energies.
```

In [7]:

```
def shoot_well(E, n):

## 10. What a shot looks like when it misses

For the ground state $E_0$, the next cell shoots across the WHOLE line from
$x = -3$ to $x = +3$ (600 RK4 steps of $h = 0.01$, so that the walls $x = \pm 1$
are grid points and the potential is constant inside every step). It starts
with the exactly decaying solution $u = e^{\kappa(x + a)}$, $u' = \kappa u$ at
$x = -3$. Only at the eigenvalue does the shot come down to zero on the right;
a little below or above $E_0$, the growing solution $e^{\kappa x}$ takes over
and the shot flies off to $+\infty$ or $-\infty$. That is the reason why only
special energies are allowed.
```

In [9]:

```
def shoot_line(E, x_start=-3.0, x_end=3.0, n=600):

## 11. The four wave functions

The next cell builds each normalised wave function on $-3 \le x \le 3$: inside
the left half of the well from the RK4 shot (200 steps), on the right half by
the symmetry $u(-x) = u(x)$ (even) or $u(-x) = -u(x)$ (odd), and outside from
the exact tails $u(-a) e^{\kappa(x + a)}$. The normalisation integral uses
Simpson's rule inside (an integration rule with error $\propto h^4$) and the
exact tail integral $\int_{-\infty}^{-a} e^{2\kappa(x + a)} dx = 1/(2\kappa)$.
It draws each wave function lifted to the height of its energy, inside the
drawing of the potential, counts the nodes, and checks the normalisation and
the orthogonality. For an even and an odd state the product $u_m u_n$ is odd
(it changes sign when $x$ is replaced by $-x$), so the contributions of the
left and the right half cancel and its integral is exactly zero; for two states
of the same parity the cell computes the integral (twice the left half: Simpson
inside, the exact tail $u_m(-a) u_n(-a)/(\kappa_m + \kappa_n)$ outside).
Finally the cell tests the cancellation for the four pairs of different parity
numerically: it integrates $u_m u_n$ with Simpson's rule over the whole drawn
range $-3 \le x \le 3$, and over the left half $-3 \le x \le 0$ alone. The
whole integral must vanish, although the half does not.
```

## 12. The order of the computed energies

The shooting energy inherits the error of the integrator. The next cell repeats
the whole level search with $n = 4, 8, \dots, 1024$ RK4 steps on $-a \le x \le 0$
and draws $|E_n(\text{RK4}) - E_n(\text{exact})|$ against the step size
$h = a/n$ on a log-log plot. The points lie on lines of slope 4: the energies
converge with the order of RK4. The higher states have larger errors, because
their wave functions oscillate faster (the error grows like $(k h)^4$).
```

In [11]:

```
N_STEPS = [4, 8, 16, 32, 64, 128, 256, 512, 1024]

## 14. What this notebook showed

- A boundary-value problem with an unknown number in it becomes a sequence of
  initial-value problems: shoot from one end, measure the mismatch at the other
  end, and find the zeros of the shooting function.
- For the string $u'' = -\lambda u$, $u(0) = u(1) = 0$, the RK4 shooting function
  equals $\sin\sqrt{\lambda}/\sqrt{\lambda}$ and its zeros are
  $\lambda_n = n^2\pi^2$. Bisection gains one binary digit per step (after 45
  steps the bracket is still $2.8 \times 10^{-13}$ wide); the secant rule
  reaches the rounding level in about 9 steps.
- The finite square well of depth 15 and half-width 1 has exactly four bound
  states, alternately even and odd, with $n$ nodes in the state $n$; shooting
  with RK4 and the parity conditions $u'(0) = 0$ or $u(0) = 0$ at the centre
  reproduces the exact energies of the transcendental equations (within
  $10^{-7}$ with 200 steps, $10^{-9}$ with 1024 steps), and the energy errors
  fall like $h^4$.
- Away from an eigenvalue the shot flies off to $\pm\infty$: only special
  energies give a solution that decays on both sides.
- The wave functions of different energies are orthogonal.
```

2.17 Line-by-line walk-through of Notebook 02b

The notebook has twelve code cells, In [1] to In [12]. As in Section 2.11, a quoted line `...)` stands for the rest of a figure caption, which Section 2.16 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 2.15. Its code is, line for line, the set-up code of Notebook 02a explained in Section 2.11, with the single difference

NOTEBOOK_ID = "02b", so that the figures are named 02b_<k>_<name>.png and the captions file is Revision/textbook/figures/02b.captions.json. It prints one line, Set-up of notebook 02b complete: repository folder found, helpers defined.

In [2], RK4 for systems, bisection and the secant rule.

```
import math  # sqrt, sin, pi for single numbers

import mpmath  # numbers with as many digits as we ask for
import numpy as np  # arrays (vectors) of numbers
```

math for single numbers, mpmath for numbers with as many digits as we ask for (used for the exact well levels), numpy for arrays.

```
# Colours that colour-blind readers can tell apart; curves also differ by style.
BLUE, ORANGE, AQUA, VIOLET = "#2a78d6", "#eb6834", "#1baf7a", "#4a3aa7"
GREY, BLACK = "#8a8986", "#000000"
LEVEL_COLORS = [BLUE, ORANGE, AQUA, VIOLET]  # one colour per bound state
```

Six colour names, given their hexadecimal codes at once (Python assigns the values on the right to the names on the left in order), and a list of four colours, one for each bound state of the well.

```
def rk4_step(f, x, Y, h):
    """One classical RK4 step for the system Y' = f(x, Y)."""
    k1 = f(x, Y)
    k2 = f(x + h / 2, Y + (h / 2) * k1)
    k3 = f(x + h / 2, Y + (h / 2) * k2)
    k4 = f(x + h, Y + h * k3)
    return Y + (h / 6) * (k1 + 2 * k2 + 2 * k3 + k4)
```

The RK4 rule of Section 2.4, now with the variable called x (a position) and the state Y a numpy array (u, u'); since numpy adds and multiplies arrays entry by entry, the formulas act on both components at once.

```
def bisection(F, lo, hi, steps):
    """steps bisection steps on the bracket (lo, hi); the list of midpoints."""
    f_lo = F(lo)
    guesses = []
    for _ in range(steps):
        mid = 0.5 * (lo + hi)
        f_mid = F(mid)
        guesses.append(mid)
        if (f_mid > 0) == (f_lo > 0):  # same sign as at lo: the root is right
            lo, f_lo = mid, f_mid
        else:  # opposite sign: the root lies between lo and mid
            hi = mid
    return guesses
```

Bisection as in Section 2.12. f_lo is the value of F at the left end. Each of the steps passes (the loop variable _ is not used) computes the midpoint and F there and records the midpoint. (f_mid >

`0) == (f_lo > 0)` is true when both values have the same sign (both positive or both not positive): then the zero lies to the right of `mid`, which becomes the new left end (with its value); otherwise `mid` becomes the new right end. The function returns all the midpoints, so that their errors can be drawn.

```
def secant(F, x0, x1, steps):
    """steps secant steps from the guesses x0, x1; the list of new guesses."""
    f0, f1 = F(x0), F(x1)
    guesses = []
    for _ in range(steps):
        if f1 == f0:  # the line is flat: no new information (converged)
            break
        x2 = x1 - f1 * (x1 - x0) / (f1 - f0)  # the zero of the line
        x0, f0, x1, f1 = x1, f1, x2, F(x2)
        guesses.append(x2)
    return guesses

say("RK4 for systems, bisection and the secant rule are defined.")
```

The secant rule of Section 2.12. If the two last values of F are equal the line is flat and has no zero; this happens when both guesses have already reached the root to the last digit, and `break` leaves the loop. Otherwise `x2` is the zero of the line through the last two points; the line `x0, f0, x1, f1 = x1, f1, x2, F(x2)` shifts the pair forward (the old newest point becomes the older one, and the new guess with its value becomes the newest). The cell prints one line.

In [3], three shots for the string.

```
def shoot_string(lam, n):
    """RK4 solution of u'' = -lam u, u(0) = 0, u'(0) = 1 on 0 <= x <= 1 in n
    steps.  Returns the n + 1 positions and the n + 1 values of u."""
    def f(x, Y):
        return np.array([Y[1], -lam * Y[0]])  # (u', v') = (v, -lam u)
    h = 1.0 / n
    Y = np.array([0.0, 1.0])  # u(0) = 0, u'(0) = 1
    xs, us = [0.0], [0.0]
    for i in range(n):
        Y = rk4_step(f, i * h, Y, h)
        xs.append((i + 1) * h)
        us.append(Y[0])
    return np.array(xs), np.array(us)
```

The string equation $u'' = -\lambda u$ as the system $u' = v$, $v' = -\lambda u$: the inner function `f` returns $(v, -\lambda u)$ for the state `Y` $= (u, v)$ (`lam` stands for λ, because `lambda` is a reserved word of Python). The shot starts with $u = 0$, $u' = 1$ and makes `n` RK4 steps of size $1/n$, recording every position and value of u.

```
def F_string(lam, n=200):
    """The shooting function: where the shot lands, u(1)."""
    return shoot_string(lam, n)[1][-1]
```

The shooting function $F(\lambda) = u(1;\lambda)$: the last value of u; `n=200` makes 200 steps the default.

```
fig, ax = plt.subplots()
for lam, color, style in ((5.0, ORANGE, "--"), (math.pi ** 2, BLUE, "-"),
                          (15.0, AQUA, "-.")):
    xs, us = shoot_string(lam, 200)
    ax.plot(xs, us, style, color=color, lw=1.6,
            label=f"$\\lambda = {lam:.4f}$: $u(1) = {us[-1]:+.4f}$")
    ax.plot([1.0], [us[-1]], "o", color=color, ms=6)
```

Three shots, with $\lambda = 5$ (dashed orange), $\lambda = \pi^2$ (solid blue) and $\lambda = 15$ (dash-dotted aqua); each is drawn with its landing value $u(1)$ in the legend (`:+.4f` writes the sign and 4 decimals), and a dot marks where it lands.

```
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.plot([0.0, 1.0], [0.0, 0.0], "s", color=BLACK, ms=7, label="the two fixed ends")
ax.set_xlabel("position $x$ along the string")
ax.set_ylabel("displacement $u(x)$")
ax.set_title("Three shots for $u'' = -\\lambda u$, $u(0) = 0$, $u'(0) = 1$")
ax.legend(fontsize=8)
save_figure(fig, "trial_solutions_string",
            "Three shots for the string equation $d^2u/dx^2 = -\\lambda u$ started at "
            ...)
check(F_string(5.0) > 0 > F_string(15.0) and abs(F_string(math.pi ** 2)) < 1e-9,
      "u(1) > 0 for lambda = 5, < 0 for lambda = 15, = 0 for lambda = pi^2")
```

The horizontal axis line, two black squares at the fixed ends, labels, the legend and the saved figure `02b_1_trial_solutions_string.png`. The check confirms the picture in numbers: the shot lands above the target for $\lambda = 5$, below it for $\lambda = 15$, and within 10^{-9} of it for $\lambda = \pi^2$. **What Figure 02b.1 shows:** a small λ bends the string too little (it comes down too late), a large one too much (it crosses zero too early); the eigenvalue π^2 lands exactly on the target.

In [4], the whole shooting function.

```
lam_points = np.linspace(0.5, 100.0, 60)  # 60 guesses for RK4
lam_fine = np.linspace(0.5, 100.0, 800)  # many points for the exact curve
F_points = np.array([F_string(lam) for lam in lam_points])
F_exact = np.sin(np.sqrt(lam_fine)) / np.sqrt(lam_fine)
```

60 values of λ between 0.5 and 100 are shot with RK4; 800 values give a smooth exact curve $\sin\sqrt{\lambda}/\sqrt{\lambda}$.

```
fig, ax = plt.subplots()
ax.plot(lam_fine, F_exact, color=BLACK, lw=1.0,
        label="exact $\\sin\\sqrt{\\lambda}/\\sqrt{\\lambda}$")
ax.plot(lam_points, F_points, "o", color=BLUE, ms=4, label="RK4 shots, 200 steps")
for n in (1, 2, 3):
    ax.axvline(n ** 2 * math.pi ** 2, ls=":", color=GREY, lw=1.0)
    ax.text(n ** 2 * math.pi ** 2, 0.62, f"${n * n}\\pi^2$", ha="center",
            fontsize=9)
```

The exact curve in black, the RK4 values as blue points, and dotted vertical lines (`axvline`) at the first three eigenvalues $n^2\pi^2$, labelled $1\pi^2$, $4\pi^2$, $9\pi^2$ near the top.

```
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.set_xlabel("guessed eigenvalue $\\lambda$")
ax.set_ylabel("$F(\\lambda) = u(1; \\lambda)$")
ax.set_ylim(-0.3, 0.7)
ax.set_title("The shooting function of the string")
ax.legend()
save_figure(fig, "shooting_function_string",
            "The shooting function $F(\\lambda) = u(1; \\lambda)$ of the string, "
            ...)
```

The zero line, labels, the vertical range and the saved figure `02b_2_shooting_function_string.png`. **What Figure 02b.2 shows:** the RK4 points lie on the exact curve; it crosses zero exactly at the dotted lines, and between two crossings it keeps its sign, so any two guesses with opposite signs of F bracket an eigenvalue.

```
worst = np.max(np.abs(F_points - np.sin(np.sqrt(lam_points)) /
                      np.sqrt(lam_points)))
report("largest difference RK4 - exact shooting function", f"{worst:.2e}")
check(worst < 1e-7, "the RK4 shooting function equals sin(sqrt(lam))/sqrt(lam)")
```

The largest distance between the 60 RK4 values and the exact formula is 4.54×10^{-8} (COMPUTED; it is largest at the biggest λ, where the solution oscillates fastest), and the check requires it to be below 10^{-7}.

In [5], bisection against the secant rule.

```
PI2 = math.pi ** 2  # the exact eigenvalue
bis = bisection(F_string, 5.0, 15.0, 45)
sec = secant(F_string, 5.0, 15.0, 12)
say("step   bisection midpoint   F(midpoint)    secant guess")
for k in range(6):
    say(f"{k + 1:4d}   {bis[k]:18.6f}   {F_string(bis[k]):+11.5f}   {sec[k]:13.7f}")
```

45 bisection steps and at most 12 secant steps, both started from 5 and 15. The table prints the first six of each: the bisection midpoints 10, 7.5, 8.75, 9.375, 9.6875, 9.84375 with the signs of F that decided each halving (only the first is negative, so the bracket moves up each time after the first step), and the secant guesses 11.7107898, 8.8043277, 10.0237185, 9.8815597, 9.8694633, 9.8696045 (the first one is the worked example of Section 2.12).

```
lam_rk4 = sec[-1]  # the converged secant value: the RK4 eigenvalue (200 steps)
report("eigenvalue by RK4 shooting (200 steps)", f"{lam_rk4:.12f}")
report("pi^2", f"{PI2:.12f}")
errors_bis = np.abs(np.array(bis) - lam_rk4)
errors_sec = np.abs(np.array(sec) - lam_rk4)
```

The last secant guess is the zero of the RK4 shooting function, 9.869604411103; it differs from $\pi^2 = 9.869604401089$ by 1.0×10^{-8}, the error of RK4 with 200 steps (COMPUTED). The errors of all guesses are measured against this zero (not against π^2), because that is the number the root finders are looking for.

```
fig, ax = plt.subplots()
ax.semilogy(range(1, len(bis) + 1), np.maximum(errors_bis, 1e-17), "s-",
            color=ORANGE, ms=4, lw=1.2, label="bisection")
ax.semilogy(range(1, len(sec) + 1), np.maximum(errors_sec, 1e-17), "o-",
            color=BLUE, ms=5, lw=1.2, label="secant rule")
k_values = np.arange(1, len(bis) + 1)
ax.semilogy(k_values, 10.0 / 2.0 ** k_values, ":", color=GREY,
            label="bracket width $10/2^k$")
```

The errors after each step on a logarithmic axis; `np.maximum(errors, 1e-17)` replaces an error of exactly 0 (which a logarithmic axis cannot show) by 10^{-17}. The dotted grey line is the bracket width $10/2^k$ of Section 2.12.

```
ax.set_xlabel("step $k$")
ax.set_ylabel("error $|\\lambda_k - \\lambda_1|$")
ax.set_ylim(1e-17, 10.0)
ax.set_title("How fast the two root finders approach the eigenvalue $\\lambda_1$")
ax.legend()
save_figure(fig, "bisection_vs_secant",
            "The error of the guess after $k$ steps, $|\\lambda_k - \\lambda_1|$, "
            ...)
```

Labels and the saved figure `02b_3_bisection_vs_secant.png`. **What Figure 02b.3 shows:** the bisection errors follow the dotted halving line, one binary digit per step, and are still about 10^{-13} after 45 steps; the secant errors fall faster and faster and reach the rounding level in about 9 steps.

```
check(bis[:6] == [10.0, 7.5, 8.75, 9.375, 9.6875, 9.84375],
      "the bisection midpoints 10, 7.5, 8.75, 9.375, 9.6875, 9.84375")
check(abs(sec[5] - PI2) < 1e-6 and abs(bis[5] - PI2) > 0.02,
      "after 6 steps: secant within 1e-6 of pi^2, bisection still 0.02 away")
check(abs(lam_rk4 - PI2) < 2e-8 and abs(bis[-1] - lam_rk4) < 1e-11,
      "RK4 eigenvalue = pi^2 within 2e-8; 45 bisections agree within 1e-11")
```

Three checks: the first six midpoints are exactly those of the worked example (these numbers are exact in binary, so `==` is safe); after six steps the secant rule is within 10^{-6} of π^2 while bisection is still more than 0.02 away; the RK4 eigenvalue is within 2×10^{-8} of π^2 and the 45th bisection midpoint within 10^{-11} of it.

In [6], the exact well levels with mpmath.

```
V0, A = 15.0, 1.0  # the depth and the half-width of the well
mpmath.mp.dps = 30  # work with 30 significant digits
Z0 = mpmath.sqrt(2 * mpmath.mpf(V0)) * A  # z0 = a sqrt(2 V0) = sqrt(30)
```

The depth $V_0 = 15$ and the half-width $a = 1$ (called `A` in the code). `mpmath.mp.dps = 30` makes mpmath compute with 30 significant digits; `mpmath.mpf(V0)` turns 15 into an mpmath number, so that $z_0 = \sqrt{30}$ is computed to 30 digits.

```
def g_even(z):
    return z * mpmath.sin(z) - mpmath.sqrt(Z0 ** 2 - z ** 2) * mpmath.cos(z)

def g_odd(z):
    return z * mpmath.cos(z) + mpmath.sqrt(Z0 ** 2 - z ** 2) * mpmath.sin(z)
```

The even condition $\tan z = \sqrt{z_0^2 - z^2}/z$ multiplied by $z\cos z$ becomes $z\sin z - \sqrt{z_0^2 - z^2}\cos z = 0$, and the odd condition $-\cot z = \sqrt{z_0^2 - z^2}/z$ multiplied by $z\sin z$ becomes $-z\cos z = \sqrt{z_0^2 - z^2}\sin z$, that is $z\cos z + \sqrt{z_0^2 - z^2}\sin z = 0$. These forms have no infinities, which makes them safe for a root finder.

```
EXACT = []  # (energy, parity) of the bound states, lowest first
for j in range(8):  # the intervals of length pi/2 between 0 and z0
    lo = j * mpmath.pi / 2
    hi = min((j + 1) * mpmath.pi / 2, Z0)
    if lo >= Z0:
        break
    g, parity = (g_even, "even") if j % 2 == 0 else (g_odd, "odd")
    # the root inside the interval (lo, hi), searched a hair away from its ends
    z = mpmath.findroot(g, (lo + mpmath.mpf("1e-20"), hi - mpmath.mpf("1e-20")),
                        solver="anderson")
    EXACT.append((z ** 2 / (2 * A ** 2) - V0, parity, z))
```

The loop walks through the intervals $(j\pi/2, (j+1)\pi/2)$, the last one cut off at z_0, and stops (`break`) when an interval starts beyond z_0. `j % 2` is the remainder of j divided by 2: on the intervals with even j the even condition has its root, on the others the odd one (Section 2.13). `mpmath.findroot` with the method `"anderson"` (a bracketing root finder) refines the root inside the interval, started a hair (10^{-20}) away from its ends; then the energy $E = z^2/(2a^2) - V_0$ is stored with the parity and z. Each entry of `EXACT` is a **tuple**, a fixed group of values in round brackets.

```
for n, (energy, parity, z) in enumerate(EXACT):
    say(f"state {n} ({parity:4}): z = {mpmath.nstr(z, 20)}, "
        f"E = {mpmath.nstr(energy, 20)}")
check(len(EXACT) == 4 and [p for _, p, _ in EXACT] == ["even", "odd", "even", "odd"],
      "the well has 4 bound states: even, odd, even, odd")
```

The four states are printed with 20 significant digits (`mpmath.nstr`): $E_0 = -14.120556743965630861$, $E_1 = -11.518123819661769376$, $E_2 = -7.3330267121044013902$, $E_3 = -2.0436840105252862495$ (COMPUTED). The check confirms that there are 4 and that the parities alternate.

```
z_axis = np.linspace(0.01, float(Z0), 2000)
rhs = np.sqrt(float(Z0) ** 2 - z_axis ** 2) / z_axis
```

```
tan_z = np.tan(z_axis)
cot_z = -1.0 / np.tan(z_axis)
tan_z[np.abs(tan_z) > 12] = np.nan  # do not draw the jumps at the poles
cot_z[np.abs(cot_z) > 12] = np.nan
```

For the graphical solution: 2000 values of z up to z_0, the right side $\sqrt{z_0^2 - z^2}/z$, and the two left sides $\tan z$ and $-\cot z$. Where these jump between $+\infty$ and $-\infty$ the plotting line would draw a misleading vertical stroke; the entries larger than 12 in size are therefore set to `np.nan` ("not a number"), which matplotlib leaves out.

```
fig, ax = plt.subplots()
ax.plot(z_axis, rhs, color=BLACK, lw=1.5, label="$\\sqrt{z_0^2 - z^2}/z$")
ax.plot(z_axis, tan_z, color=BLUE, lw=1.2, label="$\\tan z$ (even states)")
ax.plot(z_axis, cot_z, "--", color=ORANGE, lw=1.2, label="$-\\cot z$ (odd states)")
for n, (energy, parity, z) in enumerate(EXACT):
    zf = float(z)
    ax.plot([zf], [math.sqrt(float(Z0) ** 2 - zf ** 2) / zf], "o",
            color=LEVEL_COLORS[n], ms=7, zorder=5)
    ax.annotate(f"$n = {n}$", (zf, math.sqrt(float(Z0) ** 2 - zf ** 2) / zf),
                textcoords="offset points", xytext=(5, 8), fontsize=9)
```

The three curves; then a dot at each solution (on the black curve), with `zorder=5` so that the dot is drawn on top of the lines, and the label n next to it.

```
ax.axvline(float(Z0), color=GREY, ls=":", lw=1.0)
ax.text(float(Z0), 7.3, "$z_0 = \\sqrt{30}$", ha="right", fontsize=9)
ax.set_ylim(0.0, 8.0)
ax.set_xlabel("$z = k a$")
ax.set_ylabel("value of each side of the equation")
ax.set_title("Graphical solution of the finite-well equations, $z_0 = 5.477$")
ax.legend(loc="upper center", fontsize=8)
save_figure(fig, "graphical_solution",
            "The graphical solution of the finite-well equations for "
            ...)
```

A dotted line at z_0, labels and the saved figure `02b_4_graphical_solution.png`. **What Figure 02b.4 shows:** the black curve falls from large values to zero at z_0; it crosses each rising branch of $\tan z$ and $-\cot z$ once, four times in all, alternately on a blue (even) and an orange (odd) branch.

In [7], the shooting functions of the well.

```
def shoot_well(E, n):
    """RK4 from x = -a (u = 1, u' = kappa) to x = 0 inside the well; E may be an
    array.  Returns (u(0), u'(0))."""
    E = np.asarray(E, dtype=float)
    kappa = np.sqrt(-2.0 * E)  # the decay rate outside the well
```

`np.asarray` turns `E` into a numpy array (a single number becomes an array with no axes), so that the same code works for one energy and for many; `kappa` is $\kappa = \sqrt{-2E}$ for every energy.

```
    def f(x, Y):
        return np.array([Y[1], 2.0 * (-V0 - E) * Y[0]])  # (u', 2 (V - E) u)
    h = A / n
    Y = np.array([np.ones_like(E), kappa])
    for i in range(n):
        Y = rk4_step(f, -A + i * h, Y, h)
    return Y[0], Y[1]
```

The right-hand side inside the well, $(u', 2(V-E)u)$ with $V = -V_0$. The step is a/n; the start is $u = 1$ (`np.ones_like(E)` is an array of ones of the same shape as `E`) and $u' = \kappa$. After `n` RK4 steps from $x = -a$ the function returns $u(0)$ and $u'(0)$, for all energies at once.

```
def F_even(E, n=200):
    return shoot_well(E, n)[1]  # u'(0): zero for an even state

def F_odd(E, n=200):
    return shoot_well(E, n)[0]  # u(0): zero for an odd state
```

The two shooting functions of Section 2.13.

```
E_scan = np.linspace(-V0 + 1e-3, -1e-3, 400)  # 400 guesses inside (-V0, 0)
fe, fo = F_even(E_scan), F_odd(E_scan)
fig, ax = plt.subplots()
ax.plot(E_scan, fe, color=BLUE, lw=1.4, label="$F_{\\rm even}(E) = u'(0)$")
ax.plot(E_scan, fo, "--", color=ORANGE, lw=1.4, label="$F_{\\rm odd}(E) = u(0)$")
```

400 energies, kept 10^{-3} away from the ends $-V_0$ and 0 (where k or κ would be zero), are shot all at once; the two shooting functions are drawn.

```
for n, (energy, parity, _) in enumerate(EXACT):
    ax.axvline(float(energy), ls=":", color=GREY, lw=1.0)
    ax.plot([float(energy)], [0.0], "o", color=LEVEL_COLORS[n], ms=7, zorder=5)
    ax.text(float(energy), 4.6, f"$E_{n}$", ha="center", fontsize=9)
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.set_ylim(-5.5, 5.5)
ax.set_xlabel("guessed energy $E$ (units $\\hbar^2/(m a^2)$)")
ax.set_ylabel("mismatch at $x = 0$")
ax.set_title("Shooting functions of the finite well ($V_0 = 15$, $a = 1$)")
ax.legend(loc="lower left")
save_figure(fig, "shooting_functions_well",
            "The shooting functions of the finite well: $F_{\\rm even}(E) = "
            ...)
```

A dotted line, a dot and a label at each exact energy; then axis labels (the energy unit $\hbar^2/(ma^2)$ is 1 in the units of the notebook) and the saved figure `02b_5_shooting_functions_well.png`. **What Figure 02b.5 shows:** the solid blue F_{even} crosses zero exactly at E_0 and E_2, the dashed orange F_{odd} at E_1 and E_3; each crossing of a shooting function is a level of its parity.

```
even_changes = int(np.sum(np.sign(fe[:-1]) != np.sign(fe[1:])))
odd_changes = int(np.sum(np.sign(fo[:-1]) != np.sign(fo[1:])))
report("sign changes of F_even and F_odd in the scan", f"{even_changes}, {odd_changes}")
check(even_changes == 2 and odd_changes == 2,
      "the scan finds 2 even and 2 odd sign changes, one per bound state")
```

`np.sign` gives $+1$, -1 or 0 for each entry; comparing the signs of neighbouring entries with `!=` gives `True` wherever the sign changes, and `np.sum` counts the `True` entries. The scan finds 2 sign changes of each function, one per bound state of that parity.

In [8], all four levels by bisection.

```
def well_levels(n, tolerance=1e-13):
    """The four energies with n RK4 steps: scan, then bisection on the brackets."""
    lo, hi, even = [], [], []
    for values, is_even in ((F_even(E_scan, n), True), (F_odd(E_scan, n), False)):
        # the places i where the sign of the mismatch differs from that at i + 1
        for i in np.nonzero(np.sign(values[:-1]) != np.sign(values[1:]))[0]:
            lo.append(E_scan[i])
            hi.append(E_scan[i + 1])
            even.append(is_even)
```

`well_levels` first scans both shooting functions on the 400 energies with `n` RK4 steps (the same `n` as the refinement, so that the brackets belong to the same shooting function). `np.nonzero(...)[0]` lists the positions `i` at which the sign changes between `i` and `i + 1`; each such pair of neighbouring energies is a bracket, stored with its parity.

```
    order = np.argsort(lo)  # lowest energy first
    lo, hi = np.array(lo)[order], np.array(hi)[order]
    even = np.array(even)[order]
```

`np.argsort(lo)` is the order of positions that sorts the left ends; using it as an index sorts all three lists the same way, lowest energy first.

```
    def mismatch(E):
        u0, du0 = shoot_well(E, n)
        return np.where(even, du0, u0)  # u'(0) for even, u(0) for odd states
    f_lo = mismatch(lo)
    while np.max(hi - lo) > tolerance:
        mid = 0.5 * (lo + hi)
        f_mid = mismatch(mid)
        same = np.sign(f_mid) == np.sign(f_lo)  # the root is above mid
        lo, f_lo = np.where(same, mid, lo), np.where(same, f_mid, f_lo)
        hi = np.where(same, hi, mid)
    return 0.5 * (lo + hi), even
```

`mismatch` shoots an array of energies and picks, entry by entry, $u'(0)$ for the even brackets and $u(0)$ for the odd ones: `np.where(condition, a, b)` takes the entry of `a` where the condition is true and that of `b` elsewhere. The `while` loop is bisection on all four brackets at once: as long as the

widest bracket is wider than 10^{-13}, it shoots the four midpoints, and where the sign at the midpoint equals the sign at the left end it moves the left end up, elsewhere the right end down. The function returns the four midpoints of the final brackets and their parities.

```
LEVELS, EVEN = well_levels(200)
exact = np.array([float(energy) for energy, _, _ in EXACT])
for n, (E_n, E_x) in enumerate(zip(LEVELS, exact)):
    say(f"E_{n}: RK4 (200 steps) {E_n:.12f}, exact {E_x:.12f}, "
        f"difference {E_n - E_x:+.1e}")
check(np.max(np.abs(LEVELS - exact)) < 1e-7,
      "the four shooting energies agree with the exact ones within 1e-7")
check(list(EVEN) == [True, False, True, False],
      "the levels alternate: even, odd, even, odd")
```

The four levels with 200 RK4 steps are compared with the exact ones. The differences are $+2.4\times10^{-11}$, $+1.5\times10^{-9}$, $+1.5\times10^{-8}$ and $+6.1\times10^{-8}$ (COMPUTED): all below 10^{-7}, and larger for the higher levels. The second check confirms the alternation of parities.

In [9], what a shot looks like when it misses.

```
def shoot_line(E, x_start=-3.0, x_end=3.0, n=600):
    """RK4 across the whole line; the potential is taken at the middle of every
    step (constant inside a step, because the walls are grid points)."""
    kappa = math.sqrt(-2.0 * E)
    h = (x_end - x_start) / n
    Y = np.array([1.0, kappa]) * math.exp(kappa * (x_start + A))  # exact tail
    xs, us = [x_start], [Y[0]]
```

This shot crosses the whole line from $x=-3$ to $x=3$ in 600 steps of $h=0.01$. It starts with the exact decaying tail: $u=e^{\kappa(x+a)}$ and $u'=\kappa u$ at $x=-3$.

```
    for i in range(n):
        x = x_start + i * h
        V = -V0 if abs(x + h / 2) < A else 0.0  # the potential of this step

        def f(x_value, Y_value, V=V):  # V=V freezes this step's potential in f
            return np.array([Y_value[1], 2.0 * (V - E) * Y_value[0]])
        Y = rk4_step(f, x, Y, h)
        xs.append(x + h)
        us.append(Y[0])
    return np.array(xs), np.array(us)
```

For every step the potential is read at the middle of the step: $-V_0$ if $|x+h/2|<a$, else 0. Because the walls $x=\pm1$ are grid points, the potential is constant inside every step, and RK4 keeps its accuracy. The right-hand side is defined anew for each step; the default argument `V=V` stores the current step's potential inside the function. After each step the position and u are recorded.

```
E0 = float(EXACT[0][0])
fig, ax = plt.subplots()
```

```
for shift, color, style in ((-0.05, ORANGE, "--"), (0.0, BLUE, "-"),
                            (0.05, AQUA, "-.")):
    xs, us = shoot_line(E0 + shift)
    ax.plot(xs, us / np.max(np.abs(us[xs <= 0])), style, color=color, lw=1.6,
            label=f"$E = E_0 {shift:+.2f}$")
```

Three shots: at the ground-state energy E_0 and 0.05 below and above it. Each is divided by its largest size on the left half (`us[xs <= 0]` keeps the values with $x \leq 0$), so that the three curves have comparable heights.

```
ax.axvspan(-A, A, color=GREY, alpha=0.15, label="inside the well")
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.set_ylim(-2.0, 2.0)
ax.set_xlabel("position $x$ (units $a$)")
ax.set_ylabel("$u(x)$ (scaled to 1 at the left peak)")
ax.set_title("Shots across the well near the ground state $E_0 = %.4f$" % E0)
ax.legend(loc="lower left", fontsize=8)
save_figure(fig, "trial_solutions_well",
            "Shots across the whole line from $x = -3$ to $x = 3$ (horizontal "
            ...)
```

`axvspan` shades the well; `"... %.4f" % E0` is an older way of writing a number into a string (the same as an f-string with `:.4f`). The figure is saved as `02b_6_trial_solutions_well.png`; one line of its caption is an f-string, which writes the value of E_0 into the caption. **What Figure 02b.6 shows:** all three shots start alike on the left; only the one at E_0 decays again on the right, while the one just below flies off to one infinity and the one just above to the other.

```
tail = {shift: shoot_line(E0 + shift)[1][-1] for shift in (-0.05, 0.05)}
check(tail[-0.05] * tail[0.05] < 0 and min(abs(tail[-0.05]), abs(tail[0.05])) > 10,
      "slightly below and above E0 the shots fly off to opposite infinities")
```

The end values of the two missing shots have opposite signs (their product is negative) and are both larger than 10 in size.

In [10], the four wave functions.

```
def simpson(values, h):
    """Simpson's rule for equally spaced values (an even number of intervals)."""
    return h / 3 * (values[0] + values[-1] + 4 * values[1:-1:2].sum()
                    + 2 * values[2:-1:2].sum())
```

Simpson's rule of Section 2.13. `values[1:-1:2]` takes every second entry starting at position 1 and stopping before the last (the odd positions, weight 4); `values[2:-1:2]` every second entry starting at position 2 (the inner even positions, weight 2).

```
def wave_function(E, is_even, n=200):
    """Normalised u on a grid of -3 <= x <= 3 (step a/n), built as described."""
    kappa = math.sqrt(-2.0 * E)
```

```
    h = A / n

    def f(x, Y):
        return np.array([Y[1], 2.0 * (-V0 - E) * Y[0]])
    Y = np.array([1.0, kappa])
    inside = [1.0]
    for i in range(n):
        Y = rk4_step(f, -A + i * h, Y, h)
        inside.append(Y[0])
    inside = np.array(inside)  # u on -a <= x <= 0
```

For one level, the shot from $x = -a$ to 0 inside the well (as in In [7], for a single energy), keeping all $n + 1$ values of u.

```
    norm = 2.0 * (simpson(inside ** 2, h) + 1.0 / (2.0 * kappa))  # both halves
```

$\int u^2\,dx$ over the whole line: on the left half, Simpson's rule inside the well plus the exact tail integral $1/(2\kappa)$ of Section 2.13 (the tail starts with $u(-a) = 1$); the right half gives the same by symmetry, hence the factor 2.

```
    x_left = np.arange(-3.0 * n, -n) * h  # -3 <= x < -a
    left = np.concatenate([np.exp(kappa * (x_left + A)), inside])
    x_half = np.concatenate([x_left, -A + np.arange(n + 1) * h])  # up to x = 0
```

`np.arange(-3.0 * n, -n)` counts from -600 up to -201, so times $h = 1/200$ it gives the positions from -3 to just before -1. On them u is the exact tail; `np.concatenate` joins it with the inside values. `x_half` holds the matching positions from -3 to 0.

```
    sign = 1.0 if is_even else -1.0
    x_all = np.concatenate([x_half, -x_half[-2::-1]])  # mirror x -> -x
    u_all = np.concatenate([left, sign * left[-2::-1]])
    return x_all, u_all / math.sqrt(norm), kappa, inside / math.sqrt(norm), h
```

The right half is the mirror image: `x_half[-2::-1]` runs backwards from the second-to-last entry to the first (leaving out $x = 0$, which is already there), and its negatives are the positions $x > 0$; the values are copied with the sign $+1$ for an even and -1 for an odd state. The function returns the positions, the normalised wave function (divided by $\sqrt{\int u^2 dx}$), κ, the normalised inside values and the step.

```
STATES = [wave_function(E_n, bool(e)) for E_n, e in zip(LEVELS, EVEN)]
fig, ax = plt.subplots(figsize=(7.0, 5.6))
x_pot = np.array([-3.0, -A, -A, A, A, 3.0])
ax.plot(x_pot, [0.0, 0.0, -V0, -V0, 0.0, 0.0], color=BLACK, lw=1.5,
        label="potential $V(x)$")
nodes = []
```

The four wave functions are built; the potential is drawn as a black line through six corner points (the walls are vertical because two points share each $x = \pm a$).

```
for n, (x_all, u_all, kappa, inside, h) in enumerate(STATES):
    E_n = LEVELS[n]
    ax.axhline(E_n, ls=":", color=GREY, lw=0.8)
    parity = "even" if EVEN[n] else "odd"
    ax.plot(x_all, E_n + 1.8 * u_all, color=LEVEL_COLORS[n], lw=1.6,
            label=f"$E_{n} = {E_n:.4f}$ ({parity})")
    big = u_all[np.abs(u_all) > 1e-8 * np.max(np.abs(u_all))]  # drop tiny values
    nodes.append(int(np.sum(np.sign(big[:-1]) != np.sign(big[1:]))))
```

Each state is drawn lifted to its energy, as $E_n + 1.8\,u_n(x)$, on a dotted line at its energy. To count the **nodes** (sign changes), the values smaller than 10^{-8} times the largest are dropped first, so that a value that is zero up to rounding (the centre of an odd state) cannot be counted as an extra sign change; then the sign changes are counted as in In [7].

```
ax.set_xlabel("position $x$ (units $a$)")
ax.set_ylabel("energy (units $\\hbar^2/(m a^2)$) and $E_n + 1.8\\, u_n(x)$")
ax.set_ylim(-16.0, 5.0)  # room for the legend above the well
ax.set_title("The four bound states of the finite square well")
ax.legend(loc="upper center", ncol=2, fontsize=8)
save_figure(fig, "eigenfunctions",
            "The four bound states of the finite square well of depth 15 and "
            ...)
report("nodes of the states 0 to 3", nodes)
check(nodes == [0, 1, 2, 3], "the state n has exactly n nodes")
```

Labels, a legend in two columns (`ncol=2`) and the saved figure `02b_7_eigenfunctions.png`; the node counts are $[0, 1, 2, 3]$ and the check requires exactly that. **What Figure 02b.7 shows:** the state n has n nodes, even and odd states alternate, and the higher the energy, the further the wave function leaks out of the well, where it decays like $e^{-\kappa|x|}$ (κ is smaller for a higher level).

```
def overlap(m, n):
    """The integral of u_m u_n over the whole line: Simpson inside, exact tails."""
    _, _, k_m, in_m, h = STATES[m]
    _, _, k_n, in_n, _ = STATES[n]
    half = simpson(in_m * in_n, h) + in_m[0] * in_n[0] / (k_m + k_n)
    same = (EVEN[m] == EVEN[n])  # different parity: the halves cancel exactly
    return 2.0 * half if same else 0.0
```

$\int u_m u_n\,dx$ over the left half is Simpson's rule inside the well plus the exact tail integral: on the tail $u_m u_n = u_m(-a)\,u_n(-a)\,e^{(\kappa_m+\kappa_n)(x+a)}$, and $\int_{-\infty}^{-a} e^{(\kappa_m+\kappa_n)(x+a)}\,dx = 1/(\kappa_m+\kappa_n)$ (the same antiderivative as in Section 2.13), which gives the term `in_m[0] * in_n[0] / (k_m + k_n)`. For the same parity the right half equals the left half; for different parity the integral is exactly zero (Section 2.13).

```
gram = np.array([[overlap(m, n) for n in range(4)] for m in range(4)])
report("largest |integral u_m u_n - (1 if m = n else 0)|",
       f"{np.max(np.abs(gram - np.eye(4))):.1e}")
check(np.max(np.abs(gram - np.eye(4))) < 1e-8,
      "the wave functions are normalised and orthogonal within 1e-8")
```

`gram` is the 4 by 4 table of all the integrals. For normalised, orthogonal functions it must be the unit matrix `np.eye(4)` (1 on the diagonal, 0 elsewhere); the largest difference is 1.6×10^{-10} (COMPUTED), within the required 10^{-8}. The entries for two states of different parity are set to 0 by `overlap` itself, using the proof; so this check tests the normalisation and the orthogonality of states of the same parity only. The next lines test the different-parity case numerically.

```
middle = len(STATES[0][0]) // 2  # the position of x = 0 in the grid -3 ... 3
whole_line, left_half = [], []
```

`STATES[0][0]` is the grid of x values from -3 to 3 (the first entry returned by `wave_function`). It has $6n + 1 = 1201$ points, so the integer division `// 2` gives 600, the position of the middle point $x = 0$. Two empty lists will collect the results.

```
for m, n in [(0, 1), (0, 3), (1, 2), (2, 3)]:  # the pairs of different parity
    product = STATES[m][1] * STATES[n][1]  # u_m u_n on the grid
    h_grid = STATES[m][4]  # the grid spacing a/200
    whole_line.append(abs(simpson(product, h_grid)))  # from x = -3 to x = 3
    left_half.append(abs(simpson(product[:middle + 1], h_grid)))  # -3 to 0
```

The states 0 and 2 are even, 1 and 3 odd, so these are the four pairs of different parity. `STATES[m][1]` is the normalised wave function u_m on the whole grid (the second entry returned by `wave_function`) and `STATES[m][4]` the grid spacing $a/200 = 0.005$. For each pair the product $u_m u_n$ is integrated with Simpson's rule over the whole grid ($-3 \le x \le 3$, 1200 intervals, an even number as Simpson's rule needs) and over the left half alone (`product[:middle + 1]`, the points from $x = -3$ to $x = 0$, 600 intervals); the sizes are stored.

```
report("different parity: largest |whole integral|, smallest |left half|",
       f"{max(whole_line):.1e}, {min(left_half):.2f}")
check(max(whole_line) < 1e-12 < 0.01 < min(left_half),
      "different parity: the two halves cancel, the whole integral is 0")
```

The RESULT line prints the largest whole integral, 9.5×10^{-17}, and the smallest half integral, 0.16 (COMPUTED). The chained comparison `a < b < c < d` means $a < b$ and $b < c$ and $c < d$: every whole integral is below 10^{-12} (zero up to rounding), while every half integral is above 0.01. So the two halves are far from zero each but cancel exactly, as the symmetry argument of Section 2.13 says: the product of an even and an odd function is odd.

In [11], the order of the computed energies.

```
N_STEPS = [4, 8, 16, 32, 64, 128, 256, 512, 1024]
level_errors = np.array([np.abs(well_levels(n)[0] - exact) for n in N_STEPS])
h_values = A / np.array(N_STEPS, dtype=float)
```

The whole level search is repeated with 4 to 1024 RK4 steps on $-a \le x \le 0$; `level_errors` is a table with one row per step count and one column per level.

```
fig, ax = plt.subplots()
slopes = []
```

```
for n in range(4):
    ax.loglog(h_values, level_errors[:, n], "o-", color=LEVEL_COLORS[n], ms=5,
              lw=1.2, label=f"$E_{n}$")
    fit = level_errors[:, n] > 1e-12  # leave out the rounding-limited points
    slope, _ = np.polyfit(np.log10(h_values[fit]), np.log10(level_errors[fit, n]), 1)
    slopes.append(slope)
```

For each level the errors are drawn against the step on a log-log plot, and a straight line is fitted through the points above 10^{-12} (below that the errors are limited by rounding and by the bisection tolerance).

```
guide = level_errors[0, 3] * (h_values / h_values[0]) ** 4
ax.loglog(h_values, guide, "--", color=GREY, lw=1.0, label="slope 4")
ax.set_xlabel("RK4 step size $h = a/n$ (units $a$)")
ax.set_ylabel("error of the energy (units $\\hbar^2/(m a^2)$)")
ax.set_title("Shooting energies converge like $h^4$")
ax.legend()
save_figure(fig, "eigenvalue_convergence",
            "The error of the four shooting energies of the finite well, "
            ...)
```

A dashed guide of slope 4 through the first point of the highest level, labels and the saved figure `02b_8_eigenvalue_convergence.png`. **What Figure 02b.8 shows:** four parallel lines of slope 4, the highest level on top: an eigenvalue found by shooting inherits the order of the integrator, and a level whose wave function oscillates faster (larger k) has a larger error, which grows like $(kh)^4$.

```
report("measured orders of E_0 ... E_3", ", ".join(f"{s:.2f}" for s in slopes))
check(all(3.8 < s < 4.3 for s in slopes),
      "the energy errors fall with the order 4 (slopes between 3.8 and 4.3)")
check(np.all(level_errors[-1] < 1e-9), "with 1024 steps every energy is within 1e-9")
```

The measured orders are 3.99, 3.98, 3.96 and 3.92 (COMPUTED); the checks require them between 3.8 and 4.3 and every error with 1024 steps below 10^{-9}.

In [12], the last check. It is built like In [15] of Notebook 02a: it checks that the eight figure files `02b_1_trial_solutions_string.png` to `02b_8_eigenvalue_convergence.png` exist and prints ALL 16 CHECKS PASSED (notebook 02b).

```
names = ["trial_solutions_string", "shooting_function_string",
         "bisection_vs_secant", "graphical_solution", "shooting_functions_well",
         "trial_solutions_well", "eigenfunctions", "eigenvalue_convergence"]
present = [output_file(f"{FIGURE_FOLDER}/02b_{k}_{name}.png").is_file()
           for k, name in enumerate(names, 1)]
check(all(present), f"all {len(names)} figure files of notebook 02b exist")
all_checks_passed()
```

The 16 checks are: 1 in In [3], 1 in In [4], 3 in In [5], 1 in In [6], 1 in In [7], 2 in In [8], 1 in In [9], 3 in In [10], 2 in In [11] and 1 in In [12].

2.18 Functions of several variables and partial derivatives

Functions of several variables. A function of two variables is a rule $f(x, y)$ that gives a number for every pair of numbers (x, y); a function of eight variables gives a number for every list $(x_0, \dots, x_7)$. The entries of the author's metric are functions of this kind (of x_4 and x_0 only).

Partial derivatives. The **partial derivative** of f with respect to x is the ordinary derivative with respect to x while all the other variables are held fixed:

$$\frac{\partial f}{\partial x}(x, y) = \lim_{h \to 0} \frac{f(x + h, y) - f(x, y)}{h}.$$

The curly ∂ reminds us that other variables exist and are held fixed. We also write $\partial_x f$, and for the author's coordinates $\partial_4 = \partial/\partial x_4$ and $\partial_0 = \partial/\partial x_0$. Holding y fixed at a value y_0 turns f into the function $x \mapsto f(x, y_0)$ of one variable, a **slice**; the partial derivative is the slope of the slice. Every rule of one-variable calculus (sums, products, quotients, the chain rule) therefore holds for each partial derivative.

Example. $f(x, y) = x^2 \sin y$.

$$\frac{\partial f}{\partial x} = 2x \sin y$$

(with y held fixed, $\sin y$ is a constant factor, and the derivative of x^2 is $2x$);

$$\frac{\partial f}{\partial y} = x^2 \cos y$$

(with x held fixed, x^2 is a constant factor, and the derivative of $\sin y$ is $\cos y$). At the point $(x_0, y_0) = (1.2, 0.7)$ these slopes are $2 \cdot 1.2 \cdot \sin 0.7 = 1.5461$ and $1.44 \cos 0.7 = 1.1014$ (COMPUTED in Notebook 02c, In [3]).

Second and mixed derivatives. Differentiating again gives second partial derivatives; the **mixed** ones differentiate once with respect to each variable:

$$\frac{\partial}{\partial y}\Big(\frac{\partial f}{\partial x}\Big) = \frac{\partial}{\partial y}(2x \sin y) = 2x \cos y, \qquad \frac{\partial}{\partial x}\Big(\frac{\partial f}{\partial y}\Big) = \frac{\partial}{\partial x}(x^2 \cos y) = 2x \cos y$$

(each time the other variable is a constant factor). The two orders agree. This is **Schwarz's theorem**: for a function whose second partial derivatives are continuous, the order of differentiation does not matter (ASSUMED: a standard theorem of calculus, quoted without proof; Notebook 02c confirms it for this example, and Section 2.24 uses it).

The linear approximation. How much does f change when BOTH variables change a little, $x \to x + dx$ and $y \to y + dy$? Split the change into two moves, one variable at a time:

$$f(x + dx, y + dy) - f(x, y) = \big[f(x + dx, y + dy) - f(x, y + dy)\big] + \big[f(x, y + dy) - f(x, y)\big]$$

(we add and subtract $f(x, y + dy)$);

$$f(x+dx, y+dy) - f(x,y) \approx \frac{\partial f}{\partial x}(x, y+dy)\,dx + \frac{\partial f}{\partial y}(x,y)\,dy$$

(each bracket is the change of a slice, which is its slope times the step, up to terms of second order in the step);

$$f(x+dx, y+dy) - f(x,y) \approx \frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy$$

(the slope in x changes only a little when y moves by dy, if $\partial f/\partial x$ is continuous; both slopes are now taken at (x, y)).

The gradient and the level curves. The **gradient** is the arrow $\nabla f = (\partial f/\partial x,\, \partial f/\partial y)$. A **level curve** (contour) is a curve on which f has one fixed value. Move a small distance s in the direction of a unit arrow (c, d) (one with $c^2 + d^2 = 1$), that is $dx = sc$ and $dy = sd$. By the linear approximation the change of f is

$$\Delta f \approx s\left(c\,\frac{\partial f}{\partial x} + d\,\frac{\partial f}{\partial y}\right),$$

s times the **dot product** of the direction with the gradient (the dot product of two arrows (c, d) and (p, q) is the number $cp + dq$). For short write $f_x = \partial f/\partial x$ and $f_y = \partial f/\partial y$, so that $\nabla f = (f_x, f_y)$, and let

$$|\nabla f| = \sqrt{f_x^2 + f_y^2}$$

be the **length** of the gradient arrow (Pythagoras' theorem; we take a point where $\nabla f \neq (0,0)$). Two facts follow. (1) The arrow $(c, d) = (-f_y,\, f_x)/|\nabla f|$ is a unit arrow, because $c^2 + d^2 = (f_y^2 + f_x^2)/|\nabla f|^2 = 1$. Along it the bracket is $cf_x + df_y = (-f_y f_x + f_x f_y)/|\nabla f| = 0$: f does not change to first order, so this direction runs along the level curve, and it is perpendicular to the gradient (their dot product is zero). (2) Every unit arrow can be written $(c, d) = (\cos\varphi, \sin\varphi)$, where φ is its angle to the x axis, and the gradient as $(f_x, f_y) = |\nabla f|\,(\cos\psi, \sin\psi)$ with its angle ψ. Then

$$cf_x + df_y = |\nabla f|\,(\cos\varphi\cos\psi + \sin\varphi\sin\psi) = |\nabla f|\cos(\varphi - \psi)$$

(insert both; then the addition formula of the cosine, $\cos(a-b) = \cos a\cos b + \sin a\sin b$). The cosine is largest, 1, when $\varphi = \psi$: the change of f per unit length is largest when the arrow points along the gradient, and there it is $|\nabla f|$. So the gradient points uphill, in the direction of the steepest increase, and its length is the steepest slope; in the opposite direction ($\varphi - \psi = \pi$, cosine -1) f falls fastest. Notebook 02c, In [4], checks both facts at the point $(1.2, 0.7)$: a step of 10^{-4} along the level curve changes f by only -9.58×10^{-9} (a second-order amount), and along the gradient f rises at the rate 1.898407 per unit length, against $|\nabla f| = 1.898293$ (COMPUTED).

Finite differences. A computer approximates a derivative from values of the function at nearby points with a small spacing h. Taylor's theorem (Section 2.3) gives

$$f(x+h) = f(x) + hf'(x) + \frac{h^2}{2}f''(x) + \frac{h^3}{6}f'''(x) + \dots$$

and, with h replaced by $-h$ (the odd powers change sign),

$$f(x-h) = f(x) - hf'(x) + \frac{h^2}{2}f''(x) - \frac{h^3}{6}f'''(x) + \dots$$

The **forward difference**:

$$\frac{f(x+h) - f(x)}{h} = f'(x) + \frac{h}{2}f''(x) + \dots$$

(subtract $f(x)$ from the first series and divide by h): its error is proportional to h (order 1). The **central difference**:

$$\frac{f(x+h) - f(x-h)}{2h} = f'(x) + \frac{h^2}{6}f'''(x) + \dots$$

(subtract the second series from the first: the even powers cancel, $f(x+h) - f(x-h) = 2hf'(x) + \frac{h^3}{3}f'''(x) + \dots$; then divide by $2h$): its error is proportional to h^2 (order 2). For a partial derivative the same formulas are applied to a slice. A **mixed** derivative $\partial^2 f/\partial x \partial y$ is approximated by applying the central difference twice, first in y and then in x:

$$\frac{\partial^2 f}{\partial x\, \partial y} \approx \frac{f(x+h, y+h) - f(x+h, y-h) - f(x-h, y+h) + f(x-h, y-h)}{4h^2}$$

(the central difference in y, $g(x) = [f(x, y+h) - f(x, y-h)]/(2h)$, inserted into the central difference in x, $[g(x+h) - g(x-h)]/(2h)$; each of the two steps has an error of order h^2, so the result has order 2).

The best spacing. The truncation error falls as h shrinks, but rounding grows: each value of f carries a rounding error of about $\epsilon|f|$ (Section 2.6), and a difference of two such values divided by h carries an error of about $\epsilon|f|/h$. For the forward difference the total error is about

$$E(h) = \alpha h + \frac{\beta}{h}, \qquad \alpha = \frac{|f''|}{2}, \quad \beta = \epsilon|f|$$

(the truncation term of the forward difference plus the rounding term). It is smallest where its derivative vanishes:

$$E'(h) = \alpha - \frac{\beta}{h^2} = 0, \qquad h_{\text{best}} = \sqrt{\beta/\alpha}$$

(differentiate term by term; then solve for h). For $f = x^2 \sin y$ at $(1.2, 0.7)$ in the variable y: $|f| = 0.928$ and $|\partial^2 f/\partial y^2| = |x^2 \sin y| = 0.928$, so $\beta = 2.2 \times 10^{-16} \cdot 0.928 = 2.0 \times 10^{-16}$, $\alpha = 0.46$ and $h_{\text{best}} \approx 2 \times 10^{-8}$. For the central difference $E(h) = \alpha h^2 + \beta/h$ with $\alpha = |f'''|/6$, and $E'(h) =$

$2\alpha h - \beta/h^2 = 0$ gives $h_{\text{best}} = (\beta/(2\alpha))^{1/3} \approx 10^{-5}$ (here $|f'''| = |\partial^3 f/\partial y^3| = |x^2 \cos y| = 1.101$, so $\alpha = 0.184$ and $h_{\text{best}} = 8 \times 10^{-6}$).

For the mixed formula both parts of the error are different. Its truncation term: the central difference in y is $g(x) = \partial_y f(x,y) + \frac{h^2}{6}\,\partial_y^3 f(x,y) + \dots$ (the series of the central difference above, applied to the slice in y; ∂_y^3 means ∂_y applied three times), and the central difference in x of g is $\partial_x g + \frac{h^2}{6}\,\partial_x^3 g + \dots$ (the same series in x). Inserting g into the second series gives

$$\frac{g(x+h) - g(x-h)}{2h} = \partial_x \partial_y f + \frac{h^2}{6}(\partial_x \partial_y^3 f + \partial_x^3 \partial_y f) + \dots$$

(the term $\frac{h^2}{6}\partial_x^3 g$ contributes $\frac{h^2}{6}\partial_x^3 \partial_y f$; the terms with h^4 are left out). Its rounding term: each of the four values of f carries about $\epsilon|f|$, together at most about $4\epsilon|f|$, and the formula divides by $4h^2$, which gives about $\epsilon|f|/h^2$. So

$$E(h) = \alpha h^2 + \frac{\beta}{h^2}, \qquad \alpha = \frac{|\partial_x \partial_y^3 f + \partial_x^3 \partial_y f|}{6}, \quad \beta = \epsilon|f|$$

(the truncation term plus the rounding term);

$$E'(h) = 2\alpha h - \frac{2\beta}{h^3} = 0, \qquad h^4 = \frac{\beta}{\alpha}, \qquad h_{\text{best}} = \Big(\frac{\beta}{\alpha}\Big)^{1/4}$$

(differentiate term by term, using $d(h^{-2})/dh = -2h^{-3}$; multiply by $h^3/(2\alpha)$; take the fourth root). For $f = x^2 \sin y$: $\partial_y^3 f = -x^2 \cos y$, so $\partial_x \partial_y^3 f = -2x \cos y$, while $\partial_x^3 \partial_y f = \partial_x^3 (x^2 \cos y) = 0$ (the third derivative of x^2 is 0). At $(1.2, 0.7)$ this gives $\alpha = 2 \cdot 1.2 \cdot \cos 0.7/6 = 0.306$ and $h_{\text{best}} = (2.0 \times 10^{-16}/0.306)^{1/4} = 1.6 \times 10^{-4}$, of the order 10^{-4}.

These are estimates of the scale only (rounding errors are not always of their largest size); Notebook 02c (In [6]) measures the best spacings 1.0×10^{-8}, 1.8×10^{-6} and 5.6×10^{-5} (COMPUTED). The lesson: the best spacing is far from the smallest one.

2.19 The chain rule and the derivatives of the author's metric

The chain rule for $z = 6Hx_0$. The author writes the hidden direction with the variable $z = 6Hx_0$, which runs over $0 < z < \pi/2$. A function of z, such as $g_{00} = \cot^2 z$, depends on x_0 through z, and the chain rule of one-variable calculus gives

$$\frac{\partial}{\partial x_0} F(z) = \frac{dF}{dz}\,\frac{\partial z}{\partial x_0} = 6H\,\frac{dF}{dz}$$

(the chain rule, and $\partial z/\partial x_0 = 6H$ because z is $6H$ times x_0). In short, $\partial_0 = 6H\, d/dz$ on functions of z. *Example.*

$$\frac{d}{dz}\cot^2 z = 2\cot z \cdot \Big(-\frac{1}{\sin^2 z}\Big) = -\frac{2\cot z}{\sin^2 z}$$

(the chain rule for the square, and the derivative of $\cot z$ is $-1/\sin^2 z$), so $\partial_0 \cot^2(6Hx_0) = -12H \cot z/\sin^2 z$ (multiply by $6H$); Notebook 02c, In [7], prints exactly this.

The metric and its scale factors. The metric is an 8×8 table of numbers g_{ab}, a **matrix** (Chapter 1), with rows and columns numbered by the author's coordinates $x_0, \ldots, x_7$, so that $a, b = 0, 1, \ldots, 7$. In the author's coordinates it is **diagonal**: only the entries $g_{00}, \ldots, g_{77}$ on its diagonal are nonzero, with

$$g_{00} = \cot^2 z, \quad g_{11} = g_{22} = g_{33} = e^{2a_4} \sin^{1/3} z, \quad g_{44} = -1, \quad g_{55} = g_{66} = g_{77} = -b_4\, e^{-2a_4} \sin^{1/3} z$$

(the author's metric, with the two functions $a_4(x_4)$ and $b_4(x_4) > 0$ of the time; $b_4 = 1$ is the background of the Revision record; COMPUTED: Notebook 02c, In [8], reads these eight entries from the Revision record `Revision/gkd_lovelock/results/curvature.json`, key `metricDiagonal`, and checks them against the formulas). The entries are positive for the space-like directions x_0, x_1, x_2, x_3 and negative for the time-like directions x_4, x_5, x_6, x_7; four positive and four negative entries are what the **signature** (4,4) means. The scale factor $s_a = \sqrt{|g_{aa}|}$ of each direction is

$$s_0 = \cot z, \qquad s_{1,2,3} = e^{a_4} \sin^{1/6} z, \qquad s_4 = 1, \qquad s_{5,6,7} = b_4^{1/2}\, e^{-a_4} \sin^{1/6} z$$

(the square root of each absolute value, as in Section 2.2; for s_0 we use $\cot z > 0$ on $0 < z < \pi/2$).

The logarithmic rates. The rate at which a scale factor grows, as a fraction of itself, is its **logarithmic derivative** $\partial_c \ln s_a = (\partial_c s_a)/s_a$ (the chain rule for the logarithm, whose derivative is $1/s$). Since $s_a^2 = |g_{aa}|$,

$$\partial_c \ln s_a = \frac{1}{2}\, \partial_c \ln |g_{aa}| = \frac{\partial_c g_{aa}}{2 g_{aa}}$$

($\ln s = \frac{1}{2} \ln s^2$; then the chain rule for the logarithm; the absolute value does not matter because $\partial_c |g|/|g| = \partial_c g/g$). For 3-space:

$$\ln s_1 = a_4 + \tfrac{1}{6} \ln \sin z$$

(the logarithm of a product is the sum of the logarithms, $\ln e^{a_4} = a_4$, and $\ln(\sin^{1/6} z) = \frac{1}{6} \ln \sin z$);

$$\partial_4 \ln s_1 = a_4', \qquad \partial_0 \ln s_1 = \tfrac{1}{6} \cdot 6H \cdot \frac{\cos z}{\sin z} = H \cot z$$

(a_4 depends on x_4 only, z on x_0 only; the derivative of $\ln \sin z$ is $\cos z/\sin z$, and the chain rule supplies $6H$). For the extra times $\ln s_5 = \frac{1}{2} \ln b_4 - a_4 + \frac{1}{6} \ln \sin z$, so

$$\partial_4 \ln s_5 = -a_4' + \frac{b_4'}{2 b_4}, \qquad \partial_0 \ln s_5 = H \cot z$$

(the same steps with $-a_4$; the new term $\frac{1}{2} \ln b_4$ has the derivative $\frac{1}{2} b_4'/b_4$ by the chain rule for the logarithm, and does not depend on x_0). For the hidden direction $\ln s_0 = \ln \cot z$:

$$\partial_0 \ln s_0 = 6H\,\frac{-1/\sin^2 z}{\cot z} = -\frac{6H}{\sin z\cos z}$$

(the chain rule twice; then $\cot z \sin^2 z = \sin z \cos z$), and $\partial_4 \ln s_0 = 0$; the time direction has $s_4 = 1$ and both rates 0. Along the history $a_4 = AHx_4$, $b_4 = 1$ we have $a_4' = AH$ and $b_4' = 0$; with $A = H = 1$ the three 3-space factors grow at the rate $+1$ and the three extra-time factors shrink at the rate -1: 3-space inflates and the extra times deflate exponentially (Notebook 02c, In [9]).

The rates add up to the rate of the volume. Along x_4:

$$\sum_{a=0}^{7} \partial_4 \ln s_a = 0 + 3a_4' + 0 + 3\Big(-a_4' + \frac{b_4'}{2b_4}\Big) = \frac{3}{2}\,\frac{b_4'}{b_4}$$

(the hidden direction, three 3-space directions, the time, three extra times); it is 0 when b_4 is constant. Along x_0:

$$\sum_{a=0}^{7} \partial_0 \ln s_a = -\frac{6H}{\sin z\cos z} + 6H\cot z = 6H\,\frac{\cos^2 z - 1}{\sin z\cos z} = -6H\,\frac{\sin^2 z}{\sin z\cos z} = -6H\tan z$$

(six directions with $H\cot z$; both terms written over the denominator $\sin z\cos z$; then $\cos^2 z - 1 = -\sin^2 z$). We now show that these sums are the rates of the **volume factor** $\sqrt{|\det g|}$.

The determinant. The **determinant** of a diagonal matrix is the product of its diagonal entries (Chapter 1). So

$$\det g = \cot^2 z \cdot \big(e^{2a_4}\sin^{1/3} z\big)^3 \cdot (-1) \cdot \big(-b_4\, e^{-2a_4}\sin^{1/3} z\big)^3$$

(the product of the eight entries);

$$\det g = (-1)(-1)^3\, b_4^3\, e^{6a_4} e^{-6a_4} \sin^{6/3} z\, \cot^2 z = b_4^3 \sin^2 z \cot^2 z$$

(the four minus signs multiply to $+1$; $(e^{2a_4})^3 = e^{6a_4}$ and $(e^{-2a_4})^3 = e^{-6a_4}$ multiply to $e^0 = 1$; the three factors b_4 give b_4^3; the six factors $\sin^{1/3} z$ give $\sin^2 z$);

$$\det g = b_4^3 \sin^2 z\,\frac{\cos^2 z}{\sin^2 z} = b_4^3\cos^2 z, \qquad \sqrt{|\det g|} = b_4^{3/2}\sin z\cot z = b_4^{3/2}\cos z$$

($\cot z = \cos z/\sin z$; and $\cos z > 0$ on $0 < z < \pi/2$). The factors e^{6a_4} of the inflating 3-space and e^{-6a_4} of the deflating extra times cancel: the volume factor depends on x_4 only through b_4, and for constant b_4 (the background) it does not depend on x_4, for EVERY function $a_4(x_4)$ (PROVED here; COMPUTED in Notebook 02c, In [11], which reproduces the record's entry `sqrtAbsDetG` $= b_4^{3/2}\sin z\cot z$ of `Revision/gkd_lovelock/results/curvature.json` and the Wolfram check `sqrt_abs_det_g_is_cos_z` of `Revision/field_equations_a4/reports/wolfram-a4-report.json`, which states $\sqrt{|\det g|} = b_4^{3/2}\cos z$).

Jacobi's formula for the derivative of the volume factor of a diagonal metric:

$$\sqrt{|\det g|} = \prod_{a=0}^{7} s_a$$

($|\det g|$ is the product of the $|g_{aa}| = s_a^2$, and the square root of a product is the product of the square roots);

$$\partial_c \ln \sqrt{|\det g|} = \sum_{a=0}^{7} \partial_c \ln s_a = \sum_{a=0}^{7} \frac{\partial_c g_{aa}}{2 g_{aa}} = \frac{1}{2}\,\mathrm{tr}(g^{-1}\,\partial_c g)$$

(the logarithm of a product is the sum of the logarithms; then the rates computed above; finally, for a diagonal g the inverse g^{-1} is diagonal with the entries $1/g_{aa}$, the matrix $g^{-1}\partial_c g$ is diagonal with the entries $\partial_c g_{aa}/g_{aa}$, and the **trace** tr is the sum of the diagonal entries). Multiplying by $\sqrt{|\det g|}$ gives Jacobi's formula $\partial_c \sqrt{|\det g|} = \frac{1}{2}\sqrt{|\det g|}\,\mathrm{tr}(g^{-1}\partial_c g)$. With the sums above: $\partial_4 \ln(b_4^{3/2}\cos z) = \frac{3}{2} b_4'/b_4$ and $\partial_0 \ln(b_4^{3/2}\cos z) = 6H \cdot (-\sin z/\cos z) = -6H\tan z$, in agreement (Notebook 02c, In [10] and In [11]).

Christoffel symbols of a diagonal metric. The geometry of Chapter 3 combines first partial derivatives of the metric into the **Christoffel symbols** $\Gamma^a{}_{bc}$. Here we take their formula for a diagonal metric as given (ASSUMED in this chapter; derived in Chapter 3) and use it only as an exercise in partial derivatives:

$$\Gamma^a{}_{bc} = \frac{1}{2g_{aa}}(\partial_b g_{ac} + \partial_c g_{ab} - \partial_a g_{bc}) \qquad \text{(no sum over } a\text{)}.$$

Because g is diagonal, g_{ac} is zero unless $a = c$. Going through the cases: if a, b and c are all different, every term contains an off-diagonal entry and vanishes. If $b = a$ (c arbitrary):

$$\Gamma^a{}_{ac} = \frac{1}{2g_{aa}}(\partial_a g_{ac} + \partial_c g_{aa} - \partial_a g_{ac}) = \frac{\partial_c g_{aa}}{2g_{aa}} = \partial_c \ln s_a$$

(the first and third terms cancel; what remains is the logarithmic rate; the case $c = a$ gives the same by the symmetry in b and c). If $b = c \neq a$:

$$\Gamma^a{}_{bb} = \frac{1}{2g_{aa}}(\partial_b g_{ab} + \partial_b g_{ab} - \partial_a g_{bb}) = -\frac{\partial_a g_{bb}}{2g_{aa}}$$

($g_{ab} = 0$ for $b \neq a$). Since the metric depends only on x_4 and x_0, the nonzero entries are (listing $\Gamma^a{}_{bc}$ with b not after c in the order $x_0, \ldots, x_7$, because the symbol is symmetric in b and c):

entries	**value**	**how many**
$\Gamma^0{}_{00}$	$-6H/(\sin z \cos z)$	1
$\Gamma^a{}_{0a}$, $a = 1,2,3,5,6,7$	$H \cot z$	6
$\Gamma^a{}_{a4}$, $a = 1,2,3$	a_4'	3
$\Gamma^a{}_{4a}$, $a = 5,6,7$	$-a_4' + b_4'/(2b_4)$	3
$\Gamma^4{}_{bb}$, $b = 1,2,3$	$a_4'\, e^{2a_4} \sin^{1/3} z$	3
$\Gamma^4{}_{bb}$, $b = 5,6,7$	$(a_4' b_4 - \frac{1}{2} b_4')\, e^{-2a_4} \sin^{1/3} z$	3

entries	value	how many
${\Gamma^0}_{bb}$, $b = 1,2,3$	$-He^{2a_4}\sin^{1/3} z\,\tan z$	3
${\Gamma^0}_{bb}$, $b = 5,6,7$	$+Hb_4e^{-2a_4}\sin^{1/3} z\,\tan z$	3

which makes $1+6+3+3+3+3+3+3 = 25$ entries; at $b_4 = 1$ the terms with b_4' drop out. Three of them worked out: ${\Gamma^4}_{11} = -\partial_4 g_{11}/(2g_{44}) = -2a_4' g_{11}/(2\cdot(-1)) = a_4' g_{11}$ (the derivative of e^{2a_4} is $2a_4'e^{2a_4}$); ${\Gamma^4}_{55} = -\partial_4 g_{55}/(2g_{44}) = \frac{1}{2}\partial_4 g_{55} = \frac{1}{2}\partial_4(-b_4e^{-2a_4}\sin^{1/3} z) = -\frac{1}{2}(b_4' - 2a_4'b_4)e^{-2a_4}\sin^{1/3} z$ (the product rule for $b_4e^{-2a_4}$, and the derivative of e^{-2a_4} is $-2a_4'e^{-2a_4}$), which is the table's $(a_4'b_4 - \frac{1}{2}b_4')\,e^{-2a_4}\sin^{1/3} z$; and

$$ {\Gamma^0}_{11} = -\frac{\partial_0 g_{11}}{2g_{00}} = -\frac{e^{2a_4}\cdot\frac{1}{3}\sin^{-2/3} z\cos z\cdot 6H}{2\cot^2 z} $$

(the case formula; the power rule and the chain rule for $\sin^{1/3} z$);

$$ {\Gamma^0}_{11} = -He^{2a_4}\sin^{-2/3} z\,\cos z\,\frac{\sin^2 z}{\cos^2 z} = -He^{2a_4}\sin^{1/3} z\,\tan z $$

($\frac{1}{3}\cdot 6H/2 = H$ and $1/\cot^2 z = \sin^2 z/\cos^2 z$; then $\sin^{-2/3} z\sin^2 z = \sin^{4/3} z = \sin^{1/3} z\cdot\sin z$ and $\sin z/\cos z = \tan z$). The extra-time entries ${\Gamma^0}_{55}$ have the opposite sign and the factor b_4 because g_{55} carries the minus sign of a time-like direction and the factor b_4. Notebook 02c, In [12], computes all $8\times 36 = 288$ entries with b not after c from the formula, finds exactly 25 nonzero ones and compares each with the Revision record (COMPUTED: reproduces `Revision/gkd_lovelock/results/curvature.json`, key `christoffelNonzero_b_le_c`).

2.20 Example: partial derivatives of a model function and of the author's metric

Notebook 02c carries out Sections 2.18 and 2.19. It differentiates $f = x^2\sin y$ with sympy, checks Schwarz's theorem, draws the level curves with the gradient arrows and checks that the gradient is perpendicular to them and points uphill, draws two slices with their tangent lines, measures the orders and the rounding limits of three finite-difference formulas, checks the chain rule for $z = 6Hx_0$, and then reads the author's metric from the Revision record and computes its rates along x_4 and x_0, the volume factor $b_4^{3/2}\cos z$, Jacobi's formula and all 25 Christoffel entries. It ends with ALL 17 CHECKS PASSED (notebook 02c).

2.21 How to run Notebook 02c

Step 1. What this notebook does and what it needs.

Notebook 02c (Partial derivatives, finite differences and the chain rule) is the file `Revision/textbook/notebooks/02c_partial_derivatives.ipynb` of the repository Dirac_claude. It computes partial derivatives of a function of two variables with sympy and by finite differences (forward and central differences, their orders 1 and 2 and the limit set by rounding), draws level curves with the gradient and slices with their tangent lines, checks that mixed partial derivatives do not depend on the order, checks the chain rule for the author's variable z = 6 H x0, and then reads the author's

metric from a Revision record and computes its partial derivatives: the growth and deflation rates of the eight scale factors, the volume factor sqrt of the absolute determinant (equal to b4^(3/2) cos z, independent of the time x4 for constant b4), Jacobi's formula, and all 25 nonzero Christoffel entries listed in the record. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 02c_partial_derivatives.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02c_partial_derivatives.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 02c_partial_derivatives.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/02c.captions.json`
- `Revision/textbook/figures/02c_1_level_curves_gradient.png`
- `Revision/textbook/figures/02c_2_slices_and_slopes.png`
- `Revision/textbook/figures/02c_3_finite_differences.png`
- `Revision/textbook/figures/02c_4_chain_rule.png`
- `Revision/textbook/figures/02c_5_rates_along_x4.png`
- `Revision/textbook/figures/02c_6_rates_along_x0.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of notebook 02c exist
ALL 17 CHECKS PASSED (notebook 02c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/02c_partial_derivatives.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 02c_partial_derivatives.ipynb
python -m nbconvert --execute --inplace 02c_partial_derivatives.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

2.22 Notebook 02c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/02c_partial_derivatives.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The quantities of this book depend on several variables at once: the author's
```

metric depends on the time x_4 and on the hidden coordinate x_0. This
notebook teaches how to differentiate such functions and checks every step. It

- computes the partial derivatives of $f(x, y) = x^2 \sin y$ with sympy, checks
  that the two mixed second derivatives agree, and draws the level curves of f
  with its gradient arrows and two slices with their tangent lines;
- approximates partial derivatives by finite differences and measures their
  orders (1 for the forward difference, 2 for the central one) and the limit
  that rounding errors set;
- checks the chain rule for the author's variable $z = 6 H x_0$;
- reads the author's metric from the Revision record
  Revision/gkd_lovelock/results/curvature.json and computes its partial
  derivatives: the growth rates of the eight scale factors along x_4 and along
  x_0, the volume factor $\sqrt{|\det g|} = b_4^{3/2} \cos z$ (which does not
  depend on x_4 for constant b_4), Jacobi's formula for the derivative of a
  determinant, and all 25 nonzero *Christoffel symbols* listed in the record
  (combinations of first partial derivatives of the metric that the geometry of
  the book uses).

It draws 6 figures and prints a PASS line for every check.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 02c (Partial derivatives, finite differences and the chain rule) is the file
‘Revision/textbook/notebooks/02c_partial_derivatives.ipynb‘ of the repository
Dirac_claude. It computes partial derivatives of a function of two variables with sympy
and by finite differences (forward and central differences, their orders 1 and 2 and the
limit set by rounding), draws level curves with the gradient and slices with their
tangent lines, checks that mixed partial derivatives do not depend on the order, checks
the chain rule for the author's variable z = 6 H x0, and then reads the author's metric
from a Revision record and computes its partial derivatives: the growth and deflation
rates of the eight scale factors, the volume factor sqrt of the absolute determinant
(equal to b4^(3/2) cos z, independent of the time x4 for constant b4), Jacobi's formula,
and all 25 nonzero Christoffel entries listed in the record. It needs a computer with
Windows 11, macOS or Linux, an internet connection for the installation, the program Git,
and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the

default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
```

```
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 02c_partial_derivatives.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 02c_partial_derivatives.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 02c_partial_derivatives.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/02c.captions.json‘
- ‘Revision/textbook/figures/02c_1_level_curves_gradient.png‘
- ‘Revision/textbook/figures/02c_2_slices_and_slopes.png‘
- ‘Revision/textbook/figures/02c_3_finite_differences.png‘
- ‘Revision/textbook/figures/02c_4_chain_rule.png‘
- ‘Revision/textbook/figures/02c_5_rates_along_x4.png‘
- ‘Revision/textbook/figures/02c_6_rates_along_x0.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on

another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of notebook 02c exist
ALL 17 CHECKS PASSED (notebook 02c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/02c_partial_derivatives.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 02c_partial_derivatives.ipynb
  python -m nbconvert --execute --inplace 02c_partial_derivatives.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 02c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 02c (Partial derivatives, finite differences and the chain rule) is the file
# Revision/textbook/notebooks/02c_partial_derivatives.ipynb of the repository
# Dirac_claude. It computes partial derivatives of a function of two variables with sympy
# and by finite differences (forward and central differences, their orders 1 and 2 and
# the limit set by rounding), draws level curves with the gradient and slices with their
# tangent lines, checks that mixed partial derivatives do not depend on the order, checks
# the chain rule for the author's variable z = 6 H x0, and then reads the author's metric
# from a Revision record and computes its partial derivatives: the growth and deflation
# rates of the eight scale factors, the volume factor sqrt of the absolute determinant
# (equal to b4^(3/2) cos z, independent of the time x4 for constant b4), Jacobi's
# formula, and all 25 nonzero Christoffel entries listed in the record. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
```

```
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
```

```
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 02c_partial_derivatives.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
```

```
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 02c_partial_derivatives.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 02c_partial_derivatives.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/02c.captions.json
# - Revision/textbook/figures/02c_1_level_curves_gradient.png
# - Revision/textbook/figures/02c_2_slices_and_slopes.png
# - Revision/textbook/figures/02c_3_finite_differences.png
# - Revision/textbook/figures/02c_4_chain_rule.png
# - Revision/textbook/figures/02c_5_rates_along_x4.png
# - Revision/textbook/figures/02c_6_rates_along_x0.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of notebook 02c exist
#     ALL 17 CHECKS PASSED (notebook 02c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
```

```
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/02c_partial_derivatives.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 02c_partial_derivatives.ipynb
#     python -m nbconvert --execute --inplace 02c_partial_derivatives.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Function of several variables**: a rule $f(x, y)$ that gives a number for
  every pair of numbers $(x, y)$ (or for every list $x_0, \dots, x_7$).
- **Partial derivative** $\partial f/\partial x$: the ordinary derivative with
  respect to $x$ while all the other variables are held fixed. We also write
  $\partial_x f$, and for the author's coordinates $\partial_4 = \partial/\partial
  x_4$ and $\partial_0 = \partial/\partial x_0$.
- **Slice**: the function of ONE variable obtained by holding the others fixed;
  the partial derivative is the slope of its graph.
- **Level curve (contour)**: the set of points where $f$ has one fixed value.
- **Gradient**: the arrow $(\partial f/\partial x, \partial f/\partial y)$. It
  points in the direction in which $f$ grows fastest and is perpendicular to the
  level curve through its point.
- **Mixed partial derivative**: $\partial^2 f/\partial x \partial y$, first with
  respect to $y$, then $x$ (or the other way round). Schwarz's theorem: for a
  function with continuous second derivatives the order does not matter.
- **Chain rule**: if $f$ depends on $z$ and $z$ on $x_0$, then
  $\partial f/\partial x_0 = (df/dz)(\partial z/\partial x_0)$.
- **Finite difference**: an approximation of a derivative from values of the
  function at nearby points, with a small spacing $h$.
- **Metric, diagonal entries** $g_{aa}$: the eight numbers (functions of $x_4$ and
  $x_0$) that turn coordinate distances into true distances in the author's
  8-dimensional world; positive for the space directions $x_0, x_1, x_2, x_3$ and
  negative for the time directions $x_4, x_5, x_6, x_7$.
- **Scale factor** $s_a = \sqrt{|g_{aa}|}$: the factor by which a coordinate
  length along $x_a$ is multiplied to give a true length.
- **Logarithmic derivative** $\partial \ln s/\partial x = (\partial s/\partial
  x)/s$: the rate of growth of $s$ per unit of $x$, as a fraction of $s$
  itself.
- **Determinant of a diagonal matrix**: the product of its diagonal entries.
- **Christoffel symbols** $\Gamma^a{}_{bc}$: numbers built from first partial
  derivatives of the metric; the geometry of the book explains their meaning.
  Here they are only an exercise in partial derivatives.
```

```
## 4. The physical and mathematical situation

**Definition.** For a function $f(x, y)$,

$$\frac{\partial f}{\partial x}(x, y) = \lim_{h \to 0}
\frac{f(x + h, y) - f(x, y)}{h},$$

the derivative of the slice $x \mapsto f(x, y)$ with $y$ held fixed; likewise for
$y$. All the rules of one-variable calculus hold for each partial derivative.

**The first example.** $f(x, y) = x^2 \sin y$. Holding $y$ fixed, $\sin y$ is a
constant factor and $\partial f/\partial x = 2x \sin y$. Holding $x$ fixed,
$x^2$ is a constant factor and $\partial f/\partial y = x^2 \cos y$. Then
$\partial/\partial y$ of $2x \sin y$ is $2x \cos y$ and $\partial/\partial x$ of
$x^2 \cos y$ is also $2x \cos y$: the mixed derivatives agree, as Schwarz's
theorem says.
```

```
**Finite differences.** Taylor's theorem in one variable gives
$f(x + h) = f(x) + h f'(x) + \frac{h^2}{2} f''(x) + \frac{h^3}{6} f'''(x) +
\dots$ Therefore the *forward difference* $(f(x + h) - f(x))/h = f'(x) +
\frac{h}{2} f''(x) + \dots$ has an error proportional to $h$ (order 1), and the
*central difference* $(f(x + h) - f(x - h))/(2h) = f'(x) + \frac{h^2}{6}
f'''(x) + \dots$ has an error proportional to $h^2$ (order 2), because the
terms with $h^2 f''$ cancel in the difference. Rounding adds an error of about
$\epsilon |f| / h$ ($\epsilon = 2.2 \times 10^{-16}$), which GROWS as $h$
shrinks; the best $h$ balances the two.

**The author's metric** (coordinates $x_0, \dots, x_7$; $z = 6 H x_0$ with
$0 < z < \pi/2$; $a_4(x_4)$ and $b_4(x_4) > 0$ functions of the time, $b_4 = 1$
in the background of the Revision record):

$$g_{00} = \cot^2 z, \quad g_{11} = g_{22} = g_{33} = e^{2 a_4} \sin^{1/3} z, \quad
g_{44} = -1, \quad g_{55} = g_{66} = g_{77} = -b_4 e^{-2 a_4} \sin^{1/3} z .$$

The scale factors are $\cot z$ for the hidden direction $x_0$,
$e^{a_4} \sin^{1/6} z$ for 3-space ($x_1, x_2, x_3$), $1$ for the time $x_4$ and
$b_4^{1/2} e^{-a_4} \sin^{1/6} z$ for the three extra times $x_5, x_6, x_7$ (they
DEFLATE when $a_4$ grows and $b_4$ stays constant). By the chain rule,
$\partial_0 = (dz/dx_0)\, d/dz = 6H\, d/dz$ on a function of $z$. The
logarithmic rates follow from $\ln(e^{a_4} \sin^{1/6} z) = a_4 + \frac{1}{6} \ln
\sin z$ and $\ln(b_4^{1/2} e^{-a_4} \sin^{1/6} z) = \frac{1}{2} \ln b_4 - a_4 +
\frac{1}{6} \ln \sin z$:

$$\partial_4 \ln s_{1,2,3} = a_4', \quad
\partial_4 \ln s_{5,6,7} = -a_4' + \frac{b_4'}{2 b_4}, \quad
\partial_0 \ln s_{1,2,3} = \partial_0 \ln s_{5,6,7} = \tfrac{1}{6} \cdot 6H \cot z
= H \cot z,$$

and $\partial_0 \ln \cot z = 6H \cdot \frac{-1/\sin^2 z}{\cot z} =
-\frac{6H}{\sin z \cos z}$. The determinant of the diagonal metric is the
product of the entries; four of them are negative, so it is positive:
$\det g = \cot^2 z\, (e^{2a_4})^3 (b_4 e^{-2a_4})^3 (\sin^{1/3} z)^6 = b_4^3
\sin^2 z \cot^2 z = b_4^3 \cos^2 z$ and $\sqrt{|\det g|} = b_4^{3/2} \cos z$. The
factors $e^{6 a_4}$ and $e^{-6 a_4}$ cancel: the inflation of 3-space and the
deflation of the extra times compensate, and the volume factor depends on $x_4$
only through $b_4$; for constant $b_4$ (the background) it does not depend on
$x_4$.

**Christoffel symbols of a diagonal metric.** We take the formula
$\Gamma^a{}_{bc} = \frac{1}{2 g_{aa}} (\partial_b g_{ac} + \partial_c g_{ab} -
\partial_a g_{bc})$ (no sum over $a$) as given; the geometry of the book
derives it. For a diagonal metric only two kinds of entry can be nonzero:
$\Gamma^a{}_{ac} = \partial_c g_{aa}/(2 g_{aa}) = \partial_c \ln s_a$, the
logarithmic rates above, and $\Gamma^c{}_{aa} = -\partial_c g_{aa}/(2 g_{cc})$
for $c \neq a$.

## 6. Partial derivatives with sympy

‘sp.diff(f, x)‘ differentiates with respect to $x$ and treats every other
symbol as a constant: exactly the definition of a partial derivative. The cell
prints the two first derivatives and the two mixed second derivatives of
$f = x^2 \sin y$, checks them against the hand calculation of section 4, and
evaluates everything at the point $(x_0, y_0) = (1.2, 0.7)$.
```

In [3]:

```
f = x ** 2 * sp.sin(y)
f_x = sp.diff(f, x)  # hold y fixed
f_y = sp.diff(f, y)  # hold x fixed
f_xy = sp.diff(f, x, y)  # first x, then y
f_yx = sp.diff(f, y, x)  # first y, then x
say(f"df/dx = {f_x},  df/dy = {f_y}")
say(f"d2f/dxdy = {f_xy},  d2f/dydx = {f_yx}")
check(sp.simplify(f_x - 2 * x * sp.sin(y)) == 0
      and sp.simplify(f_y - x ** 2 * sp.cos(y)) == 0,
      "df/dx = 2 x sin y and df/dy = x^2 cos y")
check(sp.simplify(f_xy - f_yx) == 0 and sp.simplify(f_xy - 2 * x * sp.cos(y)) == 0,
      "the mixed derivatives agree (Schwarz): both are 2 x cos y")
X0, Y0 = 1.2, 0.7  # the point at which we evaluate
at_point = {x: X0, y: Y0}
for label, expression in (("f", f), ("df/dx", f_x), ("df/dy", f_y),
                          ("d2f/dxdy", f_xy)):
    report(f"{label} at (1.2, 0.7)", f"{float(expression.subs(at_point)):.12f}")
```

Out [3]:

```
df/dx = 2*x*sin(y),  df/dy = x**2*cos(y)
d2f/dxdy = 2*x*cos(y),  d2f/dydx = 2*x*cos(y)
PASS df/dx = 2 x sin y and df/dy = x^2 cos y
PASS the mixed derivatives agree (Schwarz): both are 2 x cos y
RESULT f at (1.2, 0.7) = 0.927673469622
RESULT df/dx at (1.2, 0.7) = 1.546122449370

## 7. Pictures of a function of two variables

The first figure is a map of $f$: coloured bands between level curves, and at
the points of a coarse grid the gradient arrow $(\partial f/\partial x,
\partial f/\partial y)$. ‘sp.lambdify‘ turns a sympy expression into a fast
numpy function. The check confirms at one point that the gradient is
perpendicular to the level curve: the direction along the level curve,
$(-\partial f/\partial y, \partial f/\partial x)$, has zero dot product with the
gradient, and moving a small step along it changes $f$ only in second order.
A second check confirms that the gradient points uphill: a small step of length
$10^{-4}$ along the unit arrow $\nabla f/|\nabla f|$, where
$|\nabla f| = \sqrt{(\partial f/\partial x)^2 + (\partial f/\partial y)^2}$ is
the length of the gradient, raises $f$ by about $10^{-4}\,|\nabla f|$ (the
steepest slope), and such a step raises $f$ at every one of the 120 arrows of
the figure.
```

In [4]:

```
F = sp.lambdify((x, y), f, "numpy")  # f as a numpy function

## 8. Finite differences: order and rounding

The next cell approximates three derivatives at $(1.2, 0.7)$ for 49 spacings
$h$ from $10^{-12}$ to $1$ (equally spaced in $\log h$):

- forward difference for $\partial f/\partial y$: $(f(x_0, y_0 + h) -
  f(x_0, y_0))/h$;
- central difference for $\partial f/\partial y$: $(f(x_0, y_0 + h) -
  f(x_0, y_0 - h))/(2h)$;
- central difference for the mixed derivative $\partial^2 f/\partial x \partial
  y$: $[f(x_0{+}h, y_0{+}h) - f(x_0{+}h, y_0{-}h) - f(x_0{-}h, y_0{+}h) +
  f(x_0{-}h, y_0{-}h)]/(4h^2)$.

It fits the slopes on the log-log plot where truncation dominates, and finds the
best $h$ of each formula, where truncation and rounding balance.
```

## 9. The chain rule with $z = 6 H x_0$

The author writes the hidden direction with $z = 6 H x_0$. A function of $z$,
such as $g_{00} = \cot^2 z$, depends on $x_0$ through $z$, and the chain rule
says $\partial_0 \cot^2(6 H x_0) = 6H \cdot \frac{d}{dz} \cot^2 z$. The cell
checks it with sympy, and the figure shows it with $H = 1$: the same curve
drawn against $z$ and against $x_0 = z/6$ is squeezed sideways by the factor 6,
so every slope is 6 times steeper.
```

In [7]:

```
x4, x0 = sp.symbols("x4 x0", real=True)  # the time and the hidden coordinate
H = sp.symbols("H", positive=True)  # the author's constant H > 0
zs = sp.symbols("z", positive=True)  # z = 6 H x0 as a symbol of its own
through_x0 = sp.diff(sp.cot(6 * H * x0) ** 2, x0)  # differentiate in x0 directly
```

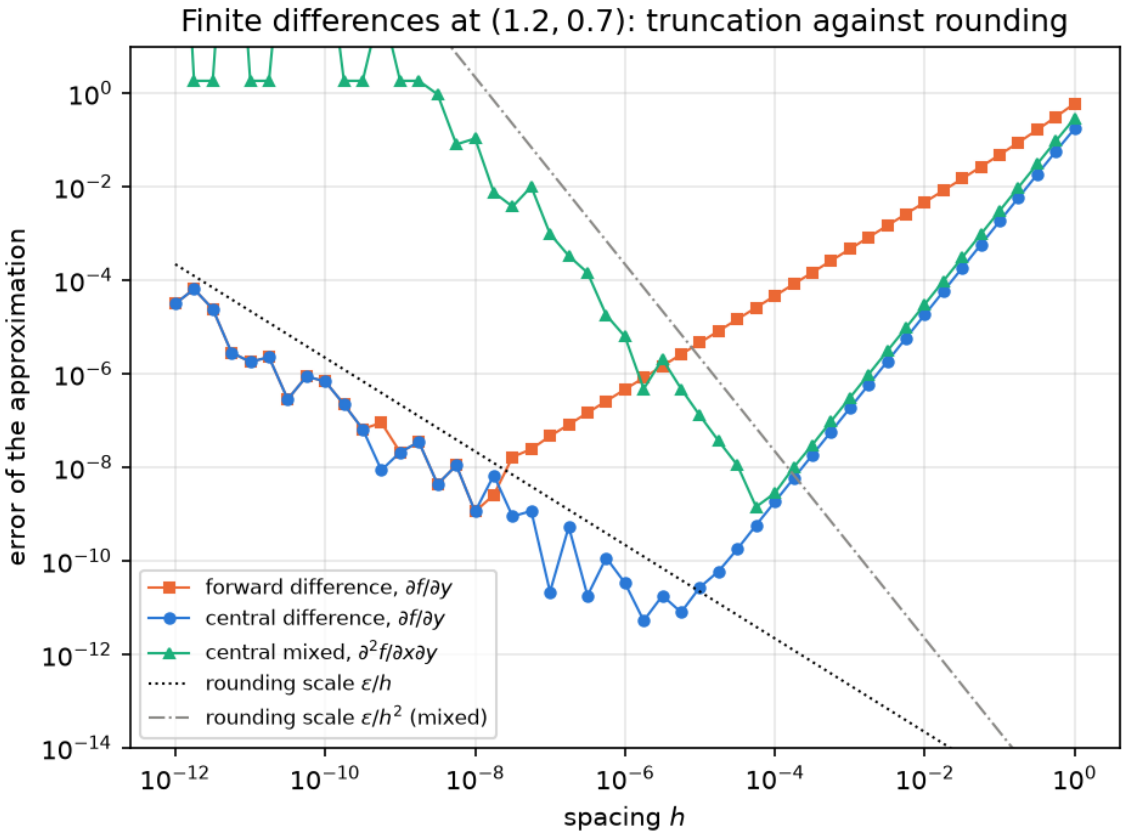

Figure 80: The error of three finite-difference approximations at the point $(1.2, 0.7)$ against the spacing h from 10^{-12} to 1, on logarithmic axes (pure numbers): forward difference for $\partial f/\partial y$ (squares), central difference for $\partial f/\partial y$ (circles) and the central formula for the mixed derivative (triangles), for $f = x^2 \sin y$. Coming from the right, the errors fall with slope 1 (forward) and slope 2 (central, mixed). Coming from the left, rounding errors, of the size ϵ/h (dotted) or ϵ/h^2 (dash-dotted) for the mixed formula, dominate. The best spacings are near 10^{-8}, 10^{-6} and 10^{-4}. (Notebook 02c, figure 3.)

## 11. How fast the scale factors change: rates along $x_4$ and $x_0$

The next cell computes the logarithmic rates $\partial_c \ln s_a =
\partial_c g_{aa}/(2 g_{aa})$ of the eight scale factors with respect to $x_4$
and $x_0$ and checks the formulas of section 4. It then evaluates them along the
linear history $a_4 = A H x_4$ with $A = 1$ and $H = 1$ (so $a_4' = 1$) and
$b_4 = 1$ (so $b_4' = 0$), the prescribed background that the book uses for its
Kohn-Sham states: the bar chart shows the rates along $x_4$, $0$ for $x_0$ and
$x_4$, $+1$ for the three 3-space directions (inflation) and $-1$ for the three
extra times (deflation). Their sum is $\frac{3}{2} b_4'/b_4$, zero for constant
```

```
$b_4$, which is why the volume then does not change with time.
sympy prints $H \cot z$ as `H/tan(6*H*x0)` and $-6H/(\sin z \cos z)$ as
`-12*H/sin(12*H*x0)`; these are the same, because $\sin 2z = 2 \sin z \cos z$.
```

## 13. All 25 Christoffel entries of the record

The record lists every nonzero $\Gamma^a{}_{bc}$ with $b$ not after $c$ in the
order $x_0, \dots, x_7$ (the symbol is symmetric in $b$ and $c$). The next cell
computes all $8 \times 36 = 288$ such entries from the formula of section 4,
keeps the nonzero ones, and compares them one by one with the record. Only
first partial derivatives of the metric entries are needed.
```

In [12]:

```
computed = {}
for a in range(8):
    for b in range(8):
        for c in range(b, 8):
            value = (sp.diff(G[a, c], X[b]) + sp.diff(G[a, b], X[c])
                     - sp.diff(G[b, c], X[a])) / (2 * G[a, a])
            value = sp.simplify(tidy(value))
            if value != 0:
                computed[(COORDS[a], COORDS[b], COORDS[c])] = value
listed = {(e["a"], e["b"], e["c"]): from_record(e["value"])

           for k, name in enumerate(names, 1)]
check(all(present), f"all {len(names)} figure files of notebook 02c exist")
all_checks_passed()
```

Out [13]:

```
PASS all 6 figure files of notebook 02c exist
ALL 17 CHECKS PASSED (notebook 02c)
```

Text cell:

```
## 15. What this notebook showed

- A partial derivative is an ordinary derivative with the other variables held
  fixed: the slope of a slice. The gradient points uphill, perpendicular to the
  level curves. The two mixed derivatives of $x^2 \sin y$ agree (Schwarz).
- Forward differences have order 1, central differences order 2; rounding
  errors grow like $\epsilon/h$, so the best spacing is about $10^{-8}$
  (forward) or $10^{-6}$ (central), not the smallest one.
- The chain rule for $z = 6 H x_0$: $\partial_0 = 6H\, d/dz$.
- The author's metric, read from the Revision record, has the scale-factor rates
  $+a_4'$ (3-space, inflating), $-a_4' + b_4'/(2 b_4)$ (the three extra times,
  deflating), $0$ (the time $x_4$ and the hidden $x_0$) along $x_4$, and
  $H \cot z$, $H \cot z$ and $-6H/(\sin z \cos z)$ along $x_0$.
- $\sqrt{|\det g|} = b_4^{3/2} \sin z \cot z = b_4^{3/2} \cos z$ for every
  $a_4(x_4)$: the inflation of 3-space and the deflation of the extra times
  cancel in the volume, which changes with $x_4$ only through $b_4$ (reproduces
  the record's sqrtAbsDetG and the Wolfram check sqrt_abs_det_g_is_cos_z).
  Jacobi's formula holds.
- All 25 nonzero Christoffel entries of the record follow from first partial
  derivatives of the metric.
```

2.23 Line-by-line walk-through of Notebook 02c

The notebook has thirteen code cells, In [1] to In [13]. A quoted line `...)` stands for the rest of a figure caption, which Section 2.22 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 2.21; its code is the set-up code of Notebook 02a explained in Section 2.11, with `NOTEBOOK_ID = "02c"`. It prints Set-up of notebook 02c complete: repository folder found, helpers defined.

In [2], packages and symbols.

```
import math  # functions of single numbers
```

```
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra and calculus with symbols

BLUE, ORANGE, AQUA, VIOLET = "#2a78d6", "#eb6834", "#1baf7a", "#4a3aa7"
GREY, BLACK = "#8a8986", "#000000"
x, y = sp.symbols("x y", real=True)  # the two variables of the first example
say("Packages imported; symbols x and y defined.")
```

The packages and the colours as in Notebook 02b, and two sympy symbols x and y, declared real (so that sympy may use rules that hold for real numbers only).

In [3], partial derivatives with sympy.

```
f = x ** 2 * sp.sin(y)
f_x = sp.diff(f, x)  # hold y fixed
f_y = sp.diff(f, y)  # hold x fixed
f_xy = sp.diff(f, x, y)  # first x, then y
f_yx = sp.diff(f, y, x)  # first y, then x
```

`f` is the expression $x^2 \sin y$. `sp.diff(f, x)` differentiates with respect to x and treats every other symbol as a constant, which is exactly the definition of the partial derivative of Section 2.18. `sp.diff(f, x, y)` differentiates first with respect to x and then with respect to y; `sp.diff(f, y, x)` in the other order.

```
say(f"df/dx = {f_x},  df/dy = {f_y}")
say(f"d2f/dxdy = {f_xy},  d2f/dydx = {f_yx}")
check(sp.simplify(f_x - 2 * x * sp.sin(y)) == 0
      and sp.simplify(f_y - x ** 2 * sp.cos(y)) == 0,
      "df/dx = 2 x sin y and df/dy = x^2 cos y")
check(sp.simplify(f_xy - f_yx) == 0 and sp.simplify(f_xy - 2 * x * sp.cos(y)) == 0,
      "the mixed derivatives agree (Schwarz): both are 2 x cos y")
```

The four derivatives are printed (`2*x*sin(y)`, `x**2*cos(y)`, and `2*x*cos(y)` twice), and two checks compare them with the hand calculation of Section 2.18: `sp.simplify` reduces the difference to its simplest form, which must be 0. The second check is Schwarz's theorem for this example.

```
X0, Y0 = 1.2, 0.7  # the point at which we evaluate
at_point = {x: X0, y: Y0}
for label, expression in (("f", f), ("df/dx", f_x), ("df/dy", f_y),
                          ("d2f/dxdy", f_xy)):
    report(f"{label} at (1.2, 0.7)", f"{float(expression.subs(at_point)):.12f}")
```

The dictionary `at_point` tells `.subs` to put $x = 1.2$ and $y = 0.7$ into an expression; `float` turns the result into an ordinary number. The RESULT lines give $f = 0.927673469622$, $\partial f/\partial x = 1.546122449370$, $\partial f/\partial y = 1.101372749690$ and $\partial^2 f/\partial x \partial y = 1.835621249483$ (COMPUTED; for example $2 \cdot 1.2 \cdot \cos 0.7 = 1.8356$).

In [4], level curves and gradient arrows.

```
F = sp.lambdify((x, y), f, "numpy")  # f as a numpy function
FX = sp.lambdify((x, y), f_x, "numpy")
FY = sp.lambdify((x, y), f_y, "numpy")
```

`sp.lambdify` turns a sympy expression into an ordinary Python function of (x, y) that computes with numpy, so that it can be applied to whole arrays of points at once: `F` computes f, `FX` and `FY` its two partial derivatives.

```
xs = np.linspace(-2.0, 2.0, 201)
ys = np.linspace(0.0, 2.0 * np.pi, 201)
XX, YY = np.meshgrid(xs, ys)  # all grid points as two 2-dimensional arrays
```

201 values of x from -2 to 2 and 201 values of y from 0 to 2π. `np.meshgrid` makes the grid of all 201×201 pairs: `XX` holds the x of every grid point and `YY` its y, both as tables of 201 rows and 201 columns.

```
fig, ax = plt.subplots(figsize=(7.0, 5.2))
bands = ax.contourf(XX, YY, F(XX, YY), levels=17, cmap="RdBu_r")  # coloured bands
ax.contour(XX, YY, F(XX, YY), levels=17, colors=BLACK, linewidths=0.4)
fig.colorbar(bands, ax=ax, label="$f(x, y) = x^2 \\sin y$")
```

`contourf` fills the regions between 17 levels of f with colours from the colour map `"RdBu_r"` (red for large, blue for small values; `_r` reverses the map); `contour` draws the level curves themselves as thin black lines; `colorbar` adds the scale that translates colours into values.

```
xq, yq = np.meshgrid(np.linspace(-1.8, 1.8, 10), np.linspace(0.3, 6.0, 12))  # coarse
# an arrow (df/dx, df/dy) at every coarse grid point; scale=40 shortens all arrows
ax.quiver(xq, yq, FX(xq, yq), FY(xq, yq), color=BLACK, scale=40, width=0.004)
ax.set_xlabel("$x$")
ax.set_ylabel("$y$")
ax.set_title("Level curves of $f = x^2 \\sin y$ and its gradient arrows")
save_figure(fig, "level_curves_gradient",
            "A map of the function $f(x, y) = x^2 \\sin y$ for $x$ from $-2$ to $2$ "
            ...)
```

A coarse grid of 10×12 points carries the gradient arrows: `quiver` draws at each point (x, y) an arrow with the components $(\partial f/\partial x, \partial f/\partial y)$, all shortened by the same factor (`scale=40`) so that they fit; `width` sets their thickness. Labels and the saved figure `02c_1_level_curves_gradient.png`. **What Figure 02c.1 shows:** every arrow points uphill, from blue towards red, and crosses the level curves at a right angle; where the level curves crowd together the arrows are long, because the slope is steep (Section 2.18).

```
gx, gy = float(f_x.subs(at_point)), float(f_y.subs(at_point))
tangent = np.array([-gy, gx]) / math.hypot(gx, gy)  # along the level curve
step = 1e-4
change = F(X0 + step * tangent[0], Y0 + step * tangent[1]) - F(X0, Y0)
report("change of f along the level curve for a step of 1e-4", f"{change:.2e}")
check(abs(gx * tangent[0] + gy * tangent[1]) < 1e-15 and abs(change) < 1e-7,
      "the gradient is perpendicular to the level curve")
```

`gx` and `gy` are the gradient's components at $(1.2, 0.7)$. `math.hypot(gx, gy)` is the length $\sqrt{g_x^2 + g_y^2}$, so `tangent` is the unit arrow $(-g_y, g_x)/|\nabla f|$ of Section 2.18. A step of 10^{-4} along it changes f by only -9.58×10^{-9} (COMPUTED), a second-order amount (10^{-8} is the square of 10^{-4}). The check requires the dot product of the gradient with this direction to vanish (up to rounding) and the change of f to be below 10^{-7}.

```
length = math.hypot(gx, gy)  # the length |grad f| of the gradient arrow
rise = F(X0 + step * gx / length, Y0 + step * gy / length) - F(X0, Y0)
report("rise of f per unit length along the gradient, |grad f|",
       f"{rise / step:.6f}, {length:.6f}")
```

Now the second fact of Section 2.18. `length` is $|\nabla f| = \sqrt{g_x^2 + g_y^2}$, and $(g_x, g_y)/|\nabla f|$ is the unit arrow along the gradient. `rise` is the change of f for a step of 10^{-4} along it, and `rise / step` the change per unit length. The RESULT line prints 1.898407 and $|\nabla f| = 1.898293$ (COMPUTED): along the gradient f rises at the rate $|\nabla f|$, the steepest slope; the two differ by 1.1×10^{-4}, the second-order term of the step.

```
gxq, gyq = FX(xq, yq), FY(xq, yq)  # the arrows of the figure
lengths = np.hypot(gxq, gyq)
rises = F(xq + step * gxq / lengths, yq + step * gyq / lengths) - F(xq, yq)
check(abs(rise / step / length - 1) < 1e-3 and np.all(rises > 0),
      "the gradient points uphill: f rises at the rate |grad f| along it")
```

The same test at all 120 points of the coarse grid of the figure: `gxq`, `gyq` are the components of the 120 arrows, `np.hypot` their lengths (one for each point), and `rises` the change of f for a step of 10^{-4} along each arrow. The check requires the measured rate at $(1.2, 0.7)$ to equal $|\nabla f|$ within one part in a thousand, and every one of the 120 rises to be positive: every arrow of Figure 02c.1 points uphill.

In [5], two slices and their slopes.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
fig.subplots_adjust(wspace=0.3)  # room between the two panels
f0 = F(X0, Y0)
x_line = np.linspace(-0.5, 2.5, 200)
left.plot(x_line, F(x_line, Y0), color=BLUE, lw=1.6,
          label="slice $f(x, 0.7)$")
left.plot(x_line, f0 + gx * (x_line - X0), "--", color=ORANGE, lw=1.2,
          label=f"slope $\\partial f/\\partial x = {gx:.4f}$")
left.set_xlabel("$x$ (with $y = 0.7$ fixed)")
```

Two panels with some room between them (`wspace`). `f0` is $f(1.2, 0.7)$. The left panel draws the slice $x \mapsto f(x, 0.7)$ and the straight line $f_0 + g_x(x - x_0)$ through the point with the slope $\partial f/\partial x$.

```
y_line = np.linspace(-0.6, 2.4, 200)
right.plot(y_line, F(X0, y_line), color=BLUE, lw=1.6, label="slice $f(1.2, y)$")
right.plot(y_line, f0 + gy * (y_line - Y0), "--", color=ORANGE, lw=1.2,
           label=f"slope $\\partial f/\\partial y = {gy:.4f}$")
right.set_xlabel("$y$ (with $x = 1.2$ fixed)")
```

The right panel does the same for the slice $y \mapsto f(1.2, y)$ and the slope $\partial f/\partial y$.

```
for ax in (left, right):
    ax.plot([X0 if ax is left else Y0], [f0], "o", color=BLACK, ms=6)
    ax.set_ylabel("$f$")
    ax.legend(fontsize=8)
save_figure(fig, "slices_and_slopes",
            "Two slices of $f(x, y) = x^2 \\sin y$ through the point "
            ...)
check(abs(gx - 2 * X0 * math.sin(Y0)) < 1e-15 and abs(gy - X0 ** 2 * math.cos(Y0))
      < 1e-15, "the slopes of the slices are 2 x0 sin y0 and x0^2 cos y0")
```

In each panel a black dot marks the point (x_0 in the left panel, y_0 in the right one: `X0 if ax is left else Y0` chooses); then the saved figure `02c_2_slices_and_slopes.png`, and a check that the two slopes are $2x_0 \sin y_0$ and $x_0^2 \cos y_0$. **What Figure 02c.2 shows:** each dashed line touches its slice at the dot: a partial derivative is the slope of a slice.

In [6], finite differences: order and rounding.

```
exact_y = X0 ** 2 * math.cos(Y0)  # df/dy at the point
exact_xy = 2 * X0 * math.cos(Y0)  # d2f/dxdy at the point
h_values = np.logspace(-12, 0, 49)  # 1e-12 ... 1
```

The exact values of $\partial f/\partial y$ and $\partial^2 f/\partial x \partial y$ at the point, and 49 spacings from 10^{-12} to 1, equally spaced in $\log_{10} h$ (`np.logspace(-12, 0, 49)` gives $10^{-12}, 10^{-11.75}, \ldots, 10^{0}$).

```
forward = np.array([(F(X0, Y0 + h) - F(X0, Y0)) / h for h in h_values])
central = np.array([(F(X0, Y0 + h) - F(X0, Y0 - h)) / (2 * h) for h in h_values])
mixed = np.array([(F(X0 + h, Y0 + h) - F(X0 + h, Y0 - h) - F(X0 - h, Y0 + h)
                   + F(X0 - h, Y0 - h)) / (4 * h * h) for h in h_values])
```

The three formulas of Section 2.18, evaluated for every spacing: the forward and the central difference in y, and the central formula for the mixed derivative.

```
err = {"forward": np.abs(forward - exact_y), "central": np.abs(central - exact_y),
       "mixed": np.abs(mixed - exact_xy)}
RANGES = {"forward": (1e-5, 1e-2), "central": (1e-3, 1e-1), "mixed": (1e-2, 1e-1)}
slope_of = {}
for name, (low, high) in RANGES.items():
    part = (h_values >= low) & (h_values <= high)
    slope_of[name], _ = np.polyfit(np.log10(h_values[part]),
                                   np.log10(err[name][part]), 1)
    best = int(np.argmin(err[name]))
    report(f"{name}: slope {slope_of[name]:.3f}, best h", f"{h_values[best]:.1e} "
           f"(error {err[name][best]:.1e})")
```

`err` holds the three error arrays. `RANGES` gives, for each formula, the range of spacings where the truncation error clearly dominates (larger than the rounding error, but small enough for the leading Taylor term to rule); `part` selects those spacings, and `np.polyfit` fits the slope there, as in

Notebook 02a. `np.argmin` finds the spacing with the smallest error. The RESULT lines: forward slope 1.000, best $h = 1.0 \times 10^{-8}$ (error 1.1×10^{-9}); central slope 2.000, best $h = 1.8 \times 10^{-6}$ (error 5.3×10^{-12}); mixed slope 2.000, best $h = 5.6 \times 10^{-5}$ (error 1.4×10^{-9}) (COMPUTED; compare the estimates of Section 2.18).

```
fig, ax = plt.subplots(figsize=(7.0, 5.0))
styles = {"forward": (ORANGE, "s", "forward difference, $\\partial f/\\partial y$"),
          "central": (BLUE, "o", "central difference, $\\partial f/\\partial y$"),
          "mixed": (AQUA, "^", "central mixed, $\\partial^2 f/\\partial x "
                               "\\partial y$")}
for name, (color, marker, label) in styles.items():
    shown = err[name] > 0  # an exact zero cannot be drawn on a log axis
    ax.loglog(h_values[shown], err[name][shown], marker=marker, color=color, ms=4,
              lw=1.0, label=label)
```

A colour, a marker and a legend text for each formula; each error curve is drawn on log-log axes, leaving out errors that happen to be exactly zero.

```
ax.loglog(h_values, 2.2e-16 / h_values, ":", color=BLACK, lw=1.0,
          label="rounding scale $\\epsilon / h$")
ax.loglog(h_values, 2.2e-16 / h_values ** 2, "-.", color=GREY, lw=1.0,
          label="rounding scale $\\epsilon / h^2$ (mixed)")
ax.set_ylim(1e-14, 10.0)
ax.set_xlabel("spacing $h$")
ax.set_ylabel("error of the approximation")
ax.set_title("Finite differences at $(1.2, 0.7)$: truncation against rounding")
ax.legend(loc="lower left", fontsize=8)
save_figure(fig, "finite_differences",
            "The error of three finite-difference approximations at the point "
            ...)
```

The two rounding scales ϵ/h (dotted) and ϵ/h^2 (dash-dotted, for the mixed formula, which divides by h^2), labels and the saved figure `02c_3_finite_differences.png`. **What Figure 02c.3 shows:** read from the right, the errors fall along straight lines of slope 1 (forward) and 2 (central, mixed); read from the left, they follow the rising rounding lines; each curve has its lowest point where the two effects balance, near 10^{-8}, 10^{-6} and 10^{-4}.

```
check(abs(slope_of["forward"] - 1) < 0.05 and abs(slope_of["central"] - 2) < 0.05
      and abs(slope_of["mixed"] - 2) < 0.05,
      "measured orders: forward 1, central 2, mixed central 2")
check(err["central"].min() < 1e-10 < err["forward"].min() < 1e-7,
      "best central error < 1e-10 < best forward error < 1e-7")
```

Two checks: the measured orders are 1, 2 and 2 within 0.05; the best central error is below 10^{-10}, which is below the best forward error, which is below 10^{-7} (a higher order buys accuracy even at the best spacing).

In [7], the chain rule with $z = 6Hx_0$.

```
x4, x0 = sp.symbols("x4 x0", real=True)  # the time and the hidden coordinate
H = sp.symbols("H", positive=True)  # the author's constant H > 0
zs = sp.symbols("z", positive=True)  # z = 6 H x0 as a symbol of its own
```

Symbols for the time x_4, the hidden coordinate x_0, the author's constant H (positive) and z as a variable of its own.

```
through_x0 = sp.diff(sp.cot(6 * H * x0) ** 2, x0)  # differentiate in x0 directly
through_z = 6 * H * sp.diff(sp.cot(zs) ** 2, zs).subs(zs, 6 * H * x0)  # chain rule
say(f"d/dx0 cot(6 H x0)^2 = {sp.simplify(through_x0)}")
check(sp.simplify(through_x0 - through_z) == 0,
      "chain rule: d/dx0 of cot(6 H x0)^2 = 6 H times d/dz of cot(z)^2")
```

`through_x0` differentiates $\cot^2(6Hx_0)$ directly with respect to x_0; `through_z` differentiates $\cot^2 z$ with respect to z, puts $z = 6Hx_0$ back in with `.subs`, and multiplies by $6H$, as the chain rule of Section 2.19 says. The printed derivative is `-12*H*cot(6*H*x0)/sin(6*H*x0)**2`, and the check confirms that both ways agree.

```
z0 = 0.6  # the point z0 and the matching x0 = z0/6 (H = 1)
slope_z = -2.0 * math.cos(z0) / math.sin(z0) ** 3  # d/dz cot^2 z = -2 cot z / sin^2 z
```

At $z_0 = 0.6$ the slope of $\cot^2 z$ is $-2\cot z_0/\sin^2 z_0 = -2\cos z_0/\sin^3 z_0$ (Section 2.19).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
z_line = np.linspace(0.35, 1.5, 300)
left.plot(z_line, 1 / np.tan(z_line) ** 2, color=BLUE, lw=1.6,
          label="$\\cot^2 z$")
left.plot(z_line, 1 / math.tan(z0) ** 2 + slope_z * (z_line - z0), "--",
          color=ORANGE, label=f"tangent, slope {slope_z:.3f}")
left.set_xlabel("$z$")
```

The left panel draws $\cot^2 z = 1/\tan^2 z$ for z from 0.35 to 1.5 and its tangent line at z_0.

```
x0_line = z_line / 6.0
right.plot(x0_line, 1 / np.tan(6 * x0_line) ** 2, color=BLUE, lw=1.6,
           label="$\\cot^2(6 H x_0)$, $H = 1$")
right.plot(x0_line, 1 / math.tan(z0) ** 2 + 6 * slope_z * (x0_line - z0 / 6), "--",
           color=ORANGE, label=f"tangent, slope $6 \\times$ {slope_z:.3f}")
right.set_xlabel("$x_0$ (units $1/H$)")
```

The right panel draws the same function against $x_0 = z/6$ (with $H = 1$) and the tangent line with 6 times the slope, through the matching point $x_0 = 0.1$.

```
for ax, where in ((left, z0), (right, z0 / 6)):
    ax.plot([where], [1 / math.tan(z0) ** 2], "o", color=BLACK, ms=6)
    ax.set_ylim(0.0, 6.0)
    ax.set_ylabel("$g_{00}$ (pure number)")
    ax.legend(fontsize=8)
save_figure(fig, "chain_rule",
            "The chain rule for the author's hidden coordinate. Left: "
            ...)
```

A dot at the point in each panel, the vertical range, labels, and the saved figure `02c_4_chain_rule.png`. **What Figure 02c.4 shows:** the right curve is the left one squeezed sideways by the factor 6, and both dashed lines touch their curves; the right slope is 6 times the left one: $\partial_0 = 6H\, d/dz$.

In [8], the author's metric from the Revision record.

```
CURVATURE = "Revision/gkd_lovelock/results/curvature.json"
record = json.loads(repository_file(CURVATURE).read_text(encoding="utf-8"))
a4 = sp.Function("a4")  # the unknown function a4(x4) of the metric
b4 = sp.Function("b4", positive=True)  # the unknown function b4(x4) > 0
NAMES = {"a4": a4, "b4": b4, "x4": x4, "x0": x0, "H": H, "Sin": sp.sin,
         "Cos": sp.cos, "Cot": sp.cot, "Tan": sp.tan}
```

The cell reads the Revision record of the curvature program. `sp.Function("a4")` makes an unknown function a_4, so that $a_4(x_4)$ can be differentiated without knowing its form, and `sp.Function("b4", positive=True)` the second metric function b_4, whose values are positive. `NAMES` tells the translator below which sympy object each name of the record stands for.

```
def from_record(text):
    """A Wolfram-Language text of the record as a sympy expression."""
    for f in ("a4", "b4"):  # Derivative[n][f][x4] is the n-th derivative of f
        for n in (1, 2):
            text = text.replace(f"Derivative[{n}][{f}][x4]",
                                f"Derivative({f}(x4), (x4, {n}))")
    text = text.replace("[", "(").replace("]", ")").replace("^", "**")
    return sp.parse_expr(text, local_dict=NAMES)
```

The record writes its formulas in the notation of the Wolfram Language: `E^(...)` for $e^{\cdots}$, `Sin[...]` for $\sin(\dots)$, `Derivative[1][a4][x4]` for a_4' and `Derivative[1][b4][x4]` for b_4'. `from_record` translates such a text: first the first and second derivatives of a_4 and b_4 (the two loops write the four possible texts with `f` and `n` filled in; `(x4, 2)` asks sympy for the second derivative), then square brackets into round ones and `^` into Python's `**`; `sp.parse_expr` reads the result as a sympy expression with the names of `NAMES` (sympy knows `E` as e by itself).

```
def tidy(expression):
    """Write cot and tan as quotients of cos and sin (helps sympy simplify)."""
    expression = expression.replace(sp.cot, lambda u: sp.cos(u) / sp.sin(u))
    return expression.replace(sp.tan, lambda u: sp.sin(u) / sp.cos(u))

def same(first, second):
    """True when sympy simplifies first - second to zero."""
    return sp.simplify(tidy(first - second)) == 0
```

`tidy` replaces every $\cot u$ by $\cos u/\sin u$ and every $\tan u$ by $\sin u/\cos u$ (a `lambda` is a one-line function without a name); with only sines and cosines left, `sp.simplify` finds cancellations more reliably. `same` decides whether two expressions are equal by simplifying their difference to 0.

```
COORDS = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
X = [sp.Symbol(name, real=True) for name in COORDS]
```

```
X[4], X[0] = x4, x0  # the metric depends on these two only
z = 6 * H * x0
third = sp.Rational(1, 3)
```

The eight coordinate names and a list of eight symbols; positions 4 and 0 (the position of x_k is k) are replaced by the symbols x_4 and x_0 already in use. `z` is now the expression $6Hx_0$, and `third` the exact fraction 1/3.

```
# the author's order x0, x1, ..., x7
BY_HAND = ([sp.cot(z) ** 2] + [sp.exp(2 * a4(x4)) * sp.sin(z) ** third] * 3
           + [sp.Integer(-1)]
           + [-b4(x4) * sp.exp(-2 * a4(x4)) * sp.sin(z) ** third] * 3)
G_RECORD = [from_record(text) for text in record["metricDiagonal"]]
for name, entry in zip(COORDS, G_RECORD):
    say(f"g_{name[1]}{name[1]} = {entry}")
```

`BY_HAND` is the diagonal of the author's metric typed in by hand: a list times 3 repeats it three times, and `+` joins lists, giving the eight entries of Section 2.19 in the author's order. `G_RECORD` translates the record's eight texts; the loop prints them (`name[1]` is the digit of the coordinate name), from `g_00 = cot(6*H*x0)**2` to `g_77 = -b4(x4)*exp(-2*a4(x4))*sin(6*H*x0)**(1/3)`.

```
check(record["coordinates"] == COORDS and len(G_RECORD) == 8
      and all(same(a, b) for a, b in zip(G_RECORD, BY_HAND)),
      "the record's metric equals the author's metric typed in by hand",
      record=f"{CURVATURE}, key metricDiagonal")
G = sp.diag(*G_RECORD)  # the metric as an 8 x 8 diagonal sympy matrix
```

The check requires the record's coordinate list to be $x_0, \ldots, x_7$, eight entries, and every entry to equal the hand-typed one (COMPUTED: reproduces `Revision/gkd_lovelock/results/curvature.json`, key `metricDiagonal`). `sp.diag(*G_RECORD)` builds the 8×8 diagonal matrix with these entries (`*` unpacks the list into eight arguments).

In [9], the rates along x_4 and x_0.

```
rate4 = [sp.simplify(sp.diff(G[a, a], x4) / (2 * G[a, a])) for a in range(8)]
rate0 = [sp.simplify(tidy(sp.diff(G[a, a], x0) / (2 * G[a, a]))) for a in range(8)]
da4 = sp.diff(a4(x4), x4)  # a4', the derivative of a4
db4 = sp.diff(b4(x4), x4)  # b4', the derivative of b4
```

For each of the eight diagonal entries `G[a, a]` the logarithmic rates $\partial_4 g_{aa}/(2g_{aa})$ and $\partial_0 g_{aa}/(2g_{aa})$ of Section 2.19. `da4` and `db4` are the symbols for a_4' and b_4'.

```
# the author's order x0, x1, ..., x7
expected4 = [0] + [da4] * 3 + [0] + [-da4 + db4 / (2 * b4(x4))] * 3
expected0 = ([-6 * H / (sp.sin(z) * sp.cos(z))] + [H * sp.cot(z)] * 3 + [0]
             + [H * sp.cot(z)] * 3)
for a, name in enumerate(COORDS):
    say(f"{name}: d4 ln s = {rate4[a]},  d0 ln s = {rate0[a]}")
```

The expected rates of Section 2.19 in the author's order, and a printout of the computed ones. sympy writes $H \cot z$ as `H/tan(6*H*x0)` and $-6H/(\sin z \cos z)$ as `-12*H/sin(12*H*x0)`; they are equal because $\sin 2z = 2 \sin z \cos z$.

```
check(all(same(r, e) for r, e in zip(rate4, expected4))
      and all(same(r, e) for r, e in zip(rate0, expected0)),
      "the rates a4', -a4' + b4'/(2 b4), H cot z and -6H/(sin z cos z) of section 4")
check(same(sum(rate4), sp.Rational(3, 2) * db4 / b4(x4))
      and sp.simplify(sum(rate4).subs(db4, 0)) == 0,
      "the eight rates along x4 add up to (3/2) b4'/b4, zero for constant b4")
```

The first check compares all sixteen rates with the expected ones; the second confirms that the eight rates along x_4 add up to $\frac{3}{2} b_4'/b_4$ and, with $b_4' = 0$ put in by `.subs(db4, 0)`, to zero (Section 2.19). (The check's text says "section 4" because it refers to section 4 of the notebook.)

```
rates_now = [float(r.subs({da4: 1, db4: 0})) for r in rate4]  # a4' = 1, b4' = 0
fig, ax = plt.subplots()
colors = [GREY] + [BLUE] * 3 + [GREY] + [ORANGE] * 3
ax.bar(range(8), rates_now, color=colors, width=0.6)
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.set_xticks(range(8), [f"$x_{k}$" for k in range(8)])
```

On the history $a_4 = AHx_4$, $b_4 = 1$ with $A = H = 1$ we have $a_4' = 1$ and $b_4' = 0$; `.subs({da4: 1, db4: 0})` puts this in (a dictionary of replacements). `ax.bar` draws a bar for each direction (grey for x_0 and x_4, blue for 3-space, orange for the extra times), and `set_xticks` labels the positions 0 to 7 with x_0 to x_7.

```
for k, value in enumerate(rates_now):
    ax.text(k, value + (0.06 if value >= 0 else -0.14), f"{value:+.0f}",
            ha="center", fontsize=9)
ax.set_ylim(-1.4, 1.4)
ax.set_xlabel("direction")
ax.set_ylabel("$\\partial_4 \\ln s_a$ (units $H$)")
ax.set_title("Growth rate of each scale factor along the time $x_4$ "
             "($A = H = 1$, $b_4 = 1$)")
save_figure(fig, "rates_along_x4",
            "The rate $\\partial_4 \\ln s_a$ at which the scale factor $s_a$ of "
            ...)
```

Each bar gets its value written just above (positive) or below (negative) it, then the axis range, labels and the saved figure `02c_5_rates_along_x4.png`. **What Figure 02c.5 shows:** two bars at 0 (x_0 and x_4), three at $+1$ (3-space inflates), three at -1 (the extra times deflate exponentially); the bars cancel, so at constant b_4 the 7-volume of space and extra times does not change with time.

In [10], the rates along the hidden coordinate.

```
rate_sum0 = sp.simplify(tidy(sum(rate0)))
check(same(rate_sum0, -6 * H * sp.tan(z)),
      "the eight rates along x0 add up to d0 ln cos z = -6 H tan z")
```

The sum of the eight rates along x_0 must be $-6H\tan z$, the rate of $\cos z$ and of $b_4^{3/2}\cos z$ (Section 2.19).

```
z_line = np.linspace(0.05, np.pi / 2 - 0.05, 400)
fig, ax = plt.subplots()
ax.plot(z_line, 1 / np.tan(z_line), color=BLUE, lw=1.6,
        label="$H \\cot z$: directions $x_1, x_2, x_3$ and $x_5, x_6, x_7$")
ax.plot(z_line, -6 / (np.sin(z_line) * np.cos(z_line)), "--", color=VIOLET, lw=1.6,
        label="$-6H/(\\sin z \\cos z)$: direction $x_0$")
ax.plot(z_line, -6 * np.tan(z_line), "-.", color=ORANGE, lw=1.6,
        label="sum of all eight $= -6 H \\tan z$")
```

With $H = 1$, on $0.05 < z < \pi/2 - 0.05$ (the ends are left out because the rates become infinite there), the three rates are drawn.

```
ax.axhline(0.0, color=BLACK, lw=0.8)
ax.set_ylim(-60.0, 20.0)
ax.set_xlabel("$z = 6 H x_0$")
ax.set_ylabel("$\\partial_0 \\ln s_a$ (units $H$)")
ax.set_title("Rates of the scale factors along the hidden coordinate ($H = 1$)")
ax.legend(loc="lower left", fontsize=8)
save_figure(fig, "rates_along_x0",
            "The rates $\\partial_0 \\ln s_a$ at which the scale factors change "
            ...)
```

Axis range, labels and the saved figure `02c_6_rates_along_x0.png`. **What Figure 02c.6 shows:** the 3-space and extra-time factors grow along x_0 near $z = 0$ and level off near $z = \pi/2$ (where $\cot z = 0$); the hidden factor $\cot z$ shrinks everywhere, fastest at both ends; the sum $-6H\tan z$ is the rate of the volume factor $b_4^{3/2}\cos z$ along x_0, which falls to zero at $z = \pi/2$.

In [11], the volume factor and Jacobi's formula.

```
det_g = sp.simplify(tidy(G.det()))  # the product of the eight entries
say(f"det g = {det_g}")
sqrt_record = from_record(record["sqrtAbsDetG"])
say(f"sqrtAbsDetG of the record = {sqrt_record}")
check(same(det_g, b4(x4) ** 3 * sp.cos(z) ** 2)
      and same(sqrt_record, b4(x4) ** sp.Rational(3, 2) * sp.cos(z)),
      "det g = b4^3 cos(z)^2 and the record's sqrt|det g| = b4^(3/2) sin z cot z "
      "= b4^(3/2) cos z",
      record=f"{CURVATURE}, key sqrtAbsDetG")
```

`G.det()` is the determinant; sympy simplifies it to $b_4^3\cos^2(6Hx_0)$, and the record's entry `sqrtAbsDetG` reads $b_4^{3/2}\sin(6Hx_0)\cot(6Hx_0)$ (the printed lines show both as sympy writes them). The check confirms $\det g = b_4^3\cos^2 z$ and $\sqrt{|\det g|} = b_4^{3/2}\sin z\cot z = b_4^{3/2}\cos z$ (COMPUTED: reproduces `Revision/gkd_lovelock/results/curvature.json`, key `sqrtAbsDetG`).

```
A4REPORT = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
a4_report = json.loads(repository_file(A4REPORT).read_text(encoding="utf-8"))
```

```
verdict = [c["verdict"] for c in a4_report["checks"]
           if c["name"] == "sqrt_abs_det_g_is_cos_z"]
db4 = sp.diff(b4(x4), x4)  # b4', the derivative of b4
check(verdict == ["PASS"]
      and same(sp.diff(sqrt_record, x4),
               sp.Rational(3, 2) * db4 / b4(x4) * sqrt_record)
      and sp.simplify(sp.diff(sqrt_record, x4).subs(db4, 0)) == 0,
      "d4 sqrt|det g| = (3/2)(b4'/b4) sqrt|det g|: for constant b4 the volume "
      "factor does not depend on x4 (inflation and deflation cancel)",
      record=f"{A4REPORT}, check sqrt_abs_det_g_is_cos_z")
```

The cell reads the Wolfram report of the a_4 field equations and collects the verdict of its check `sqrt_abs_det_g_is_cos_z` (a list comprehension with an `if` keeps only the matching check). The check requires that verdict to be PASS, the derivative of $\sqrt{|\det g|}$ with respect to x_4 to be $\frac{3}{2}(b_4'/b_4)\sqrt{|\det g|}$, and, with $b_4' = 0$, to be exactly 0 (COMPUTED: reproduces `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `sqrt_abs_det_g_is_cos_z`).

```
jacobi = [same(sp.diff(sqrt_record, c),
               sp.Rational(1, 2) * sqrt_record * (G.inv() * G.diff(c)).trace())
          for c in (x4, x0)]
check(all(jacobi), "Jacobi's formula for the derivative of sqrt|det g| (x4 and x0)")
```

Jacobi's formula of Section 2.19 for $c = x_4$ and $c = x_0$: `G.inv()` is the inverse matrix, `G.diff(c)` the matrix of the derivatives of the entries, `*` the matrix product and `.trace()` the sum of the diagonal entries.

In [12], all 25 Christoffel entries.

```
computed = {}
for a in range(8):
    for b in range(8):
        for c in range(b, 8):
            value = (sp.diff(G[a, c], X[b]) + sp.diff(G[a, b], X[c])
                     - sp.diff(G[b, c], X[a])) / (2 * G[a, a])
            value = sp.simplify(tidy(value))
            if value != 0:
                computed[(COORDS[a], COORDS[b], COORDS[c])] = value
```

Three nested loops run over a (8 values), b (8 values) and c from b to 7, that is over the $8 \times 36 = 288$ entries $\Gamma^a{}_{bc}$ with b not after c. Each is computed from the formula of Section 2.19 (the derivative with respect to the coordinate `X[b]`, and so on), simplified, and stored under the key (a, b, c) of coordinate names if it is not zero.

```
listed = {(e["a"], e["b"], e["c"]): from_record(e["value"])
          for e in record["christoffelNonzero_b_le_c"]}
for key in [("x1", "x1", "x4"), ("x5", "x4", "x5"), ("x0", "x1", "x1"),
            ("x0", "x0", "x0")]:
    say(f"Gamma^{key[0]}_({key[1]} {key[2]}) = {computed[key]}")
```

`listed` translates the record's list of nonzero entries into the same form. Four entries are printed: ${\Gamma^1}_{14} = a_4'$, ${\Gamma^5}_{45} = -a_4' + b_4'/(2b_4)$, ${\Gamma^0}_{11} = -He^{2a_4}\sin^{4/3} z/\cos z$ (which is $-He^{2a_4}\sin^{1/3} z\tan z$ of Section 2.19) and ${\Gamma^0}_{00} = -12H/\sin(12Hx_0)$.

```
report("nonzero entries computed / listed in the record",
       f"{len(computed)} / {len(listed)}")
check(sorted(computed) == sorted(listed)
      and all(same(computed[k], listed[k]) for k in listed),
      "all 25 nonzero Christoffel entries equal those of the record",
      record=f"{CURVATURE}, key christoffelNonzero_b_le_c")
```

25 entries are computed and 25 are listed. The check requires the same keys (`sorted` puts the keys of a dictionary in order) and equal values for every key (COMPUTED: reproduces `Revision/gkd_lovelock/results/curvature.json`, key `christoffelNonzero_b_le_c`).

In [13], the last check.

```
names = ["level_curves_gradient", "slices_and_slopes", "finite_differences",
         "chain_rule", "rates_along_x4", "rates_along_x0"]
present = [output_file(f"{FIGURE_FOLDER}/02c_{k}_{name}.png").is_file()
           for k, name in enumerate(names, 1)]
check(all(present), f"all {len(names)} figure files of notebook 02c exist")
all_checks_passed()
```

As in Notebook 02a: the six figure files must exist; the last line is ALL 17 CHECKS PASSED (notebook 02c). The 17 checks are: 2 in In [3], 2 in In [4], 1 in In [5], 2 in In [6], 1 in In [7], 1 in In [8], 2 in In [9], 1 in In [10], 3 in In [11], 1 in In [12] and 1 in In [13].

2.24 Two first-order equations, the Prüfer angle and Newton's method

This section prepares the last notebook, which rewrites the shooting method of the Revision Kohn-Sham solver. We use the solver's equations only as mathematics here; where they come from, and what their levels mean physically, is the subject of Chapters 14 and 15.

The equations. The Revision record `Revision/kohn_sham/ks-theory.json` gives the Kohn-Sham equation of one two-component block in a real form (key `blockEquation.realForm`): an orbital is described by two real functions $a(y)$ and $b(y)$ of the **hidden coordinate** y, which is the record's coordinate along x_0, $y = \ln(\sin z)/(6H)$ (key `geometry.hiddenCoordinate`; $y = 0$ is the end of the patch $z = \pi/2$, called the **brane**, and $y \to -\infty$ is $z \to 0$). The record's general block contains a mass M, a momentum k in 3-space, potentials and a sign $j = \pm 1$ of the block type. We take the simplest case: constant mass M, no 3-space momentum ($k = 0$), no potential, and $j = +1$. Then the equations are

$$a' = Ma - \varepsilon b, \qquad b' = \varepsilon a - Mb, \qquad -L \le y \le 0,$$

where the prime is now d/dy and ε is the unknown energy. The interval is cut off at $y = -L$, the **tip**. The conditions are

$$b(-L) = 0 \ \text{(tip)}, \qquad b(0) = 0 \ \text{(even orbitals)} \quad \text{or} \quad a(0) = 0 \ \text{(odd orbitals)}.$$

Status. The tip condition is a choice of the model (the record's status: "chosen (regular tip)"); the brane conditions follow from a mirror symmetry of the model across the brane that the record labels ASSUMED (key `boundaryConditions.brane.status`). Everything below is exact mathematics for these equations under these conditions. The record's values are $M = m = 1$, $H = 1$, $L = 3$ (units with $m = H = 1$: energies in units of the mass m, lengths along y in units of $1/H$); the program also checks $L = 2$ and $M = 2$.

The exact levels. We eliminate b.

$$b = \frac{Ma - a'}{\varepsilon} \qquad (\varepsilon \neq 0)$$

(solve the first equation for b);

$$b' = \frac{Ma' - a''}{\varepsilon}$$

(differentiate; M and ε are constants);

$$\frac{Ma' - a''}{\varepsilon} = \varepsilon a - M\,\frac{Ma - a'}{\varepsilon}$$

(insert both into the second equation);

$$Ma' - a'' = \varepsilon^2 a - M^2 a + Ma'$$

(multiply by ε);

$$a'' = (M^2 - \varepsilon^2)\, a$$

(cancel Ma' on both sides and change all signs). The condition $b = 0$ at a point means $Ma - a' = 0$ there (because $b = (Ma - a')/\varepsilon$).

Case $|\varepsilon| > M$. Put $p = \sqrt{\varepsilon^2 - M^2} > 0$; then $a'' = -p^2 a$, and $a = \cos(py + \varphi)$ up to a constant factor, with a phase φ.

- Even orbitals: $Ma - a' = 0$ at $y = 0$ and at $y = -L$. With $a = \cos(py + \varphi)$ this reads $M\cos(py + \varphi) + p\sin(py + \varphi) = 0$, that is $\tan(py + \varphi) = -M/p$ at both points ($\cos(py + \varphi)$ cannot vanish there, since then the left side would be $\pm p \neq 0$). The tangent repeats itself after π and takes each value once per period, so the two arguments φ and $-pL + \varphi$ differ by a whole multiple of π: $pL = n\pi$ with $n = 1, 2, \ldots$ Hence $\varepsilon = \pm\sqrt{M^2 + (n\pi/L)^2}$.
- Odd orbitals: $a(0) = 0$ makes a a multiple of $\sin(py)$. The tip condition $Ma(-L) - a'(-L) = 0$ becomes $M\sin(-pL) - p\cos(-pL) = 0$, that is $-M\sin(pL) - p\cos(pL) = 0$ (the sine is odd, the cosine even), or

$$\tan(pL) = -\frac{p}{M}.$$

This transcendental equation has exactly one root p_n on each interval $(n+\frac{1}{2})\pi/L < p < (n+1)\pi/L$, $n = 0, 1, 2, \ldots$, and no other positive root. The reasons, in three steps:

- On the intervals $n\pi/L < p < (n+\frac{1}{2})\pi/L$ the angle pL lies between $n\pi$ and $n\pi + \pi/2$, where the tangent is positive, while $-p/M$ is negative: no root.
- At the points $pL = n\pi$ the tangent is 0, not the negative number $-p/M$. At the points $pL = (n+\frac{1}{2})\pi$ the cosine vanishes, so the tangent is not defined, and the equation in the form $M\sin(pL) + p\cos(pL) = 0$ (multiplied by $\cos(pL)$ and by M) would demand $M\sin(pL) = \pm M = 0$: no root at these points either.
- On $(n+\frac{1}{2})\pi/L < p < (n+1)\pi/L$ consider $D(p) = \tan(pL) + p/M$, which vanishes exactly at the roots. It is continuous there and strictly increasing, because $\tan(pL)$ rises (its derivative $L/\cos^2(pL)$ is positive, by the chain rule) and p/M rises ($M > 0$); in words, the tangent rises while the line $-p/M$ falls. Just to the right of the left end $\tan(pL)$ is a large negative number, so $D < 0$; at the right end $\tan(pL) = 0$ and $D = (n+1)\pi/(LM) > 0$. By the intermediate value theorem D vanishes somewhere in between, and since it is strictly increasing it vanishes only once.

Each root gives the two odd levels $\pm\sqrt{M^2 + p_n^2}$.

Case $\varepsilon = 0$. The equations separate: $a' = Ma$ and $b' = -Mb$. With $b(-L) = 0$ the solution of $b' = -Mb$ is $b = 0$ everywhere (the uniqueness theorem of Section 2.2), and $a = e^{M(y+L)}$, a multiple of e^{My}. This is an even orbital ($b(0) = 0$) with the energy exactly 0, the **zero mode**; an odd one would need $a(0) = 0$, which $e^{M(y+L)}$ never is.

Case $0 < |\varepsilon| \le M$*: no level.* For $0 < |\varepsilon| < M$ put $q = \sqrt{M^2 - \varepsilon^2}$, with $0 < q < M$; then $a = \alpha e^{qy} + \beta e^{-qy}$ and

$$Ma - a' = (M-q)\,\alpha\, e^{qy} + (M+q)\,\beta\, e^{-qy}$$

(insert a and $a' = q\alpha e^{qy} - q\beta e^{-qy}$). For an even orbital this must vanish at two different points; setting it to zero gives $e^{2qy} = -(M+q)\beta/((M-q)\alpha)$, and the left side takes each value only once (it is strictly increasing), so this can hold at two points only if $\alpha = \beta = 0$. For an odd orbital $a(0) = 0$ gives $\beta = -\alpha$, so $a = 2\alpha\sinh(qy)$ with $\sinh u = (e^u - e^{-u})/2$ and $\cosh u = (e^u + e^{-u})/2$, and the tip condition becomes $2\alpha(-M\sinh(qL) - q\cosh(qL)) = 0$; the bracket is negative, so $\alpha = 0$. For $|\varepsilon| = M$ the same steps with $a = \alpha + \beta y$ give $\alpha = \beta = 0$ (Exercise 7). So, between $-M$ and M the only level is the zero mode (PROVED here; Notebook 02d, In [4], confirms it numerically for the three cases of the record).

These are the exact levels that the record states (key `boundaryConditions.exactK0Spectra` of `Revision/kohn_sham/ks-theory.json`) and lists in its column `eps_analytic` (Notebook 02d, In [7], recomputes all 54 of them; COMPUTED).

The Prüfer angle. The shooting method could use $b(0)$ or $a(0)$ directly as the mismatch. The Revision program does something better: it follows the ANGLE of the point (a, b). Write

$$a = r\cos\theta, \qquad b = r\sin\theta, \qquad r = \sqrt{a^2 + b^2} > 0.$$

$\theta(y)$ is the **Prüfer angle** (after the mathematician Heinz Prüfer; the notebooks, which use plain ASCII, write Pruefer). The point (a, b) never reaches the origin: if $a = b = 0$ at some y, the uniqueness theorem would make the solution zero everywhere. So θ is defined everywhere, and we let it grow continuously, counting every full turn (**winding**), so that it can exceed 2π. Where $a \neq 0$, $\theta = \arctan(b/a)$ plus a constant, and

$$\theta' = \frac{1}{1 + (b/a)^2} \cdot \frac{b'a - ba'}{a^2}$$

(the chain rule with the derivative $1/(1 + w^2)$ of $\arctan w$, and the quotient rule for b/a);

$$\theta' = \frac{ab' - ba'}{a^2 + b^2} = \frac{ab' - ba'}{r^2}$$

(multiply out: $\frac{1}{1+b^2/a^2} \cdot \frac{1}{a^2} = \frac{1}{a^2+b^2}$); the same formula holds where $a = 0$ (use $\theta = -\arctan(a/b)$ plus a constant there). Now insert the equations:

$$ab' - ba' = a(\varepsilon a - Mb) - b(Ma - \varepsilon b) = \varepsilon(a^2 + b^2) - 2Mab$$

(multiply out and collect);

$$\theta' = \varepsilon - M\,\frac{2ab}{r^2} = \varepsilon - M\sin 2\theta$$

(divide by r^2; then $2ab/r^2 = 2\sin\theta\cos\theta = \sin 2\theta$, the double-angle formula). The start $b(-L) = 0$ with $a(-L) = 1$ means $\theta(-L) = 0$. The brane conditions become conditions on the end angle $\Phi(\varepsilon) = \theta(0)$:

$$\text{even: } b(0) = 0 \iff \Phi = l\pi, \qquad \text{odd: } a(0) = 0 \iff \Phi = \frac{\pi}{2} + l\pi,$$

for a whole number l, the **label** of the level ($\sin\theta = 0$ exactly at the multiples of π, $\cos\theta = 0$ at $\pi/2$ plus multiples of π).

The end angle grows with the energy. First the radius:

$$rr' = aa' + bb' = a(Ma - \varepsilon b) + b(\varepsilon a - Mb) = M(a^2 - b^2)$$

(differentiate $r^2 = a^2 + b^2$, which gives $2rr' = 2aa' + 2bb'$; insert the equations; the terms with ε cancel);

$$\frac{r'}{r} = M\,\frac{a^2 - b^2}{r^2} = M\cos 2\theta$$

(divide by r^2; $\cos^2\theta - \sin^2\theta = \cos 2\theta$). Now let $u(y) = \partial\theta(y)/\partial\varepsilon$, the change of the angle at y per unit change of the energy (a partial derivative: θ depends on y and on ε).

$$u' = \frac{\partial}{\partial\varepsilon}\,\theta' = 1 - 2M\cos(2\theta)\,u$$

(Schwarz's theorem of Section 2.18 lets us swap the derivatives with respect to y and ε; then differentiate $\varepsilon - M\sin 2\theta$ with respect to ε by the chain rule);

$$u' = 1 - 2\,\frac{r'}{r}\,u$$

(insert $M\cos 2\theta = r'/r$);

$$r^2u' + 2rr'u = r^2$$

(multiply by r^2 and move the u term to the left);

$$(r^2u)' = r^2$$

(the product rule: $(r^2u)' = 2rr'u + r^2u'$);

$$r(0)^2u(0) - r(-L)^2u(-L) = \int_{-L}^{0} r^2\,dy$$

(integrate from $-L$ to 0: the integral of a derivative is the difference of the end values);

$$\frac{d\Phi}{d\varepsilon} = u(0) = \frac{1}{r(0)^2}\int_{-L}^{0} r^2\,dy > 0$$

($u(-L) = 0$, because $\theta(-L) = 0$ for every energy; divide by $r(0)^2$; the integral of the positive function r^2 is positive). So $\Phi(\varepsilon)$ is **strictly increasing**: each target value $l\pi$ or $\pi/2 + l\pi$ is reached for exactly one energy. Every level has its own label l, and no level in a range of energies can be missed (PROVED here; this is the argument of the program's header comment in `Revision/kohn_sham/solver/src/shoot.rs`). The formula also gives the slope that Newton's method below needs, without any extra shot.

Two values of the slope. Far from the mass, $\theta' = \varepsilon - M\sin 2\theta$ is ε on average, so $\Phi \approx \varepsilon L$ plus a bounded amount and the slope is about L. At $\varepsilon = 0$ the shot is $a = e^{M(y+L)}$, $b = 0$, so

$$\frac{d\Phi}{d\varepsilon}\Big|_{\varepsilon=0} = \frac{\int_{-L}^{0} e^{2M(y+L)}\,dy}{e^{2ML}} = \frac{(e^{2ML}-1)/(2M)}{e^{2ML}} = \frac{1 - e^{-2ML}}{2M}$$

($r^2 = e^{2M(y+L)}$; the antiderivative $e^{2M(y+L)}/(2M)$ between $-L$ and 0; divide by $r(0)^2 = e^{2ML}$), which is 0.498761 for $M = 1$, $L = 3$ (Notebook 02d, In [5]).

Counting the turns. A computer's function atan2(b, a) returns the angle of the point (a, b) in the range from $-\pi$ to π; it does not count turns. The program therefore adds up the changes of angle

from step to step: after each RK4 step it computes the new atan2, subtracts the previous one, and brings the difference into the range $(-\pi, \pi]$ by adding or subtracting 2π. This is correct as long as one step turns the point by less than π; the program refuses a shot in which a single step turns by 2 or more (radians), a safe margin. Along the way it adds up $\int r^2\,dy$ with the **trapezoid rule** (the integral over one step is the step length times the average of the two end values). When r^2 exceeds 10^{250} it divides a, b and the running integral by suitable powers of r, which changes neither the angle nor the quotient $\int r^2 dy / r(0)^2$ (in the free case of this chapter that never happens).

Newton's method. To find a level we solve $F(\varepsilon) = \Phi(\varepsilon) - t = 0$ for its target t. Replace F near the current guess ε_c by its tangent line

$$F(\varepsilon) \approx F(\varepsilon_c) + F'(\varepsilon_c)\,(\varepsilon - \varepsilon_c)$$

(the linear approximation of one-variable calculus), and take the zero of the line as the next guess:

$$\varepsilon_{\text{new}} = \varepsilon_c - \frac{F(\varepsilon_c)}{F'(\varepsilon_c)}, \qquad F'(\varepsilon) = \frac{d\Phi}{d\varepsilon} = \frac{1}{r(0)^2}\int_{-L}^{0} r^2\,dy$$

(set the line to zero and solve for ε; the slope is the formula proved above). Close to the root the number of correct digits roughly doubles at every step (ASSUMED: a standard result of numerical analysis, quoted without proof; the notebook shows it). Far from the root the tangent can point anywhere, so the program (function `find_level` in `Revision/kohn_sham/solver/src/shoot.rs`) adds a safety net:

1. Shoot at the starting guess $\varepsilon = 0$; if $F(0) = 0$ exactly (the zero mode), stop.
2. Make a bracket: walk upwards if $F < 0$ (downwards if $F > 0$), with a first step of 1.2 times Newton's estimate $|F/F'|$, but at least 10^{-4} and at most 2, doubling the step until F changes sign.
3. Inside the bracket take Newton steps; whenever Newton's point falls outside the bracket, or $|F|$ has not at least halved since the previous step, take the midpoint of the bracket instead (bisection). After each shot keep the half of the bracket that holds the sign change.
4. Stop when the bracket is narrower than the tolerance 10^{-13} (the record's `rootTolerance`), or after a Newton step shorter than it.

The orbital between the grid points. RK4 gives a and b at the ends of the steps (the **nodes**). The program also needs them in the middle of every step and takes them from the **cubic Hermite interpolation**: the polynomial of degree 3 that has the right values f_0, f_1 AND the right slopes f_0', f_1' at the two ends of a step of length h (the slopes come from the equations themselves). Put the step at $0 \le s \le h$ and write the cubic as $P(s) = f_0 + f_0' s + c s^2 + e s^3$ (its value and slope at $s = 0$ are then right). The two conditions at $s = h$ are

$$f_0 + f_0' h + c h^2 + e h^3 = f_1, \qquad f_0' + 2ch + 3eh^2 = f_1'$$

(the value and the derivative of P at $s = h$);

$$eh^3 = (f_0' + f_1')\,h - 2(f_1 - f_0), \qquad ch^2 = 3(f_1 - f_0) - (2f_0' + f_1')\,h$$

(multiply the second equation by h, subtract twice the first equation written as $ch^2 + eh^3 = f_1 - f_0 - f_0'h$, which leaves eh^3; then ch^2 from the first equation);

$$P(\tfrac{h}{2}) = f_0 + \frac{f_0'h}{2} + \frac{ch^2}{4} + \frac{eh^3}{8} = \frac{f_0 + f_1}{2} + \frac{h}{8}\,(f_0' - f_1')$$

(insert $s = h/2$; then insert ch^2 and eh^3 and collect: the values give $f_0 + (f_1 - f_0)(\frac{3}{4} - \frac{1}{4}) = \frac{f_0+f_1}{2}$, the slopes give $hf_0'(\frac{1}{2} - \frac{1}{2} + \frac{1}{8}) + hf_1'(-\frac{1}{4} + \frac{1}{8}) = \frac{h}{8}(f_0' - f_1')$). Its error is of order h^4, the order of RK4 (ASSUMED: quoted). With the values at the nodes and the midpoints the program integrates with Simpson's rule (Section 2.13) on the fine grid of $2G + 1$ points, with spacing $h/2$.

Why the error grows with the level. Far from the mass (far above $+M$ or far below $-M$) the point (a, b) turns at the rate $\theta' \approx \varepsilon$, like the oscillator of Section 2.7 with the frequency ε: forwards for $\varepsilon > 0$, backwards for $\varepsilon < 0$. One RK4 step multiplies the turning point by $R(i\omega)$ with $\omega = \varepsilon h$. Its angle ϕ is a little smaller than ω in size: a little smaller than ω for $\omega > 0$, a little larger (closer to 0) for $\omega < 0$. With $c = 1 - \frac{\omega^2}{2} + \frac{\omega^4}{24}$ and $s = \omega - \frac{\omega^3}{6}$ (the real and imaginary parts of $R(i\omega)$, Section 2.7),

$$\tan\phi = \frac{s}{c}, \qquad \tan\omega = \frac{\omega - \frac{\omega^3}{6} + \frac{\omega^5}{120} - \dots}{1 - \frac{\omega^2}{2} + \frac{\omega^4}{24} - \frac{\omega^6}{720} + \dots}$$

(the angle of a complex number has the tangent imaginary part over real part; tan = sin / cos with the Taylor series of the sine and the cosine, which follow from Section 2.3 as the series of $e^{i\omega}$);

$$\tan\phi - \tan\omega = -\frac{\omega^5/120}{c} + (\text{terms with } \omega^7 \text{ and higher}) = -\frac{\omega^5}{120} + \dots$$

(the numerators differ by $\omega^5/120$, the denominators only from ω^6 on, which changes the quotient from ω^7 on; and $1/c = 1 + \frac{\omega^2}{2} + \dots$ changes $\omega^5/120$ only from ω^7 on);

$$\phi - \omega = -\frac{\omega^5}{120} + \dots$$

(by the **mean value theorem** of calculus, $g(\phi) - g(\omega) = (\phi - \omega)\,g'(\xi)$ for some ξ between ω and ϕ; applied to $g = \tan$, whose derivative is $1 + \tan^2$, it gives $\tan\phi - \tan\omega = (\phi - \omega)(1 + \tan^2\xi)$, and $1 + \tan^2\xi = 1 + \dots$ for small angles). Every series used here holds for negative ω as well, so this result holds for both signs of the energy. So every step turns the point by $\omega^5/120 = \varepsilon^5h^5/120$ too little in the direction in which it turns: for $\varepsilon > 0$ the point turns forwards and its angle comes out too small; for $\varepsilon < 0$ it turns backwards ($\omega < 0$, $\omega^5 < 0$) and its angle comes out too large, that is, again too close to 0. After $G = L/h$ steps the computed end angle differs from the exact one by

$$\Phi_{\text{computed}}(\varepsilon) - \Phi_{\text{exact}}(\varepsilon) = -\frac{L}{h} \cdot \frac{\varepsilon^5h^5}{120} = -\frac{L\,\varepsilon^5h^4}{120}$$

(the number of steps times the change per step). The computed level is the energy $\varepsilon + \delta\varepsilon$ at which the computed end angle reaches the target, and the target is $\Phi_{\text{exact}}(\varepsilon)$, the end angle of the exact level ε. Since Φ grows by about L per unit of energy (for either sign of ε), $\Phi_{\text{computed}}(\varepsilon + \delta\varepsilon) \approx \Phi_{\text{exact}}(\varepsilon) + L\,\delta\varepsilon - L\varepsilon^5 h^4/120$, and setting this equal to the target gives

$$L\,\delta\varepsilon - \frac{L\,\varepsilon^5 h^4}{120} = 0, \qquad \delta\varepsilon \approx \frac{\varepsilon^5 h^4}{120}, \qquad \frac{\delta\varepsilon}{\varepsilon} \approx \frac{(h\varepsilon)^4}{120}$$

(subtract $\Phi_{\text{exact}}(\varepsilon)$ from both sides; divide by L; then by ε). Because ε^5 has the sign of ε, so has $\delta\varepsilon$: the energy must move away from zero to make up for the error of the angle. The computed levels come out slightly too large in size, too high for $\varepsilon > 0$ and too low for $\varepsilon < 0$, with an error of order h^4 that grows like the fifth power of the level (PROVED to leading order for levels far from the mass; near the mass the point does not turn uniformly and the error is smaller). Notebook 02d, In [12], compares this prediction with all 51 nonzero levels of the record and confirms the sign: all 33 positive levels of the record come out too high and all 18 negative ones too low (COMPUTED).

2.25 Example: the shooting method of the Revision Kohn-Sham solver, rewritten

Notebook 02d reads the theory, the parameters and the table of the free spectrum from the Revision record; rewrites the program's RK4 shot with the counted Prüfer angle and checks it against the angle equation; draws the staircase $\Phi(\varepsilon)$, checks that no level except the zero mode lies in the mass gap $|\varepsilon| \le M$, draws the slope of the staircase and checks the slope formula; draws the angle along y; recomputes the 54 exact levels; rewrites the program's Newton root finder with its safety net and compares it with plain bisection; reproduces all 54 numerical levels of the record and the numbers quoted by two checks of the program; builds the normalised orbitals as the program does; and measures the order 4 of the levels, the phase-lag law and the sign of the level errors. It ends with ALL 19 CHECKS PASSED (notebook 02d).

2.26 How to run Notebook 02d

Step 1. What this notebook does and what it needs.

Notebook 02d (Shooting two first-order equations with the Pruefer angle) is the file `Revision /textbook/notebooks/02d_pruefer_shooting.ipynb` of the repository Dirac_claude. It solves the simplest Kohn-Sham equations of the book, two first-order equations for the components a and b of an orbital in the hidden coordinate (constant mass, no momentum, no interaction), as an eigenvalue problem: it derives the exact levels, introduces the Pruefer angle, proves with the product rule that its end value increases with the energy, shoots with RK4 exactly as the Revision Rust solver does (900 steps on the interval of length 3, the winding count of the angle, the Newton root finder with a bisection safety net, tolerance 1e-13), reproduces all 54 levels of the Revision record of the free spectrum, numeric and exact, and the numbers of the solver checks of that spectrum and of the zero mode, and measures the fourth-order convergence of the levels. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself

imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 02d_pruefer_shooting.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02d_pruefer_shooting.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 02d_pruefer_shooting.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/02d.captions.json`
- `Revision/textbook/figures/02d_1_pruefer_staircase.png`
- `Revision/textbook/figures/02d_2_staircase_slope.png`
- `Revision/textbook/figures/02d_3_angle_along_y.png`
- `Revision/textbook/figures/02d_4_odd_level_equation.png`
- `Revision/textbook/figures/02d_5_newton_vs_bisection.png`
- `Revision/textbook/figures/02d_6_orbitals.png`
- `Revision/textbook/figures/02d_7_level_convergence.png`
- `Revision/textbook/figures/02d_8_record_differences.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02d exist
ALL 19 CHECKS PASSED (notebook 02d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/02d_pruefer_shooting.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 02d_pruefer_shooting.ipynb
python -m nbconvert --execute --inplace 02d_pruefer_shooting.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

2.27 Notebook 02d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/02d_pruefer_shooting.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The Kohn-Sham equations of this book (its density-functional model of the field
```

dirac16complex in the author's primordial universe) are solved by a Rust program of the Revision record, Revision/kohn_sham/solver, with the shooting method. This notebook teaches that method on the simplest case of those equations and REPRODUCES the program's results for it. It

- takes from the Revision record Revision/kohn_sham/ks-theory.json the two first-order equations for the two real components $a(y)$ and $b(y)$ of an orbital in the hidden coordinate y, in the free case (constant mass M, no 3-space momentum, no interaction), with their boundary conditions;
- derives their exact levels: $\varepsilon = 0$ and $\pm\sqrt{M^2 + (n\pi/L)^2}$ for the even orbitals, $\pm\sqrt{M^2 + p^2}$ with $\tan(pL) = -p/M$ for the odd ones;
- introduces the **Pruefer angle** $\theta = \mathrm{atan2}(b, a)$ and proves, with nothing more than the product rule, that its end value Φ grows with the energy, at the rate $d\Phi/d\varepsilon = \int r^2\,dy / r(0)^2$; so every level is found exactly once and carries a whole-number label;
- shoots with RK4 exactly as the Rust program does (900 steps on an interval of length 3) and finds every level with the program's own root finder (Newton's method with a bisection safety net, tolerance 10^{-13}), re-written here line by line;
- reproduces all 54 levels of the record Revision/kohn_sham/results/spectrum/free-k0-analytic.csv (on the computer that made the record, in all 16 printed digits), the exact column of the record, and the numbers that the program's checks of this spectrum and of the zero mode quote;
- draws the staircase of the Pruefer angle and its slope, the winding of the angle along y, Newton against bisection, the orbitals, and the fourth-order convergence of the levels.

It draws 8 figures and prints a PASS line for every check.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 02d (Shooting two first-order equations with the Pruefer angle) is the file
‘Revision/textbook/notebooks/02d_pruefer_shooting.ipynb‘ of the repository Dirac_claude.
It solves the simplest Kohn-Sham equations of the book, two first-order equations for the
components a and b of an orbital in the hidden coordinate (constant mass, no momentum, no
interaction), as an eigenvalue problem: it derives the exact levels, introduces the
Pruefer angle, proves with the product rule that its end value increases with the energy,
shoots with RK4 exactly as the Revision Rust solver does (900 steps on the interval of
length 3, the winding count of the angle, the Newton root finder with a bisection safety
net, tolerance 1e-13), reproduces all 54 levels of the Revision record of the free
spectrum, numeric and exact, and the numbers of the solver checks of that spectrum and of
the zero mode, and measures the fourth-order convergence of the levels. It needs a
computer with Windows 11, macOS or Linux, an internet connection for the installation,
the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib;
```

the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already

active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 02d_pruefer_shooting.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02d_pruefer_shooting.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 02d_pruefer_shooting.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/02d.captions.json‘
- ‘Revision/textbook/figures/02d_1_pruefer_staircase.png‘
- ‘Revision/textbook/figures/02d_2_staircase_slope.png‘
- ‘Revision/textbook/figures/02d_3_angle_along_y.png‘
- ‘Revision/textbook/figures/02d_4_odd_level_equation.png‘
- ‘Revision/textbook/figures/02d_5_newton_vs_bisection.png‘
- ‘Revision/textbook/figures/02d_6_orbitals.png‘
- ‘Revision/textbook/figures/02d_7_level_convergence.png‘
- ‘Revision/textbook/figures/02d_8_record_differences.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02d exist
ALL 19 CHECKS PASSED (notebook 02d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/02d_pruefer_shooting.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for

  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 02d_pruefer_shooting.ipynb
      python -m nbconvert --execute --inplace 02d_pruefer_shooting.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 02d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 02d (Shooting two first-order equations with the Pruefer angle) is the file
# Revision/textbook/notebooks/02d_pruefer_shooting.ipynb of the repository Dirac_claude.
# It solves the simplest Kohn-Sham equations of the book, two first-order equations for
# the components a and b of an orbital in the hidden coordinate (constant mass, no
# momentum, no interaction), as an eigenvalue problem: it derives the exact levels,
# introduces the Pruefer angle, proves with the product rule that its end value increases
# with the energy, shoots with RK4 exactly as the Revision Rust solver does (900 steps on
# the interval of length 3, the winding count of the angle, the Newton root finder with a
# bisection safety net, tolerance 1e-13), reproduces all 54 levels of the Revision record
# of the free spectrum, numeric and exact, and the numbers of the solver checks of that
# spectrum and of the zero mode, and measures the fourth-order convergence of the levels.
# It needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy,
# mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
```

```
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
```

```
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
```

```
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 02d_pruefer_shooting.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 02d_pruefer_shooting.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 02d_pruefer_shooting.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/02d.captions.json
# - Revision/textbook/figures/02d_1_pruefer_staircase.png
# - Revision/textbook/figures/02d_2_staircase_slope.png
# - Revision/textbook/figures/02d_3_angle_along_y.png
# - Revision/textbook/figures/02d_4_odd_level_equation.png
# - Revision/textbook/figures/02d_5_newton_vs_bisection.png
# - Revision/textbook/figures/02d_6_orbitals.png
# - Revision/textbook/figures/02d_7_level_convergence.png
# - Revision/textbook/figures/02d_8_record_differences.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
```

```
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 8 figure files of notebook 02d exist
#     ALL 19 CHECKS PASSED (notebook 02d)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/02d_pruefer_shooting.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 02d_pruefer_shooting.ipynb
#     python -m nbconvert --execute --inplace 02d_pruefer_shooting.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#

## 3. The words used in this notebook

- **Orbital**: a single-particle state of the Kohn-Sham model. Here it is
  described by two real functions $a(y)$ and $b(y)$, its *components*.
- **Hidden coordinate** $y$: the book's coordinate along the hidden direction
  $x_0$, $y = \ln(\sin z)/(6H)$ with $z = 6 H x_0$; $y = 0$ is the end of the
  patch $z = \pi/2$ (the *brane*), and the interval is cut off at $y = -L$ (the
  *tip*).
- **Energy level** $\varepsilon$: a value of the energy for which the equations
  have a solution with all boundary conditions; an eigenvalue. Unit: the mass
  $m$ (in units with $m = H = 1$).
- **Mass** $M$: the constant mass of the free case; here $M = m$.
- **Boundary conditions**: at the tip $b(-L) = 0$ (the *regular tip*, a choice
  of the model); at the brane $b(0) = 0$ (*even* orbitals) or $a(0) = 0$
  (*odd* orbitals), which follow from the ASSUMED mirror symmetry of the model
  (the record labels it ASSUMED).
- **Pruefer angle** $\theta(y)$: the angle of the point $(a, b)$ seen from the
  origin, $a = r \cos\theta$, $b = r \sin\theta$ with $r > 0$; we count every
  full turn, so $\theta$ can grow beyond $2\pi$ (*winding*). $r$ is the
  distance of the point from the origin, $r^2 = a^2 + b^2$.
- **atan2(b, a)**: the angle of the point $(a, b)$ between $-\pi$ and $\pi$.
- **End angle** $\Phi(\varepsilon) = \theta(0)$: the angle reached at the brane
  when we shoot with the energy $\varepsilon$.
- **Label** $l$: the whole number that names a level through its target angle,
  $\theta(0) = l\pi$ (even) or $\pi/2 + l\pi$ (odd).
- **Monotone (increasing)**: a function that grows whenever its argument grows.
- **RK4 step count** $G$: the number of RK4 steps on $-L \le y \le 0$; the step
  is $h = L/G$.
- **Trapezoid rule**: the integral over one step approximated by the step length
  times the average of the two end values.
- **Bracket**: two energies at which $\Phi$ minus the target has opposite signs;
  the level lies between them.
- **Newton's method**: replace a function by its tangent line at the current
  guess and take the zero of that line as the next guess.
- **Transcendental equation**: an equation such as $\tan(pL) = -p/M$ that has no
  solution formula and is solved numerically.
```

Text cell:

4. The physical and mathematical situation

The equations. The record gives the Kohn-Sham equation of one 2-component block in the real form (key ‘blockEquation.realForm‘)
$a’ = M a - (\kappa k + j(\varepsilon - v)) b$,
$b’ = (j(\varepsilon - v) - \kappa k) a - M b$, where the prime is d/dy. In the free case with no 3-space momentum ($k = 0$), no potential ($v = 0$), constant mass M and the block type $j = +1$ they are

$$a’ = M a - \varepsilon b, \qquad b’ = \varepsilon a - M b, \qquad -L \le y \le 0,$$

with $b(-L) = 0$ at the tip and $b(0) = 0$ (even) or $a(0) = 0$ (odd) at the brane. The record’s values are $M = m = 1$, $H = 1$, $L = 3$; the program also checks $L = 2$ and $M = 2$. In this notebook we take the equations as given; the physics chapters derive them.

The exact levels. Step 1: from the first equation, $b = (M a - a’)/\varepsilon$ (for $\varepsilon \ne 0$). Step 2: differentiate: $b’ = (M a’ - a’’)/\varepsilon$. Step 3: put both into the second equation: $(M a’ - a’’)/\varepsilon = \varepsilon a - M (M a - a’)/\varepsilon$. Step 4: multiply by ε: $M a’ - a’’ = \varepsilon^2 a - M^2 a + M a’$. Step 5: cancel $M a’$:

$$a’’ = (M^2 - \varepsilon^2)\, a .$$

For $|\varepsilon| > M$ put $p = \sqrt{\varepsilon^2 - M^2}$; then $a’’ = -p^2 a$ and $a = \cos(p y + \varphi)$ with a constant φ. The conditions on b become conditions on a: $b = 0$ means $M a - a’ = 0$.

- Even: $M a - a’ = 0$ at BOTH ends. $M\cos(py + \varphi) + p \sin(py + \varphi) = R \cos(py + \varphi - \delta)$ with $\tan\delta = p/M$ vanishes at $y = 0$ and at $y = -L$ only if the two phases differ by a multiple of π: $pL = n\pi$. So $\varepsilon = \pm\sqrt{M^2 + (n\pi/L)^2}$, $n = 1, 2, \dots$
- Odd: $a(0) = 0$ gives $a = \sin(py)$; the tip condition $M \sin(-pL) - p\cos(-pL) = 0$ gives $\tan(pL) = -p/M$.
- $\varepsilon = 0$: the equations become $a’ = M a$, $b’ = -M b$; with $b(-L) = 0$ we get $b = 0$ everywhere and $a = e^{M y}$: the *zero mode*, an even orbital ($b(0) = 0$) with energy exactly 0.

The Pruefer angle. Write $a = r\cos\theta$, $b = r\sin\theta$. Then $\theta’ = (a b’ - b a’)/r^2$ (the derivative of the angle of a moving point). Insert the equations: $a b’ - b a’ = a(\varepsilon a - M b) - b(M a - \varepsilon b) = \varepsilon (a^2 + b^2) - 2 M a b$. Divide by $r^2 = a^2 + b^2$ and use $2ab/r^2 = 2\sin\theta\cos\theta = \sin 2\theta$:

$$\theta’ = \varepsilon - M \sin 2\theta, \qquad \theta(-L) = 0 .$$

The brane conditions say $b(0) = 0$, that is $\theta(0) = l\pi$ (even), or $a(0) = 0$, that is $\theta(0) = \pi/2 + l\pi$ (odd), for a whole number l.

How fast the end angle grows. First the distance r: from $r^2 = a^2 + b^2$, $r r’ = a a’ + b b’ = a(M a - \varepsilon b) + b(\varepsilon a - M b) = M(a^2 - b^2)$, and $(a^2 - b^2)/r^2 = \cos^2\theta - \sin^2\theta = \cos 2\theta$, so $r’/r = M\cos 2\theta$. Now let $u(y) = \partial\theta(y)/\partial\varepsilon$,

```
the change of the angle at $y$ per unit change of the energy. Differentiate
$\theta' = \varepsilon - M\sin 2\theta$ with respect to $\varepsilon$ (the order
of the two derivatives does not matter): $u' = 1 - 2M\cos(2\theta)\, u =
1 - 2 (r'/r)\, u$. Multiply by $r^2$: $r^2 u' + 2 r r' u = r^2$. By the product
rule the left side is $(r^2 u)'$. Integrate from $-L$ to $0$; at the tip
$u(-L) = 0$, because $\theta(-L) = 0$ for every energy:

$$\frac{d\Phi}{d\varepsilon} = u(0) = \frac{1}{r(0)^2}\int_{-L}^{0} r^2\,dy > 0 .$$

So $\Phi(\varepsilon)$ increases strictly, and each target $l\pi$ or
$\pi/2 + l\pi$ is reached for exactly one $\varepsilon$: every level has its own
label $l$ and none can be missed. This is how the Rust program finds and names
its levels, and the formula gives its root finder the slope it needs.
```

## 6. Shooting with RK4 and counting the turns of the angle

The function ‘shoot‘ follows the Rust program (file
Revision/kohn_sham/solver/src/shoot.rs) line by line: it starts at the tip
with $(a, b) = (1, 0)$, so $\theta = 0$; makes $G$ RK4 steps of the two
equations; after every step it takes the new angle ‘atan2(b, a)‘, adds the
change of angle since the last step (brought into the range from $-\pi$ to
$\pi$, so that a full turn is never lost: one step turns the point by much less
than $\pi$) and so counts every turn. Along the way it adds up
$\int r^2\,dy$ with the trapezoid rule. It returns $\Phi = \theta(0)$, the slope
$d\Phi/d\varepsilon = \int r^2\,dy / r(0)^2$ of section 4, the largest turn of a
single step (the program refuses a shot in which one step turns by 2 or more),
and, when asked, the whole path. (The program also shrinks $(a, b)$ when they
become astronomically large, above $10^{125}$; that never happens here.)

The second function integrates the single angle equation
$\theta' = \varepsilon - M \sin 2\theta$ with RK4 instead; the two different
computations must agree up to the small RK4 errors.
```

In [3]:

```
def shoot(eps, M, L, G, keep=False):
    """RK4 from y = -L, (a, b) = (1, 0), to y = 0 in G steps.  Returns Phi =

## 7. The staircase of the Pruefer angle

The next cell computes $\Phi(\varepsilon)$ for 651 energies from $-6$ to $7$
($M = 1$, $L = 3$, 900 steps) and checks that it increases. The figure shows
it with the target lines $l\pi$ (even) and $\pi/2 + l\pi$ (odd): the levels are
the crossings, every target is crossed once, and the levels alternate between
even and odd. Away from the levels the curve rises with slope about $L = 3$,
because $\theta' = \varepsilon - M\sin 2\theta$ is $\varepsilon$ on average.

Inside the *mass gap* $|\varepsilon| \le M$ the equation
$a'' = (M^2 - \varepsilon^2)\, a$ has no oscillating solutions, and the only
level there is the zero mode. The cell checks this for the three cases
$(M, L)$ of the table: $\Phi(-M)$ and $\Phi(+M)$ both lie between $-\pi/2$ and
$\pi/2$, so the increasing staircase crosses no target except $0$ while
$|\varepsilon| \le M$.
```

## 8. The slope of the staircase

Section 4 proved $d\Phi/d\varepsilon = \int_{-L}^{0} r^2\,dy / r(0)^2$, which
is never negative. The next cell tests this formula in two ways. First, it
compares the formula (computed by ‘shoot‘ with the trapezoid rule) with the
*central difference* $(\Phi(\varepsilon + \delta) - \Phi(\varepsilon -
\delta))/(2\delta)$, $\delta = 10^{-4}$, at seven energies, and with the
value $(1 - e^{-2ML})/(2M)$ at $\varepsilon = 0$, where the shot is exactly
$a = e^{M(y + L)}$, $b = 0$ and the integral can be done by hand. Second, it
draws the formula over the whole grid together with the central differences of
```

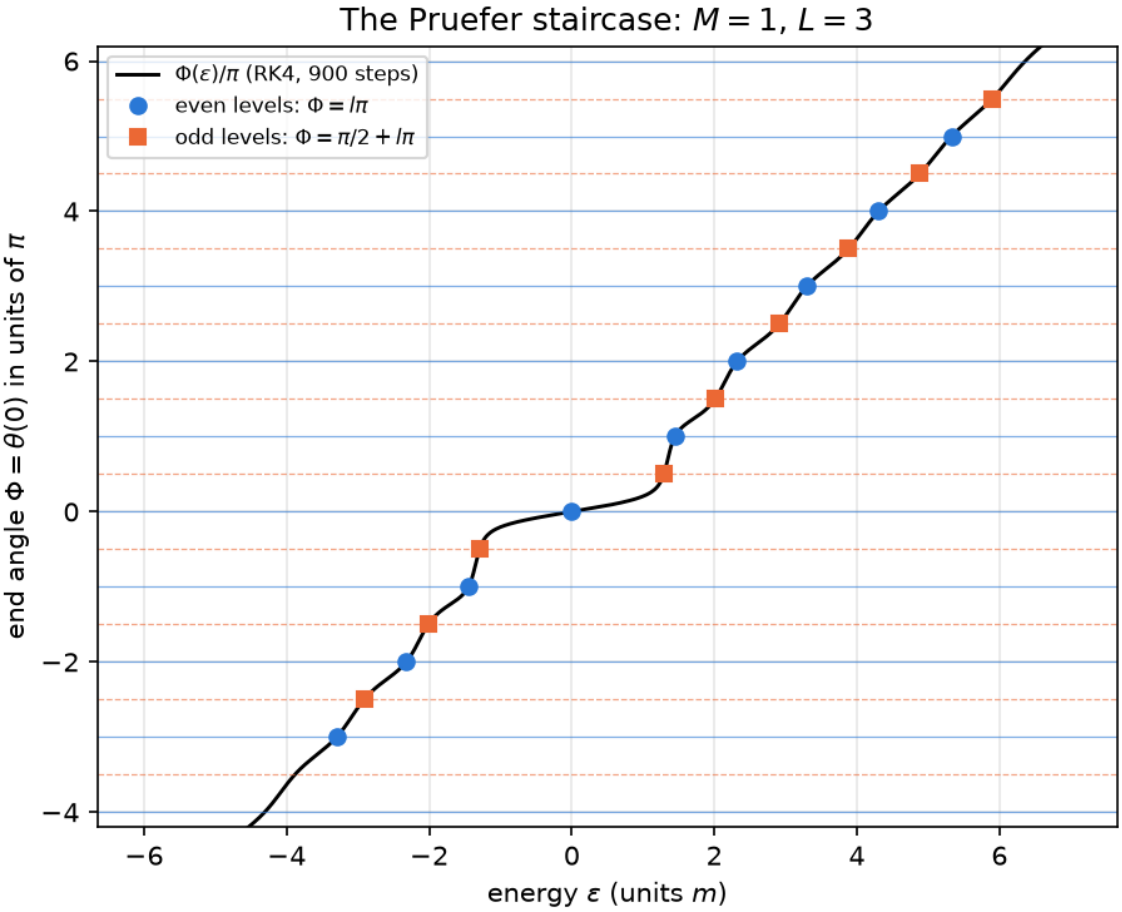

Figure 84: The end value of the Pruefer angle, $\Phi(\varepsilon) = \theta(0)$ in units of π (vertical axis), against the energy ε in units of the mass m from -6 to 7 (horizontal axis), for $M = 1$, $L = 3$ and 900 RK4 steps. Blue lines: the even targets $l\pi$; dashed orange lines: the odd targets $\pi/2 + l\pi$. Dots and squares: the 18 levels of the Revision record for this case. Φ increases steadily, so it crosses every target exactly once: each level has its own label l, and even and odd levels alternate. The zero mode sits at $\varepsilon = 0$, $\Phi = 0$. (Notebook 02d, figure 1.)

```
the grid of section 7 (spacing 0.02). The slope is about $L = 3$ far from the
mass. Near $\varepsilon = 0$ it is about $1/(2M) = 0.5$: there the shot grows
like $e^{M(y + L)}$ and is largest at the brane, so $r(0)^2$ is large. Near
$|\varepsilon| = 1.34$ it is much larger, about 12.5: there the shot ends with a
small $r(0)$ compared with its size inside the interval, so a small change of
energy turns the end angle a lot, and the staircase climbs steeply.
```

## 10. The exact levels, computed again

The odd levels need the roots $p$ of $\tan(pL) = -p/M$, which we write as
$M\sin(pL) + p\cos(pL) = 0$ (no infinities). The $n$-th root ($n = 0, 1, 2,
\dots$) lies between $(n + \frac{1}{2})\pi/L$ and $(n + 1)\pi/L$, where the
left side changes sign. The cell solves them with mpmath at 30 digits, forms
all 54 exact levels of the table (labels $-3$ to $5$ of both parities, for
$(M, L) = (1, 3), (1, 2), (2, 3)$; the odd label $l \ge 0$ uses the root
$p_l$ and $l \le -1$ the root $p_{-l-1}$ with the minus sign) and compares them
with the record's column `eps_analytic`. The figure shows the graphical
solution for $M = 1$, $L = 3$.
```

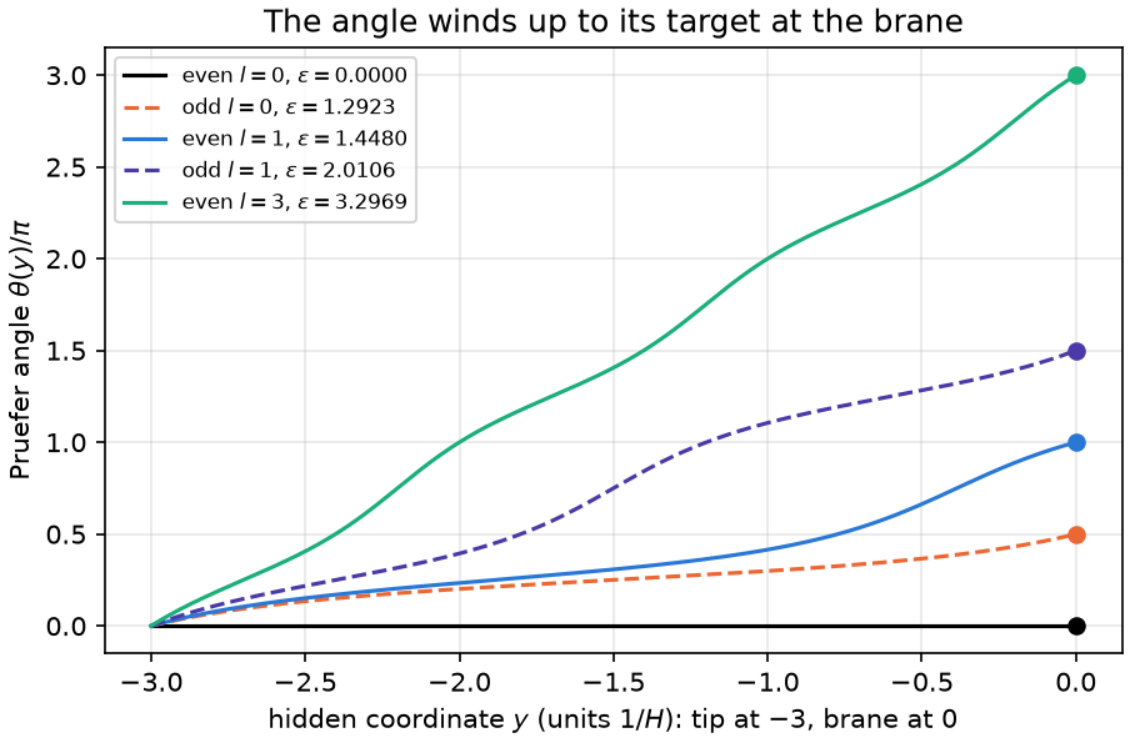

Figure 86: The Pruefer angle $\theta(y)$ in units of π (vertical axis) along the hidden coordinate y from the tip $y = -3$ to the brane $y = 0$ (horizontal axis, units $1/H$) for five levels of the case $M = 1$, $L = 3$: the zero mode (black, stays at 0), the odd label 0 (1.2923, ends at $\pi/2$), the even label 1 (1.4480, ends at π), the odd label 1 (2.0106, ends at $3\pi/2$) and the even label 3 (3.2969, ends at 3π). Solid lines are even, dashed lines odd orbitals; every curve starts at 0 and ends on its target (dots). (Notebook 02d, figure 3.)

## 11. Newton's method with a safety net: the program's root finder
```

```
To find a level we must solve $F(\varepsilon) = \Phi(\varepsilon) - t = 0$ for
its target $t$. **Newton's method** replaces $F$ by its tangent line at the
current guess $\varepsilon_c$, $F(\varepsilon) \approx F(\varepsilon_c) +
F'(\varepsilon_c)(\varepsilon - \varepsilon_c)$, and takes the zero of that line
as the next guess:

$$\varepsilon_{\rm new} = \varepsilon_c - \frac{F(\varepsilon_c)}
{F'(\varepsilon_c)}, \qquad F'(\varepsilon) = \frac{d\Phi}{d\varepsilon} =
\frac{1}{r(0)^2}\int_{-L}^{0} r^2\,dy .$$

Close to the root the number of correct digits roughly doubles at every step.
Far from it the tangent can point anywhere, so the Rust program (function
`find_level` in Revision/kohn_sham/solver/src/shoot.rs) adds a safety net:

1. Shoot at the starting guess $\varepsilon = 0$; if $F(0) = 0$ exactly (the zero
   mode), stop.
2. Make a bracket: walk upwards (if $F < 0$) or downwards (if $F > 0$) with a
   first step of 1.2 times Newton's estimate (at least $10^{-4}$, at most 2),
   doubling the step until $F$ changes sign.
3. Newton steps inside the bracket; whenever Newton's point falls outside the
   bracket, or the mismatch $|F|$ has not at least halved since the last step,
   bisect instead. After each shot the bracket shrinks to the side that keeps
   the sign change.
4. Stop when the bracket is narrower than the tolerance $10^{-13}$, or when a
   Newton step is smaller than it.

The next cell writes this down in Python, step for step as in the Rust code,
and compares it with plain bisection (bracket $-12$ to $12$, halved until it is
narrower than $10^{-13}$) on the even level with label 3 of the case $M = 1$,
$L = 3$: the figure shows the error of every energy that is shot.
```

```
## 12. All 54 levels, against the Rust program

Now the whole table. For each row the cell takes the target of its parity and
label and finds the energy with `find_level`, with the program's number of RK4
```

steps $G = 900 L/3$ (900 for $L = 3$, 600 for $L = 2$: the same step
$h = 1/300$). It writes every level as the program writes numbers (16
significant digits, exponents like ‘e0‘) and compares the text with the
record’s column ‘eps_numeric‘. On the computer that made the record all 54 are
identical; on another computer the function atan2 of the system’s mathematics
library may round differently in the last binary place, and a last digit may
differ, so the check asks for agreement within 10^{-12} (ten times the root
tolerance). The record keeps 16 digits, so even an identical level differs from
the number read back from the record by up to about 10^{-15}.

Then it recomputes the two numbers that the program’s check
‘free_k0_analytic_spectra‘ quotes: the largest $|\varepsilon_{\rm numeric} -
\varepsilon_{\rm exact}|$ for $|\varepsilon| < 4m$ and for $|\varepsilon| \ge
4m$. (The check’s text calls the second band "$4m \le |\varepsilon| < 7m$", but
the Rust code, file Revision/kohn_sham/solver/src/spectrum.rs, puts every level
with $|\varepsilon| \ge 4m$ into it, and the table goes up to $8.75m$; the cell
prints both numbers.)

Text cell:

```
## 13. The orbitals

The next cell builds the normalised orbitals of four levels of the canonical
case as the Rust program builds them (function ‘profile‘ in shoot.rs): the
values at the $G + 1$ step ends (*nodes*) come from the RK4 shot; the values in
the middle of every step from *cubic interpolation*: the cubic polynomial that
```

```
has the values $f_0, f_1$ and the slopes $f_0', f_1'$ at the two ends of a step
of length $h$ takes in the middle the value $(f_0 + f_1)/2 + h(f_0' - f_1')/8$
(check it on $f = y^2$ and $f = y^3$ on the step from 0 to $h$); the slopes
come from the equations themselves. On this fine grid of $2G + 1$ points the
norm $\int_{-L}^{0} (a^2 + b^2)\, dy$ is computed with Simpson's rule (weights
$1, 4, 2, 4, \dots, 4, 1$ times one third of the spacing $h/2$), and the orbital
is divided by its square root. The cell draws $a(y)$ and $b(y)$, checks the
brane condition of each ($b(0) = 0$ even, $a(0) = 0$ odd), and measures how far
the computed zero mode is from its exact form
$a = \sqrt{2M/(1 - e^{-2ML})}\, e^{M y}$, $b = 0$ (the normalised $e^{My}$): the
program's check `free_zero_mode_exact` quotes this distance.
```

```

Text cell:

```
**Why the error grows with the level.** Far from the mass, $\theta' \approx
\varepsilon$: the point $(a, b)$ turns at the rate $\varepsilon$ (forwards for
$\varepsilon > 0$, backwards for $\varepsilon < 0$). One RK4 step multiplies a
turning point by $R(i\omega)$ with $\omega = \varepsilon h$ (the amplification
factor of the test equation $y' = i\varepsilon y$), whose angle is a little
SMALLER IN SIZE than the exact $\omega$. The next cell lets sympy expand the
angle of $R(i\omega)$: it is $\omega - \omega^5/120 + \dots$ (for $\omega < 0$
too, because the angle of $R(-i|\omega|)$ is minus that of $R(i|\omega|)$).
After $G = L/h$ steps the computed end angle differs by about
$-L\, \varepsilon^5 h^4/120$ from the exact one: it is too small for
$\varepsilon > 0$ and too large for $\varepsilon < 0$. Since $\Phi$ grows by
about $L$ per unit of energy, the computed level must move AWAY FROM ZERO by

$$\delta\varepsilon \approx \frac{\varepsilon^5 h^4}{120}, \qquad
\frac{\delta\varepsilon}{\varepsilon} \approx \frac{(h\varepsilon)^4}{120}$$
```

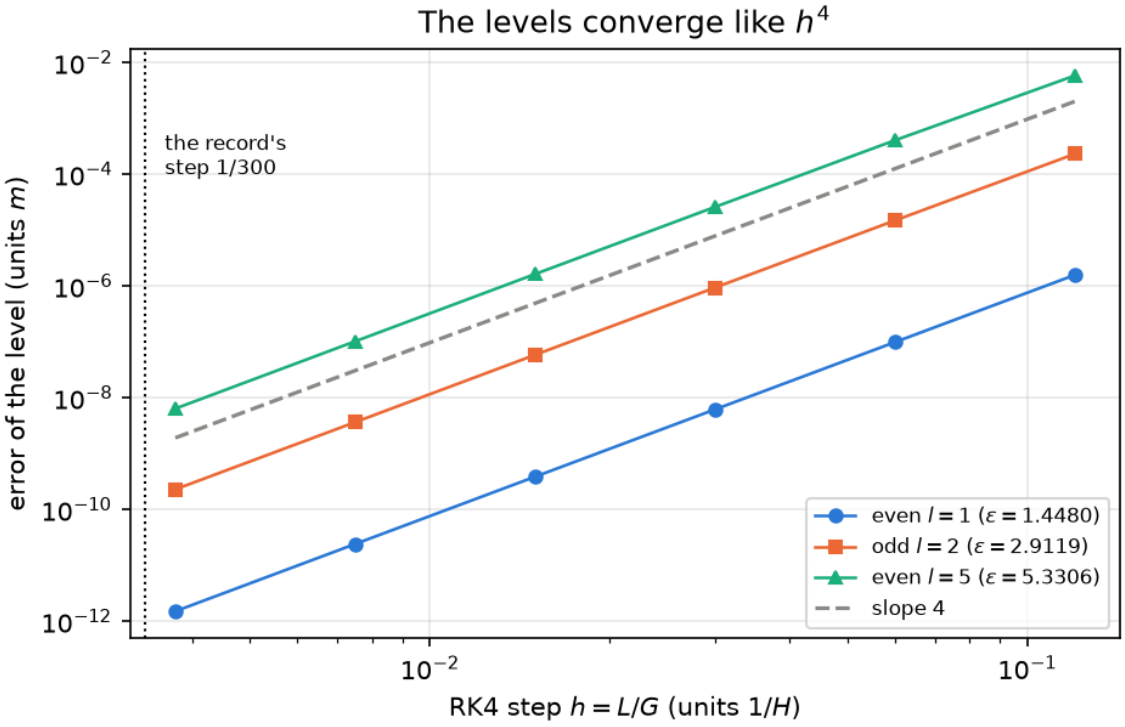

Figure 90: The error of three levels of the case $M = 1$, $L = 3$ found by shooting, against the RK4 step $h = L/G$ for $G = 25$ to 800 steps (logarithmic axes; the error in units of m, the step in units of $1/H$): even label 1 (circles), odd label 2 (squares), even label 5 (triangles). The points follow lines of slope 4 (dashed guide): the levels have the order of RK4, and higher levels have larger errors. The dotted line marks the record's step 1/300. (Notebook 02d, figure 7.)

```
to make up for it ($\varepsilon^5$ has the sign of $\varepsilon$): positive
levels come out too high, negative levels too low, both too large in size.
The cell checks this sign in the record's column 'difference'. The figure draws
the relative error $|\delta\varepsilon/\varepsilon|$ of all 51 nonzero levels
of the record against $h|\varepsilon|$ with $h = 1/300$, with our own
differences on top, and this prediction as a line. Close to the mass the point
does not turn uniformly ($\theta' = \varepsilon - M \sin 2\theta$), and the
error is smaller than the prediction; far from it the points approach the line.
```

## 16. What this notebook showed

- The free Kohn-Sham block of the book, $a' = M a - \varepsilon b$,
  $b' = \varepsilon a - M b$ with $b(-L) = 0$ and $b(0) = 0$ or $a(0) = 0$, has
  the exact levels $0$ (the zero mode $a \propto e^{My}$, $b = 0$),
  $\pm\sqrt{M^2 + (n\pi/L)^2}$ (even) and $\pm\sqrt{M^2 + p^2}$ with
  $\tan(pL) = -p/M$ (odd).
- The Pruefer angle obeys $\theta' = \varepsilon - M\sin 2\theta$, and the
  product rule gives $d\Phi/d\varepsilon = \int r^2\,dy / r(0)^2 > 0$: the end
  value increases with $\varepsilon$, so each level is the unique crossing of a
  target $l\pi$ or $\pi/2 + l\pi$; no level can be missed and each has a label.
- The Rust program finds a level with Newton's method (slope from the same
  formula) and a bisection safety net: 9 shots for the even level $l = 3$,
  where plain bisection needs 48.
- Re-written line by line in Python, the program's shooting (900 RK4 steps for
  $L = 3$) and root finder reproduce all 54 levels of the record
  Revision/kohn_sham/results/spectrum/free-k0-analytic.csv (on the computer
  that made the record, identical in all 16 printed digits), the exact column,
  the zero mode exactly, the distance $1.35 \times 10^{-12}$ of the computed zero
  mode from its exact form, and the numbers $7.23 \times 10^{-10}$ (levels below
  $4m$) and $5.05 \times 10^{-8}$ (all levels from $4m$ up to $8.75m$; the
  check's text says "below $7m$") quoted by the program's check
  free_k0_analytic_spectra.
- The level errors fall like $h^4$; for levels far from the mass the relative
  error is close to $(h\varepsilon)^4/120$, the phase lag of RK4, and every
  computed level lies farther from zero than the exact one (too high above
  zero, too low below it). The canonical step $h = 1/300$ gives errors below
  $10^{-9}$ for $|\varepsilon| < 4m$.
- Inside the mass gap $|\varepsilon| \le M$ the only level is the zero mode.
- What this notebook does not show: the physics of these equations (where they
  come from, the meaning of the levels, the interacting case); the brane
  conditions rest on the ASSUMED mirror symmetry and the tip condition is a
  choice of the model, as the record states.
```

2.28 Line-by-line walk-through of Notebook 02d

The notebook has thirteen code cells, In [1] to In [13]. A quoted line `...)` stands for the rest of a figure caption, which Section 2.27 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 2.26; its code is the set-up code of Notebook 02a explained in Section 2.11, with `NOTEBOOK_ID = "02d"`. It prints Set-up of notebook 02d complete: repository folder found, helpers defined.

In [2], the records and the settings.

```
import csv  # reads the table of levels (comma-separated values)
import math  # sqrt, atan2, pi for single numbers
import re  # finds numbers inside a text

import mpmath  # numbers with as many digits as we ask for
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols

BLUE, ORANGE, AQUA, VIOLET = "#2a78d6", "#eb6834", "#1baf7a", "#4a3aa7"
GREY, BLACK = "#8a8986", "#000000"
```

`csv` reads tables stored as comma-separated values (one row per line, the cells separated by commas), `re` finds patterns (here numbers) inside a text (**regular expressions**); the other packages and the colours are as before.

```
THEORY = "Revision/kohn_sham/ks-theory.json"
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
TABLE = "Revision/kohn_sham/results/spectrum/free-k0-analytic.csv"
SOLVER_REPORT = "Revision/kohn_sham/reports/ks-rust-solver.json"
theory = json.loads(repository_file(THEORY).read_text(encoding="utf-8"))
parameters = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))
with open(repository_file(TABLE), encoding="utf-8", newline="") as table:
    ROWS = list(csv.DictReader(table))  # one dictionary per level
```

The four Revision records of the notebook: the Kohn-Sham theory, the solver's parameters, the table of the free spectrum written by the Rust program, and the program's report of checks. The two JSON files are read as in Notebook 02a. `with open(...) as table:` opens the table file and closes it again at the end of the block; `csv.DictReader` reads it row by row, each row as a dictionary from the column names of the first line (`m`, `L`, `parity`, `label`, `eps_numeric`, `eps_analytic`, `difference`) to the cell texts.

```
say("realForm: " + theory["blockEquation"]["realForm"])
say("brane status: " + theory["boundaryConditions"]["brane"]["status"])
say("tip status: " + theory["boundaryConditions"]["tip"]["status"])
say("exact k = 0 spectra: " + theory["boundaryConditions"]["exactK0Spectra"])
```

Four statements of the theory record are printed: the real form of the block equation (with the general mass `M_eff`, momentum weight `kappa k` and potential `v_v` that Section 2.24 sets to M, 0 and 0), the status of the brane conditions (ASSUMED), the status of the tip condition (chosen, regular tip), and the exact $k = 0$ spectra derived in Section 2.24.

```
G_CANONICAL = parameters["numerics"]["rk4Steps"]  # RK4 steps for L = 3
ROOT_TOLERANCE = parameters["numerics"]["rootTolerance"]
M_RECORD, L_RECORD = parameters["physics"]["m"], parameters["physics"]["L_tipCutoff"]
report("RK4 steps, root tolerance, m, L of the record",
       f"{G_CANONICAL}, {ROOT_TOLERANCE}, {M_RECORD}, {L_RECORD}")
report("levels in the table", len(ROWS))
check(theory["boundaryConditions"]["brane"]["status"] == "ASSUMED"
      and G_CANONICAL == 900 and ROOT_TOLERANCE == 1e-13 and len(ROWS) == 54,
      "records read: brane ASSUMED, 900 RK4 steps, tolerance 1e-13, 54 levels")
```

The solver's settings: 900 RK4 steps, the root tolerance 10^{-13}, $m = 1$ and $L = 3$; the table has 54 rows. The check confirms these values and that the brane conditions are labelled ASSUMED in the record.

In [3], shooting with RK4 and counting the turns.

```
def shoot(eps, M, L, G, keep=False):
    """RK4 from y = -L, (a, b) = (1, 0), to y = 0 in G steps.  Returns Phi =
    theta(0), the slope dPhi/deps = (integral of r^2) / r(0)^2 and the largest
    turn of one step; with keep=True also the arrays y, a, b, theta of the path."""
    h = L / G  # the step
    a, b = 1.0, 0.0  # the tip: b(-L) = 0, so theta(-L) = 0
    theta, raw = 0.0, 0.0  # the counted angle and the last atan2 value
    integral, r2_before = 0.0, 1.0  # running integral of r^2; r^2 at the last node
    largest = 0.0  # the largest turn of one step so far
    path = [(-L, a, b, theta)]
```

The function follows the Rust function `shoot` of `Revision/kohn_sham/solver/src/shoot.rs` for the free case. The start at the tip is $(a, b) = (1, 0)$, so $\theta = 0$. `theta` is the counted angle and `raw` the last value returned by `atan2`; `integral` collects $\int r^2 dy$ and `r2_before` holds r^2 at the last node (1 at the start); `largest` records the largest turn of one step; `path` holds (y, a, b, θ) at the nodes when it is asked for.

```
    for i in range(G):
        p1a, p1b = M * a - eps * b, eps * a - M * b  # the slopes (a', b') at start
        a2, b2 = a + h / 2 * p1a, b + h / 2 * p1b  # half a step with them
        p2a, p2b = M * a2 - eps * b2, eps * a2 - M * b2  # the slopes there
        a3, b3 = a + h / 2 * p2a, b + h / 2 * p2b  # half a step with these
        p3a, p3b = M * a3 - eps * b3, eps * a3 - M * b3  # the slopes there
        a4, b4 = a + h * p3a, b + h * p3b  # a whole step with the third slopes
        p4a, p4b = M * a4 - eps * b4, eps * a4 - M * b4  # the slopes at the end
        a += h / 6 * (p1a + 2 * p2a + 2 * p3a + p4a)  # weights 1 : 2 : 2 : 1
        b += h / 6 * (p1b + 2 * p2b + 2 * p3b + p4b)
```

One RK4 step of the two equations $a' = Ma - \varepsilon b$, $b' = \varepsilon a - Mb$, written out component by component as the Rust code writes it: the four pairs of slopes `p1` to `p4` are the k_1 to k_4 of Section 2.4 for a and for b, and `a += ...` means "add the right side to `a`". (The names `a4`, `b4` here are the RK4 end-of-step values; they have nothing to do with the metric function a_4.)

```
        new = math.atan2(b, a)  # the angle of (a, b), between -pi and pi
        change = new - raw
        if change > math.pi:  # crossed from just below pi to just above -pi
            change -= 2 * math.pi
        elif change <= -math.pi:  # crossed the other way
            change += 2 * math.pi
        largest = max(largest, abs(change))
        theta += change
        raw = new
```

The winding count of Section 2.24: the new `atan2` angle minus the previous one, brought into $(-\pi, \pi]$ (a jump of almost $+2\pi$ means that the point crossed the negative horizontal axis downwards,

where `atan2` jumps from π to $-\pi$, and so on); the change is added to the counted angle, and the largest change is remembered.

```
        r2 = a * a + b * b  # r^2 at the new node
        integral += h / 2 * (r2_before + r2)  # the trapezoid rule for this step
        r2_before = r2
        if keep:
            path.append((-L + (i + 1) * h, a, b, theta))
```

The trapezoid rule adds the step length times the average of r^2 at the two ends of the step; the node is stored if the path was asked for.

```
    if keep:
        return theta, integral / r2_before, largest, np.array(path).T
    return theta, integral / r2_before, largest
```

After the last step `r2_before` is $r(0)^2$, so `integral / r2_before` is the slope $d\Phi/d\varepsilon$ of Section 2.24. The function returns $\Phi = \theta(0)$, that slope and the largest turn; with `keep=True` also the path, turned by `.T` (transpose) into four rows: all y, all a, all b, all θ. (The Rust function also rescales (a, b) when r^2 exceeds 10^{250}; in this free case r^2 stays far below that, so the rewrite leaves it out.)

```
def angle_equation(eps, M, L, G):
    """RK4 for the single equation theta' = eps - M sin(2 theta), theta(-L) = 0."""
    h = L / G
    theta = 0.0

    def slope(t):
        return eps - M * math.sin(2 * t)
    for _ in range(G):
        k1 = slope(theta)
        k2 = slope(theta + h / 2 * k1)
        k3 = slope(theta + h / 2 * k2)
        k4 = slope(theta + h * k3)
        theta += h / 6 * (k1 + 2 * k2 + 2 * k3 + k4)
    return theta
```

An independent way to the same end angle: RK4 applied to the single angle equation $\theta' = \varepsilon - M \sin 2\theta$ of Section 2.24 (the right side does not depend on y, so `slope` takes only the angle).

```
M1, L3 = 1.0, 3.0  # the canonical case of the record
for eps in (-2.0, 0.0, 1.0, 2.5):
    Phi = shoot(eps, M1, L3, 900)[0]  # element 0 of the result: Phi
    say(f"eps = {eps:+.1f}: Phi by (a, b) = {Phi:+.12f},  "
        f"by the angle equation = {angle_equation(eps, M1, L3, 900):+.12f}")
```

For four energies the two computations are printed side by side, for example $\Phi(2.5) = 6.798217350015$ by (a, b) and 6.798217350074 by the angle equation.

```
differences = [abs(shoot(e, M1, L3, 900)[0] - angle_equation(e, M1, L3, 900))
               for e in np.linspace(-5.0, 5.0, 21)]
check(max(differences) < 1e-8 and shoot(0.0, M1, L3, 900)[0] == 0.0,
      "both ways of computing Phi agree within 1e-8; Phi(0) is exactly 0")
```

On 21 energies from -5 to 5 the two ways agree within 10^{-8} (they are different computations, each with its own small RK4 error), and at $\varepsilon = 0$ the shot gives exactly $\Phi = 0$, because b stays exactly 0.

In [4], the staircase.

```
eps_grid = np.linspace(-6.0, 7.0, 651)
shots = [shoot(e, M1, L3, 900) for e in eps_grid]  # (Phi, slope, largest turn)
Phi_grid = np.array([s[0] for s in shots])
slope_grid = np.array([s[1] for s in shots])  # dPhi/deps by the formula
check(np.all(np.diff(Phi_grid) > 0), "Phi(eps) increases on the whole grid")
```

651 energies from -6 to 7 (spacing 0.02) are shot; `Phi_grid` holds the end angles and `slope_grid` the slopes by the formula. `np.diff` gives the differences of neighbouring entries; the check requires all of them to be positive: Φ increases, as proved in Section 2.24.

```
gap_ends = []  # Phi at eps = -M and eps = +M for the three cases of the table
for M, L in sorted({(float(r["m"]), float(r["L"])) for r in ROWS}):
    G = round(G_CANONICAL * L / 3.0)  # the record's step h = 1/300
    gap_ends += [shoot(-M, M, L, G)[0], shoot(M, M, L, G)[0]]
report("largest |Phi(-M)|, |Phi(+M)| in units of pi (three cases)",
       f"{max(abs(p) for p in gap_ends) / math.pi:.4f}")
check(max(abs(p) for p in gap_ends) < math.pi / 2,
      "for |eps| <= M the staircase crosses no target but 0: only the zero mode")
```

These lines test the statement of Section 2.24 that between $-M$ and M the only level is the zero mode. The curly brackets `{...}` make a **set**, a collection in which each element appears once: the pairs (M, L) of all 54 rows give the three cases $(1, 2)$, $(1, 3)$ and $(2, 3)$, and `sorted` puts them in a fixed order. For each case `G` is the record's number of steps for that L (900 for $L = 3$, 600 for $L = 2$), and the end angle is computed at the edges of the mass gap, $\varepsilon = -M$ and $\varepsilon = +M$ (`+=` appends both to the list). Since Φ increases with ε, every $\Phi(\varepsilon)$ with $|\varepsilon| \le M$ lies between $\Phi(-M)$ and $\Phi(+M)$. The RESULT line prints the largest of the six sizes, 0.2256π (COMPUTED, for $M = 2$); the check requires all six to be below $\pi/2$. Then for $|\varepsilon| \le M$ the end angle stays strictly between $-\pi/2$ and $\pi/2$, and the only target in that range is 0 (the even target with $l = 0$): no level except the zero mode lies in the gap, in all three cases.

```
def target(parity, label):
    """The target value of Phi for a level of the given parity and label."""
    return label * math.pi if parity == "even" else math.pi / 2 + label * math.pi

canonical = [r for r in ROWS if float(r["m"]) == 1.0 and float(r["L"]) == 3.0]
```

`target` returns $l\pi$ for an even and $\pi/2 + l\pi$ for an odd level (the program's function of the same name). `canonical` keeps the 18 rows of the table with $M = 1$ and $L = 3$ (the cells are texts, so `float` turns them into numbers).

```
fig, ax = plt.subplots(figsize=(7.0, 5.4))
ax.plot(eps_grid, Phi_grid / math.pi, color=BLACK, lw=1.4,
        label="$\\Phi(\\varepsilon)/\\pi$ (RK4, 900 steps)")
for label in range(-4, 7):
    ax.axhline(label, color=BLUE, lw=0.6, alpha=0.6)
    ax.axhline(label + 0.5, color=ORANGE, lw=0.6, ls="--", alpha=0.6)
```

The staircase Φ/π in black, and horizontal target lines: blue at the whole numbers (even targets $l\pi$), dashed orange halfway between them (odd targets).

```
for r in canonical:
    is_even = r["parity"] == "even"
    ax.plot(float(r["eps_numeric"]), target(r["parity"], int(r["label"])) / math.pi,
            "o" if is_even else "s", color=BLUE if is_even else ORANGE, ms=6)
ax.plot([], [], "o", color=BLUE, label="even levels: $\\Phi = l\\pi$")
ax.plot([], [], "s", color=ORANGE, label="odd levels: $\\Phi = \\pi/2 + l\\pi$")
```

Each of the record's 18 levels is marked at its energy and its target (a blue dot for even, an orange square for odd); two empty plots add the legend entries.

```
ax.set_ylim(-4.2, 6.2)
ax.set_xlabel("energy $\\varepsilon$ (units $m$)")
ax.set_ylabel("end angle $\\Phi = \\theta(0)$ in units of $\\pi$")
ax.set_title("The Pruefer staircase: $M = 1$, $L = 3$")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "pruefer_staircase",
            "The end value of the Pruefer angle, $\\Phi(\\varepsilon) = "
            ...)
```

Labels and the saved figure `02d_1_pruefer_staircase.png`. **What Figure 02d.1 shows:** the curve rises steadily and crosses every target line exactly once, at a level of the record; even and odd levels alternate; the zero mode sits at $\varepsilon = 0$, $\Phi = 0$; between -1 and 1 (inside the mass gap, $|\varepsilon| < M$) the curve rises only slowly (In [5] finds slopes between 0.5 and 0.7 there) and crosses only the line 0, in agreement with Section 2.24.

In [5], the slope of the staircase.

```
DELTA = 1e-4  # the half-width of the central difference
tested = [-4.0, -1.34, -0.5, 0.0, 0.7, 1.3, 3.0]  # seven energies
relative = []
for e in tested:
    formula = shoot(e, M1, L3, 900)[1]  # element 1 of the result: the slope
    central = (shoot(e + DELTA, M1, L3, 900)[0]
               - shoot(e - DELTA, M1, L3, 900)[0]) / (2 * DELTA)
    relative.append(abs(central / formula - 1))
    say(f"eps = {e:+.2f}: formula {formula:9.5f}, central difference {central:9.5f}")
```

At seven energies the slope formula $\int r^2 dy/r(0)^2$ is compared with the central difference $(\Phi(\varepsilon+\delta) - \Phi(\varepsilon-\delta))/(2\delta)$ of Section 2.18 with $\delta = 10^{-4}$; the relative differences are collected. The printout shows, for example, 3.85717 at $\varepsilon = -4$, 12.49831 at -1.34 and 0.49876 at 0.

```
report("largest relative difference formula - central difference",
       f"{max(relative):.1e}")
check(max(relative) < 1e-4 and np.all(slope_grid > 0),
      "dPhi/deps = (integral of r^2)/r(0)^2 > 0 (agrees with central differences)")
```

The largest relative difference is 3.7×10^{-6} (COMPUTED); the check requires less than 10^{-4}, and a positive slope at all 651 energies of the grid.

```
# At eps = 0 the shot is exactly a = e^(M(y + L)), b = 0, so the integral can be
# done by hand: (e^(2ML) - 1)/(2M) divided by r(0)^2 = e^(2ML).
at_zero = (1 - math.exp(-2 * M1 * L3)) / (2 * M1)
report("slope at eps = 0: formula, exact (1 - e^(-2ML))/(2M)",
       f"{shoot(0.0, M1, L3, 900)[1]:.6f}, {at_zero:.6f}")
check(abs(shoot(0.0, M1, L3, 900)[1] - at_zero) < 1e-4,
      "at eps = 0 the slope is (1 - e^(-2ML))/(2M), about 1/(2M)")
```

The slope at $\varepsilon = 0$ computed by hand in Section 2.24, $(1 - e^{-6})/2 = 0.498761$, against the program's 0.498762 (the difference is the error of the trapezoid rule).

```
grid_difference = (Phi_grid[2:] - Phi_grid[:-2]) / (eps_grid[2:] - eps_grid[:-2])
fig, ax = plt.subplots()
ax.plot(eps_grid, slope_grid, color=BLACK, lw=1.4,
        label="formula $\\int r^2 dy / r(0)^2$")
ax.plot(eps_grid[1:-1][::6], grid_difference[::6], "o", color=AQUA, ms=4,
        label="central differences of the staircase")
ax.axhline(L3, color=GREY, ls="--", lw=1.0, label="$L = 3$")
```

`grid_difference` is the central difference of the staircase on the grid itself (the value one place ahead minus the value one place back, divided by the energy distance 0.04 between them: entry i of `grid_difference` is $(\Phi_{i+2} - \Phi_i)/(\varepsilon_{i+2} - \varepsilon_i)$, centred on the grid point $i + 1$), belonging to the inner energies `eps_grid[1:-1]`; every sixth one is drawn (`[::6]`) as an aqua dot over the black formula curve, with a dashed line at $L = 3$.

```
ax.set_ylim(0.0, 17.5)  # room for the legend above the two peaks
ax.set_xlabel("energy $\\varepsilon$ (units $m$)")
ax.set_ylabel("$d\\Phi/d\\varepsilon$ (units $1/m$)")
ax.set_title("The slope of the staircase is never negative")
ax.legend(loc="upper right", fontsize=8)
save_figure(fig, "staircase_slope",
            "The slope $d\\Phi/d\\varepsilon$ of the end angle (vertical axis, "
            ...)
```

Labels and the saved figure `02d_2_staircase_slope.png`. **What Figure 02d.2 shows:** the dots lie on the formula curve; the slope is positive everywhere; it is about $L = 3$ far from the mass, about $1/(2M) = 0.5$ near $\varepsilon = 0$ (the zero-mode shot grows towards the brane, so $r(0)^2$ is large), and it has two peaks near $|\varepsilon| = 1.34$ (there the shot ends with a small $r(0)$ compared with its size inside, so a small change of energy turns the end angle a lot).

In [6], the angle along the interval.

```
chosen = [("even", 0), ("odd", 0), ("even", 1), ("odd", 1), ("even", 3)]
level_of = {(r["parity"], int(r["label"])): float(r["eps_numeric"]) for r in canonical}
fig, ax = plt.subplots()
```

Five levels of the canonical case, named by parity and label; `level_of` maps each (parity, label) of the canonical rows to the record's numerical level.

```
for (parity, label), color in zip(chosen, [BLACK, ORANGE, BLUE, VIOLET, AQUA]):
    eps = level_of[(parity, label)]
    y_path, a_path, b_path, theta_path = shoot(eps, M1, L3, 900, keep=True)[3]
    ax.plot(y_path, theta_path / math.pi, color=color, lw=1.5,
            ls="-" if parity == "even" else "--",
            label=f"{parity} $l = {label}$, $\\varepsilon = {eps:.4f}$")
    ax.plot([0.0], [target(parity, label) / math.pi], "o", color=color, ms=6)
```

For each chosen level the shot is repeated with `keep=True`; element 3 of the result is the path, unpacked into its four rows. θ/π is drawn against y (solid for even, dashed for odd), and a dot marks the target at the brane.

```
ax.set_xlabel("hidden coordinate $y$ (units $1/H$): tip at $-3$, brane at $0$")
ax.set_ylabel("Pruefer angle $\\theta(y)/\\pi$")
ax.set_title("The angle winds up to its target at the brane")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "angle_along_y",
            "The Pruefer angle $\\theta(y)$ in units of $\\pi$ (vertical axis) "
            ...)
```

Labels and the saved figure `02d_3_angle_along_y.png`. **What Figure 02d.3 shows:** every curve starts at 0 at the tip and ends exactly on its dot; the zero mode stays at 0; the number of half-turns made is the label; higher levels wind faster, at the average rate ε.

In [7], the exact levels, computed again.

```
mpmath.mp.dps = 30

def odd_root(M, L, n):
    """The n-th positive root p of M sin(pL) + p cos(pL) = 0 (30 digits)."""
    g = lambda p: M * mpmath.sin(p * L) + p * mpmath.cos(p * L)  # noqa: E731
    return mpmath.findroot(g, ((n + 0.5) * mpmath.pi / L, (n + 1) * mpmath.pi / L),
                           solver="anderson")
```

mpmath at 30 digits. The odd condition $\tan(pL) = -p/M$ multiplied by $M\cos(pL)$ is $M\sin(pL) + p\cos(pL) = 0$ (no infinities). The n-th root lies between $(n + \frac{1}{2})\pi/L$ and $(n+1)\pi/L$ (Section 2.24), and `findroot` refines it in that bracket. (The comment `noqa: E731` tells a style checker that the one-line `lambda` function is intended.)

```
def exact_level(M, L, parity, label):
    """The exact level of the given parity and label."""
```

```
    if parity == "even":
        if label == 0:
            return 0.0  # the zero mode
        return math.copysign(float(mpmath.sqrt(M ** 2 + (label * mpmath.pi / L) ** 2)),
                             label)
    n = label if label >= 0 else -label - 1
    value = float(mpmath.sqrt(M ** 2 + odd_root(M, L, n) ** 2))
    return value if label >= 0 else -value
```

The exact level for a parity and a label, as the record defines them: even label 0 is the zero mode; even label $l \neq 0$ is $\pm\sqrt{M^2 + (l\pi/L)^2}$ with the sign of l (`math.copysign(x, s)` is $|x|$ with the sign of s); the odd label $l \geq 0$ uses the root p_l and gives $+\sqrt{M^2 + p_l^2}$, the odd label $l \leq -1$ uses the root p_{-l-1} and gives the negative level.

```
analytic_ours = [exact_level(float(r["m"]), float(r["L"]), r["parity"],
                             int(r["label"])) for r in ROWS]
analytic_record = [float(r["eps_analytic"]) for r in ROWS]
worst_analytic = max(abs(a - b) for a, b in zip(analytic_ours, analytic_record))
report("largest |exact level (here) - eps_analytic (record)|", f"{worst_analytic:.1e}")
check(worst_analytic < 1e-14, "all 54 exact levels equal the column eps_analytic",
      record=f"{TABLE}, column eps_analytic")
```

All 54 exact levels are computed here and compared with the record's column `eps_analytic`: the largest difference is 1.8×10^{-15}, the size of the last printed digit (COMPUTED: reproduces `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv`, column `eps_analytic`).

```
p_axis = np.linspace(0.01, 3.3, 3000)
tangent = np.tan(p_axis * L3)
tangent[np.abs(tangent) > 8] = np.nan  # do not draw the jumps at the poles
fig, ax = plt.subplots()
ax.plot(p_axis, tangent, color=BLUE, lw=1.4, label="$\\tan(pL)$, $L = 3$")
ax.plot(p_axis, -p_axis / M1, color=ORANGE, lw=1.4, ls="--", label="$-p/M$, $M = 1$")
```

The graphical solution of the odd condition for $M = 1$, $L = 3$: the branches of $\tan(pL)$ (with the jumps removed as in Notebook 02b) and the falling line $-p/M$.

```
for n in range(3):
    p_n = float(odd_root(M1, L3, n))
    ax.plot([p_n], [-p_n], "o", color=BLACK, ms=6)
    ax.annotate(f"$p_{n} = {p_n:.4f}$", (p_n, -p_n), textcoords="offset points",
                xytext=(6, -14), fontsize=8)
ax.axhline(0.0, color=BLACK, lw=0.6)
ax.set_ylim(-6.0, 6.0)
ax.set_xlabel("$p$ (units $m$)")
ax.set_ylabel("value of each side")
ax.set_title("Odd levels: $\\tan(pL) = -p/M$, then $\\varepsilon = \\sqrt{M^2 + p^2}$")
ax.legend(loc="upper right", fontsize=8)
save_figure(fig, "odd_level_equation",
            "The equation of the odd levels for $M = 1$ and $L = 3$: the branches "
            ...)
```

The first three roots are marked and labelled on the line; labels and the saved figure `02d_4_odd_level_equation.png`. **What Figure 02d.4 shows:** one crossing on every branch of the tangent, each a root p_n; the first three give the odd levels 1.2923, 2.0106 and 2.9119.

In [8], Newton's method with a safety net.

```
def find_level(M, L, G, goal, tolerance=ROOT_TOLERANCE, log=None):
    """The energy with Phi(eps) = goal, found as the Rust program finds it.  If log
    is a list, every energy that is shot is appended to it."""
    def mismatch(eps):
        Phi, slope, largest = shoot(eps, M, L, G)
        if largest >= 2.0:  # the program refuses such a shot
            raise ValueError(f"one step turns the angle by {largest:.2f}")
        if log is not None:
            log.append(eps)
        return Phi - goal, slope  # F(eps) and F'(eps)
```

`find_level` is the program's function of the same name, line for line (Section 2.24). The inner function `mismatch` shoots one energy, refuses a shot in which one step turns by 2 or more, records the energy if a list was given, and returns $F = \Phi - t$ and $F' = d\Phi/d\varepsilon$.

```
    e_c = 0.0  # step 1: the starting guess
    F_c, dF_c = mismatch(e_c)
    if F_c == 0.0:
        return e_c
```

Step 1: shoot at $\varepsilon = 0$; for the zero mode ($t = 0$) the mismatch is exactly 0 and the search ends at once with the energy exactly 0.

```
    if F_c < 0.0:  # step 2, upwards: the level lies above
        low = e_c
        step = min(max(1.2 * (-F_c / dF_c), 1e-4), 2.0)
        while True:
            e = low + step
            F, dF = mismatch(e)
            if F >= 0.0:  # the sign changed: the bracket is (low, e)
                high = e
                if abs(F) < abs(F_c):  # keep the better of the two guesses
                    e_c, F_c, dF_c = e, F, dF
                break
            low, e_c, F_c, dF_c = e, e, F, dF  # still below: move on
            step *= 2.0
```

Step 2 when $F(0) < 0$ (the level lies above, because Φ increases): the first step is 1.2 times Newton's estimate $-F/F'$, limited to between 10^{-4} and 2 (`max` then `min`). The `while True` loop repeats until `break`: it shoots one step further up; if the sign has changed the bracket is (`low`, `e`), and the better of the two end guesses becomes the current guess; otherwise the new point becomes the lower end and the current guess, and the step is doubled.

```
    else:  # step 2, downwards: the level lies below
        high = e_c
        step = min(max(1.2 * (F_c / dF_c), 1e-4), 2.0)
        while True:
            e = high - step
            F, dF = mismatch(e)
            if F <= 0.0:  # the sign changed: the bracket is (e, high)
                low = e
                if abs(F) < abs(F_c):
                    e_c, F_c, dF_c = e, F, dF
                break
            high, e_c, F_c, dF_c = e, e, F, dF
            step *= 2.0
    if F_c == 0.0:
        return e_c
```

The same walk downwards when $F(0) > 0$. If the walk happens to land exactly on the level, the search ends. (The Rust function can also be given a known lower bound for the downward bracket, and it gives up after 400 shots without a bracket; neither is needed in this notebook.)

```
    previous = math.inf  # |F| at the previous step
    for _ in range(300):  # step 3
        if high - low <= tolerance:  # step 4: the bracket is narrow enough
            break
        e_new = e_c - F_c / dF_c  # Newton's point
        bisect = not (low < e_new < high) or abs(F_c) > 0.5 * previous
        if bisect:
            e_new = 0.5 * (low + high)  # the safety net
        previous = abs(F_c)
```

Step 3, at most 300 times: stop if the bracket is narrower than the tolerance (step 4). Otherwise compute Newton's point; if it is not strictly inside the bracket, or if $|F|$ has not at least halved since the previous pass (`math.inf`, infinity, makes the first pass always pass this test), take the midpoint of the bracket instead. `previous` remembers $|F|$ for the next pass.

```
        F, dF = mismatch(e_new)
        moved = abs(e_new - e_c)
        e_c, F_c, dF_c = e_new, F, dF
        if F == 0.0:
            break
        if F < 0.0:  # keep the half of the bracket with the sign change
            low = e_new
        else:
            high = e_new
        if moved <= tolerance and not bisect:  # step 4: a tiny Newton step
            break
    return e_c
```

Shoot the new point; it becomes the current guess. An exact zero ends the search; otherwise the new point replaces the end of the bracket with the same sign of F. A Newton step shorter than the tolerance also ends the search (step 4). The function returns the current guess.

```
def find_level_by_bisection(M, L, G, goal, tolerance=ROOT_TOLERANCE, log=None):
    """The same level by plain bisection on the bracket (-12, 12)."""
    low, high = -12.0, 12.0
    while high - low > tolerance:
        middle = 0.5 * (low + high)
        if log is not None:
            log.append(middle)
        if shoot(middle, M, L, G)[0] < goal:
            low = middle
        else:
            high = middle
    return 0.5 * (low + high)
```

For comparison, plain bisection on the bracket $(-12, 12)$: because Φ increases, $\Phi(m) <$ target means that the level lies above the midpoint m.

```
newton_log, bisection_log = [], []
by_newton = find_level(M1, L3, 900, target("even", 3), log=newton_log)
by_bisection = find_level_by_bisection(M1, L3, 900, target("even", 3),
                                       log=bisection_log)
report("even label 3 by Newton", f"{by_newton:.15f} ({len(newton_log)} shots)")
report("even label 3 by bisection",
       f"{by_bisection:.15f} ({len(bisection_log)} shots)")
for k, e in enumerate(newton_log, 1):
    say(f"Newton shot {k}: eps = {e:.15f}, error {abs(e - by_newton):.1e}")
```

Both search the even level with label 3 (target 3π) of the case $M = 1$, $L = 3$, recording every energy they shoot. Newton finds 3.296908309775607 with 9 shots, bisection 3.296908309775617 with 48 shots (COMPUTED). The nine Newton shots are printed: 0 (step 1), 2 and 6 (the bracket walk: the first step is limited to 2, the doubled step 4 reaches 6, where F has changed sign), then 3.1476, 3.2796, 3.29660, 3.2969082, ... with the errors 1.5×10^{-1}, 1.7×10^{-2}, 3.1×10^{-4}, 1.0×10^{-7}, 1.3×10^{-14}, 0: from the fourth shot on, each error is roughly the square of the previous one times a constant, so the number of correct digits about doubles.

```
fig, ax = plt.subplots()
ax.semilogy(range(1, len(bisection_log) + 1),
            np.maximum(np.abs(np.array(bisection_log) - by_newton), 1e-17), "s-",
            color=ORANGE, ms=4, lw=1.2, label="bisection on $(-12, 12)$")
ax.semilogy(range(1, len(newton_log) + 1),
            np.maximum(np.abs(np.array(newton_log) - by_newton), 1e-17), "o-",
            color=BLUE, ms=5, lw=1.2, label="the program's Newton with safety net")
ax.set_ylim(1e-17, 30.0)
ax.set_xlabel("number of the shot")
ax.set_ylabel("$|\\varepsilon - \\varepsilon_3|$ (units $m$)")
ax.set_title("Finding the even level $l = 3$ ($M = 1$, $L = 3$)")
ax.legend(loc="upper right", fontsize=8)
save_figure(fig, "newton_vs_bisection",
            "The distance $|\\varepsilon - \\varepsilon_3|$ (units of $m$, "
            ...)
```

The distance of every shot energy from the level, on a logarithmic axis (exact zeros drawn at 10^{-17}), for both methods; the saved figure is `02d_5_newton_vs_bisection.png`. **What Figure 02d.5**

shows: the bisection squares fall along a straight line (a factor 2 per shot) and need 48 shots; the Newton circles first jump around while the bracket is made, then plunge, and stop after 9 shots.

```
check(abs(by_newton - level_of[("even", 3)]) < 1e-12
      and abs(by_bisection - by_newton) < 1e-13
      and len(newton_log) < 15 < 45 < len(bisection_log),
      "Newton (fewer than 15 shots) gives the record's level; bisection agrees",
      record=f"{TABLE}, column eps_numeric")
```

The Newton result equals the record's level within 10^{-12}, bisection agrees within 10^{-13}, and the numbers of shots are fewer than 15 and more than 45 (COMPUTED: reproduces `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv`, column `eps_numeric`, for this level).

In [9], all 54 levels against the Rust program.

```
def rust_text(x):
    """x written as the Rust program writes numbers: 16 digits, exponent like e0."""
    mantissa, exponent = f"{x:.15e}".split("e")  # Python writes e+00, Rust e0
    return f"{mantissa}e{int(exponent)}"
```

`f"{x:.15e}"` writes x with 16 significant digits in scientific notation, for example `3.296908309775607e+00`; the program writes the exponent as `e0`. The function splits the text at the `e` and writes the exponent back as a whole number, which turns `+00` into `0` and `-10` into `-10`.

```
CASES = [(1.0, 3.0), (1.0, 2.0), (2.0, 3.0)]  # the three cases (M, L) of the table
numeric_ours, shots_per_level = [], []
for r in ROWS:
    M, L = float(r["m"]), float(r["L"])
    G = round(G_CANONICAL * L / 3.0)  # 900 steps for L = 3, 600 for L = 2
    log = []
    numeric_ours.append(find_level(M, L, G, target(r["parity"], int(r["label"])),
                                   log=log))
    shots_per_level.append(len(log))
```

`CASES` names the three cases of the table (a reminder; the loop takes M and L from each row). For every row the level is found with the program's number of steps, $G = 900L/3$, which keeps the step $h = 1/300$, and the number of shots is recorded.

```
numeric_record = [float(r["eps_numeric"]) for r in ROWS]
identical = sum(rust_text(x) == r["eps_numeric"] for x, r in zip(numeric_ours, ROWS))
worst_numeric = max(abs(a - b) for a, b in zip(numeric_ours, numeric_record))
report("levels whose 16 digits equal the column eps_numeric", f"{identical} of 54")
report("largest |level (here) - eps_numeric (Rust program)|", f"{worst_numeric:.1e}")
report("shots per level (fewest, most, all 54 together)",
       f"{min(shots_per_level)}, {max(shots_per_level)}, {sum(shots_per_level)}")
```

`identical` counts the levels whose text, written as the program writes it, equals the record's text (`sum` of `True`/`False` values counts the `True` ones): 54 of 54 on the computer that made the record. The largest numerical difference is 8.9×10^{-16}, and the searches needed between 1 and 15 shots, 510 in all (COMPUTED).

```
check(worst_numeric < 1e-12 and max(shots_per_level) <= 20,
      "all 54 shooting levels equal the column eps_numeric (at most 20 shots each)",
      record=f"{TABLE}, column eps_numeric")
zero_rows = [i for i, r in enumerate(ROWS) if r["parity"] == "even"
             and int(r["label"]) == 0]
check(all(numeric_ours[i] == 0.0 == numeric_record[i] for i in zero_rows),
      "the zero mode has the energy exactly 0 in all three cases",
      record=f"{SOLVER_REPORT}, check free_zero_mode_exact")
```

The first check allows 10^{-12} rather than requiring identical digits, because on another computer the system's `atan2` may round differently in the last binary place (COMPUTED: reproduces `Revision /kohn_sham/results/spectrum/free-k0-analytic.csv`, column `eps_numeric`). The second finds the three zero-mode rows and requires the energy exactly 0 both here and in the record (the chained comparison `a == 0.0 == b` means `a == 0.0` and `0.0 == b`; COMPUTED: reproduces `Revision /kohn_sham/reports/ks-rust-solver.json`, check `free_zero_mode_exact`).

```
differences_ours = [n - a for n, a in zip(numeric_ours, analytic_ours)]
pairs = list(zip(differences_ours, analytic_ours))
low_band = max(abs(d) for d, a in pairs if abs(a) < 4)  # all levels below 4 m
high_band = max(abs(d) for d, a in pairs if abs(a) >= 4)  # all levels from 4 m on
below_7 = max(abs(d) for d, a in pairs if 4 <= abs(a) < 7)
top = max(abs(a) for _, a in pairs)  # the highest level of the table
```

The numerical minus the exact level for every row, and the largest difference in three bands of $|\varepsilon|$: below $4m$, from $4m$ on, and from $4m$ to below $7m$; `top` is the highest level of the table.

```
solver_report = json.loads(repository_file(SOLVER_REPORT).read_text(encoding="utf-8"))
detail = [c["detail"] for c in solver_report["checks"]
          if c["name"] == "free_k0_analytic_spectra"][0]
quoted = float(re.findall(r"max \|difference\| ([0-9.]+e-[0-9]+) for \|eps\| < 4 m",
                          detail)[0])
quoted_high = float(re.findall(r"([0-9.]+e-[0-9]+) for 4 m <= \|eps\| < 7 m",
                               detail)[0])
```

The cell reads the text of the program's check `free_k0_analytic_spectra` and finds in it the two numbers it quotes. `re.findall(pattern, text)` returns every piece of the text that matches the pattern; in the pattern, `[0-9.]+` is one or more digits or points, `e-[0-9]+` an exponent, `\|` a literal vertical bar, and the round brackets mark the part to return. The two numbers are 7.23×10^{-10} (levels below $4m$) and 5.05×10^{-8} (the second band).

```
report("largest |numeric - exact| for |eps| < 4 m (here, record)",
       f"{low_band:.2e}, {quoted:.2e}")
report("largest |numeric - exact| for |eps| >= 4 m (here, record)",
       f"{high_band:.2e}, {quoted_high:.2e}")
say(f"Note: the record's check text names its second band 4 m <= |eps| < 7 m, but "
    f"the solver puts every level with |eps| >= 4 m into it, and the table's "
    f"levels reach {top:.4f} m; the quoted number belongs to that level. For "
    f"4 m <= |eps| < 7 m alone the largest difference is {below_7:.2e}.")
check(abs(low_band / quoted - 1) < 0.005 and abs(high_band / quoted_high - 1) < 0.005,
      "the two largest differences quoted by the solver check are reproduced",
      record=f"{SOLVER_REPORT}, check free_k0_analytic_spectra")
```

Both quoted numbers are reproduced: 7.23×10^{-10} and 5.05×10^{-8} (COMPUTED: reproduces `Revision/kohn_sham/reports/ks-rust-solver.json`, check `free_k0_analytic_spectra`). The printed note records a wording error in that record: its text calls the second band "$4m \le |\varepsilon| < 7m$", but the Rust code (file `Revision/kohn_sham/solver/src/spectrum.rs`) puts every level with $|\varepsilon| \ge 4m$ into it, and the table reaches $8.7539m$; the quoted 5.05×10^{-8} belongs to that highest level, while for $4m \le |\varepsilon| < 7m$ alone the largest difference is 9.95×10^{-9}. The check's verdict is unaffected, because its tolerance 3×10^{-7} covers both numbers.

In [10], the orbitals.

```
def orbital(eps, M, L, G):
    """The normalised orbital on the fine grid of 2G + 1 points, made as the Rust
    program makes it.  Returns the arrays y, a, b."""
    h = L / G
    nf = 2 * G + 1  # nodes and step midpoints
    y = -L * ((nf - 1 - np.arange(nf)) / (nf - 1))  # the fine grid, as in the program
    _, a_nodes, b_nodes, _ = shoot(eps, M, L, G, keep=True)[3]
```

The program's function `profile` rewritten. The fine grid has $2G + 1$ points (the nodes and the step midpoints); its positions are computed exactly as the program computes them, $y_f = -L\,(n_f - 1 - f)/(n_f - 1)$, which runs from $-L$ to 0 (the same formula, so that the rounding is the same). The shot with `keep=True` gives a and b at the $G + 1$ nodes.

```
    da = M * a_nodes - eps * b_nodes  # the slopes a' at the nodes (the equations)
    db = eps * a_nodes - M * b_nodes  # the slopes b'
    a, b = np.zeros(nf), np.zeros(nf)
    a[0::2], b[0::2] = a_nodes, b_nodes  # the nodes take the even places
    a[1::2] = 0.5 * (a_nodes[:-1] + a_nodes[1:]) + h / 8.0 * (da[:-1] - da[1:])
    b[1::2] = 0.5 * (b_nodes[:-1] + b_nodes[1:]) + h / 8.0 * (db[:-1] - db[1:])
```

The slopes at the nodes come from the equations themselves. The node values fill the even places of the fine grid (`0::2`: every second place from 0), and the odd places (`1::2`) get the cubic Hermite midpoint values $(f_0 + f_1)/2 + h(f'_0 - f'_1)/8$ of Section 2.24, for all steps at once.

```
    half = 0.5 * h  # the spacing of the fine grid
    weights = np.full(nf, 2.0 * half / 3.0)  # Simpson: 2 at the even inner places
    weights[1::2] = 4.0 * half / 3.0  # 4 at the odd places (the midpoints)
    weights[0] = weights[-1] = half / 3.0  # 1 at the two ends
    scale = 1.0 / math.sqrt(np.sum(weights * (a * a + b * b)))
    return y, a * scale, b * scale
```

Simpson's weights for the spacing $h/2$: $\frac{h/2}{3}$ times 1 at the ends, 4 at the odd places and 2 at the inner even places (`np.full` makes an array filled with one value). The norm $\int (a^2 + b^2) dy$ is the weighted sum, and the orbital is divided by its square root, so that $\int (a^2 + b^2) dy = 1$.

```
fig, axes = plt.subplots(2, 2, figsize=(9.0, 6.4), sharex=True)
residuals = []
for ax, (parity, label) in zip(axes.flat, [("even", 0), ("odd", 0), ("even", 1),
```

```
                                        ("odd", 2)]):
    eps = level_of[(parity, label)]
    y_fine, a_fine, b_fine = orbital(eps, M1, L3, 900)
    end = b_fine[-1] if parity == "even" else a_fine[-1]  # must vanish at y = 0
    residuals.append(abs(end))
```

A figure with 2×2 panels sharing the horizontal axis; `axes.flat` walks through the four panels. For four levels the orbital is built and the component that the brane condition must make zero ($b(0)$ for even, $a(0)$ for odd) is recorded.

```
    ax.plot(y_fine, a_fine, color=BLUE, lw=1.5, label="$a(y)$")
    ax.plot(y_fine, b_fine, color=ORANGE, lw=1.5, ls="--", label="$b(y)$")
    ax.axhline(0.0, color=BLACK, lw=0.6)
    ax.set_title(f"{parity}, $l = {label}$, $\\varepsilon = {eps:.4f}$", fontsize=10)
    ax.legend(fontsize=8, loc="upper left")
```

Each panel draws $a(y)$ (solid blue) and $b(y)$ (dashed orange) with the zero line and a title naming the level.

```
    if parity == "even" and label == 0:  # the zero mode against its exact form
        exact_a = math.sqrt(2 * M1 / (1 - math.exp(-2 * M1 * L3))) * np.exp(M1 * y_fine)
        zero_mode_distance = np.max(np.abs(a_fine - exact_a))
        zero_mode_b = np.max(np.abs(b_fine))
```

For the zero mode the exact normalised form is $a = \sqrt{2M/(1-e^{-2ML})}\, e^{My}$, $b = 0$ (the factor makes $\int_{-L}^{0} a^2 dy = 1$, because $\int_{-L}^{0} e^{2My} dy = (1-e^{-2ML})/(2M)$). The cell records the largest distance of the computed a from it and the largest $|b|$.

```
for ax in axes[1]:
    ax.set_xlabel("hidden coordinate $y$ (units $1/H$)")
for ax in axes[:, 0]:
    ax.set_ylabel("component (units $H^{1/2}$)")
save_figure(fig, "orbitals",
            "The normalised orbitals of four levels of the case $M = 1$, $L = 3$: "
            ...)
```

Axis labels on the bottom row (`axes[1]`) and the left column (`axes[:, 0]`); the components carry the unit $H^{1/2}$ because $\int (a^2 + b^2) dy = 1$ with y in units of $1/H$. The saved figure is `02d_6_orbitals.png`. **What Figure 02d.6 shows:** the zero mode ($a \propto e^{y}$, $b = 0$) is concentrated at the brane; every orbital has $b = 0$ at the tip $y = -3$; at the brane the even orbitals have $b = 0$ and the odd ones $a = 0$; higher levels oscillate more.

```
report("largest brane residual |b(0)| or |a(0)|", f"{max(residuals):.1e}")
zero_detail = [c["detail"] for c in solver_report["checks"]
               if c["name"] == "free_zero_mode_exact"][0]
zero_quoted = float(re.findall(r"e\^\(My\) to ([0-9.]+e-[0-9]+)", zero_detail)[0])
report("zero mode: largest distance from the exact normalised form (here, record)",
       f"{zero_mode_distance:.2e}, {zero_quoted:.2e}")
```

The largest brane residual is 8.6×10^{-16}. The text of the program's check `free_zero_mode_exact` quotes the distance of the computed zero mode from its exact form after the words `e^(My) to`; in the pattern, `\^`, `\(` and `\)` stand for the literal characters. Both distances are 1.35×10^{-12} (COMPUTED).

```
check(max(residuals) < 1e-10, "every orbital meets its brane condition within 1e-10")
check(zero_mode_b == 0.0 and abs(zero_mode_distance / zero_quoted - 1) < 0.01,
      "the zero mode: b = 0 exactly, distance 1.35e-12 from sqrt(2M/(1 - e^(-2ML))) "
      "e^(My)", record=f"{SOLVER_REPORT}, check free_zero_mode_exact")
```

Two checks: the brane conditions hold within 10^{-10}; the zero mode has b exactly 0 and reproduces the quoted distance within 1 per cent (COMPUTED: reproduces `Revision/kohn_sham/reports/ks-rust-solver.json`, check `free_zero_mode_exact`).

In [11], how the error depends on the step.

```
G_LIST = [25, 50, 100, 200, 400, 800]
tracked = [("even", 1), ("odd", 2), ("even", 5)]
fig, ax = plt.subplots()
orders = []
```

Six step counts and three levels to follow.

```
for (parity, label), color, marker in zip(tracked, [BLUE, ORANGE, AQUA],
                                          ["o", "s", "^"]):
    exact = exact_level(M1, L3, parity, label)
    errors = np.array([abs(find_level(M1, L3, G, target(parity, label)) - exact)
                       for G in G_LIST])
    h_list = L3 / np.array(G_LIST, dtype=float)
    fit = errors > 1e-11  # leave out points limited by the root tolerance
    orders.append(np.polyfit(np.log10(h_list[fit]), np.log10(errors[fit]), 1)[0])
    ax.loglog(h_list, errors, marker=marker, color=color, ms=5, lw=1.2,
              label=f"{parity} $l = {label}$ ($\\varepsilon = {exact:.4f}$)")
```

For each level the search is repeated with every step count and the error against the exact level is stored; a straight line is fitted through the errors above 10^{-11} (below that the root tolerance and rounding interfere), and its slope (element 0 of `polyfit`'s result) is the measured order. The errors are drawn on a log-log plot.

```
h_guide = L3 / np.array(G_LIST, dtype=float)
ax.loglog(h_guide, 2e-3 * (h_guide / h_guide[0]) ** 4, "--", color=GREY,
          label="slope 4")
ax.axvline(L3 / 900, color=BLACK, ls=":", lw=1.0)
ax.text(L3 / 900 * 1.08, 1e-4, "the record's\nstep 1/300", fontsize=8)
```

A guide of slope 4, and a dotted vertical line at the record's step $h = 3/900 = 1/300$ with a two-line label (`\n` starts a new line).

```
ax.set_xlabel("RK4 step $h = L/G$ (units $1/H$)")
ax.set_ylabel("error of the level (units $m$)")
ax.set_title("The levels converge like $h^4$")
ax.legend(loc="lower right", fontsize=8)
save_figure(fig, "level_convergence",
            "The error of three levels of the case $M = 1$, $L = 3$ found by "
            ...)
report("measured orders", ", ".join(f"{q:.2f}" for q in orders))
check(all(3.8 < q < 4.2 for q in orders), "the level errors fall like h^4")
```

Labels and the saved figure `02d_7_level_convergence.png`; the measured orders are 4.00, 3.99 and 3.97 (COMPUTED), and the check requires them between 3.8 and 4.2. **What Figure 02d.7 shows:** three parallel lines of slope 4; the higher the level, the larger its error at a given step; at the record's step 1/300 the errors are far below 10^{-6}.

In [12], why the error grows with the level.

```
w = sp.symbols("omega", positive=True)  # the angle turned in one step, eps h
R_rk4 = 1 + sp.I * w - w ** 2 / 2 - sp.I * w ** 3 / 6 + w ** 4 / 24  # R(i omega)
turned = sp.atan(sp.im(R_rk4) / sp.re(R_rk4))  # the angle of R(i omega)
lag = sp.series(turned - w, w, 0, 7).removeO()
say(f"angle of R(i omega) - omega = {lag} + ...")
check(sp.simplify(lag + w ** 5 / 120) == 0,
      "one RK4 step turns by omega - omega^5/120: the phase lags")
```

`R_rk4` is $R(i\omega)$ written out (Section 2.7). `sp.im` and `sp.re` take its imaginary and real parts, and the arctangent of their quotient is its angle (for small ω the real part is positive, so no turn is lost). `sp.series(..., w, 0, 7)` expands the angle minus ω up to ω^6; the printout is `-omega**5/120`, and the check confirms the phase lag $\omega^5/120$ derived in Section 2.24. The symbol is declared positive (`positive=True`), which keeps sympy's expansion simple; for a negative angle the same result follows, because $R(-i|\omega|)$ is the complex conjugate of $R(i|\omega|)$, so its angle is minus that of $R(i|\omega|)$, and $-(|\omega| - |\omega|^5/120) = \omega - \omega^5/120$ for $\omega = -|\omega|$.

```
nonzero = [i for i, a in enumerate(analytic_record) if a != 0.0]
eps_abs = np.array([abs(analytic_record[i]) for i in nonzero])
x_values = eps_abs / 300.0  # h |eps| with h = 1/300
record_diff = np.array([abs(float(ROWS[i]["difference"])) for i in nonzero])
our_diff = np.array([abs(differences_ours[i]) for i in nonzero])
masses = np.array([float(ROWS[i]["m"]) for i in nonzero])
```

The 51 rows with a nonzero level (all except the three zero modes): their sizes $|\varepsilon|$, the quantity $h|\varepsilon|$ with $h = 1/300$ (the same step for all three cases), the size (`abs`) of the record's column `difference` (numerical minus exact level), the sizes of our own differences from In [9], and the masses. The sizes are needed for the logarithmic axes; the signs are tested at the end of the cell.

```
fig, ax = plt.subplots()
for mass, color in ((1.0, BLUE), (2.0, ORANGE)):
    pick = masses == mass
    ax.loglog(x_values[pick], record_diff[pick] / eps_abs[pick], "o", color=color,
```

```
              ms=6, label=f"record, $M = {mass:.0f}$")
ax.loglog(x_values, our_diff / eps_abs, "x", color=BLACK, ms=5,
          label="this notebook")
x_guide = np.linspace(x_values.min(), x_values.max(), 50)
ax.loglog(x_guide, x_guide ** 4 / 120, "--", color=GREY,
          label="prediction $(h\\varepsilon)^4/120$")
```

The relative errors $\delta\varepsilon/|\varepsilon|$ of the record (dots, blue for $M = 1$ and orange for $M = 2$; `pick` selects the rows of one mass) and of this notebook (black crosses) against $h|\varepsilon|$ on log-log axes, with the prediction $(h\varepsilon)^4/120$ of Section 2.24 as a dashed line.

```
ax.set_xlabel("$h |\\varepsilon|$ with $h = 1/300$ (pure number)")
ax.set_ylabel("relative error $\\delta\\varepsilon / |\\varepsilon|$")
ax.set_title("The RK4 error of all 51 nonzero levels of the record")
ax.legend(loc="upper left", fontsize=8)
save_figure(fig, "record_differences",
            "The relative error $\\delta\\varepsilon/|\\varepsilon|$ of the "
            ...)
```

Labels and the saved figure `02d_8_record_differences.png`. **What Figure 02d.8 shows:** the crosses sit on the record's dots (our shooting reproduces the program's errors); all points lie below the dashed prediction, and the levels far from the mass approach it, while those near the mass (where the point does not turn uniformly) lie further below.

```
ratio = (record_diff / eps_abs) / (x_values ** 4 / 120)
report("error / prediction for the levels above 7 m",
       ", ".join(f"{q:.3f}" for q in ratio[eps_abs > 7]))
check(np.all(ratio < 1) and np.all(ratio[eps_abs > 7] > 0.9),
      "every level error lies below the prediction, within 10 % above 7 m")
```

The ratio of each measured relative error to the prediction; for the three levels above $7m$ it is 0.934, 0.953 and 0.955 (COMPUTED). The check requires every ratio below 1 and those above $7m$ above 0.9.

```
report("largest |difference (here) - difference (record)|",
       f"{np.max(np.abs(record_diff - our_diff)):.1e}")
check(np.max(np.abs(record_diff - our_diff)) < 1e-12,
      "our differences equal the record's column difference within 1e-12",
      record=f"{TABLE}, column difference")
```

Our differences equal the record's column `difference` to 1.8×10^{-15} (COMPUTED: reproduces `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv`, column `difference`).

```
signed = np.array([float(ROWS[i]["difference"]) for i in nonzero])  # with sign
levels = np.array([analytic_record[i] for i in nonzero])
report("computed too high (levels > 0), too low (levels < 0)",
       f"{np.sum((levels > 0) & (signed > 0))} of {np.sum(levels > 0)}, "
       f"{np.sum((levels < 0) & (signed < 0))} of {np.sum(levels < 0)}")
check(np.all(np.sign(signed) == np.sign(levels)),
      "every computed level lies farther from 0 than the exact one (sign of eps^5)",
      record=f"{TABLE}, columns difference and eps_analytic")
```

The last lines test the sign of the error, which Section 2.24 predicts: $\delta\varepsilon \approx \varepsilon^5 h^4/120$ has the sign of ε. `signed` holds the record's column `difference` with its sign, and `levels` the exact levels. `(levels > 0) & (signed > 0)` is `True` for a positive level computed too high (`&` means "and" for arrays), and `np.sum` counts the `True` entries. The RESULT line prints 33 of 33 and 18 of 18 (COMPUTED): every positive level comes out too high and every negative level too low. `np.sign` is $+1$, -1 or 0 for a positive, negative or zero number, and the check requires the sign of each difference to equal the sign of its level; that is, every computed level lies farther from 0 than the exact one (reproduces `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv`, columns `difference` and `eps_analytic`).

In [13], the last check.

```
names = ["pruefer_staircase", "staircase_slope", "angle_along_y",
         "odd_level_equation", "newton_vs_bisection", "orbitals",
         "level_convergence", "record_differences"]
present = [output_file(f"{FIGURE_FOLDER}/02d_{k}_{name}.png").is_file()
           for k, name in enumerate(names, 1)]
check(all(present), f"all {len(names)} figure files of notebook 02d exist")
all_checks_passed()
```

As in Notebook 02a: the eight figure files must exist, and the last line is ALL 19 CHECKS PASSED (notebook 02d). The 19 checks are: 1 in In [2], 1 in In [3], 2 in In [4], 2 in In [5], 1 in In [7], 1 in In [8], 3 in In [9], 2 in In [10], 1 in In [11], 4 in In [12] and 1 in In [13].

2.29 What we proved, what we computed, what we assumed

PROVED in this chapter (by elementary algebra and calculus, each derivation written out line by line). Each statement is also confirmed by a check of a notebook, directly or through the check of a computation that uses it, with two exceptions that the notebooks only illustrate: the conservation of the oscillator energy by the exact solution (the dashed circle of Figure 02a.6) and the estimates of the best spacing (Notebook 02c, In [6], measures the best spacings but does not check the estimates).

- along the history $a_4 = AHx_4$ the extra-time scale factor obeys $ds_5/dx_4 = -AH\, s_5$ (it deflates exponentially) and the 3-space factor $ds_1/dx_4 = +AH\, s_1$; their product is constant (Section 2.2); the oscillator conserves $E = (x^2 + v^2)/2$;
- one step of size 1/2 for $y' = -y$ gives 1/2, 5/8 and 233/384; the amplification factors of Euler, midpoint and RK4 are the first 2, 3 and 5 terms of the series of e^z (Sections 2.4 and 2.5);
- to leading order, the error of a method of order p for Problem A at $t = 1$ is $e^{-1}(-1)^p h^p/(p+1)!$; halving the step divides an error Ch^p by 2^p; Richardson's estimate $(Y_h - Y_{h/2})/(2^p - 1)$ (Section 2.6);
- the energy factors per step $1 + h^2$, $1 + h^4/4$, $1 - h^6/72 + h^8/576$ and the scale-factor product factors $1 - h^2$ (Euler) and $1 + h^6/72 + h^8/576$ (RK4) (Section 2.7);
- the string's eigenvalues $n^2\pi^2$; the secant formula; the even and odd conditions of the finite well, $\tan z = \sqrt{z_0^2 - z^2}/z$ and $-\cot z = \sqrt{z_0^2 - z^2}/z$, and its four bound states for $z_0 = \sqrt{30}$; the

tail integral $1/(2\kappa)$; the orthogonality of states of different parity; Simpson's weights (Sections 2.12 and 2.13);

- the partial derivatives of $x^2 \sin y$; the linear approximation; the gradient is perpendicular to the level curves and points uphill; the orders 1 and 2 of the forward and central differences and the scale of the best spacing (Section 2.18);

- $\partial_0 = 6H\, d/dz$; the rates a_4', $-a_4' + b_4'/(2b_4)$, $H \cot z$ and $-6H/(\sin z \cos z)$ of the scale factors; $\det g = b_4^3 \cos^2 z$ and $\sqrt{|\det g|} = b_4^{3/2} \sin z \cot z = b_4^{3/2} \cos z$, independent of x_4 for every $a_4(x_4)$ when b_4 is constant, because the inflation of 3-space and the deflation of the extra times cancel; Jacobi's formula for a diagonal metric; the 25 nonzero Christoffel entries, given their formula (Section 2.19);

- the exact levels of the free Kohn-Sham block (the zero mode, $\pm\sqrt{M^2 + (n\pi/L)^2}$, $\pm\sqrt{M^2 + p^2}$ with $\tan(pL) = -p/M$) and the absence of any other level with $|\varepsilon| \le M$; the Prüfer equation $\theta' = \varepsilon - M \sin 2\theta$; $d\Phi/d\varepsilon = \int r^2 dy / r(0)^2 > 0$, so every level is found exactly once with its own label; the slope $(1 - e^{-2ML})/(2M)$ at $\varepsilon = 0$; the cubic Hermite midpoint formula; the RK4 phase lag $\omega^5/120$ per step and the level error $\delta\varepsilon \approx \varepsilon^5 h^4/120$ far from the mass, which has the sign of ε, so that every computed level lies farther from zero than the exact one (Section 2.24).

COMPUTED by the notebooks (each number in the cell named; where a Revision record is reproduced, the record file and its key or check):

- Notebook 02a: measured orders 1.0014, 2.0025, 4.0439 (In [7]); halving ratios 2.00020, 4.00073, 16.1047 (In [9]); the smallest RK4 error 1.110×10^{-16} at $N = 4096$ and 5.773×10^{-15} at $N = 262144$, past the minimum 524 to 3709 times below the bound $N\epsilon e^{-1}$ (In [10]); the Revision solver's step $h = L/G = 3/900 = 1/300$ and the history constants $A = H = 1$ (In [11]; reproduces `Revision/kohn_sham/results/parameters.json`, keys `rk4Steps`, `L_tipCutoff`, `historyA` and `H`); the errors at that step, -6.1399×10^{-4}, $+6.8296 \times 10^{-7}$, $+3.7920 \times 10^{-13}$, within 0.3 per cent of the predictions (In [11]); the oscillator energies (In [12], In [13]); the radii 2.6658, 1.0100, 1.0000 and the angles -0.1302, $+0.06586$ and -1.314×10^{-4} rad by which Euler, midpoint and RK4 run ahead of the exact solution at $t = 10$, each equal to $50\,(\arg R(ih) - h)$ (In [12]); Richardson's estimate within 6 per cent from $N = 8$ on (In [14]).

- Notebook 02b: the RK4 eigenvalue of the string 9.869604411103, within 1.0×10^{-8} of π^2; 45 bisection steps against about 9 secant steps (In [5]); the four well levels -14.1206, -11.5181, -7.3330, -2.0437 (In [6]) and their shooting values within 10^{-7} (In [8]); nodes 0, 1, 2, 3 and orthonormality within 1.6×10^{-10}; for the four pairs of different parity the integral over $-3 \le x \le 3$ at most 9.5×10^{-17}, although each half integral is at least 0.16 in size (In [10]); orders 3.99, 3.98, 3.96, 3.92 (In [11]).

- Notebook 02c: the rise of f along the gradient, 1.898407 per unit length against $|\nabla f| = 1.898293$ (In [4]); the best finite-difference spacings 1.0×10^{-8}, 1.8×10^{-6}, 5.6×10^{-5} (In [6]); the metric (In [8]; reproduces `Revision/gkd_lovelock/results/curvature.json`, key `metricDiagonal`); the volume factor (In [11]; reproduces the same record's key `sqrtAbsDetG` and `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `sqrt_abs_det_g_is_cos_z`); all 25 Christoffel entries (In [12]; reproduces `Revision/gkd_lovelock/results/curvature.json`, key `christoffelNonzero_b_le_c`).

- Notebook 02d: all 54 levels of the free spectrum, identical in all 16 printed digits on the computer that made the record, largest difference 8.9×10^{-16} (In [9]; reproduces `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv`, column `eps_numeric`); the exact column to 1.8×10^{-15} (In [7]; column `eps_analytic`) and the column `difference` to 1.8×10^{-15} (In [12]); the zero mode exactly 0 and its distance 1.35×10^{-12} from the exact form (In [9], In [10]; reproduces `Revision/kohn_sham/reports/ks-rust-solver.json`, check `free_zero_mode_exact`); the quoted largest differences 7.23×10^{-10} and 5.05×10^{-8} (In [9]; reproduces the same report's check `free_k0_analytic_spectra`, whose text misnames its second band as "$4m \leq |\varepsilon| < 7m$" although it contains every level from $4m$ up to $8.7539m$; for the band below $7m$ alone the largest difference is 9.95×10^{-9}; the verdict is unaffected); Newton with 9 shots against bisection with 48 (In [8]); orders 4.00, 3.99, 3.97 (In [11]); errors 0.934 to 0.955 times the phase-lag prediction above $7m$, and the signs of all 51 nonzero differences: 33 of 33 positive levels too high, 18 of 18 negative levels too low (In [12]; reproduces the same table's columns `difference` and `eps_analytic`); the end angles at the edges of the mass gap, $|\Phi(\pm M)| \leq 0.2256\pi < \pi/2$ in all three cases, so no level but the zero mode lies in the gap (In [4]).

ASSUMED (used, not derived here):

- standard theorems of calculus and numerical analysis, quoted without proof: the existence and uniqueness of solutions of initial-value problems (Picard and Lindelöf); Taylor's theorem; the intermediate value theorem; Schwarz's theorem; the mean value theorem; the speed of the secant rule (digits multiplied by about 1.618) and of Newton's method (digits doubled); the h^4 error orders of Simpson's rule and of cubic Hermite interpolation;
- from quantum mechanics, used only as an example: the Schrödinger equation, the uniqueness (up to a factor) of a one-dimensional bound state, and the orthogonality of states of different energies;
- the formula of the Christoffel symbols (derived in Chapter 3) and the Kohn-Sham block equations (taken from `Revision/kohn_sham/ks-theory.json`; derived in Chapter 14);
- the linear history $a_4 = AHx_4$ with $A = 1$, a PRESCRIBED BACKGROUND, not a solution of the field equations with the Kohn-Sham source (`Revision/field_equations_a4/reports/ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`);
- the brane conditions $b(0) = 0$ or $a(0) = 0$, which rest on the mirror symmetry that the record labels ASSUMED; the tip condition $b(-L) = 0$ is a choice of the model ("chosen (regular tip)").

HYPOTHESIS and OPEN. No hypothesis enters this chapter, and it leaves no question open. It does not show where the Kohn-Sham equations come from or what their levels mean physically; that is the work of Chapters 14 and 15.

2.30 Exercises

Exercise 1. Make one Euler step and one midpoint step for $y' = -2y$ from $y(0) = 1$ with the step $h = 1/4$, with exact fractions. Compare with Section 2.4 and explain the agreement.

Answer. Euler: $y_1 = 1 + \frac{1}{4}\cdot(-2) = \frac{1}{2}$. Midpoint: $k_1 = -2$; the midpoint value is $1 + \frac{1}{8}\cdot(-2) = \frac{3}{4}$; $k_2 = -2\cdot\frac{3}{4} = -\frac{3}{2}$; $y_1 = 1 + \frac{1}{4}\cdot(-\frac{3}{2}) = 1 - \frac{3}{8} = \frac{5}{8}$. These are the same numbers as for $y' = -y$ with $h = 1/2$ in Section 2.4, because one step of each method multiplies y by $R(z)$, which depends only on $z = \lambda h$, and here $z = -2\cdot\frac{1}{4} = -\frac{1}{2}$ as there: $R_{\text{Euler}}(-\frac{1}{2}) = \frac{1}{2}$ and $R_{\text{midpoint}}(-\frac{1}{2}) = 1 - \frac{1}{2} + \frac{1}{8} = \frac{5}{8}$.

Exercise 2. A method gives the errors 2.0×10^{-4} with $h = 0.1$ and 1.25×10^{-5} with $h = 0.05$. What is its order, and what error do you expect with $h = 0.025$?

Answer. Halving the step divided the error by $2.0 \times 10^{-4}/1.25 \times 10^{-5} = 16 = 2^4$, so (Section 2.6) the order is $p = 4$. Halving again divides by 16 once more: about $1.25 \times 10^{-5}/16 = 7.8 \times 10^{-7}$. Equivalently, the slope on a log-log plot is $(\log_{10} 1.25{\times}10^{-5} - \log_{10} 2.0{\times}10^{-4})/(\log_{10} 0.05 - \log_{10} 0.1) = (-1.2041)/(-0.30103) = 4.0$.

Exercise 3. Two RK4 runs of Problem A up to $t = 1$ give $Y_h = 0.3678802720$ (8 steps) and $Y_{h/2} = 0.3678794905$ (16 steps). Without using e^{-1}, estimate the error of $Y_{h/2}$ and give the extrapolated value. Then compare with $e^{-1} = 0.3678794412$.

Answer. By Richardson's rule (Section 2.6) with $p = 4$, the error of $Y_{h/2}$ is about $(Y_h - Y_{h/2})/15 = 7.815 \times 10^{-7}/15 = 5.21 \times 10^{-8}$. The extrapolated value is $Y_{h/2} - 5.21 \times 10^{-8} = 0.3678794384$. The true error of $Y_{h/2}$ is $0.3678794905 - 0.3678794412 = 4.93 \times 10^{-8}$ (the estimate is 6 per cent too large), and the extrapolated value is off by only -2.8×10^{-9}, about 17 times better; these are the numbers of the row $N = 8 \to 16$ printed by Notebook 02a, In [14].

Exercise 4. Using the energy factor of the midpoint method (Section 2.7), compute the oscillator's energy after 50 steps of $h = 0.2$, starting from $E_0 = 1/2$.

Answer. Each step multiplies E by $1 + h^4/4 = 1 + 0.0016/4 = 1.0004$. After 50 steps $E = \frac{1}{2}\cdot 1.0004^{50}$. With $1.0004^{50} = e^{50\ln 1.0004} = e^{50\cdot 0.00039992} = e^{0.019996} = 1.020197$, we get $E = 0.5100986$, the value 0.5100986302 printed by Notebook 02a, In [12].

Exercise 5. How many bound states does a finite square well of half-width $a = 1$ have when its depth is $V_0 = 2$? And when $V_0 = 1$?

Answer. The number is the number of intervals of length $\pi/2$ that begin below $z_0 = a\sqrt{2V_0}$ (Section 2.13). For $V_0 = 2$: $z_0 = 2$ and $z_0/(\pi/2) = 1.27$, so two intervals begin below z_0 (at 0 and at $\pi/2 = 1.571$): two bound states, one even and one odd. For $V_0 = 1$: $z_0 = \sqrt{2} = 1.414 < \pi/2$: one bound state, the even ground state. (A symmetric well in one dimension always has at least one bound state, however shallow, because the first interval starts at 0.)

Exercise 6. Plain bisection starts from the bracket $(-12, 12)$ and stops when the bracket is narrower than 10^{-13}. How many shots does it need?

Answer. After k shots the width is $24/2^k$ (Section 2.12). We need $24/2^k \le 10^{-13}$, that is $2^k \ge 2.4 \times 10^{14}$, or $k \ge \log_2(2.4 \times 10^{14}) = \log_{10}(2.4 \times 10^{14})/\log_{10} 2 = 14.380/0.30103 = 47.8$. So $k = 48$ shots, the number printed by Notebook 02d, In [8].

Exercise 7. Show that the free block of Section 2.24 has no level with $\varepsilon = +M$ or $\varepsilon = -M$.

Answer. For $\varepsilon^2 = M^2$ the equation $a'' = (M^2 - \varepsilon^2)a$ becomes $a'' = 0$, so $a = \alpha + \beta y$ with constants α, β, and $b = (Ma - a')/\varepsilon$ vanishes where $Ma - a' = M(\alpha + \beta y) - \beta = 0$. Even orbitals need this at $y = 0$ and at $y = -L$: $M\alpha - \beta = 0$ and $M\alpha - M\beta L - \beta = 0$; subtracting the first from the second gives $-M\beta L = 0$, so $\beta = 0$ (because $M > 0$ and $L > 0$), and then $\alpha = \beta/M = 0$. Odd orbitals need $a(0) = \alpha = 0$ and the tip condition $M(-\beta L) - \beta = -\beta(ML + 1) = 0$, so $\beta = 0$. In both cases $a = 0$,

and then $b = 0$: no level.

Exercise 8. Check the cubic Hermite midpoint formula $(f_0 + f_1)/2 + h(f_0' - f_1')/8$ of Section 2.24 on $f(s) = s^2$ and $f(s) = s^3$ on the step $0 \le s \le h$.

Answer. For s^2: $f_0 = 0$, $f_1 = h^2$, $f_0' = 0$, $f_1' = 2h$; the formula gives $\frac{h^2}{2} + \frac{h}{8}(0 - 2h) = \frac{h^2}{2} - \frac{h^2}{4} = \frac{h^2}{4} = (h/2)^2$, the exact value at $s = h/2$. For s^3: $f_0 = 0$, $f_1 = h^3$, $f_0' = 0$, $f_1' = 3h^2$; the formula gives $\frac{h^3}{2} - \frac{3h^3}{8} = \frac{h^3}{8} = (h/2)^3$, exact again. (It is exact for every polynomial of degree at most 3, because then the cubic through the four data is the polynomial itself.)

Exercise 9. For $M = 0$ the Prüfer equation is $\theta' = \varepsilon$. Find the even and odd levels directly from it and compare with the formulas of Section 2.24 at $M = 0$.

Answer. With $\theta(-L) = 0$ and $\theta' = \varepsilon$ we get $\theta(y) = \varepsilon(y + L)$, so $\Phi = \varepsilon L$. Even: $\varepsilon L = l\pi$, $\varepsilon = l\pi/L$. Odd: $\varepsilon L = \pi/2 + l\pi$, $\varepsilon = (l + \frac{1}{2})\pi/L$. The general formulas give the same: $\pm\sqrt{0 + (n\pi/L)^2} = \pm n\pi/L$ for the even levels; and as $M \to 0$ the odd condition $\tan(pL) = -p/M$ demands an infinitely large tangent, $pL = (n + \frac{1}{2})\pi$, so $\pm p = \pm(n + \frac{1}{2})\pi/L$.

Exercise 10. Compute $\partial_0 g_{11}$ for $g_{11} = e^{2a_4}\sin^{1/3}(6Hx_0)$, and use it to confirm the Christoffel entry $\Gamma^1{}_{01} = H\cot z$ of Section 2.19.

Answer. With $z = 6Hx_0$: $\partial_0 \sin^{1/3} z = \frac{1}{3}\sin^{-2/3} z \cdot \cos z \cdot 6H = 2H\sin^{-2/3} z\cos z$ (the power rule, the derivative of the sine, and the chain rule with $\partial z/\partial x_0 = 6H$). So $\partial_0 g_{11} = 2He^{2a_4}\sin^{-2/3} z\cos z$. Then $\Gamma^1{}_{01} = \partial_0 g_{11}/(2g_{11}) = 2He^{2a_4}\sin^{-2/3} z\cos z/(2e^{2a_4}\sin^{1/3} z) = H\cos z/\sin z = H\cot z$ (the factors e^{2a_4} cancel and $\sin^{-2/3} z/\sin^{1/3} z = 1/\sin z$), the value listed in the record and in the table of Section 2.19.

3 Spacetime geometry and the author's metric; curvature

Gravity, in Einstein's theory, is not a force that acts inside space and time: it is the shape of space and time itself. This chapter builds, from nothing but school algebra and one-variable calculus, the language in which that shape is written down and measured: coordinates, the metric, its signature, scale factors and volumes, the Christoffel symbols, geodesics (the paths of free fall), and curvature in the form of the Riemann tensor, the Ricci tensor, the Ricci scalar, the Einstein tensor and the Kretschmann scalar. Every tool is tried first where we can picture it, on the flat plane and on a sphere, and then applied, completely and line by line, to the metric that the author wrote down for the primordial gravitational field. The chapter has four worked examples, Notebooks 03a, 03c, 03b and 03d (in the order in which the chapter uses them); each reproduces, number for number, the parts of the Revision record that it overlaps and says so in a PASS line.

3.1 What this chapter is for

Every later chapter of the book lives in the author's eight-dimensional spacetime. The spinor fields of Chapters 4 to 10 need its vielbein (the scale factors of Section 3.7); the energy-momentum tensor of Chapter 9 needs its Christoffel symbols (Section 3.23); the field equations of the metric functions a_4 and b_4 in Chapter 12 need its Einstein tensor (Section 3.25); the Kohn-Sham model of Chapters 14 to 17 (**Kohn-Sham**: an approximation of density functional theory that replaces many interacting particles by independent particles, each moving in one common effective potential;

Chapter 13 teaches it from zero) is written in the hidden coordinate y of Section 3.9. This chapter derives all of these from the metric itself, and it ends with what the metric does to a body that moves freely in it (Section 3.31).

The author's metric is the following diagonal 8×8 matrix, in the order of the author's coordinates $x_0, \dots, x_7$ (Section 3.5 reads it exactly as the author typed it):

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}\sin^{1/3} z,\ e^{2a_4}\sin^{1/3} z,\ e^{2a_4}\sin^{1/3} z,\ -1,\\ -b_4 e^{-2a_4}\sin^{1/3} z,\ -b_4 e^{-2a_4}\sin^{1/3} z,\ -b_4 e^{-2a_4}\sin^{1/3} z\big), \qquad z = 6Hx_0.$$

The coordinates have fixed roles. x_0 is the **hidden** space direction, with $z = 6Hx_0$ between 0 and $\pi/2$ and $g_{00} = \cot^2 z$. x_1, x_2, x_3 are ordinary **3-space**; it inflates, with the scale factor $e^{a_4}\sin^{1/6} z$. x_4 is **the time**. x_5, x_6, x_7 are three **extra times**: they are time-like like x_4, and they **deflate exponentially**, with the scale factor $b_4^{1/2} e^{-a_4}\sin^{1/6} z$, while a_4 grows. $H > 0$ is a constant of the author, and $a_4(x_4)$ and $b_4(x_4)$ are functions of the time only, the **metric functions**, with $b_4 > 0$; a prime means a derivative with respect to x_4, $a_4' = da_4/dx_4$ and $b_4' = db_4/dx_4$. The function b_4 is the author's change of 2026-10-14: with $b_4 = 1$ the metric is the one used before that date (the record of the change: `Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`). Every formula of this chapter is derived for general $a_4(x_4)$ and $b_4(x_4)$; the pictures and numbers along a history take $b_4 = 1$, as the Revision record does, and say so (Section 3.8 gives the reason).

The four notebooks of the chapter are:

notebook	**what it computes**	**Revision records it reproduces**
03a	reads the metric exactly as the author typed it; determinant, signature (4,4), vielbein, expansion rates, the deflating history, proper volumes, the hidden coordinate y and the warped form; 7 figures, 29 checks	`Revision/gkd_lovelock/results/curvature.json`, `python-lovelock-report.json`, `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`, `Revision/kohn_sham/results/parameters.json`, `Revision/kohn_sham/ks-theory.json`
03c	curvature where it can be pictured: the flat plane in polar coordinates and the sphere; parallel transport, geodesics, geodesic deviation, all with RK4; 5 figures, 16 checks	none (exact formulas only)

notebook	what it computes	Revision records it reproduces
03b	all Christoffel symbols, Riemann, Ricci and Einstein components and the Kretschmann scalar of the author's metric, exactly; finite differences; the curvature along the deflating history; the source Einstein's equations would require; a negative control; 7 figures, 40 checks	`curvature.json`, `python-lovelock-report.json`, `lovelock-report.json` (all three in `Revision/gkd_lovelock/results/`), `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, `Revision/field_equations_a4/a4-equations.json`, `Revision/field_equations_a4/reports/python-a4-report.json`
03d	free fall in the author's metric: conserved momenta, redshift in 3-space, blueshift along the extra times, the push along the hidden direction, the turning point in x_4; RK4 paths with the record's Christoffel symbols; 5 figures, 23 checks	`curvature.json`, `parameters.json`, `ks-theory.json`, `Revision/theory/reports/python-scope.json`

Every statement of the chapter carries one of the five labels of Chapter 0. **PROVED** means derived exactly here, line by line, and confirmed by an exact check of a notebook; where the Revision record proves the same, the record file and its check are named. **COMPUTED** means a number obtained numerically by a notebook, with its measured accuracy. **ASSUMED** marks two kinds of statements: standard theorems that we quote without proof (each is named where it is used), and the physical inputs: that the history of the metric functions is $a_4 = AHx_4$, $b_4 = 1$, which the Revision record itself calls a PRESCRIBED BACKGROUND (Section 3.8), and that the bodies of Section 3.31 are test particles, too small to change the metric. One question is **OPEN** (Section 3.31): whether wave packets of the fields follow the free-fall paths computed here. No HYPOTHESIS enters this chapter. Nothing in this chapter concerns pairs of universes, their creation, or matter and antimatter; those questions belong to Chapters 18 to 21, which also state precisely what is and what is not proved about them.

3.2 Coordinates, indices and sums

Coordinates. A point of the author's spacetime is named by eight real numbers, its **coordinates** $x_0, x_1, \ldots, x_7$. Their roles were listed in Section 3.1. In Python a list of eight numbers is counted from 0, and the author's names are counted from 0 too: position k holds x_k, so position 0 is the hidden coordinate x_0 and position 4 the time x_4; every notebook says so where it matters.

Indices. A letter written as a small label, such as the a in x_a, is an **index**: it stands for any one of the numbers $0, \ldots, 7$. An equation with an index is eight equations, one for each value. Many objects of this chapter carry several indices: the metric g_{ab} has two (it is a table with 64 entries), the

Christoffel symbols $\Gamma^a{}_{bc}$ have three (512 entries), the Riemann tensor $R^a{}_{bcd}$ has four (4096 entries). An index may be written **up** or **down**; Section 3.14 explains why the position matters for vectors and tensors. For the coordinates themselves the position carries no meaning: x_4 and x^4 name the same coordinate, and we write x_a in prose and dx^a for a small step along x_a.

Sums. In this chapter every sum is written with the sign $\sum$; for example $\sum_{a=0}^{7} V^a W_a = V^0W_0 + V^1W_1 + \cdots + V^7W_7$. When the range is the eight coordinates we write $\sum_a$. Where a formula repeats an index but does not sum over it we write "(no sum)".

The Kronecker delta. $\delta^a{}_b$ (also written δ_{ab}) is 1 when $a = b$ and 0 otherwise. It is the table of the 8×8 unit matrix.

Partial derivatives. For a function $f(x_0, \ldots, x_7)$ the **partial derivative** $\partial_a f = \partial f / \partial x_a$ is the ordinary derivative with respect to x_a while the seven other coordinates are held fixed (Chapter 2 teaches it from zero). The author's metric depends on two coordinates only: on x_4 through $a_4(x_4)$ and $b_4(x_4)$, and on x_0 through $z = 6Hx_0$. By the **chain rule**, a function of z has

$$\partial_0 f = \frac{df}{dz}\,\frac{dz}{dx_0} = 6H\,\frac{df}{dz},$$

(the derivative of a function of z with respect to x_0 is its derivative with respect to z times $dz/dx_0 = 6H$), and a function of a_4 and b_4 has $\partial_4 f = a_4' \,\partial f/\partial a_4 + b_4' \,\partial f/\partial b_4$ (the same rule for each of the two functions, with $da_4/dx_4 = a_4'$ and $db_4/dx_4 = b_4'$). Every other partial derivative of the metric is zero.

3.3 The metric: lengths from coordinate steps

Pythagoras. On a flat sheet of paper with perpendicular axes x and y, a small step dx to the right and dy upwards has the squared length

$$ds^2 = dx^2 + dy^2.$$

The coefficients of dx^2 and dy^2 are both 1, and there is no term with $dx\,dy$.

The same plane in polar coordinates. Name a point instead by its distance r from the origin and its angle φ from the x axis, so that $x = r\cos\varphi$ and $y = r\sin\varphi$. We compute ds^2 in these coordinates, line by line.

$$dx = \cos\varphi\, dr - r\sin\varphi\, d\varphi, \qquad dy = \sin\varphi\, dr + r\cos\varphi\, d\varphi$$

(the change of a function of two variables is the sum of its two partial derivatives times the two small changes: $dx = (\partial x/\partial r)\,dr + (\partial x/\partial\varphi)\,d\varphi$, and the same for y)

$$dx^2 = \cos^2\varphi\, dr^2 - 2r\sin\varphi\cos\varphi\, dr\, d\varphi + r^2\sin^2\varphi\, d\varphi^2$$

(the square of a difference, $(p-q)^2 = p^2 - 2pq + q^2$)

$$dy^2 = \sin^2\varphi\, dr^2 + 2r\sin\varphi\cos\varphi\, dr\, d\varphi + r^2\cos^2\varphi\, d\varphi^2$$

(the square of a sum, $(p+q)^2 = p^2 + 2pq + q^2$)

$$ds^2 = dx^2 + dy^2 = dr^2 + r^2\, d\varphi^2$$

(add the two lines: the mixed terms cancel, and $\cos^2\varphi + \sin^2\varphi = 1$ in both remaining pairs). The plane has not changed, but the coefficient of $d\varphi^2$ is now r^2, a number that depends on the point. A step $d\varphi$ in angle is a true length $r\, d\varphi$: the farther from the origin, the longer the arc.

The metric. In general coordinates $x_1, \ldots, x_n$ of an n-dimensional space the squared length of a small step $dx^1, \ldots, dx^n$ is a sum of products of two steps,

$$ds^2 = \sum_{a=1}^{n}\sum_{b=1}^{n} g_{ab}\, dx^a dx^b,$$

with coefficients g_{ab} that may depend on the point. The table g_{ab} is the **metric**; we always take it **symmetric**, $g_{ab} = g_{ba}$ (the two products $dx^a dx^b$ and $dx^b dx^a$ are the same number, so only the sum $g_{ab} + g_{ba}$ matters, and we may share it equally). The formula for ds^2 is called the **line element**. A metric is **diagonal** when $g_{ab} = 0$ for $a \neq b$; then $ds^2 = \sum_a g_{aa}\,(dx^a)^2$. The plane in polar coordinates has the diagonal metric $g = \mathrm{diag}(1, r^2)$ in the order (r, φ).

The sphere. On a sphere of radius a name a point by the angle θ from the north pole and the angle φ around the axis; in three dimensions it is $(a\sin\theta\cos\varphi,\ a\sin\theta\sin\varphi,\ a\cos\theta)$. A step $d\theta$ moves the point along a meridian, a circle of radius a, by the length $a\, d\theta$. A step $d\varphi$ moves it along the circle of latitude, whose radius is $a\sin\theta$, by the length $a\sin\theta\, d\varphi$. The two directions are perpendicular, so by Pythagoras

$$ds^2 = a^2\, d\theta^2 + a^2\sin^2\theta\, d\varphi^2, \qquad g = \mathrm{diag}(a^2,\ a^2\sin^2\theta).$$

The inverse metric. The inverse matrix of g_{ab} is written with upper indices, g^{ab}: $\sum_c g^{ac} g_{cb} = \delta^a{}_b$. For a diagonal metric it is diagonal too, with $g^{aa} = 1/g_{aa}$ (no sum), because the product of two diagonal matrices is the diagonal matrix of the products of their entries.

3.4 Signature: space-like and time-like directions

In the spacetime of special relativity with one space direction x and the time t (in units in which the speed of light is 1) the line element is

$$ds^2 = dx^2 - dt^2.$$

The coefficient of dt^2 is negative. A step dt alone has $ds^2 = -dt^2 < 0$: it is not a length but a **duration**, and the time that a clock carried along the step shows, its **proper time**, is $d\tau = \sqrt{-ds^2} = dt$. A step with $dx = dt$ (one unit of distance per unit of time: a flash of light) has $ds^2 = 0$.

Definitions. A vector V with components $V^1, \ldots, V^n$ (Section 3.14 makes this precise) has the **squared length** $g(V,V) = \sum_{a,b} g_{ab} V^a V^b$. It is **space-like** if $g(V,V) > 0$, **time-like** if $g(V,V) < 0$ and **null** if $g(V,V) = 0$ but V is not zero. For a diagonal metric a step along one coordinate x_a is space-like when $g_{aa} > 0$ and time-like when $g_{aa} < 0$.

Signature. The **signature** (p, q) of a metric at a point is the number p of positive and the number q of negative eigenvalues of the matrix g_{ab}. For a diagonal matrix the eigenvalues are the diagonal entries, so the signature counts the positive and the negative diagonal entries. A theorem of linear algebra, **Sylvester's law of inertia**, says that the signature does not depend on the coordinates (ASSUMED: quoted without proof). The flat metric with the signs of the author's metric is

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

in the order $x_0, \ldots, x_7$: four positive and four negative entries, the signature **(4,4)**. Four directions are space-like (x_0, x_1, x_2, x_3) and four are time-like (x_4, x_5, x_6, x_7). With four time-like directions one of them must be chosen as the time in which everything evolves; the author chooses x_4, and the other three are the extra times.

3.5 The author's metric

The Rust program `lovelock_gkd`, which computed the curvature of the metric for the Revision record, stored the author's text of the metric under the name `metricAsGiven` in its output file `Revision/gkd_lovelock/results/curvature.json`, followed by a note in brackets. Printed with one row of the matrix per line (Notebook 03a, In [3]):

```
{{Cot[6 H x0]^2,0,0,0,0,0,0,0},
{0,E^(2 a4[x4]) Sin[6 H x0]^(1/3),0,0,0,0,0,0},
{0,0,E^(2 a4[x4]) Sin[6 H x0]^(1/3),0,0,0,0,0},
{0,0,0,E^(2 a4[x4]) Sin[6 H x0]^(1/3),0,0,0,0},
{0,0,0,0,-1,0,0,0},
{0,0,0,0,0,-E^(-2 a4[x4]) b4[x4] Sin[6 H x0]^(1/3),0,0},
{0,0,0,0,0,0,-E^(-2 a4[x4]) b4[x4] Sin[6 H x0]^(1/3),0},
{0,0,0,0,0,0,0,-E^(-2 a4[x4]) b4[x4] Sin[6 H x0]^(1/3)}}
```

It is written in the notation of Mathematica: braces enclose a list (the matrix is a list of eight rows of eight entries, the rows and columns in the order $x_0, x_1, \ldots, x_7$), `E^(...)` is e to the power in brackets, `Sin` and `Cot` are the sine and the cotangent, `a4[x4]` and `b4[x4]` are the values of the functions a_4 and b_4 at x_4, and a blank between two factors means times. The note of the record says that this is the user's metric of 2026-10-14 in the author's coordinates $x_0, \ldots, x_7$, as in the author's notebook `Dirac_Einstein-Lovelock_4+4_Nash.nb`, and that $b_4 = 1$ is the metric before 2026-10-14. Only the eight diagonal entries are non-zero; the line element is therefore

$$\begin{aligned} ds^2 = {} & \cot^2 z\, dx_0^2 + e^{2a_4} \sin^{1/3} z\, (dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2 \\ & - b_4 e^{-2a_4} \sin^{1/3} z\, (dx_5^2 + dx_6^2 + dx_7^2), \qquad z = 6Hx_0. \end{aligned}$$

Reading it term by term. A step dx_1 in 3-space has the true (proper) length $e^{a_4} \sin^{1/6} z\, dx_1$, the square root of its coefficient: when a_4 grows, 3-space **inflates**. A step dx_5 along an extra time

has the proper duration $b_4^{1/2} e^{-a_4} \sin^{1/6} z \, dx_5$: when a_4 grows and b_4 stays constant, the three extra times **deflate exponentially** (in general their rate of change is $-a_4' + b_4'/(2b_4)$, Section 3.7). A step dx_4 has $ds^2 = -dx_4^2$, so a clock at rest shows exactly x_4: the coordinate x_4 is the proper time of an observer at rest (Section 3.23 shows that such an observer is in free fall). The hidden direction has the coefficient $\cot^2 z$, which depends on x_0 only.

Units. $z = 6Hx_0$ is an angle (a pure number), so H has the unit of an inverse length. In all numerical work of the chapter lengths and times are measured in units of $1/H$, which is the same as setting $H = 1$.

The patch. The metric is used for $0 < z < \pi/2$, that is $0 < x_0 < \pi/(12H)$; we call this range the **patch**. Its end $z \to 0$ is the **tip** and its end $z = \pi/2$ the **patch end**. Inside the patch $\sin z > 0$, so the cube root $\sin^{1/3} z$ is a positive number, and $\cot z = \cos z / \sin z > 0$. At the patch end $\cot z = 0$, so $g_{00} = 0$ there and the matrix g has no inverse: the coordinate x_0 stops being a good label there (Section 3.9 shows that another coordinate, y, has no such problem, just as polar coordinates fail at $r = 0$ while the plane is perfectly regular there).

The signature is (4,4) at every point of the patch, for every a_4 and every $b_4 > 0$ (PROVED). The proof is one line per sign: $\cot^2 z > 0$ because $\cot z > 0$ inside the patch; $e^{2a_4} > 0$ and $e^{-2a_4} > 0$ for every real a_4 (an exponential is positive), $b_4 > 0$, and $\sin^{1/3} z > 0$ inside the patch (shown above); hence the three 3-space entries are positive and the three extra-time entries, which carry a minus sign, are negative; and $g_{44} = -1 < 0$. So the signs are $(+,+,+,+,-,-,-,-)$, those of η. Notebook 03a confirms this on a grid of 400 values of z, 13 values of a_4 and three values of b_4 (In [8]); at $z = 0.7$, $a_4 = 0.5$ and $b_4 = 1$ it prints $g_{11} = 2.347679$ and $g_{55} = -0.317724$.

3.6 The determinant and proper volumes

The volume of a small box. In flat Cartesian coordinates a small box with edges dx, dy, dz has the volume $dx\,dy\,dz$. In the plane in polar coordinates a small box with edges dr and $d\varphi$ has the true edge lengths dr and $r\,d\varphi$, so its area is $r\,dr\,d\varphi$. For any diagonal metric the same reasoning gives: a box with coordinate edges $dx^1, \ldots, dx^n$ has the proper edge lengths $\sqrt{|g_{aa}|}\,dx^a$, and its proper volume is the product

$$\prod_{a=1}^{n} \sqrt{|g_{aa}|}\; dx^1 \cdots dx^n = \sqrt{|\det g|}\; dx^1 \cdots dx^n,$$

because the **determinant** of a diagonal matrix is the product of its diagonal entries, and the square root of a product of positive numbers is the product of their square roots. (For a metric that is not diagonal the volume factor is also $\sqrt{|\det g|}$; we quote this without proof, ASSUMED, and do not need it.) The factor $\sqrt{|\det g|}$ is the **volume factor**.

The determinant of the author's metric. We compute it line by line; after each line we name the rule that produced it.

$$\det g = g_{00}\, g_{11}\, g_{22}\, g_{33}\, g_{44}\, g_{55}\, g_{66}\, g_{77}$$

(the determinant of a diagonal matrix is the product of its diagonal entries)

$$= \cot^2 z \cdot \left(e^{2a_4} \sin^{1/3} z\right)^3 \cdot (-1) \cdot \left(-b_4 e^{-2a_4} \sin^{1/3} z\right)^3$$

(the entries inserted; three equal factors written as a cube)

$$= \cot^2 z \cdot e^{6a_4} \sin z \cdot (-1) \cdot \left(-b_4^3 e^{-6a_4} \sin z\right)$$

(a power of a product is the product of the powers: $(e^{2a_4})^3 = e^{6a_4}$, $(\sin^{1/3} z)^3 = \sin z$, $(b_4)^3 = b_4^3$, and an odd power keeps the minus sign, $(-1)^3 = -1$)

$$= b_4^3 \, e^{6a_4} e^{-6a_4} \, \sin^2 z \, \cot^2 z = b_4^3 \sin^2 z \, \cot^2 z$$

(the two minus signs multiply to $+1$, and $e^{6a_4} e^{-6a_4} = e^0 = 1$)

$$= b_4^3 \sin^2 z \, \frac{\cos^2 z}{\sin^2 z} = b_4^3 \cos^2 z$$

($\cot z = \cos z / \sin z$). Inside the patch $\cos z > 0$, and $b_4 > 0$, so

$$\sqrt{|\det g|} = b_4^{3/2} \cos z.$$

This is PROVED here and in the Revision record (`Revision/gkd_lovelock/results/python-lovelock-report.json`, check `sqrt_abs_det_g`; `curvature.json` stores $\sqrt{|\det g|}$ as `Sin[6*H*x0]*Cot[6*H*x0]*b4[x4]^(3/2)` under the name `sqrtAbsDetG`); Notebook 03a reproduces both (In [7]). The function a_4 has dropped out in the fourth line: the factor e^{6a_4} of the three inflating 3-space directions and the factor e^{-6a_4} of the three deflating extra times cancel. The factor b_4^3 of the three extra-time entries stays; at $b_4 = 1$ the volume factor is $\cos z$.

The volume of a slice of constant time. The time x_4 is the time in which everything in this book evolves (it is the time shown by the clocks of observers at rest, Section 3.23). The natural volume is therefore that of a slice $x_4 = \text{const}$, the whole space at one instant of x_4: a seven-dimensional space with the coordinates $x_0, x_1, x_2, x_3, x_5, x_6, x_7$. This 7-volume still mixes kinds of steps: four of its edges are lengths (along x_0, x_1, x_2, x_3) and three are durations (along the extra times x_5, x_6, x_7, which are time-like, Section 3.4), and its volume factor multiplies all seven proper sizes. Its volume factor is the product of the seven scale factors other than that of x_4, which is $\sqrt{|g_{44}|} = 1$; so it equals $\sqrt{|\det g|} = b_4^{3/2} \cos z$. It does not depend on a_4: **the proper 7-volume of a region with fixed coordinate ranges changes in time only through the factor $b_4^{3/2}$; for a constant b_4, in particular on the backgrounds of this book with $b_4 = 1$, it does not change at all** (PROVED; Notebook 03a, In [17]).

Three partial volumes. Take a box with the coordinate edges $\Delta x_1 = \Delta x_2 = \Delta x_3 = 1$ (small enough that z hardly changes along it, or at one value of z). Its proper 3-volume in 3-space is

$$V_3 = \left(e^{a_4} \sin^{1/6} z\right)^3 = e^{3a_4} \sin^{1/2} z$$

(the product of three equal scale factors; a power of a product is the product of the powers). The same box in the three extra times has $V_t = (b_4^{1/2} e^{-a_4} \sin^{1/6} z)^3 = b_4^{3/2} e^{-3a_4} \sin^{1/2} z$, and $V_3 V_t = b_4^{3/2} \sin z$

(the exponentials cancel and $\sin^{1/2} z \cdot \sin^{1/2} z = \sin z$). What 3-space gains in volume through a_4, the extra times lose.

The 7-volume of the whole patch. Per unit coordinate volume of the six directions $x_1, x_2, x_3, x_5, x_6, x_7$, the proper 7-volume of the patch is the integral of the volume factor $b_4^{3/2} \cos(6Hx_0)$ over x_0. The factor $b_4^{3/2}$ does not depend on x_0 and comes out of the integral, which leaves

$$\int_0^{\pi/(12H)} \cos(6Hx_0)\, dx_0 = \Big[\frac{\sin(6Hx_0)}{6H}\Big]_0^{\pi/(12H)}$$

(an antiderivative of $\cos(6Hx_0)$ is $\sin(6Hx_0)/(6H)$: differentiate it with the chain rule to check)

$$= \frac{\sin(\pi/2) - \sin 0}{6H} = \frac{1}{6H}$$

(insert the two limits; $6H \cdot \pi/(12H) = \pi/2$). So the 7-volume is $b_4^{3/2}/(6H)$, which is $1/(6H)$ at $b_4 = 1$. PROVED; Notebook 03a computes the integral of $\cos(6Hx_0)$ with sympy (In [17]).

3.7 Scale factors, the vielbein and the rates of expansion

Scale factors. Write each diagonal entry as a sign times a square, $g_{aa} = \eta_{aa}\, h_a^2$ with a positive number h_a, the **scale factor** of the direction x_a: a coordinate interval Δx_a over which h_a does not change has the proper length (or, for a time-like direction, the proper duration) $h_a\, \Delta x_a$. For the author's metric, inside the patch,

$$\begin{aligned} h = (&\cot z,\ e^{a_4} \sin^{1/6} z,\ e^{a_4} \sin^{1/6} z,\ e^{a_4} \sin^{1/6} z,\ 1,\\ &b_4^{1/2} e^{-a_4} \sin^{1/6} z,\ b_4^{1/2} e^{-a_4} \sin^{1/6} z,\ b_4^{1/2} e^{-a_4} \sin^{1/6} z) \end{aligned}$$

in the order $x_0, \ldots, x_7$ (the positive square roots of the absolute values of the diagonal entries: $\sqrt{\cot^2 z} = \cot z$ because $\cot z > 0$ in the patch, $\sqrt{e^{2a_4} \sin^{1/3} z} = e^{a_4} \sin^{1/6} z$, and $\sqrt{b_4 e^{-2a_4} \sin^{1/3} z} = b_4^{1/2} e^{-a_4} \sin^{1/6} z$ because the root of a product is the product of the roots).

The vielbein. At every point imagine eight measuring rods and clocks of unit proper length, one along each coordinate direction, all perpendicular to each other. Such a set is a **frame**, and the matrix $e^a{}_\mu$ that converts coordinate steps into frame components is the **vielbein** (German for "many legs"): the metric is

$$g_{\mu\nu} = \sum_{a,b} e^a{}_\mu\, \eta_{ab}\, e^b{}_\nu .$$

For a diagonal metric the diagonal vielbein $e^a{}_\mu = h_\mu\, \delta^a{}_\mu$ (no sum) does this: the double sum keeps only $a = b = \mu = \nu$ and gives $\eta_{\mu\mu} h_\mu^2 = g_{\mu\mu}$. The spinor fields of the book need exactly this frame (Chapter 6). PROVED here. The Revision record also contains the **lead checks**: short, independent Python programs in the folder `Revision/lead_checks`, written from scratch by the coordinator of the Revision work (the "lead") without using any other Revision code, each of which writes a

report listing its named checks and their verdicts. The lead's check `vielbein_reproduces_metric` of `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json` checks the same, and Notebook 03a reproduces it (In [11]).

The rate of expansion. A coordinate interval Δx_a has the proper length $L = h_a\,\Delta x_a$. The fraction by which it grows per unit of time is

$$\frac{1}{L}\frac{\partial L}{\partial x_4} = \frac{\partial_4 h_a}{h_a} = \partial_4 \ln h_a$$

(the coordinate interval does not change; the derivative of $\ln u$ is u'/u). For 3-space,

$$\ln h_1 = a_4 + \tfrac{1}{6}\ln\sin z \quad \Rightarrow \quad \partial_4 \ln h_1 = a_4'$$

(the logarithm of a product is the sum of the logarithms, $\ln e^{a_4} = a_4$, $\ln \sin^{1/6} z = \frac{1}{6}\ln\sin z$; only a_4 depends on x_4). For an extra time,

$$\ln h_5 = \tfrac{1}{2}\ln b_4 - a_4 + \tfrac{1}{6}\ln\sin z \quad \Rightarrow \quad \partial_4 \ln h_5 = -a_4' + \frac{b_4'}{2b_4} \equiv \alpha_t$$

(the same rules, with $\ln b_4^{1/2} = \frac{1}{2}\ln b_4$ and the derivative b_4'/b_4 of $\ln b_4$). We call α_t the **expansion rate of the extra times**. $h_0 = \cot z$ and $h_4 = 1$ do not depend on x_4, so their rates are 0. When $a_4' > 0$ and b_4 is constant, $\alpha_t = -a_4'$: **3-space expands at the rate a_4' and the three extra times shrink at the same rate**. The six **transverse** scale factors (those of $x_1, x_2, x_3, x_5, x_6, x_7$) multiply to

$$h_1 h_2 h_3 h_5 h_6 h_7 = e^{3a_4}\sin^{1/2} z \cdot b_4^{3/2} e^{-3a_4}\sin^{1/2} z = b_4^{3/2}\sin z,$$

without a_4. All of this is PROVED and is checked exactly by Notebook 03a (In [12]). The factor $\sin^{1/6} z$ that the six transverse scale factors share is the **warp factor** $W = \sin^{1/6} z$; the six transverse metric entries contain its square $W^2 = \sin^{1/3} z$.

3.8 The deflating history: a prescribed background

The metric does not fix the functions $a_4(x_4)$ and $b_4(x_4)$. The field equations of gravity relate them to the energy and the pressures of the matter in the spacetime; Chapter 12 derives them. With the author's own weights of the field equations every vacuum solution has a constant b_4 (record `Revision/metric_b4/results/vacuum-b4.json`), and a constant b_4 is removed by the rescaling $x_5, x_6, x_7 \to b_4^{1/2}x_5, b_4^{1/2}x_6, b_4^{1/2}x_7$ of the extra times: it gives back the metric with $b_4 = 1$. Every Revision calculation that needs a background history therefore keeps $b_4 = 1$ and says so (`Revision/SPEC.md`, section 1). For pictures and numbers this chapter does the same and uses the simplest member of the family, the **linear history**

$$a_4 = AHx_4, \qquad a_4' = AH, \qquad a_4'' = 0, \qquad b_4 = 1,$$

with a constant **slope** A. With $A > 0$ the function a_4 increases, 3-space inflates like e^{AHx_4} and the extra times deflate like e^{-AHx_4}: exponential deflation, as the author requires. The Revision Kohn-Sham work uses $A = 1$ and $H = 1$, and computes its states on five **slices** $a_4 = 0, 0.5, 1, 1.5, 2$ (record `Revision/kohn_sham/results/parameters.json`, keys `physics.H`, `physics.historyA`, `physics.slicesA4`; Notebook 03a, In [13]). Between the first and the last slice, 3-space lengths grow by the factor $e^2 = 7.389056$ and extra-time durations shrink by the factor $e^{-2} = 0.135335$ (Notebook 03a, In [14]); the product of the two factors stays 1.

Status: ASSUMED. The history is not a solution of the coupled field equations. The Revision record says so in its own words (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.historyStatus`): "PRESCRIBED BACKGROUND: the history a4 = A H x4 is prescribed, not solved for." The reason, also stated there: the field equations of a_4 allow this linear member only for a source with equal pressures in all directions and a constant energy density, and the Kohn-Sham states computed along it do not have these properties (record `Revision/field_equations_a4/reports/ks-source-conditions.json`). Every formula of this chapter written with general $a_4(x_4)$ and $b_4(x_4)$ is exact; only the pictures and the numbers along the history use the assumption. The pictures and numbers of this chapter use only slopes $A > 0$, for which the extra times deflate, as the author requires; a slope $A = 0$ would freeze the extra times and a slope $A < 0$ would make them inflate and 3-space deflate.

3.9 The hidden coordinate y and the warped form of the metric

The entry $\cot^2 z$ makes the hidden direction awkward: it grows without bound at the tip and vanishes at the patch end. The Revision Kohn-Sham work uses instead the coordinate

$$y = \frac{\ln(\sin z)}{6H}, \qquad z = 6Hx_0.$$

It measures proper distance. Line by line:

$$\frac{dy}{dx_0} = \frac{1}{6H} \cdot \frac{\cos z}{\sin z} \cdot 6H$$

(the chain rule: the derivative of $\ln u$ is $1/u$, the derivative of $\sin z$ is $\cos z$, and $dz/dx_0 = 6H$)

$$= \cot z$$

(the factors $6H$ cancel, and $\cos z / \sin z = \cot z$). So $dy = \cot z \, dx_0$ and $dy^2 = \cot^2 z \, dx_0^2 = g_{00} \, dx_0^2$: a step dy is a step of proper length dy along the hidden direction. (Record: `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`, check `ks_coordinate_jacobian`; Notebook 03a, In [19].)

The warp factor in y. From the definition, $6Hy = \ln \sin z$, so

$$\sin z = e^{6Hy}$$

(e to the power of both sides; $e^{\ln u} = u$), and therefore

$$W = \sin^{1/6} z = \left(e^{6Hy}\right)^{1/6} = e^{Hy}, \qquad W^2 = \sin^{1/3} z = e^{2Hy}$$

(a power of a power multiplies the exponents). Inserting dy^2 and W^2 into the line element of Section 3.5 gives the **warped form**

$$ds^2 = dy^2 - dx_4^2 + W^2\Big[e^{2a_4}\left(dx_1^2 + dx_2^2 + dx_3^2\right) - b_4 e^{-2a_4}\left(dx_5^2 + dx_6^2 + dx_7^2\right)\Big], \qquad W = e^{Hy}.$$

At $b_4 = 1$ this is exactly the line element of the record (`Revision/kohn_sham/ks-theory.json`, keys `geometry.lineElement` and `geometry.warp`), which is written for the Kohn-Sham background with $b_4 = 1$; Notebook 03a checks the form with b_4 entry by entry with sympy (In [19]). PROVED.

The range of y. As z runs from 0 to $\pi/2$, $\sin z$ runs from 0 to 1 and $\ln \sin z$ from $-\infty$ to 0. So y runs from $-\infty$ (the tip) to 0 (the patch end). The tip lies at an infinite proper distance from every point of the patch (PROVED; Notebook 03a, In [19]). At the patch end $y = 0$ nothing goes wrong in the warped form: the coefficient of dy^2 is 1. The failure of g_{00} there was a failure of the coordinate x_0, not of the geometry.

The volume factor in y. In the coordinates $(y, x_1, \ldots, x_7)$ the scale factor of the hidden direction is 1, so the volume factor is the product of the six transverse scale factors, $b_4^{3/2} W^6 = b_4^{3/2} e^{6Hy} = b_4^{3/2} \sin z$; at $b_4 = 1$ it is $e^{6Hy} = \sin z$ (record key `geometry.sqrtDetG`: "e^{6Hy} (= cos z in the author's chart x0..x7)"). The two volume factors $b_4^{3/2} \sin z$ (in y) and $b_4^{3/2} \cos z$ (in x_0) describe the same volume, because $\cos z\, dx_0 = \cos z\, \tan z\, dy = \sin z\, dy$ (from $dx_0 = dy/\cot z = \tan z\, dy$).

The tip cut-off. The Revision Kohn-Sham solver keeps only $-L \le y \le 0$ with $L = 3/H$ (record key `physics.L_tipCutoff`). The fraction of the 7-volume that it leaves out is (the factor $b_4^{3/2}$ does not depend on y and cancels in the ratio)

$$\frac{\int_{-\infty}^{-L} e^{6Hy}\, dy}{\int_{-\infty}^{0} e^{6Hy}\, dy} = \frac{e^{-6HL}/(6H)}{1/(6H)} = e^{-6HL}$$

(an antiderivative of e^{6Hy} is $e^{6Hy}/(6H)$, which tends to 0 as $y \to -\infty$), which for $L = 3/H$ is $e^{-18} = 1.5230 \times 10^{-8}$. The cut-off lies at the tiny angle $z = \arcsin e^{-18} = 1.5230 \times 10^{-8}$ (both COMPUTED in Notebook 03a, In [20]; the fraction is exact).

3.10 Example: the author's metric, read and checked

Notebook 03a puts Sections 3.2 to 3.9 to work. It reads the metric exactly as the author typed it from the record `curvature.json` and turns the text into an exact sympy matrix; checks it against a second, hand-typed copy and against the record's diagonal entries; computes the determinant and the volume factor; checks the signature on a grid; builds the vielbein and the expansion rates; reads the history of the Revision Kohn-Sham work ($b_4 = 1$) and draws the scale factors along it; computes the proper volumes; and checks the hidden coordinate y, the warped form and the volume factor in y against the record `ks-theory.json`. It needs no Rust, runs in about 15 seconds and ends with the line ALL 29 CHECKS PASSED (notebook 03a).

3.11 How to run Notebook 03a

Step 1. What this notebook does and what it needs.

Notebook 03a (The author's metric: signature, scale factors, warp and proper volumes) is the file `Revision/textbook/notebooks/03a_authors_metric.ipynb` of the repository Dirac_claude. It reads the metric of the primordial gravitational field exactly as the author typed it, with the two metric functions a4 and b4 (from the Revision record of the curvature computation), turns the text into an exact sympy matrix, and checks its diagonal entries, its determinant, its signature (4,4) and its diagonal vielbein against the Revision records. It then computes the expansion rate of every direction, the proper volumes and the hidden coordinate y, and draws the metric as a heat map, its entries versus z, the scale factors of 3-space (inflating) and of the three extra times (deflating exponentially) along the deflating history a4 = A H x4, b4 = 1 of the Revision Kohn-Sham work, the warp factor and the proper volumes. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
```

```
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 03a_authors_metric.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a

number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03a_authors_metric.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 03a_authors_metric.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/03a.captions.json`
- `Revision/textbook/figures/03a_1_metric_heat_map.png`
- `Revision/textbook/figures/03a_2_diagonal_entries.png`
- `Revision/textbook/figures/03a_3_history_scale_factors.png`
- `Revision/textbook/figures/03a_4_hidden_direction.png`
- `Revision/textbook/figures/03a_5_scale_factor_maps.png`
- `Revision/textbook/figures/03a_6_proper_volumes.png`
- `Revision/textbook/figures/03a_7_hidden_coordinate_y.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all seven figure files exist
ALL 29 CHECKS PASSED (notebook 03a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/03a_authors_metric.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 03a_authors_metric.ipynb
python -m nbconvert --execute --inplace 03a_authors_metric.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

- "FileNotFoundError" for curvature.json, python-lovelock-report.json, emt-divergence-and-spin-connection.json, parameters.json or ks-theory.json: the notebook reads these five Revision records of the repository, so the folder Revision of your copy is incomplete. Restore it with the following command in the repository folder (or clone the repository again) and run the notebook again:

```
git checkout -- Revision
```

- "AssertionError: record check failed": a Revision report no longer lists a check that the notebook relies on as passed, so your copy of the folder Revision differs from the one the book was built with. Restore it with the same command and run the notebook again:

```
git checkout -- Revision
```

3.12 Notebook 03a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/03a_authors_metric.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook studies the **metric of the primordial gravitational field**, the
$8 \times 8$ matrix that the author wrote down and on which every later computation
of the book is built. It

- reads the metric **exactly as the author typed it** (the text is stored in the
  Revision record `Revision/gkd_lovelock/results/curvature.json`) and turns the text
  into an exact sympy matrix, step by step;
- checks the eight diagonal entries, the determinant $\det g = b_4^3 \cos^2 z$ and
  $\sqrt{|\det g|} = b_4^{3/2} \cos z$ against the Revision records;
- checks the **signature** (4,4): four space-like directions $x_0, x_1, x_2, x_3$ and
  four time-like directions $x_4, x_5, x_6, x_7$;
- builds the diagonal **vielbein** (the scale factors) and checks that it reproduces
  the metric;
- computes the **expansion rate** of every direction: 3-space expands with the rate
  $a_4'$, the three extra times shrink (deflate) with the rate $-a_4' + b_4'/(2b_4)$;
- draws the scale factors along the **deflating history** $a_4 = A H x_4$, $b_4 = 1$
  that the Revision Kohn-Sham work uses as a prescribed background ($A = 1$, $H = 1$);
- computes the **proper volumes** (3-space grows like $e^{3 a_4}$, the extra times
  shrink like $b_4^{3/2} e^{-3 a_4}$, the 7-volume stays constant when $b_4$ does) and
  the **hidden coordinate** $y = \ln(\sin z)/(6H)$ in which the metric takes its
  warped form;
- draws 7 figures and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 03a (The author's metric: signature, scale factors, warp and proper volumes) is
the file 'Revision/textbook/notebooks/03a_authors_metric.ipynb' of the repository
Dirac_claude. It reads the metric of the primordial gravitational field exactly as the
author typed it, with the two metric functions a4 and b4 (from the Revision record of the
curvature computation), turns the text into an exact sympy matrix, and checks its
diagonal entries, its determinant, its signature (4,4) and its diagonal vielbein against
the Revision records. It then computes the expansion rate of every direction, the proper
volumes and the hidden coordinate y, and draws the metric as a heat map, its entries
versus z, the scale factors of 3-space (inflating) and of the three extra times
(deflating exponentially) along the deflating history a4 = A H x4, b4 = 1 of the Revision
Kohn-Sham work, the warp factor and the proper volumes. It needs a computer with Windows
11, macOS or Linux, an internet connection for the installation, the program Git, and
Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv

Then close the terminal and open a NEW one (a terminal opened before the installation
does not know the new programs), and check the version of Python; it must print 3.12 or a
higher number:
```

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 03a_authors_metric.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 15 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.
```

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03a_authors_metric.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 03a_authors_metric.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/03a.captions.json‘
- ‘Revision/textbook/figures/03a_1_metric_heat_map.png‘
- ‘Revision/textbook/figures/03a_2_diagonal_entries.png‘
- ‘Revision/textbook/figures/03a_3_history_scale_factors.png‘
- ‘Revision/textbook/figures/03a_4_hidden_direction.png‘
- ‘Revision/textbook/figures/03a_5_scale_factor_maps.png‘
- ‘Revision/textbook/figures/03a_6_proper_volumes.png‘
- ‘Revision/textbook/figures/03a_7_hidden_coordinate_y.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all seven figure files exist
ALL 29 CHECKS PASSED (notebook 03a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel

  called python3; with the environment active, run the following command and start
  JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from
  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/03a_authors_metric.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 03a_authors_metric.ipynb
      python -m nbconvert --execute --inplace 03a_authors_metric.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for curvature.json, python-lovelock-report.json,
  emt-divergence-and-spin-connection.json, parameters.json or ks-theory.json: the
  notebook reads these five Revision records of the repository, so the folder Revision of
  your copy is incomplete. Restore it with the following command in the repository folder
  (or clone the repository again) and run the notebook again:

      git checkout -- Revision

- "AssertionError: record check failed": a Revision report no longer lists a check that
  the notebook relies on as passed, so your copy of the folder Revision differs from the
  one the book was built with. Restore it with the same command and run the notebook
  again:

      git checkout -- Revision

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a

RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 03a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 03a (The author’s metric: signature, scale factors, warp and proper volumes)
# is the file Revision/textbook/notebooks/03a_authors_metric.ipynb of the repository
# Dirac_claude. It reads the metric of the primordial gravitational field exactly as the
# author typed it, with the two metric functions a4 and b4 (from the Revision record of
# the curvature computation), turns the text into an exact sympy matrix, and checks its
# diagonal entries, its determinant, its signature (4,4) and its diagonal vielbein
# against the Revision records. It then computes the expansion rate of every direction,
# the proper volumes and the hidden coordinate y, and draws the metric as a heat map, its
# entries versus z, the scale factors of 3-space (inflating) and of the three extra times
# (deflating exponentially) along the deflating history a4 = A H x4, b4 = 1 of the
# Revision Kohn-Sham work, the warp factor and the proper volumes. It needs a computer
# with Windows 11, macOS or Linux, an internet connection for the installation, the
# program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
```

```
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 03a_authors_metric.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
```

```
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 03a_authors_metric.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 03a_authors_metric.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/03a.captions.json
# - Revision/textbook/figures/03a_1_metric_heat_map.png
# - Revision/textbook/figures/03a_2_diagonal_entries.png
# - Revision/textbook/figures/03a_3_history_scale_factors.png
# - Revision/textbook/figures/03a_4_hidden_direction.png
# - Revision/textbook/figures/03a_5_scale_factor_maps.png
# - Revision/textbook/figures/03a_6_proper_volumes.png
# - Revision/textbook/figures/03a_7_hidden_coordinate_y.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all seven figure files exist
#     ALL 29 CHECKS PASSED (notebook 03a)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/03a_authors_metric.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
```

```
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 03a_authors_metric.ipynb
#     python -m nbconvert --execute --inplace 03a_authors_metric.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for curvature.json, python-lovelock-report.json,
#   emt-divergence-and-spin-connection.json, parameters.json or ks-theory.json: the
#   notebook reads these five Revision records of the repository, so the folder Revision
#   of your copy is incomplete. Restore it with the following command in the repository
#   folder (or clone the repository again) and run the notebook again:
#     git checkout -- Revision
# - "AssertionError: record check failed": a Revision report no longer lists a check that
#   the notebook relies on as passed, so your copy of the folder Revision differs from
#   the one the book was built with. Restore it with the same command and run the
#   notebook again:
#     git checkout -- Revision
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$: eight numbers that name a point of the
  8-dimensional spacetime. The author's names and roles: $x_0$ the **hidden** space
  direction; $x_1, x_2, x_3$ ordinary 3-space; $x_4$ the time; $x_5, x_6, x_7$ the
  three **extra times**. (In Python lists they are counted 0 to 7 as well: $x_k$ is
  entry $k$.)
- **Metric** $g_{\mu\nu}$: the table of numbers (a symmetric matrix) that turns a
  small coordinate step $dx^\mu$ into a squared length,
  $ds^2 = \sum_{\mu,\nu} g_{\mu\nu}\, dx^\mu dx^\nu$. The entries may depend on the
  point.
- **Diagonal metric**: $g_{\mu\nu} = 0$ whenever $\mu \ne \nu$; then
  $ds^2 = \sum_\mu g_{\mu\mu} (dx^\mu)^2$.
- **Line element**: the formula for $ds^2$.
- **Space-like, time-like**: a step along a direction with $g_{\mu\mu} > 0$ has a
  positive squared length (space-like); with $g_{\mu\mu} < 0$ a negative one
  (time-like: it measures a time, not a distance).
- **Signature** $(p, q)$: the number $p$ of positive and $q$ of negative eigenvalues
  of the metric matrix. For a diagonal matrix the eigenvalues are the diagonal
  entries. The author's metric has signature (4,4).
- $\eta$: the flat metric with the same signs, $\eta = \mathrm{diag}(+1, +1, +1,
  +1, -1, -1, -1, -1)$ in the order $x_0, \dots, x_7$.
- **Determinant** $\det g$: for a diagonal matrix the product of its diagonal
  entries. $\sqrt{|\det g|}\, d^8x$ is the proper (true) volume of a small
  coordinate box.
- **Scale factor** of a direction: the number $h_\mu = \sqrt{|g_{\mu\mu}|}$ that
  turns a coordinate interval $\Delta x^\mu$ into a proper length
  $h_\mu \Delta x^\mu$.
- **Vielbein** $e^a{}_\mu$: a matrix with $g_{\mu\nu} = \sum_{a,b} e^a{}_\mu
  \eta_{ab} e^b{}_\nu$; for a diagonal metric the diagonal matrix of the scale
  factors.
- **Expansion rate** (Hubble rate) of a direction: $\partial_{x_4} \ln h_\mu$, the
  fraction by which its lengths grow per unit of time $x_4$.
- **Inflate, deflate**: grow, shrink exponentially. 3-space inflates; the extra
  times deflate.
- $z = 6 H x_0$: the hidden coordinate in angle form, between $0$ and $\pi/2$.
- **Patch**: the range $0 < z < \pi/2$ on which the metric is used. Its end
  $z = \pi/2$ is the **patch end**; the end $z \to 0$ is the **tip**.
- **Warp factor** $W = \sin^{1/6} z$: the factor that the scale factors of the six
  **transverse** directions $x_1, x_2, x_3, x_5, x_6, x_7$ share; the six transverse
  entries $g_{11}, g_{22}, g_{33}, g_{55}, g_{66}, g_{77}$ of the metric contain its
  square $W^2 = \sin^{1/3} z$.
- **Hidden coordinate** $y = \ln(\sin z)/(6H)$: a second coordinate for the hidden
  direction, in which the warp factor is $W = e^{Hy}$ (section 13).
- **Prescribed background**: a metric that is given and not solved for from field
  equations.
- **Lead checks**: short independent Python programs of the Revision record (folder
  `Revision/lead_checks`), written from scratch by the coordinator of the Revision
  work (the "lead") without importing any other Revision code; each writes a report
  with a list of named checks and their verdicts.
- **sympy**: the Python package for exact algebra with symbols; **numpy**: arrays of
  numbers; **matplotlib**: plots.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's metric of the primordial gravitational field is diagonal. In the order
$x_0, \dots, x_7$ its diagonal entries are

$$g = \mathrm{diag}\bigl(\cot^2 z,\ e^{2a_4}\sin^{1/3}z,\ e^{2a_4}\sin^{1/3}z,\
e^{2a_4}\sin^{1/3}z,\ -1,\ -b_4 e^{-2a_4}\sin^{1/3}z,\ -b_4 e^{-2a_4}\sin^{1/3}z,\
-b_4 e^{-2a_4}\sin^{1/3}z\bigr),\qquad z = 6 H x_0 .$$

Here $H > 0$ is a constant of the author (a number with the unit 1/length), and
$a_4 = a_4(x_4)$ and $b_4 = b_4(x_4) > 0$ are functions of the time $x_4$ only, the
**metric functions**; $b_4$ is the author's change of 2026-10-14, and $b_4 = 1$ gives
the metric used before. A prime means the derivative with respect to $x_4$:
$a_4' = d a_4 / d x_4$, $b_4' = d b_4 / d x_4$.

The line element is therefore

$$ds^2 = \cot^2 z\, dx_0^2 + e^{2a_4}\sin^{1/3}z\,(dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2
- b_4 e^{-2a_4}\sin^{1/3}z\,(dx_5^2 + dx_6^2 + dx_7^2) .$$

Read it term by term. A step $dx_1$ in 3-space has the proper length
$e^{a_4}\sin^{1/6} z\, dx_1$: when $a_4$ grows, 3-space **inflates**. A step $dx_5$
along an extra time has the proper duration $b_4^{1/2} e^{-a_4}\sin^{1/6} z\, dx_5$:
when $a_4$ grows and $b_4$ stays constant, the extra times **deflate
exponentially**. The time $x_4$ has the coefficient
$-1$, so a step $dx_4$ is a proper time interval of exactly $dx_4$: the clock of an
observer at rest shows $x_4$. The hidden direction has the coefficient $\cot^2 z$,
which depends on $x_0$ only.

The metric alone does not fix the functions $a_4(x_4)$ and $b_4(x_4)$; the field
equations of $a_4$ and $b_4$, derived later in the book, relate them to the energy
and the pressures of the matter that fills the spacetime (in the vacuum they force
$b_4$ to be constant). For the plots this notebook uses the simplest member of the
family, $a_4 = A H x_4$ and $b_4 = 1$, with the values of the Revision Kohn-Sham
work: $A = 1$ and the unit of length chosen so that $H = 1$. This history is a
**prescribed background** (it is assumed, not solved for). With $A > 0$ the function
$a_4$ increases, so the extra times deflate, as the author requires.
```

Text cell:

```
## 5. Reading the metric exactly as the author wrote it

First a technical step. While a cell runs, Jupyter sends what the cell prints to the
notebook in pieces, about one piece every 0.2 seconds, so where one piece ends and
the next begins depends on the speed of the computer. The tools that build this
book read the PASS line of a check together with the line under it that names the
Revision record, and they read the two correctly only when both arrive in the same
piece. The next cell therefore defines the function `in_one_piece(helper)`: it
returns a new function that does exactly what `helper` does, but lets `helper`
print into a text buffer in memory (an `io.StringIO`, with
```

‘contextlib.redirect_stdout‘) and then writes the whole buffer with one call of ‘sys.stdout.write‘, which arrives as one piece. (The stars in ‘*arguments‘ and ‘**options‘ pass on all the values the new function is given, whatever they are.) The cell then replaces the helpers ‘check‘ and ‘report‘ of the set-up cell by such functions. Nothing else changes: the same checks, the same PASS lines, the same numbers.

In [2]:

```
import contextlib  # redirect_stdout: send printed text into a buffer
import io  # StringIO: a text buffer in memory
import sys  # sys.stdout: the place where printed text goes

def in_one_piece(helper):
    """A function that does what helper does, with all the lines that helper prints
    written in one piece."""
    def helper_in_one_piece(*arguments, **options):
        collected = io.StringIO()  # an empty text buffer
        with contextlib.redirect_stdout(collected):  # print() writes into it
            helper(*arguments, **options)  # a failing check stops here, as before
        sys.stdout.write(collected.getvalue())  # all the lines with one write
    return helper_in_one_piece

check = in_one_piece(check)  # a PASS line and its record line stay together
report = in_one_piece(report)  # a long RESULT line and its second line, too
say("From now on check and report print each of their results in one piece.")
```

Out [2]:

```
From now on check and report print each of their results in one piece.
```

Text cell:

The Rust program ‘lovelock_gkd‘, which computed the curvature of this metric for the Revision record, stored the author’s text of the metric in its output file ‘Revision/gkd_lovelock/results/curvature.json‘ under the name ‘metricAsGiven‘. The next cell reads that file and prints the text, one row of the matrix per line (it only starts a new line after each ‘},‘ and changes nothing else). It is written in the language of Mathematica: ‘{...}‘ is a list (the whole matrix is a list of eight rows, each row a list of eight entries), ‘E^(...)‘ means e to the power $(...)$, ‘Sin[...]‘ and ‘Cot[...]‘ are the sine and the cotangent, ‘a4[x4]‘ and ‘b4[x4]‘ are the values of the functions a_4 and b_4 at x_4, and a blank between two factors means times. After the matrix the record adds, in brackets, where the text comes from.

The cell also defines the function ‘record_check(report_file, check_name, detail_part)‘. Some PASS lines below say that a result reproduces a named check of a Revision report (a JSON file with a list or a dictionary ‘checks‘, each check with its name, its verdict and a detail text). ‘record_check‘ opens the report, finds the

check with that name and stops the notebook with an error unless the check is there
and passed (and, if ‘detail_part‘ is given, its detail contains that text). Every
PASS line that names a check of a Revision report calls it first, so that a renamed,
missing or failing check in the record is caught.

In [3]:

```
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
from sympy.parsing.sympy_parser import (implicit_multiplication, parse_expr,
                                        standard_transformations)

def record_check(report_file, check_name, detail_part=""):
    """Return True when the Revision report report_file lists the check check_name
    as passed (and its detail contains detail_part); otherwise stop the notebook."""
    checks = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
    checks = checks["checks"]  # a dictionary or a list, depending on the report
    if isinstance(checks, dict):  # {name: {"passed": true, "detail": ...}}
        entry = checks.get(check_name, {})
        passed = entry.get("passed") is True
    else:  # [{"name": ..., "verdict": "PASS", "detail": ...}, ...]
        entry = next((e for e in checks if e.get("name") == check_name), {})
        passed = entry.get("verdict") == "PASS"
    if not passed or detail_part not in entry.get("detail", ""):
        raise AssertionError(f"record check failed: {report_file} does not list "
                             f"{check_name} as passed")
    return True

CURVATURE_RECORD = "Revision/gkd_lovelock/results/curvature.json"
record = json.loads(repository_file(CURVATURE_RECORD).read_text(encoding="utf-8"))

```

Text cell:

```
The next cell makes the **symbols** of the computation: the eight coordinates, the
constant $H$ (declared positive), the metric functions $a_4(x_4)$ and $b_4(x_4)$
(unknown functions of $x_4$, so that sympy can differentiate them; $b_4$ declared
positive), and five plain symbols that we use for printing: ‘a4p‘ and ‘b4p‘ stand for
$a_4'$ and $b_4'$, ‘a4v‘ and ‘b4v‘ for the values of $a_4$ and $b_4$, and ‘z‘ for
$6 H x_0$.
```

In [4]:

```
x0, x1, x2, x3, x4, x5, x6, x7 = sp.symbols("x0:8", real=True)  # 8 coordinates
COORDS = [x0, x1, x2, x3, x4, x5, x6, x7]
H = sp.symbols("H", positive=True)  # the constant of the author, H > 0
a4 = sp.Function("a4")(x4)  # the metric function a4: an unknown function of x4
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4 > 0 of x4
a4p, a4v = sp.symbols("a4p a4v", real=True)  # a4p = a4 prime, a4v = value of a4
b4p = sp.symbols("b4p", real=True)  # b4p = b4 prime
b4v = sp.symbols("b4v", positive=True)  # b4v = value of b4
z = sp.symbols("z", positive=True)  # z = 6 H x0, for printing

def plain(expression):
    """Write the derivatives of a4 and b4 as a4p and b4p, their values as a4v and
    b4v, and 6 H x0 as z."""
    expression = expression.subs(sp.Derivative(a4, x4), a4p).subs(a4, a4v)
    expression = expression.subs(sp.Derivative(b4, x4), b4p).subs(b4, b4v)
    return expression.subs(x0, z / (6 * H))  # then 6*H*x0 becomes z

say("Symbols: x0 ... x7, H > 0, the functions a4(x4) and b4(x4), and a4p, a4v, b4p, "
    "b4v, z for printing.")
```

Out [4]:

```
Symbols: x0 ... x7, H > 0, the functions a4(x4) and b4(x4), and a4p, a4v, b4p, b4v, z for
    printing.
```

Text cell:

```
The next cell turns the author's text into Python, one rule at a time, and lets
sympy read the result. Each ‘replace‘ changes one piece of Mathematica notation into
the Python notation that sympy understands: ‘exp^‘ (which an older text of the
author used) becomes ‘E^‘ (sympy's ‘E‘ is the number $e = 2.718\ldots$), the square
brackets of ‘Sin[6 H x0]‘ and ‘Cot[6 H x0]‘ become round brackets, ‘a4[x4]‘ and
‘b4[x4]‘ become ‘a4‘ and ‘b4‘ (which the dictionary ‘names‘ connects to the functions
```

```
$a_4(x_4)$ and $b_4(x_4)$), the curly brackets of the lists become square brackets,
and the power sign ‘^‘ becomes ‘**‘. The option ‘implicit_multiplication‘ reads a
blank between two factors as a multiplication, as Mathematica does: ‘6 H x0‘ means
$6 \cdot H \cdot x_0$.
```

In [5]:

```
text = author_text
text = text.replace("exp^", "E^")  # e to the power ...
text = text.replace("Sin[6 H x0]", "sin(6 H x0)")  # Mathematica [ ] -> Python ( )
text = text.replace("Cot[6 H x0]", "cot(6 H x0)")
text = text.replace("a4[x4]", "a4")  # the value of the function a4 at x4
text = text.replace("b4[x4]", "b4")  # the value of the function b4 at x4
text = text.replace("{", "[").replace("}", "]")  # Mathematica lists -> Python lists
text = text.replace("^", "**")  # Mathematica power ^ -> Python power **

PASS the 56 entries off the diagonal are zero: the metric is diagonal
```

Text cell:

```
Two independent checks of this reading follow. First, the next cell types the
metric a second time by hand, from the formula of section 4 of this notebook, and
checks that the two matrices agree entry by entry (the difference of every entry
simplifies to $0$). Second, it compares each diagonal entry with the entry that the
Rust program ‘lovelock_gkd‘ wrote into the record (‘metricDiagonal‘, in Mathematica
notation with explicit ‘*‘ signs). The small function ‘from_mathematica‘ translates
such a record entry into sympy with the same rules as above; the check that no
square bracket is left proves that every piece of notation was translated.
```

```
## 6. The determinant and the volume factor

The determinant of a diagonal matrix is the product of its diagonal entries:

$$\det g = \cot^2 z \cdot \bigl(e^{2a_4}\sin^{1/3}z\bigr)^3 \cdot (-1) \cdot
\bigl(-b_4 e^{-2a_4}\sin^{1/3}z\bigr)^3 .$$

Line by line: $\bigl(e^{2a_4}\sin^{1/3}z\bigr)^3 = e^{6a_4}\sin z$ (a power of a
product is the product of the powers); $\bigl(-b_4 e^{-2a_4}\sin^{1/3}z\bigr)^3 =
-b_4^3 e^{-6a_4}\sin z$ (an odd power keeps the minus sign); the two minus signs
multiply to $+1$ and $e^{6a_4} e^{-6a_4} = 1$, so $\det g = b_4^3 \sin^2 z \cot^2 z$;
and $\cot z = \cos z / \sin z$ gives $\det g = b_4^3 \cos^2 z$. On the patch
$0 < z < \pi/2$ the cosine is positive, so $\sqrt{|\det g|} = b_4^{3/2} \cos z$.
The function $a_4$ has dropped out: the volume factor changes with time only through
```

```
$b_4$, and not at all when $b_4$ is constant. The next cell lets sympy do the same and
compares with the record (‘sqrtAbsDetG‘, written there as
‘Sin[6*H*x0]*Cot[6*H*x0]*b4[x4]^(3/2)‘); then it compares numbers at seven points with
$b_4 = 1$.
```

In [7]:

```

## 7. The signature (4,4)

For a diagonal matrix the eigenvalues are the diagonal entries, so the signature is
read off the signs of the eight entries. The next cell turns the eight entries into
fast numerical functions of $z$ and of the values of $a_4$ and $b_4$
(‘sp.lambdify‘), evaluates them on a grid of 400 values of $z$ strictly inside the
patch, 13 values of $a_4$ from $-3$ to $3$ and the three values $b_4 = 0.5$, 1 and 2,
and checks that the sign pattern is always that of $\eta = (+,+,+,+,-,-,-,-)$: four
positive and four negative entries. It also checks two vectors: a step along $x_1$ has
a positive squared length (space-like), a step along $x_5$ a negative one
(time-like).
```

In [8]:

```
ETA = np.array([1, 1, 1, 1, -1, -1, -1, -1])  # the flat metric diag(+,+,+,+,-,-,-,-)

## 8. The vielbein: the scale factor of each direction

Write each diagonal entry as a sign times a square: $g_{\mu\mu} = \eta_{\mu\mu}
h_\mu^2$ with a positive **scale factor** $h_\mu$. On the patch all the factors below
are positive (and $\cot z > 0$), so

$$h = \bigl(\cot z,\ e^{a_4}\sin^{1/6}z,\ e^{a_4}\sin^{1/6}z,\ e^{a_4}\sin^{1/6}z,\
1,\ b_4^{1/2}e^{-a_4}\sin^{1/6}z,\ b_4^{1/2}e^{-a_4}\sin^{1/6}z,\
b_4^{1/2}e^{-a_4}\sin^{1/6}z\bigr).$$

The diagonal matrix of these numbers is the **vielbein** $e^a{}_\mu$ used for the
```

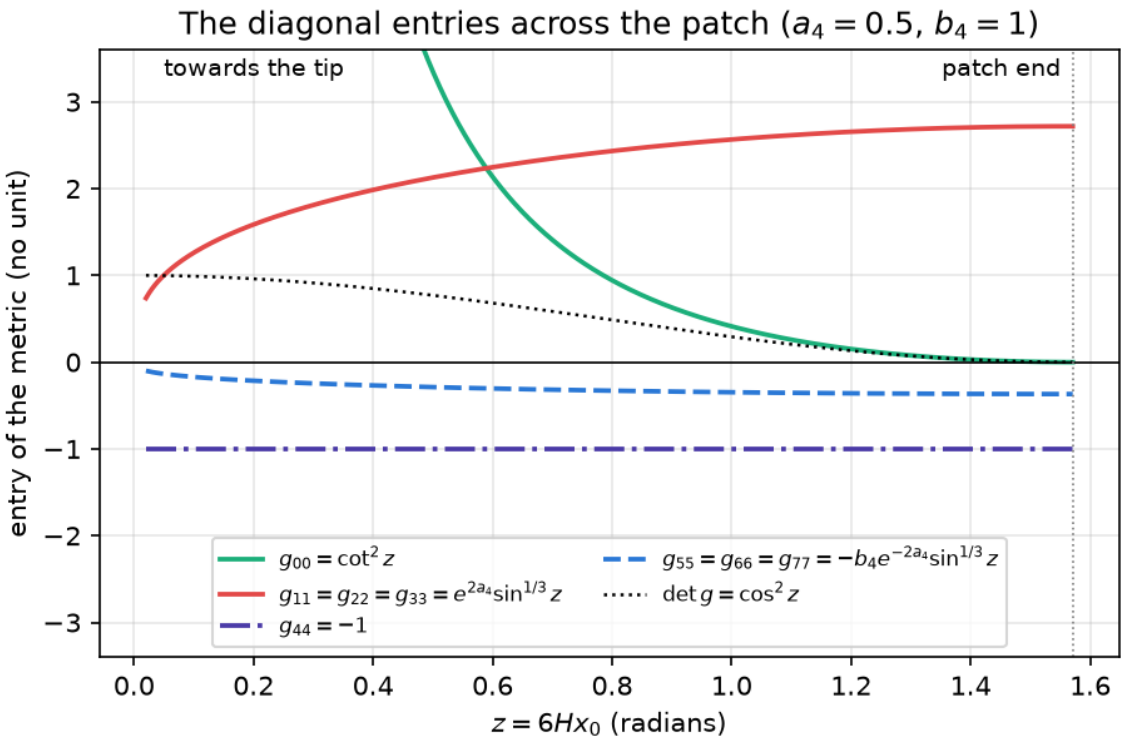

Figure 93: The diagonal entries of the author's metric as functions of $z = 6Hx_0$ from the tip side to the patch end $z = \pi/2$, for $a_4 = 0.5$ and $b_4 = 1$; horizontal axis z in radians, vertical axis the value of the entry (pure numbers). The three 3-space entries (solid red) stay positive and the three extra-time entries (dashed blue) and the time entry (dash-dotted) stay negative everywhere, so the signature is (4,4) at every point; the hidden entry $\cot^2 z$ (aqua) grows without bound towards the tip and reaches 0 at the patch end, where the determinant $\cos^2 z$ (dotted) also vanishes. (Notebook 03a, figure 2.)

spinors later in the book. The next cell checks $\eta_{\mu\mu} h_\mu^2 = g_{\mu\mu}$ for all eight directions; the lead's independent check of the Revision record did the same.

In [11]:

```

```
## 9. The expansion rate of each direction

The proper length of a coordinate interval $\Delta x_\mu$ is $h_\mu \Delta x_\mu$.
Its relative growth per unit time is $\partial_{x_4} \ln h_\mu$. For 3-space,
$\ln h_1 = a_4 + \tfrac16 \ln \sin z$, and only $a_4$ depends on $x_4$, so the rate
is $a_4'$; for an extra time $\ln h_5 = \tfrac12 \ln b_4 - a_4 + \tfrac16 \ln \sin z$
and the rate is $-a_4' + b_4'/(2b_4)$; $h_0$ and $h_4$ do not depend on $x_4$, so their
rates are $0$. The next cell lets sympy differentiate. It also checks that the six
transverse scale factors multiply to $b_4^{3/2} \sin z$, without $a_4$: what 3-space
gains, the extra times lose.
```

In [12]:

```
rates = [sp.simplify(sp.diff(sp.log(h[k]), x4)) for k in range(8)]

## 10. The deflating history of the Revision Kohn-Sham work

The next cell reads the parameters of the Revision Kohn-Sham solver
(‘Revision/kohn_sham/results/parameters.json‘): the constant $H$, the slope $A$ of
the history $a_4 = A H x_4$, the five values of $a_4$ (the **slices**) at which that
solver computes its states, and the tip cut-off $L$ (used in section 13 of this
notebook). It also reads the theory record of that work
(‘Revision/kohn_sham/ks-theory.json‘) and prints the first and the last sentence of
its statement about the **status of the history** (key ‘historyStatus‘). The
sentence in between, not printed, says why: the field equations of $a_4$ allow the
history $a_4 = A H x_4$ only for a source with equal pressures in all directions
and a constant energy density, and the Kohn-Sham states computed along it do not
have these properties. So the history is assumed, not derived; this notebook uses
it only to draw the time dependence of the metric.
```

In [13]:

```
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
parameters = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))

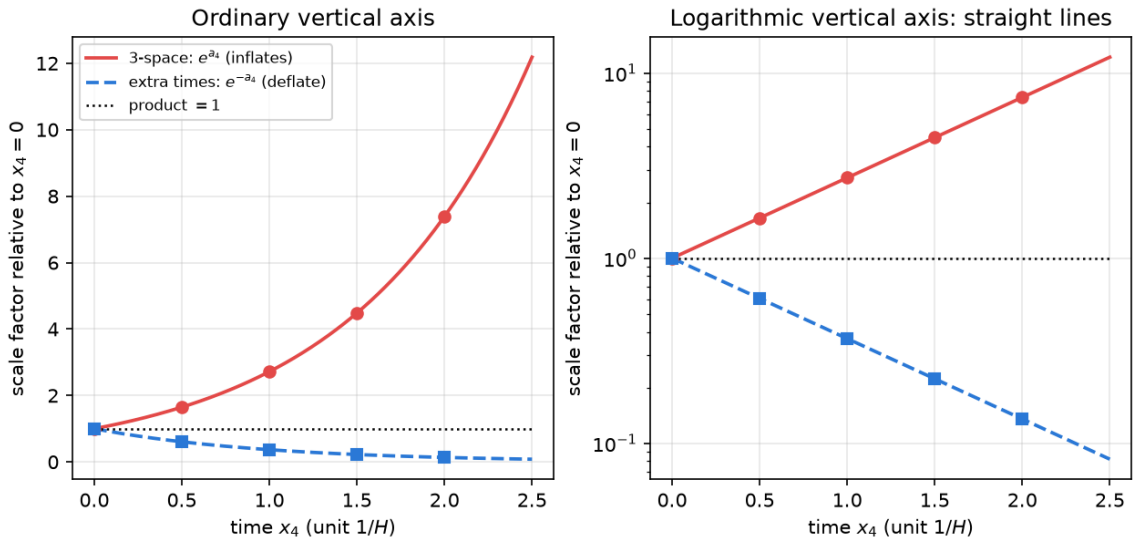

Figure 94: The time dependence of the scale factors along the deflating history $a_4 = AHx_4$, $b_4 = 1$ with $A = 1$, $H = 1$ of the Revision Kohn-Sham work: 3-space e^{a_4} (solid red), the three extra times e^{-a_4} (dashed blue) and their product (dotted black), on an ordinary (left) and a logarithmic (right) vertical axis; horizontal axis the time x_4 in units of $1/H$, vertical axis the factor by which lengths have grown since $x_4 = 0$ (a pure number). Dots and squares mark the five slices $a_4 = 0, 0.5, 1, 1.5, 2$. 3-space grows by $e^2 = 7.39$ and the extra times shrink to $e^{-2} = 0.135$; on the logarithmic axis both are straight lines with slopes $+1$ and -1, the product stays 1. (Notebook 03a, figure 3.)

## 11. The hidden direction: the functions of $z$

The scale factors also depend on the hidden direction through $z$. The six
transverse directions share the warp factor $W = \sin^{1/6} z$ (their metric
entries share its square $W^2 = \sin^{1/3} z$), and the hidden direction itself
has the scale factor $\cot z$ (its metric entry is $\cot^2 z$). The next cell draws
these four functions across the patch: the first two on an ordinary axis (they lie
between 0 and 1 and reach 1 at the patch end), the last two on a logarithmic axis
(they grow without bound at the tip and vanish at the patch end).

## 12. Proper volumes: 3-space inflates, the extra times deflate, the 7-volume stays

Take a box with coordinate edges $\Delta x_1 = \Delta x_2 = \Delta x_3 = 1$. Its
proper 3-volume is the product of the three scale factors,
$V_3 = (e^{a_4}\sin^{1/6}z)^3 = e^{3a_4}\sin^{1/2}z$. The same box in the three extra
times has the proper 3-volume $V_t = b_4^{3/2} e^{-3a_4}\sin^{1/2}z$, and
$V_3 V_t = b_4^{3/2} \sin z$. The slice $x_4 = \mathrm{const}$ is 7-dimensional
($x_0, x_1, x_2, x_3, x_5, x_6, x_7$); its volume factor is the product of the seven
scale factors other than $h_4 = 1$, which is $b_4^{3/2} \sin z \cot z =
b_4^{3/2} \cos z$: it changes with $x_4$ only through $b_4$, and not at all when $b_4$
is constant. The next cell computes these products and, at $b_4 = 1$, by an integral
over the whole patch $0 < x_0 < \pi/(12H)$, the proper 7-volume of the patch per unit
coordinate volume of the six transverse directions:
$\int_0^{\pi/(12H)} \cos(6Hx_0)\, dx_0 = \bigl[\sin(6Hx_0)/(6H)\bigr]_0^{\pi/(12H)}
= 1/(6H)$ (for a constant $b_4$ it is $b_4^{3/2}/(6H)$).
```

## 13. The hidden coordinate $y$ and the warped form of the metric

The entry $\cot^2 z$ makes the hidden direction awkward. The Revision Kohn-Sham work
uses the coordinate $y = \ln(\sin z)/(6H)$, which measures proper distance along
$x_0$. Line by line: the chain rule gives
$dy/dx_0 = \frac{1}{6H}\,\frac{\cos z}{\sin z}\, 6H = \cot z$, so
$dy^2 = \cot^2 z\, dx_0^2 = g_{00}\, dx_0^2$. Next, $6Hy = \ln \sin z$ gives
$\sin z = e^{6Hy}$ ($e$ to the power of both sides), so the warp factor is
$W = \sin^{1/6} z = e^{Hy}$ and its square is $W^2 = \sin^{1/3} z = e^{2Hy}$. Hence
the **warped form**

$$ds^2 = dy^2 - dx_4^2 + W^2\bigl[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2)
```

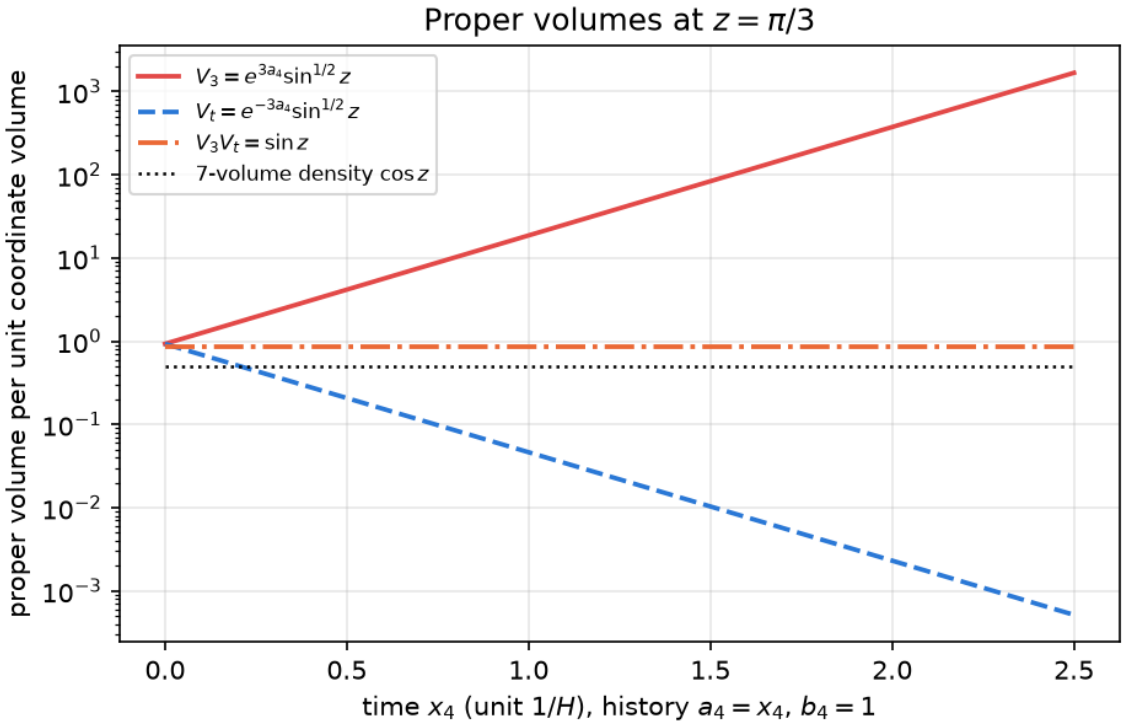

Figure 97: Proper volumes per unit coordinate volume at the fixed hidden position $z = \pi/3$ along the history $a_4 = x_4$, $b_4 = 1$, on a logarithmic vertical axis; horizontal axis the time x_4 in units of $1/H$. The proper 3-volume of 3-space V_3 (solid red) grows like e^{3x_4}, the proper 3-volume of the three extra times V_t (dashed blue) shrinks like e^{-3x_4}, and both their product $\sin z = 0.866$ (dash-dotted) and the density $\cos z = 0.5$ of the proper 7-volume (dotted) stay constant: the inflation of 3-space is exactly compensated by the deflation of the extra times. (Notebook 03a, figure 6.)

```
- b_4 e^{-2a_4}(dx_5^2 + dx_6^2 + dx_7^2)\bigr], \qquad W = e^{Hy}.$$

As $z$ runs from $0$ to $\pi/2$, $y$ runs from $-\infty$ (the tip) to $0$ (the patch
end). In the coordinates $(y, x_1, \dots, x_7)$ the scale factor of the hidden
direction is $1$, so the volume factor is the product of the six transverse scale
factors, $b_4^{3/2} W^6 = b_4^{3/2} e^{6Hy} = b_4^{3/2} \sin z$. The Kohn-Sham record
works at $b_4 = 1$, where these are $W^6 = e^{6Hy} = \sin z$.

The next cell prints four statements of the record
‘Revision/kohn_sham/ks-theory.json‘ (read in section 10): the definition of $y$, the
line element, the warp factor and the volume factor. Then it checks them with sympy;
the checks of the warp factor and of the volume factor also require that the record
still writes them as ‘W(y) = e^{Hy}‘ and as a text that starts with
‘e^{6Hy} (= cos z‘.
To write the metric in the coordinate $y$ it uses the inverse relation
$x_0 = \arcsin(e^{6Hy})/(6H)$: the hidden entry becomes $g_{00}\,(dx_0/dy)^2$
(because $dx_0 = (dx_0/dy)\,dy$), and the seven entries $g_{11}, \dots, g_{77}$ only
need $\sin z = e^{6Hy}$ put in. The record's line element is the case $b_4 = 1$; the
cell checks the warped form for every $b_4$ and compares with the record at $b_4 = 1$.
```

Text cell:

```
The Revision Kohn-Sham solver keeps only the part $-L \le y \le 0$ of the hidden
direction, with the tip cut-off $L = 3/H$ read in section 10. How much of the
7-volume does the cut-off remove? In $y$ the 7-volume density is $b_4^{3/2} e^{6Hy}$,
and the constant factor $b_4^{3/2}$ cancels in a fraction, so the
fraction of the 7-volume beyond the cut-off is
$\int_{-\infty}^{-L} e^{6Hy} dy \big/ \int_{-\infty}^{0} e^{6Hy} dy = e^{-6HL}$,
which is $e^{-18} \approx 1.5 \times 10^{-8}$ for $L = 3/H$. The cut-off lies at the
tiny angle $z = \arcsin e^{-18} \approx 1.5 \times 10^{-8}$. The next cell computes
the fraction with sympy and draws $y$ as a function of $z$ (left; the $z$ axis is
logarithmic, so that the region near the tip is visible: there
$y \approx \ln(z)/(6H)$ is a straight line) and the warp factor $W = e^{Hy}$, its
square $W^2 = e^{2Hy}$ and the volume density $W^6 = e^{6Hy}$ as functions of $y$
(right).

## 14. The last check

The last cell checks that the seven figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [21]:

```
figure_names = ["metric_heat_map", "diagonal_entries", "history_scale_factors",
                "hidden_direction", "scale_factor_maps", "proper_volumes",
                "hidden_coordinate_y"]
files = [output_file(f"{FIGURE_FOLDER}/03a_{k}_{n}.png")
         for k, n in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all seven figure files exist")
all_checks_passed()
```

Out [21]:

```
PASS all seven figure files exist
ALL 29 CHECKS PASSED (notebook 03a)
```

Text cell:

```
## 15. What this notebook showed

- The metric was read **exactly as the author typed it**, and the text agrees with
  the formula and with the Revision record of the Rust program ‘lovelock_gkd‘
  (all 8 diagonal entries; the 56 other entries are zero).
- $\det g = b_4^3 \cos^2 z$ and $\sqrt{|\det g|} = b_4^{3/2} \cos z$, without $a_4$:
  PROVED here by exact algebra (and in the Revision record).
- The signature is (4,4) at every point of the patch: $x_0, x_1, x_2, x_3$ are
  space-like, $x_4, x_5, x_6, x_7$ time-like.
- The diagonal vielbein $h = (\cot z, e^{a_4}\sin^{1/6}z\ (\times 3), 1,
  b_4^{1/2} e^{-a_4}\sin^{1/6}z\ (\times 3))$ reproduces the metric.
- 3-space expands with the rate $a_4'$ and the three extra times **deflate** with the
  rate $-a_4' + b_4'/(2b_4)$; along the prescribed history $a_4 = x_4$, $b_4 = 1$
  ($A = 1$, $H = 1$) 3-space
  lengths grow by $e^2 = 7.39$ and extra-time durations shrink to $e^{-2} = 0.135$
  between the first and the last slice.
- The proper 3-volume of 3-space grows like $e^{3a_4}$, that of the extra times
  shrinks like $b_4^{3/2} e^{-3a_4}$, and the 7-volume density $b_4^{3/2} \cos z$ is
  constant in time when $b_4$ is; at $b_4 = 1$ the whole patch has the 7-volume
  $1/(6H)$ per unit transverse coordinate volume.
- In the hidden coordinate $y = \ln(\sin z)/(6H)$ the metric has the warped form
  of the Revision record, with the warp factor $W = e^{Hy}$ and the volume factor
  $W^6 = e^{6Hy}$; the tip is at infinite proper distance, and the tip
  cut-off $y = -3/H$ of the Kohn-Sham solver removes only the fraction $e^{-18}$ of
  the 7-volume.
- ASSUMED: the history $a_4 = A H x_4$, $b_4 = 1$ is a prescribed background (the
  Revision
  record says so in its own words), used here only to draw the time dependence; the
  field equations of $a_4$ come later.
```

3.13 Line-by-line walk-through of Notebook 03a

The notebook has 21 code cells, In [1] to In [21]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted and then explained. A line that starts with **#** is a **comment**, which Python skips; it is there for the reader. In the quoted code a line **...** stands for the remaining lines of a long figure caption; every caption is printed in full under its figure in Section 3.12, and a paragraph "What Figure 03a.k shows" after the code says what to look for.

In [1], the set-up cell. Its first part is the complete run instructions of Section 3.11 again, as comment lines, so that the notebook file carries its own instructions. The code starts below the line that announces THE SET-UP. The set-up code is the same in every notebook of the book except for one line (the notebook's name); we explain it here once, and the walk-throughs of Notebooks 03c, 03b and 03d refer back to this explanation.

```
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ================================================================================
```

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json` reads and writes the text format JSON, in which the Revision record stores its results; `os` gives access to the computer's environment; `textwrap` breaks long text into lines; `from pathlib import Path` takes the single name `Path` out of the module `pathlib`. A `Path` is the address of a file or a folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "03a"  # this notebook: chapter 03, example a
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell. A **variable** is a name for a value: the last line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"03a"`. It is the only line of the set-up code that differs between notebooks.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description that Python stores but does not run. `Path.cwd()` is the folder in which the notebook runs and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with all of them (the star unpacks one list into another). The `for` loop takes these folders one after the other; the operator `/` joins a folder and a name into a longer path; `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
```

```
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

`REPO` is the repository folder. `os.environ` holds the **environment variables** of the running program (named texts that the computer hands to it); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and otherwise the default, the repository folder written as a string. When you run the notebook the variable is not set, so the notebook writes into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` gives the full path of a repository file, for reading a Revision record. `output_file("Revision/...")` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder that will hold it (and any missing folder above it) and does nothing if it exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))

matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`say` prints a text in lines of at most 89 characters; `textwrap.fill` breaks it at blanks, and every line after the first starts with four blanks. `matplotlib.rcdefaults()` returns to matplotlib's built-in settings, so that a personal settings file cannot change the figures. `plt.rcParams.update({...})` then sets, for every figure of the notebook, the size (7.0 by 4.2 inches), the size of the letters (10 points) and a faint grid (30 per cent opaque). The braces make a **dictionary**: pairs `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/03a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, and a cell that is run twice keeps its numbers. The file name joins the notebook id, the number and the name, for example `03a_1_metric_heat_map.png`. `fig.savefig` writes the PNG file with 150 dots per inch, without an empty margin and without the program's name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory. The caption is stored, and the whole dictionary of captions is written into the captions file (`json.dumps` turns it into JSON text with sorted keys). `display(Image(...))` shows the saved picture below the cell; its `metadata` tells the book's tools which file it is. The last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection in square brackets). `check` is the function behind every check of the book. `condition` is either `True` or `False`; if it is false, `raise AssertionError(...)` stops the notebook with an error that names the check. Otherwise the name is appended to `PASSED` and the line PASS followed by the name is printed. `record=None` makes the third argument optional; a check that reproduces a Revision record passes the record's file and check name, and a second line names them.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a RESULT line; the expression in round brackets adds a blank and the unit when a unit is given and nothing otherwise. `all_checks_passed` prints the last line of the notebook; `len(PASSED)` is the number of checks that passed. The last statement prints the one output line of In [1].

In [2], every result in one piece. While a cell runs, Jupyter receives what it prints in pieces, about one piece every 0.2 seconds; where one piece ends depends on the speed of the computer. The book's tools read a PASS line together with the line under it that names the Revision record, and they read the two correctly only when both arrive in the same piece. This cell makes sure that they do.

```
import contextlib  # redirect_stdout: send printed text into a buffer
import io  # StringIO: a text buffer in memory
import sys  # sys.stdout: the place where printed text goes
```

Three modules of Python: `contextlib` holds `redirect_stdout`, which sends everything that `print` writes to another place; `io` holds `StringIO`, a text buffer in memory; `sys.stdout` is the normal destination of printed text.

```
def in_one_piece(helper):
    """A function that does what helper does, with all the lines that helper prints
    written in one piece."""
    def helper_in_one_piece(*arguments, **options):
        collected = io.StringIO()  # an empty text buffer
        with contextlib.redirect_stdout(collected):  # print() writes into it
            helper(*arguments, **options)  # a failing check stops here, as before
        sys.stdout.write(collected.getvalue())  # all the lines with one write
    return helper_in_one_piece
```

`in_one_piece` takes a function `helper` and returns a new function, `helper_in_one_piece`, defined inside it. The stars in `*arguments` and `**options` collect whatever values the new function is called with and pass all of them on to `helper` unchanged. Inside, `collected` is an empty buffer; the `with` block redirects printing into it while `helper` runs, so the PASS line and the record line land in the buffer; if the check fails, the `AssertionError` stops everything here exactly as before. After the block, `sys.stdout.write` writes the whole buffer at once, which reaches Jupyter as one piece.

```
check = in_one_piece(check)  # a PASS line and its record line stay together
report = in_one_piece(report)  # a long RESULT line and its second line, too
say("From now on check and report print each of their results in one piece.")
```

The names `check` and `report` now stand for the wrapped functions. They print the same lines as before; only the timing of the printing changes. The last line prints the output of In [2].

In [3], the author's text.

```
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
from sympy.parsing.sympy_parser import (implicit_multiplication, parse_expr,
                                        standard_transformations)
```

numpy (short name `np`) works with **arrays**, lists of numbers on which arithmetic acts entry by entry; sympy (short name `sp`) does exact algebra with symbols. `parse_expr` turns a text such as `"2*x + 1"` into a sympy expression; `standard_transformations` and `implicit_multiplication` are reading rules for it (explained at In [5]).

```
def record_check(report_file, check_name, detail_part=""):
    checks = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
    checks = checks["checks"]  # a dictionary or a list, depending on the report
```

Several PASS lines of this notebook say that a result reproduces a named check of a Revision report. A **report** is a JSON file in which a program of the Revision record lists the checks it ran, each with its name, its verdict and a short detail text. The function `record_check` makes sure that such a check really exists and passed; without it, a PASS line could name a check that has since been renamed, removed or failed. Its three **parameters** (the names in brackets, which receive the values given in a call) are the report file, the name of the check and an optional piece of text `detail_part`; `=""` makes the empty text its default, used when a call gives only two values. (Its docstring, a description in triple quotes under the `def` line, is not printed here; In [1] explained docstrings.) The first line reads the report into a dictionary, as for the record above; the second keeps only its entry `"checks"`. The reports of the Revision record store their checks in one of two ways, and the function accepts both.

```
    if isinstance(checks, dict):  # {name: {"passed": true, "detail": ...}}
        entry = checks.get(check_name, {})
        passed = entry.get("passed") is True
```

`isinstance(checks, dict)` is true when the checks form a dictionary whose keys are the check names (the Rust program writes them so). Then `checks.get(check_name, {})` is the entry of

that name, or an empty dictionary `{}` if there is none, and the check counts as passed only if the entry's `"passed"` is exactly `True` (`is True` compares with the value `True` itself). For a missing entry, `entry.get("passed")` gives `None`, which is not `True`.

```
    else:  # [{"name": ..., "verdict": "PASS", "detail": ...}, ...]
        entry = next((e for e in checks if e.get("name") == check_name), {})
        passed = entry.get("verdict") == "PASS"
```

Otherwise the checks form a list of dictionaries, each with its own `"name"` (the Python programs and the lead checks write them so). `(e for e in checks if ...)` runs through the list and keeps the entries with the wanted name; `next(..., {})` takes the first of them, or `{}` if there is none. The check counts as passed only if its `"verdict"` is the text `"PASS"`.

```
    if not passed or detail_part not in entry.get("detail", ""):
        raise AssertionError(f"record check failed: {report_file} does not list "
                             f"{check_name} as passed")
    return True
```

If the check did not pass, or its detail text does not contain `detail_part`, `raise AssertionError(...)` stops the notebook with an error message that names the report and the check (every text contains the empty text, so without a `detail_part` only the verdict matters). Otherwise the function returns `True`. It prints nothing, so it adds no PASS line and does not change the number of checks; it only guarantees that each record line printed under a PASS line names a check that exists and passed. Notebook 03b uses the same function.

```
CURVATURE_RECORD = "Revision/gkd_lovelock/results/curvature.json"
record = json.loads(repository_file(CURVATURE_RECORD).read_text(encoding="utf-8"))
# the metric exactly as the author typed it, then a note in brackets
author_text, note = record["metricAsGiven"].split("}} ", 1)
author_text += "}}"  # the two closing brackets that split removed
say(f"The metric as the author wrote it ({len(author_text)} characters):")
for line in author_text.replace("},", "},\n").split("\n"):  # one row per line
    print(line)
say("The note of the record: " + note)
```

The first line names the record file. The second reads the file as text (`read_text`) and turns the JSON text into a Python dictionary (`json.loads`). `record["metricAsGiven"]` is the author's text of the metric followed by a note in brackets. `split("}} ", 1)` cuts this text once, at the first `}}` followed by a blank: `author_text` gets the matrix (without its two closing braces, which the split removed and `+= "}}"` puts back) and `note` the note. The matrix is 359 characters long, as the output shows. The loop prints it with one row of the matrix per line: `replace("},", "},\n")` puts a line break (`\n`) after every row and `split("\n")` cuts the text at the breaks. The output is the matrix of Section 3.5, in the author's order $x_0, x_1, \ldots, x_7$, with the two functions `a4[x4]` and `b4[x4]`; the last line prints the note, which says that $b_4 = 1$ gives the metric used before 2026-10-14.

In [4], the symbols.

```
x0, x1, x2, x3, x4, x5, x6, x7 = sp.symbols("x0:8", real=True)  # 8 coordinates
COORDS = [x0, x1, x2, x3, x4, x5, x6, x7]
```

```
H = sp.symbols("H", positive=True)  # the constant of the author, H > 0
a4 = sp.Function("a4")(x4)  # the metric function a4: an unknown function of x4
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4 > 0 of x4
a4p, a4v = sp.symbols("a4p a4v", real=True)  # a4p = a4 prime, a4v = value of a4
b4p = sp.symbols("b4p", real=True)  # b4p = b4 prime
b4v = sp.symbols("b4v", positive=True)  # b4v = value of b4
z = sp.symbols("z", positive=True)  # z = 6 H x0, for printing
```

`sp.symbols("x0:8", real=True)` makes the eight symbols `x0`, ..., `x7` (the range `0:8` means 0 to 7), declared real; `COORDS` is their list, in the author's order, so that `COORDS[k]` is x_k. `H` is declared positive, which lets sympy simplify, for example, $\sqrt{H^2} = H$. `sp.Function("a4")(x4)` is an unknown function of `x4`: sympy can differentiate it (giving a_4') without knowing it. `b4` is the second metric function, declared positive (`positive=True`), so that sympy may write $\sqrt{b_4^3} = b_4^{3/2}$. `a4p`, `a4v`, `b4p`, `b4v` and `z` are plain symbols used only for printing.

```
def plain(expression):
    """Write the derivatives of a4 and b4 as a4p and b4p, their values as a4v and
    b4v, and 6 H x0 as z."""
    expression = expression.subs(sp.Derivative(a4, x4), a4p).subs(a4, a4v)
    expression = expression.subs(sp.Derivative(b4, x4), b4p).subs(b4, b4v)
    return expression.subs(x0, z / (6 * H))  # then 6*H*x0 becomes z

say("Symbols: x0 ... x7, H > 0, the functions a4(x4) and b4(x4), and a4p, a4v, b4p, "
    "b4v, z for printing.")
```

`plain` rewrites an expression for printing: `.subs(old, new)` replaces `old` by `new`, first the derivative a_4' by `a4p`, then the function value by `a4v`, the same for b_4 (`b4p`, `b4v`); then x_0 by $z/(6H)$, so that $6Hx_0$ becomes z. The derivative is replaced before the value: otherwise the value inside the derivative would be replaced first and the derivative would no longer be recognised. The last line prints the output of In [4].

In [5], the text becomes a matrix.

```
text = author_text
text = text.replace("exp^", "E^")  # e to the power ...
text = text.replace("Sin[6 H x0]", "sin(6 H x0)")  # Mathematica [ ] -> Python ( )
text = text.replace("Cot[6 H x0]", "cot(6 H x0)")
text = text.replace("a4[x4]", "a4")  # the value of the function a4 at x4
text = text.replace("b4[x4]", "b4")  # the value of the function b4 at x4
text = text.replace("{", "[").replace("}", "]")  # Mathematica lists -> Python lists
text = text.replace("^", "**")  # Mathematica power ^ -> Python power **
```

Eight replacements translate Mathematica into Python, one rule each: `exp^` becomes `E^` (sympy's `E` is the number $e = 2.718\ldots$; the record's text already writes `E^`, and the rule is kept so that a text written with `exp^` is read the same way); the square brackets of the sine and the cotangent become round brackets; `a4[x4]` becomes `a4` and `b4[x4]` becomes `b4`; the braces of lists become square brackets (a Python list); the power sign `^` becomes `**`. The order matters: the square brackets of the functions are translated before any other bracket.

```
names = {"E": sp.E, "a4": a4, "b4": b4, "H": H, "x0": x0, "sin": sp.sin,
         "cot": sp.cot}
rows = parse_expr(text, local_dict=names,
                  transformations=standard_transformations + (implicit_multiplication,))
g = sp.Matrix(rows)  # the metric of the author as an exact 8 x 8 sympy matrix
```

The dictionary `names` tells `parse_expr` what each name in the text means: `a4` and `b4` are the functions $a_4(x_4)$ and $b_4(x_4)$, `H` and `x0` the symbols, `sin` and `cot` sympy's functions. `implicit_multiplication` reads a blank between two factors as a product, as Mathematica does (`6 H x0` is $6 \cdot H \cdot x_0$). The result `rows` is a list of eight lists, and `sp.Matrix(rows)` makes the exact 8×8 matrix `g`.

```
say(f"The matrix has {g.rows} rows and {g.cols} columns. Its diagonal entries:")
for k in range(8):
    say(f"  g[x{k}, x{k}] = {g[k, k]}")
off_diagonal = [g[i, j] for i in range(8) for j in range(8) if i != j]
check(all(entry == 0 for entry in off_diagonal),
      "the 56 entries off the diagonal are zero: the metric is diagonal")
```

The loop prints the eight diagonal entries; `range(8)` runs over $k = 0, \ldots, 7$ and `g[k, k]` is the entry in row k and column k, printed with the author's name `x{k}` (row k belongs to x_k). `off_diagonal` is a **list comprehension**, a list built by a loop inside square brackets: the $64-8 = 56$ entries with $i \neq j$. `all(...)` is true when every one of them is zero: the first PASS line. The output shows the diagonal of Section 3.5, written by sympy (`exp(2*a4(x4))*sin(6*H*x0)**(1/3)` is $e^{2a_4} \sin^{1/3}(6Hx_0)$, and `-b4(x4)*exp(-2*a4(x4))*sin(6*H*x0)**(1/3)` is $-b_4 e^{-2a_4} \sin^{1/3}(6Hx_0)$).

In [6], two independent checks of the reading.

```
warp = sp.sin(6 * H * x0) ** sp.Rational(1, 3)  # sin(z)^(1/3), Rational: exact 1/3
typed = sp.diag(sp.cot(6 * H * x0) ** 2,  # the author's order x0, x1, ..., x7
                sp.exp(2 * a4) * warp, sp.exp(2 * a4) * warp, sp.exp(2 * a4) * warp,
                -1,
                -b4 * sp.exp(-2 * a4) * warp, -b4 * sp.exp(-2 * a4) * warp,
                -b4 * sp.exp(-2 * a4) * warp)
difference = (g - typed).applyfunc(sp.simplify)  # simplify every entry
check(difference == sp.zeros(8, 8),
      "the text of the author equals the metric typed by hand from the formula")
```

`sp.Rational(1, 3)` is the exact fraction 1/3 (the Python number `1/3` would be rounded). `warp` is $\sin^{1/3} z$, the square W^2 of the warp factor. `sp.diag(...)` builds the diagonal matrix of the formula of Section 3.5, typed by hand in the author's order: first the hidden entry $\cot^2 z$, then the three 3-space entries, the time entry -1 and the three extra-time entries with the factor b_4. `applyfunc(sp.simplify)` simplifies every entry of the difference, and the check requires the 8×8 zero matrix `sp.zeros(8, 8)`: the reading of the text agrees with the formula.

```
def from_mathematica(entry_text):
    """A record entry in Mathematica notation, as a sympy expression."""
    t = entry_text.replace("Sin[6*H*x0]", "sin(6*H*x0)")
    t = t.replace("Cot[6*H*x0]", "cot(6*H*x0)")
```

```
    t = t.replace("a4[x4]", "a4").replace("b4[x4]", "b4").replace("^", "**")
    if "[" in t or "]" in t:  # a piece of notation that was not translated
        raise ValueError(f"cannot translate {entry_text}")
    return parse_expr(t, local_dict=names)
```

The record also stores the diagonal entries one by one (`metricDiagonal`), in Mathematica notation with explicit `*` signs, for example `E^(2*a4[x4])*Sin[6*H*x0]^(1/3)` and `-E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*b4[x4]`. `from_mathematica` translates such an entry with the same rules. If a square bracket is left, some notation was not translated, and the function stops with a `ValueError` instead of misreading it silently.

```
agree = [sp.simplify(g[k, k] - from_mathematica(entry)) == 0
         for k, entry in enumerate(record["metricDiagonal"])]
check(len(agree) == 8 and all(agree),
      "the 8 diagonal entries equal those of the Rust program lovelock_gkd",
      record=f"{CURVATURE_RECORD}, metricDiagonal")
```

`enumerate` hands out each record entry with its position k. For each, the difference between our entry and the translated record entry is simplified and compared with 0. The check requires eight agreements and prints the PASS line with the record line under it.

In [7], the determinant and the volume factor (Section 3.6).

```
det_g = g.det()  # the product of the diagonal entries; sympy cancels exp(6 a4)
say(f"det g = {plain(det_g)}")
record_check("Revision/gkd_lovelock/results/python-lovelock-report.json",
             "sqrt_abs_det_g", "det g = b4^3 cos^2(6 H x0) exactly")  # stops if not
check(sp.simplify(det_g - b4 ** 3 * sp.cos(6 * H * x0) ** 2) == 0,
      "det g = b4^3 cos(z)^2: the function a4 drops out",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "check sqrt_abs_det_g")
```

`g.det()` is the determinant. It prints as `b4v**3*sin(z)**2*cot(z)**2`, the fourth line of the derivation of Section 3.6. `record_check` (In [3]) then confirms that the independent verification of the record lists its check `sqrt_abs_det_g` as passed and that the detail of that check contains the text `det g = b4^3 cos^2(6 H x0) exactly`; otherwise the notebook stops here. The check confirms that our determinant equals $b_4^3 \cos^2 z$. The function a_4 is gone; b_4 stays, with the power 3, once for each extra time. The two strings of the `record=` argument are written next to each other, which Python joins into one string.

```
# sqrt|det g| on the patch, where cos z > 0 and b4 > 0
volume_factor = b4 ** sp.Rational(3, 2) * sp.cos(6 * H * x0)
check(sp.simplify(from_mathematica(record["sqrtAbsDetG"]) - volume_factor) == 0,
      "sqrt|det g| = b4^(3/2) sin(z) cot(z) = b4^(3/2) cos(z)",
      record=f"{CURVATURE_RECORD}, sqrtAbsDetG")
```

The record writes the volume factor as `Sin[6*H*x0]*Cot[6*H*x0]*b4[x4]^(3/2)`; translated and simplified, it equals $b_4^{3/2} \cos z$ (`sp.Rational(3, 2)` is the exact power 3/2; sympy may take the square root of b_4^3 because `b4` is declared positive).

```
# numbers: sqrt(|det g|) at 7 points of the patch with b4 = 1, compared with cos z
z_points = np.linspace(0.1, 1.5, 7)
det_numbers = np.array([float(det_g.subs(b4, 1).subs({H: 1, x0: zp / 6}))
                        for zp in z_points])
check(np.max(np.abs(np.sqrt(np.abs(det_numbers)) - np.cos(z_points))) < 1e-14,
      "at b4 = 1, sqrt|det g| equals cos z at 7 points of the patch")
```

A numerical check of the same fact for $b_4 = 1$. `np.linspace(0.1, 1.5, 7)` gives seven equally spaced values of z from 0.1 to 1.5. For each, the exact determinant is evaluated with $b_4 = 1$ (`subs(b4, 1)`), $H = 1$ and $x_0 = z/6$ (a dictionary in `subs` replaces several symbols at once) and turned into a floating-point number with `float`. The check requires $\sqrt{|\det g|}$ to differ from $\cos z$ by less than 10^{-14} at all seven points.

In [8], the signature (Section 3.5).

```
ETA = np.array([1, 1, 1, 1, -1, -1, -1, -1])  # the flat metric diag(+,+,+,+,-,-,-,-)
# the entries as functions of z, a4v and b4v
diagonal_z = [plain(g[k, k]) for k in range(8)]
functions = [sp.lambdify((z, a4v, b4v), entry, "numpy") for entry in diagonal_z]
```

`ETA` holds the eight signs of η, in the author's order: $+$ for x_0, x_1, x_2, x_3 and $-$ for $x_4, \ldots, x_7$. `diagonal_z` holds the eight entries written with `z`, `a4v` and `b4v`. `sp.lambdify((z, a4v, b4v), entry, "numpy")` turns an exact expression into a fast numerical Python function of the three arguments that works on whole numpy arrays.

```
def diagonal_values(z_values, a4_value, b4_value=1.0):
    """The 8 diagonal entries at the points z_values (one row per entry)."""
    return np.array([np.broadcast_to(f(z_values, a4_value, b4_value), z_values.shape)
                     for f in functions], dtype=float)
```

`diagonal_values` evaluates the eight functions at an array of values of z for one value of a_4 and one of b_4 (`b4_value=1.0` is a **default value**: a call that leaves out the third argument gets $b_4 = 1$) and returns a table with eight rows, row k for g_{kk}. The entry -1 does not depend on z, so its function returns one number; `np.broadcast_to` repeats it so that every row has the same length as `z_values`.

```
z_grid = np.linspace(0.0, np.pi / 2, 402)[1:-1]  # 400 points strictly inside
patterns = set()
for b4_value in (0.5, 1.0, 2.0):
    for a4_value in np.linspace(-3.0, 3.0, 13):
        # +1 or -1 for each entry
        signs = np.sign(diagonal_values(z_grid, a4_value, b4_value))
        patterns.update(tuple(int(s) for s in column) for column in signs.T)
say(f"sign patterns found on the grid: {sorted(patterns)}")
check(patterns == {tuple(int(s) for s in ETA)},
      "on the whole grid the signs are (+,+,+,+,-,-,-,-): signature (4,4)")
```

`np.linspace(0.0, np.pi / 2, 402)` gives 402 points from 0 to $\pi/2$; `[1:-1]` drops the first and the last, leaving 400 points strictly inside the patch. A `set` is a collection without repetitions. For

three values of b_4 (0.5, 1, 2) and 13 values of a_4 from -3 to 3, `np.sign` replaces each entry by its sign; `signs.T` is the table turned on its side, so that each `column` holds the eight signs at one point; `tuple(...)` turns them into a fixed sequence that a set can store. At the end the set holds every sign pattern met anywhere on the grid. It is printed (sorted) and must be the single pattern of η. (The grid includes negative values of a_4 only to test the sign argument of Section 3.5, which holds for every real a_4 and every $b_4 > 0$.)

```
step_x1 = diagonal_values(np.array([0.7]), 0.5)[1, 0]  # g11: step along x1
step_x5 = diagonal_values(np.array([0.7]), 0.5)[5, 0]  # g55: step along x5
say(f"at z = 0.7, a4 = 0.5, b4 = 1: g11 = {step_x1:.6f} (space-like), "
    f"g55 = {step_x5:.6f} (time-like)")
check(step_x1 > 0 > step_x5, "a step along x1 is space-like, along x5 time-like")
```

At the single point $z = 0.7$, $a_4 = 0.5$, $b_4 = 1$ (the default): row 1 is g_{11} and row 5 is g_{55}; the second index `0` picks the only column. The format `:.6f` prints six digits after the decimal point: $g_{11} = 2.347679$ and $g_{55} = -0.317724$. A unit step along x_1 has the squared length $g_{11} > 0$ (space-like), along x_5 the squared length $g_{55} < 0$ (time-like). Python reads `step_x1 > 0 > step_x5` as both comparisons at once.

In [9], the colours and the heat map of the metric.

```
from matplotlib.colors import LinearSegmentedColormap

BLUE, ORANGE, AQUA, YELLOW = "#2a78d6", "#eb6834", "#1baf7a", "#eda100"
MAGENTA, GREEN, VIOLET, RED = "#e87ba4", "#008300", "#4a3aa7", "#e34948"
GREY = "#f0efec"  # the neutral middle of the two-sided colour scale
DIVERGING = LinearSegmentedColormap.from_list("blue_grey_red", [BLUE, GREY, RED])
LABELS = [f"$x_{k}$" for k in range(8)]
```

Each colour is written as a **hex code**: `#` and three pairs of hexadecimal digits for the amounts of red, green and blue. The palette is chosen so that readers with a colour-vision deficiency can tell the colours apart; every figure also uses line styles and labels, so that it can be read in black and white. `DIVERGING` is a colour scale that runs from blue through grey to red; it will show negative numbers blue, zero grey and positive numbers red. `LABELS` holds the eight axis labels `$x_0$` to `$x_7$`, written in the math notation that matplotlib understands.

```
z_point, a4_point = np.pi / 4, 0.5
values = np.zeros((8, 8))
values[np.diag_indices(8)] = diagonal_values(np.array([z_point]), a4_point)[:, 0]
fig, ax = plt.subplots(figsize=(6.4, 5.4))
image = ax.imshow(values, cmap=DIVERGING, vmin=-3.0, vmax=3.0)
```

At the point $z = \pi/4$, $a_4 = 0.5$ the table `values` starts as an 8×8 table of zeros, and its diagonal (`np.diag_indices(8)`) is filled with the eight entries of the metric. `plt.subplots` makes a figure `fig` with one drawing area `ax`; `ax.imshow` draws the table as coloured squares, with the colour scale running from -3 (blue) to 3 (red).

```
for i in range(8):
    for j in range(8):
```

```
        ax.text(j, i, f"{values[i, j]:.3f}" if i == j else "0", ha="center",
                va="center", fontsize=8)
ax.set_xticks(range(8), LABELS)
ax.set_yticks(range(8), LABELS)
ax.grid(False)  # no grid lines across the squares
ax.set_title("The metric $g_{\\mu\\nu}$ at $z = \\pi/4$, $a_4 = 0.5$, $b_4 = 1$")
fig.colorbar(image, ax=ax, label="value of the entry (no unit)")
```

The double loop writes the value into each square: three decimals on the diagonal, a plain `0` elsewhere (`ha` and `va` centre the text). The two tick lines label the rows and the columns x_0 to x_7. In a Python string `\\` stands for one backslash, so the title reads $g_{\mu\nu}$ in math notation. `fig.colorbar` adds the colour scale with its label.

```
save_figure(fig, "metric_heat_map",
            "The author's metric $g_{\\mu\\nu}$ at the point $z = 6Hx_0 = \\pi/4$ "
            "with $a_4 = 0.5$ and $b_4 = 1$, drawn as a heat map: row $\\mu$ and "
            "column $\\nu$ run "
            "over the coordinates $x_0$ to $x_7$, red squares are positive entries, "
...
check(abs(values[1, 1] - np.e * np.sin(np.pi / 4) ** (1 / 3)) < 1e-12,
      "g11 at z = pi/4, a4 = 0.5 equals e times (sin pi/4)^(1/3)")
```

`save_figure` saves and shows the figure with its caption (printed in full under Figure 03a.1). The check compares the entry `values[1, 1]`, which is g_{11}, with $e^{2 \cdot 0.5}(\sin \pi/4)^{1/3} = e\,(\sin \pi/4)^{1/3}$.

What Figure 03a.1 shows. An 8×8 table of coloured squares at $b_4 = 1$: only the diagonal is coloured. In the author's order, the top-left square is the hidden one, $\cot^2(\pi/4) = 1$; then come the three red squares of 3-space with 2.422, the time square -1, and the three pale blue squares of the extra times with -0.328. Four positive and four negative entries: the signature (4,4) at a glance. The 3-space entries are larger than the extra-time entries by the factor $e^{4a_4} = e^2$, because $a_4 = 0.5 > 0$ has already inflated 3-space and deflated the extra times.

In [10], the diagonal entries across the patch.

```
z_line = np.linspace(0.02, np.pi / 2, 600)
entries = diagonal_values(z_line, 0.5)  # at b4 = 1
fig, ax = plt.subplots()
ax.plot(z_line, entries[0], color=AQUA, lw=1.8, label="$g_{00} = \\cot^2 z$")
ax.plot(z_line, entries[1], color=RED, lw=1.8,
        label="$g_{11} = g_{22} = g_{33} = e^{2a_4}\\sin^{1/3}z$")
ax.plot(z_line, entries[4], color=VIOLET, lw=1.8, ls="-.", label="$g_{44} = -1$")
ax.plot(z_line, entries[5], color=BLUE, lw=1.8, ls="--",
        label="$g_{55} = g_{66} = g_{77} = -b_4 e^{-2a_4}\\sin^{1/3}z$")
ax.plot(z_line, np.cos(z_line) ** 2, color="black", lw=1.2, ls=":",
        label="$\\det g = \\cos^2 z$")
```

600 values of z from 0.02 to $\pi/2$ and the eight entries at $a_4 = 0.5$ and $b_4 = 1$ (the default of `diagonal_values`). `ax.plot(x, y, ...)` draws a curve; `lw` is the line width, `ls` the line style (a dash and a dot mean dash-dotted, two dashes mean dashed, a colon means dotted) and `label` its text in the legend. Equal entries are drawn once: row 0 for the hidden direction, row 1 for

3-space, row 4 for the time, row 5 for the extra times; the black dotted curve is $\det g = \cos^2 z$, the determinant at $b_4 = 1$.

```
ax.axhline(0.0, color="black", lw=0.8)
ax.axvline(np.pi / 2, color="grey", lw=0.8, ls=":")
ax.text(np.pi / 2 - 0.02, 3.3, "patch end", ha="right", fontsize=9)
ax.text(0.05, 3.3, "towards the tip", fontsize=9)
ax.set_ylim(-3.4, 3.6)  # room below the curves for the legend
ax.set_xlabel("$z = 6 H x_0$ (radians)")
ax.set_ylabel("entry of the metric (no unit)")
ax.set_title("The diagonal entries across the patch ($a_4 = 0.5$, $b_4 = 1$)")
ax.legend(fontsize=8, loc="lower center", ncol=2)
```

A horizontal line at 0 (`axhline`), a vertical dotted line at the patch end (`axvline`), two labels written into the drawing (`ax.text(x, y, text)`), the range of the vertical axis, the two axis labels, the title and the legend in two columns at the bottom.

```
save_figure(fig, "diagonal_entries",
            "The diagonal entries of the author's metric as functions of "
...
check(np.all(entries[0] > 0) and np.cos(np.pi / 2) ** 2 < 1e-30,
      "g00 > 0 inside the patch and det g = 0 at the patch end")
```

The figure is saved with its caption. The check: $g_{00} > 0$ at all 600 points, and $\cos^2(\pi/2)$ is zero up to rounding (the computer's $\cos(\pi/2)$ is about 6×10^{-17}, whose square is below 10^{-30}).

What Figure 03a.2 shows. The red 3-space curve stays above zero and the blue extra-time curve and the violet time line stay below it across the whole patch: the signature never changes. The aqua curve $\cot^2 z$ rises steeply towards the tip and reaches 0 at the patch end, where the black dotted determinant $\cos^2 z$ also reaches 0: there the coordinate x_0 fails (Section 3.9). The 3-space entry falls towards the tip because the warp $\sin^{1/3} z$ goes to 0 there.

In [11], the vielbein (Section 3.7).

```
sixth = sp.sin(6 * H * x0) ** sp.Rational(1, 6)  # sin(z)^(1/6)
# the author's order x0, x1, ..., x7
h = [sp.cot(6 * H * x0)] + [sp.exp(a4) * sixth] * 3 + [sp.Integer(1)] \
    + [sp.sqrt(b4) * sp.exp(-a4) * sixth] * 3
```

`sixth` is the warp factor $W = \sin^{1/6} z$. The list `h` holds the eight scale factors in the author's order: first $h_0 = \cot z$, then $h_1 = h_2 = h_3 = e^{a_4} W$, $h_4 = 1$ and $h_5 = h_6 = h_7 = b_4^{1/2} e^{-a_4} W$. `[...] * 3` repeats a one-element list three times, `+` joins lists, and a backslash at the end of a line continues the statement on the next line. `sp.Integer(1)` is the exact number 1.

```
for k in range(8):
    say(f"  h[x{k}] = {plain(h[k])}")
LEAD_EMT = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
record_check(LEAD_EMT, "vielbein_reproduces_metric")  # stops if not passed
check(all(sp.simplify(int(ETA[k]) * h[k] ** 2 - g[k, k]) == 0 for k in range(8)),
      "eta times h squared reproduces every diagonal entry of the metric",
      record=f"{LEAD_EMT}, check vielbein_reproduces_metric")
```

The loop prints the eight scale factors (the output lists them; `exp(a4v)*sin(z)**(1/6)` is $e^{a_4}\sin^{1/6} z$ and `sqrt(b4v)*exp(-a4v)*sin(z)**(1/6)` is $b_4^{1/2}e^{-a_4}\sin^{1/6} z$). `LEAD_EMT` names the report of one of the lead checks (Section 3.7 says what the lead checks are), and `record_check` (In [3]) stops the notebook unless that report lists its check `vielbein_reproduces_metric` as passed. The check is $\eta_{kk}h_k^2 = g_{kk}$ for all eight k, the diagonal vielbein reproducing the metric, as in the lead's check.

In [12], the expansion rates.

```
rates = [sp.simplify(sp.diff(sp.log(h[k]), x4)) for k in range(8)]
for k in range(8):
    say(f"  expansion rate of x{k}: {plain(rates[k])}")
a4_prime, b4_prime = sp.Derivative(a4, x4), sp.Derivative(b4, x4)
expected = ([0] + [a4_prime] * 3 + [0]
            + [-a4_prime + b4_prime / (2 * b4)] * 3)  # the order x0, x1, ..., x7
check([sp.simplify(r - e) == 0 for r, e in zip(rates, expected)] == [True] * 8,
      "3-space expands with rate a4p, the extra times shrink with rate "
      "-a4p + b4p/(2 b4)")
```

`sp.diff(sp.log(h[k]), x4)` is $\partial_4 \ln h_k$, the rate of Section 3.7. The output prints `0` for x_0 and x_4, `a4p` for 3-space and `-a4p + b4p/(2*b4v)` for the extra times: the rate $\alpha_t = -a_4' + b_4'/(2b_4)$. `zip` pairs each rate with the expected one in the list `expected` (in the order $x_0, \ldots, x_7$: 0, three times a_4', 0, three times α_t), and the check requires all eight differences to vanish. For a constant b_4 the extra-time rate is $-a_4'$.

```
transverse = sp.simplify(h[1] * h[2] * h[3] * h[5] * h[6] * h[7])
say(f"product of the six transverse scale factors = {plain(transverse)}")
check(sp.simplify(transverse - b4 ** sp.Rational(3, 2) * sp.sin(6 * H * x0)) == 0,
      "the six transverse scale factors multiply to b4^(3/2) sin z, without a4")
```

The product of the six transverse scale factors (positions 1, 2, 3 and 5, 6, 7) prints as `b4v**(3/2)*sin(z)`: what 3-space gains through e^{a_4}, the extra times lose through e^{-a_4}; only the factor $b_4^{3/2}$ of the extra times remains.

In [13], the history of the Revision Kohn-Sham work (Section 3.8).

```
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
parameters = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))
physics = parameters["physics"]
H_value, A_value = physics["H"], physics["historyA"]
slices = physics["slicesA4"]  # the values of a4 at which the solver works
L_tip = physics["L_tipCutoff"]  # the tip cut-off, in units of 1/H
say(f"H = {H_value}, A = {A_value}, slices a4 = {slices}, tip cut-off L = {L_tip}")
check(H_value == 1.0 and A_value == 1.0 and slices == [0.0, 0.5, 1.0, 1.5, 2.0],
      "the history of the record is a4 = x4 (A = 1, H = 1) with slices 0 to 2")
```

The record of the Revision Kohn-Sham solver is read, and from its part `physics` the constant H, the slope A, the five slices and the tip cut-off L. A line `a, b = c, d` gives two names at once. The output prints $H = 1$, $A = 1$, the slices $0, 0.5, 1, 1.5, 2$ and $L = 3$, and the check confirms them.

```
KS_THEORY = "Revision/kohn_sham/ks-theory.json"
ks_theory = json.loads(repository_file(KS_THEORY).read_text(encoding="utf-8"))
status = ks_theory["adiabaticity"]["historyStatus"]  # the record's own statement
sentences = status.split(". ")  # the statement, cut into its sentences
say("status of the history (record): " + sentences[0] + ".")
say(sentences[-1])  # the last sentence already ends with a full stop
check(status.startswith("PRESCRIBED BACKGROUND") and "not solved for" in status,
      "the record states that the history is a prescribed background",
      record=f"{KS_THEORY}, adiabaticity.historyStatus")
```

The theory record of the Kohn-Sham work is read and its statement about the status of the history is cut into sentences at every full stop followed by a blank. The first and the last sentence are printed (`sentences[-1]` is the last element of a list). The check requires the statement to start with PRESCRIBED BACKGROUND and to contain "not solved for": the record itself labels the history an assumption.

In [14], the scale factors along the history.

```
x4_line = np.linspace(0.0, 2.5, 251)
a4_line = A_value * H_value * x4_line  # the history a4 = A H x4
slice_x4 = np.array(slices) / (A_value * H_value)  # the times of the slices
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2))
```

251 times from 0 to 2.5 (in units of $1/H$), the history $a_4 = AHx_4$ at those times (with $b_4 = 1$, so that the extra-time scale factor relative to $x_4 = 0$ is e^{-a_4}), and the times $x_4 = a_4/(AH)$ of the five slices. `plt.subplots(1, 2, ...)` makes a figure with two drawing areas side by side, `axes[0]` and `axes[1]`.

```
for ax, scale in zip(axes, ["linear", "log"]):
    ax.plot(x4_line, np.exp(a4_line), color=RED, lw=1.8,
            label="3-space: $e^{a_4}$ (inflates)")
    ax.plot(x4_line, np.exp(-a4_line), color=BLUE, lw=1.8, ls="--",
            label="extra times: $e^{-a_4}$ (deflate)")
    ax.plot(x4_line, np.exp(a4_line) * np.exp(-a4_line), color="black", lw=1.2,
            ls=":", label="product $= 1$")
    ax.plot(slice_x4, np.exp(slices), "o", color=RED, ms=6)
    ax.plot(slice_x4, np.exp(-np.array(slices)), "s", color=BLUE, ms=6)
    ax.set_yscale(scale)
    ax.set_xlabel("time $x_4$ (unit $1/H$)")
    ax.set_ylabel("scale factor relative to $x_4 = 0$")
```

The loop draws the same picture twice, once with an ordinary and once with a logarithmic vertical axis (`set_yscale`). In each: e^{a_4} (red), e^{-a_4} (blue dashed), their product (black dotted), and the five slices as dots (`"o"`) and squares (`"s"`) of size `ms=6`.

```
axes[0].set_title("Ordinary vertical axis")
axes[1].set_title("Logarithmic vertical axis: straight lines")
axes[0].legend(fontsize=8)
save_figure(fig, "history_scale_factors",
            "The time dependence of the scale factors along the deflating history "
```

```
...
report("3-space growth factor at the last slice a4 = 2", f"{np.exp(2.0):.6f}")
report("extra-time shrink factor at the last slice a4 = 2", f"{np.exp(-2.0):.6f}")
check(abs(np.exp(slices[-1]) * np.exp(-slices[-1]) - 1.0) < 1e-15,
      "at every slice the two factors multiply to 1")
```

Titles, legend, the saved figure, two RESULT lines ($e^2 = 7.389056$ and $e^{-2} = 0.135335$) and a check that the two factors multiply to 1 at the last slice (and so, since $e^a e^{-a} = 1$ for every a, at every slice).

What Figure 03a.3 shows. Along the history with $b_4 = 1$, on the ordinary axis (left) the red curve of 3-space bends upwards to 7.39 at $x_4 = 2$ and the blue extra-time curve falls towards 0; on the logarithmic axis (right) both are straight lines, rising and falling with slopes $+1$ and -1: that is what exponential growth and exponential deflation look like. The product stays exactly 1. The dots and squares mark the five slices on which the Revision Kohn-Sham states are computed.

In [15], the functions of z.

```
z_line = np.linspace(0.005, np.pi / 2 - 0.005, 600)
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2))
axes[0].plot(z_line, np.sin(z_line) ** (1 / 6), color=RED, lw=1.8,
             label="warp factor $W = \\sin^{1/6} z$")
axes[0].plot(z_line, np.sin(z_line) ** (1 / 3), color=ORANGE, lw=1.8, ls="--",
             label="$W^2 = \\sin^{1/3} z$ (in the entries of $g$)")
axes[0].set_ylim(0.0, 1.05)
axes[0].set_title("The warp of the six transverse directions")
```

600 values strictly inside the patch. The left panel shows the warp factor $W = \sin^{1/6} z$ and its square $W^2 = \sin^{1/3} z$, which stands in the six transverse metric entries; the vertical axis runs from 0 to 1.05.

```
axes[1].plot(z_line, 1 / np.tan(z_line), color=AQUA, lw=1.8,
             label="$\\cot z$ (scale factor of $x_0$)")
axes[1].plot(z_line, 1 / np.tan(z_line) ** 2, color=VIOLET, lw=1.8, ls="--",
             label="$\\cot^2 z$ (entry $g_{00}$)")
axes[1].set_yscale("log")
axes[1].set_title("The hidden direction (logarithmic axis)")
for ax in axes:
    ax.set_xlabel("$z = 6 H x_0$ (radians)")
    ax.set_ylabel("value (no unit)")
    ax.legend(fontsize=8)
```

The right panel shows $\cot z = 1/\tan z$ and $\cot^2 z$ on a logarithmic axis. The loop gives both panels their axis labels and legends.

```
save_figure(fig, "hidden_direction",
            "The functions of the hidden coordinate $z = 6Hx_0$ in the author's "
...
check(abs(np.sin(np.pi / 2) ** (1 / 6) - 1.0) < 1e-15,
      "the warp factor equals 1 at the patch end z = pi/2")
```

The figure is saved; the check confirms $W = 1$ at the patch end.

What Figure 03a.4 shows. Left: both warp curves rise from 0 at the tip to 1 at the patch end; $W = \sin^{1/6} z$ rises very steeply near the tip (a sixth root of a small number is not small: $(10^{-6})^{1/6} = 0.1$). Right: $\cot z$ and $\cot^2 z$ fall over many powers of ten from the tip to the patch end, where they reach 0 (off the bottom of the logarithmic axis).

In [16], maps of the scale factors over time and z.

```
x4_grid, z_grid2 = np.meshgrid(np.linspace(0.0, 2.5, 251),
                               np.linspace(0.01, np.pi / 2, 200))
a4_grid = A_value * H_value * x4_grid
space_map = np.log10(np.exp(a4_grid) * np.sin(z_grid2) ** (1 / 6))
extra_map = np.log10(np.exp(-a4_grid) * np.sin(z_grid2) ** (1 / 6))
```

`np.meshgrid` makes two tables of the same shape (200 rows for z, 251 columns for x_4) that hold, at every grid point, its x_4 and its z. Along the history $a_4 = AHx_4$, $b_4 = 1$, the two maps hold the logarithm to base 10 of the scale factor of 3-space and of an extra time at every grid point.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2), sharey=True)
for ax, data, title in zip(axes, [space_map, extra_map],
                           ["3-space: $e^{a_4}\\sin^{1/6}z$",
                            "extra time: $e^{-a_4}\\sin^{1/6}z$"]):
    mesh = ax.pcolormesh(x4_grid, z_grid2, data, cmap=DIVERGING, vmin=-1.3,
                         vmax=1.3, shading="auto")
    ax.contour(x4_grid, z_grid2, data, levels=[0.0], colors="black",
               linewidths=1.0)
    ax.set_title(title)
    ax.set_xlabel("time $x_4$ (unit $1/H$)")
    ax.grid(False)
axes[0].set_ylabel("$z = 6 H x_0$ (radians)")
fig.colorbar(mesh, ax=axes, label="$\\log_{10}$ of the scale factor")
```

Two panels that share their vertical axis (`sharey=True`). `pcolormesh` colours every grid cell by its value on the blue-grey-red scale from -1.3 to 1.3; `contour(..., levels=[0.0])` draws the black line on which the value is 0, the factor 1. One colour scale serves both panels.

```
save_figure(fig, "scale_factor_maps",
            "Maps of the logarithm to base 10 of the scale factor of 3-space "
...
check(np.all(np.diff(space_map, axis=1) > 0) and np.all(np.diff(extra_map, axis=1) < 0),
      "along the history 3-space grows and the extra times shrink at every z")
```

`np.diff(..., axis=1)` is the difference between neighbouring columns, that is between successive times. The check: at every z, the 3-space map increases and the extra-time map decreases from each time to the next.

What Figure 03a.5 shows. Left: from left to right the colour turns from grey to deeper and deeper red: 3-space grows at every height z. The black line is the factor 1; left of it, near the tip, the small warp makes the factor smaller than 1 although $a_4 > 0$. Right: the colour deepens to

blue from left to right: the extra times shrink at every z at the same rate, and their scale factor is smallest near the tip, where the small warp makes it smaller still.

In [17], proper volumes (Section 3.6).

```
V3 = sp.simplify(h[1] * h[2] * h[3])  # proper 3-volume of a unit coordinate box
Vt = sp.simplify(h[5] * h[6] * h[7])  # the same in the three extra times
# the 7-volume: every scale factor except h[4] = 1 of the time x4
V7 = sp.simplify(h[0] * h[1] * h[2] * h[3] * h[5] * h[6] * h[7])
say(f"V3 = {plain(V3)},  Vt = {plain(Vt)},  V7 density = {plain(V7)}")
check(sp.simplify(V7 - b4 ** sp.Rational(3, 2) * sp.cos(6 * H * x0)) == 0
      and sp.simplify(sp.diff(V7 / b4 ** sp.Rational(3, 2), x4)) == 0,
      "the 7-volume density is b4^(3/2) cos z and changes with x4 only through b4")
```

The three products of scale factors of Section 3.6. The output: `exp(3*a4v)*sqrt(sin(z))`, `b4v**(3/2)*exp(-3*a4v)*sqrt(sin(z))` and `b4v**(3/2)*cos(z)`. The check: the 7-volume density is $b_4^{3/2}\cos z$, and after division by $b_4^{3/2}$ its derivative with respect to x_4 is zero: the 7-volume changes with time only through b_4, never through a_4.

```
patch_volume = sp.integrate(sp.cos(6 * H * x0), (x0, 0, sp.pi / (12 * H)))
say(f"proper 7-volume of the patch per unit transverse coordinate volume = "
    f"{patch_volume}")
check(sp.simplify(patch_volume - 1 / (6 * H)) == 0,
      "the whole patch has the proper 7-volume 1/(6H) per unit coordinate volume")
```

`sp.integrate(f, (x0, 0, upper))` is the exact definite integral of Section 3.6 of the density $\cos z$, the density at $b_4 = 1$; it prints `1/(6*H)`. For another value of b_4 the result is multiplied by $b_4^{3/2}$, which does not depend on x_0.

In [18], the volumes along the history.

```
z_fixed = np.pi / 3
v3 = np.exp(3 * a4_line) * np.sin(z_fixed) ** 0.5
vt = np.exp(-3 * a4_line) * np.sin(z_fixed) ** 0.5
fig, ax = plt.subplots()
ax.plot(x4_line, v3, color=RED, lw=1.8, label="$V_3 = e^{3a_4}\\sin^{1/2}z$")
ax.plot(x4_line, vt, color=BLUE, lw=1.8, ls="--",
        label="$V_t = e^{-3a_4}\\sin^{1/2}z$")
ax.plot(x4_line, v3 * vt, color=ORANGE, lw=1.8, ls="-.",
        label="$V_3 V_t = \\sin z$")
ax.plot(x4_line, np.full_like(x4_line, np.cos(z_fixed)), color="black", lw=1.2,
        ls=":", label="7-volume density $\\cos z$")
```

At the fixed height $z = \pi/3$ ($\sin z = 0.866$, $\cos z = 0.5$) the numbers V_3 and V_t along the history with $b_4 = 1$, their product, and the constant 7-volume density (`np.full_like` makes an array of the same length filled with one number).

```
ax.set_yscale("log")
ax.set_xlabel("time $x_4$ (unit $1/H$), history $a_4 = x_4$, $b_4 = 1$")
```

```
ax.set_ylabel("proper volume per unit coordinate volume")
ax.set_title("Proper volumes at $z = \\pi/3$")
ax.legend(fontsize=8)
save_figure(fig, "proper_volumes",
            "Proper volumes per unit coordinate volume at the fixed hidden position "
...
check(np.max(np.abs(v3 * vt - np.sin(z_fixed))) < 1e-12,
      "V3 times Vt stays equal to sin z along the history")
```

A logarithmic vertical axis, labels, title, legend, the saved figure and the check that $V_3 V_t = \sin z$ at all 251 times.

What Figure 03a.6 shows. At $b_4 = 1$, on the logarithmic axis V_3 is a straight line rising with slope 3 (it grows like e^{3x_4}) and V_t a straight line falling with slope -3; their product and the 7-volume density are flat lines. The inflation of 3-space is exactly compensated by the deflation of the extra times.

In [19], the hidden coordinate y and the warped form (Section 3.9).

```
geometry = ks_theory["geometry"]  # the statements of the record about the geometry
for key in ("hiddenCoordinate", "lineElement", "warp", "sqrtDetG"):
    say(f"record, {key}: {geometry[key]}")
```

Four statements of the record `ks-theory.json` are printed: the definition of y, the line element in y, the warp factor and the volume factor (the output shows them).

```
y_of_x0 = sp.log(sp.sin(6 * H * x0)) / (6 * H)  # y = ln(sin z)/(6H)
dy_dx0 = sp.diff(y_of_x0, x0)  # the chain rule, done by sympy
say(f"dy/dx0 = {plain(dy_dx0)}")
record_check(LEAD_EMT, "ks_coordinate_jacobian")  # stops if not passed
check(sp.simplify(dy_dx0 - sp.cot(6 * H * x0)) == 0,
      "dy/dx0 = cot z",
      record=f"{LEAD_EMT}, check ks_coordinate_jacobian")
check(sp.simplify(dy_dx0 ** 2 - g[0, 0]) == 0,
      "dy^2 = g00 dx0^2: y measures proper distance along x0")
check(sp.simplify(sp.exp(H * y_of_x0) - sixth) == 0,
      "the warp factor W = sin(z)^(1/6) equals e^(H y)")
```

y as a function of x_0 and its derivative, which prints as `cos(z)/sin(z)`. `record_check` (In [3]) stops the notebook unless the lead's report `LEAD_EMT` (named in In [11]) lists its check `ks_coordinate_jacobian` as passed. Three checks: $dy/dx_0 = \cot z$ (the lead's check), $(dy/dx_0)^2 = g_{00}$, and $e^{Hy} = \sin^{1/6} z$.

```
y = sp.symbols("y", real=True)  # the hidden coordinate as a symbol of its own
x0_of_y = sp.asin(sp.exp(6 * H * y)) / (6 * H)  # the inverse: sin z = e^(6 H y)
dx0_dy = sp.diff(x0_of_y, y)  # dx0/dy
# the metric in y, x1, ..., x7: the hidden entry first, as in the author's order
g_y = sp.diag(g[0, 0].subs(x0, x0_of_y) * dx0_dy ** 2,
              *[g[k, k].subs(x0, x0_of_y) for k in range(1, 8)])
```

To write the metric in the coordinate y, the notebook needs x_0 as a function of y: from $\sin z = e^{6Hy}$, $x_0 = \arcsin(e^{6Hy})/(6H)$ (`sp.asin` is the inverse sine). The seven entries of $x_1, \ldots, x_7$ only need this put in. The hidden entry, the first in the author's order, becomes $g_{00}\,(dx_0/dy)^2$, because $dx_0 = (dx_0/dy)\,dy$ turns $g_{00}\,dx_0^2$ into $g_{00}(dx_0/dy)^2\,dy^2$. The star in `sp.diag(..., *[...])` unpacks the list of the seven entries with $k = 1, \ldots, 7$ into seven separate arguments.

```
W = sp.exp(H * y)  # the warp factor in the coordinate y
warped = sp.diag(*([1] + [W ** 2 * sp.exp(2 * a4)] * 3 + [-1]
                   + [-W ** 2 * b4 * sp.exp(-2 * a4)] * 3))  # the warped form
for k in (0, 1, 4, 5):
    say(f"  in the coordinate y: g[{k}, {k}] = {plain(g_y[k, k])}")
check((g_y - warped).applyfunc(sp.simplify) == sp.zeros(8, 8)
      and geometry["warp"] == "W(y) = e^{Hy}",
      "in the coordinate y the metric is the warped form with W = e^(H y)",
      record="Revision/kohn_sham/ks-theory.json, geometry.lineElement and "
             "geometry.warp")
```

`warped` is the warped form of Section 3.9, with $W = e^{Hy}$: the record's line element, which is written for $b_4 = 1$, with the factor b_4 in the three extra-time entries. Four entries of the transformed metric are printed, g_{00}, g_{11}, g_{44} and g_{55}: 1, $e^{2a_4}e^{2Hy}$, -1 and $-b_4e^{-2a_4}e^{2Hy}$. The check requires the transformed metric to equal the warped form entry by entry, and (after `and`) the record's statement of the warp factor to be still exactly the text `W(y) = e^{Hy}`, so that a change of the record would be caught.

```
check(sp.simplify(g_y.det() - b4 ** 3 * sp.exp(12 * H * y)) == 0
      and sp.simplify(g_y.det().subs(b4, 1) - sp.exp(12 * H * y)) == 0
      and geometry["sqrtDetG"].startswith("e^{6Hy} (= cos z"),
      "in the coordinate y, sqrt|det g| is b4^(3/2) e^(6 H y); at b4 = 1 it is "
      "e^(6 H y) = sin z",
      record="Revision/kohn_sham/ks-theory.json, geometry.sqrtDetG")
distance_to_end = -y_of_x0  # proper distance from the point to the patch end
check(sp.limit(distance_to_end, x0, 0, "+") == sp.oo,
      "the tip z -> 0 lies at an infinite proper distance (y -> minus infinity)")
```

The determinant in y is $b_4^3e^{12Hy}$, so the volume factor is $b_4^{3/2}e^{6Hy}$; at $b_4 = 1$ (`subs(b4, 1)`) the determinant is e^{12Hy}, the case of the record, and the check also requires the record's statement of the volume factor to start with the text `e^{6Hy} (= cos z` (`startswith`). Since y measures proper distance and the patch end is $y = 0$, the proper distance from a point to the patch end is $-y$; `sp.limit(f, x0, 0, "+")` is the limit as x_0 tends to 0 from above, and `sp.oo` is infinity: the tip is infinitely far away.

In [20], the tip cut-off and the coordinate y in pictures.

```
L_exact = sp.nsimplify(L_tip)  # the number 3.0 of the record as the exact integer 3
fraction = sp.integrate(sp.exp(6 * H * y), (y, -sp.oo, -L_exact / H)) \
    / sp.integrate(sp.exp(6 * H * y), (y, -sp.oo, 0))  # y: the symbol made above
fraction = sp.simplify(fraction.subs(H, 1))
report("fraction of the 7-volume beyond the tip cut-off y = -3", sp.sstr(fraction),
       f"= {float(fraction):.4e}")
z_cut = float(sp.asin(sp.exp(-18)))  # the angle z of the cut-off, sin z = e^(-18)
report("angle z of the tip cut-off", f"{z_cut:.4e}", "radians")
```

`sp.nsimplify(3.0)` gives the exact integer 3. The fraction of Section 3.9 is computed as a ratio of two exact integrals and simplified with $H = 1$ (the factor $b_4^{3/2}$ of the density does not depend on y and cancels in the ratio, so the fraction is the same for every b_4); it is `exp(-18)`, and the RESULT line prints it also as 1.5230×10^{-8} (the format `.4e` writes four digits after the point and a power of ten). The angle of the cut-off, $\arcsin e^{-18}$, is 1.5230×10^{-8} radians too, because $\arcsin u \approx u$ for small u.

```
z_line = np.logspace(-10, np.log10(np.pi / 2), 800)  # 1e-10 ... pi/2, evenly in log
y_line = np.log(np.sin(z_line)) / 6.0  # with H = 1
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2))
axes[0].plot(z_line, y_line, color=VIOLET, lw=1.8, label="$y(z)$")
axes[0].axhline(-L_tip, color="black", lw=1.0, ls="--",
                label=f"tip cut-off $y = -L = -{L_tip:g}$")
axes[0].plot([z_cut], [-L_tip], "o", color="black", ms=6)
axes[0].set_xscale("log")
axes[0].set_xlabel("$z = 6 H x_0$ (radians, logarithmic axis)")
axes[0].set_ylabel("$y = \\ln(\\sin z)/(6H)$ (unit $1/H$)")
axes[0].set_title("The hidden coordinate $y$")
axes[0].legend(fontsize=8)
```

`np.logspace(-10, np.log10(np.pi / 2), 800)` gives 800 values of z spread evenly on a logarithmic scale from 10^{-10} to $\pi/2$, so that the region near the tip is visible. The left panel draws $y(z)$ with $H = 1$, the cut-off line $y = -3$ (the format `:g` prints `3.0` as `3`) and a black dot at the cut-off, with a logarithmic horizontal axis.

```
y_axis = np.linspace(-4.0, 0.0, 400)
axes[1].plot(y_axis, np.exp(y_axis), color=RED, lw=1.8,
             label="warp factor $W = e^{Hy} = \\sin^{1/6} z$")
axes[1].plot(y_axis, np.exp(2 * y_axis), color=ORANGE, lw=1.8, ls="-.",
             label="$W^2 = e^{2Hy} = \\sin^{1/3} z$")
axes[1].plot(y_axis, np.exp(6 * y_axis), color=AQUA, lw=1.8, ls="--",
             label="7-volume density $W^6 = e^{6Hy} = \\sin z$")
axes[1].axvspan(-4.0, -L_tip, color="grey", alpha=0.25,
                label="removed by the tip cut-off")
axes[1].set_xlabel("$y$ (unit $1/H$)")
axes[1].set_ylabel("value (no unit)")
axes[1].set_title("Warp and volume density in $y$")
axes[1].legend(fontsize=8, loc="upper left")
```

The right panel draws W, W^2 and W^6 as functions of y from -4 to 0, and shades (`axvspan`) the band beyond the cut-off.

```
save_figure(fig, "hidden_coordinate_y",
            "The hidden coordinate $y = \\ln(\\sin z)/(6H)$ with $H = 1$. Left: $y$ "
...
check(fraction == sp.exp(-18), "the cut-off removes exactly the fraction e^(-18)")
```

The figure is saved, and the check confirms that the fraction is exactly e^{-18}.

What Figure 03a.7 shows. Left: on the logarithmic z axis, y is a straight line near the tip, because there $\sin z \approx z$ and $y \approx \ln(z)/6$; it bends over to 0 at the patch end. The cut-off $y = -3$ sits at $z = 1.5 \times 10^{-8}$. Right: the warp factor and its powers fall towards 0 as y decreases; the volume density e^{6y} is already tiny at $y = -1$, and the grey band beyond the cut-off holds only the fraction e^{-18} of the 7-volume.

In [21], the last check.

```
figure_names = ["metric_heat_map", "diagonal_entries", "history_scale_factors",
                "hidden_direction", "scale_factor_maps", "proper_volumes",
                "hidden_coordinate_y"]
files = [output_file(f"{FIGURE_FOLDER}/03a_{k}_{n}.png")
         for k, n in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all seven figure files exist")
all_checks_passed()
```

The names of the seven figures; `enumerate(figure_names, 1)` numbers them from 1, giving the file names `03a_1_metric_heat_map.png` to `03a_7_hidden_coordinate_y.png`. The check requires all seven files to exist, and `all_checks_passed()` prints the last line, ALL 29 CHECKS PASSED (notebook 03a). The 29 checks are: 1 in In [5], 2 in In [6], 3 in In [7], 2 in In [8], 1 each in In [9] and In [10], 1 in In [11], 2 in In [12], 2 in In [13], 1 each in In [14], In [15] and In [16], 2 in In [17], 1 in In [18], 6 in In [19], 1 in In [20] and 1 in In [21].

3.14 Vectors, covectors and tensors

The metric turns coordinate steps into lengths. To speak about curvature we must first say precisely what a vector is and why some indices are written up and others down. The idea is simple: the same arrow has different components in different coordinates, and the rule by which the components change decides where the index goes.

A change of coordinates. Suppose a second set of coordinates $x'^1, \dots, x'^n$ names the same points, each new coordinate being a function of the old ones, $x'^a = x'^a(x^1, \dots, x^n)$, and each old one a function of the new ones. The $n \times n$ table of partial derivatives $\partial x'^a / \partial x^b$ is the **Jacobian matrix** of the change. The two tables $\partial x'^a / \partial x^b$ and $\partial x^a / \partial x'^b$ are inverse matrices:

$$\sum_{b=1}^{n} \frac{\partial x'^a}{\partial x^b} \frac{\partial x^b}{\partial x'^c} = \frac{\partial x'^a}{\partial x'^c} = \delta^a{}_c$$

(the chain rule applied to the function $x'^a(x(x'))$, which is just x'^a; the derivative of a coordinate with respect to a coordinate of the same set is 1 for the same one and 0 for another).

Vectors. A **curve** is a point that moves with a parameter λ (a time, or a length along the curve): $x^a(\lambda)$. Its **velocity** has the components $u^a = dx^a/d\lambda$. In the new coordinates the same curve is $x'^a(x(\lambda))$, and

$$u'^a = \frac{dx'^a}{d\lambda} = \sum_b \frac{\partial x'^a}{\partial x^b} \frac{dx^b}{d\lambda} = \sum_b \frac{\partial x'^a}{\partial x^b} u^b$$

(the chain rule for a function of several variables, each of which depends on λ). A **vector** at a point is a set of n numbers V^a, one set for every system of coordinates, such that the sets of two systems are related by exactly this rule, $V'^a = \sum_b (\partial x'^a/\partial x^b)\, V^b$. Its index is written **up**. A small coordinate step dx^a is a vector, which is why we write its index up.

Covectors. The **gradient** of a function f has the components $W_a = \partial_a f$. In the new coordinates

$$W'_a = \frac{\partial f}{\partial x'^a} = \sum_b \frac{\partial x^b}{\partial x'^a}\, \frac{\partial f}{\partial x^b} = \sum_b \frac{\partial x^b}{\partial x'^a}\, W_b$$

(the chain rule again, now for $f(x(x'))$). A **covector** is a set of n numbers W_a for every system of coordinates that changes by this rule. Its index is written **down**. The table that converts it is the inverse Jacobian matrix, $\partial x/\partial x'$ instead of $\partial x'/\partial x$.

An upper index summed with a lower index gives the same number in every system of coordinates. For a vector V and a covector W:

$$\sum_a V'^a W'_a = \sum_a \Big(\sum_b \frac{\partial x'^a}{\partial x^b} V^b\Big)\Big(\sum_c \frac{\partial x^c}{\partial x'^a} W_c\Big)$$

(the two rules inserted)

$$= \sum_{b,c} \Big(\sum_a \frac{\partial x^c}{\partial x'^a}\, \frac{\partial x'^a}{\partial x^b}\Big) V^b W_c$$

(the order of finite sums may be changed, and numbers may be multiplied in any order)

$$= \sum_{b,c} \delta^c{}_b\, V^b W_c = \sum_b V^b W_b$$

(the inverse-matrix identity above, with the roles of the two systems exchanged; then the Kronecker delta keeps only $c = b$). Such a sum is called a **contraction**. For example the rate of change of a function along a curve, $df/d\lambda = \sum_a u^a\, \partial_a f$ (the chain rule), is a contraction of a vector with a covector, so it does not depend on the coordinates, as it must not. A warning: summing an upper index with another upper index does NOT have this property. In one dimension, under the change $x' = 2x$ every vector is doubled, $V' = 2V$ and $W' = 2W$ for two vectors, so the product $V'W' = 4VW$ depends on the coordinates.

Tensors. A **tensor** with p upper and q lower indices is a table of n^{p+q} numbers for every system of coordinates that changes with one factor $\partial x'/\partial x$ for every upper index and one factor $\partial x/\partial x'$ for every lower index. For example $T'^a{}_b = \sum_{c,d} (\partial x'^a/\partial x^c)(\partial x^d/\partial x'^b)\, T^c{}_d$. Three facts follow from the definition, by the computation just made: a contraction of one upper with one lower index of a tensor is again a tensor (with two fewer indices); a product of tensors is a tensor; and a quantity in which every index is contracted, an **invariant** (or scalar), has the same value in every system of coordinates. Moreover, if all the numbers of a tensor are zero in one system of coordinates, they are zero in every system, because each new number is a sum of old numbers times factors.

The metric is a tensor with two lower indices. The squared length of a small step is a property of the step, not of the coordinates in which we describe it. So

$$\sum_{a,b} g_{ab}\,dx^a dx^b = \sum_{a,b} g_{ab}\Big(\sum_c \frac{\partial x^a}{\partial x'^c} dx'^c\Big)\Big(\sum_d \frac{\partial x^b}{\partial x'^d} dx'^d\Big)$$

(each old step written with the new steps by the chain rule), and comparing with $\sum_{c,d} g'_{cd}\,dx'^c dx'^d$, the coefficients of the new metric are

$$g'_{cd} = \sum_{a,b} \frac{\partial x^a}{\partial x'^c}\,\frac{\partial x^b}{\partial x'^d}\,g_{ab}$$

(the coefficient of $dx'^c dx'^d$ collected from the double sum; we may compare coefficient by coefficient because both metrics are symmetric). Two lower indices, two factors $\partial x/\partial x'$. The inverse metric g^{ab} is a tensor with two upper indices.

Raising and lowering indices. The metric turns a vector into a covector, $V_a = \sum_b g_{ab} V^b$, and the inverse metric turns a covector into a vector, $W^a = \sum_b g^{ab} W_b$; doing both returns the original, because $\sum_b g^{ab} g_{bc} = \delta^a{}_c$. The same rule raises or lowers any index of any tensor. The squared length of a vector is the invariant $g(V,V) = \sum_{a,b} g_{ab} V^a V^b = \sum_a V^a V_a$. For a diagonal metric raising or lowering only multiplies: $V_a = g_{aa} V^a$ (no sum).

Example: a constant field in polar coordinates. In the plane take the field e_x that points one unit to the right everywhere: Cartesian components $(V^x, V^y) = (1, 0)$. With $r = \sqrt{x^2+y^2}$ and the angle φ (in the right half of the plane $\varphi = \arctan(y/x)$),

$$\frac{\partial r}{\partial x} = \frac{x}{r} = \cos\varphi, \qquad \frac{\partial \varphi}{\partial x} = \frac{1}{1+y^2/x^2}\cdot\Big(-\frac{y}{x^2}\Big) = -\frac{y}{x^2+y^2} = -\frac{\sin\varphi}{r}$$

(the chain rule: the derivative of $\sqrt{u}$ is $1/(2\sqrt{u})$ times $du/dx = 2x$; the derivative of $\arctan u$ is $1/(1+u^2)$ times $du/dx = -y/x^2$; then $x = r\cos\varphi$ and $y = r\sin\varphi$). The vector rule gives the polar components

$$V^r = \frac{\partial r}{\partial x}\cdot 1 + \frac{\partial r}{\partial y}\cdot 0 = \cos\varphi, \qquad V^\varphi = \frac{\partial \varphi}{\partial x}\cdot 1 + \frac{\partial \varphi}{\partial y}\cdot 0 = -\frac{\sin\varphi}{r}.$$

The field is constant, yet its polar components change from point to point. So the plain derivatives $\partial_b V^a$ of the components are not a good measure of how a vector field changes. The next section repairs this.

3.15 The covariant derivative and the Christoffel symbols

The problem. In the example of Section 3.14, $\partial_\varphi V^r = -\sin\varphi$ is not zero, although the field does not change at all: the derivative also records the turning of the coordinate directions. In general, differentiating the vector rule $V'^a = \sum_b (\partial x'^a/\partial x^b) V^b$ produces, besides the tensor rule, a term with the second derivatives $\partial^2 x'^a/\partial x^b \partial x^c$ of the change of coordinates, so $\partial_b V^a$ is not a tensor.

Definition (covariant derivative). We add a correction that is linear in V:

$$\nabla_b V^a = \partial_b V^a + \sum_c \Gamma^a{}_{bc}\, V^c.$$

The n^3 numbers $\Gamma^a{}_{bc}$ at each point are the **connection coefficients**; they are chosen so that $\nabla_b V^a$ is a tensor, which fixes how they change between systems of coordinates (we do not need that rule). For a function f (a tensor without indices) we set $\nabla_b f = \partial_b f$.

Covectors. We require the product rule for the function $\sum_a V^a W_a$:

$$\partial_b\Big(\sum_a V^a W_a\Big) = \sum_a (\nabla_b V^a) W_a + \sum_a V^a\, \nabla_b W_a.$$

The left side is $\sum_a (\partial_b V^a) W_a + \sum_a V^a\, \partial_b W_a$ (the ordinary product rule). The first term on the right is $\sum_a (\partial_b V^a) W_a + \sum_{a,c} \Gamma^a{}_{bc} V^c W_a$ (the definition). Subtracting,

$$\sum_a V^a\, \nabla_b W_a = \sum_a V^a\, \partial_b W_a - \sum_{a,c} \Gamma^a{}_{bc} V^c W_a = \sum_a V^a \Big(\partial_b W_a - \sum_c \Gamma^c{}_{ba} W_c\Big)$$

(in the double sum the two summed letters a and c were renamed c and a; a summed letter is only a name). This holds for every vector V, so

$$\nabla_b W_a = \partial_b W_a - \sum_c \Gamma^c{}_{ba}\, W_c.$$

Tensors with two indices. Again we require the product rule. Take first a product $T^a{}_b = V^a W_b$ of a vector and a covector (a tensor with one upper and one lower index, Section 3.14):

$$\nabla_c (V^a W_b) = (\nabla_c V^a) W_b + V^a\, \nabla_c W_b$$

(the product rule, required)

$$= \Big(\partial_c V^a + \sum_e \Gamma^a{}_{ce} V^e\Big) W_b + V^a \Big(\partial_c W_b - \sum_e \Gamma^e{}_{cb} W_e\Big)$$

(the two formulas just proved, with the letters b, c of the vector formula renamed c, e and the letters b, a, c of the covector formula renamed c, b, e)

$$= \partial_c (V^a W_b) + \sum_e \Gamma^a{}_{ce}\, (V^e W_b) - \sum_e \Gamma^e{}_{cb}\, (V^a W_e)$$

(the ordinary product rule $\partial_c (V^a W_b) = (\partial_c V^a) W_b + V^a\, \partial_c W_b$ collects the two terms without Γ; in the other two terms the factors are regrouped). In the notation $T^a{}_b = V^a W_b$, so that $V^e W_b = T^e{}_b$ and $V^a W_e = T^a{}_e$, this reads

$$\nabla_c T^a{}_b = \partial_c T^a{}_b + \sum_e \Gamma^a{}_{ce}\, T^e{}_b - \sum_e \Gamma^e{}_{cb}\, T^a{}_e.$$

The same three steps for a product $T_{ab} = W_a U_b$ of two covectors give

$$\nabla_c(W_a U_b) = (\nabla_c W_a) U_b + W_a\, \nabla_c U_b = \partial_c(W_a U_b) - \sum_e \Gamma^e{}_{ca}\, (W_e U_b) - \sum_e \Gamma^e{}_{cb}\, (W_a U_e)$$

(the product rule; the covector formula twice; the ordinary product rule collects the terms without Γ). Every tensor with two indices is a sum of such products. For example, let $E_{(d)}$ be the vector field with the components $\delta^a{}_d$ (the unit step along x_d) and $\theta^{(f)}$ the covector field with the components $\delta^f{}_b$; then

$$T^a{}_b = \sum_{d,f} T^d{}_f\, \delta^a{}_d\, \delta^f{}_b = \sum_{d,f} \left(T^d{}_f\, E_{(d)}\right)^a \left(\theta^{(f)}\right)_b$$

(in the double sum only $d = a$ and $f = b$ give a non-zero product of deltas), a sum of products (64 of them in eight dimensions) of a vector (the field $E_{(d)}$ multiplied by the function $T^d{}_f$) and a covector. Both sides of the formula for $\nabla_c T^a{}_b$ are sums of terms each containing T once, so the formula holds for a sum of products when it holds for each product; it therefore holds for every such tensor, and in the same way the formula for two lower indices holds for every tensor with two lower indices. With more indices the same steps, with more factors, give the general rule: **one term $+\sum_e \Gamma$ for every upper index and one term $-\sum_e \Gamma$ for every lower index**. For the metric (two lower indices):

$$\nabla_c\, g_{ab} = \partial_c\, g_{ab} - \sum_e \Gamma^e{}_{ca}\, g_{eb} - \sum_e \Gamma^e{}_{cb}\, g_{ae}.$$

The two conditions of Levi-Civita. A metric singles out one connection by two natural conditions:

1. no torsion: $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$ (symmetric in the two lower indices);
2. metric compatibility: $\nabla_c\, g_{ab} = 0$ (lengths and angles do not change when vectors are carried along without turning).

Theorem (the Christoffel formula). Exactly one connection satisfies both conditions:

$$\Gamma^a{}_{bc} = \tfrac{1}{2} \sum_d g^{ad} (\partial_b\, g_{dc} + \partial_c\, g_{db} - \partial_d\, g_{bc}).$$

These are the **Christoffel symbols**. Every Revision record and every notebook of the book uses this connection.

Proof, line by line. Lower the upper index: $\Gamma_{dbc} = \sum_a g_{da} \Gamma^a{}_{bc}$. Condition 1 says $\Gamma_{dbc} = \Gamma_{dcb}$. Condition 2, with the formula for $\nabla_c\, g_{ab}$, reads

$$\partial_c\, g_{ab} = \Gamma_{bca} + \Gamma_{acb}$$

(the two sums $\sum_e \Gamma^e{}_{ca} g_{eb}$ and $\sum_e \Gamma^e{}_{cb} g_{ae}$ are, by the definition of the lowered symbol and the symmetry of g, Γ_{bca} and Γ_{acb}). Write this equation three times, with the three letters in the three cyclic orders:

$$\partial_b g_{cd} = \Gamma_{dbc} + \Gamma_{cbd}, \qquad \partial_c g_{bd} = \Gamma_{dcb} + \Gamma_{bcd}, \qquad \partial_d g_{bc} = \Gamma_{cdb} + \Gamma_{bdc}$$

(the previous equation with the letters renamed). Add the first two and subtract the third:

$$\partial_b g_{cd} + \partial_c g_{bd} - \partial_d g_{bc} = \Gamma_{dbc} + \Gamma_{dcb} + (\Gamma_{cbd} - \Gamma_{cdb}) + (\Gamma_{bcd} - \Gamma_{bdc}) = 2\,\Gamma_{dbc}$$

(by condition 1, $\Gamma_{cbd} = \Gamma_{cdb}$ and $\Gamma_{bcd} = \Gamma_{bdc}$, so the two brackets are zero, and $\Gamma_{dcb} = \Gamma_{dbc}$). Multiply by $\frac{1}{2}g^{ad}$ and sum over d:

$$\Gamma^a{}_{bc} = \sum_d g^{ad}\,\Gamma_{dbc} = \tfrac{1}{2}\sum_d g^{ad}(\partial_b g_{cd} + \partial_c g_{bd} - \partial_d g_{bc})$$

(the inverse metric undoes the lowering, because $\sum_d g^{ad}g_{de} = \delta^a{}_e$; and $g_{cd} = g_{dc}$, $g_{bd} = g_{db}$). So a connection with the two properties can only be this one. Conversely, the formula is symmetric in b and c (exchanging them exchanges the first two terms), and putting it into $\Gamma_{bca} + \Gamma_{acb}$ gives back $\partial_c g_{ab}$ (the four terms with derivatives of g along other directions cancel in pairs), so it has both properties. (That the symbols computed in two systems of coordinates describe the same ∇ is a standard fact that we quote, ASSUMED.) $\square$

Diagonal metrics: four cases. All metrics of this chapter are diagonal. Write $g_{aa} = \eta_{aa}h_a^2$ with the sign $\eta_{aa} = \pm 1$ and the positive scale factor h_a (Section 3.7), so that $g^{aa} = \eta_{aa}/h_a^2$ (no sum here and in the four cases). In the formula only $d = a$ survives, because $g^{ad} = 0$ for $d \neq a$:

$$\Gamma^a{}_{bc} = \tfrac{1}{2}\,g^{aa}(\partial_b g_{ac} + \partial_c g_{ab} - \partial_a g_{bc}) \quad \text{(no sum)}.$$

(a) All three indices equal: $\Gamma^a{}_{aa} = \frac{1}{2}g^{aa}\,\partial_a g_{aa} = \frac{1}{2}\,\frac{\eta_{aa}}{h_a^2}\,\eta_{aa}\,2h_a\,\partial_a h_a = \partial_a \ln h_a$ (two of the three terms cancel; the derivative of h_a^2 is $2h_a\,\partial_a h_a$; $\eta_{aa}^2 = 1$; and $\partial h/h = \partial \ln h$).

(b) One lower index equal to the upper one, $b \neq a$: $\Gamma^a{}_{ab} = \Gamma^a{}_{ba} = \frac{1}{2}g^{aa}(\partial_a g_{ab} + \partial_b g_{aa} - \partial_a g_{ab}) = \frac{1}{2}g^{aa}\,\partial_b g_{aa} = \partial_b \ln h_a$ (the first and the third terms cancel; the rest as in (a)).

(c) Two equal lower indices different from the upper one, $b \neq a$: $\Gamma^a{}_{bb} = \frac{1}{2}g^{aa}(2\,\partial_b g_{ab} - \partial_a g_{bb}) = -\frac{1}{2}\,g^{aa}\,\partial_a g_{bb} = -\eta_{aa}\eta_{bb}\,\frac{h_b^2}{h_a^2}\,\partial_a \ln h_b$ (here $g_{ab} = 0$ because $a \neq b$; then $\partial_a g_{bb} = \eta_{bb}\,2h_b\,\partial_a h_b = 2\eta_{bb}h_b^2\,\partial_a \ln h_b$).

(d) Three different indices: $\Gamma^a{}_{bc} = 0$ (every metric entry in the bracket has two different indices and is zero).

Example: the plane in polar coordinates. $h_r = 1$, $h_\varphi = r$, both signs $+1$. Only h_φ depends on a coordinate, on r. Case (b): $\Gamma^\varphi{}_{r\varphi} = \Gamma^\varphi{}_{\varphi r} = \partial_r \ln r = 1/r$. Case (c): $\Gamma^r{}_{\varphi\varphi} = -\frac{r^2}{1}\,\partial_r \ln r = -r$. All others are zero. Now the constant field $V^r = \cos\varphi$, $V^\varphi = -\sin\varphi/r$ of Section 3.14:

$$\nabla_r V^r = \partial_r \cos\varphi + \Gamma^r{}_{rr}V^r + \Gamma^r{}_{r\varphi}V^\varphi = 0 + 0 + 0 = 0,$$

$$\nabla_\varphi V^r = \partial_\varphi \cos\varphi + \Gamma^r{}_{\varphi\varphi}V^\varphi = -\sin\varphi + (-r)\Big(-\frac{\sin\varphi}{r}\Big) = 0,$$

$$\nabla_r V^\varphi = \partial_r\Big(-\frac{\sin\varphi}{r}\Big) + \Gamma^\varphi{}_{r\varphi} V^\varphi = \frac{\sin\varphi}{r^2} + \frac{1}{r}\Big(-\frac{\sin\varphi}{r}\Big) = 0,$$

$$\nabla_\varphi V^\varphi = \partial_\varphi\Big(-\frac{\sin\varphi}{r}\Big) + \Gamma^\varphi{}_{\varphi r} V^r = -\frac{\cos\varphi}{r} + \frac{1}{r}\cos\varphi = 0$$

(in each line the definition of ∇, then the symbols just found, the others being zero). The covariant derivative of the constant field is zero, as it must be: the Christoffel terms remove exactly the change of the components that comes from the turning of the polar directions. Notebook 03c checks these four numbers (In [5]).

Example: the sphere of radius a. $h_\theta = a$, $h_\varphi = a\sin\theta$, both signs $+1$; only h_φ depends on a coordinate, on θ, with $\partial_\theta \ln(a\sin\theta) = \cos\theta/\sin\theta = \cot\theta$ (the logarithm of a product is the sum of the logarithms; the derivative of $\ln\sin\theta$ is $\cos\theta/\sin\theta$). Case (b): $\Gamma^\varphi{}_{\theta\varphi} = \Gamma^\varphi{}_{\varphi\theta} = \cot\theta$. Case (c): $\Gamma^\theta{}_{\varphi\varphi} = -\frac{a^2\sin^2\theta}{a^2}\cot\theta = -\sin\theta\cos\theta$. All others are zero.

The contracted symbol and the volume factor. For a diagonal metric, summing case (a) and case (b) over the upper index,

$$\sum_a \Gamma^a{}_{ab} = \sum_a \partial_b \ln h_a = \partial_b \ln\Big(\prod_a h_a\Big) = \partial_b \ln\sqrt{|\det g|}$$

(for $a = b$ case (a), for $a \neq b$ case (b), both give $\partial_b \ln h_a$; a sum of logarithms is the logarithm of the product; the product of the scale factors is the volume factor of Section 3.6). This identity is used for the author's metric in Section 3.23.

3.16 Parallel transport and geodesics

The derivative along a curve. Let $x^a(\lambda)$ be a curve with velocity $u^a = dx^a/d\lambda$, and $V^a(\lambda)$ a vector given at each point of the curve. If V is the value of a vector field on the curve, then $dV^a/d\lambda = \sum_b u^b\,\partial_b V^a$ (the chain rule), and therefore

$$\sum_b u^b\,\nabla_b V^a = \frac{dV^a}{d\lambda} + \sum_{b,c}\Gamma^a{}_{bc}\,u^b V^c =: \frac{DV^a}{d\lambda}$$

(the definition of ∇, multiplied by u^b and summed). The right side needs V only on the curve, so it defines the **covariant derivative along the curve** for any $V(\lambda)$. A vector is **parallel transported** along the curve when $DV^a/d\lambda = 0$: it is carried along without turning.

Geodesics. A **geodesic** is a curve whose velocity is parallel transported along itself:

$$\frac{d^2x^a}{d\lambda^2} + \sum_{b,c}\Gamma^a{}_{bc}\,\frac{dx^b}{d\lambda}\,\frac{dx^c}{d\lambda} = 0 \qquad (a = 1,\ldots,n).$$

In flat space with Cartesian coordinates every Γ is zero, and the equation says $d^2x^a/d\lambda^2 = 0$: straight lines, run through at constant speed. A geodesic is the straightest curve that a curved space allows. In Einstein's theory a body on which no force other than gravity acts (a body in **free**

fall) moves on a time-like geodesic; this is the physical content of the equation, which we take from the theory of gravity (ASSUMED).

The squared speed does not change along a geodesic. Lower the first index of the Christoffel symbol: by the proof of Section 3.15, $2\Gamma_{abc} = \partial_b g_{ca} + \partial_c g_{ba} - \partial_a g_{bc}$. Then, along a geodesic,

$$\frac{d}{d\lambda}\sum_{a,b} g_{ab}u^a u^b = \sum_{a,b,c}(\partial_c g_{ab})\, u^c u^a u^b + 2\sum_{a,b} g_{ab}\, u^a \frac{du^b}{d\lambda}$$

(the product rule; the metric changes along the curve by the chain rule; the two terms with $du/d\lambda$ are equal because g is symmetric)

$$= \sum_{a,b,c}(\partial_c g_{ab})\, u^c u^a u^b - 2\sum_{a,b,c}\Gamma_{abc}\, u^a u^b u^c$$

(the geodesic equation $du^b/d\lambda = -\sum \Gamma^b{}_{cd} u^c u^d$, and $\sum_b g_{ab}\Gamma^b{}_{cd} = \Gamma_{acd}$, with the summed letters renamed)

$$= \sum_{a,b,c}(\partial_c g_{ab})\, u^c u^a u^b - \sum_{a,b,c}(\partial_b g_{ca} + \partial_c g_{ba} - \partial_a g_{bc}) u^a u^b u^c = 0$$

(the formula for $2\Gamma_{abc}$; each of the three terms in the bracket, after renaming the summed letters, equals the first sum, with the signs $+$, $+$, $-$, so together they are exactly the first sum). So a geodesic that starts time-like stays time-like with the same $g(u,u)$. For a time-like geodesic we choose the parameter so that $g(u,u) = -1$; then λ is the **proper time** τ of the body, the time shown by a clock carried along (since $d\tau^2 = -ds^2$, Section 3.4).

A conserved momentum. Suppose the diagonal metric does not depend on one coordinate x_k at all. Then the **momentum** $p_k = g_{kk}u^k$ (no sum) does not change along a geodesic. Line by line:

$$\frac{dp_k}{d\lambda} = \sum_c (\partial_c g_{kk})\, u^c\, u^k + g_{kk}\frac{du^k}{d\lambda}$$

(the product rule and the chain rule).

$$\frac{du^k}{d\lambda} = -\sum_{b,c}\Gamma^k{}_{bc} u^b u^c = -2\sum_{c\neq k}\Gamma^k{}_{kc}\, u^k u^c$$

(of the four cases of Section 3.15, case (a) $\Gamma^k{}_{kk} = \partial_k \ln h_k$ and case (c) $\Gamma^k{}_{bb} = -\frac{1}{2}g^{kk}\partial_k g_{bb}$ are zero because nothing depends on x_k, case (d) is zero, and case (b) appears twice, as $\Gamma^k{}_{kc}$ and $\Gamma^k{}_{ck}$)

$$= -2\sum_{c\neq k}\frac{\partial_c g_{kk}}{2\, g_{kk}}\, u^k u^c = -\frac{1}{g_{kk}}\sum_c (\partial_c g_{kk})\, u^c u^k$$

(case (b) written as $\frac{1}{2}g^{kk}\partial_c g_{kk}$; the term $c = k$ may be added because $\partial_k g_{kk} = 0$). Inserting the last line into the first, the two terms cancel: $dp_k/d\lambda = 0$. **A metric that does not depend on a**

coordinate conserves the momentum of that coordinate. In the plane in polar coordinates the metric does not depend on φ, and $p_\varphi = r^2\, d\varphi/d\lambda$ is the angular momentum of mechanics; on the sphere $p_\varphi = a^2 \sin^2\theta\, d\varphi/d\lambda$ is conserved.

The geodesics of the sphere. With the two symbols of Section 3.15 (${\Gamma^\theta}_{\varphi\varphi} = -\sin\theta\cos\theta$ and ${\Gamma^\varphi}_{\theta\varphi} = {\Gamma^\varphi}_{\varphi\theta} = \cot\theta$) and the length s along the curve as parameter,

$$\frac{d^2\theta}{ds^2} = \sin\theta\cos\theta\Big(\frac{d\varphi}{ds}\Big)^2, \qquad \frac{d^2\varphi}{ds^2} = -2\cot\theta\,\frac{d\theta}{ds}\,\frac{d\varphi}{ds}$$

(the geodesic equation for $a = \theta$ has the single term ${\Gamma^\theta}_{\varphi\varphi}(d\varphi/ds)^2$ moved to the right; for $a = \varphi$ the two equal terms ${\Gamma^\varphi}_{\theta\varphi}$ and ${\Gamma^\varphi}_{\varphi\theta}$ give the factor 2). The **equator** $\theta = \pi/2$, $\varphi = s/a$ is a geodesic: $d^2\theta/ds^2 = 0$ and $\sin(\pi/2)\cos(\pi/2) = 0$, and $d^2\varphi/ds^2 = 0$ with $d\theta/ds = 0$. A **circle of latitude** $\theta = \theta_0$ with $0 < \theta_0 < \pi/2$, run through at unit speed, is NOT a geodesic: along it $d^2\theta/ds^2 = 0$, while the right side is $\sin\theta_0\cos\theta_0\,(d\varphi/ds)^2 = \sin\theta_0\cos\theta_0/(a^2\sin^2\theta_0) = \cot\theta_0/a^2 \neq 0$ (unit speed means $a\sin\theta_0\, d\varphi/ds = 1$). For $a = 1$ and $\theta_0 = \pi/3$ the missing acceleration is $\cot(\pi/3) = 1/\sqrt{3} = 0.577350$, the number Notebook 03c prints (In [11]). The geodesics of the sphere are its **great circles**, the circles whose centre is the centre of the sphere (the equator, the meridians and all their rotations); Notebook 03c shows this numerically for three of them (In [11]).

Parallel transport around a circle of latitude. Carry a vector once around the circle $\theta = \theta_0$, using φ as the parameter (so $d\theta/d\varphi = 0$ and $d\varphi/d\varphi = 1$). The transport equation $dV^a/d\varphi + \sum_c {\Gamma^a}_{\varphi c} V^c = 0$ has one term for each component:

$$\frac{dV^\theta}{d\varphi} = \sin\theta_0\cos\theta_0\, V^\varphi, \qquad \frac{dV^\varphi}{d\varphi} = -\cot\theta_0\, V^\theta$$

(for $a = \theta$ the only symbol is ${\Gamma^\theta}_{\varphi\varphi}$, for $a = \varphi$ the only one is ${\Gamma^\varphi}_{\varphi\theta}$). Measure the vector with the unit vectors pointing south and east: its lengths along them are $u = aV^\theta$ and $w = a\sin\theta_0\, V^\varphi$ (the scale factors $h_\theta = a$, $h_\varphi = a\sin\theta_0$). Multiplying the two equations by a and by $a\sin\theta_0$,

$$\frac{du}{d\varphi} = \cos\theta_0\, w, \qquad \frac{dw}{d\varphi} = -\cos\theta_0\, u$$

(in the first, $a\sin\theta_0\cos\theta_0 V^\varphi = \cos\theta_0\, w$; in the second, $a\sin\theta_0\cot\theta_0 V^\theta = \cos\theta_0\, u$). Start with the unit vector pointing south, $u = 1$, $w = 0$. The solution is

$$u = \cos(\varphi\cos\theta_0), \qquad w = -\sin(\varphi\cos\theta_0)$$

(check: $du/d\varphi = -\cos\theta_0\sin(\varphi\cos\theta_0) = \cos\theta_0\, w$ and $dw/d\varphi = -\cos\theta_0\cos(\varphi\cos\theta_0) = -\cos\theta_0\, u$, and at $\varphi = 0$ the values are 1 and 0; the solution with given starting values is unique, a standard theorem that we quote, ASSUMED). The length $\sqrt{u^2 + w^2} = 1$ never changes, and relative to the local south and east directions the vector turns at the constant rate $\cos\theta_0$. After one round, $\varphi = 2\pi$, it has turned by $-2\pi\cos\theta_0$, which is the same direction as a turn by $2\pi - 2\pi\cos\theta_0 = 2\pi(1 - \cos\theta_0)$ (two angles that differ by a whole turn 2π give the same direction). At $\theta_0 = \pi/3$, $\cos\theta_0 = 1/2$: $u = \cos\pi = -1$, $w = -\sin\pi = 0$. The vector comes back pointing north, exactly reversed. On the plane the same walk would return the vector unchanged.

The turning angle is the enclosed area times the curvature. The cap north of the circle has the area

$$\int_0^{\theta_0}\int_0^{2\pi} a^2 \sin\theta \, d\varphi \, d\theta = 2\pi a^2 \int_0^{\theta_0} \sin\theta \, d\theta = 2\pi a^2 \big[-\cos\theta\big]_0^{\theta_0} = 2\pi a^2(1-\cos\theta_0)$$

(the area factor $\sqrt{\det g} = a \cdot a\sin\theta$ of Section 3.6; the inner integral gives 2π; an antiderivative of $\sin\theta$ is $-\cos\theta$; $\cos 0 = 1$). So the turning angle $2\pi(1-\cos\theta_0)$ equals the enclosed area divided by a^2. Section 3.18 shows that $1/a^2$ is the curvature of the sphere. Notebook 03c measures the turning angle for 15 circles with RK4 and finds it equal to the area divided by a^2 within 5.0×10^{-12} radians (In [10]).

3.17 Curvature: the Riemann tensor and its contractions

The idea. On a flat sheet a vector carried around a closed loop without turning comes back unchanged; on the sphere it comes back turned (Section 3.16). For a very small loop the turning is measured by the difference between taking two covariant derivatives in one order and in the other order. In flat Cartesian coordinates $\nabla_c\nabla_d = \partial_c\partial_d$, and partial derivatives can be taken in either order; in a curved space covariant derivatives cannot.

Theorem (the Riemann tensor). For every vector field V,

$$\nabla_c\nabla_d V^a - \nabla_d\nabla_c V^a = \sum_b R^a{}_{bcd}\, V^b, \qquad R^a{}_{bcd} = \partial_c\Gamma^a{}_{bd} - \partial_d\Gamma^a{}_{bc} + \sum_e (\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}\Gamma^e{}_{bc}).$$

This is the convention of the textbook of Misner, Thorne and Wheeler (MTW), used by every Revision record (`Revision/gkd_lovelock/results/python-lovelock-report.json`, key `conventions.riemann`).

Proof, line by line. $\nabla_d V^a$ has one upper index a and one lower index d, so by the rule of Section 3.15

$$\nabla_c(\nabla_d V^a) = \partial_c(\nabla_d V^a) + \sum_e \Gamma^a{}_{ce}\,\nabla_d V^e - \sum_e \Gamma^e{}_{cd}\,\nabla_e V^a$$

(one $+\Gamma$ for the upper index, one $-\Gamma$ for the lower index). Insert $\nabla_d V^a = \partial_d V^a + \sum_b \Gamma^a{}_{db} V^b$:

$$= \partial_c\partial_d V^a + \sum_b (\partial_c\Gamma^a{}_{db}) V^b + \sum_b \Gamma^a{}_{db}\,\partial_c V^b + \sum_e \Gamma^a{}_{ce}\,\partial_d V^e + \sum_{e,b} \Gamma^a{}_{ce}\Gamma^e{}_{db} V^b - \sum_e \Gamma^e{}_{cd}\,\nabla_e V^a$$

(the product rule for $\partial_c(\Gamma V)$). Now subtract the same expression with c and d exchanged. Three kinds of terms drop out: $\partial_c\partial_d V^a$ (partial derivatives can be taken in either order); the pair $\sum_b \Gamma^a{}_{db}\partial_c V^b + \sum_e \Gamma^a{}_{ce}\partial_d V^e$, which after renaming e to b is unchanged by the exchange of c and d; and $\sum_e \Gamma^e{}_{cd}\nabla_e V^a$ (no torsion: $\Gamma^e{}_{cd} = \Gamma^e{}_{dc}$). What remains is

$$\sum_b \Big(\partial_c \Gamma^a{}_{db} - \partial_d \Gamma^a{}_{cb} + \sum_e \Gamma^a{}_{ce}\Gamma^e{}_{db} - \sum_e \Gamma^a{}_{de}\Gamma^e{}_{cb} \Big) V^b,$$

which is $\sum_b R^a{}_{bcd} V^b$ because $\Gamma^a{}_{db} = \Gamma^a{}_{bd}$, $\Gamma^a{}_{cb} = \Gamma^a{}_{bc}$, $\Gamma^e{}_{db} = \Gamma^e{}_{bd}$ and $\Gamma^e{}_{cb} = \Gamma^e{}_{bc}$. □

The left side is a tensor for every V and contains no derivative of V, so $R^a{}_{bcd}$ is a tensor (one upper, three lower indices). Hence: **if it is zero in one system of coordinates, it is zero in every system** (Section 3.14). A space whose Riemann tensor is zero everywhere is **flat**; conversely, near each point of a space with zero Riemann tensor there are coordinates in which the metric is constant (a standard theorem, quoted, ASSUMED).

Symmetries. (S1) $R^a{}_{bcd} = -R^a{}_{bdc}$: exchanging c and d in the formula exchanges the two derivative terms with a sign change, and so for the two products. (S2) The **first Bianchi identity** $R^a{}_{bcd} + R^a{}_{cdb} + R^a{}_{dbc} = 0$. Proof: write the three terms with the formula. The six derivative terms are $\partial_c \Gamma^a{}_{bd} - \partial_d \Gamma^a{}_{bc} + \partial_d \Gamma^a{}_{cb} - \partial_b \Gamma^a{}_{cd} + \partial_b \Gamma^a{}_{dc} - \partial_c \Gamma^a{}_{db}$; they cancel in pairs because the symbols are symmetric in their lower indices. The six products are $\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}\Gamma^e{}_{bc} + \Gamma^a{}_{de}\Gamma^e{}_{cb} - \Gamma^a{}_{be}\Gamma^e{}_{cd} + \Gamma^a{}_{be}\Gamma^e{}_{dc} - \Gamma^a{}_{ce}\Gamma^e{}_{db}$ (summed over e); they cancel in pairs for the same reason. □ Two more symmetries hold for every metric; we quote them (ASSUMED as general theorems; Notebook 03b checks both exactly for the author's metric, In [14]): with the first index lowered, $R_{abcd} = \sum_e g_{ae} R^e{}_{bcd}$, (S3) $R_{abcd} = -R_{bacd}$ and (S4) $R_{abcd} = R_{cdab}$ (pair symmetry).

The form with two upper indices. The Revision records store the tensor as

$$R^{ab}{}_{cd} = \sum_e g^{be} R^a{}_{ecd},$$

which for a diagonal metric is $g^{bb} R^a{}_{bcd}$ (no sum). By (S1) and (S3) it is antisymmetric in a, b and in c, d; with all indices down, for a diagonal metric, $R_{abcd} = g_{aa} g_{bb} R^{ab}{}_{cd}$ (no sum). For two different coordinates x_a and x_b the number

$$\sigma(a,b) = R^{ab}{}_{ab} \quad \text{(no sum)}$$

is the **curvature of the coordinate plane** of x_a and x_b (its **sectional curvature**; "plane" means here the plane of the two directions x_a and x_b at one point). We write it with the Greek letter σ (sigma), because the letter K is kept for the Kretschmann scalar below. What its sign means depends on the kind of directions:

- **Two space-like directions.** Then every step in the plane has a positive squared length, as on an ordinary surface, and $\sigma(a,b)$ is read like the curvature of a surface: positive for a plane curved like a sphere, negative for one curved like a saddle, zero for a flat one. Section 3.18 makes this precise: geodesics that start parallel in such a plane approach each other when $\sigma > 0$ and separate when $\sigma < 0$.
- **One space-like and one time-like direction.** There is no shape of this kind to picture. The sign is read from free fall instead: for two neighbouring free-fall paths that run along the time-like direction, the positive sign means that they accelerate APART, the opposite of the sphere. Section 3.18 states the rule and Section 3.24 verifies it by hand in the author's metric.

- **Two time-like directions.** Every step in the plane has a negative squared length. Replace g by $-g$: the Christoffel symbols do not change (both factors of $\frac{1}{2}g^{ad}(\partial g + \partial g - \partial g)$ change sign), so $R^a{}_{bcd}$ does not change, but every g^{bb} changes sign, so $\sigma(a,b) = g^{bb}R^a{}_{bab}$ (diagonal metric) changes sign. With $-g$ the plane has positive squared lengths, so its shape is that of the curvature $-\sigma(a,b)$: here a negative σ means curved like a sphere, the reverse of the first case. The free-fall reading of the second case still holds, because free-fall paths along a time-like direction are involved.

By the two antisymmetries, $R^{ba}{}_{ba} = R^{ab}{}_{ab}$ and $R^{ab}{}_{ba} = R^{ba}{}_{ab} = -R^{ab}{}_{ab}$.

Contractions. The **Ricci tensor**, the **Ricci scalar**, the **Einstein tensor** and the **Kretschmann scalar** are

$$R^a{}_b = \sum_c R^{ac}{}_{bc}, \qquad R = \sum_a R^a{}_a, \qquad G^a{}_b = R^a{}_b - \tfrac{1}{2}\,\delta^a{}_b\,R, \qquad K = \sum_{a,b,c,d} R^{ab}{}_{cd}\,R^{cd}{}_{ab}.$$

R and K have every index contracted: they are invariants, the same in every system of coordinates (Section 3.14). The Einstein tensor is the combination that enters Einstein's field equations (Section 3.26). Two consequences for the diagonal entries are used again and again:

$$R^a{}_a = \sum_c R^{ac}{}_{ac} = \sum_{c\neq a} \sigma(a,c)$$

(the definition with $b = a$; the term $c = a$ is $R^{aa}{}_{aa} = 0$ by the antisymmetry in the upper pair): **each diagonal entry of the Ricci tensor is the sum of the curvatures of the $n-1$ coordinate planes that contain that direction**; and

$$R = \sum_a \sum_{c\neq a} \sigma(a,c) = 2\sum_{a<c} \sigma(a,c)$$

(every plane is counted twice, once as (a,c) and once as (c,a), with $\sigma(c,a) = \sigma(a,c)$).

A surface. A space of two dimensions has a single coordinate plane, and its curvature $\sigma(1,2)$ is the **Gaussian curvature**. Then $R^1{}_1 = R^2{}_2 = \sigma(1,2)$ and $R = 2\sigma(1,2)$. The non-zero components $R^{ab}{}_{cd}$ are the four $R^{12}{}_{12} = R^{21}{}_{21} = \sigma(1,2)$ and $R^{12}{}_{21} = R^{21}{}_{12} = -\sigma(1,2)$, so the Kretschmann scalar is $K = 4\sigma(1,2)^2$ (each of the four products $R^{ab}{}_{cd}R^{cd}{}_{ab}$ is $\sigma(1,2)^2$).

3.18 The curvature of the plane and of the sphere, by hand; geodesic deviation

The plane in polar coordinates is flat. With the symbols of Section 3.15:

$$R^r{}_{\varphi r\varphi} = \partial_r\Gamma^r{}_{\varphi\varphi} - \partial_\varphi\Gamma^r{}_{\varphi r} + \sum_e (\Gamma^r{}_{re}\Gamma^e{}_{\varphi\varphi} - \Gamma^r{}_{\varphi e}\Gamma^e{}_{\varphi r})$$

(the formula with $a = r$, $b = \varphi$, $c = r$, $d = \varphi$)

$$= \partial_r(-r) - 0 + 0 - \Gamma^r{}_{\varphi\varphi}\Gamma^\varphi{}_{\varphi r} = -1 - (-r)\cdot\frac{1}{r} = 0$$

($\Gamma^r{}_{\varphi r} = 0$; every $\Gamma^r{}_{re}$ is zero; in the last sum only $e = \varphi$ survives). In two dimensions this is the only independent component, so the Riemann tensor of the plane is zero, although its polar Christoffel symbols are not. **Christoffel symbols describe the coordinates; the Riemann tensor describes the space.**

The sphere of radius a.

$$R^\theta{}_{\varphi\theta\varphi} = \partial_\theta \Gamma^\theta{}_{\varphi\varphi} - \partial_\varphi \Gamma^\theta{}_{\varphi\theta} + \sum_e \left(\Gamma^\theta{}_{\theta e}\Gamma^e{}_{\varphi\varphi} - \Gamma^\theta{}_{\varphi e}\Gamma^e{}_{\varphi\theta}\right)$$

(the formula with $a = \theta$, $b = \varphi$, $c = \theta$, $d = \varphi$)

$$= \partial_\theta(-\sin\theta\cos\theta) - 0 + 0 - \Gamma^\theta{}_{\varphi\varphi}\Gamma^\varphi{}_{\varphi\theta} = -(\cos^2\theta - \sin^2\theta) - (-\sin\theta\cos\theta)\cot\theta$$

(the product rule: the derivative of $\sin\theta\cos\theta$ is $\cos^2\theta - \sin^2\theta$; $\Gamma^\theta{}_{\varphi\theta} = 0$ and every $\Gamma^\theta{}_{\theta e} = 0$; in the last sum only $e = \varphi$ survives)

$$= -\cos^2\theta + \sin^2\theta + \cos^2\theta = \sin^2\theta$$

($\sin\theta\cos\theta\cot\theta = \cos^2\theta$). Raising the second index,

$$\sigma(\theta,\varphi) = R^{\theta\varphi}{}_{\theta\varphi} = g^{\varphi\varphi} R^\theta{}_{\varphi\theta\varphi} = \frac{\sin^2\theta}{a^2\sin^2\theta} = \frac{1}{a^2}$$

(Section 3.17; $g^{\varphi\varphi} = 1/(a^2\sin^2\theta)$). The Gaussian curvature of the sphere is $1/a^2$ at every point: a small sphere is strongly curved, a large one weakly. By Section 3.17, $R^\theta{}_\theta = R^\varphi{}_\varphi = 1/a^2$, the Ricci scalar is $R = 2/a^2$, and the Kretschmann scalar is $K = 4/a^4$. All PROVED here and computed exactly by Notebook 03c (In [7]). With Section 3.16: the turning angle $2\pi(1-\cos\theta_0)$ of a vector carried around a circle of latitude is the enclosed area $2\pi a^2(1-\cos\theta_0)$ times the Gaussian curvature $1/a^2$.

Geodesic deviation. Two meridians cross the equator at right angles, so they start out parallel. On a plane, lines that start parallel keep their distance for ever. On the sphere, after the length s along the meridians from the equator ($\theta = \pi/2 - s/a$), two meridians a small angle $\Delta\varphi$ apart are separated along the circle of latitude by

$$\xi(s) = a\sin\theta\,\Delta\varphi = a\sin\Big(\frac{\pi}{2} - \frac{s}{a}\Big)\Delta\varphi = a\cos\Big(\frac{s}{a}\Big)\Delta\varphi$$

(the length of an arc of the circle of latitude, whose radius is $a\sin\theta$; $\sin(\pi/2 - x) = \cos x$). Differentiating twice with respect to s,

$$\frac{d^2\xi}{ds^2} = -\frac{1}{a^2}\,a\cos\Big(\frac{s}{a}\Big)\Delta\varphi = -\frac{1}{a^2}\,\xi$$

(the chain rule: each derivative of $\cos(s/a)$ brings a factor $1/a$ and turns cos into $-\sin$ and sin into cos). The distance shrinks, and it is zero at $s = \pi a/2$: the meridians meet at the pole. In general the distance $\xi(s)$ between two neighbouring geodesics of a surface obeys the **geodesic deviation**

equation $d^2\xi/ds^2 = -\sigma\,\xi$ with the Gaussian curvature $\sigma = \sigma(1,2)$ of Section 3.17 (a standard theorem, quoted, ASSUMED; on the sphere we have just verified it, with $\sigma = 1/a^2$). On a surface, where all lengths are positive, positive curvature focuses neighbouring geodesics, negative curvature drives them apart, zero curvature does neither. In a spacetime the same theorem also covers free-fall paths that run along a time-like direction (the paths of observers, with their proper time τ in place of the length s), and for them the sign is reversed: if two such paths are a small proper distance ξ apart along the other direction of a coordinate plane with the curvature σ, then $d^2\xi/d\tau^2 = +\sigma\,\xi$ (quoted, ASSUMED in general; the reversal comes from the negative squared length of a time-like step). There a positive curvature drives the paths apart. Section 3.24 verifies this by hand for the observers at rest in the author's metric. Notebook 03c solves the equation with RK4 and finds it equal to the exact distance of two meridians within 8.0×10^{-14} (In [13]).

3.19 Example: curvature where it can be pictured

Notebook 03c applies Sections 3.14 to 3.18 to the plane and the sphere. It defines general functions that compute the Christoffel symbols, the Riemann tensor, the tensor with two upper indices, the Ricci tensor and the Kretschmann scalar of any metric given as a sympy matrix; these are the same formulas that Notebook 03b later applies to the author's metric. It computes the polar Christoffel symbols of the plane and finds its Riemann tensor zero; checks that the constant field e_x has zero covariant derivative; computes the curvature $1/a^2$, the Ricci scalar $2/a^2$ and the Kretschmann scalar $4/a^4$ of the sphere; carries a vector around circles of latitude with RK4 and compares the turning angle with the enclosed area; integrates three geodesics and finds great circles; and solves the geodesic deviation equation. It reads no Revision record (everything is exact mathematics), needs no Rust, runs in about 15 seconds and ends with the line ALL 16 CHECKS PASSED (notebook 03c).

3.20 How to run Notebook 03c

Step 1. What this notebook does and what it needs.

Notebook 03c (Curvature from zero: the plane, the sphere, parallel transport and geodesics) is the file `Revision/textbook/notebooks/03c_sphere_curvature.ipynb` of the repository Dirac_claude. It applies the formulas of the Christoffel symbols, the Riemann tensor, the Ricci tensor and the Ricci and Kretschmann scalars to two surfaces that can be pictured, the flat plane in polar coordinates and a sphere of radius a; it shows that the plane has zero curvature although its Christoffel symbols are not zero, computes the curvature 1/a^2 of the sphere, carries a vector around a circle of latitude by parallel transport (a numerical integration with the Runge-Kutta method) and finds the turning angle equal to the enclosed area divided by a^2, integrates geodesics and shows that they are great circles, and shows that initially parallel geodesics approach each other as the curvature predicts. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private

Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 03c_sphere_curvature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03c_sphere_curvature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 03c_sphere_curvature.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- Revision/textbook/figures/03c.captions.json
- Revision/textbook/figures/03c_1_plane_polar_components.png
- Revision/textbook/figures/03c_2_parallel_transport_sphere.png
- Revision/textbook/figures/03c_3_turning_angle.png
- Revision/textbook/figures/03c_4_geodesics_sphere.png
- Revision/textbook/figures/03c_5_geodesic_deviation.png

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files exist
ALL 16 CHECKS PASSED (notebook 03c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/03c_sphere_curvature.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 03c_sphere_curvature.ipynb
python -m nbconvert --execute --inplace 03c_sphere_curvature.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

3.21 Notebook 03c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/03c_sphere_curvature.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Curvature is the central idea of this chapter, and it is easiest to understand on
surfaces that we can picture. This notebook applies exactly the formulas that
Notebook 03b applies to the author's 8-dimensional metric to two 2-dimensional
surfaces:

- the **flat plane in polar coordinates** $(r, \varphi)$: its Christoffel symbols are
  not zero, yet its Riemann tensor is zero: Christoffel symbols describe the
  coordinates, the Riemann tensor describes the space;
- a **sphere of radius** $a$ in the coordinates $(\theta, \varphi)$ (angle from the
  north pole, angle around the axis): its curvature is $1/a^2$, its Ricci scalar
  $2/a^2$, its Kretschmann scalar $4/a^4$.

Then it shows what curvature does, with numerical integrations (the Runge-Kutta
```

```
method RK4):

- a vector carried around a circle of latitude **without turning** (parallel
  transport) comes back turned, by an angle equal to the enclosed area divided by
  $a^2$;
- the straightest curves of the sphere (**geodesics**) are great circles;
- two geodesics that start **parallel** approach each other and meet, at the rate
  that the curvature predicts.

It draws 5 figures and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 03c (Curvature from zero: the plane, the sphere, parallel transport and
geodesics) is the file ‘Revision/textbook/notebooks/03c_sphere_curvature.ipynb‘ of the
repository Dirac_claude. It applies the formulas of the Christoffel symbols, the Riemann
tensor, the Ricci tensor and the Ricci and Kretschmann scalars to two surfaces that can
be pictured, the flat plane in polar coordinates and a sphere of radius a; it shows that
the plane has zero curvature although its Christoffel symbols are not zero, computes the
curvature 1/a^2 of the sphere, carries a vector around a circle of latitude by parallel
transport (a numerical integration with the Runge-Kutta method) and finds the turning
angle equal to the enclosed area divided by a^2, integrates geodesics and shows that they
are great circles, and shows that initially parallel geodesics approach each other as the
curvature predicts. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
```

```
    jupyter lab 03c_sphere_curvature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 03c_sphere_curvature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 03c_sphere_curvature.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/03c.captions.json‘
- ‘Revision/textbook/figures/03c_1_plane_polar_components.png‘
- ‘Revision/textbook/figures/03c_2_parallel_transport_sphere.png‘
- ‘Revision/textbook/figures/03c_3_turning_angle.png‘
- ‘Revision/textbook/figures/03c_4_geodesics_sphere.png‘
- ‘Revision/textbook/figures/03c_5_geodesic_deviation.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS all five figure files exist
    ALL 16 CHECKS PASSED (notebook 03c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/03c_sphere_curvature.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 03c_sphere_curvature.ipynb
  python -m nbconvert --execute --inplace 03c_sphere_curvature.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 03c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 03c (Curvature from zero: the plane, the sphere, parallel transport and
# geodesics) is the file Revision/textbook/notebooks/03c_sphere_curvature.ipynb of the
# repository Dirac_claude. It applies the formulas of the Christoffel symbols, the
# Riemann tensor, the Ricci tensor and the Ricci and Kretschmann scalars to two surfaces
# that can be pictured, the flat plane in polar coordinates and a sphere of radius a; it
# shows that the plane has zero curvature although its Christoffel symbols are not zero,
# computes the curvature 1/a^2 of the sphere, carries a vector around a circle of
# latitude by parallel transport (a numerical integration with the Runge-Kutta method)
# and finds the turning angle equal to the enclosed area divided by a^2, integrates
# geodesics and shows that they are great circles, and shows that initially parallel
# geodesics approach each other as the curvature predicts. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
```

```
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
```

```
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 03c_sphere_curvature.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 03c_sphere_curvature.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
```

```
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 03c_sphere_curvature.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/03c.captions.json
# - Revision/textbook/figures/03c_1_plane_polar_components.png
# - Revision/textbook/figures/03c_2_parallel_transport_sphere.png
# - Revision/textbook/figures/03c_3_turning_angle.png
# - Revision/textbook/figures/03c_4_geodesics_sphere.png
# - Revision/textbook/figures/03c_5_geodesic_deviation.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files exist
#     ALL 16 CHECKS PASSED (notebook 03c)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/03c_sphere_curvature.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
```

```
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 03c_sphere_curvature.ipynb
#     python -m nbconvert --execute --inplace 03c_sphere_curvature.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#

Set-up of notebook 03c complete: repository folder found, helpers defined.
```

Text cell:

```
## 3. The words used in this notebook

- **Coordinates**: numbers that name the points of a space. **Polar coordinates**
  of the plane: the distance $r$ from the origin and the angle $\varphi$ from the
  horizontal axis; $x = r\cos\varphi$, $y = r\sin\varphi$.
- **Coordinates on the sphere** of radius $a$: $\theta$ (from $0$ at the north pole
  to $\pi$ at the south pole) and $\varphi$ (around the axis); the point is
  $(a\sin\theta\cos\varphi,\ a\sin\theta\sin\varphi,\ a\cos\theta)$.
- **Metric** $g_{\mu\nu}$: the rule $ds^2 = \sum g_{\mu\nu}\,dx^\mu dx^\nu$ for the
  squared length of a small step. Plane: $ds^2 = dr^2 + r^2 d\varphi^2$. Sphere:
  $ds^2 = a^2(d\theta^2 + \sin^2\theta\, d\varphi^2)$.
- **Vector components**: a vector $V = V^r e_r + V^\varphi e_\varphi$ is written with
  the coordinate basis vectors $e_r$ (length 1) and $e_\varphi$ (length $r$).
- **Christoffel symbols** $\Gamma^a{}_{bc}$, **covariant derivative**
  $\nabla_b V^a = \partial_b V^a + \sum_c \Gamma^a{}_{bc} V^c$: the derivative of a
```

```
  vector field corrected for the turning of the coordinate basis.
- **Parallel transport** along a curve $x^a(t)$: carrying a vector so that its
  covariant derivative along the curve is zero,
  $dV^a/dt + \sum_{b,c} \Gamma^a{}_{bc}\, (dx^b/dt)\, V^c = 0$ ("not turning").
- **Geodesic**: a curve whose velocity is parallel transported along itself,
  $d^2x^a/ds^2 + \sum_{b,c}\Gamma^a{}_{bc}\,(dx^b/ds)(dx^c/ds) = 0$; the straightest
  possible curve. **Great circle**: a circle on the sphere whose centre is the
  centre of the sphere (the equator, the meridians, and all their rotations).
- **Riemann tensor** $R^a{}_{bcd}$ (the MTW convention of the Revision records),
  **Gaussian curvature** $\sigma = R^{\theta\varphi}{}_{\theta\varphi}$ of a surface,
  **Ricci scalar** $R$, **Kretschmann scalar** $K$: the measures of curvature.
- **Holonomy** (turning angle): the angle by which a parallel-transported vector is
  turned after going once around a closed curve.
- **RK4**: the classical Runge-Kutta method of order 4 for solving
  $dy/dt = f(t, y)$ step by step.
```

Text cell:

```
## 4. The physical and mathematical situation

Two surfaces, each with two coordinates:

$$\text{plane: } g = \begin{pmatrix} 1 & 0 \\ 0 & r^2 \end{pmatrix},\qquad
\text{sphere: } g = \begin{pmatrix} a^2 & 0 \\ 0 & a^2 \sin^2\theta
\end{pmatrix}.$$

The plane is flat: on a sheet of paper a vector carried around any closed loop
without turning comes back unchanged, parallel lines stay parallel, and the angles
of a triangle add up to $\pi$. The sphere is curved: a vector carried around a loop
comes back turned, lines that start parallel meet (two meridians that cross the
equator at right angles meet at the poles), and the angles of a triangle add up to
more than $\pi$. The Riemann tensor measures exactly this. The formulas are those
used for the author's metric:

$$\Gamma^a{}_{bc} = \tfrac12 \sum_d g^{ad}(\partial_b g_{dc} + \partial_c g_{db}
- \partial_d g_{bc}),\qquad
R^a{}_{bcd} = \partial_c \Gamma^a{}_{bd} - \partial_d \Gamma^a{}_{bc}
+ \sum_e (\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}\Gamma^e{}_{bc}),$$

$R^{ab}{}_{cd} = \sum_e g^{be} R^a{}_{ecd}$, $R^a{}_b = \sum_c R^{ac}{}_{bc}$,
$R = \sum_a R^a{}_a$, $K = \sum R^{ab}{}_{cd} R^{cd}{}_{ab}$. For a surface the only
independent component is the **Gaussian curvature** $R^{12}{}_{12}$; a sphere of
radius $a$ has the Gaussian curvature $1/a^2$, the same at every point.
```

Text cell:

```
## 5. The curvature machinery for any metric

First a technical step. While a cell runs, Jupyter sends what the cell prints to the
notebook in pieces, about one piece every 0.2 seconds, so where one piece ends and
the next begins depends on the speed of the computer. The tools that build this
book read the PASS line of a check together with the line under it that names the
```

Revision record, and they read the two correctly only when both arrive in the same piece. The next cell therefore defines the function ‘in_one_piece(helper)‘: it returns a new function that does exactly what ‘helper‘ does, but lets ‘helper‘ print into a text buffer in memory (an ‘io.StringIO‘, with ‘contextlib.redirect_stdout‘) and then writes the whole buffer with one call of ‘sys.stdout.write‘, which arrives as one piece. (The stars in ‘*arguments‘ and ‘**options‘ pass on all the values the new function is given, whatever they are.) The cell then replaces the helpers ‘check‘ and ‘report‘ of the set-up cell by such functions. Nothing else changes: the same checks, the same PASS lines, the same numbers.

In [2]:

```
import contextlib  # redirect_stdout: send printed text into a buffer
import io  # StringIO: a text buffer in memory
import sys  # sys.stdout: the place where printed text goes

def in_one_piece(helper):
    """A function that does what helper does, with all the lines that helper prints
    written in one piece."""
    def helper_in_one_piece(*arguments, **options):
        collected = io.StringIO()  # an empty text buffer
        with contextlib.redirect_stdout(collected):  # print() writes into it
            helper(*arguments, **options)  # a failing check stops here, as before
        sys.stdout.write(collected.getvalue())  # all the lines with one write
    return helper_in_one_piece

check = in_one_piece(check)  # a PASS line and its record line stay together
report = in_one_piece(report)  # a long RESULT line and its second line, too
say("From now on check and report print each of their results in one piece.")
```

Out [2]:

```
From now on check and report print each of their results in one piece.
```

Text cell:

The next cell imports the packages and defines, for a metric of any size given as a sympy matrix, the functions ‘christoffel‘, ‘riemann‘ (the non-zero $R^a{}_{bcd}$), ‘raise_second‘ ($R^{ab}{}_{cd}$), ‘ricci‘ ($R^a{}_b$), and ‘kretschmann‘. They apply the formulas of section 4 literally, with every result simplified by sympy; they are the same formulas that Notebook 03b applies to the author’s metric.

In [3]:

```
import itertools  # loops over all index combinations
```

```
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols

def christoffel(metric, coordinates):
    """All Christoffel symbols table[a][b][c] of a metric."""
    n = len(coordinates)
    inverse = metric.inv()
    d_metric = [metric.diff(c) for c in coordinates]  # d_metric[c][i, j] = d_c g_ij
    table = [[[0] * n for _ in range(n)] for _ in range(n)]
    for a, b, c in itertools.product(range(n), repeat=3):
        table[a][b][c] = sp.simplify(sum(
            inverse[a, d] * (d_metric[b][d, c] + d_metric[c][d, b]
                             - d_metric[d][b, c]) for d in range(n)) / 2)

## 6. The flat plane in polar coordinates

With $x = r\cos\varphi$ and $y = r\sin\varphi$ a small step has
$dx = \cos\varphi\, dr - r\sin\varphi\, d\varphi$ and
$dy = \sin\varphi\, dr + r\cos\varphi\, d\varphi$; squaring and adding (the mixed
terms cancel, and $\cos^2 + \sin^2 = 1$) gives $ds^2 = dr^2 + r^2 d\varphi^2$. The
next cell computes the Christoffel symbols of this metric and its Riemann tensor.
By hand: only $g_{\varphi\varphi} = r^2$ depends on a coordinate, so
$\Gamma^r{}_{\varphi\varphi} = -\tfrac12 \partial_r r^2 = -r$ and
$\Gamma^\varphi{}_{r\varphi} = \Gamma^\varphi{}_{\varphi r} = \tfrac12 r^{-2}
\partial_r r^2 = 1/r$. The Riemann tensor must be zero, because the plane is flat.
```

In [4]:

```
r, phi = sp.symbols("r varphi", positive=True)  # polar coordinates, r > 0
plane = sp.diag(1, r ** 2)  # ds^2 = dr^2 + r^2 dphi^2

## 8. Parallel transport around a circle of latitude

Walk once around the circle of latitude $\theta = \theta_0$ (so $\varphi$ runs from
$0$ to $2\pi$ and $d\theta/d\varphi = 0$), carrying a vector without turning it. The
transport equation $dV^a/d\varphi + \sum_c \Gamma^a{}_{\varphi c} V^c = 0$ has only
two terms, one for each component:

$$\frac{dV^\theta}{d\varphi} = \sin\theta_0\cos\theta_0\, V^\varphi,\qquad
\frac{dV^\varphi}{d\varphi} = -\cot\theta_0\, V^\theta .$$

With the lengths $u = a V^\theta$ and $w = a\sin\theta_0\, V^\varphi$ along the unit
vectors $e_\theta$ (south) and $e_\varphi/(a \sin\theta_0)$ (east) this reads
$du/d\varphi = \cos\theta_0\, w$, $dw/d\varphi = -\cos\theta_0\, u$: the vector
turns relative to the local south-east frame at the constant rate $\cos\theta_0$.
After one round it has turned by $-2\pi\cos\theta_0$, which is the same direction as
a turn by $2\pi(1 - \cos\theta_0)$ (they differ by one whole turn). And
$2\pi a^2(1 - \cos\theta_0)$ is the area of the cap north of the circle: **the
turning angle is the enclosed area times the curvature $1/a^2$**. On the plane the
angle would be zero.

The next cell defines a general RK4 integrator and integrates the two equations
numerically with $a = 1$, starting with the unit vector pointing south
($u = 1$, $w = 0$), for $\theta_0 = \pi/3$; there $1 - \cos\theta_0 = 1/2$, so the
vector must come back pointing north, exactly reversed.
```

```

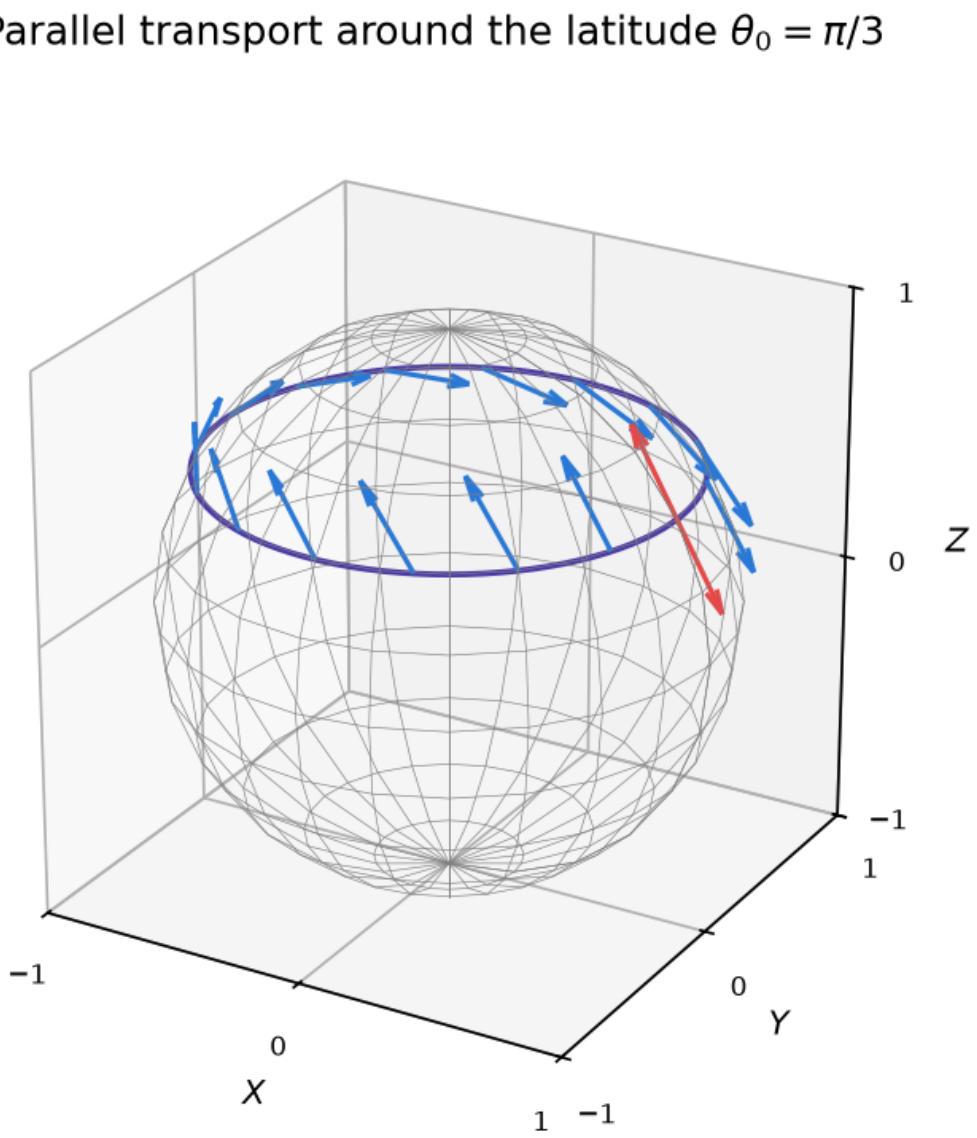

Figure 100: Parallel transport on the unit sphere (wire model; axes X, Y, Z in units of the radius $a = 1$): a vector that starts at $\varphi = 0$ on the circle of latitude $\theta_0 = \pi/3$ (violet) pointing south is carried once around the circle without turning; the blue arrows show it at fifteen intermediate points, computed with RK4. Seen from the local south and east directions it turns steadily, and when it is back at the start (red arrow, drawn at both ends) it points north: it has turned by π, the area $2\pi(1 - \cos\theta_0) = \pi$ of the cap above the circle divided by a^2. (Notebook 03c, figure 2.)

Out [10]:

```
RESULT largest difference between the turning angle and area/a^2 = 5.0e-12 radians
```

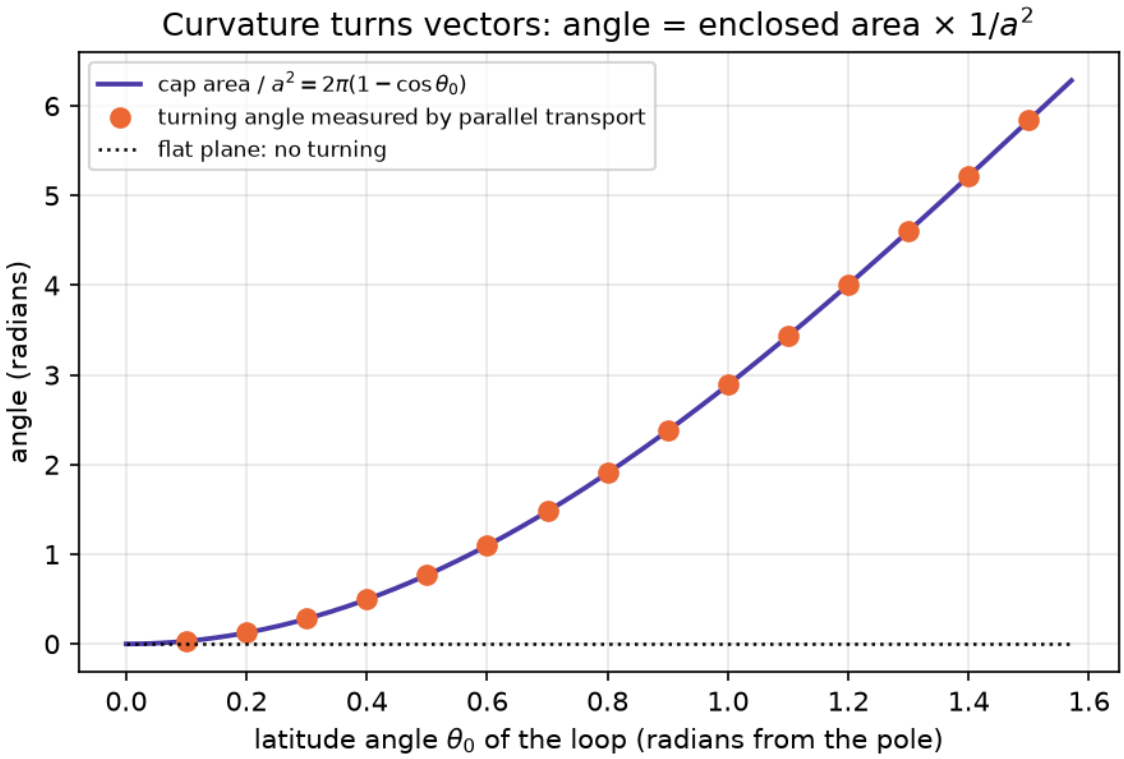

Figure 101: The turning angle of a vector carried once around a circle of latitude on a sphere of radius $a = 1$ (orange dots, computed by parallel transport with RK4 for 15 circles) and the area of the cap enclosed by the circle divided by a^2, $2\pi(1 - \cos\theta_0)$ (violet line), against the angle θ_0 of the circle from the north pole in radians; vertical axis the angle in radians. The dots lie on the line: the turning angle equals the enclosed area times the Gaussian curvature $1/a^2$. On the flat plane (dotted line) a vector never turns. (Notebook 03c, figure 3.)

## 9. Geodesics are great circles

The geodesic equations of the sphere follow from its two Christoffel symbols
($s$ is the length along the curve, $a = 1$):

$$\frac{d^2\theta}{ds^2} = \sin\theta\cos\theta \Bigl(\frac{d\varphi}{ds}\Bigr)^2,
```

```
\qquad \frac{d^2\varphi}{ds^2} = -2\cot\theta\, \frac{d\theta}{ds}
\frac{d\varphi}{ds}.$$

(The factor 2 comes from the two equal terms $\Gamma^\varphi{}_{\theta\varphi}$ and
$\Gamma^\varphi{}_{\varphi\theta}$.) The next cell writes them as four first-order
equations for $(\theta, \varphi, d\theta/ds, d\varphi/ds)$, integrates three
geodesics with RK4 that leave the point $\theta = \pi/2$, $\varphi = 0$ on the
equator in three directions (at $20$, $50$ and $80$ degrees north of east), each for
the length $2\pi$ (once around), and checks that each stays in the plane through the
centre of the sphere spanned by its starting point and starting direction, which
means it is a great circle. It also checks that the circle of latitude
$\theta_0 = \pi/3$ is NOT a geodesic: along it $d^2\theta/ds^2 = 0$, but the
right-hand side $\sin\theta_0\cos\theta_0 (d\varphi/ds)^2$ is not zero.
```

In [11]:

```

## 10. Initially parallel geodesics meet

Two meridians cross the equator at right angles, so they start parallel; on a
plane they would stay at the same distance for ever. On the sphere their distance,
measured along the circle of latitude, is $a\sin\theta\,\Delta\varphi =
```

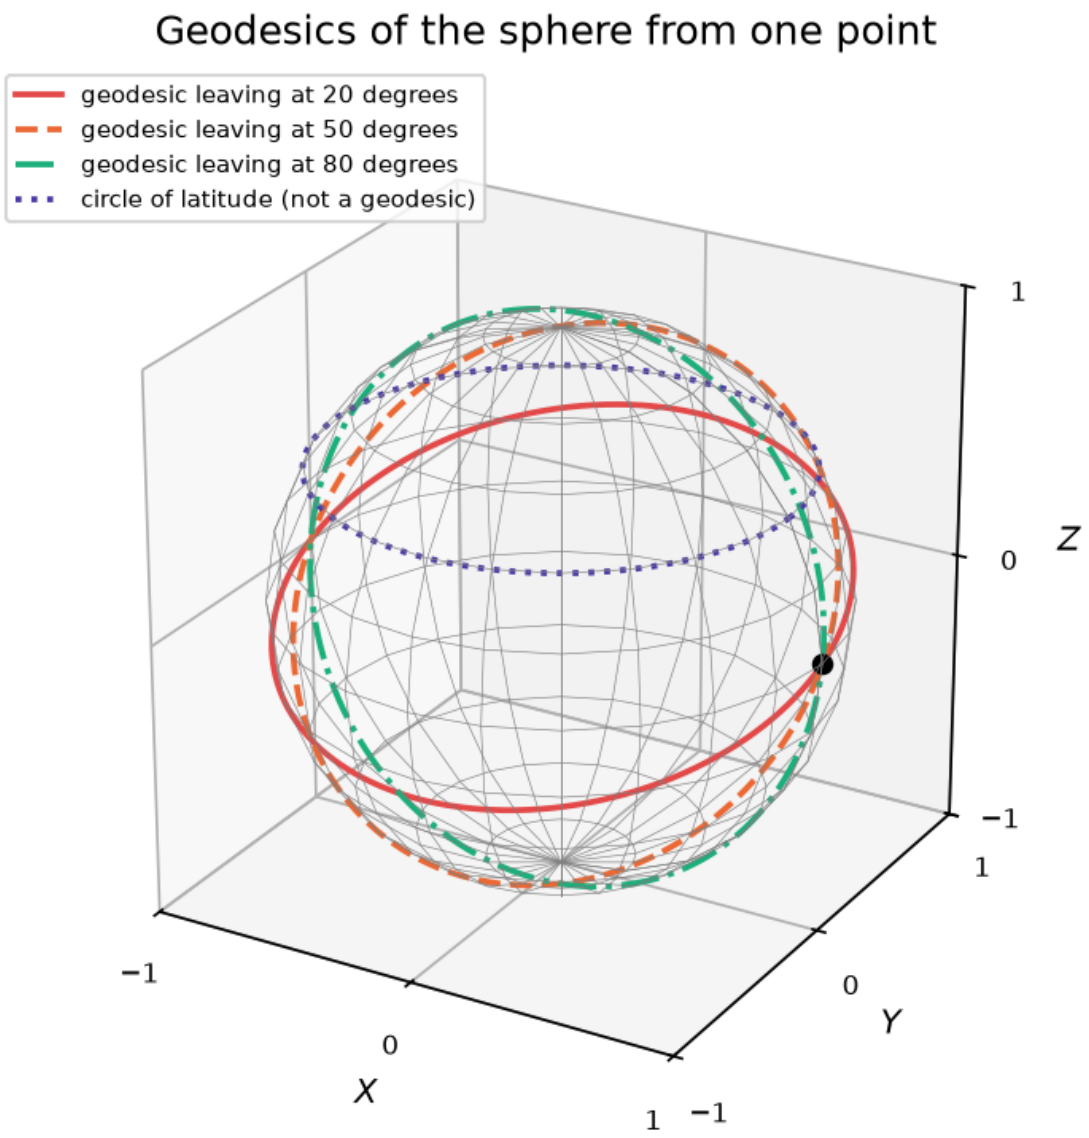

Figure 102: Three geodesics of the unit sphere (axes X, Y, Z in units of the radius), computed with RK4 from the geodesic equations, leaving the point $(1, 0, 0)$ on the equator (black dot) at 20, 50 and 80 degrees north of east (solid, dashed and dash-dotted); each is a great circle, a circle whose centre is the centre of the sphere, and comes back to its start after the length $2\pi a$. The dotted circle of latitude $\theta_0 = \pi/3$ is not a geodesic: a traveller who follows it must keep turning towards the pole. (Notebook 03c, figure 4.)

```
a\cos(s/a)\,\Delta\varphi$ after the length $s$ ($\theta = \pi/2 - s/a$): they
approach each other and meet at the pole, $s = \pi a/2$. In general the distance
$\xi(s)$ between two neighbouring geodesics obeys the **geodesic deviation
equation** $d^2\xi/ds^2 = -\sigma\,\xi$ with the Gaussian curvature $\sigma =
R^{\theta\varphi}{}_{\theta\varphi} = 1/a^2$ computed in section 7 (this sign rule
holds for geodesics and distances measured with ordinary positive lengths, as on a
surface: a positive curvature brings neighbouring geodesics together). The next cell
solves this equation with RK4 from $\xi = 1$, $d\xi/ds = 0$ (in units of the starting
distance, $a = 1$), compares it with the exact distance of two meridians
$\Delta\varphi = 10^{-3}$ apart (the length of the straight chord between them,
divided by its starting value), and draws both together with the flat plane.
```

In [13]:

## 12. What this notebook showed

- The flat plane in polar coordinates has the non-zero Christoffel symbols
  $\Gamma^r{}_{\varphi\varphi} = -r$ and $\Gamma^\varphi{}_{r\varphi} = 1/r$, but its
  Riemann tensor is zero: Christoffel symbols belong to the coordinates, curvature to
  the space. The constant field $e_x$ has changing polar components and zero
  covariant derivative.
- The sphere of radius $a$ has the Gaussian curvature
  $R^{\theta\varphi}{}_{\theta\varphi} = 1/a^2$ at every point, the Ricci scalar
  $2/a^2$ and the Kretschmann scalar $4/a^4$ (exact, with sympy).
- Parallel transport around a circle of latitude turns a vector by the enclosed area
  divided by $a^2$ (numerically, RK4, to better than $10^{-9}$); at
  $\theta_0 = \pi/3$ the vector comes back reversed. Its length never changes.
- The geodesics of the sphere are great circles; a circle of latitude other than
  the equator is not a geodesic.
- Geodesics that start parallel approach each other as the geodesic deviation
  equation with the curvature $1/a^2$ predicts, and meet at the pole.
- These are the same formulas, applied in the same order (Christoffel symbols,
  Riemann tensor, Ricci tensor, scalars), that Notebook 03b applies to the author's
  8-dimensional metric, where they give the curvature of the primordial
  gravitational field.
```

3.22 Line-by-line walk-through of Notebook 03c

The notebook has 14 code cells, In [1] to In [14]. As in Section 3.13, a line or a small group of lines is quoted and then explained, and a line `...` in a quoted figure command stands for the remaining lines of the caption, which is printed in full under its figure in Section 3.21.

In [1], the set-up cell. Its comment lines are the run instructions of Section 3.20. Its code is, line for line, the set-up code of Notebook 03a explained in Section 3.13 under In [1], with the single difference `NOTEBOOK_ID = "03c" # this notebook: chapter 03, example c`, so that the figures are named `03c_<k>_<name>.png` and the captions file is `Revision/textbook/figures/03c.captions.json`. It prints one line, Set-up of notebook 03c complete: repository folder found, helpers defined.

In [2], every result in one piece. The cell is, word for word, In [2] of Notebook 03a, explained in Section 3.13: it defines `in_one_piece` and replaces `check` and `report` by functions that write each of their results with one call of `sys.stdout.write`. It prints From now on check and report print each of their results in one piece.

In [3], the curvature machinery for any metric.

```
import itertools  # loops over all index combinations

import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
```

`itertools` is a module of Python with tools for loops; its function `product` runs through all combinations of indices. numpy (arrays of numbers) and sympy (exact algebra) are loaded under their usual short names.

```
def christoffel(metric, coordinates):
    """All Christoffel symbols table[a][b][c] of a metric."""
    n = len(coordinates)
    inverse = metric.inv()
    d_metric = [metric.diff(c) for c in coordinates]  # d_metric[c][i, j] = d_c g_ij
    table = [[[0] * n for _ in range(n)] for _ in range(n)]
```

The function receives the metric as a sympy matrix and the list of its coordinates. `n` is the dimension (`len` counts the list). `metric.inv()` is the inverse matrix g^{ab}. `metric.diff(c)` differentiates every entry with respect to the coordinate `c`; the list `d_metric` holds one such matrix per coordinate, so `d_metric[c][i, j]` is $\partial_c g_{ij}$. `table` is a list of n lists of n lists of n zeros, the empty table $\Gamma^a{}_{bc}$ (the name `_` is used for a loop counter that is not needed).

```
    for a, b, c in itertools.product(range(n), repeat=3):
        table[a][b][c] = sp.simplify(sum(
            inverse[a, d] * (d_metric[b][d, c] + d_metric[c][d, b]
                             - d_metric[d][b, c]) for d in range(n)) / 2)
    return table
```

`itertools.product(range(n), repeat=3)` gives every list of three indices (a, b, c), n^3 of them. For each, the formula of Section 3.15 is applied literally: the sum over d of $g^{ad}(\partial_b g_{dc} + \partial_c g_{db} - \partial_d g_{bc})$, divided by 2 and simplified by `sp.simplify`. The finished table is returned.

```
def riemann(table, coordinates):
    """The non-zero R^a_bcd (MTW convention) as a dictionary."""
    n = len(coordinates)
    result = {}
    for a, b, c, d in itertools.product(range(n), repeat=4):
        value = sp.simplify(
            sp.diff(table[a][b][d], coordinates[c])
            - sp.diff(table[a][b][c], coordinates[d])
            + sum(table[a][c][e] * table[e][b][d] - table[a][d][e] * table[e][b][c]
                  for e in range(n)))
        if value != 0:
            result[(a, b, c, d)] = value
    return result
```

For every list of four indices the formula of Section 3.17 is applied literally: $\partial_c \Gamma^a{}_{bd} - \partial_d \Gamma^a{}_{bc} + \sum_e (\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}\Gamma^e{}_{bc})$, simplified. Only the components that are not zero are kept, in a **dictionary** whose keys are the index lists `(a, b, c, d)`; the zero ones are simply absent.

```
def raise_second(riemann_table, metric):
    """The non-zero R^ab_cd = sum over e of g^(be) R^a_ecd."""
    inverse = metric.inv()
    result = {}
    for (a, e, c, d), value in riemann_table.items():
        for b in range(metric.rows):
            result[(a, b, c, d)] = result.get((a, b, c, d), 0) + inverse[b, e] * value
    return {k: sp.simplify(v) for k, v in result.items() if sp.simplify(v) != 0}
```

This raises the second index, $R^{ab}{}_{cd} = \sum_e g^{be} R^a{}_{ecd}$. `items()` hands out every key with its value; writing the key as `(a, e, c, d)` gives the four indices names. For each b the product $g^{be}R^a{}_{ecd}$ is added to the entry `(a, b, c, d)`; `result.get(key, 0)` is the value collected so far, or 0 if there is none yet. The last line is a **dictionary comprehension**: it builds a new dictionary from the simplified values and keeps only those that are not zero.

```
def ricci(mixed_table, n):
    """R^a_b = sum over c of R^ac_bc."""
    result = sp.zeros(n, n)
    for (a, c, b, d), value in mixed_table.items():
        if c == d:
            result[a, b] += value
    return result.applyfunc(sp.simplify)
```

The Ricci tensor $R^a{}_b = \sum_c R^{ac}{}_{bc}$ of Section 3.17. The key of the table is read as (a, c, b, d): upper indices a, c and lower indices b, d; a component contributes to $R^a{}_b$ exactly when its second upper index equals its second lower index, $c = d$. `+=` adds to the entry. Every entry of the result is simplified.

```
def kretschmann(mixed_table):
    """K = sum of R^ab_cd R^cd_ab."""
    return sp.simplify(sum(v * mixed_table.get((c, d, a, b), 0)
```

```
                        for (a, b, c, d), v in mixed_table.items()))

say("Defined: christoffel, riemann, raise_second, ricci, kretschmann.")
```

The Kretschmann scalar $K = \sum R^{ab}{}_{cd} R^{cd}{}_{ab}$: each stored component is multiplied by its partner with the two pairs exchanged (0 if the partner is absent), and everything is summed. The last line prints the output of In [3].

In [4], the flat plane in polar coordinates.

```
r, phi = sp.symbols("r varphi", positive=True)  # polar coordinates, r > 0
plane = sp.diag(1, r ** 2)  # ds^2 = dr^2 + r^2 dphi^2
POLAR = [r, phi]
POLAR_NAMES = ["r", "phi"]
plane_gamma = christoffel(plane, POLAR)
```

Two positive symbols, the distance r and the angle φ (sympy's name for it is `varphi`). `sp.diag(1, r ** 2)` is the metric $\mathrm{diag}(1, r^2)$ of Section 3.3. `POLAR` is the list of the coordinates and `POLAR_NAMES` their names for printing. The last line computes all $2^3 = 8$ Christoffel symbols.

```
for a, b, c in itertools.product(range(2), repeat=3):
    if plane_gamma[a][b][c] != 0:
        say(f"  Gamma^{POLAR_NAMES[a]}_({POLAR_NAMES[b]} {POLAR_NAMES[c]}) = "
            f"{plane_gamma[a][b][c]}")
check(plane_gamma[0][1][1] == -r and plane_gamma[1][0][1] == 1 / r
      and plane_gamma[1][1][0] == 1 / r,
      "plane in polar coordinates: Gamma^r_(phi phi) = -r, Gamma^phi_(r phi) = 1/r")
```

The loop prints the symbols that are not zero: the output shows $\Gamma^r{}_{\varphi\varphi} = -r$ and $\Gamma^\varphi{}_{r\varphi} = \Gamma^\varphi{}_{\varphi r} = 1/r$, the values found by hand in Section 3.15. Position 0 is r and position 1 is φ, so `plane_gamma[0][1][1]` is $\Gamma^r{}_{\varphi\varphi}$. The check confirms the three values.

```
plane_riemann = riemann(plane_gamma, POLAR)
say(f"non-zero Riemann components of the plane: {len(plane_riemann)}")
check(plane_riemann == {},
      "the Riemann tensor of the plane is zero: the plane is flat")
```

The Riemann tensor of the plane has no non-zero component: the output prints 0 and the check requires the empty dictionary `{}` (Section 3.18).

In [5], the constant field has zero covariant derivative.

```
V = [sp.cos(phi), -sp.sin(phi) / r]  # the constant field e_x in polar components
nabla = [[sp.simplify(sp.diff(V[a], POLAR[b])
                      + sum(plane_gamma[a][b][c] * V[c] for c in range(2)))
          for b in range(2)] for a in range(2)]
say(f"covariant derivative of e_x: {nabla}")
check(nabla == [[0, 0], [0, 0]],
      "the covariant derivative of the constant field e_x is zero")
```

`V` holds the polar components of e_x found in Section 3.14. The nested list comprehension computes $\nabla_b V^a = \partial_b V^a + \sum_c \Gamma^a{}_{bc} V^c$ for $a = 0, 1$ (outer list) and $b = 0, 1$ (inner list), exactly the four lines of Section 3.15. The output prints `[[0, 0], [0, 0]]` and the check requires it.

In [6], Figure 03c.1.

fig.subplots_adjust(wspace=0.3)  # room for the label of the right vertical axis
ax = axes[0]
angles = np.linspace(0.0, 2 * np.pi, 400)
```

Five colours of the palette of Section 3.13 (In [9] of Notebook 03a). A figure with two panels side by side; `subplots_adjust(wspace=0.3)` widens the gap between them. `ax` names the left panel. `angles` holds 400 angles from 0 to 2π.

```
for radius in (0.5, 1.0, 1.5, 2.0):  # circles of constant r
    ax.plot(radius * np.cos(angles), radius * np.sin(angles), color="grey", lw=0.6)
for ray in np.arange(12) * np.pi / 6:  # rays of constant phi
    ax.plot([0, 2.2 * np.cos(ray)], [0, 2.2 * np.sin(ray)], color="grey", lw=0.6)
```

The polar grid: four grey circles of constant r (a circle is the curve $(r\cos\varphi, r\sin\varphi)$), and twelve grey rays of constant φ, one every $\pi/6$ (`np.arange(12)` is $0, 1, \ldots, 11$), each a straight segment from the origin to the distance 2.2.

```
points = np.arange(12) * np.pi / 6 + np.pi / 12  # the angles of the 12 points
px, py = 1.5 * np.cos(points), 1.5 * np.sin(points)
ax.quiver(px, py, np.ones(12), np.zeros(12), color="black", scale=8, width=0.006,
          label="constant field $e_x$")
ax.quiver(px, py, np.cos(points), np.sin(points), color=RED, scale=12,
          width=0.005, label="unit vector $e_r$")
ax.quiver(px, py, -np.sin(points), np.cos(points), color=BLUE, scale=12,
          width=0.005, label="unit vector $e_\\varphi / r$")
```

Twelve points on the circle $r = 1.5$, halfway between the rays. `ax.quiver(x, y, dx, dy, ...)` draws an arrow at each point (x, y) in the direction (dx, dy); `scale` sets how long the arrows are drawn (a larger scale gives shorter arrows) and `width` their thickness. Black: the constant field, $(1, 0)$ everywhere. Red: the unit vector $e_r = (\cos\varphi, \sin\varphi)$, pointing away from the origin. Blue: the unit vector $e_\varphi / r = (-\sin\varphi, \cos\varphi)$, pointing around the circle.

```
ax.set_aspect("equal")
ax.set_xlim(-2.4, 2.4)
ax.set_ylim(-2.4, 2.4)
ax.set_xlabel("$x$")
ax.set_ylabel("$y$")
ax.set_title("A constant field on the polar grid")
ax.legend(fontsize=7, loc="lower left")
```

Equal units on both axes (so circles look round), the ranges of both axes, their labels, the title and the legend in the lower left corner.

```
ax = axes[1]
ax.plot(angles, np.cos(angles), color=RED, lw=1.8,
        label="component along $e_r$: $\\cos\\varphi$")
ax.plot(angles, -np.sin(angles), color=BLUE, lw=1.8, ls="--",
        label="component along $e_\\varphi/r$: $-\\sin\\varphi$")
ax.set_xlabel("$\\varphi$ (radians)")
ax.set_ylabel("component (no unit)")
ax.set_title("Its polar components change")
ax.legend(fontsize=8, loc="lower left")
```

The right panel: the components of e_x along the two unit vectors, $\cos\varphi$ (solid) and $-\sin\varphi$ (dashed), against φ. (Along the unit vector e_φ/r the component is $rV^\varphi = -\sin\varphi$.)

```
save_figure(fig, "plane_polar_components",
            "The flat plane in polar coordinates. Left: the polar grid (grey circles "
...
check(np.allclose(np.cos(points) ** 2 + np.sin(points) ** 2, 1.0),
      "the components of the unit field e_x have length 1 at every point")
```

The figure is saved with its caption. The check is a simple consistency test of the drawing: at each of the twelve points the two components $\cos\varphi$ and $-\sin\varphi$ of the unit field e_x along the two perpendicular unit vectors give the length $\sqrt{\cos^2\varphi + \sin^2\varphi} = 1$ (`np.allclose` compares arrays up to rounding).

What Figure 03c.1 shows. Left: all twelve black arrows are equal, while the red and blue unit vectors at the same points turn as one goes around the circle. Right: the two components of the constant field oscillate between -1 and 1 as φ runs once around. A derivative that only looked at components would call this field changing; the covariant derivative, with the Christoffel symbols, correctly says it does not change.

In [7], the sphere of radius a.

```
theta = sp.symbols("theta", positive=True)
a = sp.symbols("a", positive=True)  # the radius of the sphere
sphere = sp.diag(a ** 2, a ** 2 * sp.sin(theta) ** 2)
ANGLES = [theta, phi]
ANGLE_NAMES = ["theta", "phi"]
sphere_gamma = christoffel(sphere, ANGLES)
```

The angle θ and the radius a as positive symbols; the metric $\mathrm{diag}(a^2, a^2\sin^2\theta)$ of Section 3.3; the coordinates (θ, φ) (the symbol φ of In [4] is reused) and their names; all eight Christoffel symbols.

```
for i, j, k in itertools.product(range(2), repeat=3):
    if sphere_gamma[i][j][k] != 0:
        say(f"  Gamma^{ANGLE_NAMES[i]}_({ANGLE_NAMES[j]} {ANGLE_NAMES[k]}) = "
            f"{sphere_gamma[i][j][k]}")
sphere_riemann = riemann(sphere_gamma, ANGLES)
sphere_mixed = raise_second(sphere_riemann, sphere)
```

The loop prints the non-zero symbols. sympy writes $\Gamma^{\theta}{}_{\varphi\varphi} = -\sin\theta\cos\theta$ as `-sin(2*theta)/2`, the same number because $\sin 2\theta = 2\sin\theta\cos\theta$, and $\cot\theta$ as `1/tan(theta)`. Then the Riemann tensor and its form with two upper indices.

```
for key, value in sorted(sphere_mixed.items()):
    say(f"  R^({ANGLE_NAMES[key[0]]} {ANGLE_NAMES[key[1]]})_"
        f"({ANGLE_NAMES[key[2]]} {ANGLE_NAMES[key[3]]}) = {value}")
sphere_ricci = ricci(sphere_mixed, 2)
sphere_R = sp.simplify(sphere_ricci.trace())
sphere_K = kretschmann(sphere_mixed)
say(f"Ricci tensor R^a_b = {sphere_ricci.tolist()}")
say(f"Ricci scalar R = {sphere_R},  Kretschmann scalar K = {sphere_K}")
```

`sorted` puts the components in a fixed order (by their index lists) before printing; `key[0]` to `key[3]` are the four indices. The output shows the four components of a surface (Section 3.17): $R^{\theta\varphi}{}_{\theta\varphi} = R^{\varphi\theta}{}_{\varphi\theta} = 1/a^2$ (written `a**(-2)`) and $R^{\theta\varphi}{}_{\varphi\theta} = R^{\varphi\theta}{}_{\theta\varphi} = -1/a^2$. `trace()` is the sum of the diagonal entries of the Ricci matrix, the Ricci scalar; `tolist()` writes a matrix as a list of rows for printing. The output: $R^a{}_b = \mathrm{diag}(1/a^2, 1/a^2)$, $R = 2/a^2$, $K = 4/a^4$.

```
check(sp.simplify(sphere_gamma[0][1][1] + sp.sin(theta) * sp.cos(theta)) == 0
      and sp.simplify(sphere_gamma[1][0][1] - sp.cot(theta)) == 0,
      "sphere: Gamma^theta_(phi phi) = -sin cos, Gamma^phi_(theta phi) = cot theta")
check(sphere_mixed[(0, 1, 0, 1)] == 1 / a ** 2,
      "the Gaussian curvature of the sphere is 1/a^2 at every point")
check(sphere_R == 2 / a ** 2 and sphere_K == 4 / a ** 4,
      "Ricci scalar 2/a^2 and Kretschmann scalar 4/a^4")
```

Three checks of Section 3.18: the two Christoffel symbols found by hand (the difference with the hand result simplifies to zero), the Gaussian curvature $R^{\theta\varphi}{}_{\theta\varphi} = 1/a^2$ (key `(0, 1, 0, 1)`), and $R = 2/a^2$, $K = 4/a^4$.

In [8], parallel transport around a circle of latitude.

```
def rk4(f, y0, t0, t1, steps):
    """Solve dy/dt = f(t, y) from t0 to t1 with the classical Runge-Kutta method in
    steps equal steps; return the times and the states (one row per time)."""
    h = (t1 - t0) / steps
    times = t0 + h * np.arange(steps + 1)
    states = np.zeros((steps + 1, len(y0)))
    states[0] = y0
```

The RK4 method of Chapter 2 for a system $dy/dt = f(t, y)$ of several equations. `h` is the step; `times` holds the $steps + 1$ times $t_0, t_0 + h, \ldots, t_1$; `states` is a table with one row per time and one column per unknown, filled with zeros; its first row is the starting state `y0`.

```
    for n in range(steps):
        t, y = times[n], states[n]
        k1 = f(t, y)
        k2 = f(t + h / 2, y + h / 2 * k1)
```

```
        k3 = f(t + h / 2, y + h / 2 * k2)
        k4 = f(t + h, y + h * k3)
        states[n + 1] = y + h / 6 * (k1 + 2 * k2 + 2 * k3 + k4)
    return times, states
```

One RK4 step per pass: four evaluations of the right side (at the start, twice at the middle, at the end of the step) and the weighted average $(k_1 + 2k_2 + 2k_3 + k_4)/6$ times h added to the state. The function returns the times and the table of states.

```
def transport(theta0, steps=2000):
    """Parallel transport of the unit south vector once around latitude theta0
    (a = 1): the components V^theta, V^phi as functions of phi."""
    def f(t, y):
        return np.array([np.sin(theta0) * np.cos(theta0) * y[1],
                         -np.cos(theta0) / np.sin(theta0) * y[0]])
    return rk4(f, np.array([1.0, 0.0]), 0.0, 2 * np.pi, steps)
```

The transport equations of Section 3.16 with $a = 1$: the state is $y = (V^\theta, V^\varphi)$, and `f` returns $(\sin\theta_0 \cos\theta_0 \, V^\varphi, \ -\cot\theta_0 \, V^\theta)$. The parameter is φ, from 0 to 2π in 2000 steps (the default value of `steps`). The start $(1, 0)$ is the unit vector pointing south ($u = aV^\theta = 1$, $w = 0$).

```
def turning_angle(theta0):
    """The angle (0 to 2 pi) by which the vector comes back turned."""
    _, states = transport(theta0)
    u, w = states[-1, 0], np.sin(theta0) * states[-1, 1]  # lengths south, east
    return np.mod(np.arctan2(w, u), 2 * np.pi)
```

After one round (the last row, `states[-1]`) the lengths along south and east are $u = V^\theta$ and $w = \sin\theta_0 \, V^\varphi$ (with $a = 1$). `np.arctan2(w, u)` is the angle of the arrow (u, w) measured from the south direction towards the east, between $-\pi$ and π; `np.mod(..., 2 * np.pi)` adds 2π to a negative angle, so the result lies between 0 and 2π.

```
theta0 = np.pi / 3
phis, states = transport(theta0)
lengths = np.sqrt(states[:, 0] ** 2 + (np.sin(theta0) * states[:, 1]) ** 2)
# round to 12 digits; adding 0.0 turns a rounded -0.0 into 0.0
say(f"start: V = {(states[0].round(12) + 0.0).tolist()},  end: V = "
    f"{(states[-1].round(12) + 0.0).tolist()}")
```

The transport around $\theta_0 = \pi/3$. `lengths` holds $\sqrt{u^2 + w^2}$ at all 2001 points (`states[:, 0]` is the first column, all rows). The start and end vectors are printed rounded to 12 digits; a tiny negative number rounds to -0.0, which would print as `-0.0`, and adding 0.0 turns it into 0.0. The output: start $[1.0, 0.0]$, end $[-1.0, 0.0]$.

```
check(np.max(np.abs(lengths - 1.0)) < 1e-12,
      "parallel transport keeps the length of the vector")
check(np.max(np.abs(states[-1] - np.array([-1.0, 0.0]))) < 1e-10,
      "at theta0 = pi/3 the vector comes back exactly reversed")
```

Two checks: the length stays 1 within 10^{-12} at every point, and the vector comes back reversed within 10^{-10}, as derived in Section 3.16.

In [9], Figure 03c.2: the transport drawn on the sphere.

```
def point(th, ph):
    """The point of the unit sphere at the angles th, ph."""
    return np.array([np.sin(th) * np.cos(ph), np.sin(th) * np.sin(ph), np.cos(th)])
```

The point $(\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)$ of the unit sphere, as an array of its three coordinates X, Y, Z.

```
def wire_sphere(ax):
    """Draw a light wire model of the unit sphere into the 3-D axes ax."""
    th, ph = np.meshgrid(np.linspace(0, np.pi, 13), np.linspace(0, 2 * np.pi, 25))
    ax.plot_wireframe(np.sin(th) * np.cos(ph), np.sin(th) * np.sin(ph), np.cos(th),
                      color="grey", lw=0.3)
    ax.set_box_aspect((1, 1, 1), zoom=0.9)  # a little smaller: the labels fit
```

A helper that draws the sphere as a grey net of 13 circles of latitude and 25 meridians: `np.meshgrid` makes the grid of angles, and `plot_wireframe` connects the corresponding points. `set_box_aspect((1, 1, 1), zoom=0.9)` makes the three axes equally long and the box a little smaller, so that the labels fit in the picture.

```
    ax.set_xlim(-1, 1)
    ax.set_ylim(-1, 1)
    ax.set_zlim(-1, 1)
    ax.view_init(elev=25, azim=-60)
    for set_ticks in (ax.set_xticks, ax.set_yticks, ax.set_zticks):
        set_ticks([-1.0, 0.0, 1.0])  # three ticks per axis: labels do not overlap
    ax.tick_params(labelsize=8)
    ax.set_xlabel("$X$")
    ax.set_ylabel("$Y$")
    ax.set_zlabel("$Z$")
```

The ranges of the three axes; the point of view (25 degrees above the equator, turned by -60 degrees around the vertical axis); three tick marks per axis (the loop calls each of the three tick functions in turn); small tick labels; the axis names.

```
fig = plt.figure(figsize=(6.4, 6.0))
ax = fig.add_subplot(projection="3d")
wire_sphere(ax)
circle = np.array([point(theta0, p) for p in np.linspace(0, 2 * np.pi, 200)])
ax.plot(circle[:, 0], circle[:, 1], circle[:, 2], color=VIOLET, lw=1.8)
```

A figure with one three-dimensional drawing area (`projection="3d"`), the wire sphere, and the circle of latitude $\theta_0 = \pi/3$ as 200 points joined by a violet line.

```
for n in range(0, 2001, 125):  # 17 points, the last one equal to the first
    ph = phis[n]
    u, w = states[n, 0], np.sin(theta0) * states[n, 1]
    e_theta = np.array([np.cos(theta0) * np.cos(ph), np.cos(theta0) * np.sin(ph),
                        -np.sin(theta0)])
    e_phi = np.array([-np.sin(ph), np.cos(ph), 0.0])
```

`range(0, 2001, 125)` gives $n = 0, 125, \ldots, 2000$: 17 steps of the transport, one every $2\pi \cdot 125/2000 = \pi/8$. At each, `ph` is the angle and u, w the lengths south and east. `e_theta` is the unit vector pointing south at that point (the derivative of the point with respect to θ), and `e_phi` the unit vector pointing east (the derivative with respect to φ, divided by $\sin\theta_0$).

```
    arrow = 0.35 * (u * e_theta + w * e_phi)
    start = point(theta0, ph)
    colour = RED if n in (0, 2000) else BLUE
    ax.quiver(*start, *arrow, color=colour, lw=1.5, arrow_length_ratio=0.25)
ax.set_title("Parallel transport around the latitude $\\theta_0 = \\pi/3$")
```

The transported vector in three dimensions, $u\,e_\theta + w\,e_\varphi$, shortened to 0.35 for the drawing. It is drawn at its point on the circle, red at the start and the end, blue in between. In `ax.quive r(*start, *arrow, ...)` the stars unpack the three coordinates of the point and of the arrow into six arguments; `arrow_length_ratio` is the size of the arrow head.

```
save_figure(fig, "parallel_transport_sphere",
            "Parallel transport on the unit sphere (wire model; axes $X$, $Y$, $Z$ "
...
check(abs(turning_angle(theta0) - np.pi) < 1e-10,
      "the turning angle at theta0 = pi/3 is pi")
```

The figure is saved; the check confirms that the turning angle at $\theta_0 = \pi/3$ is π within 10^{-10}.

What Figure 03c.2 shows. The violet circle of latitude on the grey wire sphere and the transported vector along it. At the start (red, on the right) it points south, down the sphere. The blue arrows turn steadily relative to the circle, and at the end (red again, at the same place) the vector points north, up the sphere: it has turned by π although it was never turned along the way. On a flat sheet it would have come back unchanged.

In [10], Figure 03c.3: the turning angle for 15 circles.

```
latitudes = np.linspace(0.1, 1.5, 15)
measured = np.array([turning_angle(t0) for t0 in latitudes])
curve = np.linspace(0.0, np.pi / 2, 300)
fig, ax = plt.subplots()
```

Fifteen circles of latitude, $\theta_0 = 0.1, 0.2, \ldots, 1.5$; for each the turning angle measured by the transport of In [8]; 300 values of θ_0 for the smooth curve.

```
ax.plot(curve, 2 * np.pi * (1 - np.cos(curve)), color=VIOLET, lw=1.8,
        label="cap area / $a^2 = 2\\pi(1 - \\cos\\theta_0)$")
```

```
ax.plot(latitudes, measured, "o", color=ORANGE, ms=7,
        label="turning angle measured by parallel transport")
ax.plot(curve, np.zeros_like(curve), ":", color="black", lw=1.2,
        label="flat plane: no turning")
ax.set_xlabel("latitude angle $\\theta_0$ of the loop (radians from the pole)")
ax.set_ylabel("angle (radians)")
ax.set_title("Curvature turns vectors: angle = enclosed area $\\times$ $1/a^2$")
ax.legend(fontsize=8)
```

The violet line is the area of the cap divided by a^2 (Section 3.16), the orange dots are the measured angles, and the dotted line at zero is the flat plane (`np.zeros_like` makes an array of zeros of the same length). Labels, title and legend.

```
deviation = np.max(np.abs(measured - 2 * np.pi * (1 - np.cos(latitudes))))
report("largest difference between the turning angle and area/a^2",
       f"{deviation:.1e}", "radians")
save_figure(fig, "turning_angle",
            "The turning angle of a vector carried once around a circle of latitude "
...
check(deviation < 1e-9, "the turning angle equals the enclosed area over a^2")
```

The largest difference between the measured angles and the formula is printed in a RESULT line: 5.0×10^{-12} radians (the format `.1e` writes one digit after the point and a power of ten). The figure is saved, and the check requires the difference to be below 10^{-9}.

What Figure 03c.3 shows. The fifteen orange dots lie exactly on the violet curve $2\pi(1 - \cos\theta_0)$: the larger the cap enclosed by the loop, the more the vector turns. The dotted line shows that on the flat plane every loop gives zero.

In [11], geodesics are great circles.

```
def geodesic_rhs(s, y):
    """The geodesic equations of the unit sphere for y = (theta, phi, dtheta,
    dphi)."""
    th, ph, dth, dph = y
    return np.array([dth, dph, np.sin(th) * np.cos(th) * dph ** 2,
                     -2 * np.cos(th) / np.sin(th) * dth * dph])
```

The two second-order geodesic equations of Section 3.16 (with $a = 1$) written as four first-order equations for the state $(\theta, \varphi, d\theta/ds, d\varphi/ds)$: the derivatives of the first two are the last two, and the derivatives of the last two are the right sides $\sin\theta\cos\theta(d\varphi/ds)^2$ and $-2\cot\theta\,(d\theta/ds)(d\varphi/ds)$. The first line of the body unpacks the four numbers of `y`.

```
geodesics = {}
for degrees in (20, 50, 80):
    alpha = np.radians(degrees)  # the direction, measured from east towards north
    # unit speed at the equator: dtheta/ds = -sin(alpha) (north), dphi/ds = cos(alpha)
    start = np.array([np.pi / 2, 0.0, -np.sin(alpha), np.cos(alpha)])
    _, path = rk4(geodesic_rhs, start, 0.0, 2 * np.pi, 4000)
    xyz = np.array([point(th, ph) for th, ph in path[:, :2]])
```

Three geodesics start at the point $\theta = \pi/2$, $\varphi = 0$ on the equator, in the directions 20, 50 and 80 degrees north of east (`np.radians` converts degrees to radians). Moving north decreases θ (the angle from the north pole), hence $d\theta/ds = -\sin\alpha$; moving east increases φ, $d\varphi/ds = \cos\alpha$. The speed is 1, because $(d\theta/ds)^2 + \sin^2\theta\,(d\varphi/ds)^2 = \sin^2\alpha + \cos^2\alpha = 1$ at the equator. RK4 integrates each path over the length 2π (once around a great circle) in 4000 steps, and `xyz` holds the path as points in three dimensions (`path[:, :2]` is the table of the first two columns, θ and φ).

```
    # the starting direction in X, Y, Z: east is (0, 1, 0), north is (0, 0, 1)
    velocity0 = np.array([0.0, np.cos(alpha), np.sin(alpha)])
    normal = np.cross(xyz[0], velocity0)  # perpendicular to the expected plane
    geodesics[degrees] = (xyz, np.max(np.abs(xyz @ normal)))
```

A great circle lies in the plane through the centre of the sphere spanned by its starting point and its starting direction. `np.cross` is the cross product of two vectors in space, a vector perpendicular to both; it has length 1 here because the two are perpendicular unit vectors. The distance of a point from that plane is the size of its dot product with the perpendicular vector; `xyz @ normal` computes this dot product for every point of the path at once (`@` is the product of a matrix with a vector). The path and its largest distance from the plane are stored in the dictionary under the angle.

```
    say(f"  direction {degrees:2d} degrees: largest distance from the plane "
        f"= {geodesics[degrees][1]:.1e}, end point back at start: "
        f"{np.allclose(xyz[-1], xyz[0], atol=1e-8)}")
check(all(distance < 1e-8 for _, distance in geodesics.values()),
      "the three geodesics stay in planes through the centre: great circles")
```

For each direction one line is printed: the largest distance (1.2×10^{-13}, 6.2×10^{-13} and 7.1×10^{-11}) and whether the end point equals the start within 10^{-8} (`True` for all three). The check requires all three distances to be below 10^{-8}.

```
theta_circle = np.pi / 3
residual = np.sin(theta_circle) * np.cos(theta_circle) * (1 / np.sin(theta_circle)) ** 2
report("geodesic equation of the latitude theta0 = pi/3: missing acceleration",
       f"{residual:.6f}")
check(residual > 0.5, "the circle of latitude theta0 = pi/3 is not a geodesic")
```

The circle of latitude $\theta_0 = \pi/3$ at unit speed has $d\varphi/ds = 1/\sin\theta_0$ and $d^2\theta/ds^2 = 0$; the right side of the first geodesic equation is then $\sin\theta_0\cos\theta_0/\sin^2\theta_0 = \cot\theta_0$, printed as 0.577350 (Section 3.16). It is not zero, so the circle of latitude is not a geodesic.

In [12], Figure 03c.4.

```
fig = plt.figure(figsize=(6.4, 6.0))
ax = fig.add_subplot(projection="3d")
wire_sphere(ax)
for (degrees, (xyz, _)), colour, style in zip(geodesics.items(),
                                              (RED, ORANGE, AQUA), ("-", "--", "-.")):
    ax.plot(xyz[:, 0], xyz[:, 1], xyz[:, 2], color=colour, ls=style, lw=1.8,
            label=f"geodesic leaving at {degrees} degrees")
```

The wire sphere again, and the three geodesics, each in its own colour and line style; `zip` walks through the stored geodesics, the colours and the styles together, and the pattern `(degrees, (xyz, _))` takes apart each dictionary entry (the stored distance is not needed).

```
ax.plot(circle[:, 0], circle[:, 1], circle[:, 2], color=VIOLET, ls=":", lw=1.8,
        label="circle of latitude (not a geodesic)")
ax.scatter([1.0], [0.0], [0.0], color="black", s=30)
ax.set_title("Geodesics of the sphere from one point")
ax.legend(fontsize=7, loc="upper left")
```

The circle of latitude of In [9], dotted; the common starting point $(1, 0, 0)$ as a black dot (`scatter` draws points, `s` is their size); title and legend.

```
save_figure(fig, "geodesics_sphere",
            "Three geodesics of the unit sphere (axes $X$, $Y$, $Z$ in units of the "
...
check(all(np.allclose(xyz[-1], xyz[0], atol=1e-8) for xyz, _ in geodesics.values()),
      "every geodesic returns to its start after the length 2 pi")
```

The figure is saved; the check requires each geodesic to come back to its start after the length 2π, within 10^{-8}.

What Figure 03c.4 shows. The three geodesics leave the black dot on the equator in three directions; each is a full circle around the sphere, centred at its centre (a great circle), tilted the more steeply the more northward it starts, and each passes through the opposite point $(-1, 0, 0)$. The dotted circle of latitude is smaller and is not centred at the centre of the sphere: a traveller following it would have to keep turning towards the pole.

In [13], Figure 03c.5: geodesic deviation.

```
sigma = float(sphere_mixed[(0, 1, 0, 1)].subs(a, 1))  # the Gaussian curvature, a = 1
s_values, deviation_states = rk4(lambda s, y: np.array([y[1], -sigma * y[0]]),
                                 np.array([1.0, 0.0]), 0.0, np.pi / 2, 1000)
```

`sigma` is the Gaussian curvature σ computed in In [7], $1/a^2$, with $a = 1$, as a floating-point number. The deviation equation $\xi'' = -\sigma\xi$ of Section 3.18 as two first-order equations for (ξ, ξ'); `lambda s , y: ...` is a short function without a name that returns $(\xi', -\sigma\xi)$. RK4 solves it from $\xi = 1$, $\xi' = 0$ (start parallel, distance 1) over the length $\pi/2$ in 1000 steps.

```
d_phi = 1e-3  # the angle between the two meridians
chord = np.array([np.linalg.norm(point(np.pi / 2 - s, 0.0) - point(np.pi / 2 - s, d_phi))
                  for s in s_values]) / np.linalg.norm(point(np.pi / 2, 0.0)
                                                       - point(np.pi / 2, d_phi))
```

Two meridians 10^{-3} apart, followed from the equator northwards ($\theta = \pi/2 - s$). Their distance is measured as the length of the straight chord between the two points (`np.linalg.norm` is the length of a vector), divided by its value at the equator. The chord is $2\sin\theta\sin(\Delta\varphi/2)$, so the ratio is exactly $\sin\theta/\sin(\pi/2) = \cos s$, the result of Section 3.18 with $a = 1$.

```
fig, ax = plt.subplots()
ax.plot(s_values, chord, color=BLUE, lw=3.0, alpha=0.6,
        label="two meridians $10^{-3}$ apart (exact)")
ax.plot(s_values, deviation_states[:, 0], "--", color=RED, lw=1.8,
        label="deviation equation $\\xi^{\\prime\\prime} = -\\xi/a^2$ (RK4)")
ax.plot(s_values, np.ones_like(s_values), ":", color="black", lw=1.2,
        label="flat plane: parallel lines keep their distance")
ax.set_xlabel("length $s$ along the geodesics (unit $a$)")
ax.set_ylabel("distance / starting distance")
ax.set_title("Initially parallel geodesics meet at the pole")
ax.legend(fontsize=8)
```

The exact distance as a thick, partly transparent blue line (`alpha=0.6`), the RK4 solution as a dashed red line on top of it, and the flat plane as a dotted line at 1. Labels, title, legend.

```
agreement = np.max(np.abs(chord - deviation_states[:, 0]))
report("largest difference between the meridians and the deviation equation",
       f"{agreement:.1e}")
save_figure(fig, "geodesic_deviation",
            "The distance between two neighbouring geodesics that start parallel, "
...
check(agreement < 1e-6,
      "the curvature 1/a^2 predicts how fast neighbouring geodesics approach")
```

The largest difference between the two curves is printed: 8.0×10^{-14}. The figure is saved; the check requires the difference to be below 10^{-6}.

What Figure 03c.5 shows. The red dashed curve lies exactly on the blue one: both fall from 1 like $\cos s$ and reach 0 at $s = \pi/2$, the pole, where the meridians meet. The curvature $1/a^2$, computed from the Riemann tensor, predicts how fast two geodesics that start parallel approach each other. On the plane (dotted) the distance would stay 1.

In [14], the last check.

```
figure_names = ["plane_polar_components", "parallel_transport_sphere",
                "turning_angle", "geodesics_sphere", "geodesic_deviation"]
files = [output_file(f"{FIGURE_FOLDER}/03c_{k}_{n}.png")
         for k, n in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all five figure files exist")
all_checks_passed()
```

The names of the five figures, numbered from 1 by `enumerate(figure_names, 1)`; the check that all five files exist; and the last line, ALL 16 CHECKS PASSED (notebook 03c). The 16 checks are: 2 in In [4], 1 each in In [5] and In [6], 3 in In [7], 2 in In [8], 1 each in In [9] and In [10], 2 in In [11], and 1 each in In [12], In [13] and In [14].

3.23 The Christoffel symbols of the author's metric

Now the tools of Sections 3.15 to 3.17 are applied to the author's metric, by hand and completely. Throughout, i stands for any of the three 3-space directions x_1, x_2, x_3, j for any of the three

extra times x_5, x_6, x_7, and k for any of the six **transverse** directions (i or j). The scale factors (Section 3.7) are $h_0 = \cot z$, $h_i = e^{a_4}\sin^{1/6} z$, $h_4 = 1$, $h_j = b_4^{1/2} e^{-a_4}\sin^{1/6} z$, with the signs $\eta = (+,+,+,+,-,-,-,-)$ in the order $x_0, \ldots, x_7$.

The logarithmic derivatives of the scale factors. Only x_4 and x_0 appear in the metric, so only ∂_4 and ∂_0 can give something non-zero.

$$\partial_4 \ln h_i = \partial_4\big(a_4 + \tfrac{1}{6}\ln\sin z\big) = a_4' \equiv \alpha, \qquad \partial_4 \ln h_j = \partial_4\big(\tfrac{1}{2}\ln b_4 - a_4 + \tfrac{1}{6}\ln\sin z\big) = -a_4' + \frac{b_4'}{2b_4} \equiv \alpha_t$$

(the logarithm of a product is the sum of the logarithms; $\ln e^{\pm a_4} = \pm a_4$; $\ln b_4^{1/2} = \frac{1}{2}\ln b_4$, whose derivative is $b_4'/(2b_4)$; z does not depend on x_4). These are the two expansion rates of Section 3.7: α of 3-space and α_t of the extra times. We write α_k for the rate of the transverse direction k ($\alpha_i = \alpha$, $\alpha_j = \alpha_t$). For a constant b_4, $\alpha_t = -\alpha$.

$$\partial_0 \ln h_k = \tfrac{1}{6}\,\frac{\cos z}{\sin z}\cdot 6H = H\cot z$$

(for every transverse k, the parts a_4 and $\ln b_4$ do not depend on x_0; the chain rule with $dz/dx_0 = 6H$, Section 3.2).

$$\partial_0 \ln h_0 = \frac{1}{\cot z}\cdot\Big(-\frac{1}{\sin^2 z}\Big)\cdot 6H = -\frac{\sin z}{\cos z}\cdot\frac{6H}{\sin^2 z} = -\frac{6H}{\sin z\cos z}$$

(the derivative of $\ln u$ is u'/u; the derivative of $\cot z$ is $-1/\sin^2 z$; the chain rule). Since $1 = \sin^2 z + \cos^2 z$, $\frac{1}{\sin z\cos z} = \frac{\sin^2 z+\cos^2 z}{\sin z\cos z} = \tan z + \cot z$, so $\partial_0 \ln h_0 = -6H(\tan z + \cot z)$. Finally $h_4 = 1$ gives $\partial_4 \ln h_4 = \partial_0 \ln h_4 = 0$, and h_0 does not depend on x_4.

The four cases of Section 3.15. Case (a), $\Gamma^a{}_{aa} = \partial_a \ln h_a$: only $a = x_0$ gives a non-zero value,

$$\Gamma^{x_0}{}_{x_0x_0} = -6H(\tan z + \cot z) = -\frac{6H}{\sin z\cos z}.$$

Case (b), $\Gamma^a{}_{ab} = \Gamma^a{}_{ba} = \partial_b \ln h_a$ with $b \neq a$: with $b = x_4$,

$$\Gamma^{x_i}{}_{x_ix_4} = \alpha = a_4', \qquad \Gamma^{x_j}{}_{x_jx_4} = \alpha_t = -a_4' + \frac{b_4'}{2b_4},$$

and with $b = x_0$, for all six transverse directions,

$$\Gamma^{x_k}{}_{x_kx_0} = H\cot z$$

(the pairs $a = x_4$, $b = x_0$ and $a = x_0$, $b = x_4$ give zero, because h_4 is constant and h_0 does not depend on x_4). Case (c), $\Gamma^a{}_{bb} = -\eta_{aa}\eta_{bb}\,(h_b^2/h_a^2)\,\partial_a \ln h_b$ with $b \neq a$: it needs $\partial_a \ln h_b \neq 0$, so a is x_4 or x_0. For $a = x_4$ ($\eta_{44} = -1$, $h_4 = 1$) it is $+\eta_{bb}\,h_b^2\,\partial_4 \ln h_b = \eta_{kk}\,\alpha_k\,h_k^2$:

$$\Gamma^{x_4}{}_{x_ix_i} = (+1)\,h_i^2\,\alpha = a_4'\,e^{2a_4}\sin^{1/3} z, \qquad \Gamma^{x_4}{}_{x_jx_j} = (-1)\,h_j^2\,\alpha_t = \Big(a_4'b_4 - \frac{b_4'}{2}\Big)e^{-2a_4}\sin^{1/3} z$$

(with $h_j^2 = b_4 e^{-2a_4}\sin^{1/3} z$; for a constant b_4 the two minus signs of the extra times, from η_{jj} and from the deflation $\alpha_t = -a_4'$, multiply to $+1$). For $a = x_0$ ($\eta_{00} = +1$, $h_0^2 = \cot^2 z$) it is $-\eta_{bb}\,(h_b^2/\cot^2 z)\,H\cot z = -\eta_{bb}\,H\tan z\,h_b^2$:

$$\Gamma^{x_0}{}_{x_i x_i} = -H\tan z\; e^{2a_4}\sin^{1/3} z, \qquad \Gamma^{x_0}{}_{x_j x_j} = +H\tan z\; b_4 e^{-2a_4}\sin^{1/3} z$$

($\cot z/\cot^2 z = 1/\cot z = \tan z$). Case (d) gives only zeros.

The complete list. Counting both orders of the lower indices: case (a) 1 symbol; case (b) 2×6 with x_4 and 2×6 with x_0; case (c) 6 with upper x_4 and 6 with upper x_0: $1+12+12+6+6 = 37$ non-zero symbols of the $8^3 = 512$. With the lower indices ordered ($b \le c$, in the order $x_0,\dots,x_7$) there are $1+6+6+6+6 = 25$:

symbol ($b \le c$)	**value**	**how many**
$\Gamma^{x_0}{}_{x_0 x_0}$	$-6H(\tan z + \cot z)$	1
$\Gamma^{x_0}{}_{x_i x_i}$	$-H\tan z\, e^{2a_4}\sin^{1/3} z$	3
$\Gamma^{x_0}{}_{x_j x_j}$	$H\tan z\, b_4 e^{-2a_4}\sin^{1/3} z$	3
$\Gamma^{x_k}{}_{x_0 x_k}$, $k = 1,2,3,5,6,7$	$H\cot z$	6
$\Gamma^{x_i}{}_{x_i x_4}$, $i = 1,2,3$	a_4'	3
$\Gamma^{x_4}{}_{x_i x_i}$	$a_4'\, e^{2a_4}\sin^{1/3} z$	3
$\Gamma^{x_4}{}_{x_j x_j}$	$\big(a_4' b_4 - \frac{1}{2}b_4'\big)e^{-2a_4}\sin^{1/3} z$	3
$\Gamma^{x_j}{}_{x_4 x_j}$, $j = 5,6,7$	$-a_4' + b_4'/(2b_4)$	3

This is exactly the list `christoffelNonzero_b_le_c` of the record `Revision/gkd_lovelock/results/curvature.json` (PROVED here by hand; Notebook 03b reproduces it symbol by symbol, In [7]; the independent verification of the record agrees, `python-lovelock-report.json`, check `rust_christoffels_agree`). The record writes $\tan z$ as `Cot[6*H*x0]^(-1)` and $\Gamma^{x_4}{}_{x_j x_j}$ as the sum `-(1/2)*E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*Derivative[1][b4][x4] + Derivative[1][a4][x4]*E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*b4[x4]`. Every symbol has at least one index x_4 or x_0, the two coordinates on which the metric depends. The deflation is visible in the last row: for a constant b_4 the extra-time symbols $\Gamma^{x_j}{}_{x_4 x_j} = -a_4'$ have the opposite sign of the 3-space ones.

Observers at rest fall freely. No symbol has the lower pair (x_4, x_4): case (a) with $a = x_4$ is $\partial_4 \ln h_4 = 0$, and case (c) with $b = x_4$ contains $\partial_a \ln h_4 = 0$. So $\Gamma^a{}_{x_4 x_4} = 0$ for every a, for all functions a_4 and b_4. An observer who keeps $x_0, x_1, x_2, x_3, x_5, x_6, x_7$ fixed while $x_4 = \tau$ runs has $u^a = dx^a/d\tau = 1$ for $a = x_4$ and 0 otherwise, and $du^a/d\tau = 0$; the geodesic equation of Section 3.16 reads $0 + \Gamma^a{}_{x_4 x_4}\cdot 1\cdot 1 = 0$, which holds. The squared speed is $g(u,u) = g_{44} = -1$, so $\tau = x_4$ is the observer's proper time. **Observers at rest are in free fall, and their clocks show** x_4 (PROVED; Notebook 03b, In [12]).

The contracted symbols. By Section 3.15, $\sum_a \Gamma^a{}_{ab} = \partial_b \ln\sqrt{|\det g|} = \partial_b \ln(b_4^{3/2}\cos z)$. Check with the list: for $b = x_4$, $\sum_a \Gamma^a{}_{a4} = 3\alpha + 3\alpha_t = 3a_4' - 3a_4' + \frac{3}{2}b_4'/b_4 = \frac{3}{2}b_4'/b_4$, and $\partial_4 \ln b_4^{3/2} = \frac{3}{2}b_4'/b_4$; for $b = x_0$, $\sum_a \Gamma^a{}_{a0} = 6H\cot z - 6H(\tan z + \cot z) = -6H\tan z$, and $\partial_0 \ln\cos z = -\frac{\sin z}{\cos z}\cdot 6H = -6H\tan z$. Both agree (Notebook 03b, In [12]). In the x_4 sum the three inflating and the three deflating directions cancel through a_4; only b_4 is left.

3.24 The curvature of the author's metric, by hand

The curvature of every coordinate plane. For a diagonal metric, Section 3.17 gives $\sigma(a,b) = R^{ab}{}_{ab} = g^{bb}R^{a}{}_{bab}$ (no sum), with

$$R^{a}{}_{bab} = \partial_a\Gamma^{a}{}_{bb} - \partial_b\Gamma^{a}{}_{ba} + \sum_e (\Gamma^{a}{}_{ae}\Gamma^{e}{}_{bb} - \Gamma^{a}{}_{be}\Gamma^{e}{}_{ba})$$

(the formula of Section 3.17 with $c = a$ and $d = b$). The 28 coordinate planes fall into seven kinds. We compute each kind once, with general labels, so that the computation holds for every plane of that kind. Two facts from the list of Section 3.23 are used again and again: a derivative ∂_i, ∂_j of anything is zero (nothing depends on the transverse coordinates), and the only non-zero symbols with the upper index x_k are $\Gamma^{x_k}{}_{x_kx_4}$, $\Gamma^{x_k}{}_{x_4x_k}$, $\Gamma^{x_k}{}_{x_kx_0}$ and $\Gamma^{x_k}{}_{x_0x_k}$. In the list, $\Gamma^{4}{}_{kk} = \eta_{kk}\alpha_k h_k^2$ and $\Gamma^{0}{}_{kk} = -\eta_{kk}H\tan z\, h_k^2$.

(1) Two different 3-space directions i and i' (3 planes):

$$R^{i}{}_{i'ii'} = 0 - 0 + \Gamma^{i}{}_{i4}\Gamma^{4}{}_{i'i'} + \Gamma^{i}{}_{i0}\Gamma^{0}{}_{i'i'} - 0 = \alpha\cdot\alpha h_{i'}^2 + H\cot z\cdot\left(-H\tan z\, h_{i'}^2\right) = (\alpha^2 - H^2)\, h_{i'}^2$$

($\Gamma^{i}{}_{i'i'} = \Gamma^{i}{}_{i'i} = 0$ because $i' \neq i$; in $\sum_e \Gamma^{i}{}_{ie}\Gamma^{e}{}_{i'i'}$ only $e = x_4$ and $e = x_0$ survive; every $\Gamma^{i}{}_{i'e}$ is zero; $\cot z\tan z = 1$), so $\sigma(i,i') = g^{i'i'}(\alpha^2 - H^2)h_{i'}^2 = \alpha^2 - H^2$ (with $g^{i'i'} = 1/h_{i'}^2$).

(2) Two different extra times j and j' (3 planes):

$$R^{j}{}_{j'jj'} = \Gamma^{j}{}_{j4}\Gamma^{4}{}_{j'j'} + \Gamma^{j}{}_{j0}\Gamma^{0}{}_{j'j'} = \alpha_t\cdot(-\alpha_t h_{j'}^2) + H\cot z\cdot H\tan z\, h_{j'}^2 = (H^2 - \alpha_t^2)\, h_{j'}^2$$

($\Gamma^{j}{}_{j'j'} = \Gamma^{j}{}_{j'j} = 0$ because $j' \neq j$, so both derivative terms vanish; in $\sum_e \Gamma^{j}{}_{je}\Gamma^{e}{}_{j'j'}$ only $e = x_4$ and $e = x_0$ survive; every $\Gamma^{j}{}_{j'e}$ is zero; $\cot z\tan z = 1$), so $\sigma(j,j') = g^{j'j'}(H^2 - \alpha_t^2)h_{j'}^2 = \alpha_t^2 - H^2$ (with $g^{j'j'} = -1/h_{j'}^2$).

(3) A 3-space direction i and an extra time j (9 planes):

$$R^{i}{}_{jij} = \Gamma^{i}{}_{i4}\Gamma^{4}{}_{jj} + \Gamma^{i}{}_{i0}\Gamma^{0}{}_{jj} = \alpha\cdot(-\alpha_t h_j^2) + H\cot z\cdot H\tan z\, h_j^2 = (H^2 - \alpha\alpha_t)\, h_j^2,$$

($\Gamma^{i}{}_{jj} = \Gamma^{i}{}_{ji} = 0$, so both derivative terms vanish; in $\sum_e \Gamma^{i}{}_{ie}\Gamma^{e}{}_{jj}$ only $e = x_4$ and $e = x_0$ survive; every $\Gamma^{i}{}_{je}$ is zero; $\cot z\tan z = 1$), so $\sigma(i,j) = g^{jj}(H^2 - \alpha\alpha_t)h_j^2 = \alpha\alpha_t - H^2$ (with $g^{jj} = -1/h_j^2$).

(4) A 3-space direction i and the time x_4 (3 planes):

$$R^{i}{}_{4i4} = \partial_i\Gamma^{i}{}_{44} - \partial_4\Gamma^{i}{}_{4i} + \sum_e \Gamma^{i}{}_{ie}\Gamma^{e}{}_{44} - \sum_e \Gamma^{i}{}_{4e}\Gamma^{e}{}_{4i} = 0 - \alpha' + 0 - \alpha^2$$

(∂_i gives zero; $\partial_4\alpha = \alpha' = a_4''$; every $\Gamma^{e}{}_{44}$ is zero, Section 3.23; in the last sum only $e = i$ survives), so $\sigma(i,4) = g^{44}(-\alpha' - \alpha^2) = \alpha^2 + \alpha'$ (with $g^{44} = -1$).

(5) An extra time j and the time x_4 (3 planes): the same three steps with $a = j$,

$$R^{j}{}_{4j4} = -\partial_4 \Gamma^{j}{}_{4j} - (\Gamma^{j}{}_{4j})^2 = -\alpha_t' - \alpha_t^2,$$

so $\sigma(j,4) = g^{44}(-\alpha_t' - \alpha_t^2) = \alpha_t^2 + \alpha_t'$, with the derivative of the extra-time rate

$$\alpha_t' = -a_4'' + \frac{b_4''}{2b_4} - \frac{b_4'^2}{2b_4^2}$$

(the quotient rule for $b_4'/(2b_4)$).

(6) A transverse direction k and the hidden direction x_0 (6 planes):

$$R^{k}{}_{0k0} = \partial_k \Gamma^{k}{}_{00} - \partial_0 \Gamma^{k}{}_{0k} + \Gamma^{k}{}_{k0}\Gamma^{0}{}_{00} - \Gamma^{k}{}_{0k}\Gamma^{k}{}_{0k}$$

(in $\sum_e \Gamma^{k}{}_{ke}\Gamma^{e}{}_{00}$ only $e = x_0$ survives, because $\Gamma^{e}{}_{00}$ is non-zero only for $e = x_0$; in $\sum_e \Gamma^{k}{}_{0e}\Gamma^{e}{}_{0k}$ only $e = k$)

$$= 0 + \frac{6H^2}{\sin^2 z} + H\cot z \cdot \big(-6H(\tan z + \cot z)\big) - H^2\cot^2 z = \frac{6H^2}{\sin^2 z} - 6H^2(1 + \cot^2 z) - H^2\cot^2 z$$

($\partial_0(H\cot z) = H\cdot(-1/\sin^2 z)\cdot 6H$, so $-\partial_0\Gamma^{k}{}_{0k} = +6H^2/\sin^2 z$; $\cot z \tan z = 1$)

$$= -H^2\cot^2 z$$

($1 + \cot^2 z = (\sin^2 z + \cos^2 z)/\sin^2 z = 1/\sin^2 z$, so the first two terms cancel). Hence $\sigma(k,0) = g^{00}(-H^2\cot^2 z) = \tan^2 z \cdot (-H^2\cot^2 z) = -H^2$. Neither a_4 nor b_4 enters: the x_0-dependence of every h_k is the same factor $\sin^{1/6} z$.

(7) The time x_4 and the hidden direction x_0 (1 plane):

$$R^{4}{}_{040} = \partial_4 \Gamma^{4}{}_{00} - \partial_0 \Gamma^{4}{}_{04} + \sum_e \Gamma^{4}{}_{4e}\Gamma^{e}{}_{00} - \sum_e \Gamma^{4}{}_{0e}\Gamma^{e}{}_{04} = 0$$

(the only non-zero symbols with upper index x_4 are $\Gamma^{4}{}_{kk}$, and none of $\Gamma^{4}{}_{00}$, $\Gamma^{4}{}_{04}$, $\Gamma^{4}{}_{4e}$, $\Gamma^{4}{}_{0e}$ is of that form), so $\sigma(4,0) = 0$: this plane is flat.

The table of the plane curvatures (PROVED; Notebook 03b computes all 28 and finds these seven formulas, In [16]), with $\alpha = a_4'$ and $\alpha_t = -a_4' + b_4'/(2b_4)$:

plane	**how many**	**curvature** $\sigma(a,b) = R^{ab}{}_{ab}$	**for a constant** b_4
two 3-space directions	3	$\alpha^2 - H^2$	$a_4'^2 - H^2$
two extra times	3	$\alpha_t^2 - H^2$	$a_4'^2 - H^2$
a 3-space direction and an extra time	9	$\alpha\alpha_t - H^2$	$-(a_4'^2 + H^2)$
a 3-space direction and the time x_4	3	$\alpha^2 + \alpha'$	$a_4'^2 + a_4''$

plane	**how many**	**curvature** $\sigma(a,b) = R^{ab}{}_{ab}$	**for a constant** b_4
an extra time and the time x_4	3	$\alpha_t^2 + \alpha_t'$	$a_4'^2 - a_4''$
a transverse direction and the hidden x_0	6	$-H^2$	$-H^2$
the time x_4 and the hidden x_0	1	0	0

None depends on z or on the value of a_4; only H, the rates α, α_t and their derivatives appear (and so a_4', a_4'', b_4'/b_4 and b_4''/b_4). Along the history $a_4 = AHx_4$, $b_4 = 1$ ($a_4' = AH$, $a_4'' = 0$) the planes inside 3-space and inside the extra times have $H^2(A^2-1)$: negative for $A < 1$, zero for the canonical $A = 1$, positive for $A > 1$. The planes that mix 3-space and the extra times have $-H^2(A^2+1)$, negative for every A.

What the signs mean. By Section 3.17 the sign of $\sigma(a,b)$ describes a shape only in the 6 planes of two space-like directions: the 3 planes inside 3-space ($\alpha^2 - H^2$; along the history saddle-like for $A < 1$, flat for $A = 1$, sphere-like for $A > 1$) and the 3 planes of a 3-space direction with x_0 ($-H^2$, saddle-like). In the 6 planes of two time-like directions (inside the extra times, and an extra time with x_4) the shape reading is reversed: there a positive σ would mean saddle-like. The other 16 planes contain one space-like and one time-like direction; for them, and for every plane that contains x_4, the sign is read from free fall, $d^2\xi/d\tau^2 = +\sigma\,\xi$ (Section 3.18). We now verify this rule by hand where it can be seen most simply: for the observers at rest of Section 3.23, which fall freely along x_4 with the proper time $\tau = x_4$. Take two of them that differ only by a small coordinate distance Δx_k along a transverse direction x_k. Their proper distance is

$$\xi = h_k\,\Delta x_k$$

(Section 3.7; Δx_k and z do not change along the two paths). Differentiate twice with respect to $\tau = x_4$, with $\partial_4 h_k = \alpha_k h_k$:

$$\frac{d\xi}{d\tau} = \alpha_k\,h_k\,\Delta x_k = \alpha_k\,\xi, \qquad \frac{d^2\xi}{d\tau^2} = \alpha_k'\,\xi + \alpha_k\,\frac{d\xi}{d\tau} = (\alpha_k^2 + \alpha_k')\,\xi$$

(the product rule). For $k = x_1$ the factor is exactly $\sigma(x_1,x_4) = \alpha^2 + \alpha'$ of case (4), and for $k = x_5$ exactly $\sigma(x_5,x_4) = \alpha_t^2 + \alpha_t'$ of case (5): $d^2\xi/d\tau^2 = +\sigma\,\xi$. For two observers a distance Δx_0 apart along x_0, $\xi = \cot z\,\Delta x_0$ does not change in time, $d^2\xi/d\tau^2 = 0$, in agreement with the flat plane of case (7). All three PROVED; Notebook 03b checks the first two exactly (In [16]). Along the history both $\sigma(x_1,x_4)$ and $\sigma(x_5,x_4)$ equal $A^2H^2 > 0$: a positive curvature, and yet the 3-space distance grows like $e^{AH\tau}$ and the extra-time distance $e^{-AH\tau}$ falls ever more slowly, both with a positive second derivative. On the sphere of Section 3.18 a positive curvature pulls neighbouring geodesics together; here it drives them apart.

The components that are not plane curvatures. Each plane with $\sigma \neq 0$ gives four non-zero components, $R^{ab}{}_{ab} = R^{ba}{}_{ba} = \sigma(a,b)$ and $R^{ab}{}_{ba} = R^{ba}{}_{ab} = -\sigma(a,b)$ (Section 3.17): $27 \times 4 = 108$ components (for general functions every one of the 27 curved planes has $\sigma \neq 0$). The other non-zero components connect the planes (x_4,x_k) and (x_0,x_k). First

$$R^4{}_{k0k} = \partial_0\Gamma^4{}_{kk} - \partial_k\Gamma^4{}_{k0} + \sum_e \Gamma^4{}_{0e}\Gamma^e{}_{kk} - \sum_e \Gamma^4{}_{ke}\Gamma^e{}_{k0} = \partial_0\Gamma^4{}_{kk} - \Gamma^4{}_{kk}\Gamma^k{}_{k0}$$

(the formula with $a = x_4$, $b = k$, $c = x_0$, $d = k$; $\Gamma^4{}_{k0} = 0$ and every $\Gamma^4{}_{0e} = 0$; in the last sum only $e = k$). With $\Gamma^4{}_{kk} = \eta_{kk}\alpha_k h_k^2$ (Section 3.23) and $\partial_0 h_k^2 = 2H\cot z\, h_k^2$ (twice the logarithmic derivative),

$$R^4{}_{k0k} = 2\eta_{kk}\alpha_k H\cot z\, h_k^2 - \eta_{kk}\alpha_k h_k^2\, H\cot z = \eta_{kk}\,\alpha_k H\cot z\, h_k^2,$$

and raising the second index, $R^{4k}{}_{0k} = g^{kk}R^4{}_{k0k}$ with $g^{kk} = \eta_{kk}/h_k^2$ and $\eta_{kk}^2 = 1$:

$$R^{4k}{}_{0k} = H\alpha_k\cot z, \qquad \text{that is} \qquad R^{4i}{}_{0i} = Ha_4'\cot z, \quad R^{4j}{}_{0j} = H\alpha_t\cot z.$$

Next, the components with the upper index x_0:

$$R^0{}_{k4k} = \partial_4\Gamma^0{}_{kk} - \partial_k\Gamma^0{}_{k4} + \sum_e \Gamma^0{}_{4e}\Gamma^e{}_{kk} - \sum_e \Gamma^0{}_{ke}\Gamma^e{}_{k4} = \partial_4\Gamma^0{}_{kk} - \Gamma^0{}_{kk}\Gamma^k{}_{k4}$$

(the formula with $a = x_0$, $b = k$, $c = x_4$, $d = k$; $\Gamma^0{}_{k4} = 0$, every $\Gamma^0{}_{4e} = 0$; in the last sum only $e = k$). With $\Gamma^0{}_{kk} = -\eta_{kk}H\tan z\, h_k^2$, $\partial_4 h_k^2 = 2\alpha_k h_k^2$ and $\Gamma^k{}_{k4} = \alpha_k$,

$$R^0{}_{k4k} = -2\eta_{kk}H\alpha_k\tan z\, h_k^2 + \eta_{kk}H\tan z\, h_k^2\,\alpha_k = -\eta_{kk}\,H\alpha_k\tan z\, h_k^2, \qquad R^{0k}{}_{4k} = -H\alpha_k\tan z.$$

For each of the six transverse k, the antisymmetries give four components of each of these two kinds: $6 \times 8 = 48$ components, of size $H|\alpha_k|\cot z$ or $H|\alpha_k|\tan z$. Together $108 + 48 = 156$, exactly the number of non-zero components $R^{ab}{}_{cd}$ that the Rust program of the record and Notebook 03b find (`Revision/gkd_lovelock/results/lovelock-report.json`, check `riemann_antisymmetry`: "156 nonzero entries"); so the list is complete. They take 20 different values: $\pm$ the five plane curvatures that are not $\pm H^2$, $\pm H^2$, and $\pm H\alpha\cot z$, $\pm H\alpha\tan z$, $\pm H\alpha_t\cot z$, $\pm H\alpha_t\tan z$ (Notebook 03b, In [15]). These 48 components depend on z, and they grow without bound at one end of the patch or the other. This is an effect of the coordinate x_0, not of the geometry. Measured with the rulers and clocks of the frame of Section 3.7, an upper index a is multiplied by its scale factor h_a (a step dx^a has the proper length $h_a\,dx^a$), and a lower index is divided by it (so that a contraction keeps its value, Section 3.14). The frame component of $R^{4k}{}_{0k}$ is therefore $\frac{h_4 h_k}{h_0 h_k}R^{4k}{}_{0k} = \tan z\cdot H\alpha_k\cot z = H\alpha_k$, and that of $R^{0k}{}_{4k}$ is $\cot z\cdot(-H\alpha_k\tan z) = -H\alpha_k$: they no longer depend on z. The plane curvatures keep their values, because there the factors cancel.

Where the deflation shows. Every formula above holds for each transverse direction with its own rate α_k; 3-space and the extra times differ only through α and α_t. For a constant b_4, $\alpha_t = -\alpha$: then the 48 components of 3-space and of the extra times have opposite signs, and the next section shows that these opposite signs make the Ricci tensor diagonal. When b_4 changes, $\alpha + \alpha_t = b_4'/(2b_4) \neq 0$ and the cancellation is incomplete.

3.25 Ricci, Einstein and Kretschmann of the author's metric; the contracted Bianchi identity

The diagonal of the Ricci tensor. By Section 3.17, $R^a{}_a$ is the sum of the curvatures of the seven planes that contain x_a. From the table of Section 3.24:

$$R^i{}_i = 2(\alpha^2 - H^2) + 3(\alpha\alpha_t - H^2) + (\alpha^2 + \alpha') - H^2 = 3\alpha^2 + 3\alpha\alpha_t + \alpha' - 6H^2$$

(two planes with the other 3-space directions, three with the extra times, one with x_4, one with x_0; then collect: $-2-3-1=-6$ times H^2);

$$R^4{}_4 = 3(\alpha^2 + \alpha') + 3(\alpha_t^2 + \alpha_t') + 0$$

(three planes with 3-space, three with the extra times, one with x_0);

$$R^j{}_j = 3(\alpha\alpha_t - H^2) + 2(\alpha_t^2 - H^2) + (\alpha_t^2 + \alpha_t') - H^2 = 3\alpha\alpha_t + 3\alpha_t^2 + \alpha_t' - 6H^2$$

(three planes with 3-space, two with the other extra times, one with x_4, one with x_0);

$$R^0{}_0 = 6\cdot(-H^2) + 0 = -6H^2$$

(six planes with the transverse directions, one with x_4). The Ricci scalar is the sum of the diagonal:

$$R = 3R^i{}_i + R^4{}_4 + 3R^j{}_j + R^0{}_0 = 12\alpha^2 + 18\alpha\alpha_t + 12\alpha_t^2 + 6\alpha' + 6\alpha_t' - 42H^2$$

(collect: $9+3=12$ times α^2, $9+9=18$ times $\alpha\alpha_t$, $3+9=12$ times α_t^2, $3+3=6$ times α' and α_t', $-18-18-6=-42$ times H^2). Inserting $\alpha = a_4'$, $\alpha_t = -a_4' + \beta$ with $\beta = b_4'/(2b_4)$, and $\alpha_t' = -a_4'' + b_4''/(2b_4) - 2\beta^2$: the terms $12\alpha^2 + 18\alpha\alpha_t + 12\alpha_t^2$ become $6a_4'^2 - 6a_4'\beta + 12\beta^2$, the terms $6\alpha' + 6\alpha_t'$ become $3b_4''/b_4 - 12\beta^2$, and

$$R = 6a_4'^2 - 3a_4'\frac{b_4'}{b_4} + 3\frac{b_4''}{b_4} - 42H^2.$$

For a constant b_4 ($\alpha_t = -\alpha$, $\alpha_t' = -\alpha'$) the four diagonal entries are $R^i{}_i = a_4'' - 6H^2$, $R^4{}_4 = 6a_4'^2$, $R^j{}_j = -a_4'' - 6H^2$, $R^0{}_0 = -6H^2$, and $R = 6a_4'^2 - 42H^2$.

The entries off the diagonal. An entry $R^a{}_b = \sum_c R^{ac}{}_{bc}$ with $a \neq b$ needs a non-zero component whose upper pair (a,c) and lower pair (b,c) differ in one index. The 108 plane components have the same two indices up and down, so they give nothing. The 48 others have the pairs $\{x_4, x_k\}$ and $\{x_0, x_k\}$, so the only candidates are $R^4{}_0$ and $R^0{}_4$:

$$R^4{}_0 = \sum_i R^{4i}{}_{0i} + \sum_j R^{4j}{}_{0j} = 3H(\alpha + \alpha_t)\cot z = \frac{3}{2}H\cot z\,\frac{b_4'}{b_4},$$

$$R^0{}_4 = \sum_i R^{0i}{}_{4i} + \sum_j R^{0j}{}_{4j} = -3H(\alpha + \alpha_t)\tan z = -\frac{3}{2}H\tan z\,\frac{b_4'}{b_4}$$

(Section 3.24; the terms $c = x_4$ and $c = x_0$ vanish by the antisymmetries; $\alpha + \alpha_t = b_4'/(2b_4)$). **The Ricci tensor is diagonal exactly when b_4 is constant**: then the three inflating and the three deflating directions cancel exactly. A changing b_4 leaves the two entries above. If the extra times inflated like 3-space, $g_{jj} = -e^{2a_4}\sin^{1/3} z$ (the member $b_4 = e^{4a_4}$ of the family, with $\alpha_t = +a_4'$), the extra-time terms would have the same sign as the 3-space terms, and $R^4{}_0$ would be $6Ha_4'\cot z$: Notebook 03b computes exactly this negative control (In [27]) and finds $G^{x_4}{}_{x_0} = 6Ha_4'\cot z$ and $G^{x_0}{}_{x_4} = -6Ha_4'\tan z$, the two general entries with $b_4'/b_4 = 4a_4'$.

The Einstein tensor. $G^a{}_b = R^a{}_b - \frac{1}{2}\delta^a{}_b R$. Off the diagonal $\delta^a{}_b = 0$, so $G^4{}_0 = R^4{}_0$ and $G^0{}_4 = R^0{}_4$. On the diagonal, subtracting $\frac{1}{2}R = 3a_4'^2 - \frac{3}{2}a_4'b_4'/b_4 + \frac{3}{2}b_4''/b_4 - 21H^2$ from each entry of the Ricci tensor (written out with a_4 and b_4 as above):

$$G^0{}_0 = 15H^2 - 3a_4'^2 + \frac{3a_4'b_4'}{2b_4} - \frac{3b_4''}{2b_4}, \quad G^i{}_i = 15H^2 - 3a_4'^2 + a_4'' + \frac{3a_4'b_4'}{b_4} - \frac{3b_4''}{2b_4},$$
$$G^4{}_4 = 21H^2 + 3a_4'^2 - \frac{3a_4'b_4'}{2b_4} - \frac{3b_4'^2}{4b_4^2}, \quad G^j{}_j = 15H^2 - 3a_4'^2 - a_4'' + \frac{b_4'^2}{4b_4^2} - \frac{b_4''}{b_4}.$$

$G^4{}_4$ contains no second derivative: in the rates, $G^4{}_4 = 21H^2 - 3(\alpha^2 + 3\alpha\alpha_t + \alpha_t^2)$. For a constant b_4,

$$G^0{}_0 = 15H^2 - 3a_4'^2, \qquad G^i{}_i = a_4'' - 3a_4'^2 + 15H^2, \qquad G^4{}_4 = 3a_4'^2 + 21H^2, \qquad G^j{}_j = -a_4'' - 3a_4'^2 + 15H^2,$$

and every entry off the diagonal is zero. These are exactly the entries `ricciMixed`, `ricciScalar` and `einsteinMixed` of `Revision/gkd_lovelock/results/curvature.json` (PROVED here; Notebook 03b reproduces all 64 + 64 + 1 of them, In [17]; record check `rust_ricci_einstein_scalar_agree` of `python-lovelock-report.json`), and the components `b4.lovelockTensors.E1` of the record `Revision/field_equations_a4/a4-equations.json`. The verifier of the metric with b_4 states the off-diagonal pair (`Revision/metric_b4/results/wolfram-metric-b4-report.json`, checks `off_diagonal_entries_x0_x4_only` and `off_diagonal_proportional_to_b4prime`). The lead's independent check, made for $b_4 = 1$, states the same properties there (`Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, checks `einstein_off_diagonal_zero`, `einstein_x0_independent`, `einstein_isotropy`): at $b_4 = 1$, G is diagonal and no entry depends on x_0; for every b_4 the three 3-space entries are equal, as are the three extra-time entries. Moreover, at $b_4 = 1$,

$$G^4{}_4 - G^0{}_0 = 3a_4'^2 + 21H^2 - 15H^2 + 3a_4'^2 = 6(a_4'^2 + H^2) > 0 \quad \text{for } H > 0$$

(record check `no_vacuum_for_H_positive`), a fact used in Section 3.26.

The Kretschmann scalar. In $K = \sum_{a,b,c,d} R^{ab}{}_{cd}R^{cd}{}_{ab}$ each component is multiplied by its partner with the two pairs exchanged. The four components of a plane are their own partners or each other's, and each of the four products is $\sigma(a,b)^2$ (Section 3.17), so the planes contribute $4\sum_{\text{planes}}\sigma(a,b)^2$. Each of the 48 other components is paired with one of the other kind, $R^{4k}{}_{0k}R^{0k}{}_{4k} = (H\alpha_k\cot z)(-H\alpha_k\tan z) = -H^2\alpha_k^2$; the sign changes of the antisymmetries act on both factors, so the 24 products of 3-space equal $-H^2\alpha^2$ and the 24 of the extra times $-H^2\alpha_t^2$. Therefore

$$K = 4\sum_{\text{planes}}\sigma(a,b)^2 - 24H^2(\alpha^2 + \alpha_t^2),$$

$$\sum_{\text{planes}} \sigma(a,b)^2 = 3(\alpha^2 - H^2)^2 + 3(\alpha_t^2 - H^2)^2 + 9(\alpha\alpha_t - H^2)^2 + 3(\alpha^2 + \alpha')^2 + 3(\alpha_t^2 + \alpha_t')^2 + 6H^4$$

(the table of Section 3.24). In every product $\cot z$ meets $\tan z$, so although 48 components depend on z and grow without bound at the ends of the patch, the invariant K does not depend on z, and it does not depend on the value of a_4. For a constant b_4 ($\alpha_t = -\alpha = -a_4'$, $\alpha_t' = -a_4''$) the sum is

$$\sum_{\text{planes}} \sigma(a,b)^2 = 6(a_4'^2 - H^2)^2 + 9(a_4'^2 + H^2)^2 + 3(a_4'^2 + a_4'')^2 + 3(a_4'^2 - a_4'')^2 + 6H^4$$

$$= (6a_4'^4 - 12a_4'^2H^2 + 6H^4) + (9a_4'^4 + 18a_4'^2H^2 + 9H^4) + (6a_4'^4 + 6a_4''^2) + 6H^4 = 21a_4'^4 + 6a_4'^2H^2 + 21H^4 + 6a_4''^2$$

(the squares expanded; in $3(p+q)^2 + 3(p-q)^2 = 6p^2 + 6q^2$ the mixed terms cancel), and therefore

$$K = 4(21a_4'^4 + 6a_4'^2H^2 + 21H^4 + 6a_4''^2) - 48H^2a_4'^2 = 12(7H^4 - 2H^2a_4'^2 + 7a_4'^4 + 2a_4''^2)$$

($24 - 48 = -24$ times $a_4'^2H^2$; then 12 taken out). Completing the square,

$$\frac{K}{12} = 7\Big(a_4'^2 - \frac{H^2}{7}\Big)^2 + \frac{48}{7}H^4 + 2a_4''^2$$

(expand: $7a_4'^4 - 2H^2a_4'^2 + H^4/7$, and $H^4/7 + 48H^4/7 = 7H^4$), so $K \geq \frac{576}{7}H^4 > 0$ for every history with a constant b_4: **with a constant b_4 the author's metric is curved everywhere, for every function $a_4(x_4)$ and every $H > 0$** (PROVED; Notebook 03b checks the formula and computes K a second time from the 156 components of the record, In [22]). For a changing b_4 there is no such bound: for the member $b_4 = e^{4a_4}$ of the negative control ($\alpha_t = \alpha$, $\alpha_t' = \alpha'$) the same two formulas give $K = 12\big(7(a_4'^2 - H^2)^2 + 4a_4'^2a_4'' + 2a_4''^2\big)$, which vanishes for $a_4' = H$, $a_4'' = 0$ (Notebook 03b, In [27]). Along the history $a_4 = AHx_4$, $b_4 = 1$: $R = 6H^2(A^2 - 7)$ and $K = 12H^4(7A^4 - 2A^2 + 7)$; for the canonical $A = 1$, $R = -36H^2$ and $K = 144H^4$.

The contracted Bianchi identity. For every metric the Einstein tensor has zero **divergence**, $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$ for each ν (the divergence is the covariant derivative with its index μ set equal to the upper index of G and summed; a standard theorem, the **contracted Bianchi identity**; quoted, ASSUMED in general). For the author's metric we prove it directly. By the rule of Section 3.15 (one $+\Gamma$ for the upper index, one $-\Gamma$ for the lower one, then the upper index contracted with the derivative),

$$\sum_\mu \nabla_\mu G^\mu{}_\nu = \sum_\mu \partial_\mu G^\mu{}_\nu + \sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda} G^\lambda{}_\nu - \sum_{\mu,\lambda} \Gamma^\lambda{}_{\mu\nu} G^\mu{}_\lambda .$$

For the diagonal entries of G the first sum keeps $\mu = \nu$, the second $\lambda = \nu$ and the third $\lambda = \mu$; the two entries $G^4{}_0$ and $G^0{}_4$ add their own terms. Write $\Gamma_b = \sum_\mu \Gamma^\mu{}_{\mu b}$ for the contracted symbols of Section 3.23: $\Gamma_4 = 3(\alpha + \alpha_t)$ and $\Gamma_0 = -6H\tan z$.

For $\nu = x_4$: the diagonal part is $\partial_4 G^4{}_4 + 3\alpha(G^4{}_4 - G^i{}_i) + 3\alpha_t(G^4{}_4 - G^j{}_j)$ (the sum over μ of $\Gamma^\mu{}_{\mu 4}(G^4{}_4 - G^\mu{}_\mu)$, with $\Gamma^i{}_{i4} = \alpha$ and $\Gamma^j{}_{j4} = \alpha_t$), and $G^0{}_4$ adds $\partial_0 G^0{}_4 + \Gamma_0\, G^0{}_4$:

$$\partial_0 G^0{}_4 + \Gamma_0\, G^0{}_4 = -\frac{3}{2}\,6H^2 \frac{1}{\cos^2 z}\frac{b_4'}{b_4} + 6H\tan z \cdot \frac{3}{2} H \tan z\, \frac{b_4'}{b_4} = -9H^2 \frac{b_4'}{b_4}\Big(\frac{1}{\cos^2 z} - \tan^2 z\Big) = -9H^2 \frac{b_4'}{b_4}$$

(the derivative of $\tan z$ is $1/\cos^2 z$, times $6H$; and $1/\cos^2 z - \tan^2 z = (1-\sin^2 z)/\cos^2 z = 1$). For a constant b_4 this term is zero, $\partial_4 G^4{}_4 = \partial_4(3a_4'^2 + 21H^2) = 6a_4' a_4''$ (the chain rule), and with $\alpha_t = -a_4'$:

$$\begin{aligned}\sum_\mu \nabla_\mu G^\mu{}_4 &= 6a_4' a_4'' + 3a_4'(G^4{}_4 - G^i{}_i) - 3a_4'(G^4{}_4 - G^j{}_j) \\ &= 6a_4' a_4'' + 3a_4'(G^j{}_j - G^i{}_i) = 6a_4' a_4'' + 3a_4'(-2a_4'') = 0.\end{aligned}$$

For a changing b_4 the H^2 terms show how the off-diagonal entry is needed: in $G^4{}_4 - G^i{}_i$ and $G^4{}_4 - G^j{}_j$ the constants are $21H^2 - 15H^2 = 6H^2$, which contribute $3(\alpha+\alpha_t)\cdot 6H^2 = 9H^2\, b_4'/b_4$, and this is cancelled exactly by $-9H^2\, b_4'/b_4$ from $G^0{}_4$; the terms without H cancel among themselves, as sympy confirms.

For $\nu = x_0$: the diagonal part has $\partial_0 G^0{}_0 = 0$ and $\Gamma^k{}_{k0} = H\cot z$ for the six transverse k (the term $\mu = x_0$ has the factor $G^0{}_0 - G^0{}_0 = 0$), and $G^4{}_0$ adds $\partial_4 G^4{}_0 + \Gamma_4\, G^4{}_0$:

$$\sum_\mu \nabla_\mu G^\mu{}_0 = H\cot z\Big[3(G^0{}_0 - G^i{}_i) + 3(G^0{}_0 - G^j{}_j) + \frac{3}{2}\Big(\frac{b_4'}{b_4}\Big)' + \frac{9}{4}\Big(\frac{b_4'}{b_4}\Big)^2\Big]$$

(with $\Gamma_4 = 3(\alpha+\alpha_t) = \frac{3}{2}b_4'/b_4$). From the entries above, $3(G^0{}_0 - G^i{}_i) + 3(G^0{}_0 - G^j{}_j) = -\frac{3}{2}b_4''/b_4 - \frac{3}{4}(b_4'/b_4)^2$, and $\frac{3}{2}(b_4'/b_4)' = \frac{3}{2}b_4''/b_4 - \frac{3}{2}(b_4'/b_4)^2$ (the quotient rule): the bracket is $-\frac{3}{2} + \frac{3}{2} = 0$ times b_4''/b_4 and $-\frac{3}{4} - \frac{3}{2} + \frac{9}{4} = 0$ times $(b_4'/b_4)^2$, so it vanishes. (For a constant b_4 the bracket is $3(-a_4'') + 3a_4''$.)

For ν a transverse direction: $\partial_\nu G^\mu{}_\nu = 0$, every $\Gamma^\mu{}_{\mu\nu}$ is zero (case (b) of Section 3.15 gives $\partial_\nu \ln h_\mu = 0$), and every term $\Gamma^\lambda{}_{\mu\nu} G^\mu{}_\lambda$ needs an entry of G with one transverse index and one other index, which is zero. So $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$ for all eight ν and all functions $a_4(x_4)$, $b_4(x_4)$ (PROVED; Notebook 03b, In [21]; record `Revision/gkd_lovelock/results/lovelock-report.json`, checks `k1_equals_minus_4_einstein` and `k1_divergence_free`). The same computation for a diagonal energy-momentum tensor $T = \mathrm{diag}(p_0, p_3, p_3, p_3, -\rho, p_t, p_t, p_t)$ gives $\sum_\mu \nabla_\mu T^\mu{}_4 = -\partial_4\rho - 3\alpha(\rho+p_3) - 3\alpha_t(\rho+p_t)$, which for a constant b_4 is $-\partial_4\rho - 3a_4'(p_3 - p_t)$: energy flows between 3-space and the extra times when their pressures differ (record `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`, check `divergence_x4_component`, made for $b_4 = 1$; Chapter 9 derives and uses it).

3.26 What Einstein's equations would ask of the source

Einstein's field equations. In Einstein's theory of gravity the curvature is tied to the matter by

$$G^\mu{}_\nu + \Lambda\, \delta^\mu{}_\nu = \kappa\, T^\mu{}_\nu,$$

with a positive constant κ (the strength of gravity), a constant Λ (the **cosmological constant**) and the **energy-momentum tensor** $T^{\mu}{}_{\nu}$ of the matter, whose diagonal for the sources of this book is $T = \mathrm{diag}(p_0, p_3, p_3, p_3, -\rho, p_t, p_t, p_t)$ in the order $x_0, \ldots, x_7$: the **energy density** ρ and the **pressures** p_0 of the hidden direction, p_3 of 3-space and p_t of the extra times (record `Revision/field_equations_a4/a4-equations.json`, key `conventions.source`). We take this form of the equations as given here (ASSUMED in this chapter); Chapter 9 derives T for the fields of the book, and Chapter 12 derives the equations, together with their higher-order Lovelock companions, and solves them. (The **Lovelock tensors** are curvature tensors built from products of one, two or three Riemann tensors with the generalized Kronecker delta of Chapter 1; the first of them is a multiple of the Einstein tensor, $P_{(1)} = -4G$, and the other two vanish identically in four dimensions; Chapters 11 and 12 treat them in full.) Why does the left side have this form? The conservation of energy and momentum demands that the right side has zero divergence, $\sum_{\mu} \nabla_{\mu} T^{\mu}{}_{\nu} = 0$, so the left side must have zero divergence for every metric. The contracted Bianchi identity of Section 3.25 shows that the Einstein tensor has this property, and $\Lambda\, \delta^{\mu}{}_{\nu}$ has it too (its covariant derivative is zero, by the rule of Section 3.15 with constant entries, because the $+\Gamma$ and the $-\Gamma$ term cancel). The Einstein tensor is the simplest curvature tensor with zero divergence, but not the only one: in eight dimensions the second and the third Lovelock tensors also have zero divergence for every metric (record `Revision/gkd_lovelock/results/lovelock-report.json`, checks `k2_divergence_free` and `k3_divergence_free`), and the field equations of the Revision record use all three, $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^{\mu}{}_{\nu} + \Lambda\, \delta^{\mu}{}_{\nu} = \kappa\, T^{\mu}{}_{\nu}$ with $E_{(1)} = G$ (record `Revision/field_equations_a4/a4-equations.json`, key `conventions.fieldEquations`). This chapter uses only the simplest case, Einstein's equations ($\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$).

A diagonal source fixes b_4. The x_4-x_0 component of the equations reads $G^4{}_0 = \kappa T^4{}_0$. For a source of the diagonal form above, $T^4{}_0 = 0$, and so $\frac{3}{2} H \cot z\, b_4'/b_4 = 0$: since $H > 0$ and $\cot z > 0$ inside the patch, $b_4' = 0$ (PROVED here, from Section 3.25). Within Einstein's equations a diagonal source therefore requires a constant b_4, and a constant b_4 is removed by the rescaling of the extra times of Section 3.8, which gives back $b_4 = 1$. (With the higher Lovelock terms the x_4-x_0 component carries a further factor, and the statement changes; `Revision/SPEC.md`, section 5, and Chapter 12.) The rest of this section therefore takes $b_4 = 1$.

The equations for the author's metric. With the Einstein tensor of Section 3.25 at $b_4 = 1$ the four independent diagonal components are

$$3a_4'^2 + 21H^2 + \Lambda = -\kappa\rho, \qquad -3a_4'^2 + a_4'' + 15H^2 + \Lambda = \kappa p_3,$$

$$-3a_4'^2 - a_4'' + 15H^2 + \Lambda = \kappa p_t, \qquad -3a_4'^2 + 15H^2 + \Lambda = \kappa p_0$$

(the x_4 component uses $T^4{}_4 = -\rho$; the others $T^{\mu}{}_{\mu} = p_{\mu}$). These are the four equations `einstein.constraint_x4`, `einstein.space_x1`, `einstein.extraTime_x5` and `einstein.hidden_x0` of the record `a4-equations.json`. Subtracting the third from the second gives $2a_4'' = \kappa(p_3 - p_t)$, the **evolution equation** of the record (`einstein.evolution`): the acceleration a_4'' of the metric function is driven by the difference between the pressure of 3-space and that of the extra times. The record also states that every twice-differentiable function $a_4(x_4)$ is allowed, with the source then fixed by these equations (`einstein.allowedA4`).

No empty spacetime has this metric. Without matter, $T = 0$, the x_4-x_0 component gives a constant b_4, that is $b_4 = 1$ after the rescaling, and the x_4 and x_0 components would give $G^4{}_4 + \Lambda = 0$

and $G^0{}_0 + \Lambda = 0$, hence $G^4{}_4 = G^0{}_0$; but $G^4{}_4 - G^0{}_0 = 6(a_4'^2 + H^2) > 0$ (Section 3.25). So for $H > 0$ the author's metric is not a solution of Einstein's equations without matter, for any Λ and any b_4 (PROVED; record `a4-equations.json`, key `einstein.noVacuum`; lead check `no_vacuum_for_H_positive`). Subtracting the x_0 equation from the x_4 equation also gives $\kappa(\rho+p_0) = -6(a_4'^2+H^2) < 0$ for every history (record key `einstein.nullEnergy`; lead check `einstein_null_energy`). (With the author's own Lovelock weights the vacuum equations do have solutions, b_4 constant and $a_4 = \pm Hx_4 + \text{const}$: `Revision/metric_b4/results/vacuum-b4.json`; Chapter 12.)

The source along the deflating history. For $a_4 = AHx_4$, $b_4 = 1$ ($a_4' = AH$, $a_4'' = 0$) the evolution equation forces $p_3 = p_t$, and the hidden, 3-space and extra-time equations have the same left side, so all three pressures are one number p:

$$\kappa\rho = -3H^2(7 + A^2) - \Lambda, \qquad \kappa p = 3H^2(5 - A^2) + \Lambda, \qquad \kappa(\rho + p) = -6H^2(A^2 + 1)$$

(the x_4 equation solved for $\kappa\rho$; the x_1 equation with $a_4'' = 0$; the sum of the two, in which Λ cancels). These are the entries `rhoEinstein`, `pEinstein` and `rhoPlusPEinstein` of the key `linearMember` of the record `Revision/field_equations_a4/a4-equations.json` (PROVED here; Notebook 03b reads the three texts of the record and checks them against its Einstein tensor, In [26]). For the canonical $A = 1$, $H = 1$: $G = \text{diag}(12, 12, 12, 12, 24, 12, 12, 12)$ in the order $x_0, \ldots, x_7$, $\kappa\rho = -24 - \Lambda$ and $\kappa p = 12 + \Lambda$.

What this means, with its status. Ordinary matter (dust, radiation, a gas) has $\rho + p \geq 0$; this is the **null energy condition** (a standard condition of physics, used here as the definition of "ordinary", ASSUMED). Within Einstein's equations, the deflating history needs $\kappa(\rho + p) = -6H^2(A^2 + 1) < 0$ for every slope A and every Λ: whatever fills such a spacetime, it is not ordinary matter (PROVED). Three things are NOT shown here: whether a field of this book can supply such a source (Chapters 9, 12 and 17 answer this; the Kohn-Sham states computed along the history cannot, `Revision/field_equations_a4/reports/ks-source-conditions.json`, which is why the history is a PRESCRIBED BACKGROUND, Section 3.8); what the higher-order Lovelock terms change (Chapter 12); and anything about pairs of universes or about matter and antimatter, which this chapter does not touch.

3.27 Example: the curvature of the author's metric

Notebook 03b does Sections 3.23 to 3.26 by computer algebra, for general functions $a_4(x_4)$ and $b_4(x_4)$. It reads the metric exactly as the author typed it; computes all 512 Christoffel symbols with the formula of Section 3.15 and compares the 25 non-zero ones with the record; draws them; checks them a second way by finite differences at the test point of the record's brute-force check; checks that observers at rest fall freely; computes the 156 non-zero Riemann components, checks their symmetries and the first Bianchi identity and compares every one with the record; computes the 28 plane curvatures, the Ricci tensor, the Ricci scalar and the Einstein tensor and compares them with the record, with the verifier of the metric with b_4 and, at $b_4 = 1$, with the lead's checks; compares 310 components with the record numerically with 30 digits at the record's five test points; checks the contracted Bianchi identity; computes the Kretschmann scalar; evaluates everything along the deflating history ($b_4 = 1$); reproduces the source of Section 3.26 from the record; and repeats the curvature for the negative control with inflating extra times ($b_4 = e^{4a_4}$). It needs no Rust, runs in about 1 minute (the cells with the Riemann tensor and the negative control take up to half a minute each) and ends with the line ALL 40 CHECKS PASSED (notebook 03b).

3.28 How to run Notebook 03b

Step 1. What this notebook does and what it needs.

Notebook 03b (The curvature of the author's metric: Christoffel, Riemann, Ricci, Einstein, Kretschmann) is the file `Revision/textbook/notebooks/03b_curvature.ipynb` of the repository Dirac_claude. It computes with sympy, from the metric exactly as the author typed it and with general functions a4(x4) and b4(x4), all 512 Christoffel symbols, the Riemann tensor, the Ricci tensor, the Ricci scalar, the Einstein tensor and the Kretschmann scalar; it compares every component with the Revision record of the Rust program lovelock_gkd (exactly, and numerically at the five test points of the independent Revision verification), checks the symmetries of the Riemann tensor, the first and the contracted Bianchi identities, the Christoffel symbols by finite differences, and a negative control with inflating extra times; and it draws the Christoffel symbols, the curvature of every coordinate plane, the components and the curvature scalars versus z and versus the expansion rate, and the Einstein tensor; along the deflating history a4 = A H x4, b4 = 1 it reproduces the source that the Einstein equations require in the Revision record of the field equations of a4. It shows that the Einstein tensor has the off-diagonal components G^x4_x0 and G^x0_x4, proportional to b4', and that for the planes that contain the time x4 the plane curvature is the relative acceleration of neighbouring observers at rest. Every check of a Revision report that a PASS line names is opened and asserted to exist and to have passed. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
```

```
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 03b_curvature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03b_curvature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 03b_curvature.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/03b.captions.json`
- `Revision/textbook/figures/03b_1_christoffel_heat_maps.png`
- `Revision/textbook/figures/03b_2_christoffel_versus_z.png`
- `Revision/textbook/figures/03b_3_finite_differences.png`
- `Revision/textbook/figures/03b_4_plane_curvatures.png`
- `Revision/textbook/figures/03b_5_riemann_and_kretschmann_z.png`
- `Revision/textbook/figures/03b_6_scalars_versus_a.png`
- `Revision/textbook/figures/03b_7_einstein_tensor.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all seven figure files exist
ALL 40 CHECKS PASSED (notebook 03b)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/03b_curvature.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 03b_curvature.ipynb
python -m nbconvert --execute --inplace 03b_curvature.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The cells with the Riemann tensor and the negative control run for up to half a minute each, and their label shows a star meanwhile: this is normal: sympy simplifies several thousand expressions exactly; wait until the label shows a number.

3.29 Notebook 03b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/03b_curvature.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook computes the **curvature** of the author's metric of the primordial
gravitational field, exactly, with sympy, for general metric functions $a_4(x_4)$
and $b_4(x_4)$. It

- reads the metric exactly as the author typed it (from the Revision record
  `Revision/gkd_lovelock/results/curvature.json`);
- computes all $8^3 = 512$ **Christoffel symbols** $\Gamma^a{}_{bc}$, finds the 37
  that are not zero, checks them against the record of the Rust program
  `lovelock_gkd`, draws them as heat maps and as functions of $z$, and checks them a
  second, independent way by **finite differences** (a numerical derivative);
- shows that the lines along the time $x_4$ are **geodesics** (free fall) with
  proper time $x_4$;
- computes the **Riemann tensor** $R^a{}_{bcd}$ and its form $R^{ab}{}_{cd}$ with two
  upper indices, finds its 156 non-zero components, checks its symmetries and the
  first Bianchi identity, and compares all 156 with the record;
- computes the curvature $\sigma(a, b)$ of each of the 28 coordinate planes and
  shows that for the planes with the time $x_4$ it is the relative acceleration of
  two neighbouring observers at rest;
- computes the **Ricci tensor**, the **Ricci scalar** and the **Einstein tensor**,
  compares them with the record and the lead checks, finds its two off-diagonal
  components $G^{x_4}{}_{x_0}$ and $G^{x_0}{}_{x_4}$, proportional to $b_4'$, and
  checks the contracted Bianchi identity $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$;
- computes the **Kretschmann scalar** $K = R^{ab}{}_{cd} R^{cd}{}_{ab}$, shows that it
  does not depend on $z$ although single components do, and that for a constant
  $b_4$ it is never zero for $H > 0$;
- evaluates everything along the **deflating history** $a_4 = A H x_4$ ($A > 0$),
  $b_4 = 1$ and
  checks that minus the time component and the space component of the Einstein
  tensor are exactly the energy density and the pressure that the Revision record
  of the field equations of $a_4$ lists for this history;
```

- repeats the curvature for a **negative control** in which the extra times inflate
  instead of deflating, and shows what then changes;
- opens every Revision report whose check a PASS line names, and stops unless that
  check is listed there as passed;
- draws 7 figures and prints a PASS line for every check.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 03b (The curvature of the author's metric: Christoffel, Riemann, Ricci,
Einstein, Kretschmann) is the file 'Revision/textbook/notebooks/03b_curvature.ipynb' of
the repository Dirac_claude. It computes with sympy, from the metric exactly as the
author typed it and with general functions a4(x4) and b4(x4), all 512 Christoffel
symbols, the Riemann tensor, the Ricci tensor, the Ricci scalar, the Einstein tensor and
the Kretschmann scalar; it compares every component with the Revision record of the Rust
program lovelock_gkd (exactly, and numerically at the five test points of the independent
Revision verification), checks the symmetries of the Riemann tensor, the first and the
contracted Bianchi identities, the Christoffel symbols by finite differences, and a
negative control with inflating extra times; and it draws the Christoffel symbols, the
curvature of every coordinate plane, the components and the curvature scalars versus z
and versus the expansion rate, and the Einstein tensor; along the deflating history a4 =
A H x4, b4 = 1 it reproduces the source that the Einstein equations require in the
Revision record of the field equations of a4. It shows that the Einstein tensor has the
off-diagonal components G^x4_x0 and G^x0_x4, proportional to b4', and that for the planes
that contain the time x4 the plane curvature is the relative acceleration of neighbouring
observers at rest. Every check of a Revision report that a PASS line names is opened and
asserted to exist and to have passed. It needs a computer with Windows 11, macOS or
Linux, an internet connection for the installation, the program Git, and Python 3.12 or
newer (the notebooks were built with Python 3.14.5) with these packages at exactly these
versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10,
nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook
itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the
program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):
```

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 03b_curvature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03b_curvature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 03b_curvature.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/03b.captions.json‘
- ‘Revision/textbook/figures/03b_1_christoffel_heat_maps.png‘
- ‘Revision/textbook/figures/03b_2_christoffel_versus_z.png‘
- ‘Revision/textbook/figures/03b_3_finite_differences.png‘
- ‘Revision/textbook/figures/03b_4_plane_curvatures.png‘
- ‘Revision/textbook/figures/03b_5_riemann_and_kretschmann_z.png‘
- ‘Revision/textbook/figures/03b_6_scalars_versus_a.png‘
- ‘Revision/textbook/figures/03b_7_einstein_tensor.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all seven figure files exist
ALL 40 CHECKS PASSED (notebook 03b)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/03b_curvature.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 03b_curvature.ipynb
  python -m nbconvert --execute --inplace 03b_curvature.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The cells with the Riemann tensor and the negative control run for up to half a minute each, and their label shows a star meanwhile: this is normal: sympy simplifies several thousand expressions exactly; wait until the label shows a number.

The first code cell below (the set-up cell) repeats these instructions as comments; then

it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 03b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 03b (The curvature of the author's metric: Christoffel, Riemann, Ricci,
# Einstein, Kretschmann) is the file Revision/textbook/notebooks/03b_curvature.ipynb of
# the repository Dirac_claude. It computes with sympy, from the metric exactly as the
# author typed it and with general functions a4(x4) and b4(x4), all 512 Christoffel
# symbols, the Riemann tensor, the Ricci tensor, the Ricci scalar, the Einstein tensor
# and the Kretschmann scalar; it compares every component with the Revision record of the
# Rust program lovelock_gkd (exactly, and numerically at the five test points of the
# independent Revision verification), checks the symmetries of the Riemann tensor, the
# first and the contracted Bianchi identities, the Christoffel symbols by finite
# differences, and a negative control with inflating extra times; and it draws the
# Christoffel symbols, the curvature of every coordinate plane, the components and the
# curvature scalars versus z and versus the expansion rate, and the Einstein tensor;
# along the deflating history a4 = A H x4, b4 = 1 it reproduces the source that the
# Einstein equations require in the Revision record of the field equations of a4. It
# shows that the Einstein tensor has the off-diagonal components G^x4_x0 and G^x0_x4,
# proportional to b4', and that for the planes that contain the time x4 the plane
# curvature is the relative acceleration of neighbouring observers at rest. Every check
# of a Revision report that a PASS line names is opened and asserted to exist and to have
# passed. It needs a computer with Windows 11, macOS or Linux, an internet connection for
# the installation, the program Git, and Python 3.12 or newer (the notebooks were built
# with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy,
# mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
```

```
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
```

```
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 03b_curvature.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 1 minute
```

```
# on a typical laptop. Scroll to the end and compare the last printed lines with the
# lines in the step "What the notebook writes and what you must see" below. To keep the
# results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the
# menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 03b_curvature.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 03b_curvature.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/03b.captions.json
# - Revision/textbook/figures/03b_1_christoffel_heat_maps.png
# - Revision/textbook/figures/03b_2_christoffel_versus_z.png
# - Revision/textbook/figures/03b_3_finite_differences.png
# - Revision/textbook/figures/03b_4_plane_curvatures.png
# - Revision/textbook/figures/03b_5_riemann_and_kretschmann_z.png
# - Revision/textbook/figures/03b_6_scalars_versus_a.png
# - Revision/textbook/figures/03b_7_einstein_tensor.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all seven figure files exist
#     ALL 40 CHECKS PASSED (notebook 03b)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
```

```
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/03b_curvature.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 03b_curvature.ipynb
#     python -m nbconvert --execute --inplace 03b_curvature.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - The cells with the Riemann tensor and the negative control run for up to half a
#   minute each, and their label shows a star meanwhile: this is normal: sympy simplifies
#   several thousand expressions exactly; wait until the label shows a number.
#

## 3. The words used in this notebook

- **Metric** $g_{\mu\nu}$, **inverse metric** $g^{\mu\nu}$ (the inverse matrix:
  $\sum_\lambda g^{\mu\lambda} g_{\lambda\nu} = \delta^\mu{}_\nu$, which is $1$ when
  $\mu = \nu$ and $0$ otherwise). For a diagonal metric $g^{\mu\mu} = 1/g_{\mu\mu}$.
- **Index notation**: $a, b, c, \dots$ each run over the eight coordinates
  $x_0, \dots, x_7$; an upper and a lower index are positions in a table of numbers;
  $\partial_c$ means the partial derivative $\partial/\partial x_c$.
- **Christoffel symbols** $\Gamma^a{}_{bc} = \tfrac12 \sum_d g^{ad}(\partial_b g_{dc}
  + \partial_c g_{db} - \partial_d g_{bc})$: the correction terms that make
  derivatives of vectors independent of the coordinates. They are symmetric in $b$
  and $c$.
- **Geodesic**: a curve $x^a(\tau)$ with $d^2x^a/d\tau^2 + \sum_{b,c}
  \Gamma^a{}_{bc}\,(dx^b/d\tau)(dx^c/d\tau) = 0$, the path of free fall, the
  straightest possible curve.
- **Riemann tensor** $R^a{}_{bcd} = \partial_c \Gamma^a{}_{bd} - \partial_d
  \Gamma^a{}_{bc} + \sum_e (\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}
  \Gamma^e{}_{bc})$ (the convention of the textbook of Misner, Thorne and Wheeler,
  MTW, used by every Revision record): it measures how much a vector turns when it
  is carried around a small closed loop. It is zero everywhere exactly when the space
  is flat.
- $R^{ab}{}_{cd} = \sum_e g^{be} R^a{}_{ecd}$: the same tensor with the second index
  raised. For the coordinate plane of $x_a$ and $x_b$, $\sigma(a, b) =
  R^{ab}{}_{ab}$ (no sum) is the **curvature of that plane** (the sectional
  curvature). Only for a plane of two space-like directions does its sign describe
  a shape: positive curved like a sphere, negative like a saddle. For a plane with
  a time-like direction the sign is read from free fall: two neighbouring
  free-fall paths that move along the time-like direction $x_b$, a small proper
  distance $\xi$ apart along $x_a$, accelerate apart as $d^2\xi/d\tau^2 =
  +\sigma(a, b)\,\xi$, while on a sphere $d^2\xi/ds^2 = -\sigma\,\xi$: the same sign
  of $\sigma$ has the opposite effect.
- **Lead checks**: short independent Python programs of the Revision record (folder
  ‘Revision/lead_checks‘), written from scratch by the coordinator of the Revision
  work (the "lead") without importing any other Revision code.
- **Ricci tensor** $R^a{}_b = \sum_c R^{ac}{}_{bc}$, **Ricci scalar**
  $R = \sum_a R^a{}_a$, **Einstein tensor** $G^a{}_b = R^a{}_b - \tfrac12
  \delta^a{}_b R$: the averages of the curvature that enter Einstein’s field
  equations.
- **Kretschmann scalar** $K = \sum_{a,b,c,d} R^{ab}{}_{cd} R^{cd}{}_{ab}$: one number
  per point, the same in every coordinate system (an **invariant**).
- **Einstein’s field equations** $G^\mu{}_\nu + \Lambda\,\delta^\mu{}_\nu =
  \kappa\, T^\mu{}_\nu$: the Einstein tensor plus a constant $\Lambda$ (the
  **cosmological constant**) times $\delta^\mu{}_\nu$ equals a positive constant
  $\kappa$ times the **energy-momentum tensor** $T^\mu{}_\nu$ of the matter. For the
  sources of this book its diagonal is $T = \mathrm{diag}(p_0, p_3, p_3, p_3, -\rho,
  p_t, p_t, p_t)$ in the order $x_0, \dots, x_7$: the **energy density** $\rho$
  (energy per unit volume) and the
  **pressures** $p_3$ of 3-space, $p_t$ of the extra times and $p_0$ of the hidden
  direction. A later chapter derives these equations; this notebook only reads
```

```
  them in a Revision record.
- **Bianchi identities**: $R^a{}_{bcd} + R^a{}_{cdb} + R^a{}_{dbc} = 0$ (first) and
  $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$ (contracted): identities that every metric
  satisfies; checking them checks the computation.
- **Lovelock scalars and tensors**: curvature quantities built from products of one,
  two or three Riemann tensors with the generalized Kronecker delta; the first
  Lovelock scalar is $L_{(1)} = 2R$ and the first Lovelock tensor is
  $P_{(1)} = -4G$. A later chapter treats them in full.
- **Finite difference**: the numerical derivative $f'(x) \approx (f(x+h) -
  f(x-h))/(2h)$; its error shrinks like $h^2$.
- `a4p`, `a4pp`, `a4v`: the names the notebook prints for $a_4'$, $a_4''$ and the
  value of $a_4$; `b4p`, `b4pp`, `b4v` the same for $b_4$; `z` stands for $6 H x_0$.
```

Text cell:

```
## 4. The physical and mathematical situation

The metric of the author is diagonal,

$$g = \mathrm{diag}\bigl(\cot^2 z,\ e^{2a_4}\sin^{1/3}z\ (\times 3),\ -1,\
-b_4 e^{-2a_4}\sin^{1/3}z\ (\times 3)\bigr), \qquad z = 6 H x_0,$$

in the order $x_0, \dots, x_7$, with the constant $H > 0$ and the metric functions
$a_4(x_4)$ and $b_4(x_4) > 0$ ($b_4 = 1$ is the metric used before 2026-10-14). It
depends on two coordinates only, $x_4$ (through $a_4$ and $b_4$) and $x_0$ (through
$z$). Every derivative along $x_1, x_2, x_3, x_5, x_6, x_7$ is therefore
zero, which is why most of the $512$ Christoffel symbols and most of the $4096$
Riemann components vanish.

Curvature is computed in three steps, each from the previous one: the Christoffel
symbols need the first derivatives of the metric; the Riemann tensor needs the
first derivatives of the Christoffel symbols and their products (so the second
derivatives of the metric, and $a_4''$ and $b_4''$ appear); the Ricci tensor, the
Ricci scalar
and the Einstein tensor are sums of Riemann components. The Revision record
computed all of this with an exact Rust program (`lovelock_gkd`); an independent
sympy program checked every component, and the lead checks recomputed the Einstein
tensor with their own sympy code. This notebook does it once more, in small steps,
and compares every single component.

Nothing here involves the matter fields yet: these are exact properties of the given
metric. The field equations, which connect the Einstein tensor to the energy and the
pressures of the fields, are the subject of a later chapter. For the plots the
notebook uses $H = 1$ and the deflating history $a_4 = A H x_4$, $b_4 = 1$ of the
Revision Kohn-Sham work (so $a_4' = A H$, $a_4'' = 0$ and $b_4' = b_4'' = 0$, with
$A = 1$ the canonical value): a PRESCRIBED BACKGROUND, assumed here and not obtained
by solving the field equations. Every formula with general $a_4(x_4)$ and
$b_4(x_4)$ is exact.
```

Text cell:

```
## 5. The metric, read from the record
```

First a technical step. While a cell runs, Jupyter sends what the cell prints to the notebook in pieces, about one piece every 0.2 seconds, so where one piece ends and the next begins depends on the speed of the computer. The tools that build this book read the PASS line of a check together with the line under it that names the Revision record, and they read the two correctly only when both arrive in the same piece. The next cell therefore defines the function ‘in_one_piece(helper)‘: it returns a new function that does exactly what ‘helper‘ does, but lets ‘helper‘ print into a text buffer in memory (an ‘io.StringIO‘, with ‘contextlib.redirect_stdout‘) and then writes the whole buffer with one call of ‘sys.stdout.write‘, which arrives as one piece. (The stars in ‘*arguments‘ and ‘**options‘ pass on all the values the new function is given, whatever they are.) The cell then replaces the helpers ‘check‘ and ‘report‘ of the set-up cell by such functions. Nothing else changes: the same checks, the same PASS lines, the same numbers.

In [2]:

```
import contextlib  # redirect_stdout: send printed text into a buffer
import io  # StringIO: a text buffer in memory
import sys  # sys.stdout: the place where printed text goes

def in_one_piece(helper):
    """A function that does what helper does, with all the lines that helper prints
    written in one piece."""
    def helper_in_one_piece(*arguments, **options):
        collected = io.StringIO()  # an empty text buffer
        with contextlib.redirect_stdout(collected):  # print() writes into it
            helper(*arguments, **options)  # a failing check stops here, as before
        sys.stdout.write(collected.getvalue())  # all the lines with one write
    return helper_in_one_piece

check = in_one_piece(check)  # a PASS line and its record line stay together
report = in_one_piece(report)  # a long RESULT line and its second line, too
say("From now on check and report print each of their results in one piece.")
```

Out [2]:

```
From now on check and report print each of their results in one piece.
```

Text cell:

The next cell imports the packages, reads the record, and makes the symbols: the eight coordinates, $H > 0$, the unknown functions $a_4(x_4)$ and $b_4(x_4)$ (b_4 positive), and the printing names ‘a4p‘, ‘a4pp‘, ‘a4v‘, ‘b4p‘, ‘b4pp‘, ‘b4v‘ and ‘z‘. The function ‘plain‘ rewrites an expression with these printing names; the function ‘symbolic‘ does the same but keeps x_0 (the record writes its components with x_0). It also names the two reports of the Revision curvature computation and defines the function ‘record_check(report_file, check_name, detail_part)‘, the same as in Notebook 03a: it opens a Revision report,

finds the check with that name, and stops the notebook with an error unless the
check is there and passed (and, if ‘detail_part‘ is given, its detail contains that
text). Every PASS line below that names a check of a Revision report calls it
first, so that a renamed, missing or failing check in the record is caught.

In [3]:

  g[x5, x5] = -b4v*exp(-2*a4v)*sin(z)**(1/3)
  g[x6, x6] = -b4v*exp(-2*a4v)*sin(z)**(1/3)
  g[x7, x7] = -b4v*exp(-2*a4v)*sin(z)**(1/3)
PASS the metric read from the text of the author is diagonal
```

Text cell:

```
The record writes its components in Mathematica notation, for example
‘Derivative[1][a4][x4]*E^(2*a4[x4])*Sin[6*H*x0]^(1/3)‘. The next cell defines the
function ‘from_mathematica‘ that translates such a text into sympy:
‘Derivative[1][a4][x4]‘ ($a_4’$) becomes ‘a4p‘, ‘Derivative[2][a4][x4]‘ becomes
‘a4pp‘, ‘a4[x4]‘ becomes ‘a4v‘, the same for $b_4$ (‘b4p‘, ‘b4pp‘, ‘b4v‘), the sine
and the cotangent get round brackets, and ‘^‘ becomes ‘**‘. If any square bracket is
left, the translation is incomplete and the function stops with an error, so a
silent mistranslation is impossible.

The cell also defines three helpers. ‘tidy(expression)‘ simplifies an expression:
it writes $6Hx_0$ as $z$, simplifies it once as it is and once after writing
$\sin 2z$ as $2\sin z\cos z$ (‘expand_trig‘), and keeps the shorter of the two
results (sympy sometimes reaches the simplest form only one way: it writes, for
example, $-6H/(\sin z\cos z)$ as $-12H/\sin(2z)$, the same number because
$\sin 2z = 2\sin z\cos z$, and a sum such as $6H\cot z - 12H/\sin 2z + 6H\tan z$ is
recognised as $0$ only after the rewriting). ‘vanishes(expression)‘ is true when
‘tidy‘ gives $0$, and ‘same(mine, theirs)‘ is true when the difference of our
expression and the record’s vanishes.
```

## 6. The Christoffel symbols

The Christoffel symbols of the metric are

$$\Gamma^a{}_{bc} = \tfrac12 \sum_{d} g^{ad}\bigl(\partial_b g_{dc} +
\partial_c g_{db} - \partial_d g_{bc}\bigr).$$

The next cell defines the function ‘christoffel(metric, coordinates)‘, which applies
this formula literally to every one of the $8 \times 8 \times 8 = 512$ index
combinations (it does not use the symmetry in $b$ and $c$, so that the symmetry can
be checked afterwards), simplifies each result, and returns the table
‘Gamma[a][b][c]‘. Then it computes the symbols of the author’s metric and counts
the non-zero ones.
```

In [6]:

```
def christoffel(metric, coordinates):

Text cell:

```
The next cell prints the 25 non-zero symbols with $b \le c$ (the others follow by the
symmetry) and compares them with the list ‘christoffelNonzero_b_le_c‘ of the record:
first that the two lists name the same 25 index combinations, then that each value
agrees exactly. In the record the keys ‘a‘, ‘b‘, ‘c‘ are the indices of
$\Gamma^a{}_{bc}$, and the list runs in the author’s order $x_0, \dots, x_7$.
sympy chooses its own way of writing some symbols: $H\cot z$ appears as
‘H/tan(z)‘, $-He^{2a_4}\sin^{1/3}z\,\tan z$ as ‘-H*exp(2*a4v)*sin(z)**(4/3)/cos(z)‘
(because $\sin^{1/3}z\,\tan z = \sin^{4/3}z/\cos z$), and
$\Gamma^{x_0}{}_{x_0x_0} = -6H/(\sin z\cos z)$ as ‘-12*H/sin(2*z)‘. The symbols of
the extra times contain $b_4$: $\Gamma^{x_5}{}_{x_4x_5} = -a_4’ + b_4’/(2b_4)$.
```

Text cell:

```
The next cell sets the colours of the figures (a palette whose colours can also be
told apart with a colour-vision deficiency; the figures also use line styles and
labels) and turns every Christoffel symbol into a fast numerical function of $z$,
$a_4$, $a_4'$, $H$, $b_4$ and $b_4'$ (`sp.lambdify`). It then draws the eight
$8 \times 8$ tables $\Gamma^{x_k}{}_{bc}$ at the point $z = \pi/4$ with $H = 1$,
$a_4 = 0.5$, $a_4' = 1$, $b_4 = 1$, $b_4' = 0$ as heat maps. The colour scale is
**symmetric-logarithmic**: above $0.1$ in size, equal steps of colour stand for
equal factors of size (below $0.1$ the scale is
ordinary), so that small and large symbols are both visible; grey is zero, red
positive, blue negative.
```

```

Text cell:

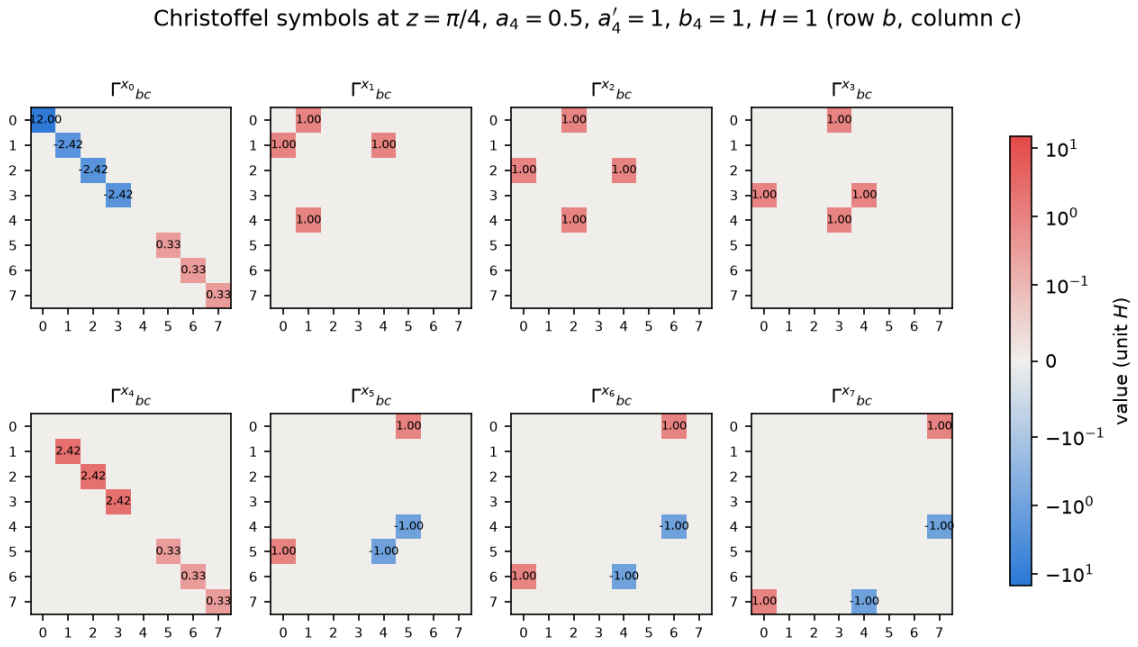

Figure 104: The 512 Christoffel symbols $\Gamma^{a}{}_{bc}$ of the author's metric at the point $z = \pi/4$ on the slice $a_4 = 0.5$ of the history $a_4 = x_4$, $b_4 = 1$ ($a_4' = 1$, $H = 1$), as eight heat maps, one for each upper index $a = x_0, \ldots, x_7$; in each map the row is b and the column is c (numbers 0 to 7 for x_0 to x_7), the colour is the value on a symmetric logarithmic scale (grey zero, red positive, blue negative) and every non-zero value is printed. Only 37 of the 512 squares are coloured, each map is symmetric about its diagonal, and every non-zero symbol has at least one index equal to x_4 or x_0, the two coordinates on which the metric depends. (Notebook 03b, figure 1.)

```
The symbols with an index $x_0$ depend on $z$. The next cell draws the size of five
typical symbols across the patch on a logarithmic axis (for $a_4 = 0.5$,
$a_4' = 1$, $b_4 = 1$, $H = 1$): $\Gamma^{x_1}{}_{x_1 x_0} = H\cot z$ and
$\Gamma^{x_0}{}_{x_0 x_0}$ grow without bound at the tip $z \to 0$;
$\Gamma^{x_0}{}_{x_1 x_1}$, $\Gamma^{x_0}{}_{x_0 x_0}$ and
$\Gamma^{x_0}{}_{x_5 x_5}$ grow without bound at the patch end $z \to \pi/2$;
$\Gamma^{x_1}{}_{x_1 x_4} = a_4'$ does not depend on $z$. Large Christoffel symbols
are a property of the coordinates; whether the geometry itself is extreme is decided
by invariants such as the Kretschmann scalar of section 12.

```
## 7. A second, independent check: finite differences

The exact symbols can be checked without any algebra. Take concrete functions
$a_4(x_4) = 0.17 + 0.61\,x_4 - 0.185\,x_4^2$ and
$b_4(x_4) = 1.37 + 0.31\,x_4 - 0.115\,x_4^2$ (so that at $x_4 = 0$:
$a_4 = 0.17$, $a_4' = 0.61$, $a_4'' = -0.37$, $b_4 = 1.37$, $b_4' = 0.31$,
$b_4'' = -0.23$), $H = 0.23$ and the point $x_0 = 0.41$: the test point at which the
Rust program checked its Lovelock tensors by brute force (record
‘lovelock-report.json‘, check ‘k1_brute_force_numeric‘).
The next cell first confirms these numbers in the record. Then it computes the
metric as a plain table of numbers at points $x \pm h\,e_c$ (one coordinate moved by
$\pm h$), the derivative of the metric by the central difference
$\partial_c g \approx (g(x + h e_c) - g(x - h e_c))/(2h)$, and from it all 512
Christoffel symbols with the same formula; it compares them with the exact symbols
for eight step sizes $h$ from $10^{-1}$ to $10^{-8}$.
```

## 8. Free fall along the time $x_4$

Consider an observer who stays at fixed $x_1, x_2, x_3, x_5, x_6, x_7, x_0$ while
$x_4 = \tau$ runs. Then $dx^a/d\tau$ is $1$ for $a = x_4$ and $0$ otherwise, and
$d^2x^a/d\tau^2 = 0$, so the geodesic equation reduces to
$\Gamma^a{}_{x_4 x_4} = 0$ for every $a$. Since $g_{44} = -1$, the proper time of
the observer is $\sqrt{-g_{44}}\, d\tau = d\tau$: $x_4$ is the time shown by the
observer's clock. The next cell checks that the eight symbols $\Gamma^a{}_{x_4x_4}$
are zero. It also checks the useful identity $\sum_a \Gamma^a{}_{ab} =
\partial_b \ln\sqrt{|\det g|}$, with $\sqrt{|\det g|} = b_4^{3/2} \cos z$.
```

In [12]:

```
check(all(Gamma[a][4][4] == 0 for a in range(8)),
      "Gamma^a_(x4 x4) = 0: observers at rest fall freely, x4 is their proper time")
volume = b4 ** sp.Rational(3, 2) * sp.cos(6 * H * x0)  # sqrt|det g|
contracted = [vanishes(sum(Gamma[a][a][b] for a in range(8))
                       - sp.diff(sp.log(volume), X[b]))
              for b in range(8)]
check(all(contracted),
      "sum over a of Gamma^a_(a b) equals the derivative of ln(b4^(3/2) cos z)")
```

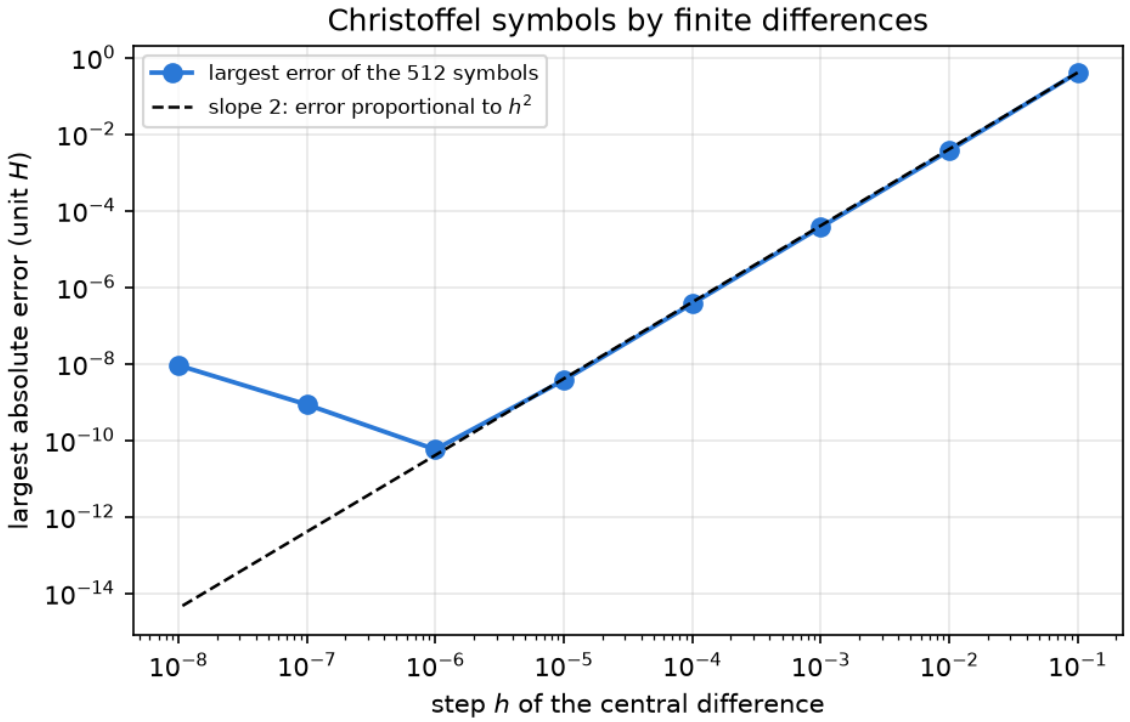

Figure 106: The largest difference between the 512 Christoffel symbols computed numerically by central differences of the metric and the exact symbols, at the test point $H = 0.23$, $a_4 = 0.17$, $a_4' = 0.61$, $a_4'' = -0.37$, $b_4 = 1.37$, $b_4' = 0.31$, $b_4'' = -0.23$, $x_0 = 0.41$ of the Revision record, against the step h, on logarithmic axes; horizontal axis h, vertical axis the error in units of H. For large steps the error follows the dashed line of slope 2 (error proportional to h^2); the smallest error, 5.7×10^{-11}, is reached at $h = 10^{-6}$; for smaller steps the rounding errors of the computer, which grow like $1/h$, take over. (Notebook 03b, figure 3.)

Out [12]:

## 9. The Riemann tensor

The Riemann tensor in the convention of all Revision records (MTW) is

$$R^a{}_{bcd} = \partial_c \Gamma^a{}_{bd} - \partial_d \Gamma^a{}_{bc}
+ \sum_e \bigl(\Gamma^a{}_{ce}\Gamma^e{}_{bd} - \Gamma^a{}_{de}\Gamma^e{}_{bc}\bigr).$$

It is antisymmetric in its last two indices $c, d$ (exchanging $c$ and $d$ turns the
formula into its negative: the first two terms exchange places and signs, and so do
the two products), so the next cell computes it for $c < d$ and fills $c > d$ with
the opposite sign; the components with $c = d$ are zero. It keeps only the
non-zero components in a dictionary. Then it raises the second index,
$R^{ab}{}_{cd} = \sum_e g^{be} R^a{}_{ecd}$, the form in which the record stores
the tensor. This cell takes a few seconds.
```

In [13]:

```

The next cell checks the symmetries that every Riemann tensor has, as a test of the
computation: (1) $R^{ab}{}_{cd} = -R^{ba}{}_{cd} = -R^{ab}{}_{dc}$; (2) with all
indices lowered, $R_{abcd} = g_{aa} g_{bb} R^{ab}{}_{cd}$ (diagonal metric), the
pair symmetry $R_{abcd} = R_{cdab}$; (3) the first Bianchi identity
$R^a{}_{bcd} + R^a{}_{cdb} + R^a{}_{dbc} = 0$ for all $8^4 = 4096$ index lists.
It also checks that no component $R^{ab}{}_{cd}$ contains the factor
$\sin^{1/3} z$ of the transverse metric entries (the square $W^2$ of the warp factor
$W = \sin^{1/6} z$ of Notebook 03a) or the exponential $e^{a_4}$: they cancel when
one index is raised.

## 10. The curvature of every coordinate plane

For two different coordinates $x_a$ and $x_b$ the number $\sigma(a, b) =
R^{ab}{}_{ab}$ (no sum) is the curvature of the coordinate plane spanned by them.
The next cell computes all 28 of them as formulas, prints one plane of each kind,
and checks seven formulas. Write $\alpha = a_4'$ for the expansion rate of 3-space
and $\alpha_t = -a_4' + b_4'/(2b_4)$ for that of the extra times (Notebook 03a). Then:
3-space with 3-space $\alpha^2 - H^2$; extra time with extra time
```

$\alpha_t^2 - H^2$; 3-space with an extra time $\alpha\alpha_t - H^2$; 3-space with the time x_4 $\alpha^2 + \alpha'$; the time with an extra time $\alpha_t^2 + \alpha_t'$; a 3-space or extra-time direction with the hidden x_0 $-H^2$; the time with the hidden x_0 zero. For a constant b_4, $\alpha_t = -\alpha$ and these are the formulas $a_4'^2 - H^2$, $-(a_4'^2 + H^2)$, $a_4'^2 \pm a_4''$ of the metric with $b_4 = 1$. None depends on z or on the value of a_4.

What does the sign mean? Only 6 of the 28 planes are spanned by two space-like directions (two of x_1, x_2, x_3, or one of them with x_0); only for these does a positive value mean curved like a sphere and a negative one like a saddle. The other 22 planes contain a time-like direction, and there the sign is read from free fall. The clearest case: two observers at rest (they fall freely, section 8), a small coordinate distance Δx_a apart along a transverse direction x_a, are a proper distance $\xi = h_a\,\Delta x_a$ apart, where h_a is the scale factor; the proper time of both is $\tau = x_4$. The cell computes $(d^2\xi/d\tau^2)/\xi = (\partial_4^2 h_a)/h_a$ for $x_a = x_1$ (with $h_1 = e^{a_4}\sin^{1/6}z$) and $x_a = x_5$ (with $h_5 = b_4^{1/2} e^{-a_4}\sin^{1/6}z$) and checks that it is exactly $\sigma(a, x_4)$: $d^2\xi/d\tau^2 = +\sigma(a, x_4)\,\xi$. Along the history $a_4 = AHx_4$, $b_4 = 1$ both are $A^2H^2 > 0$: a positive curvature, and yet the 3-space distance grows like $e^{AH\tau}$ (the extra-time distance shrinks like $e^{-AH\tau}$, also with a positive second derivative); on a sphere a positive curvature pulls neighbouring paths together, $d^2\xi/ds^2 = -\sigma\,\xi$. For the 6 planes of two time-like directions (two extra times, or an extra time and x_4) even the shape reading is reversed: if g is replaced by $-g$, the Christoffel symbols and $R^a{}_{bcd}$ do not change but every g^{bb} changes sign, so $\sigma(a, b)$ changes sign; with $-g$ such a plane has positive squared lengths, and its shape is that of the curvature $-\sigma(a, b)$.

Then the cell draws the 28 plane curvatures as 8×8 heat maps along the deflating history $a_4 = AHx_4$, $b_4 = 1$ ($a_4' = AH$, $a_4'' = 0$, $H = 1$) for the three
slopes $A = 0.5$, 1 (the canonical value of the Revision record) and 2, all positive, so that in all three the extra times deflate; the diagonal is left empty. The planes inside 3-space and inside the extra times change sign at $A = 1$: $a_4'^2 - H^2 = H^2(A^2 - 1)$ is negative for $A < 1$, zero at $A = 1$ and positive for $A > 1$.

Text cell:

```
The Ricci scalar appears in one more Revision record, in a different form. The
record of the field equations of $a_4$ builds them from three **Lovelock
scalars** $L_{(1)}, L_{(2)}, L_{(3)}$ (the subject of a later chapter), and the
first of them is exactly twice the Ricci scalar, $L_{(1)} = 2R$ (this identity is
the check ‘L1_equals_2R‘ of the record
‘Revision/gkd_lovelock/results/python-lovelock-report.json‘). The sympy
verification of the record of the field equations,
‘Revision/field_equations_a4/reports/python-a4-report.json‘, prints $L_{(1)}$ in its
check ‘L1_equals_gkd_branch‘, with the name ‘ad1‘ for $a_4’$, for the metric at
$b_4 = 1$. The next cell reads this text, checks that the record marks the check as
passed, turns the text after the equals sign into a sympy expression, confirms with
‘record_check‘ that the check ‘L1_equals_2R‘ passed, and checks $L_{(1)} = 2R$ with
our $R$ at $b_4 = 1$.
```

Text cell:

```
Exact agreement was decided by sympy's simplification. A second, independent test
uses numbers only: the independent Revision verification
(‘Revision/gkd_lovelock/results/python-lovelock-report.json‘, list ‘randomPoints‘)
chose five test points, each a set of exact fractions for $H$, $x_0$, $a_4$, $a_4'$,
$a_4''$, $b_4$, $b_4'$ and $b_4''$. The next cell evaluates every component of the
record (25 Christoffel symbols, 156 Riemann components, 64 Ricci and 64 Einstein
components and the Ricci scalar) and our component with the same indices at these
five points, with
**30 significant digits** (the package mpmath; ‘sp.lambdify(..., "mpmath")‘ turns an
expression into an mpmath function), and reports the largest relative difference
```

$|{\rm ours} - {\rm record}| / \max(1, |{\rm record}|)$. Before it reports, it
confirms with ‘record_check‘ that the three exact comparisons of that verification
(‘rust_christoffels_agree‘, ‘rust_riemann_agrees‘,
‘rust_ricci_einstein_scalar_agree‘) passed.

Text cell:

```
The lead's independent check of the field equations
(`Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`) states four
properties of the Einstein tensor of the metric at $b_4 = 1$. The next cell first
confirms with `record_check` that the lead's report lists the four checks as passed,
then checks the four properties on our result with $b_4$ set to 1: $G$ is diagonal
(in particular $G^{x_4}{}_{x_0} = 0$), no component depends on $x_0$, the three
3-space components are equal and the three extra-time components are equal, and
$G^{x_4}{}_{x_4} - G^{x_0}{}_{x_0} = 6(a_4'^2 + H^2)$, which is positive for $H > 0$
(a later chapter uses this to show that for $H > 0$ no empty spacetime, not even one
with a cosmological constant, has this metric: some matter is needed). For a
general $b_4$ the first check also confirms what the verifier of the metric with
$b_4$ recorded (`Revision/metric_b4/results/wolfram-metric-b4-report.json`, checks
`off_diagonal_entries_x0_x4_only` and `off_diagonal_proportional_to_b4prime`): the
only off-diagonal components are $G^{x_4}{}_{x_0} = \tfrac32 H\cot z\, b_4'/b_4$
and $G^{x_0}{}_{x_4} = -\tfrac32 H\tan z\, b_4'/b_4$, both zero when $b_4$ is
constant; and the isotropy holds for every $b_4$.

Every Einstein tensor satisfies the **contracted Bianchi identity**
$\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$, where for a tensor with one upper and one
lower index $\sum_\mu \nabla_\mu G^\mu{}_\nu = \sum_\mu \partial_\mu G^\mu{}_\nu +
\sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda} G^\lambda{}_\nu - \sum_{\mu,\lambda}
\Gamma^\lambda{}_{\mu\nu} G^\mu{}_\lambda$. Within Einstein's equations it makes the
energy and momentum of the matter that sources the metric conserved. The next cell
computes the eight components with the function $a_4(x_4)$ (so that sympy can
differentiate $a_4''$ and produce $a_4'''$) and checks that each simplifies to zero.
The Rust program checked the same for its tensor $P_{(1)} = -4G$ (its checks
`k1_equals_minus_4_einstein` and `k1_divergence_free`, which the cell confirms with
`record_check`).

## 12. The Kretschmann scalar: an invariant that does not see $z$

The next cell computes $K = \sum R^{ab}{}_{cd} R^{cd}{}_{ab}$ and
$\sum_{a,b} R^a{}_b R^b{}_a$ from our components, and computes $K$ a second time
from the 156 components of the record alone. Although some components depend on
$z$ (for example $R^{x_1x_4}{}_{x_1x_0} = H a_4' \cot z$), their products combine so
that $K$ depends only on $H$, $a_4'$, $a_4''$, $b_4$, $b_4'$ and $b_4''$. For a
constant $b_4$ (then $b_4$ drops out entirely), completing the square,

$$\frac{K}{12} = 7H^4 - 2H^2 a_4'^2 + 7 a_4'^4 + 2 a_4''^2
= 7\Bigl(a_4'^2 - \frac{H^2}{7}\Bigr)^2 + \frac{48}{7} H^4 + 2 a_4''^2 ,$$

(expand the square: $7 a_4'^4 - 2 H^2 a_4'^2 + H^4/7$, and $H^4/7 + 48 H^4/7 =
7 H^4$), so $K \ge \frac{576}{7} H^4 > 0$ for every history with a constant $b_4$:
the metric is curved for every $H > 0$. (For a changing $b_4$ there is no such
bound: section 14 shows a member of the family whose $K$ vanishes.) The cell checks
all of this.
```

## 13. The curvature along the deflating history

Along the history $a_4 = A H x_4$, $b_4 = 1$ we have $a_4' = A H$, $a_4'' = 0$ and
$b_4' = b_4'' = 0$, so every curvature scalar is a polynomial in the slope $A$. The
author's extra times deflate when $a_4$ increases, that is for $A > 0$; the Revision
record uses $A = 1$. The next cell evaluates the Ricci scalar $R = 6H^2(A^2 - 7)$,
the sum $\sum R^a{}_b R^b{}_a$ and $K$ as formulas in $A$, checks that they are
**even** in $A$ (they do not change when $A$ is replaced by $-A$; so these three
scalars cannot tell which of the two families of directions deflates, the metric and
the components of the curvature tensors can), and draws them for $0.1 \le A \le 3$
```

```
(every one of these histories deflates the extra times): $R$ on an ordinary axis
(it vanishes at $A = \sqrt 7$), the two squares on a logarithmic axis.
```

In [24]:

```
A = sp.symbols("A", real=True)  # the slope of the history a4 = A H x4

PASS diagonal of G: 12 (24 for x4) at A = 1 and 3 (33 for x4) at A = 2, unit H^2
```

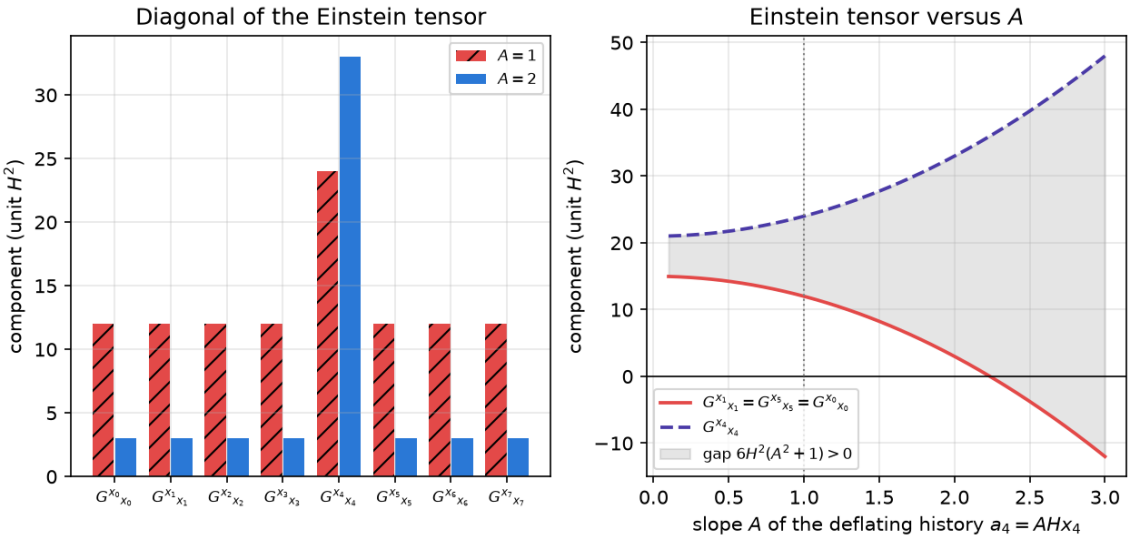

Figure 110: The Einstein tensor $G^{\mu}{}_{\nu}$ of the author's metric along the deflating history $a_4 = AHx_4$, $b_4 = 1$ with $H = 1$, in units of H^2. Left: the eight diagonal components (the only non-zero ones) for the canonical slope $A = 1$ of the Revision record (hatched bars: $12, 12, 12, 12, 24, 12, 12, 12$) and for $A = 2$ (plain bars: $3, 3, 3, 3, 33, 3, 3, 3$). Right: the hidden, 3-space and extra-time components $3H^2(5 - A^2)$ (solid) and the time component $3H^2(7 + A^2)$ (dashed) as functions of the slope A from 0.1 to 3; the shaded gap $6H^2(A^2 + 1)$ between them never closes. (Notebook 03b, figure 7.)

Text cell:

```
What do these numbers mean for matter? Einstein's field equations (section 3 of
this notebook) set $G^\mu{}_\nu + \Lambda\,\delta^\mu{}_\nu = \kappa\, T^\mu{}_\nu$
with $T = \mathrm{diag}(p_0, p_3, p_3, p_3, -\rho, p_t, p_t, p_t)$. Their $x_4$
component reads $G^{x_4}{}_{x_4} + \Lambda = -\kappa\rho$, so
$\kappa\rho = -G^{x_4}{}_{x_4} - \Lambda$; their $x_1$, $x_5$ and $x_0$ components
read $G^{x_1}{}_{x_1} + \Lambda = \kappa p_3$, $G^{x_5}{}_{x_5} + \Lambda = \kappa
p_t$ and $G^{x_0}{}_{x_0} + \Lambda = \kappa p_0$. Along the history (with
$b_4 = 1$) the three components on the left are equal (previous cell), so all three
pressures must be the same number $p$. The Revision record of the field equations of
$a_4$ (‘Revision/field_equations_a4/a4-equations.json‘, entry ‘linearMember‘) lists this
required source in its texts ‘rhoEinstein‘ ($\rho$), ‘pEinstein‘ ($p$) and
‘rhoPlusPEinstein‘ ($\rho + p$), written with ‘AA‘ for $A$ and ‘Lam‘ for $\Lambda$.
The next cell reads the three texts, turns them into sympy expressions, confirms
with ‘record_check‘ that the sympy verification of that record
(‘python-a4-report.json‘, check ‘json_linear_member‘) passed, and checks the three
texts against our Einstein tensor. The sum $\kappa(\rho + p) = -6(A^2 + 1)H^2$ is
negative for every $A$. Ordinary matter (dust, radiation, a gas) has
$\rho + p \ge 0$ (the **null energy condition**), so within Einstein's equations
the source that this history requires is not ordinary matter; a later chapter
discusses this, also for the field equations with the additional Lovelock terms.
Here we only check that the record and our curvature agree.
```

## 14. A negative control: what if the extra times inflated?

A check that cannot fail teaches nothing. So the next cell changes the metric on
purpose: the extra times now **inflate** like 3-space, $g_{55} = g_{66} = g_{77} =
-e^{+2a_4}\sin^{1/3} z$, and computes the curvature again with the same functions.
```

```
This is not a deflating metric; within the author's family it is the member
$b_4 = e^{4a_4}$, whose extra-time rate $\alpha_t = -a_4' + b_4'/(2b_4) = +a_4'$
equals that of 3-space. With a constant $b_4$ the $x_4$-$x_0$ components of the
Einstein tensor cancel between the three inflating and the three deflating
directions; here they add up. The cell prints the off-diagonal Einstein components
that appear and checks that they are not zero, that they depend on $z$, and that
they are the general components $\pm\tfrac32 H (\cot z, \tan z)\, b_4'/b_4$ of
section 11 with $b_4 = e^{4a_4}$. It also computes the Kretschmann scalar of the
control and checks that it vanishes for $a_4' = H$, $a_4'' = 0$: the bound
$K \ge 576H^4/7$ of section 12 needs a constant $b_4$.
```

In [27]:

```
g_control = g.copy()
for k in (5, 6, 7):  # the three extra times, now inflating

         for k, n in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all seven figure files exist")
all_checks_passed()
```

Out [28]:

```
PASS all seven figure files exist
ALL 40 CHECKS PASSED (notebook 03b)
```

Text cell:

```
## 16. What this notebook showed

- From the metric exactly as the author typed it, with general $a_4(x_4)$ and
  $b_4(x_4)$, sympy computed 37 non-zero Christoffel symbols (25 with $b \le c$),
  156 non-zero Riemann components $R^{ab}{}_{cd}$ with 20 different values, the Ricci
  tensor, the Ricci scalar ($R = 6a_4'^2 - 42H^2$ at $b_4 = 1$) and the Einstein
  tensor; every component agrees exactly
  with the Revision record of the Rust program `lovelock_gkd` (PROVED by exact
  algebra, here and in the record); at the five test points of the independent
  Revision verification all 310 recorded components agree with ours to more than 25
  significant digits. At $b_4 = 1$ twice our Ricci scalar equals the first Lovelock
  scalar $L_{(1)}$ of the record of the field equations of $a_4$.
- The Christoffel symbols were confirmed a second way, by finite differences, with
  an error that falls like $h^2$.
- The lines along $x_4$ are geodesics: observers at rest fall freely and $x_4$ is
  their proper time.
- The Riemann tensor has all the symmetries of a Riemann tensor and satisfies the
  first Bianchi identity; the Einstein tensor satisfies the contracted Bianchi
  identity and is isotropic in 3-space and in the extra times; its only off-diagonal
  components are $G^{x_4}{}_{x_0} = \tfrac32 H\cot z\, b_4'/b_4$ and
  $G^{x_0}{}_{x_4} = -\tfrac32 H\tan z\, b_4'/b_4$. At $b_4 = 1$ it is diagonal,
  does not depend on $x_0$, and $G^{x_4}{}_{x_4} - G^{x_0}{}_{x_0} = 6(a_4'^2 + H^2)
  > 0$.
- The Kretschmann scalar does not depend on $z$ although single components do; for
  a constant $b_4$ it is $K = 12(7H^4 - 2H^2a_4'^2 + 7a_4'^4 + 2a_4''^2)
  \ge 576H^4/7 > 0$: the metric is curved for every $H > 0$.
- Along the deflating history $a_4 = AHx_4$, $b_4 = 1$ the curvature scalars are
  $R = 6H^2(A^2 - 7)$, $K = 12H^4(7A^4 - 2A^2 + 7)$ and
  $\sum R^a{}_b R^b{}_a = 36H^4(A^4 + 7)$, all even in $A$. For the canonical
  history of the Revision record ($A = 1$, $H = 1$): $R = -36$, $K = 144$ and
  $G = \mathrm{diag}(12, 12, 12, 12, 24, 12, 12, 12)$ (units $H^2$ and $H^4$); for
  $A = 2$: $G = \mathrm{diag}(3, 3, 3, 3, 33, 3, 3, 3)$.
- Through Einstein's equations this Einstein tensor is exactly the source that the
  Revision record of the field equations of $a_4$ lists for the linear history:
  $\kappa\rho = -3(7 + A^2)H^2 - \Lambda$, $\kappa p = 3(5 - A^2)H^2 + \Lambda$ for
  all three pressures, and $\kappa(\rho + p) = -6(A^2 + 1)H^2 < 0$.
- Negative control: if the extra times inflated instead of deflating (the member
```

```
  $b_4 = e^{4a_4}$ of the family), the Einstein tensor acquires the off-diagonal
  components $G^{x_4}{}_{x_0}$ and $G^{x_0}{}_{x_4}$ of the general formula, and its
  Kretschmann scalar can vanish; with a constant $b_4$ the deflation of the extra
  times makes the Einstein tensor of the author's metric diagonal.
- ASSUMED for the plots and the evaluation along the history only: the history
  $a_4 = AHx_4$ with $A > 0$ and $b_4 = 1$ (a prescribed background, not solved
  for); every formula with general $a_4(x_4)$ and $b_4(x_4)$ is exact.
```

3.30 Line-by-line walk-through of Notebook 03b

The notebook has 28 code cells, In [1] to In [28]. As before, a line or a small group of lines is quoted and then explained, and a line `...` in a quoted figure command stands for the remaining lines of the caption, printed in full under its figure in Section 3.29.

In [1], the set-up cell. Its comment lines are the run instructions of Section 3.28. Its code is, line for line, the set-up code of Notebook 03a explained in Section 3.13 under In [1], with the single difference `NOTEBOOK_ID = "03b" # this notebook:  chapter 03, example b`. It prints Set-up of notebook 03b complete: repository folder found, helpers defined.

In [2], every result in one piece. Word for word In [2] of Notebook 03a (Section 3.13). It prints From now on check and report print each of their results in one piece.

In [3], packages, record and symbols.

```
import itertools  # loops over all index combinations

import mpmath  # numbers with many digits
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
from sympy.parsing.sympy_parser import (implicit_multiplication, parse_expr,
                                        standard_transformations)
```

The packages: `itertools` for loops over indices (Section 3.22), `mpmath` for numbers with many digits (used in In [19]), numpy, sympy, and the text reader `parse_expr` of sympy with its two reading rules (Section 3.13, In [3] and In [5]).

```
CURVATURE_RECORD = "Revision/gkd_lovelock/results/curvature.json"
record = json.loads(repository_file(CURVATURE_RECORD).read_text(encoding="utf-8"))
PYTHON_REPORT = "Revision/gkd_lovelock/results/python-lovelock-report.json"  # sympy
RUST_REPORT = "Revision/gkd_lovelock/results/lovelock-report.json"  # the Rust checks

def record_check(report_file, check_name, detail_part=""):
    checks = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
    checks = checks["checks"]  # a dictionary or a list, depending on the report
    if isinstance(checks, dict):  # {name: {"passed": true, "detail": ...}}
        entry = checks.get(check_name, {})
        passed = entry.get("passed") is True
    else:  # [{"name": ..., "verdict": "PASS", "detail": ...}, ...]
        entry = next((e for e in checks if e.get("name") == check_name), {})
        passed = entry.get("verdict") == "PASS"
```

```
    if not passed or detail_part not in entry.get("detail", ""):
        raise AssertionError(f"record check failed: {report_file} does not list "
                             f"{check_name} as passed")
    return True

x0, x1, x2, x3, x4, x5, x6, x7 = sp.symbols("x0:8", real=True)
X = [x0, x1, x2, x3, x4, x5, x6, x7]  # the coordinates, counted 0 to 7 in Python
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
H = sp.symbols("H", positive=True)  # the constant of the author
a4 = sp.Function("a4")(x4)  # the metric function a4, unknown
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4 > 0, unknown
a4p, a4pp, a4v = sp.symbols("a4p a4pp a4v", real=True)  # a4 prime, a4 two primes, a4
b4p, b4pp = sp.symbols("b4p b4pp", real=True)  # b4 prime, b4 two primes
b4v = sp.symbols("b4v", positive=True)  # the value of b4
z = sp.symbols("z", positive=True)  # z = 6 H x0, for printing
```

The record of the Rust program `lovelock_gkd` is read into the dictionary `record`. `PYTHON_REPORT` and `RUST_REPORT` are the names of two further Revision reports: the report of the independent sympy checker and the report of the Rust program's own checks. The function `record_check` reads such a report and requires that it lists the check `check_name` as passed. The reports come in two layouts: in one, `checks` is a dictionary from each check name to an entry with the key `passed`; in the other, it is a list of entries, each with a `name` and a `verdict`. `isinstance(checks, dict)` asks which layout this report has; `checks.get(check_name, {})` gives the entry or an empty dictionary when the name is missing, and `next(..., {})` finds the entry with that name in the list (or the empty dictionary). The entry must say passed (the value `True`, or the verdict `"PASS"`), and, when `detail_part` is given, its `detail` text must contain that piece; otherwise `raise AssertionError(...)` stops the notebook with a message that names the report and the check. So whenever this notebook says that a number agrees with a Revision record, it also confirms, from the record itself, that the record's own check of that number passed. Then the eight coordinates, their list `X` and their printed names `NAMES`, in the author's order, so that `X[k]` is x_k and `NAMES[k]` is `"xk"`; the constant $H > 0$; the unknown functions $a_4(x_4)$ and $b_4(x_4)$, the second declared positive; and seven plain symbols for printing: `a4p` for a_4', `a4pp` for a_4'', `a4v` for the value of a_4, the same three for b_4 (`b4p`, `b4pp`, `b4v`, the last one positive), and `z` for $6Hx_0$.

```
def symbolic(expression):
    """Write the derivatives of a4 and b4 as a4p, a4pp, b4p, b4pp and the values
    a4(x4), b4(x4) as a4v, b4v."""
    expression = expression.subs(sp.Derivative(a4, (x4, 2)), a4pp)  # second first
    expression = expression.subs(sp.Derivative(b4, (x4, 2)), b4pp)
    expression = expression.subs(sp.Derivative(a4, x4), a4p).subs(a4, a4v)
    return expression.subs(sp.Derivative(b4, x4), b4p).subs(b4, b4v)

def plain(expression):
    """As symbolic, and 6 H x0 written as z."""
    return symbolic(expression).subs(x0, z / (6 * H))

say("Record read; symbols x0 ... x7, H, a4(x4), b4(x4), a4p, a4pp, a4v, b4p, b4pp, "
    "b4v and z defined.")
```

`symbolic` replaces the second derivatives of a_4 and b_4 (written `sp.Derivative(a4, (x4, 2))` and `sp.Derivative(b4, (x4, 2))`) by `a4pp` and `b4pp`, then the first derivatives by `a4p` and `b4p`, then the functions themselves by `a4v` and `b4v`. The second derivative is replaced first, because replacing the first derivative first could also change the second one (which is the derivative of the first). `plain` does the same and also writes $6Hx_0$ as z. The last line prints the output of In [3].

In [4], the metric from the author's text.

```
# the metric exactly as the author typed it, without the note in brackets after it
text = record["metricAsGiven"].split("}} ", 1)[0] + "}}"
text = text.replace("exp^", "E^").replace("a4[x4]", "a4").replace("b4[x4]", "b4")
text = text.replace("Sin[6 H x0]", "sin(6 H x0)").replace("Cot[6 H x0]", "cot(6 H x0)")
text = text.replace("{", "[").replace("}", "]").replace("^", "**")
metric_names = {"E": sp.E, "a4": a4, "b4": b4, "H": H, "x0": x0, "sin": sp.sin,
                "cot": sp.cot}
g = sp.Matrix(parse_expr(text, local_dict=metric_names, transformations=(
    standard_transformations + (implicit_multiplication,))))
```

The first line cuts the record's text at the first `}}` followed by a blank, as Notebook 03a does (Section 3.13, In [3]): `[0]` keeps the matrix, without the note in brackets, and `+ "}}"` puts back its two closing braces. Then the same translation of the author's Mathematica text as in Notebook 03a (Section 3.13, In [5]), with two or three replacements per line, eight in all: `exp^` becomes `E^`, `a4[x4]` becomes `a4` and `b4[x4]` becomes `b4`, the square brackets of the sine and the cotangent become round ones, the braces of lists become square brackets and `^` becomes `**`. The dictionary `metric_names` says what each name means, and `parse_expr` with implicit multiplication reads the text; `sp.Matrix` makes the exact 8×8 matrix `g`.

```
for k in range(8):
    say(f"  g[{NAMES[k]}, {NAMES[k]}] = {plain(g[k, k])}")
check(all(g[i, j] == 0 for i in range(8) for j in range(8) if i != j),
      "the metric read from the text of the author is diagonal")
```

The eight diagonal entries are printed with `plain`, in the order $x_0, \ldots, x_7$, for example `exp(2*a4v)*sin(z)**(1/3)` for $e^{2a_4} \sin^{1/3} z$ and `-b4v*exp(-2*a4v)*sin(z)**(1/3)` for $-b_4 e^{-2a_4} \sin^{1/3} z$, and the check requires the 56 entries off the diagonal to be zero.

In [5], reading the record's components.

```
record_names = {"a4p": a4p, "a4pp": a4pp, "a4v": a4v, "b4p": b4p, "b4pp": b4pp,
                "b4v": b4v, "H": H, "x0": x0, "E": sp.E, "sin": sp.sin, "cot": sp.cot}

def from_mathematica(entry_text):
    """A component of the record (Mathematica notation) as a sympy expression."""
    t = entry_text.replace("Derivative[1][a4][x4]", "a4p")
    t = t.replace("Derivative[2][a4][x4]", "a4pp").replace("a4[x4]", "a4v")
    t = t.replace("Derivative[1][b4][x4]", "b4p")
    t = t.replace("Derivative[2][b4][x4]", "b4pp").replace("b4[x4]", "b4v")
    t = t.replace("Sin[6*H*x0]", "sin(6*H*x0)").replace("Cot[6*H*x0]", "cot(6*H*x0)")
    t = t.replace("^", "**")
```

```
    if "[" in t or "]" in t:
        raise ValueError(f"cannot translate {entry_text}")
    return parse_expr(t, local_dict=record_names)
```

The record writes a_4' as `Derivative[1][a4][x4]` and a_4'' as `Derivative[2][a4][x4]`, and the same for b_4. `from_mathematica` translates a component of the record into sympy: the two derivatives of a_4 become `a4p` and `a4pp` and `a4[x4]` becomes `a4v`, the same for b_4 (`b4p`, `b4pp`, `b4v`), the functions get round brackets, `^` becomes `**`. If a square bracket is left, some notation was not translated and the function stops with an error instead of misreading silently. The dictionary `record_names` says what the names in the translated text mean.

```
def tidy(expression):
    """Simplify an expression.  It writes 6 H x0 as z (so that 12 H x0 becomes 2z),
    simplifies it twice, once as it is and once after writing sin(2z) as
    2 sin(z) cos(z) (expand_trig), keeps the shorter result (count_ops counts the
    operations), and writes z as 6 H x0 again."""
    expression = sp.sympify(expression).subs(x0, z / (6 * H))
    first = sp.simplify(expression)
    second = sp.simplify(sp.expand_trig(expression))
    best = second if sp.count_ops(second) < sp.count_ops(first) else first
    return best.subs(z, 6 * H * x0)
```

`tidy` is the simplifier of the notebook. `sp.sympify` turns a plain Python number into a sympy number (so that `.subs` works on it). It writes $6Hx_0$ as z, simplifies once directly and once after `sp.expand_trig`, which writes $\sin 2z$ as $2\sin z\cos z$, and keeps the result with fewer operations (`sp.count_ops` counts them); sympy sometimes reaches the simplest form only one of the two ways. At the end z is written as $6Hx_0$ again. The line `best = second if ...  else first` chooses one of two values by a condition.

```
def vanishes(expression):
    """True when the expression simplifies to zero."""
    return tidy(expression) == 0

def same(mine, theirs):
    """True when mine (with the function a4) equals theirs (record symbols)."""
    return vanishes(symbolic(mine) - theirs)
```

`vanishes` is true when an expression simplifies to 0; `same` compares one of our expressions (written with the functions a_4 and b_4) with one of the record (written with `a4p`, `a4pp`, `a4v`, `b4p`, `b4pp`, `b4v`): it rewrites ours with `symbolic` and asks whether the difference vanishes.

```
example = next(e["value"] for e in record["christoffelNonzero_b_le_c"]
               if (e["a"], e["b"], e["c"]) == ("x4", "x5", "x5"))  # Gamma^x4_(x5 x5)
say(f"example of a record entry: {example}")
say(f"translated: {from_mathematica(example)}")
```

The entry of the record's Christoffel list with the indices `a = "x4"`, `b = "x5"`, `c = "x5"` serves as an example: `next(...  for e in ...  if ...)` runs through the list and takes the first entry

whose three indices, compared as one tuple, are these. The output shows it in the record's notation and then its translation:

```
example of a record entry: -(1/2)*E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*Derivative[1][b4][x4] +
    Derivative[1][a4][x4]*E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*b4[x4]
translated: a4p*b4v*exp(-2*a4v)*sin(6*H*x0)**(1/3) - b4p*exp(-2*a4v)*sin(6*H*x0)**(1/3)/2
```

This is the symbol $\Gamma^{x_4}{}_{x_5x_5} = (a_4'b_4 - \frac{1}{2}b_4')e^{-2a_4}\sin^{1/3} z$ of Section 3.23, the one in which both functions appear.

In [6], the Christoffel symbols.

```
def christoffel(metric, coordinates):
    """All Christoffel symbols Gamma[a][b][c] of a metric, by the formula above."""
    n = len(coordinates)
    inverse = metric.inv()  # the inverse metric g^(ad)
    d_metric = [metric.diff(c) for c in coordinates]  # d_metric[c][i, j] = d_c g_ij
    table = [[[0] * n for _ in range(n)] for _ in range(n)]
    for a, b, c in itertools.product(range(n), repeat=3):
        value = sum(inverse[a, d] * (d_metric[b][d, c] + d_metric[c][d, b]
                                     - d_metric[d][b, c]) for d in range(n)) / 2
        table[a][b][c] = tidy(value)
    return table
```

The same function as in Notebook 03c (Section 3.22, In [3]), with `tidy` instead of `sp.simplify`: the Christoffel formula of Section 3.15 applied to all $8^3 = 512$ index lists, without using the symmetry in b and c (so that the symmetry can be checked).

```
Gamma = christoffel(g, X)
nonzero = [(a, b, c) for a, b, c in itertools.product(range(8), repeat=3)
           if Gamma[a][b][c] != 0]
upper_half = [(a, b, c) for a, b, c in nonzero if b <= c]
report("non-zero Christoffel symbols (all orders of b, c)", len(nonzero))
report("non-zero Christoffel symbols with b <= c", len(upper_half))
check(all(Gamma[a][b][c] == Gamma[a][c][b]
          for a, b, c in itertools.product(range(8), repeat=3)),
      "the Christoffel symbols are symmetric in their two lower indices")
```

`Gamma` is the table of the author's metric. `nonzero` lists the index lists of the non-zero symbols and `upper_half` those with $b \le c$. The two RESULT lines print 37 and 25, the counts of Section 3.23, and the check confirms the symmetry $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$ for all 512.

In [7], comparison with the record.

```
for a, b, c in upper_half:
    say(f"  Gamma^{NAMES[a]}_({NAMES[b]} {NAMES[c]}) = {plain(Gamma[a][b][c])}")
```

The 25 symbols are printed, in the order of their index lists (first Γ^{x_0}, last Γ^{x_7}): they are the table of Section 3.23, in sympy's way of writing. It writes $H\cot z$ as `H/tan(z)`, $-H\tan z\, e^{2a_4}\sin^{1/3} z$

as `-H*exp(2*a4v)*sin(z)**(4/3)/cos(z)` (because $\sin^{1/3} z \tan z = \sin^{4/3} z / \cos z$), $-6H(\tan z + \cot z) = -6H/(\sin z \cos z)$ as `-12*H/sin(2*z)` (because $\sin 2z = 2 \sin z \cos z$), and the extra-time rate as `-a4p + b4p/(2*b4v)`.

```
record_gamma = {(NAMES.index(e["a"]), NAMES.index(e["b"]), NAMES.index(e["c"])):
                from_mathematica(e["value"])
                for e in record["christoffelNonzero_b_le_c"]}
check(sorted(record_gamma) == upper_half and len(upper_half) == 25,
      "the same 25 non-zero Christoffel symbols as the record")
record_check(PYTHON_REPORT, "rust_christoffels_agree")  # stops if not passed
check(all(same(Gamma[a][b][c], value) for (a, b, c), value in record_gamma.items()),
      "every Christoffel symbol equals the record exactly",
      record=f"{CURVATURE_RECORD}, christoffelNonzero_b_le_c (and "
             "python-lovelock-report.json, check rust_christoffels_agree)")
```

The line `record_check(PYTHON_REPORT, "rust_christoffels_agree")` confirms that the sympy checker of the Revision record found every Christoffel symbol of the Rust program correct; the notebook stops there if that check had not passed.

`record_gamma` is a dictionary built from the record's list: the key is the index list (`NAMES.index("x4")` is 4, the position of a name in the list) and the value is the translated symbol. The first check requires the record and the notebook to name the same 25 index lists (`sorted` turns the keys into an ordered list); the second requires every value to agree exactly. The PASS line names the record and its independent verification.

In [8], Figure 03b.1: the Christoffel symbols as heat maps.

```
from matplotlib.colors import LinearSegmentedColormap, SymLogNorm

BLUE, ORANGE, AQUA, YELLOW = "#2a78d6", "#eb6834", "#1baf7a", "#eda100"
MAGENTA, GREEN, VIOLET, RED = "#e87ba4", "#008300", "#4a3aa7", "#e34948"
DIVERGING = LinearSegmentedColormap.from_list("blue_grey_red", [BLUE, "#f0efec", RED])
LABELS = [f"$x_{k}$" for k in range(8)]
ARGS = (z, a4v, a4p, H, b4v, b4p)  # the arguments of the numerical functions
```

The colour palette and the blue-grey-red colour scale of Notebook 03a (Section 3.13, In [9]); `SymLogNorm` is a colour scale that is logarithmic on both sides of zero. `LABELS` are the axis labels x_0 to x_7. `ARGS` lists the six arguments of the numerical functions made next: z, a_4, a_4', H, b_4, b_4' (no Christoffel symbol contains a second derivative).

```
def numeric(expression):
    """A numerical function f(z, a4v, a4p, H, b4v, b4p) of an expression."""
    return sp.lambdify(ARGS, plain(expression), "numpy")

gamma_functions = {(a, b, c): numeric(Gamma[a][b][c]) for a, b, c in nonzero}
# z, a4, a4p, H, b4, b4p: the canonical slice a4 = 0.5 of the history, b4 = 1
POINT = (np.pi / 4, 0.5, 1.0, 1.0, 1.0, 0.0)
tables = np.zeros((8, 8, 8))
for (a, b, c), f in gamma_functions.items():
    tables[a, b, c] = f(*POINT)
```

`numeric` turns an exact expression into a fast numerical function (`sp.lambdify`, Section 3.13, In [8]). `gamma_functions` holds one such function for each of the 37 non-zero symbols. `POINT` is the point $z = \pi/4$ on the slice $a_4 = 0.5$ of the history $a_4 = x_4$, $b_4 = 1$ (so $a'_4 = 1$ and $b'_4 = 0$), with $H = 1$; `f(*POINT)` calls a function with the six numbers. The $8 \times 8 \times 8$ array `tables` holds the 512 numbers (zero where the symbol is zero).

```
fig, axes = plt.subplots(2, 4, figsize=(11.0, 5.4))
norm = SymLogNorm(linthresh=0.1, vmin=-15.0, vmax=15.0, base=10)
for a, ax in enumerate(axes.flat):
    image = ax.imshow(tables[a], cmap=DIVERGING, norm=norm)
    for b, c in itertools.product(range(8), repeat=2):
        if tables[a, b, c] != 0:
            ax.text(c, b, f"{tables[a, b, c]:.2f}", ha="center", va="center",
                    fontsize=6.0)
```

Eight panels in two rows of four, one for each upper index a (`axes.flat` runs through them in order). The colour scale is ordinary between -0.1 and 0.1 and logarithmic beyond, up to ± 15, so that small and large symbols are both visible. In each panel the 8×8 table ${\Gamma^a}_{bc}$ is drawn with row b and column c, and every non-zero value is written into its square with two decimals.

```
    ax.set_title(f"$\\Gamma^{{x_{a}}}{{}}_{{bc}}$", fontsize=10)
    ax.set_xticks(range(8), [str(k) for k in range(8)], fontsize=7)
    ax.set_yticks(range(8), [str(k) for k in range(8)], fontsize=7)
    ax.grid(False)
fig.colorbar(image, ax=axes, shrink=0.8, label="value (unit $H$)")
fig.suptitle("Christoffel symbols at $z = \\pi/4$, $a_4 = 0.5$, "
             "$a_4^{\\prime} = 1$, $b_4 = 1$, $H = 1$ (row $b$, column $c$)")
```

Each panel gets the title ${\Gamma^{x_a}}_{bc}$ (in an f-string a doubled brace `{{` prints one brace, so that the braces of the math notation survive) and the tick labels 0 to 7, the indices of x_0 to x_7. One colour bar serves all panels; `suptitle` is the title of the whole figure.

```
save_figure(fig, "christoffel_heat_maps",
            "The 512 Christoffel symbols $\\Gamma^{a}{}_{bc}$ of the author's metric "
...
check(np.allclose(tables, tables.transpose(0, 2, 1))
      and all(4 in key or 0 in key for key in nonzero),
      "the tables are symmetric in b, c; every non-zero symbol has an index x4 or x0")
```

The figure is saved. The check: `tables.transpose(0, 2, 1)` exchanges the second and the third index, so the first condition is ${\Gamma^a}_{bc} = {\Gamma^a}_{cb}$ as numbers; the second requires every non-zero index list to contain position 4 (x_4) or position 0 (x_0).

What Figure 03b.1 shows. At $b_4 = 1$, only 37 of the 512 squares are coloured. In the panels of 3-space (Γ^{x_1}, Γ^{x_2}, Γ^{x_3}) the value 1.00 appears four times, at the positions (x_k, x_4), (x_4, x_k), (x_k, x_0), (x_0, x_k): here both $a'_4 = 1$ and $H \cot(\pi/4) = 1$. In the panels of the extra times the squares with x_4 are blue, -1.00: the deflation. The panel Γ^{x_4} has 2.42 on the 3-space diagonal and 0.33 on the extra-time diagonal; the panel Γ^{x_0} has -2.42, 0.33 and the largest value, ${\Gamma^{x_0}}_{x_0 x_0} = -12$. Each panel is symmetric about its diagonal.

In [9], Figure 03b.2: the symbols across the patch.

```
z_line = np.linspace(0.01, np.pi / 2 - 0.01, 500)
chosen = [((1, 1, 0), RED, "-", "$\\Gamma^{x_1}{}_{x_1 x_0}$"),
          ((0, 0, 0), VIOLET, "--", "$\\Gamma^{x_0}{}_{x_0 x_0}$"),
          ((0, 1, 1), ORANGE, "-.", "$\\Gamma^{x_0}{}_{x_1 x_1}$"),
          ((0, 5, 5), BLUE, ":", "$\\Gamma^{x_0}{}_{x_5 x_5}$"),
          ((1, 1, 4), AQUA, "-", "$\\Gamma^{x_1}{}_{x_1 x_4}$")]
fig, ax = plt.subplots()
```

500 values of z inside the patch, and five chosen symbols, each with its index list, colour, line style and label.

```
for index, colour, style, label in chosen:
    values = np.broadcast_to(gamma_functions[index](z_line, 0.5, 1.0, 1.0, 1.0,
                                                    0.0), z_line.shape)
    sign = "+" if values[len(values) // 2] > 0 else "minus"
    ax.plot(z_line, np.abs(values), color=colour, ls=style, lw=1.8,
            label=f"{label} (sign {sign})")
```

For each symbol the values at the 500 points ($a_4 = 0.5$, $a_4' = 1$, $H = 1$, $b_4 = 1$, $b_4' = 0$); `np.broadcast_to` repeats a constant (the symbol a_4' does not depend on z, and its function returns one number). The sign is read at the middle point (`//` divides and rounds down), and the absolute value is drawn, because a logarithmic axis can only show positive numbers.

```
ax.set_yscale("log")
ax.set_xlabel("$z = 6 H x_0$ (radians)")
ax.set_ylabel("absolute value of the symbol (unit $H$)")
ax.set_title("Christoffel symbols across the patch "
             "($a_4 = 0.5$, $a_4^{\\prime} = 1$, $b_4 = 1$, $H = 1$)")
ax.set_ylim(1e-5, 3e3)  # room below the curves for the legend
ax.legend(fontsize=8, loc="lower center", ncol=2)
save_figure(fig, "christoffel_versus_z",
            "The absolute values of five Christoffel symbols of the author's metric "
...
check(abs(gamma_functions[(1, 1, 0)](np.pi / 4, 0.5, 1.0, 1.0, 1.0, 0.0) - 1.0)
      < 1e-14,
      "Gamma^x1_(x1 x0) = H cot z equals 1 at z = pi/4, H = 1")
```

A logarithmic vertical axis, labels, title, the range of the axis and the legend; the figure is saved; the check confirms $H \cot(\pi/4) = 1$.

What Figure 03b.2 shows. ${\Gamma^{x_1}}_{x_1 x_0} = H \cot z$ (red) falls from about 100 near the tip to almost 0 at the patch end; ${\Gamma^{x_0}}_{x_0 x_0}$ (violet dashed) is large at both ends and smallest, 12, at $z = \pi/4$; ${\Gamma^{x_0}}_{x_1 x_1}$ and ${\Gamma^{x_0}}_{x_5 x_5}$ grow towards the patch end, where $\tan z$ grows without bound; ${\Gamma^{x_1}}_{x_1 x_4} = a_4' = 1$ (aqua) is flat. Large Christoffel symbols belong to the coordinates; whether the geometry itself is extreme is decided by an invariant, the Kretschmann scalar of In [22].

In [10], a second check by finite differences.

```
prime = chr(39)  # the apostrophe (character number 39): the record writes a4 prime so
point_text = (f"H = 0.23, a4 = 0.17, a4{prime} = 0.61, a4{prime}{prime} = -0.37, "
```

```
            f"b4 = 1.37, b4{prime} = 0.31, b4{prime}{prime} = -0.23, "
            "x0 = 0.41")  # the test point as the record writes it
check(record_check(RUST_REPORT, "k1_brute_force_numeric", point_text),
      "the test point is the one of the brute-force check of the Rust program")
H_n, a0, a1, a2, x0_n = 0.23, 0.17, 0.61, -0.37, 0.41  # the test point
b0, b1, b2 = 1.37, 0.31, -0.23  # b4, b4' and b4'' at x4 = 0
```

The Rust program's check `k1_brute_force_numeric` names its test point in a text that writes $H = 0.23$, $a_4 = 0.17$, $a_4' = 0.61$, $a_4'' = -0.37$, $b_4 = 1.37$, $b_4' = 0.31$, $b_4'' = -0.23$ and $x_0 = 0.41$, with one apostrophe for each prime (the line `point_text` builds exactly this text). `chr(39)` is the character number 39, the apostrophe, and the f-string puts it after `a4` and `b4` once for the first and twice for the second derivative (the comment at the end of the line says so; the book prints a straight apostrophe in code as a curly one, and the character number makes plain which character is meant). `record_check(RUST_REPORT, "k1_brute_force_numeric", point_text)` (In [3]) confirms that this check of the record passed and that its detail contains exactly this text; `check` prints the PASS line. The eight numbers are then named: `a0`, `a1`, `a2` for a_4 and its two derivatives and `b0`, `b1`, `b2` for b_4 and its two derivatives at $x_4 = 0$.

```
def metric_numbers(x):
    """The metric as an 8 x 8 numpy table at the point x (8 coordinates)."""
    a = a0 + a1 * x[4] + 0.5 * a2 * x[4] ** 2  # a4(x4) with a4(0) = 0.17, ...
    b = b0 + b1 * x[4] + 0.5 * b2 * x[4] ** 2  # b4(x4) with b4(0) = 1.37, ...
    warp_n = np.sin(6 * H_n * x[0]) ** (1 / 3)
    # the author's order x0, x1, ..., x7
    return np.diag([1 / np.tan(6 * H_n * x[0]) ** 2] + [np.exp(2 * a) * warp_n] * 3
                   + [-1.0] + [-b * np.exp(-2 * a) * warp_n] * 3)
```

The metric as a plain table of numbers at a point `x` (a list of eight coordinates in the author's order, `x[4]` is x_4 and `x[0]` is x_0), for the concrete functions $a_4(x_4) = 0.17 + 0.61x_4 - 0.185x_4^2$ and $b_4(x_4) = 1.37 + 0.31x_4 - 0.115x_4^2$, which have at $x_4 = 0$ the values, slopes and second derivatives of the test point. `np.diag` makes the diagonal matrix, with the hidden entry first.

```
def christoffel_numbers(x, h):
    """All 512 Christoffel symbols at x from central differences with step h."""
    d_metric = np.zeros((8, 8, 8))  # d_metric[c] = derivative of g along x_c
    for c in range(8):
        step = np.zeros(8)
        step[c] = h
        d_metric[c] = (metric_numbers(x + step) - metric_numbers(x - step)) / (2 * h)
```

The derivatives of the metric without any algebra: for each coordinate c the point is moved by $\pm h$ along x_c (`step` is zero except at position c), and the **central difference** $(g(x+he_c) - g(x-he_c))/(2h)$ approximates $\partial_c g$ (Chapter 2).

```
    inverse = np.linalg.inv(metric_numbers(x))
    table = np.zeros((8, 8, 8))
    for a, b, c in itertools.product(range(8), repeat=3):
        table[a, b, c] = 0.5 * sum(inverse[a, d] * (d_metric[b][d, c]
                                   + d_metric[c][d, b] - d_metric[d][b, c])
```

```
                                    for d in range(8))
    return table
```

The inverse metric as numbers (`np.linalg.inv`) and the Christoffel formula of Section 3.15, now with numbers.

```
x_point = np.array([x0_n, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0])  # x0 = 0.41, x4 = 0
exact = np.zeros((8, 8, 8))
for (a, b, c), f in gamma_functions.items():
    exact[a, b, c] = f(6 * H_n * x0_n, a0, a1, H_n, b0, b1)
steps = 10.0 ** -np.arange(1, 9)  # h = 0.1, 0.01, ..., 1e-8
errors = np.array([np.max(np.abs(christoffel_numbers(x_point, h) - exact))
                   for h in steps])
for h, e in zip(steps, errors):
    say(f"  h = {h:.0e}: largest error of the 512 symbols = {e:.2e}")
```

The test point in the author's order (only $x_0 = 0.41$, the first entry, matters, with $x_4 = 0$); the exact symbols there from the functions of In [8], with $z = 6 \cdot 0.23 \cdot 0.41$, $a_4 = 0.17$, $a_4' = 0.61$, $H = 0.23$, $b_4 = 1.37$, $b_4' = 0.31$; eight steps $h = 10^{-1}, \ldots, 10^{-8}$ (`10.0 ** -np.arange(1, 9)` raises 10 to the powers -1 to -8); for each the largest difference between the 512 numerical and exact symbols. The eight output lines show the errors 4.01×10^{-1}, 3.66×10^{-3}, 3.65×10^{-5}, 3.65×10^{-7}, 3.66×10^{-9}, 5.67×10^{-11}, 8.46×10^{-10}, 9.00×10^{-9}.

```
order = np.log10(errors[0] / errors[1])  # the slope between h = 0.1 and h = 0.01
report("measured order of the error between h = 0.1 and h = 0.01", f"{order:.3f}")
check(1.9 < order < 2.1 and errors.min() < 1e-8,
      "finite differences reproduce all 512 symbols; the error falls like h^2")
```

When h shrinks tenfold, an error Ch^p shrinks by 10^p, so $p = \log_{10}$ of the ratio of the errors. The RESULT line prints 2.040: the central difference has order 2 (Chapter 2). The check requires the order between 1.9 and 2.1 and the best error below 10^{-8}.

In [11], Figure 03b.3.

```
fig, ax = plt.subplots()
ax.loglog(steps, errors, "o-", color=BLUE, lw=1.8, ms=7,
          label="largest error of the 512 symbols")
ax.loglog(steps, errors[0] * (steps / steps[0]) ** 2, "--", color="black", lw=1.2,
          label="slope 2: error proportional to $h^2$")
ax.set_xlabel("step $h$ of the central difference")
ax.set_ylabel("largest absolute error (unit $H$)")
ax.set_title("Christoffel symbols by finite differences")
ax.legend(fontsize=8)
```

`ax.loglog` draws with logarithmic scales on both axes: the errors as dots joined by lines, and a reference line proportional to h^2 that starts at the first error. Labels, title, legend.

```
best = int(np.argmin(errors))  # the position of the smallest error in the list
report("best step and its error", f"h = {steps[best]:.0e}, error {errors[best]:.1e}")
```

```
mantissa, exponent = f"{errors[best]:.1e}".split("e")  # e.g. "3.2" and "-10"
best_error = f"{mantissa} \\times 10^{{{int(exponent)}}}"  # 3.2 x 10^-10 in LaTeX
best_step = f"10^{{{round(np.log10(steps[best]))}}}"  # the step as a power of 10
```

`np.argmin` gives the position of the smallest error; the RESULT line prints h = 1e-06, error 5.7e-11. The next three lines write the best error and step in math notation for the caption: the text `5.7e-11` is split at the letter e into `5.7` and `-11`, and the caption receives 5.7×10^{-11} and 10^{-6} (a tripled brace in an f-string gives one literal brace around the inserted value).

```
save_figure(fig, "finite_differences",
            "The largest difference between the 512 Christoffel symbols computed "
...
check(errors[0] > errors[1] > errors[2] > errors[3],
      "the error shrinks as the step shrinks from 0.1 to 0.0001")
```

The figure is saved; its caption is assembled from pieces, two of which are the f-strings just made. The check requires the error to decrease over the first four steps.

What Figure 03b.3 shows. From $h = 10^{-1}$ to $h = 10^{-6}$ the blue dots lie on the dashed line of slope 2: each tenfold smaller step gives a hundredfold smaller error. Below $h = 10^{-6}$ the error grows again: the rounding errors of the computer, about 10^{-16} of each number, are divided by h in the difference quotient. The best step, 10^{-6}, gives 5.7×10^{-11}. Numbers computed without any algebra agree with the exact symbols, also for the symbols that contain b_4 and b_4'.

In [12], free fall along x_4 and the contracted symbols.

```
check(all(Gamma[a][4][4] == 0 for a in range(8)),
      "Gamma^a_(x4 x4) = 0: observers at rest fall freely, x4 is their proper time")
volume = b4 ** sp.Rational(3, 2) * sp.cos(6 * H * x0)  # sqrt|det g|
contracted = [vanishes(sum(Gamma[a][a][b] for a in range(8))
                       - sp.diff(sp.log(volume), X[b]))
              for b in range(8)]
check(all(contracted),
      "sum over a of Gamma^a_(a b) equals the derivative of ln(b4^(3/2) cos z)")
```

The first check: the eight symbols ${\Gamma^a}_{x_4 x_4}$ (lower positions 4 and 4) are zero, so observers at rest fall freely (Section 3.23). The second: for each b, $\sum_a {\Gamma^a}_{ab} - \partial_b \ln(b_4^{3/2} \cos z)$ vanishes (Sections 3.15 and 3.23); `X[b]` is the coordinate x_b.

In [13], the Riemann tensor.

```
def riemann(table, coordinates):
    """The non-zero R^a_bcd (MTW) as a dictionary {(a, b, c, d): value}."""
    n = len(coordinates)
    result = {}
    for a, b in itertools.product(range(n), repeat=2):
        for c, d in itertools.combinations(range(n), 2):  # all pairs c < d
            value = (sp.diff(table[a][b][d], coordinates[c])
                     - sp.diff(table[a][b][c], coordinates[d])
                     + sum(table[a][c][e] * table[e][b][d]
```

```
                        - table[a][d][e] * table[e][b][c] for e in range(n)))
            value = tidy(value)
            if value != 0:
                result[(a, b, c, d)] = value
                result[(a, b, d, c)] = -value  # antisymmetric in c and d
    return result
```

The formula of Section 3.17, as in Notebook 03c, but with less work: `itertools.combinations(range(n), 2)` gives only the pairs $c < d$ (28 of them); the component with c and d exchanged is stored with the opposite sign (symmetry (S1)), and those with $c = d$ are zero. Non-zero values are kept in a dictionary.

```
def raise_second(riemann_table, metric):
    """R^ab_cd = sum over e of g^(be) R^a_ecd, the non-zero ones."""
    inverse = metric.inv()
    result = {}
    for (a, e, c, d), value in riemann_table.items():
        for b in range(metric.rows):
            if inverse[b, e] != 0:
                result[(a, b, c, d)] = result.get((a, b, c, d), 0) \
                    + inverse[b, e] * value
    result = {k: tidy(v) for k, v in result.items()}
    return {k: v for k, v in result.items() if v != 0}
```

The same as in Notebook 03c, except that products with a zero entry of the inverse metric are skipped (for a diagonal metric only $b = e$ remains), and the results are simplified with `tidy`.

```
R_down = riemann(Gamma, X)  # R^a_bcd
R_mixed = raise_second(R_down, g)  # R^ab_cd
report("non-zero components R^a_bcd", len(R_down))
report("non-zero components R^ab_cd", len(R_mixed))
record_check(RUST_REPORT, "riemann_antisymmetry", "156 nonzero entries")
check(len(R_mixed) == 156, "R^ab_cd has 156 non-zero components, as in the record",
      record="Revision/gkd_lovelock/results/lovelock-report.json, check "
             "riemann_antisymmetry (156 nonzero entries)")
```

The call of `record_check` with `RUST_REPORT`, the check name `riemann_antisymmetry` and the text `156 nonzero entries` confirms that the Rust program's own check passed and that its detail text reports the same 156 non-zero components.

The two forms of the tensor for the author's metric; both have 156 non-zero components (two RESULT lines), the number found by hand in Section 3.24 and by the Rust program. This cell takes a few seconds.

In [14], the symmetries.

```
def get(table, key):
    return table.get(key, 0)
```

```
antisymmetric = all(vanishes(v + get(R_mixed, (b, a, c, d)))
                    and vanishes(v + get(R_mixed, (a, b, d, c)))
                    for (a, b, c, d), v in R_mixed.items())
```

`get` returns a component, or 0 if it is absent. `antisymmetric` is true when every component plus the component with the upper pair exchanged vanishes, and the same for the lower pair: $R^{ab}{}_{cd} = -R^{ba}{}_{cd} = -R^{ab}{}_{dc}$.

```
lowered = {(a, b, c, d): g[a, a] * g[b, b] * v
          for (a, b, c, d), v in R_mixed.items()}
pair_symmetric = all(vanishes(v - get(lowered, (c, d, a, b)))
                     for (a, b, c, d), v in lowered.items())
record_check(PYTHON_REPORT, "riemann_antisymmetry_and_pair_symmetry")
check(antisymmetric and pair_symmetric,
      "R^ab_cd is antisymmetric in a, b and in c, d; R_abcd = R_cdab",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "riemann_antisymmetry_and_pair_symmetry")
```

`record_check(PYTHON_REPORT, "riemann_antisymmetry_and_pair_symmetry")` confirms that the sympy checker's check of the same symmetries passed.

All indices lowered, $R_{abcd} = g_{aa} g_{bb} R^{ab}{}_{cd}$ (Section 3.17), and the pair symmetry $R_{abcd} = R_{cdab}$ (S4) checked for every component. One check for both, naming the record's check.

```
bianchi = [vanishes(get(R_down, (a, b, c, d)) + get(R_down, (a, c, d, b))
                    + get(R_down, (a, d, b, c)))
           for a, b, c, d in itertools.product(range(8), repeat=4)]
record_check(RUST_REPORT, "riemann_first_bianchi")
check(all(bianchi) and len(bianchi) == 4096,
      "the first Bianchi identity holds for all 4096 index lists",
      record="Revision/gkd_lovelock/results/lovelock-report.json, check "
             "riemann_first_bianchi")
```

`record_check(RUST_REPORT, "riemann_first_bianchi")` confirms that the Rust program's check of the same identity passed.

The first Bianchi identity (S2) for all $8^4 = 4096$ index lists.

```
warp_free = all(not symbolic(v).has(a4v) and not any(
    isinstance(p, sp.Pow) and p.base == sp.sin(6 * H * x0) and not p.exp.is_integer
    for p in sp.preorder_traversal(symbolic(v))) for v in R_mixed.values())
record_check(RUST_REPORT, "mixed_riemann_free_of_sin_third")
record_check(PYTHON_REPORT, "mixed_riemann_free_of_warp_and_exponential")
check(warp_free, "no R^ab_cd contains sin(z)^(1/3) or e^(a4): the warp cancels",
      record="Revision/gkd_lovelock/results/lovelock-report.json, check "
             "mixed_riemann_free_of_sin_third, and python-lovelock-report.json, "
             "check mixed_riemann_free_of_warp_and_exponential")
```

The two `record_check` lines confirm that both records' checks of the same two properties passed: the Rust program's `mixed_riemann_free_of_sin_third` and the sympy checker's `mixed_riemann_free_of_warp_and_exponential`.

`sp.preorder_traversal` walks through every piece of an expression (its sums, products, powers and their parts). The condition says: no component contains the value a_4 (only its derivatives), and no piece is a power of $\sin z$ with an exponent that is not a whole number (`p.base` and `p.exp` are the base and the exponent of a power `p`; `isinstance(p, sp.Pow)` asks whether `p` is a power). So the warp $\sin^{1/3} z$ and the exponentials $e^{\pm 2a_4}$ of the metric entries cancel in every $R^{ab}{}_{cd}$, as found by hand in Section 3.24; b_4 is left only in the ratios b_4'/b_4 and b_4''/b_4 of the rate α_t and its derivative.

In [15], comparison with the record's 156 components.

```
record_riemann = {}
for entry in record["riemannMixedNonzero"]:
    key = tuple(NAMES.index(n) for n in entry["up"] + entry["down"])
    record_riemann[key] = from_mathematica(entry["value"])
check(sorted(record_riemann) == sorted(R_mixed),
      "the same 156 non-zero components R^ab_cd as the record")
record_check(PYTHON_REPORT, "rust_riemann_agrees")
check(all(same(R_mixed[k], v) for k, v in record_riemann.items()),
      "every component R^ab_cd equals the record exactly",
      record=f"{CURVATURE_RECORD}, riemannMixedNonzero (and "
             "python-lovelock-report.json, check rust_riemann_agrees)")
```

`record_check(PYTHON_REPORT, "rust_riemann_agrees")` confirms that the sympy checker of the Revision record found all 156 components of the Rust program correct.

Each entry of the record's list `riemannMixedNonzero` has the upper indices `up`, the lower indices `down` and the value; `entry["up"] + entry["down"]` joins the two lists of names, and `tuple(...)` turns their positions into a key. Two checks: the same 156 index lists, and every value equal exactly.

```
groups = {}
for key in sorted(R_mixed):
    # the value multiplied out: one value written in two ways counts once
    groups.setdefault(sp.sstr(sp.expand(plain(R_mixed[key]))), []).append(key)
for value_text in sorted(groups):
    a, b, c, d = groups[value_text][0]
    say(f"  {len(groups[value_text]):2d} x  {value_text:30s}  e.g. "
        f"R^({NAMES[a]} {NAMES[b]})_({NAMES[c]} {NAMES[d]})")
report("different values among the 156 components", len(groups))
```

The components are grouped by their value, multiplied out (`sp.expand`) and written as text (`sp.sstr`): multiplying out first gives every value one standard form, so that a value that sympy happens to write in two ways is counted once (without it, sympy writes $\pm(\alpha_t^2 + \alpha_t')$ in two different ways and the count would be 22). `setdefault` starts an empty list for a new value, and `append` adds the index list. For each of the 20 different values the number of components, the value (padded to 30 characters by `:30s`) and one example are printed. The output is the result of Section 3.24 in symbols (with `/tan(z)` for $\cot z$): the plane values $\pm(\alpha^2 - H^2)$, $\pm(\alpha_t^2 - H^2)$, $\pm(\alpha^2 + \alpha')$ and $\pm(\alpha_t^2 + \alpha_t')$ 6 times each, $\pm(\alpha\alpha_t - H^2)$ 18 times each, $\pm H^2$ 12 times each, and the 48 components $\pm H\alpha \cot z$, $\pm H\alpha \tan z$, $\pm H\alpha_t \cot z$ and $\pm H\alpha_t \tan z$, 6 times each.

In [16], Figure 03b.4: the curvature of every coordinate plane.

```
plane = {(a, b): plain(sp.S(get(R_mixed, (a, b, a, b))))  # sp.S: 0 as a sympy 0
         for a, b in itertools.product(range(8), repeat=2) if a != b}
alpha_t = -a4p + b4p / (2 * b4v)  # the expansion rate of the extra times
alpha_t_prime = -a4pp + b4pp / (2 * b4v) - b4p ** 2 / (2 * b4v ** 2)  # its derivative
# the planes (row, column) in the author's order x0, x1, ..., x7
expected = {(1, 2): a4p ** 2 - H ** 2, (5, 6): alpha_t ** 2 - H ** 2,
            (1, 5): a4p * alpha_t - H ** 2, (1, 4): a4p ** 2 + a4pp,
            (4, 5): alpha_t ** 2 + alpha_t_prime, (1, 0): -H ** 2, (5, 0): -H ** 2,
            (4, 0): 0}
for (a, b), formula in expected.items():
    say(f"  plane ({NAMES[a]}, {NAMES[b]}): R^ab_ab = {plane[(a, b)]}")
```

`plane` holds the curvature $\sigma(a,b) = R^{ab}{}_{ab}$ of all 56 ordered pairs of different coordinates (`sp.S` turns the Python number 0 into a sympy zero, which understands `.has` below). `alpha_t` and `alpha_t_prime` are the extra-time rate $\alpha_t = -a_4' + b_4'/(2b_4)$ and its derivative α_t' (Section 3.24, case (5)), written with the printing symbols. `expected` lists one plane of each of the seven kinds of Section 3.24 (two for the transverse-hidden kind) with its formula, the pairs given by positions in the author's order (`(1, 2)` is the plane of x_1 and x_2, `(4, 0)` that of x_4 and x_0); the loop prints them. The output shows the formulas written out with a_4 and b_4, for example `-H**2 + a4p**2 - a4p*b4p/b4v + b4p**2/(4*b4v**2)` for $\alpha_t^2 - H^2$.

```
check(all(sp.expand(plane[key] - formula) == 0 for key, formula in expected.items())
      and all(not v.has(z) and not v.has(a4v) for v in plane.values()),
      "the plane curvatures have the seven formulas and do not depend on z or a4")
```

The check: the printed planes have the formulas of Section 3.24 (`sp.expand` multiplies out, so equal polynomials give a zero difference), and no plane curvature depends on z or on the value of a_4.

```
sixth = sp.sin(6 * H * x0) ** sp.Rational(1, 6)  # sin(z)^(1/6)
apart = {1: sp.exp(a4) * sixth, 5: sp.sqrt(b4) * sp.exp(-a4) * sixth}  # h1, h5
growth = {}  # (d^2 xi/d tau^2)/xi for observers at rest apart along x1 or x5
for a, h_a in apart.items():  # xi = h_a times a fixed coordinate distance, tau = x4
    growth[a] = sp.expand(plain(sp.simplify(sp.diff(h_a, x4, 2) / h_a)))
    say(f"  at rest, apart along {NAMES[a]}: (d^2 xi/d tau^2)/xi = {growth[a]}")
```

The meaning of the sign, computed (Section 3.24, "What the signs mean"). `apart` holds the scale factors $h_1 = e^{a_4}\sin^{1/6} z$ and $h_5 = b_4^{1/2} e^{-a_4}\sin^{1/6} z$ of x_1 and x_5, with the functions $a_4(x_4)$ and $b_4(x_4)$ themselves, so that sympy can differentiate them. Two observers at rest a fixed coordinate distance apart along x_a are the proper distance $\xi = h_a\,\Delta x_a$ apart, and their proper time is $\tau = x_4$; so $(d^2\xi/d\tau^2)/\xi = (\partial_4^2 h_a)/h_a$, which `sp.diff(h_a, x4, 2) / h_a` computes (the second derivative with respect to x_4, divided by h_a). `plain` writes the result with `a4p`, `a4pp`, `b4p`, `b4pp` and `b4v`. The output shows `a4p**2 + a4pp` for x_1, that is $\alpha^2 + \alpha'$, and for x_5 the long expression $\alpha_t^2 + \alpha_t'$ written out.

```
check(sp.simplify(apart[1] ** 2 - g[1, 1]) == 0
      and sp.simplify(apart[5] ** 2 + g[5, 5]) == 0
      and all(sp.simplify(growth[a] - plane[(a, 4)]) == 0 for a in apart),
      "observers at rest: d^2 xi/d tau^2 = +R^ab_ab xi in the planes (x1, x4) and "
      "(x5, x4)")
```

The check has three parts: the two scale factors are the right ones ($h_1^2 = g_{11}$ and $h_5^2 = -g_{55}$), and for both directions $(d^2\xi/d\tau^2)/\xi$ equals the plane curvature `plane[(a, 4)]` $= \sigma(x_a, x_4)$ (position 4 is x_4). So $d^2\xi/d\tau^2 = +\sigma\,\xi$: a positive curvature of a plane with the time drives observers at rest apart, the opposite of the sphere.

```
SLOPES = (0.5, 1.0, 2.0)  # three deflating histories, A > 0
fig, axes = plt.subplots(1, 3, figsize=(14.0, 4.8))  # wide: room for -1.25
for ax, slope in zip(axes, SLOPES):
    curv = np.full((8, 8), np.nan)  # NaN: an empty square on the diagonal
    for (a, b), value in plane.items():
        curv[a, b] = float(value.subs({a4p: slope, a4pp: 0, H: 1, b4v: 1, b4p: 0,
                                       b4pp: 0}))
    image = ax.imshow(curv, cmap=DIVERGING, vmin=-5.0, vmax=5.0)
```

Three panels for the slopes $A = 0.5$, 1 and 2 of the history $a_4 = AHx_4$, $b_4 = 1$, with $H = 1$, $a_4' = A$, $a_4'' = 0$ and $b_4' = b_4'' = 0$ (the dictionary in `subs` sets all six symbols). `np.full((8, 8), np.nan)` is an 8×8 table of NaN ("not a number"), which matplotlib leaves blank: the diagonal stays empty. The other squares receive the plane curvatures, and the table is drawn with the colour scale from -5 to 5.

```
    for a, b in plane:
        ax.text(b, a, f"{curv[a, b]:g}", ha="center", va="center", fontsize=6.5)
    ax.set_xticks(range(8), LABELS, fontsize=8)
    ax.set_yticks(range(8), LABELS, fontsize=8)
    ax.grid(False)
    ax.set_title(f"$A = {slope:g}$")
fig.colorbar(image, ax=axes, shrink=0.85, label="curvature (unit $H^2$)")
```

The value written into each square (`:g` writes a number without needless digits), the labels x_0 to x_7, the title with the slope, and one colour bar.

```
save_figure(fig, "plane_curvatures",
            "The curvature $\\sigma(a, b) = R^{ab}{}_{ab}$ (no sum) of the plane of "
...
check([float(plane[(1, 2)].subs({a4p: s, H: 1})) for s in SLOPES] == [-0.75, 0.0, 3.0],
      "the planes inside 3-space: -0.75, 0 and 3 for A = 0.5, 1 and 2")
```

The figure is saved; the check confirms $a_4'^2 - H^2 = -0.75$, 0, 3 for the three slopes.

What Figure 03b.4 shows. Three symmetric tables, with x_0 in the first row and column. The blocks inside 3-space and inside the extra times change from pale blue (-0.75 at $A = 0.5$) through grey (0 at $A = 1$) to red (3 at $A = 2$). The blocks that mix 3-space with the extra times are always blue and deepen: -1.25, -2, -5. The row and column of x_4 are red, A^2: 0.25, 1, 4. The row and column of x_0 are -1 everywhere, except the flat plane of x_4 and x_0, which is 0. The colours give signs, not shapes: only the squares of two of x_1, x_2, x_3 and those of one of them with x_0 belong to planes of two space-like directions, where red means curved like a sphere and blue like a saddle (so the 3-space planes are saddle-like at $A = 0.5$ and sphere-like at $A = 2$). In the planes of two extra times the shape reading is reversed, and the red row and column of x_4 mean, by In [16]'s check, that

observers at rest drift apart ever faster along 3-space and that their extra-time separation shrinks ever more slowly (Section 3.24).

In [17], Ricci, Ricci scalar and Einstein tensor.

```
def ricci(mixed_table, n):
    """R^a_b = sum over c of R^ac_bc, as an n x n sympy matrix."""
    result = sp.zeros(n, n)
    for (a, c, b, d), value in mixed_table.items():
        if c == d:
            result[a, b] += value
    return result.applyfunc(tidy)
```

The function of Notebook 03c (Section 3.22, In [3]), with `tidy` as the simplifier.

```
Ric = ricci(R_mixed, 8)
R_scalar = tidy(Ric.trace())
G = (Ric - R_scalar / 2 * sp.eye(8)).applyfunc(tidy)
for k in range(8):
    say(f"  {NAMES[k]}: R^a_a = {sp.sstr(plain(Ric[k, k])):18s} "
        f"G^a_a = {plain(G[k, k])}")
say(f"Ricci scalar R = {plain(R_scalar)}")
```

The Ricci tensor, its trace (the Ricci scalar) and the Einstein tensor $G = \mathrm{Ric} - \frac{R}{2}\mathbb{1}$ (`sp.eye(8)` is the 8×8 unit matrix). The loop prints the diagonal of both tensors (`:18s` pads the text to at least 18 characters, so that short entries line up), and the last line the scalar. The output is the result of Section 3.25, written out with a_4 and b_4: $R^a{}_a = -6H^2$ for x_0, $-6H^2 + \frac{3}{2}a_4'b_4'/b_4 + a_4''$ for 3-space, the long entry for x_4, and $-6H^2 - \frac{3}{2}a_4'b_4'/b_4 - a_4'' + \frac{1}{4}b_4'^2/b_4^2 + \frac{1}{2}b_4''/b_4$ for the extra times; $G^4{}_4 = 21H^2 + 3a_4'^2 - \frac{3}{2}a_4'b_4'/b_4 - \frac{3}{4}b_4'^2/b_4^2$; $R = -42H^2 + 6a_4'^2 - 3a_4'b_4'/b_4 + 3b_4''/b_4$. For a constant b_4 these are $a_4'' - 6H^2$, $6a_4'^2$, $-a_4'' - 6H^2$, $3a_4'^2 + 21H^2$ and $6a_4'^2 - 42H^2$.

```
ricci_ok = all(same(Ric[i, j], from_mathematica(
    record["ricciMixed"][f"{NAMES[i]},{NAMES[j]}"]["mathematica"]))
    for i in range(8) for j in range(8))
einstein_ok = all(same(G[i, j], from_mathematica(
    record["einsteinMixed"][f"{NAMES[i]},{NAMES[j]}"]["mathematica"]))
    for i in range(8) for j in range(8))
scalar_ok = same(R_scalar, from_mathematica(record["ricciScalar"]))
record_check(PYTHON_REPORT, "rust_ricci_einstein_scalar_agree")  # stops if not
check(ricci_ok and einstein_ok and scalar_ok,
      "all 64 Ricci, all 64 Einstein components and R equal the record",
      record=f"{CURVATURE_RECORD}, ricciMixed, einsteinMixed, ricciScalar (and "
             "python-lovelock-report.json, check rust_ricci_einstein_scalar_agree)")
```

The record stores each of the 64 components under a key such as `"x1,x4"`, with its Mathematica text under `"mathematica"`. `record_check` (In [3]) stops the notebook unless the independent verification of the record (`PYTHON_REPORT`, named in In [3]) lists its check `rust_ricci_einstein_scalar_agree` as passed. All 64 Ricci and all 64 Einstein components and the scalar are compared exactly, in one check.

In [18], the first Lovelock scalar of the record of the field equations.

```
A4_REPORT = "Revision/field_equations_a4/reports/python-a4-report.json"
a4_report = json.loads(repository_file(A4_REPORT).read_text(encoding="utf-8"))
# the report's checks form a list of dictionaries; take the one with this name
L1_entry = next(entry for entry in a4_report["checks"]
                if entry["name"] == "L1_equals_gkd_branch")
L1_detail, L1_verdict = L1_entry["detail"], L1_entry["verdict"]
say(f"record: {L1_detail} ({L1_verdict})")
```

The sympy verification of the record of the field equations of a_4 is read. Its checks form a list; `next(...)` takes the first entry whose name is `L1_equals_gkd_branch`. The output prints its text and verdict: $L_{(1)} = -84H^2 + 12\,ad1^2$ (PASS), where `ad1` is the record's name for a_4'; this check is made for the metric at $b_4 = 1$. $L_{(1)}$ is the first **Lovelock scalar**: the Revision record builds the field equations from three curvature scalars $L_{(1)}, L_{(2)}, L_{(3)}$, made from products of one, two or three Riemann tensors with the generalized Kronecker delta of Chapter 1, and the first of them is exactly twice the Ricci scalar, $L_{(1)} = 2R$ (Chapter 11 treats all three).

```
L1_text = L1_detail.split("=")[1]  # the text after the equals sign
L1_record = parse_expr(L1_text, local_dict={"H": H, "ad1": a4p})
record_check(PYTHON_REPORT, "L1_equals_2R", "L_(1) = 2 R exactly")  # stops if not
R_at_b4_1 = plain(R_scalar).subs({b4pp: 0, b4p: 0, b4v: 1})  # R at b4 = 1
check(L1_verdict == "PASS" and sp.expand(L1_record - 2 * R_at_b4_1) == 0,
      "at b4 = 1 the first Lovelock scalar of the record is twice our Ricci scalar",
      record=f"{A4_REPORT}, check L1_equals_gkd_branch (with "
             "python-lovelock-report.json, check L1_equals_2R)")
```

The text after the equals sign is read as a sympy expression, with `ad1` meaning a_4'. `record_check` stops the notebook unless the independent verification of the curvature record lists its check `L1_equals_2R` as passed with the detail `L_(1) = 2 R exactly`. `R_at_b4_1` is our Ricci scalar at $b_4 = 1$: the dictionary in `subs` sets $b_4'' = 0$, $b_4' = 0$ and $b_4 = 1$, and R becomes $6a_4'^2 - 42H^2$. The check: the record marks the check `L1_equals_gkd_branch` as passed, and $L_{(1)} = 2R$ with our R at $b_4 = 1$ ($2(6a_4'^2 - 42H^2) = 12a_4'^2 - 84H^2$).

In [19], all 310 components at five test points with 30 digits.

```
PYTHON_REPORT = "Revision/gkd_lovelock/results/python-lovelock-report.json"
python_report = json.loads(repository_file(PYTHON_REPORT).read_text(encoding="utf-8"))
mpmath.mp.dps = 30  # mpmath works with 30 significant digits from now on

def exact(text):
    """A fraction such as 46/75 of the record as an mpmath number."""
    fraction = sp.Rational(text)
    return mpmath.mpf(fraction.p) / fraction.q  # numerator / denominator
```

The independent verification of the record lists five test points (`randomPoints`), each a set of exact fractions written as texts such as `"46/75"`. `mpmath.mp.dps = 30` makes mpmath compute with 30 significant digits. `exact` reads such a text as an exact fraction (`sp.Rational`) and divides its numerator `p` by its denominator `q` with 30 digits.

```
test_points = [[exact(p["H"]), exact(p["x0"]), exact(p["a4"]),
                exact(p["a4" + prime]), exact(p["a4" + prime + prime]),
                exact(p["b4"]), exact(p["b4" + prime]), exact(p["b4" + prime + prime])]
               for p in python_report["randomPoints"]]
pairs = [(Gamma[a][b][c], v) for (a, b, c), v in record_gamma.items()]
pairs += [(R_mixed[key], v) for key, v in record_riemann.items()]
```

Each test point becomes the eight numbers H, x_0, a_4, a_4', a_4'', b_4, b_4', b_4'' (the record's keys contain the apostrophe, built from `prime` of In [10]). `pairs` collects pairs (our expression, the record's expression): first the 25 Christoffel symbols, then (`+=` appends a list) the 156 Riemann components.

```
pairs += [(Ric[i, j], from_mathematica(record["ricciMixed"][f"{NAMES[i]},{NAMES[j]}"]
                                       ["mathematica"]))
          for i in range(8) for j in range(8)]
pairs += [(G[i, j], from_mathematica(record["einsteinMixed"][f"{NAMES[i]},{NAMES[j]}"]
                                     ["mathematica"]))
          for i in range(8) for j in range(8)]
pairs += [(R_scalar, from_mathematica(record["ricciScalar"]))]
# the order of the eight numbers of a test point
ARGS30 = (H, x0, a4v, a4p, a4pp, b4v, b4p, b4pp)
largest, evaluations = mpmath.mpf(0), 0
```

Then the 64 Ricci and 64 Einstein components and the scalar: $25 + 156 + 64 + 64 + 1 = 310$ pairs. `ARGS30` names the eight arguments in the order of a test point. The largest relative difference starts at zero and the count of evaluations at 0.

```
for mine, theirs in pairs:
    f_mine = sp.lambdify(ARGS30, symbolic(sp.S(mine)), "mpmath")
    f_record = sp.lambdify(ARGS30, sp.S(theirs), "mpmath")
    for point in test_points:
        ours, recorded = f_mine(*point), f_record(*point)
        largest = max(largest, abs(ours - recorded) / max(1, abs(recorded)))
        evaluations += 1
for name in ("rust_christoffels_agree", "rust_riemann_agrees",
             "rust_ricci_einstein_scalar_agree"):
    record_check(PYTHON_REPORT, name)  # stops unless the check passed
```

For each pair, both expressions become functions that compute with mpmath's 30 digits (`"mpmath"` instead of `"numpy"`); at each of the five points both are evaluated, and the relative difference $|\text{ours} - \text{record}|/\max(1, |\text{record}|)$ updates the largest one so far (`max(1, ...)` avoids dividing by a tiny number when a value is close to zero). The last loop runs `record_check` for the three checks that the PASS line below names: the notebook stops unless the independent verification lists all three as passed.

```
report("components compared numerically", len(pairs))
report("evaluations at the five test points", evaluations)
report("largest relative difference (30 digits)", mpmath.nstr(largest, 3))
check(len(test_points) == 5 and largest < mpmath.mpf(10) ** -25,
      "at the five test points every component agrees to more than 25 digits",
```

```
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, "
             "randomPoints, checks rust_christoffels_agree, rust_riemann_agrees, "
             "rust_ricci_einstein_scalar_agree")
```

Three RESULT lines: 310 components, 1550 evaluations, and the largest relative difference 2.96×10^{-31} (`mpmath.nstr` writes an mpmath number with 3 digits), which is the rounding of the last of the 30 digits. The check requires more than 25 agreeing digits. This is a second, purely numerical confirmation of the exact agreement of In [7], In [15] and In [17].

In [20], the lead's four properties of the Einstein tensor.

```
LEAD = "Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json"
for name in ("einstein_off_diagonal_zero", "einstein_x0_independent",
             "einstein_isotropy", "no_vacuum_for_H_positive"):
    record_check(LEAD, name)  # stops unless the lead check passed
METRIC_B4 = "Revision/metric_b4/results/wolfram-metric-b4-report.json"
for name in ("off_diagonal_entries_x0_x4_only", "off_diagonal_proportional_to_b4prime"):
    record_check(METRIC_B4, name)  # stops unless the check passed
G_b4_1 = G.applyfunc(lambda e: symbolic(e).subs({b4pp: 0, b4p: 0, b4v: 1}))
off_diagonal = {(i, j): plain(G[i, j]) for i in range(8) for j in range(8)
                if i != j and G[i, j] != 0}
for (i, j), value in sorted(off_diagonal.items()):
    say(f"  G^{NAMES[i]}_{NAMES[j]} = {value}")
check(sorted(off_diagonal) == [(0, 4), (4, 0)]
      and vanishes(symbolic(G[4, 0]) - sp.Rational(3, 2) * H * sp.cot(6 * H * x0)
                   * b4p / b4v)
      and vanishes(symbolic(G[0, 4]) + sp.Rational(3, 2) * H * sp.tan(6 * H * x0)
                   * b4p / b4v)
      and all(G_b4_1[i, j] == 0 for i in range(8) for j in range(8) if i != j),
      "the only off-diagonal components G^x4_x0, G^x0_x4 are proportional to b4p; "
      "at b4 = 1 the Einstein tensor is diagonal",
      record=f"{LEAD}, check einstein_off_diagonal_zero, and "
             "wolfram-metric-b4-report.json, checks off_diagonal_entries_x0_x4_only, "
             "off_diagonal_proportional_to_b4prime")
check(all(sp.diff(G_b4_1[i, j], x0) == 0 for i in range(8) for j in range(8)),
      "at b4 = 1 no component of the Einstein tensor depends on x0",
      record=f"{LEAD}, check einstein_x0_independent")
check(G[1, 1] == G[2, 2] == G[3, 3] and G[5, 5] == G[6, 6] == G[7, 7],
      "3-space components equal, extra-time components equal",
      record=f"{LEAD}, check einstein_isotropy")
```

`LEAD` names the report of the lead check of the field equations (the lead checks are explained in Section 3.7), made for the metric at $b_4 = 1$, and `METRIC_B4` the report of the verifier of the metric with b_4. The two loops run `record_check` (In [3]) for the four checks of the first report and the two of the second that this cell's PASS lines name; the notebook stops unless each is listed as passed. `G_b4_1` is the Einstein tensor at $b_4 = 1$: `applyfunc` applies a function to every entry, and `lambda e: ...` is a function without a name that writes an entry with the printing symbols and sets $b_4'' = 0$, $b_4' = 0$, $b_4 = 1$. `off_diagonal` collects the non-zero entries off the diagonal; the output prints the two of them, `G^x0_x4 = -3*H*b4p*tan(z)/(2*b4v)` and `G^x4_x0 = 3*H*b4p/(2*b4v *tan(z))`. Then three checks of Section 3.25, each naming the check of the reports: the only entries off the diagonal are ${G^{x_4}}_{x_0} = \frac{3}{2} H \cot z \, b_4'/b_4$ and ${G^{x_0}}_{x_4} = -\frac{3}{2} H \tan z \, b_4'/b_4$, so that at $b_4 = 1$ there is

none; at $b_4 = 1$ no entry depends on x_0; and, for every b_4, equal 3-space entries and equal extra-time entries.

```
gap = sp.simplify(G_b4_1[4, 4] - G_b4_1[0, 0])
say(f"at b4 = 1: G^x4_x4 - G^x0_x0 = {sp.factor(gap)}")
check(sp.simplify(gap - 6 * (a4p ** 2 + H ** 2)) == 0,
      "at b4 = 1: G^x4_x4 - G^x0_x0 = 6 (a4p^2 + H^2) > 0",
      record=f"{LEAD}, check no_vacuum_for_H_positive")
```

The difference $G^{x_4}{}_{x_4} - G^{x_0}{}_{x_0}$ at $b_4 = 1$, printed in factored form (`sp.factor`) as `6*(H**2 + a4p**2)`, and the check of Section 3.25 behind the statement that no empty spacetime has this metric (Section 3.26).

In [21], the contracted Bianchi identity.

```
divergence = []
for nu in range(8):
    value = sum(sp.diff(G[mu, nu], X[mu]) for mu in range(8)) \
        + sum(Gamma[mu][mu][lam] * G[lam, nu] for mu in range(8) for lam in range(8)) \
        - sum(Gamma[lam][mu][nu] * G[mu, lam] for mu in range(8) for lam in range(8))
    divergence.append(vanishes(value))
record_check(RUST_REPORT, "k1_equals_minus_4_einstein")  # stops if not passed
record_check(RUST_REPORT, "k1_divergence_free")
check(all(divergence),
      "the contracted Bianchi identity: the divergence of G vanishes",
      record="Revision/gkd_lovelock/results/lovelock-report.json, checks "
             "k1_equals_minus_4_einstein and k1_divergence_free")
```

For each ν the three sums of the divergence formula of Section 3.25 are computed with the functions $a_4(x_4)$ and $b_4(x_4)$ themselves (so that sympy can differentiate a_4' and b_4' into a_4'' and b_4''; the backslashes continue the statement), with all entries of G, including the two off the diagonal, and the list `divergence` records whether each simplifies to zero. The check requires all eight. The record's Rust program checked the same for its tensor $P_{(1)} = -4G$, the first Lovelock tensor (Section 3.26; Chapter 11): the two calls of `record_check` stop the notebook unless the Rust report (`RUST_REPORT`, named in In [3]) lists its checks `k1_equals_minus_4_einstein` ($P_{(1)} = -4G$) and `k1_divergence_free` (the divergence of $P_{(1)}$ is zero) as passed.

In [22], the Kretschmann scalar.

```
K = sp.factor(sp.expand(symbolic(sum(v * get(R_mixed, (c, d, a, b))
                                     for (a, b, c, d), v in R_mixed.items()))))
K_record = sp.factor(sp.expand(sum(v * record_riemann.get((c, d, a, b), 0)
                                   for (a, b, c, d), v in record_riemann.items())))
ricci_square = sp.factor(sp.expand(symbolic(sum(Ric[i, j] * Ric[j, i]
                                                for i in range(8)
                                                for j in range(8)))))
say(f"Kretschmann scalar K = {K}")
say(f"sum of R^a_b R^b_a  = {ricci_square}")
```

$K = \sum R^{ab}{}_{cd} R^{cd}{}_{ab}$ from our 156 components, then a second time from the record's 156 components alone, and $\sum_{a,b} R^a{}_b R^b{}_a$; each is multiplied out (`sp.expand`) and factored (`sp.factor`). The output

shows two long fractions in H, a_4', a_4'', b_4, b_4' and b_4''; b_4 appears in them only together with its derivatives, in the ratios b_4'/b_4 and b_4''/b_4. For a constant b_4 the first is $K = 12(7H^4 - 2H^2a_4'^2 + 7a_4'^4 + 2a_4''^2)$, the result of Section 3.25 (printed by the next block), and the second is $\sum R^a{}_b R^b{}_a = 6(42H^4 + 6a_4'^4 + a_4''^2)$ (the sum of the squares of the four kinds of diagonal entries, three, one, three and one of them, and the entries off the diagonal are then zero).

```
check(sp.simplify(K - K_record) == 0,
      "K from our components equals K from the 156 components of the record")
check(not K.has(x0) and not K.has(a4v),
      "K depends only on H, a4p, a4pp, b4v, b4p and b4pp, not on z and not on a4")
square_form = 7 * (a4p ** 2 - H ** 2 / 7) ** 2 + sp.Rational(48, 7) * H ** 4 \
    + 2 * a4pp ** 2
K_constant_b4 = sp.factor(K.subs({b4pp: 0, b4p: 0}))  # b4 constant: b4v drops out
say(f"for a constant b4: K = {K_constant_b4}")
check(sp.expand(K_constant_b4 / 12 - square_form) == 0,
      "for constant b4: K/12 = 7 (a4p^2 - H^2/7)^2 + 48 H^4/7 + 2 a4pp^2, so K > 0 "
      "for H > 0")
report("smallest possible K for constant b4 (at a4p^2 = H^2/7, a4pp = 0)",
       sp.sstr(sp.Rational(576, 7) * H ** 4))
```

Three checks: our K equals the record's; K contains neither x_0 nor the value of a_4; and, for a constant b_4, the completed square of Section 3.25 is exactly $K/12$. `K_constant_b4` is K with $b_4'' = 0$ and $b_4' = 0$, after which b_4 drops out; the printed line shows it, `12*(7*H**4 - 2*H**2*a4p**2 + 7*a4p**4 + 2*a4pp**2)`. The RESULT line prints the smallest possible value $576H^4/7$ for a constant b_4.

In [23], Figure 03b.5: components that see z and an invariant that does not.

```
# numerical functions of the 156 components with a4pp = 0 and b4pp = 0 (true on
# the history a4 = A H x4, b4 = 1); the second derivatives are set to 0 first
riemann_functions = {k: numeric(v.subs({sp.Derivative(a4, (x4, 2)): 0,
                                        sp.Derivative(b4, (x4, 2)): 0}))
                     for k, v in R_mixed.items()}
```

The 156 components as numerical functions of $(z, a_4, a_4', H, b_4, b_4')$, with $a_4'' = 0$ and $b_4'' = 0$, which hold on every linear history with $b_4 = 1$; the second derivatives are replaced by 0 before `numeric` (In [8]) is applied.

```
def kretschmann_numbers(z_values, rate):
    """K at the points z_values, summed from the 156 numerical components."""
    total = np.zeros_like(z_values)
    for (a, b, c, d), f in riemann_functions.items():
        partner = riemann_functions.get((c, d, a, b))
        if partner is not None:
            total += (f(z_values, 0.5, rate, 1.0, 1.0, 0.0)
                      * partner(z_values, 0.5, rate, 1.0, 1.0, 0.0))
    return total
```

K summed numerically at many values of z at once, for a given rate a_4' (with $a_4 = 0.5$, $H = 1$, $b_4 = 1$, $b_4' = 0$): each component times its partner with the pairs exchanged (`None` means that no partner was found; every component has one).

```
z_line = np.linspace(0.02, np.pi / 2 - 0.02, 300)
cot_part = riemann_functions[(1, 4, 1, 0)](z_line, 0.5, 1.5, 1.0, 1.0, 0.0)
tan_part = riemann_functions[(1, 0, 1, 4)](z_line, 0.5, 1.5, 1.0, 1.0, 0.0)
fig, axes = plt.subplots(1, 2, figsize=(10.5, 4.2))
fig.subplots_adjust(wspace=0.32)  # room for the label of the right vertical axis
```

300 values of z; the two components ${R^{x_1x_4}}_{x_1x_0} = Ha_4' \cot z$ (key `(1, 4, 1, 0)`) and ${R^{x_1x_0}}_{x_1x_4} = -Ha_4' \tan z$ (key `(1, 0, 1, 4)`) at $a_4' = 1.5$, $b_4 = 1$; a figure with two panels.

```
axes[0].plot(z_line, np.abs(cot_part), color=RED, lw=1.8,

             label="minus $R^{x_1x_0}{}_{x_1x_4} = Ha_4^{\\prime}\\tan z$")
axes[0].plot(z_line, np.abs(cot_part * tan_part), color="black", lw=1.2, ls=":",
             label="minus their product $= H^2 a_4^{\\prime 2}$")
axes[0].plot(z_line, np.abs(np.broadcast_to(
    riemann_functions[(1, 0, 1, 0)](z_line, 0.5, 1.5, 1.0, 1.0, 0.0), z_line.shape)),
    color=AQUA, lw=1.8, ls="-.", label="minus $R^{x_1x_0}{}_{x_1x_0} = H^2$")
```

The left panel: the sizes of the two components, of their product, and of the constant plane component ${R^{x_1x_0}}_{x_1x_0} = -H^2$ (key `(1, 0, 1, 0)`; repeated to the length of `z_line` by `np.broadcast_to`).

```
axes[0].set_yscale("log")
axes[0].set_xlabel("$z = 6 H x_0$ (radians)")
axes[0].set_ylabel("absolute value (unit $H^2$)")
axes[0].set_title("Riemann components, $a_4^{\\prime} = 1.5$")
axes[0].legend(fontsize=8)
rates = (0.5, 1.0, 1.5, 2.0)  # four expansion rates a4p = A H (A > 0), unit H
for rate, colour, style in zip(rates, (VIOLET, AQUA, RED, ORANGE),
                               ("-", "--", "-.", ":")):
    axes[1].plot(z_line, kretschmann_numbers(z_line, rate), color=colour, ls=style,
                 lw=1.8, label=f"$a_4^{{\\prime}} = {rate:g}\\,H$")
```

A logarithmic axis, labels, title and legend for the left panel. The right panel: K summed numerically at the 300 points for four rates $a_4' = 0.5, 1, 1.5, 2$ (in units of H), each with its colour and line style.

```
axes[1].set_yscale("log")
axes[1].set_xlabel("$z = 6 H x_0$ (radians)")
axes[1].set_ylabel("$K$ (unit $H^4$)")
axes[1].set_title("Kretschmann scalar summed from 156 components")
axes[1].legend(fontsize=8)
# the values of the formula for K at the four rates, for the caption and the check
K_values = [float(K.subs({a4p: r, a4pp: 0, H: 1, b4v: 1, b4p: 0, b4pp: 0}))
            for r in rates]
K_text = ", ".join(f"${k:g}$" for k in K_values)
```

The right panel's axis, labels, title and legend. `K_values` are the values of the formula for K at the four rates, and `K_text` joins them with commas for the caption: 83.25, 144, 455.25, 1332 (from $12(7 - 2r^2 + 7r^4)$ with $H = 1$).

```
save_figure(fig, "riemann_and_kretschmann_z",
            "Left: the absolute values of the Riemann components "
...
numbers = [kretschmann_numbers(z_line, r) for r in rates]
check(all(np.max(np.abs(n - k)) < 1e-9 * k for n, k in zip(numbers, K_values)),
      "summed numerically, K is the same at all 300 values of z and equals the "
      "formula")
```

The figure is saved; the check requires the numerical sum to equal the formula at all 300 points within a relative 10^{-9}, for all four rates.

What Figure 03b.5 shows. At $b_4 = 1$. Left: the red curve $Ha_4' \cot z$ falls by more than three powers of ten across the patch, the blue dashed curve $Ha_4' \tan z$ rises by as much; their product (dotted) is the constant $H^2 a_4'^2 = 2.25$, and the plane component $H^2 = 1$ (dash-dotted) is constant too. Right: the four values of K are four flat lines, 83.25, 144, 455.25 and 1332: although single components blow up at the ends of the patch, the invariant is the same at every z. The Kretschmann scalar therefore gives no sign of a singularity anywhere in the patch: the large components are an effect of the coordinates.

In [24], Figure 03b.6: the curvature scalars along the history.

```
A = sp.symbols("A", real=True)  # the slope of the history a4 = A H x4
on_history = {a4p: A * H, a4pp: 0, b4pp: 0, b4p: 0, b4v: 1}
R_A = sp.factor(symbolic(R_scalar).subs(on_history))
K_A = sp.factor(K.subs(on_history))
RR_A = sp.factor(ricci_square.subs(on_history))
say(f"on the history: R = {R_A},  K = {K_A},  R^a_b R^b_a = {RR_A}")
check(all(sp.expand(f.subs(A, -A) - f) == 0 for f in (R_A, K_A, RR_A)),
      "the curvature scalars are even in A")
```

The slope A as a symbol and the history $a_4' = AH$, $a_4'' = 0$, $b_4 = 1$, $b_4' = b_4'' = 0$ (the dictionary `on_history`) put into the three scalars. The output: $R = 6H^2(A^2 - 7)$, $K = 12H^4(7A^4 - 2A^2 + 7)$, $\sum R^a{}_b R^b{}_a = 36H^4(A^4 + 7)$. The check: all three are **even** in A (replacing A by $-A$ changes nothing), because they contain only A^2. These three numbers therefore cannot tell which of the two families of directions deflates; the metric and the components of the curvature can (Section 3.24).

```
A_line = np.linspace(0.1, 3.0, 291)  # slopes 0.1, 0.11, ..., 3; A_line[90] = 1
R_numbers = sp.lambdify(A, R_A.subs(H, 1))(A_line)
K_numbers = sp.lambdify(A, K_A.subs(H, 1))(A_line)
RR_numbers = sp.lambdify(A, RR_A.subs(H, 1))(A_line)
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2))
```

291 slopes from 0.1 to 3 in steps of 0.01 (position 90 is $A = 1$), all positive, so every history drawn deflates the extra times; the three scalars at these slopes with $H = 1$; a figure with two panels.

```
axes[0].plot(A_line, R_numbers, color=VIOLET, lw=1.8, label="$R = 6H^2(A^2 - 7)$")
axes[0].axhline(0.0, color="black", lw=0.8)
axes[0].plot([np.sqrt(7)], [0.0], "o", color=VIOLET, ms=7)  # the zero of R
axes[0].set_ylabel("Ricci scalar $R$ (unit $H^2$)")
```

```
axes[0].set_title("Ricci scalar")
axes[1].plot(A_line, K_numbers, color=RED, lw=1.8, label="Kretschmann $K$")
axes[1].plot(A_line, RR_numbers, color=BLUE, lw=1.8, ls="--",
             label="$\\sum R^a{}_b R^b{}_a$")
axes[1].set_yscale("log")
axes[1].set_ylabel("value (unit $H^4$)")
axes[1].set_title("Squares of the curvature")
```

Left: R against A, the zero line, and a dot at the zero $A = \sqrt{7}$. Right, on a logarithmic axis: K and $\sum R^a{}_b R^b{}_a$.

```
for ax in axes:
    ax.axvline(1.0, color="grey", lw=1.0, ls=":")  # the canonical slope A = 1
    ax.set_xlabel("slope $A$ of the deflating history $a_4 = A H x_4$")
    ax.legend(fontsize=8, loc="upper left")
axes[0].text(1.05, -40, "$A = 1$", fontsize=9)
save_figure(fig, "scalars_versus_a",
            "The curvature scalars of the author's metric along the deflating "
...
check(abs(R_numbers[90] - (-36.0)) < 1e-9 and abs(K_numbers[90] - 144.0) < 1e-9,
      "at A = 1: R = -36 H^2 and K = 144 H^4")
```

A dotted vertical line at the canonical $A = 1$ in both panels, the axis label and legend, a label at the line; the figure is saved; the check confirms $R = -36$ and $K = 144$ at $A = 1$ (Section 3.25).

What Figure 03b.6 shows. Left: the Ricci scalar rises from -42 near $A = 0$ through -36 at $A = 1$ and crosses zero at $A = \sqrt{7} = 2.65$ (the dot). Right: K (red) is smallest, $576/7 = 82.3$, near $A = 1/\sqrt{7} = 0.38$ and grows like $84A^4$ for large slopes; $\sum R^a{}_b R^b{}_a$ (blue dashed) starts at 252 and grows like $36A^4$. Both stay far above zero: every deflating history is curved.

In [25], Figure 03b.7: the Einstein tensor along the history.

```
G_A = [sp.factor(symbolic(G[k, k]).subs(on_history)) for k in range(8)]
for k in (0, 1, 4, 5):
    say(f"  on the history: G^{NAMES[k]}_{NAMES[k]} = {G_A[k]}")
bars = {value: [float(G_A[k].subs({A: value, H: 1})) for k in range(8)]
        for value in (1, 2)}
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.2))
positions = np.arange(8)
```

The eight diagonal entries of G on the history (with $b_4 = 1$), factored; four of them, those of x_0, x_1, x_4 and x_5, are printed: $G^{x_1}{}_{x_1} = G^{x_5}{}_{x_5} = G^{x_0}{}_{x_0} = -3H^2(A^2 - 5)$ and $G^{x_4}{}_{x_4} = 3H^2(A^2 + 7)$. `bars` holds their values for $A = 1$ and $A = 2$ with $H = 1$.

```
axes[0].bar(positions - 0.2, bars[1], width=0.38, color=RED, hatch="//",
            label="$A = 1$")
axes[0].bar(positions + 0.2, bars[2], width=0.38, color=BLUE, label="$A = 2$")
axes[0].set_xticks(positions, [f"$G^{{x_{k}}}{{}}_{{x_{k}}}$" for k in range(8)],
                   fontsize=8)
axes[0].set_ylabel("component (unit $H^2$)")
axes[0].set_title("Diagonal of the Einstein tensor")
axes[0].legend(fontsize=8)
```

The left panel is a bar chart: `ax.bar(x, heights, width=...)` draws bars; the bars of $A = 1$ are shifted left by 0.2 and hatched (`hatch="//"`), those of $A = 2$ shifted right, so that each pair stands side by side. The tick labels name the eight components, from ${G^{x_0}}_{x_0}$ to ${G^{x_7}}_{x_7}$.

```
space_numbers = sp.lambdify(A, G_A[1].subs(H, 1))(A_line)
time_numbers = sp.lambdify(A, G_A[4].subs(H, 1))(A_line)
axes[1].plot(A_line, space_numbers, color=RED, lw=1.8,
             label="$G^{x_1}{}_{x_1} = G^{x_5}{}_{x_5} = G^{x_0}{}_{x_0}$")
axes[1].plot(A_line, time_numbers, color=VIOLET, lw=1.8, ls="--",
             label="$G^{x_4}{}_{x_4}$")
axes[1].fill_between(A_line, space_numbers, time_numbers, color="grey", alpha=0.2,
                     label="gap $6H^2(A^2 + 1) > 0$")
```

The right panel: the common 3-space, extra-time and hidden entry and the time entry against A; `fill_between` shades the gap between the two curves.

```
axes[1].axhline(0.0, color="black", lw=0.8)
axes[1].axvline(1.0, color="grey", lw=1.0, ls=":")  # the canonical slope A = 1
axes[1].set_xlabel("slope $A$ of the deflating history $a_4 = A H x_4$")
axes[1].set_ylabel("component (unit $H^2$)")
axes[1].set_title("Einstein tensor versus $A$")
axes[1].legend(fontsize=8, loc="lower left")
save_figure(fig, "einstein_tensor",
            "The Einstein tensor $G^{\\mu}{}_{\\nu}$ of the author's metric along "
...
check(bars[1] == [12.0, 12.0, 12.0, 12.0, 24.0, 12.0, 12.0, 12.0]
      and bars[2] == [3.0, 3.0, 3.0, 3.0, 33.0, 3.0, 3.0, 3.0],
      "diagonal of G: 12 (24 for x4) at A = 1 and 3 (33 for x4) at A = 2, unit H^2")
```

The zero line, the line at $A = 1$, labels, title, legend; the figure is saved; the check confirms the two rows of bar heights.

What Figure 03b.7 shows. At $b_4 = 1$. Left: for $A = 1$ seven bars of height 12 and the time bar 24 (the fifth bar, x_4); for $A = 2$ seven bars of height 3 and the time bar 33. Right: the common entry $3H^2(5 - A^2)$ falls and becomes negative beyond $A = \sqrt{5} = 2.24$, the time entry $3H^2(7 + A^2)$ rises, and the shaded gap $6H^2(A^2 + 1)$ never closes: no cosmological constant, which adds the same number to every entry, can make all of them zero (Section 3.26).

In [26], the source required by Einstein's equations, from the record.

```
A4_EQUATIONS = "Revision/field_equations_a4/a4-equations.json"
a4_equations = json.loads(repository_file(A4_EQUATIONS).read_text(encoding="utf-8"))
linear = a4_equations["linearMember"]  # the entry of the linear history
kappa = sp.symbols("kappa", positive=True)  # the constant of Einstein's equations
Lam = sp.symbols("Lam", real=True)  # the cosmological constant Lambda
source_names = {"AA": A, "H": H, "kappa": kappa, "Lam": Lam}
```

The record of the field equations of a_4 is read and its entry `linearMember` taken. κ and Λ become symbols; the dictionary says that the record's names `AA` and `Lam` mean A and Λ.

```
def source(key):
    """The record's text linear[key] (Mathematica notation) as sympy."""
    return parse_expr(linear[key]["input"].replace("^", "**"),
                      local_dict=source_names)

rho_record, p_record = source("rhoEinstein"), source("pEinstein")
sum_record = source("rhoPlusPEinstein")  # rho + p
say(f"record: kappa rho       = {sp.expand(kappa * rho_record)}")
say(f"record: kappa p         = {sp.expand(kappa * p_record)}")
say(f"record: kappa (rho + p) = {sp.factor(kappa * sum_record)}")
```

`source` reads the Mathematica text (key `"input"`) of an entry as a sympy expression. The three texts are read and printed multiplied by κ: $\kappa\rho = -3A^2H^2 - 21H^2 - \Lambda$, $\kappa p = -3A^2H^2 + 15H^2 + \Lambda$, $\kappa(\rho + p) = -6H^2(A^2 + 1)$.

```
record_check(A4_REPORT, "json_linear_member")  # stops if not passed
check(sp.expand(kappa * rho_record - (-G_A[4] - Lam)) == 0,
      "kappa rho of the record equals -G^x4_x4 - Lambda",
      record=f"{A4_EQUATIONS}, linearMember.rhoEinstein (and "
             "python-a4-report.json, check json_linear_member)")
check(all(sp.expand(kappa * p_record - (G_A[k] + Lam)) == 0 for k in (1, 5, 0)),
      "kappa p of the record equals G^x1_x1, G^x5_x5 and G^x0_x0 plus Lambda",
      record=f"{A4_EQUATIONS}, linearMember.pEinstein")
check(sp.expand(kappa * sum_record - (G_A[1] - G_A[4])) == 0,
      "kappa (rho + p) of the record equals G^x1_x1 - G^x4_x4 = -6 (A^2 + 1) H^2",
      record=f"{A4_EQUATIONS}, linearMember.rhoPlusPEinstein")
```

`record_check` (In [3]) stops the notebook unless the sympy verification of the record of the field equations (`A4_REPORT`, named in In [18]) lists its check `json_linear_member` as passed: that check confirmed that the entries of `linearMember` agree with its own computation. Then three checks, the three lines of Section 3.26: $\kappa\rho = -G^{x_4}{}_{x_4} - \Lambda$; $\kappa p = G^{x_1}{}_{x_1} + \Lambda = G^{x_5}{}_{x_5} + \Lambda = G^{x_0}{}_{x_0} + \Lambda$; and $\kappa(\rho + p) = G^{x_1}{}_{x_1} - G^{x_4}{}_{x_4}$.

In [27], the negative control.

```
g_control = g.copy()
for k in (5, 6, 7):  # the three extra times, now inflating
    g_control[k, k] = -sp.exp(2 * a4) * sp.sin(6 * H * x0) ** sp.Rational(1, 3)
Gamma_control = christoffel(g_control, X)
R_control = raise_second(riemann(Gamma_control, X), g_control)
Ric_control = ricci(R_control, 8)
G_control = (Ric_control - Ric_control.trace() / 2 * sp.eye(8)).applyfunc(tidy)
```

A check that cannot fail teaches nothing, so the metric is changed on purpose: `g.copy()` is a copy of the author's metric, and its three extra-time entries (positions 5, 6, 7) are replaced by $-e^{+2a_4}\sin^{1/3} z$, extra times that INFLATE like 3-space. This is NOT a deflating metric; within the author's family it is the member $b_4 = e^{4a_4}$, with the extra-time rate $\alpha_t = +a_4'$. The curvature is computed again with the same functions, up to the Einstein tensor. This cell runs for up to half a minute.

```
off = {(i, j): plain(G_control[i, j]) for i in range(8) for j in range(8)
       if i != j and G_control[i, j] != 0}
for (i, j), value in sorted(off.items()):
    say(f"  control: G^{NAMES[i]}_{NAMES[j]} = {value}")
b4_control = {sp.Derivative(b4, x4): 4 * sp.Derivative(a4, x4) * sp.exp(4 * a4),
              b4: sp.exp(4 * a4)}  # b4 = e^(4 a4) and its derivative
general_off = [G[i, j].subs(b4_control) for i, j in ((0, 4), (4, 0))]
K_control = sp.expand(symbolic(sum(
    v * get(R_control, (c, d, a, b)) for (a, b, c, d), v in R_control.items())))
check(sorted(off) == [(0, 4), (4, 0)] and all(v.has(z) for v in off.values())
      and vanishes(G_control[0, 4] - general_off[0])
      and vanishes(G_control[4, 0] - general_off[1])
      and sp.simplify(K_control.subs({a4pp: 0, a4p: H})) == 0,
      "negative control: with inflating extra times (b4 = e^(4 a4)) G^x4_x0 and "
      "G^x0_x4 are not zero, depend on z, equal the general ones; K = 0 at a4p = H")
```

The entries off the diagonal that are not zero are collected and printed: ${G^{x_0}}_{x_4} = -6Ha_4'\tan z$ and ${G^{x_4}}_{x_0} = 6Ha_4'/\tan z$, exactly as derived by hand in Section 3.25. `b4_control` replaces b_4 by e^{4a_4} and b_4' by $4a_4'e^{4a_4}$, and `general_off` holds the two general off-diagonal entries of In [20] with this b_4 ($b_4'/b_4 = 4a_4'$). `K_control` is the Kretschmann scalar of the control. The check requires these two entries and only these two, that both depend on z (`.has(z)`), that they equal the general entries with $b_4 = e^{4a_4}$, and that K of the control vanishes at $a_4' = H$, $a_4'' = 0$ (Section 3.25). With the author's deflating extra times and a constant b_4 the two entries are zero (In [20]): the deflation of the extra times, at the same rate as the inflation of 3-space, is what makes the Einstein tensor of the author's metric diagonal; and the bound $K \geq 576H^4/7$ of In [22] needs a constant b_4.

In [28], the last check.

```
figure_names = ["christoffel_heat_maps", "christoffel_versus_z",
                "finite_differences", "plane_curvatures",
                "riemann_and_kretschmann_z", "scalars_versus_a", "einstein_tensor"]
files = [output_file(f"{FIGURE_FOLDER}/03b_{k}_{n}.png")
         for k, n in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all seven figure files exist")
all_checks_passed()
```

The seven figure files must exist; the last line prints ALL 40 CHECKS PASSED (notebook 03b). The 40 checks are: 1 in In [4], 1 in In [6], 2 in In [7], 1 each in In [8] and In [9], 2 in In [10], 1 in In [11], 2 in In [12], 1 in In [13], 3 in In [14], 2 in In [15], 3 in In [16], 1 each in In [17], In [18] and In [19], 4 in In [20], 1 in In [21], 3 in In [22], 1 in In [23], 2 in In [24], 1 in In [25], 3 in In [26], and 1 each in In [27] and In [28].

3.31 Free fall in the author's metric

What does the author's metric do to a body that moves in it with no force acting on it, only the geometry? This section answers with the geodesic equation of Section 3.16 and the Christoffel symbols of Section 3.23.

Test particles in free fall. A **test particle** is a body so small that it does not change the metric (ASSUMED: the particles of this section are test particles). In free fall it moves on a time-like

geodesic (Section 3.16; ASSUMED from the theory of gravity), parametrised by its proper time τ, with the velocity $u^a = dx^a/d\tau$ and $g(u,u) = -1$. We keep the labels of Section 3.23: i for 3-space, j for the extra times, k for any of these six transverse directions.

The geodesic equations. $du^a/d\tau = -\sum_{b,c} \Gamma^a{}_{bc} u^b u^c$ with the 37 symbols of Section 3.23 (a symbol with two different lower indices appears twice, once in each order, hence the factors 2), with the two rates $\alpha = a_4'$ and $\alpha_t = -a_4' + b_4'/(2b_4)$:

$$\frac{du^0}{d\tau} = H\tan z \sum_i h_i^2 (u^i)^2 - H\tan z \sum_j h_j^2 (u^j)^2 + 6H(\tan z + \cot z)(u^0)^2,$$

$$\frac{du^i}{d\tau} = -2\alpha\, u^i u^4 - 2H\cot z\, u^i u^0, \qquad \frac{du^j}{d\tau} = -2\alpha_t\, u^j u^4 - 2H\cot z\, u^j u^0,$$

$$\frac{du^4}{d\tau} = -\alpha \sum_i h_i^2 (u^i)^2 + \alpha_t \sum_j h_j^2 (u^j)^2$$

(for u^0 the symbols $\Gamma^0{}_{ii} = -H\tan z\, h_i^2$, $\Gamma^0{}_{jj} = +H\tan z\, h_j^2$ and $\Gamma^0{}_{00} = -6H(\tan z + \cot z)$; for u^i the symbols $\Gamma^i{}_{i4} = \alpha$ and $\Gamma^i{}_{i0} = H\cot z$; for u^j the symbols $\Gamma^j{}_{j4} = \alpha_t$ and $\Gamma^j{}_{j0} = H\cot z$; for u^4 the symbols $\Gamma^4{}_{ii} = \alpha h_i^2$ and $\Gamma^4{}_{jj} = -\alpha_t h_j^2$; each moved to the right side with its minus sign). For a constant b_4, $\alpha_t = -a_4'$: then $du^j/d\tau = +2a_4' u^j u^4 - 2H\cot z\, u^j u^0$ and $du^4/d\tau = -a_4' \sum_k h_k^2 (u^k)^2$. Together with $dx^a/d\tau = u^a$ these are 16 first-order equations for the 8 coordinates and the 8 velocities.

Six conserved momenta. The metric does not depend on the six transverse coordinates, so by Section 3.16 the six **momenta** $p_k = g_{kk} u^k$ (no sum) do not change during free fall:

$$p_i = h_i^2\, u^i, \qquad p_j = -h_j^2\, u^j \qquad \text{(both constant)}$$

(PROVED in Section 3.16 for every diagonal metric that does not depend on x_k; Notebook 03d proves it again with sympy for all six, for general $a_4(x_4)$ and $b_4(x_4)$, In [4]). The squared speed $g(u,u)$ is conserved too (Section 3.16).

Frame velocities: redshift in 3-space, blueshift along the extra times. An observer at rest at the particle's place measures lengths and durations with the frame of Section 3.7. Per unit of the particle's proper time, the particle covers along x_a the proper length (along an extra time, the proper duration) $\hat{u}^a = h_a u^a$, its **frame velocity**. From the momenta:

$$\hat{u}^i = h_i u^i = \frac{p_i}{h_i} = p_i\, e^{-a_4} \sin^{-1/6} z, \qquad \hat{u}^j = h_j u^j = -\frac{p_j}{h_j} = -p_j\, b_4^{-1/2} e^{a_4} \sin^{-1/6} z$$

(divide the momentum by the scale factor; $1/h_i = e^{-a_4}\sin^{-1/6} z$ and $1/h_j = b_4^{-1/2} e^{a_4} \sin^{-1/6} z$). With $\sin^{1/6} z = e^{Hy}$ (Section 3.9):

$$\hat{u}^i = p_i\, e^{-Hy - a_4}, \qquad \hat{u}^j = -p_j\, b_4^{-1/2} e^{a_4 - Hy}.$$

At a fixed height y, along a deflating history (a_4 increasing, b_4 constant), the frame velocity in 3-space falls like e^{-a_4}: motion in 3-space is **redshifted**, because 3-space inflates and stretches it out. The frame velocity along an extra time grows like e^{a_4}: motion along the extra times is **blueshifted**, because they deflate (in general it grows like $1/h_j$, that is like $e^{-\int \alpha_t\, dx_4}$). The factor e^{-Hy-a_4} is exactly the **momentum weight** $\kappa(y, x_4) = e^{-Hy-a_4(x_4)}$ (the Revision record's name for it; this $\kappa(y, x_4)$, always written in this chapter with its two arguments, is a function and has nothing to do with the constant κ of Einstein's equations in Section 3.26) that the Revision Kohn-Sham record uses to turn a conserved 3-space momentum into the momentum seen at height y and time x_4 (`Revision/kohn_sham/ks-theory.json`, key `geometry.kappa`; PROVED here; Notebook 03d, In [5]). It does not contain b_4: the 3-space scale factors do not.

The push along the hidden direction. Write $S = \sum_i (\hat{u}^i)^2$ and $E = \sum_j (\hat{u}^j)^2$ for the squared frame velocities in 3-space and along the extra times. The frame velocity along the hidden direction is $\hat{u}^0 = h_0 u^0 = \cot z\, u^0$, and it equals $dy/d\tau$, because $dy/d\tau = (dy/dx_0)(dx_0/d\tau) = \cot z\, u^0$ (Section 3.9). Its rate of change, line by line:

$$\frac{d\hat{u}^0}{d\tau} = \frac{d\cot z}{d\tau}\, u^0 + \cot z\, \frac{du^0}{d\tau}$$

(the product rule)

$$= -\frac{6H}{\sin^2 z}\,(u^0)^2 + \cot z\Big[H\tan z\,(S-E) + 6H(\tan z + \cot z)(u^0)^2\Big]$$

($d\cot z/d\tau = -\frac{1}{\sin^2 z}\cdot 6H\cdot u^0$ by the chain rule; the geodesic equation for u^0 with $h_i^2(u^i)^2 = (\hat{u}^i)^2$ and $h_j^2(u^j)^2 = (\hat{u}^j)^2$)

$$= -\frac{6H}{\sin^2 z}(u^0)^2 + H(S-E) + 6H\big(1+\cot^2 z\big)(u^0)^2 = H(S-E)$$

($\cot z \tan z = 1$; $1 + \cot^2 z = 1/\sin^2 z$, so the two terms with $(u^0)^2$ cancel). Hence

$$\frac{d^2y}{d\tau^2} = H\Big(\sum_i (\hat{u}^i)^2 - \sum_j (\hat{u}^j)^2\Big).$$

Motion in 3-space pushes the particle towards the patch end (y grows); motion along an extra time pushes it towards the tip (y falls). A particle at rest feels no push. Neither a_4 nor b_4 appears in this law (PROVED; Notebook 03d, In [6]).

The slowing of x_4. The geodesic equation for u^4, written with frame velocities, is

$$\frac{du^4}{d\tau} = -a_4' \sum_i (\hat{u}^i)^2 + \alpha_t \sum_j (\hat{u}^j)^2 = -a_4' S + \alpha_t E$$

(again $h_k^2(u^k)^2 = (\hat{u}^k)^2$). Along a deflating history, $a_4' > 0$ and $\alpha_t < 0$ (for a constant b_4, $\alpha_t = -a_4'$ and $du^4/d\tau = -a_4'(S+E)$), the x_4 velocity can never increase, and it decreases whenever the particle moves in a transverse direction (PROVED; Notebook 03d, In [6]).

The x_4 velocity from the squared speed. The squared speed, written with frame velocities, is

$$g(u,u) = h_0^2(u^0)^2 + \sum_i h_i^2(u^i)^2 - (u^4)^2 - \sum_j h_j^2(u^j)^2 = (\hat{u}^0)^2 + S - (u^4)^2 - E$$

(the diagonal entries $+h_0^2$, $+h_i^2$, -1, $-h_j^2$ of the metric). Setting it equal to -1 and solving for $(u^4)^2$:

$$(u^4)^2 = 1 + (\hat{u}^0)^2 + \sum_i (\hat{u}^i)^2 - \sum_j (\hat{u}^j)^2 = 1 + (\hat{u}^0)^2 + S - E$$

(PROVED, for every a_4 and b_4; Notebook 03d, In [6]).

No turning without extra-time motion; turning with it. A particle with no extra-time motion at the start has $p_j = 0$, so $\hat{u}^j = 0$ for ever (the momenta are conserved), and $(u^4)^2 = 1+(\hat{u}^0)^2+S \geq 1$: u^4 never reaches zero, keeps its sign, and x_4 keeps advancing. A particle that moves along an extra time is different: its E grows by the blueshift, and $(u^4)^2$ can reach zero. There $u^4 = 0$, the **turning point**; there $E = 1 + (\hat{u}^0)^2 + S \geq 1$, so along a deflating history $du^4/d\tau = -a_4' S + \alpha_t E < 0$, u^4 becomes negative and x_4 decreases afterwards. With four time-like directions, a time-like path need not keep advancing in the chosen time x_4 (PROVED; computed in Notebook 03d, In [11]). At the turning point of a particle that moves only along x_5 and y, the formula gives $(\hat{u}^5)^2 - (\hat{u}^0)^2 = 1$.

The same quadratic form as the plane waves of the Revision record. Multiply the last formula by m^2, the squared mass of the particle, and write $k_a = m\hat{u}^a$ for its frame momenta and $\mathcal{E} = mu^4$ for its energy:

$$\mathcal{E}^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2.$$

The Revision scope report finds exactly this expression for the squared frequency of plane waves of the fields of the book in flat 4+4 space (or with the coefficients of the field equation frozen at one instant): a wave with the momenta k_a has $\mathcal{E}^2$ equal to it, and when the extra-time momentum is so large that $\mathcal{E}^2 < 0$ the frequency is imaginary and the wave grows exponentially in x_4, with a rate that has no upper bound (`Revision/theory/reports/python-scope.json`, check `extra_time_growth_rates_unbounded`; Chapter 8 studies this). The identity of the two quadratic forms is PROVED (Notebook 03d, In [7]). A particle can never be where $\mathcal{E}^2 < 0$, because $(u^4)^2 \geq 0$; where a plane wave would start to grow, the particle reaches its turning point instead. Whether wave packets of the fields follow these geodesics in the curved metric is NOT computed in this book: **OPEN**.

The good sector. The Revision Kohn-Sham work keeps only states that do not depend on x_5, x_6, x_7: their extra-time momenta are zero (`Revision/kohn_sham/ks-theory.json`, key `sectorAndAnsatz.sector`: "good sector: no dependence on x5, x6, x7 (extra-time momenta zero)"). The particle with the same property, $p_j = 0$, is the one that never turns. The reason for this choice of the record comes from the quantum theory (Chapter 10).

Numbers along the history (COMPUTED by Notebook 03d). With the history of the record ($A = 1$, $H = 1$, so $a_4 = x_4$, and $b_4 = 1$; ASSUMED, a prescribed background, Section 3.8), RK4 with the step $\Delta\tau = 0.001$, all particles starting at $x_4 = 0$ and $y = -1$ ($z = \arcsin e^{-6} = 0.002479$): a particle at rest stays at rest with $x_4 = \tau$ (In [9]). Three particles started along x_1 with the frame velocities 0.25, 0.5 and 1 keep p_1 and $g(u,u)$ constant within a relative 10^{-9}, their frame

velocity equals $p_1\kappa(y, x_4)$ within 10^{-9}, and u^4 falls at every step; the fastest has at $\tau = 3$ the values $x_4 = 3.3070$, $\hat{u}^1 = 0.014370$, $u^4 = 1.060733$ and $y = -0.0643$: it has slowed down by redshift and risen towards the patch end (In [10]). A particle started along x_5 with $\hat{u}^5 = 0.2$ reaches its turning point at $\tau = 1.987$, where x_4 is largest, 1.4864, with $\hat{u}^5 = 1.4013$ and $\hat{u}^0 = -0.9817$ (it has sunk towards the tip), and x_4 decreases afterwards (In [11]). The numerical acceleration of y agrees with the push law within 3.4×10^{-6} (In [14]), and halving the RK4 step divides the error by 16.2 to 17.2, the order 4 of RK4 (In [16]).

3.32 Example: free fall in the author's metric

Notebook 03d reads the 25 Christoffel symbols of the record, builds the geodesic equations, and proves with sympy, for general $a_4(x_4)$ and $b_4(x_4)$, the conservation of the six momenta and of $g(u, u)$, the momentum weight $\kappa(y, x_4)$ of the Kohn-Sham record, the push law, the law of the x_4 velocity, the formula for $(u^4)^2$, and its identity with the quadratic form of the record's plane-wave check. Then it integrates five paths with RK4 along the history of the record ($b_4 = 1$), checks every exact law on the computed paths, finds the turning point of the particle that moves along an extra time, measures the order of RK4, and draws five figures. It needs no Rust, runs in about 10 seconds and ends with the line ALL 23 CHECKS PASSED (notebook 03d).

3.33 How to run Notebook 03d

Step 1. What this notebook does and what it needs.

Notebook 03d (Free fall in the author's metric: conserved momenta, redshift, blueshift and the push along the hidden direction) is the file `Revision/textbook/notebooks/03d_free_fall.ipynb` of the repository Dirac_claude. It integrates the geodesic equations of free fall in the author's metric with the Christoffel symbols of the Revision record, along the deflating history a4 = A H x4, b4 = 1 with A = 1 and H = 1, by the Runge-Kutta method RK4. With sympy it proves exactly, for general a4(x4) and b4(x4), that the six momenta along x1, x2, x3, x5, x6, x7 and the squared length of the velocity are conserved, that the frame velocity in 3-space falls like e^(-a4) (redshift) while the frame velocity along an extra time grows like e^(a4) b4^(-1/2) (blueshift), that the hidden coordinate y is pushed with the acceleration H times the difference of the squared 3-space and extra-time frame velocities, and the law of the x4 velocity, which can only decrease along a deflating history; it reproduces the momentum weight of the Revision Kohn-Sham record and the quadratic form of the plane-wave check of the Revision scope report. It checks all of this on the computed paths, finds the turning point in x4 of a particle that moves along an extra time, measures the order 4 of RK4, and draws 5 figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at

a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are

those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 03d_free_fall.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 50 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 03d_free_fall.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 03d_free_fall.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/03d.captions.json`

- `Revision/textbook/figures/03d_1_frame_velocities.png`
- `Revision/textbook/figures/03d_2_x4_velocity.png`
- `Revision/textbook/figures/03d_3_hidden_push.png`
- `Revision/textbook/figures/03d_4_quadratic_form.png`
- `Revision/textbook/figures/03d_5_accuracy.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files exist
ALL 23 CHECKS PASSED (notebook 03d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/03d_free_fall.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 03d_free_fall.ipynb
python -m nbconvert --execute --inplace 03d_free_fall.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for curvature.json, parameters.json, ks-theory.json or python-scope.json: the notebook reads these four Revision records of the repository, so the folder Revision of your copy is incomplete. Restore it with the following command in the repository folder (or clone the repository again) and run the notebook again:

```
git checkout -- Revision
```

3.34 Notebook 03d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/03d_free_fall.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Notebooks 03a and 03b described the author's metric and its curvature. This notebook
asks what the metric DOES: how does a small body move when no force acts on it, only
the geometry? Such a body is in **free fall**, and its path is a **geodesic**. The
notebook

- reads the 25 non-zero Christoffel symbols of the Revision record
  `Revision/gkd_lovelock/results/curvature.json` and builds from them the geodesic
  equations, 16 first-order equations for the 8 coordinates and the 8 velocities;
```

- proves exactly, with sympy, what stays constant during free fall: the six
  momenta along x_1, x_2, x_3 and x_5, x_6, x_7 and the squared length of the
  velocity;
- proves that the velocity of a body moving in 3-space, measured with rulers and
  clocks at its place, falls like e^{-a_4} at a fixed height in the hidden
  direction (**redshift**: 3-space inflates), while its velocity along an extra time
  grows like $e^{a_4} b_4^{-1/2}$ (**blueshift**: the extra times deflate), and
  reproduces the
  momentum weight $\kappa = e^{-Hy - a_4}$ of the Revision Kohn-Sham record;
- proves that motion in 3-space pushes the body towards the patch end of the hidden
  direction, motion along an extra time towards the tip, and finds the law of the
  velocity along the time x_4, which can only decrease along a deflating history;
- shows that the squared x_4 velocity of the body is the same quadratic form as the
  squared frequency of a plane wave in the Revision record's check
  `extra_time_growth_rates_unbounded`;
- integrates the geodesic equations numerically (RK4) for a body at rest, three
  bodies moving in 3-space and one body moving along an extra time, along the
  deflating history $a_4 = AHx_4$, $b_4 = 1$ ($A = 1$, $H = 1$), checks every exact
  law on the
  computed paths, finds the instant at which the last body stops advancing in x_4,
  and measures the accuracy of RK4;
- draws 5 figures and prints a PASS line for every check.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 03d (Free fall in the author's metric: conserved momenta, redshift, blueshift
and the push along the hidden direction) is the file
`Revision/textbook/notebooks/03d_free_fall.ipynb` of the repository Dirac_claude. It
integrates the geodesic equations of free fall in the author's metric with the
Christoffel symbols of the Revision record, along the deflating history a4 = A H x4, b4 =
1 with A = 1 and H = 1, by the Runge-Kutta method RK4. With sympy it proves exactly, for
general a4(x4) and b4(x4), that the six momenta along x1, x2, x3, x5, x6, x7 and the
squared length of the velocity are conserved, that the frame velocity in 3-space falls
like e^(-a4) (redshift) while the frame velocity along an extra time grows like e^(a4)
b4^(-1/2) (blueshift), that the hidden coordinate y is pushed with the acceleration H
times the difference of the squared 3-space and extra-time frame velocities, and the law
of the x4 velocity, which can only decrease along a deflating history; it reproduces the
momentum weight of the Revision Kohn-Sham record and the quadratic form of the plane-wave
check of the Revision scope report. It checks all of this on the computed paths, finds
the turning point in x4 of a particle that moves along an extra time, measures the order
4 of RK4, and draws 5 figures. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**
```

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the

packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 03d_free_fall.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 50 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 03d_free_fall.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 03d_free_fall.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/03d.captions.json‘
- ‘Revision/textbook/figures/03d_1_frame_velocities.png‘
- ‘Revision/textbook/figures/03d_2_x4_velocity.png‘
- ‘Revision/textbook/figures/03d_3_hidden_push.png‘

- ‘Revision/textbook/figures/03d_4_quadratic_form.png‘
- ‘Revision/textbook/figures/03d_5_accuracy.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files exist
ALL 23 CHECKS PASSED (notebook 03d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/03d_free_fall.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 03d_free_fall.ipynb
  python -m nbconvert --execute --inplace 03d_free_fall.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event

  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for curvature.json, parameters.json, ks-theory.json or python-scope.json: the notebook reads these four Revision records of the repository, so the folder Revision of your copy is incomplete. Restore it with the following command in the repository folder (or clone the repository again) and run the notebook again:

      git checkout -- Revision

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 03d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 03d (Free fall in the author's metric: conserved momenta, redshift, blueshift
# and the push along the hidden direction) is the file
# Revision/textbook/notebooks/03d_free_fall.ipynb of the repository Dirac_claude. It
# integrates the geodesic equations of free fall in the author's metric with the
# Christoffel symbols of the Revision record, along the deflating history a4 = A H x4, b4
# = 1 with A = 1 and H = 1, by the Runge-Kutta method RK4. With sympy it proves exactly,
# for general a4(x4) and b4(x4), that the six momenta along x1, x2, x3, x5, x6, x7 and
# the squared length of the velocity are conserved, that the frame velocity in 3-space
# falls like e^(-a4) (redshift) while the frame velocity along an extra time grows like
# e^(a4) b4^(-1/2) (blueshift), that the hidden coordinate y is pushed with the
# acceleration H times the difference of the squared 3-space and extra-time frame
# velocities, and the law of the x4 velocity, which can only decrease along a deflating
# history; it reproduces the momentum weight of the Revision Kohn-Sham record and the
# quadratic form of the plane-wave check of the Revision scope report. It checks all of
# this on the computed paths, finds the turning point in x4 of a particle that moves
# along an extra time, measures the order 4 of RK4, and draws 5 figures. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
```

```
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
```

```
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
```

```
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 03d_free_fall.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 50
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 03d_free_fall.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 03d_free_fall.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/03d.captions.json
# - Revision/textbook/figures/03d_1_frame_velocities.png
# - Revision/textbook/figures/03d_2_x4_velocity.png
# - Revision/textbook/figures/03d_3_hidden_push.png
# - Revision/textbook/figures/03d_4_quadratic_form.png
# - Revision/textbook/figures/03d_5_accuracy.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
```

```
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files exist
#     ALL 23 CHECKS PASSED (notebook 03d)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/03d_free_fall.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 03d_free_fall.ipynb
#     python -m nbconvert --execute --inplace 03d_free_fall.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for curvature.json, parameters.json, ks-theory.json or
#   python-scope.json: the notebook reads these four Revision records of the repository,
#   so the folder Revision of your copy is incomplete. Restore it with the following
#   command in the repository folder (or clone the repository again) and run the notebook
#   again:
#     git checkout -- Revision
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$ (the author's names): $x_0$ the **hidden**
  direction, $x_1, x_2, x_3$ ordinary 3-space, $x_4$ the time, $x_5, x_6, x_7$ the
  three **extra times**; $z = 6Hx_0$ with $0 < z < \pi/2$. In Python lists they are
  counted 0 to 7 as well: $x_k$ is entry $k$, its velocity $u^k$ too.
- **Hidden coordinate** $y = \ln(\sin z)/(6H)$: the proper distance along the
  hidden direction, $y = 0$ at the **patch end** $z = \pi/2$ and $y \to -\infty$ at
  the **tip** $z \to 0$.
- **Free fall**: motion under no force other than the geometry. **Test particle**: a
  body so small that it does not change the metric.
- **Proper time** $\tau$: the time shown by a clock carried by the body.
- **Velocity** $u^a = dx^a/d\tau$: how fast each coordinate changes per unit of
  proper time.
- **Geodesic equation**: $du^a/d\tau = -\sum_{b,c} \Gamma^a{}_{bc}\, u^b u^c$, with
  the Christoffel symbols $\Gamma^a{}_{bc}$ of the metric; its solutions are the
  paths of free fall.
- **Squared length of the velocity**: $g(u, u) = \sum_a g_{aa} (u^a)^2$ (the metric
  is diagonal). For a body with mass it equals $-1$ when $\tau$ is its proper time.
- **Scale factor** $h_a = \sqrt{|g_{aa}|}$ and **frame velocity**
  $\hat u^a = h_a u^a$: the proper length (along an extra time: the proper
  duration) that the body covers along $x_a$ per unit of its own proper time,
  measured with the rulers and clocks of an observer at rest at its place; divided
  by $u^4$ it is the velocity that this observer measures.
- **Momentum** $p_a = g_{aa} u^a$ (no sum) of a direction $x_a$. **Conserved**: the
  same number at every point of the path.
- **Redshift, blueshift**: the decrease, increase of a frame velocity (or momentum)
  caused by the expansion, contraction of the space it points along.
- **History** $a_4 = AHx_4$, $b_4 = 1$: the time dependence of the metric used for
  the numbers, the one of the Revision Kohn-Sham work ($A = 1$, $H = 1$); with $A > 0$
  the extra times deflate. It is a **prescribed background**: assumed, not solved
  for.
- **RK4**: the classical Runge-Kutta method of order 4; halving its step makes its
  error about $2^4 = 16$ times smaller.
```

```
- **Turning point**: the instant at which the $x_4$ velocity $u^4$ passes through
  zero, so that $x_4$ stops growing.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's metric is diagonal,
$g = \mathrm{diag}(h_0^2, h_1^2, h_2^2, h_3^2, -1, -h_5^2, -h_6^2, -h_7^2)$ with
the scale factors $h_0 = \cot z$, $h_1 = h_2 = h_3 = e^{a_4}\sin^{1/6}z$ (3-space,
inflating) and $h_5 = h_6 = h_7 = b_4^{1/2} e^{-a_4}\sin^{1/6}z$ (the extra times,
deflating when $b_4$ is constant). A test particle with mass falls freely along a
solution of the **geodesic equations**

$$\frac{dx^a}{d\tau} = u^a, \qquad \frac{du^a}{d\tau} = -\sum_{b,c}
\Gamma^a{}_{bc}\, u^b u^c \qquad (a = 0, \dots, 7),$$

sixteen first-order equations. The Christoffel symbols are those of the Revision
record (Notebook 03b checked them component by component). The metric depends only
on $x_4$ and $x_0$; for each of the other six directions this makes a momentum
$p_a = g_{aa} u^a$ conserved (section 6). The squared length $g(u, u)$ of the
velocity is conserved too, and we choose it equal to $-1$: then $\tau$ is the
proper time of the particle and the path is time-like.

For the numbers the notebook uses the deflating history $a_4 = AHx_4$, $b_4 = 1$ of
the Revision Kohn-Sham work with $A = 1$ and $H = 1$ (so $a_4' = 1$, $b_4' = 0$). It
is a prescribed background, and the particles are test particles: they move in the
given metric and do not change it. Everything in sections 6 to 9 holds for general
functions $a_4(x_4)$ and $b_4(x_4)$; only the numerical paths of sections 10 to 12
use the history.
```

Text cell:

```
## 5. The Christoffel symbols, read from the record

First a technical step. While a cell runs, Jupyter sends what the cell prints to the
notebook in pieces, about one piece every 0.2 seconds, so where one piece ends and
the next begins depends on the speed of the computer. The tools that build this
book read the PASS line of a check together with the line under it that names the
Revision record, and they read the two correctly only when both arrive in the same
piece. The next cell therefore defines the function `in_one_piece(helper)`: it
returns a new function that does exactly what `helper` does, but lets `helper`
print into a text buffer in memory (an `io.StringIO`, with
`contextlib.redirect_stdout`) and then writes the whole buffer with one call of
`sys.stdout.write`, which arrives as one piece. (The stars in `*arguments` and
`**options` pass on all the values the new function is given, whatever they are.)
The cell then replaces the helpers `check` and `report` of the set-up cell by such
functions. Nothing else changes: the same checks, the same PASS lines, the same
numbers.
```

In [2]:

```
import contextlib  # redirect_stdout: send printed text into a buffer
import io  # StringIO: a text buffer in memory
import sys  # sys.stdout: the place where printed text goes

def in_one_piece(helper):
    """A function that does what helper does, with all the lines that helper prints
    written in one piece."""
    def helper_in_one_piece(*arguments, **options):
        collected = io.StringIO()  # an empty text buffer
        with contextlib.redirect_stdout(collected):  # print() writes into it
            helper(*arguments, **options)  # a failing check stops here, as before
        sys.stdout.write(collected.getvalue())  # all the lines with one write
    return helper_in_one_piece

check = in_one_piece(check)  # a PASS line and its record line stay together
report = in_one_piece(report)  # a long RESULT line and its second line, too
say("From now on check and report print each of their results in one piece.")
```

Out [2]:

```
From now on check and report print each of their results in one piece.
```

Text cell:

```
The next cell imports the packages, makes the symbols (the eight coordinates, the
constant $H > 0$, the functions $a_4(x_4)$ and $b_4(x_4)$, and the printing names
‘a4p‘ for $a_4’$, ‘a4v‘ for the value of $a_4$, ‘b4p‘ and ‘b4v‘ the same for $b_4$),
and reads the list ‘christoffelNonzero_b_le_c‘ of
the record. Each entry gives the three indices ‘a‘, ‘b‘, ‘c‘ of
$\Gamma^a{}_{bc}$ (with $b \le c$) and its value in Mathematica notation, which the
function ‘from_mathematica‘ translates into sympy (the same translation as in
Notebook 03b: ‘Derivative[1][a4][x4]‘ becomes ‘a4p‘, ‘a4[x4]‘ becomes ‘a4v‘, the
same for $b_4$, square brackets of functions become round ones, ‘^‘ becomes ‘**‘).
Because $\Gamma^a{}_{bc} = \Gamma^a{}_{cb}$, every entry with $b < c$ is stored
twice, once for each order of the lower indices: the 25 entries give 37 symbols. The
cell prints four of them.
```

## 6. What stays constant during free fall (exact)

A quantity $f$ that depends on the position $x$ and the velocity $u$ changes along a
path at the rate given by the chain rule,

$$\frac{df}{d\tau} = \sum_a \frac{\partial f}{\partial x^a}\, u^a
+ \sum_a \frac{\partial f}{\partial u^a}\, \frac{du^a}{d\tau},$$
```

```
and on a path of free fall $du^a/d\tau$ is given by the geodesic equation. The next
cell defines this rate as the function ‘along_path(f)‘, with the record’s
Christoffel symbols for general functions $a_4(x_4)$ and $b_4(x_4)$ (‘a4p‘ becomes
the derivative of $a_4$, ‘a4v‘ the value $a_4(x_4)$, and the same for $b_4$).

By hand, for the momentum $p_1 = g_{11} u^1$ of the direction $x_1$. Line 1, the
chain rule (only $x_4$ and $x_0$ appear in $g_{11}$):
$dp_1/d\tau = (\partial_4 g_{11}\, u^4 + \partial_0 g_{11}\, u^0)\, u^1
+ g_{11}\, du^1/d\tau$. Line 2, the geodesic equation for $u^1$ has the four terms
with $\Gamma^{x_1}{}_{x_1x_4} = \Gamma^{x_1}{}_{x_4x_1} = a_4'$ and
$\Gamma^{x_1}{}_{x_1x_0} = \Gamma^{x_1}{}_{x_0x_1} = H\cot z$:
$du^1/d\tau = -2a_4' u^1 u^4 - 2H\cot z\, u^1 u^0$. Line 3, from
$g_{11} = e^{2a_4}\sin^{1/3}z$: $\partial_4 g_{11} = 2a_4' g_{11}$ and
$\partial_0 g_{11} = \tfrac13 \cdot 6H \cot z\, g_{11} = 2H\cot z\, g_{11}$
(the derivative of $\sin^{1/3} z$ is $\tfrac13 \sin^{-2/3}z \cos z$ times
$dz/dx_0 = 6H$). Line 4, inserting lines 2 and 3 into line 1:
$dp_1/d\tau = 2a_4' g_{11} u^4 u^1 + 2H\cot z\, g_{11} u^0 u^1 - 2a_4' g_{11} u^1 u^4
- 2H\cot z\, g_{11} u^1 u^0 = 0$. The momentum is conserved because the metric does
not depend on $x_1$. The cell lets sympy do the same for all six momenta of
$x_1, x_2, x_3, x_5, x_6, x_7$, and for the squared length
$g(u, u) = \sum_a g_{aa} (u^a)^2$.
```

In [4]:

```
u = sp.symbols("u0:8", real=True)  # the velocity components u^0 ... u^7

```

Text cell:

```
## 7. Redshift in 3-space, blueshift along the extra times (exact)

The frame velocity is $\hat u^a = h_a u^a$. Since $p_a = g_{aa} u^a = \pm h_a^2 u^a$
(plus for 3-space, minus for the extra times),

$$\hat u^1 = \frac{p_1}{h_1} = p_1\, e^{-a_4} \sin^{-1/6} z, \qquad
\hat u^5 = -\frac{p_5}{h_5} = -p_5\, b_4^{-1/2} e^{a_4} \sin^{-1/6} z .$$

With $p_1$ and $p_5$ constant, the frame velocity in 3-space falls like $e^{-a_4}$
when $a_4$ grows (redshift), and the frame velocity along an extra time grows like
$e^{a_4} b_4^{-1/2}$, like $e^{a_4}$ for a constant $b_4$ (blueshift). In the hidden
coordinate, $\sin^{1/6} z = e^{Hy}$, so
$1/h_1 = e^{-Hy - a_4}$: exactly the **momentum weight**
$\kappa(y, x_4) = e^{-Hy - a_4(x_4)}$ that the Revision Kohn-Sham record uses to turn
a conserved 3-space momentum into the momentum seen at height $y$ and time $x_4$.
The next cell reads that statement of the record and checks it, and checks
$1/h_5 = b_4^{-1/2} e^{a_4 - Hy}$ for the extra times.
```

In [5]:

```
KS_THEORY = "Revision/kohn_sham/ks-theory.json"

```

Text cell:

```
## 8. The push along the hidden direction and the slowing of $x_4$ (exact)

Two more exact laws follow from the record's symbols. First the hidden direction.
The geodesic equation for $u^0$ has the terms with
$\Gamma^{x_0}{}_{x_ix_i} = -H h_i^2 \tan z$ (3-space, $i = 1, 2, 3$),
$\Gamma^{x_0}{}_{x_jx_j} = +H h_j^2 \tan z$ (extra times, $j = 5, 6, 7$; with the
factor $b_4$ inside $h_j^2$) and $\Gamma^{x_0}{}_{x_0x_0} = -6H(\tan z + \cot z)$, so
$du^0/d\tau = H\tan z\,(\sum_i (\hat u^i)^2 - \sum_j (\hat u^j)^2)
+ 6H(\tan z + \cot z)(u^0)^2$. The frame velocity along $x_0$ is
$\hat u^0 = \cot z\, u^0 = dy/d\tau$ (because $dy/dx_0 = \cot z$). Its rate is
$d\hat u^0/d\tau = -6H (u^0)^2/\sin^2 z + \cot z\, du^0/d\tau$ (the product rule,
with $d\cot z/d\tau = -6H u^0/\sin^2 z$); inserting $du^0/d\tau$ and using
$\cot z \tan z = 1$ and $1 + \cot^2 z = 1/\sin^2 z$, the $(u^0)^2$ terms cancel:

$$\frac{d^2 y}{d\tau^2} = \frac{d\hat u^0}{d\tau}
= H\Bigl(\sum_{i=1}^{3} (\hat u^i)^2 - \sum_{j=5}^{7} (\hat u^j)^2\Bigr).$$

Motion in 3-space pushes the particle towards the patch end ($y$ grows), motion
along an extra time towards the tip ($y$ falls). Second, the time $x_4$: the only
symbols with upper index $x_4$ are $\Gamma^{x_4}{}_{x_ix_i} = a_4' h_i^2$ and
$\Gamma^{x_4}{}_{x_jx_j} = -\alpha_t h_j^2$, with the expansion rate
$\alpha_t = -a_4' + b_4'/(2b_4)$ of the extra times (Notebook 03a), so

$$\frac{du^4}{d\tau} = -a_4' \sum_{i=1}^{3} (\hat u^i)^2
+ \alpha_t \sum_{j=5}^{7} (\hat u^j)^2 :$$

for a deflating history ($a_4' > 0$ and $\alpha_t < 0$; with a constant $b_4$,
$\alpha_t = -a_4'$ and $du^4/d\tau = -a_4'(\sum_i (\hat u^i)^2 + \sum_j
(\hat u^j)^2)$) the $x_4$ velocity can only decrease. Third, in frame velocities the
squared length reads
$g(u, u) = (\hat u^0)^2 + \sum_i (\hat u^i)^2 - (u^4)^2 - \sum_j (\hat u^j)^2$, so
with $g(u, u) = -1$:

$$(u^4)^2 = 1 + (\hat u^0)^2 + \sum_{i=1}^{3} (\hat u^i)^2
- \sum_{j=5}^{7} (\hat u^j)^2 .$$

The next cell checks all three with sympy for general $a_4(x_4)$ and $b_4(x_4)$.

## 9. The same quadratic form as the plane waves of the Revision record

Multiply the last formula by $m^2$, the squared mass of the particle, and call
$k_a = m\,\hat u^a$ its frame momenta and $E = m\,u^4$ its energy: then
$E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$. The Revision
scope report `Revision/theory/reports/python-scope.json` has, in its check
`extra_time_growth_rates_unbounded`, exactly this expression for plane waves of the
fields in flat 4+4 space (or with the coefficients of the equation frozen at one
instant): a wave $e^{i(k \cdot x - E x_4)}$ has $E^2$ equal to it, and when the
extra-time momentum is so large that $E^2 < 0$, $E$ is imaginary and the wave grows
exponentially in $x_4$ instead of oscillating. The next cell cuts the expression out
of the record's text, turns it into sympy and compares it with $m^2 (u^4)^2$ of the
particle. For the particle $(u^4)^2$ can never be negative; where a plane wave would
start to grow, the particle instead reaches $u^4 = 0$, its **turning point** in
$x_4$ (section 11). (That a wave packet of the fields follows such a path in the
curved metric is not computed here.)
```

## 10. Free fall computed step by step (RK4)

Now the numbers. The next cell reads the history of the Revision Kohn-Sham record
($H = 1$, slope $A = 1$, so $a_4 = x_4$ and $a_4' = 1$; and $b_4 = 1$) and its
statement that this
history is a prescribed background, and builds the tools of the computation:

- ‘gamma_numbers‘: the 37 symbols as fast numerical functions of $a_4$, $a_4'$,
  $x_0$, $H$, $b_4$ and $b_4'$ (‘sp.lambdify‘ with the module ‘math‘);
- ‘free_fall(state)‘: the right-hand side of the 16 equations for the state
  $(x^0, \dots, x^7, u^0, \dots, u^7)$ on the history, with $b_4 = 1$, $b_4' = 0$
  (entry $k$ of the state is $x^k$ and entry $8 + k$ is $u^k$);
- ‘rk4_path(state0, tau_end, steps)‘: the RK4 method, the same as in chapter 2,
  from $\tau = 0$ to ‘tau_end‘ in ‘steps‘ equal steps;
- ‘start(y0, frame_velocity)‘: the state at $\tau = 0$ at the point
  $x_4 = 0$, $y = y_0$ (all other coordinates 0) with the given frame velocities;
  $u^4$ is chosen so that $g(u, u) = -1$, by the last formula of section 8;
- ‘describe(states)‘: for every computed state the frame velocities, $y$ and
  $g(u, u)$.

All particles start at $y_0 = -1$ (that is $z_0 = \arcsin e^{-6} = 0.0025$), well
inside the patch, on the slice $x_4 = 0$ where $a_4 = 0$.

**Three particles moving in 3-space.** The next three particles start with the
frame velocities $\hat u^1 = 0.25$, $0.5$ and $1$ along $x_1$, so
$u^4 = \sqrt{1 + (\hat u^1)^2}$. (The velocity that an
observer at rest at the particle's place measures is $\hat u^1/u^4$; for
$\hat u^1 = 1$ it is $1/\sqrt 2 = 0.71$ times the velocity of light, which is $1$
in these units.) The next cell integrates each from $\tau = 0$ to $3$ in 3000
steps and checks on every computed state: the momentum $p_1 = g_{11} u^1$ stays
constant (relative change below $10^{-9}$); $g(u, u)$ stays $-1$; the frame velocity
equals $p_1 \kappa(y, x_4)$ (section 7); $u^4$ decreases at every step (section 8);
the particle stays inside the patch ($y < 0$). It reports the final values for the
fastest particle.

## 11. A particle moving along an extra time: the turning point

The last particle starts with the frame velocity $\hat u^5 = 0.2$ along the extra
time $x_5$, so $u^4 = \sqrt{1 - 0.04} = 0.980$ (rounded). Along the deflating
history ($b_4 = 1$) its frame velocity $-p_5\, e^{a_4 - Hy}$ grows, it is pushed
towards the tip, and by section 8 its $x_4$ velocity obeys
$(u^4)^2 = 1 + (\hat u^0)^2 - (\hat u^5)^2$. The
next cell integrates its path from $\tau = 0$ to $2.5$ in 2500 steps, checks the
conservation laws, finds the step at which $u^4$ changes sign (the turning point:
$x_4$ is largest there and decreases afterwards), and checks that there
$(\hat u^5)^2 - (\hat u^0)^2 = 1$, as the formula demands for $u^4 = 0$.

The cell also prints the definition of the **good sector** of the Revision
Kohn-Sham work: its states have no dependence on $x_5, x_6, x_7$, that is no
extra-time momenta (the reason, from the quantum theory, comes in a later chapter).
For a classical particle without extra-time momentum, $(u^4)^2 = 1 + (\hat u^0)^2 +
\sum_i (\hat u^i)^2 \ge 1$: such a particle never has a turning point.
```

In [11]:

## 12. Pictures of free fall

The next cell draws the frame velocities. Left: the three particles that move in
3-space, their frame velocity $\hat u^1$ against the time $x_4$ on a logarithmic
axis, computed by RK4 (solid lines), together with the pure redshift
$\hat u^1(0)\, e^{-a_4}$ (dotted lines; on a logarithmic axis straight lines of
slope $-1$). The computed curves fall a little faster than $e^{-a_4}$ because the
particles also rise in $y$, where the warp factor $e^{Hy}$ is larger. Right: the
particle moving along the extra time $x_5$, its frame velocity $\hat u^5$ against
$x_4$ up to its turning point, together with the pure blueshift
$0.2\, e^{a_4}$ (dotted); it grows faster than $e^{a_4}$ because the particle sinks
towards the tip, where $e^{-Hy}$ is larger.
```

PASS the extra-time frame velocity grows faster than the pure blueshift
```

Text cell:

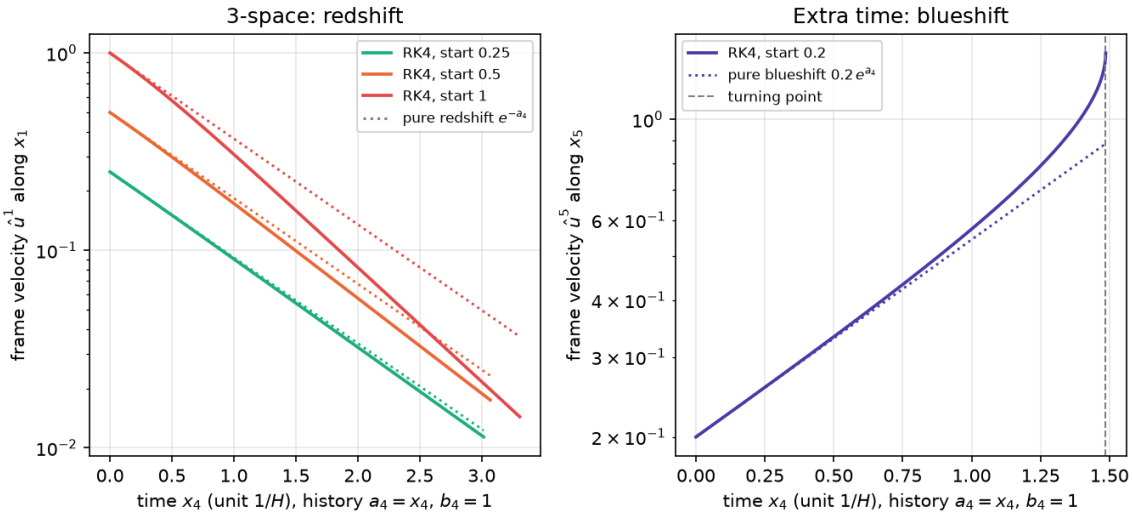

Figure 111: Frame velocities of freely falling test particles in the author's metric along the deflating history $a_4 = x_4$, $b_4 = 1$ ($A = 1$, $H = 1$), all started at $x_4 = 0$, $y = -1$, computed with RK4 from the Christoffel symbols of the Revision record; horizontal axes the time x_4 in units of $1/H$, vertical axes the frame velocity (proper length per proper time, a pure number) on logarithmic scales. Left: three particles started along x_1 with 0.25, 0.5 and 1; their frame velocity falls, a little faster than the pure redshift e^{-a_4} (dotted), because they also rise towards the patch end. Right: a particle started along the extra time x_5 with 0.2; its frame velocity grows, faster than the pure blueshift $0.2\,e^{a_4}$ (dotted), until its turning point at $x_4 = 1.486$ (dashed). (Notebook 03d, figure 1.)

```
The next cell draws the $x_4$ velocity $u^4$ (left) and the time $x_4$ itself
(right) against the proper time $\tau$ for all five particles. The particle at rest
keeps $u^4 = 1$. The particles in 3-space start with $u^4 = \sqrt{1 + (\hat u^1)^2}$
and slow down towards $1$ as their frame velocity is redshifted away. The particle
on the extra time starts with $u^4 = 0.98$, slows down to $0$ at its turning point
and continues with $u^4 < 0$: its $x_4$ reaches a largest value and then decreases.
With four time-like directions a time-like path need not keep advancing in $x_4$.
```

```
## 13. How accurate is the computation?

Two tests. First, the conserved quantities: the next cell draws, against $\tau$, how
far the computed $p_1$ (fastest 3-space particle), $p_5$ (extra-time particle) and
$g(u, u)$ (both) drift from their starting values, on a logarithmic axis. Second,
the order of RK4: it integrates both particles from $\tau = 0$ to $2$ with
$50, 100, 200, 400, 800, 1600$ steps and measures the largest difference of the end
states of two successive step sizes; for a method of order 4 each halving of the
step divides this difference by about $2^4 = 16$, so on logarithmic axes the points
lie on a line of slope 4.
```

## 15. What this notebook showed

- PROVED (exact, sympy, for all functions $a_4(x_4)$ and $b_4(x_4)$, with the
  Christoffel symbols of the Revision record): in free fall the six momenta
  $p_a = g_{aa} u^a$ of $x_1, x_2, x_3, x_5, x_6, x_7$ and the squared length
  $g(u, u)$ are conserved; the frame velocity in 3-space is $p_1 e^{-Hy - a_4}$ (the
  momentum weight $\kappa$ of the Revision Kohn-Sham record) and along an extra time
  $-p_5 b_4^{-1/2} e^{a_4 - Hy}$;
  $d^2y/d\tau^2 = H(\sum_i (\hat u^i)^2 - \sum_j (\hat u^j)^2)$;
  $du^4/d\tau = -a_4'\sum_i (\hat u^i)^2 + \alpha_t \sum_j (\hat u^j)^2$ with
  $\alpha_t = -a_4' + b_4'/(2b_4)$; and
  $(u^4)^2 = 1 + (\hat u^0)^2 + \sum_i (\hat u^i)^2 - \sum_j (\hat u^j)^2$, which,
  times $m^2$, is the quadratic form of the plane-wave check of the Revision scope
  report.
- So along a deflating history ($a_4$ increasing, $b_4$ constant) motion in 3-space
  is redshifted like $e^{-a_4}$ and motion along an extra time is blueshifted like
  $e^{a_4}$;
  3-space motion pushes a particle towards the patch end, extra-time motion towards
  the tip; the $x_4$ velocity can only decrease.
- COMPUTED (RK4 with the step $0.001$, along the prescribed history $a_4 = x_4$,
  $b_4 = 1$, $H = 1$, from $y = -1$): a particle at rest stays at rest with
  $x_4 = \tau$; three particles moving in 3-space slow down and rise towards the
  patch end; a particle
```

```
  started along the extra time $x_5$ with frame velocity $0.2$ reaches a largest
  $x_4$ (the RESULT lines above) and then moves back in $x_4$; every exact law holds
  on the computed paths, and RK4 shows its order 4.
- A particle without extra-time momentum has $(u^4)^2 \ge 1$ and never turns
  (PROVED); the Revision Kohn-Sham work keeps only states without extra-time
  momenta (its good sector).
- ASSUMED: the history $a_4 = AHx_4$, $b_4 = 1$ (a prescribed background); test
  particles
  that do not change the metric. NOT computed here: whether the waves of the fields
  follow these paths in the curved metric.
```

3.35 Line-by-line walk-through of Notebook 03d

The notebook has 17 code cells, In [1] to In [17]. The conventions of the earlier walk-throughs apply (a line `...` in a quoted figure command stands for the rest of the caption, printed in full in Section 3.34).

In [1], the set-up cell. Its comment lines are the run instructions of Section 3.33. Its code is, line for line, the set-up code of Notebook 03a explained in Section 3.13 under In [1], with the single difference `NOTEBOOK_ID = "03d" # this notebook:  chapter 03, example d`. It prints Set-up of notebook 03d complete: repository folder found, helpers defined.

In [2], every result in one piece. Word for word In [2] of Notebook 03a (Section 3.13). It prints From now on check and report print each of their results in one piece.

In [3], the Christoffel symbols of the record.

```
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
from sympy.parsing.sympy_parser import parse_expr  # text -> sympy expression

CURVATURE_RECORD = "Revision/gkd_lovelock/results/curvature.json"
record = json.loads(repository_file(CURVATURE_RECORD).read_text(encoding="utf-8"))
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
X = sp.symbols("x0:8", real=True)  # the coordinates x0 ... x7 (X[0] ... X[7])
x4, x0 = X[4], X[0]
```

The packages, the record of the curvature computation, the names of the coordinates in the author's order, and the eight coordinates as the tuple `X` (a tuple is a list that cannot be changed); `x4` and `x0` name its positions 4 and 0.

```
H = sp.symbols("H", positive=True)  # the constant of the author
a4 = sp.Function("a4")(x4)  # the metric function a4, any function of x4
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4 > 0
a4p, a4v, b4p = sp.symbols("a4p a4v b4p", real=True)  # printing names
b4v = sp.symbols("b4v", positive=True)  # printing name of the value of b4
record_names = {"a4p": a4p, "a4v": a4v, "b4p": b4p, "b4v": b4v, "H": H, "x0": x0,
                "E": sp.E, "sin": sp.sin, "cot": sp.cot}
```

$H > 0$, the functions $a_4(x_4)$ and $b_4(x_4)$ (the second positive), the plain symbols `a4p`, `a4v`, `b4p` and

b4v (the last positive), and the dictionary of names for reading the record (as in Notebook 03b, Section 3.30, In [5]).

```
def from_mathematica(entry_text):
    """A value of the record (Mathematica notation) as a sympy expression."""
    t = entry_text.replace("Derivative[1][a4][x4]", "a4p").replace("a4[x4]", "a4v")
    t = t.replace("Derivative[1][b4][x4]", "b4p").replace("b4[x4]", "b4v")
    t = t.replace("Sin[6*H*x0]", "sin(6*H*x0)").replace("Cot[6*H*x0]", "cot(6*H*x0)")
    t = t.replace("^", "**")
    if "[" in t or "]" in t:  # a piece of notation that was not translated
        raise ValueError(f"cannot translate {entry_text}")
    return parse_expr(t, local_dict=record_names)
```

The translation of a record entry into sympy, the same as in Notebook 03b but without a_4'' and b_4'', which no Christoffel symbol contains.

```
Gamma = {}  # (a, b, c) -> the value of Gamma^a_bc, with a4p, a4v, b4p, b4v
for entry in record["christoffelNonzero_b_le_c"]:
    a, b, c = (NAMES.index(entry[key]) for key in ("a", "b", "c"))
    Gamma[(a, b, c)] = from_mathematica(entry["value"])
    Gamma[(a, c, b)] = Gamma[(a, b, c)]  # the same symbol with b and c exchanged
```

The dictionary `Gamma` holds the symbols. For each of the 25 entries of the record, the three names of `a`, `b`, `c` become positions (the expression in round brackets produces three numbers, which are unpacked into `a, b, c`), the value is translated, and it is stored under both orders of the lower indices. For the 13 entries with $b = c$ both keys are the same, so the 25 entries give $13 + 2 \times 12 = 37$ keys.

```
for key in [(1, 1, 4), (4, 5, 5), (0, 1, 1), (0, 0, 0)]:
    a, b, c = key
    say(f"  Gamma^{NAMES[a]}_({NAMES[b]} {NAMES[c]}) = {Gamma[key]}")
report("entries of the record (b <= c)", len(record["christoffelNonzero_b_le_c"]))
check(len(record["christoffelNonzero_b_le_c"]) == 25 and len(Gamma) == 37,
      "the 25 entries of the record give 37 non-zero Christoffel symbols",
      record=f"{CURVATURE_RECORD}, christoffelNonzero_b_le_c")
```

Four symbols are printed in the record's own form, because the translation does not simplify:

```
  Gamma^x1_(x1 x4) = a4p
  Gamma^x4_(x5 x5) = a4p*b4v*exp(-2*a4v)*sin(6*H*x0)**(1/3) -
    b4p*exp(-2*a4v)*sin(6*H*x0)**(1/3)/2
  Gamma^x0_(x1 x1) = -H*exp(2*a4v)*sin(6*H*x0)**(1/3)/cot(6*H*x0)
  Gamma^x0_(x0 x0) = -6*H*cot(6*H*x0) - 6*H/cot(6*H*x0)
```

They are $\Gamma^{x_1}{}_{x_1x_4} = a_4'$, $\Gamma^{x_4}{}_{x_5x_5} = (a_4'b_4 - \frac{1}{2}b_4')e^{-2a_4}\sin^{1/3} z$, $\Gamma^{x_0}{}_{x_1x_1} = -H\tan z\, e^{2a_4}\sin^{1/3} z$ and $\Gamma^{x_0}{}_{x_0x_0} = -6H(\cot z + \tan z)$ (Section 3.23); the keys are positions in the author's order, `(1, 1, 4)` for $\Gamma^{x_1}{}_{x_1x_4}$ and `(0, 0, 0)` for $\Gamma^{x_0}{}_{x_0x_0}$. The RESULT line prints 25, and the check confirms the counts 25 and 37.

In [4], what stays constant (exact).

```
u = sp.symbols("u0:8", real=True)  # the velocity components u^0 ... u^7
# back to the functions a4(x4) and b4(x4)
to_function = {a4p: sp.Derivative(a4, x4), a4v: a4, b4p: sp.Derivative(b4, x4),
               b4v: b4}
acceleration = [sp.S(0)] * 8  # du^a/dtau from the geodesic equation
for (a, b, c), value in Gamma.items():
    acceleration[a] -= value.subs(to_function) * u[b] * u[c]
```

The eight velocity components $u^0, \ldots, u^7$ as symbols (`u[k]` is u^k). `to_function` turns the plain symbols back into the derivatives and the values of the functions $a_4(x_4)$ and $b_4(x_4)$, so that sympy can differentiate along the path. `acceleration` starts as eight zeros (`sp.S(0)` is sympy's zero); the loop subtracts $\Gamma^a{}_{bc} u^b u^c$ for every one of the 37 keys, which is the geodesic equation $du^a/d\tau = -\sum_{b,c} \Gamma^a{}_{bc} u^b u^c$ (the two orders of the lower indices are both in the dictionary, so the factors 2 of Section 3.31 appear by themselves).

```
def along_path(f):
    """The rate of change df/dtau of f(x, u) along a path of free fall."""
    return sum(sp.diff(f, X[k]) * u[k] + sp.diff(f, u[k]) * acceleration[k]
               for k in range(8))
```

The rate of change of a quantity $f(x, u)$ along a path of free fall, by the chain rule: $df/d\tau = \sum_a (\partial f/\partial x^a)\, u^a + \sum_a (\partial f/\partial u^a)\, du^a/d\tau$, with $du^a/d\tau$ from the geodesic equation.

```
warp = sp.sin(6 * H * x0) ** sp.Rational(1, 6)  # sin(z)^(1/6), z = 6 H x0
# the eight scale factors h_a in the author's order x0, x1, ..., x7
h = [sp.cot(6 * H * x0)] + [sp.exp(a4) * warp] * 3 + [sp.Integer(1)] \
    + [sp.sqrt(b4) * sp.exp(-a4) * warp] * 3
ETA = [1, 1, 1, 1, -1, -1, -1, -1]  # the signs of the metric entries
g = [ETA[k] * h[k] ** 2 for k in range(8)]  # the diagonal of the metric
say(f"du1/dtau = {sp.factor(acceleration[1]).subs(sp.Derivative(a4, x4), a4p)}")
```

The warp factor, the eight scale factors in the author's order (Section 3.7: $h_0 = \cot z$ first, then three times $e^{a_4} W$, 1 and three times $b_4^{1/2} e^{-a_4} W$), the signs, and the diagonal $g_{aa} = \eta_{aa} h_a^2$. The printed line is the geodesic equation for u^1 (`acceleration[1]`), factored: `-2*u1*(H*u0*cot(6*H*x0) + a4p*u4)`, the equation for u^i of Section 3.31.

```
momenta = {k: g[k] * u[k] for k in (1, 2, 3, 5, 6, 7)}  # p_a = g_aa u^a
rates = [sp.simplify(along_path(p)) for p in momenta.values()]
check(rates == [0] * 6,
      "the six momenta of x1, x2, x3, x5, x6, x7 are conserved in free fall")
squared_length = sum(g[k] * u[k] ** 2 for k in range(8))  # g(u, u)
check(sp.simplify(along_path(squared_length)) == 0,
      "the squared length g(u, u) of the velocity is conserved in free fall")
```

The six momenta $p_k = g_{kk} u^k$, at the positions 1, 2, 3, 5, 6, 7; their rates along the path simplify to zero (first check). The squared speed $g(u, u) = \sum_a g_{aa} (u^a)^2$; its rate simplifies to zero (second check). Both hold for all functions $a_4(x_4)$ and $b_4(x_4)$.

In [5], the momentum weight of the Kohn-Sham record.

```
KS_THEORY = "Revision/kohn_sham/ks-theory.json"
ks_theory = json.loads(repository_file(KS_THEORY).read_text(encoding="utf-8"))
say("record, geometry.kappa: " + ks_theory["geometry"]["kappa"])
y_of_x0 = sp.log(sp.sin(6 * H * x0)) / (6 * H)  # the hidden coordinate y
kappa = sp.exp(-H * y_of_x0 - a4)  # the record's e^{-Hy - a4(x4)}
```

The Kohn-Sham theory record is read and its statement about the momentum weight printed: kappa(y, x4) = e^{-Hy - a4(x4)} (the momentum weight). Then y as a function of x_0 (Section 3.9) and the weight $\kappa = e^{-Hy-a_4}$.

```
check(sp.simplify(1 / h[1] - kappa) == 0,
      "1/h1 = e^(-H y - a4): the frame velocity in 3-space is p1 times kappa",
      record=f"{KS_THEORY}, geometry.kappa")
check(sp.simplify(1 / h[5] - sp.exp(a4 - H * y_of_x0) / sp.sqrt(b4)) == 0,
      "1/h5 = b4^(-1/2) e^(a4 - H y): the frame velocity along an extra time grows "
      "with a4")
```

Two checks of Section 3.31: $1/h_1 = \kappa(y, x_4)$, so $\hat{u}^1 = p_1/h_1 = p_1\kappa(y, x_4)$; and $1/h_5 = b_4^{-1/2}e^{a_4-Hy}$, so $\hat{u}^5 = -p_5 b_4^{-1/2}e^{a_4-Hy}$.

In [6], the push, the slowing, and $(u^4)^2$ (exact).

```
frame = [h[k] * u[k] for k in range(8)]  # the frame velocities u-hat^a = h_a u^a
space_squared = sum(frame[k] ** 2 for k in (1, 2, 3))  # 3-space part
extra_squared = sum(frame[k] ** 2 for k in (5, 6, 7))  # extra-time part
push = along_path(frame[0]) - H * (space_squared - extra_squared)
check(sp.simplify(push) == 0,
      "d^2y/dtau^2 = H (3-space frame velocity squared - extra-time one squared)")
```

The frame velocities $\hat{u}^a = h_a u^a$, the sums S (positions 1, 2, 3) and E (positions 5, 6, 7) of Section 3.31, and the difference between the rate of $\hat{u}^0 = dy/d\tau$ (`frame[0]`) and the push law $H(S - E)$, which simplifies to zero.

```
alpha_t = -sp.diff(a4, x4) + sp.diff(b4, x4) / (2 * b4)  # the extra-time rate
slowing = (along_path(u[4]) + sp.diff(a4, x4) * space_squared
           - alpha_t * extra_squared)
check(sp.simplify(slowing) == 0,
      "du4/dtau = -a4' (3-space frame velocities squared) + alpha_t (extra-time ones "
      "squared)")
in_frame = frame[0] ** 2 + space_squared - u[4] ** 2 - extra_squared
check(sp.simplify(squared_length - in_frame) == 0,
      "g(u, u) written with the frame velocities")
```

`alpha_t` is the extra-time rate $\alpha_t = -a_4' + b_4'/(2b_4)$, written with the functions. The law $du^4/d\tau = -a_4'S + \alpha_t E$ for the velocity `u[4]`, and $g(u, u) = (\hat{u}^0)^2 + S - (u^4)^2 - E$, both checked exactly, for all functions a_4 and b_4.

In [7], the quadratic form of the plane-wave check.

```
SCOPE = "Revision/theory/reports/python-scope.json"
scope = json.loads(repository_file(SCOPE).read_text(encoding="utf-8"))
growth = next(entry for entry in scope["checks"]
              if entry["name"] == "extra_time_growth_rates_unbounded")
form_text = growth["detail"].split("h_k^2 = (")[1].split(") I16")[0]  # the formula
say(f"record ({growth['verdict']}): E^2 = {form_text}")
```

The scope report is read and its check `extra_time_growth_rates_unbounded` taken from its list of checks. Its text contains the piece `h_k^2 = (` followed by the quadratic form and `) I16` (times the 16×16 unit matrix); the two `split` calls cut out the form between them. The output prints `PASS` and the form $k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2 + m^2$.

```
k = sp.symbols("k0:8", real=True)  # frame momenta k0 ... k7 (k4 is not used)
m = sp.symbols("m", positive=True)  # the mass
form = parse_expr(form_text, local_dict={**{f"k{n}": k[n] for n in range(8)},
                                         "m": m})
U = sp.symbols("U0:8", real=True)  # the frame velocities as plain symbols
particle = m ** 2 * (1 + U[0] ** 2 + U[1] ** 2 + U[2] ** 2 + U[3] ** 2 - U[5] ** 2
                     - U[6] ** 2 - U[7] ** 2)  # m^2 (u^4)^2 from section 8
```

The form is read with the momenta $k_0, \ldots, k_7$ and the mass m as symbols (the name `k{n}` of the text means `k[n]`); `{**{...}, "m": m}` builds one dictionary from a dictionary comprehension (unpacked by `**`) and one more entry. `particle` is $m^2(u^4)^2$ from the formula of Section 3.31, with the frame velocities as plain symbols $U_0, \ldots, U_7$.

```
same_form = sp.expand(form.subs({k[n]: m * U[n] for n in range(8)}) - particle)
check(growth["verdict"] == "PASS" and same_form == 0,
      "m^2 (u4)^2 of the particle is the plane-wave E^2 of the record",
      record=f"{SCOPE}, check extra_time_growth_rates_unbounded")
```

With $k_a = m\hat{u}^a$ put into the record's form, the difference from $m^2(u^4)^2$ multiplies out to zero; the check also requires the record's verdict PASS.

In [8], the numerical tools.

```
import math  # sin, tan, exp, ... for single numbers (faster than numpy here)

PARAMETERS = "Revision/kohn_sham/results/parameters.json"
physics = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))
H_value, A_value = physics["physics"]["H"], physics["physics"]["historyA"]
status = ks_theory["adiabaticity"]["historyStatus"]
say(f"H = {H_value}, A = {A_value}; record: " + status.split(". ")[0] + ".")
```

The module `math` computes functions of single numbers, faster than numpy for one number at a time. The parameters of the Revision Kohn-Sham solver give $H = 1$ and the slope $A = 1$; the first sentence of the record's statement on the status of the history is printed: PRESCRIBED BACKGROUND: the history a4 = A H x4 is prescribed, not solved for.

```
check(H_value == 1.0 and A_value == 1.0 and status.startswith("PRESCRIBED BACKGROUND"),
      "the history of the record: a4 = A H x4 with A = 1, H = 1, prescribed",
      record=f"{PARAMETERS}, physics.H and physics.historyA; {KS_THEORY}, "
             "adiabaticity.historyStatus")
ARGUMENTS = (a4v, a4p, x0, H, b4v, b4p)
gamma_numbers = [(a, b, c, sp.lambdify(ARGUMENTS, value, "math"))
                 for (a, b, c), value in sorted(Gamma.items())]
ETA_N = np.array(ETA, dtype=float)  # the signs as numbers
```

The check confirms the history and its status. `gamma_numbers` is a list of the 37 symbols as fast numerical functions of $(a_4, a_4', x_0, H, b_4, b_4')$, each with its three indices (`"math"` makes functions of single numbers). `ETA_N` holds the signs as floating-point numbers.

```
def free_fall(state):
    """d state/d tau for state = (x0..x7, u0..u7) on the history a4 = A H x4,
    b4 = 1."""
    x, v = state[:8], state[8:]
    a4_now, rate = A_value * H_value * x[4], A_value * H_value  # a4 and a4'
    change = np.zeros(8)
    for a, b, c, f in gamma_numbers:  # du^a/dtau = - sum Gamma^a_bc u^b u^c
        change[a] -= f(a4_now, rate, x[0], H_value, 1.0, 0.0) * v[b] * v[c]
    return np.concatenate([v, change])
```

The right side of the 16 equations: the state holds the 8 coordinates (`state[:8]`, entry k is x^k) and the 8 velocities (`state[8:]`, entry $8+k$ of the state is u^k). On the history, $a_4 = AHx_4$ with x_4 = `x[4]`, $a_4' = AH$, $b_4 = 1$ and $b_4' = 0$ (the numbers `1.0, 0.0` in the call), and x_0 = `x[0]`. The accelerations are summed over the 37 symbols, and the function returns the derivatives of the state: the velocities, then the accelerations (`np.concatenate` joins two arrays).

```
def rk4_path(state0, tau_end, steps):
    """RK4 from tau = 0 to tau_end; returns the times and the states (rows)."""
    dt = tau_end / steps
    states = np.zeros((steps + 1, 16))
    states[0] = state0
    for n in range(steps):
        s = states[n]
        k1 = free_fall(s)
        k2 = free_fall(s + dt / 2 * k1)
        k3 = free_fall(s + dt / 2 * k2)
        k4 = free_fall(s + dt * k3)
        states[n + 1] = s + dt / 6 * (k1 + 2 * k2 + 2 * k3 + k4)
    return np.linspace(0.0, tau_end, steps + 1), states
```

The RK4 method of Chapter 2 (the same as in Notebook 03c, Section 3.22, In [8]) for the 16 unknowns, from $\tau = 0$ to `tau_end` in `steps` equal steps; it returns the times and the table of states.

```
def scale_numbers(x):
    """The eight scale factors h_a at the point x on the history (numbers)."""
    a4_now, z_now = A_value * H_value * x[4], 6 * H_value * x[0]
    w = math.sin(z_now) ** (1 / 6)  # the warp factor sin(z)^(1/6)
```

```
    return np.array([1 / math.tan(z_now)] + [math.exp(a4_now) * w] * 3 + [1.0]
                    + [math.exp(-a4_now) * w] * 3)  # with b4 = 1
```

The eight scale factors as numbers at a point on the history, in the author's order and with $b_4 = 1$.

```
def start(y0, frame_velocity):
    """The state at tau = 0: x4 = 0, y = y0, frame velocities as given (the entry
    for x4 is replaced by the value that makes g(u, u) = -1)."""
    x = np.zeros(8)
    x[0] = math.asin(math.exp(6 * H_value * y0)) / (6 * H_value)  # sin z = e^(6Hy)
    w = np.array(frame_velocity, dtype=float)
    w[4] = 0.0
    w[4] = math.sqrt(1.0 + np.sum(ETA_N * w ** 2))  # (u^4)^2 = 1 + sum eta w^2
    return np.concatenate([x, w / scale_numbers(x)])  # u^a = u-hat^a / h_a
```

The starting state: all coordinates zero except x_0, which is set from the height y_0 by $\sin z = e^{6Hy_0}$. The frame velocities are given in the author's order; the entry for x_4 (`w[4]`) is first set to zero, and then to $\sqrt{1 + \sum_a \eta_{aa} (\hat{u}^a)^2}$, which is the formula $(u^4)^2 = 1 + (\hat{u}^0)^2 + S - E$ of Section 3.31, so that $g(u, u) = -1$. The velocities are $u^a = \hat{u}^a / h_a$.

```
def describe(states):
    """Frame velocities (rows), the coordinate y and g(u, u) along a path."""
    h_rows = np.array([scale_numbers(s[:8]) for s in states])
    frame_rows = h_rows * states[:, 8:]
    y_values = np.log(np.sin(6 * H_value * states[:, 0])) / (6 * H_value)
    lengths = np.sum(ETA_N * frame_rows ** 2, axis=1)  # g(u, u)
    return frame_rows, y_values, lengths, h_rows
```

For every computed state: the scale factors, the frame velocities $\hat{u}^a = h_a u^a$ (a product of two tables entry by entry), the height y from x_0 (column 0), and $g(u, u) = \sum_a \eta_{aa} (\hat{u}^a)^2$ (`axis=1` sums along each row).

```
Y0 = -1.0  # the starting height of every particle
say(f"start: y0 = {Y0}, z0 = {math.asin(math.exp(6 * Y0)):.6f}")
```

Every particle starts at $y = -1$, that is $z = \arcsin e^{-6} = 0.002479$, as printed.

In [9], the particle at rest.

```
tau, rest = rk4_path(start(Y0, [0.0] * 8), 3.0, 3000)
others = [0, 1, 2, 3, 5, 6, 7]  # every coordinate except x4
moved = np.max(np.abs(rest[:, others] - rest[0, others]))
check(moved == 0.0 and np.max(np.abs(rest[:, 4] - tau)) < 1e-12
      and np.max(np.abs(rest[:, 12] - 1.0)) < 1e-12,
      "the particle at rest stays at rest and x4 equals its proper time")
```

A particle with all frame velocities zero (so $u^4 = 1$) is followed from $\tau = 0$ to 3 in 3000 steps. `rest[:, others]` is the table of the seven other coordinates; their largest change is exactly zero,

because every acceleration contains a factor $u^b u^c$ with a zero velocity (no symbol $\Gamma^a{}_{x_4 x_4}$ exists, Section 3.23). The check also requires $x_4 = \tau$ (column 4) and $u^4 = 1$ (column 12 of a state is u^4: 8 coordinates come first) within 10^{-12}.

In [10], three particles moving in 3-space.

```
SPEEDS = (0.25, 0.5, 1.0)  # starting frame velocities along x1
space_paths = {}
for speed in SPEEDS:
    tau, states = rk4_path(start(Y0, [0, speed, 0, 0, 0, 0, 0, 0]), 3.0, 3000)
    frame_rows, y_values, lengths, h_rows = describe(states)
    p1 = h_rows[:, 1] ** 2 * states[:, 9]  # p_1 = g_11 u^1 = h_1^2 u^1
    weight = np.exp(-H_value * y_values - A_value * H_value * states[:, 4])  # kappa
    space_paths[speed] = (states, frame_rows, y_values, lengths, p1)
```

For each starting frame velocity along x_1 (entry 1 of the list) the path from $\tau = 0$ to 3 in 3000 steps, its description, the momentum $p_1 = h_1^2 u^1$ along the path (column 9 is u^1), and the momentum weight $\kappa = e^{-Hy - a_4}$; everything is stored under the speed.

```
    check(np.max(np.abs(p1 / p1[0] - 1)) < 1e-9
          and np.max(np.abs(lengths + 1)) < 1e-9
          and np.max(np.abs(frame_rows[:, 1] - p1[0] * weight)) < 1e-9
          and np.all(np.diff(states[:, 12]) < 0) and np.all(y_values < 0),
          f"3-space speed {speed}: p1 and g(u, u) conserved, frame velocity "
          "p1 kappa, u4 falls")
```

One check per particle with five conditions: p_1 constant within a relative 10^{-9}; $g(u,u) = -1$ within 10^{-9}; the frame velocity equals $p_1 \kappa(y, x_4)$ within 10^{-9}; u^4 decreases at every step (`np.diff` gives the differences of successive values); the particle stays inside the patch ($y < 0$).

```
states, frame_rows, y_values, lengths, p1 = space_paths[1.0]
report("fastest particle at tau = 3: x4", f"{states[-1, 4]:.4f}")
report("fastest particle at tau = 3: frame velocity along x1",
       f"{frame_rows[-1, 1]:.6f}")
report("fastest particle at tau = 3: u4", f"{states[-1, 12]:.6f}")
report("fastest particle at tau = 3: height y", f"{y_values[-1]:.4f}")
```

Four RESULT lines for the fastest particle at $\tau = 3$: $x_4 = 3.3070$ (its clock has run 3 while x_4 advanced by more), $\hat{u}^1 = 0.014370$ (down from 1), $u^4 = 1.060733$ (down from $\sqrt{2} = 1.414$), $y = -0.0643$ (risen from -1 almost to the patch end).

In [11], the particle moving along an extra time.

```
tau_t, extra = rk4_path(start(Y0, [0, 0, 0, 0, 0, 0.2, 0, 0]), 2.5, 2500)
frame_t, y_t, lengths_t, h_t = describe(extra)
p5 = -h_t[:, 5] ** 2 * extra[:, 13]  # p_5 = g_55 u^5 = -h_5^2 u^5
check(np.max(np.abs(p5 / p5[0] - 1)) < 1e-8 and np.max(np.abs(lengths_t + 1)) < 1e-7
      and np.all(np.diff(extra[:, 12]) < 0),
      "extra-time particle: p5 and g(u, u) conserved, u4 decreases at every step")
```

A particle started with $\hat{u}^5 = 0.2$ (entry 5 of the list), so $u^4 = \sqrt{1 - 0.04} = 0.980$, followed from $\tau = 0$ to 2.5 in 2500 steps. Its momentum $p_5 = -h_5^2 u^5$ (column 13 is u^5) stays constant within a relative 10^{-8}, $g(u, u)$ stays -1 within 10^{-7}, and u^4 decreases at every step.

```
n_turn = int(np.argmax(extra[:, 12] < 0))  # the first step with u4 < 0
x4_max = float(np.max(extra[:, 4]))  # the largest x4 of the path
report("turning point: proper time tau", f"{tau_t[n_turn]:.3f}")
report("turning point: largest x4 reached", f"{x4_max:.4f}")
report("turning point: frame velocity along x5", f"{frame_t[n_turn, 5]:.4f}")
report("turning point: frame velocity along y", f"{frame_t[n_turn, 0]:.4f}")
```

`extra[:, 12] < 0` is a list of `True` and `False`, one per step; `np.argmax` of it is the position of the first `True`, the first step with $u^4 < 0$: the turning point, to within one step. Four RESULT lines: $\tau = 1.987$, the largest $x_4 = 1.4864$, $\hat{u}^5 = 1.4013$ (column 5 of `frame_t`), $\hat{u}^0 = -0.9817$ (column 0).

```
balance = frame_t[n_turn, 5] ** 2 - frame_t[n_turn, 0] ** 2 - 1  # 0 when u4 = 0
check(0 < n_turn and abs(balance) < 1e-4 and extra[-1, 4] < x4_max,
      "at the turning point (u5 hat)^2 - (u0 hat)^2 = 1, and x4 decreases afterwards")
say("record, sectorAndAnsatz.sector: " + ks_theory["sectorAndAnsatz"]["sector"])
check("extra-time momenta zero" in ks_theory["sectorAndAnsatz"]["sector"],
      "the good sector of the Kohn-Sham record has no extra-time momenta",
      record=f"{KS_THEORY}, sectorAndAnsatz.sector")
```

At the turning point $(\hat{u}^5)^2 - (\hat{u}^0)^2 = 1$ (Section 3.31; within 10^{-4}, because the step found is the first after the sign change), and the last x_4 of the path is smaller than the largest. Then the record's definition of the good sector is printed and checked to contain "extra-time momenta zero" (Section 3.31).

In [12], Figure 03d.1: redshift and blueshift.

```
BLUE, ORANGE, AQUA, YELLOW = "#2a78d6", "#eb6834", "#1baf7a", "#eda100"
MAGENTA, GREEN, VIOLET, RED = "#e87ba4", "#008300", "#4a3aa7", "#e34948"
COLOURS = {0.25: AQUA, 0.5: ORANGE, 1.0: RED}  # one colour per 3-space particle
fig, axes = plt.subplots(1, 2, figsize=(10.5, 4.3))
fig.subplots_adjust(wspace=0.3)  # room for the label of the right vertical axis
```

The palette, one colour per 3-space particle, and a figure with two panels.

```
for speed in SPEEDS:
    states, frame_rows = space_paths[speed][0], space_paths[speed][1]
    axes[0].plot(states[:, 4], frame_rows[:, 1], color=COLOURS[speed], lw=1.8,
                 label=f"RK4, start {speed:g}")
    axes[0].plot(states[:, 4], speed * np.exp(-A_value * H_value * states[:, 4]),
                 ":", color=COLOURS[speed], lw=1.4)
axes[0].plot([], [], ":", color="grey", label="pure redshift $e^{-a_4}$")
```

For each 3-space particle its frame velocity $\hat{u}^1$ against x_4 (solid) and the pure redshift $\hat{u}^1(0)e^{-a_4}$ that it would have at a fixed height (dotted). `axes[0].plot([], [], ...)` draws nothing; it only adds one grey dotted entry to the legend for all three dotted lines.

```
axes[0].set_yscale("log")
axes[0].set_xlabel("time $x_4$ (unit $1/H$), history $a_4 = x_4$, $b_4 = 1$")
axes[0].set_ylabel("frame velocity $\\hat u^1$ along $x_1$")
axes[0].set_title("3-space: redshift")
axes[0].legend(fontsize=8)
before = slice(0, n_turn)  # the states before the turning point
axes[1].plot(extra[before, 4], frame_t[before, 5], color=VIOLET, lw=1.8,
             label="RK4, start 0.2")
axes[1].plot(extra[before, 4], 0.2 * np.exp(A_value * H_value * extra[before, 4]),
             ":", color=VIOLET, lw=1.4, label="pure blueshift $0.2\\,e^{a_4}$")
```

A logarithmic axis and labels for the left panel. `slice(0, n_turn)` selects the rows before the turning point (after it x_4 runs backwards, and the curve would fold back). The right panel: $\hat{u}^5$ against x_4 and the pure blueshift $0.2e^{a_4}$.

```
axes[1].axvline(x4_max, color="grey", lw=1.0, ls="--", label="turning point")
axes[1].set_yscale("log")
axes[1].set_xlabel("time $x_4$ (unit $1/H$), history $a_4 = x_4$, $b_4 = 1$")
axes[1].set_ylabel("frame velocity $\\hat u^5$ along $x_5$")
axes[1].set_title("Extra time: blueshift")
axes[1].legend(fontsize=8, loc="upper left")
save_figure(fig, "frame_velocities",
            "Frame velocities of freely falling test particles in the author's metric "
...
check(frame_t[n_turn - 1, 5] > 0.2 * math.exp(extra[n_turn - 1, 4]),
      "the extra-time frame velocity grows faster than the pure blueshift")
```

A dashed line at the largest x_4, the logarithmic axis, labels and legend; the figure is saved (its caption contains the turning point $x_4 = 1.486$ through an f-string). The check: just before the turning point, $\hat{u}^5$ exceeds the pure blueshift.

What Figure 03d.1 shows. Along the history with $b_4 = 1$. Left: on the logarithmic axis the three frame velocities fall almost like straight lines of slope -1, the redshift e^{-a_4}; they fall a little faster than the dotted lines, most visibly for the fastest particle, because the particles rise towards the patch end where the warp factor e^{Hy} is larger and $\kappa(y, x_4) = e^{-Hy-a_4}$ smaller. Right: the frame velocity along x_5 grows from 0.2, first like the pure blueshift $0.2e^{a_4}$, then faster, because the particle sinks towards the tip where e^{-Hy} is larger; at the dashed line it reaches its turning point.

In [13], Figure 03d.2: the x_4 velocity and the time x_4.

```
fig, axes = plt.subplots(1, 2, figsize=(10.5, 4.3))
fig.subplots_adjust(wspace=0.3)
axes[0].plot(tau, rest[:, 12], color="black", lw=1.4, ls="--", label="at rest")
axes[1].plot(tau, rest[:, 4], color="black", lw=1.4, ls="--", label="at rest")
for speed in SPEEDS:
    states = space_paths[speed][0]
    axes[0].plot(tau, states[:, 12], color=COLOURS[speed], lw=1.8,
                 label=f"3-space, start {speed:g}")
    axes[1].plot(tau, states[:, 4], color=COLOURS[speed], lw=1.8,
                 label=f"3-space, start {speed:g}")
```

Two panels against the proper time τ: u^4 on the left, x_4 on the right; first the particle at rest (dashed black), then the three 3-space particles.

```
axes[0].plot(tau_t, extra[:, 12], color=VIOLET, lw=1.8, ls="-.",
             label="extra time, start 0.2")
axes[1].plot(tau_t, extra[:, 4], color=VIOLET, lw=1.8, ls="-.",
             label="extra time, start 0.2")
axes[0].axhline(0.0, color="grey", lw=0.8)
axes[0].plot([tau_t[n_turn]], [0.0], "o", color=VIOLET, ms=7)  # the turning point
axes[1].plot([tau_t[n_turn]], [x4_max], "o", color=VIOLET, ms=7)
```

The extra-time particle (dash-dotted), the zero line, and a dot at the turning point in each panel.

```
axes[0].set_ylabel("$x_4$ velocity $u^4 = dx_4/d\\tau$")
axes[1].set_ylabel("time $x_4$ (unit $1/H$)")
axes[0].set_title("The $x_4$ velocity can only decrease")
axes[1].set_title("The time $x_4$ along each path")
for ax, place in zip(axes, ("lower left", "upper left")):  # legends off the lines
    ax.set_xlabel("proper time $\\tau$ of the particle (unit $1/H$)")
    ax.legend(fontsize=8, loc=place)
save_figure(fig, "x4_velocity",
            "The $x_4$ velocity $u^4 = dx_4/d\\tau$ (left) and the time $x_4$ "
...
check(np.all(np.diff(space_paths[1.0][0][:, 4]) > 0),
      "the particles in 3-space keep advancing in x4")
```

Labels and titles; the loop gives both panels their horizontal label and a legend placed where no curve runs. The figure is saved; the check confirms that the fastest 3-space particle advances in x_4 at every step.

What Figure 03d.2 shows. Left: the particle at rest keeps $u^4 = 1$; the 3-space particles start above 1 and settle down towards 1 as their motion is redshifted away; the extra-time particle starts at 0.98 and its u^4 falls ever faster, through zero at the dot ($\tau = 1.99$) and on to negative values. Right: x_4 grows steadily for the first four particles, while for the extra-time particle it reaches a largest value, 1.486, and then decreases.

In [14], Figure 03d.3: the push along the hidden direction.

```
L_tip = physics["physics"]["L_tipCutoff"]  # the tip cut-off of the record, 3/H
fig, axes = plt.subplots(1, 2, figsize=(10.5, 4.3))
fig.subplots_adjust(wspace=0.3)
axes[0].plot(tau, np.full_like(tau, Y0), color="black", lw=1.4, ls="--",
             label="at rest")
for speed in SPEEDS:
    axes[0].plot(tau, space_paths[speed][2], color=COLOURS[speed], lw=1.8,
                 label=f"3-space, start {speed:g}")
axes[0].plot(tau_t, y_t, color=VIOLET, lw=1.8, ls="-.", label="extra time, start 0.2")
```

The tip cut-off $L = 3$ of the record (Section 3.9), a figure with two panels, and in the left panel the height y of every particle against τ (the particle at rest stays at $y = -1$, drawn with `np.full_like`).

```
axes[0].axhline(0.0, color="grey", lw=1.0, label="patch end $y = 0$")
axes[0].axhline(-L_tip, color="grey", lw=1.0, ls=":", label="tip cut-off $y = -3$")
axes[0].set_xlabel("proper time $\\tau$ (unit $1/H$)")
axes[0].set_ylabel("height $y$ in the hidden direction (unit $1/H$)")
axes[0].set_title("Rising and sinking along $y$")
axes[0].legend(fontsize=7, loc="lower left")
largest_gap = 0.0
```

Horizontal lines at the patch end and at the tip cut-off, labels, title and legend. `largest_gap` will collect the largest disagreement found below.

```
for (t_values, frame_rows), colour, label in (
        ((tau, space_paths[1.0][1]), RED, "3-space, start 1"),
        ((tau_t, frame_t), VIOLET, "extra time, start 0.2")):
    law = H_value * (np.sum(frame_rows[:, 1:4] ** 2, axis=1)
                     - np.sum(frame_rows[:, 5:8] ** 2, axis=1))
    numeric = np.gradient(frame_rows[:, 0], t_values)  # d(u0 hat)/dtau
    largest_gap = max(largest_gap, float(np.max(np.abs(numeric - law)[1:-1])))
```

For the fastest 3-space particle and the extra-time particle: the push law $H(S - E)$ at every computed state (`frame_rows[:, 1:4]` are the three 3-space columns 1, 2, 3, `frame_rows[:, 5:8]` the three extra-time columns 5, 6, 7), and the acceleration $d\hat{u}^0/d\tau$ (column 0) obtained from the computed states by `np.gradient`, which takes central differences inside the path and one-sided differences at its two ends. The largest difference inside the path (`[1:-1]` leaves out the two ends, where the one-sided differences are less accurate) is kept.

```
    axes[1].plot(t_values, law, color=colour, lw=1.8, label=f"law, {label}")
    axes[1].plot(t_values[::100], numeric[::100], "o", color=colour, ms=5,
                 label=f"from RK4, {label}")
axes[1].axhline(0.0, color="grey", lw=0.8)
axes[1].set_xlabel("proper time $\\tau$ (unit $1/H$)")
axes[1].set_ylabel("$d^2y/d\\tau^2$ (unit $H$)")
axes[1].set_title("The push: $H$ times the difference of squares")
axes[1].legend(fontsize=7, loc="lower left")
```

The law as a line and every hundredth numerical value as a dot (`[::100]` takes every hundredth element); the zero line, labels, title and legend.

```
report("largest difference between the numerical acceleration and the law",
       f"{largest_gap:.1e}")
save_figure(fig, "hidden_push",
            "The push along the hidden direction on freely falling test particles in "
...
check(largest_gap < 1e-4,
      "the computed acceleration of y agrees with the exact push law")
```

The RESULT line prints 3.4×10^{-6}, the error of the numerical derivative; the figure is saved, and the check requires agreement within 10^{-4}.

What Figure 03d.3 shows. Left: the 3-space particles rise towards the patch end $y = 0$, the faster the higher (the fastest reaches -0.06); the particle at rest stays at $y = -1$; the extra-time particle sinks towards the tip, ever faster, to about -2.3 at $\tau = 2.5$, still above the cut-off $y = -3$. Right: the dots computed from the paths lie on the lines of the exact law; the push is positive and dies away for the 3-space particle (its frame velocity is redshifted), negative and growing for the extra-time particle (its frame velocity is blueshifted).

In [15], Figure 03d.4: the quadratic form as a map.

```
grid5, grid0 = np.meshgrid(np.linspace(0.0, 3.0, 301), np.linspace(-3.0, 0.5, 351))
squared_u4 = 1 + grid0 ** 2 - grid5 ** 2  # (u^4)^2 over the plane
fig, ax = plt.subplots(figsize=(6.4, 5.2))
ax.contourf(grid5, grid0, squared_u4, levels=[-100.0, 0.0], colors=["#d9d9d9"])
ax.contour(grid5, grid0, squared_u4, levels=[0.0], colors="black", linewidths=1.2)
```

A grid of frame velocities, $\hat{u}^5$ from 0 to 3 (`grid5`) and $\hat{u}^0$ from -3 to 0.5 (`grid0`), and on it $(u^4)^2 = 1 + (\hat{u}^0)^2 - (\hat{u}^5)^2$, the formula of Section 3.31 for a particle that moves only along x_5 and y. `contourf` with the levels -100 and 0 fills in grey the region where the value is negative; `contour` at the level 0 draws the black boundary curve $(\hat{u}^5)^2 = 1 + (\hat{u}^0)^2$.

```
ax.plot(frame_t[:, 5], frame_t[:, 0], color=VIOLET, lw=2.0,
        label="path of the extra-time particle")
ax.plot([frame_t[0, 5]], [frame_t[0, 0]], "s", color=VIOLET, ms=7, label="start")
ax.plot([frame_t[n_turn, 5]], [frame_t[n_turn, 0]], "o", color=VIOLET, ms=8,
        label="turning point, $u^4 = 0$")
ax.text(2.05, 0.15, "$(u^4)^2 < 0$:\nno particle;\nplane waves grow", fontsize=8)
ax.text(0.3, -1.2, "$(u^4)^2 > 0$", fontsize=9)
```

The path of the extra-time particle in this plane (columns 5 and 0 of `frame_t`), a square at its start, a dot at its turning point, and two labels written into the regions (`\n` starts a new line of the label).

```
ax.set_xlabel("frame velocity $\\hat u^5$ along the extra time $x_5$")
ax.set_ylabel("frame velocity $\\hat u^0 = dy/d\\tau$")
ax.set_title("The quadratic form $(u^4)^2 = 1 + (\\hat u^0)^2 - (\\hat u^5)^2$")
ax.grid(False)
ax.legend(fontsize=8, loc="lower left")
save_figure(fig, "quadratic_form",
            "The squared $x_4$ velocity $(u^4)^2 = 1 + (\\hat u^0)^2 - (\\hat u^5)^2$ "
...
check(np.all(1 + frame_t[:, 0] ** 2 - frame_t[:, 5] ** 2 > -1e-6),
      "the path never enters the region where (u4)^2 < 0")
```

Labels, title, no grid lines, legend; the figure is saved; the check: along the whole path $(u^4)^2 > -10^{-6}$ (zero up to rounding at the turning point).

What Figure 03d.4 shows. The violet path starts at $(0.2, 0)$, moves to the right (blueshift) and downwards (it sinks, $dy/d\tau < 0$), touches the black curve at the turning point and then runs back into the white region, without ever entering the grey one. In the grey region the plane waves of the record's check would grow instead of oscillating; the particle avoids it by turning in x_4.

In [16], Figure 03d.5: how accurate the computation is.

```
from matplotlib.ticker import NullFormatter  # an empty label for minor ticks

p1_fast = space_paths[1.0][4]  # p_1 along the fastest 3-space path
drift = {"$p_1$, 3-space particle": (tau, np.abs(p1_fast / p1_fast[0] - 1)),
         "$g(u,u) + 1$, 3-space particle": (tau, np.abs(space_paths[1.0][3] + 1)),
         "$p_5$, extra-time particle": (tau_t, np.abs(p5 / p5[0] - 1)),
         "$g(u,u) + 1$, extra-time particle": (tau_t, np.abs(lengths_t + 1))}
```

`NullFormatter` is used below to suppress the labels of small ticks. `drift` is a dictionary of four curves, each a label with its times and the drift of a conserved quantity from its starting value: p_1 and $g(u,u)+1$ for the fastest 3-space particle, p_5 and $g(u,u)+1$ for the extra-time particle.

```
STEPS = (50, 100, 200, 400, 800, 1600)
differences = {}
for label, state0 in (("3-space, start 1", start(Y0, [0, 1, 0, 0, 0, 0, 0, 0])),
                      ("extra time, start 0.2", start(Y0, [0, 0, 0, 0, 0, 0.2, 0, 0]))):
    ends = [rk4_path(state0, 2.0, n)[1][-1] for n in STEPS]
    differences[label] = np.array([np.max(np.abs(ends[i] - ends[i + 1]))
                                   for i in range(len(STEPS) - 1)])
    ratios = differences[label][:-1] / differences[label][1:]
    say(f"  {label}: ratios of successive differences "
        + ", ".join(f"{r:.1f}" for r in ratios))
```

The order of RK4: each of the two particles is integrated from $\tau = 0$ to 2 with 50, 100, 200, 400, 800 and 1600 steps; `ends` holds the six end states (`[1][-1]` is the last row of the table of states). `differences` holds the five largest differences between the end states of successive step counts, and `ratios` the four ratios of successive differences, printed: 17.1, 16.6, 16.3, 16.2 and 17.2, 16.7, 16.3, 16.2. For a method of order 4 halving the step divides the error by about $2^4 = 16$ (Chapter 2).

```
fig, axes = plt.subplots(1, 2, figsize=(10.5, 4.3))
fig.subplots_adjust(wspace=0.3)
for (label, (t_values, values)), colour, style in zip(
        drift.items(), (RED, ORANGE, VIOLET, AQUA), ("-", "--", "-.", ":")):
    axes[0].semilogy(t_values[1:], np.maximum(values[1:], 1e-17), color=colour,
                     ls=style, lw=1.6, label=label)
axes[0].set_xlabel("proper time $\\tau$ (unit $1/H$)")
axes[0].set_ylabel("relative drift from the start")
axes[0].set_title("Conserved quantities, RK4 with step $0.001$")
axes[0].legend(fontsize=7, loc="lower right")
```

The left panel draws the four drifts on a logarithmic axis (`semilogy`); the first point ($\tau = 0$, where the drift is exactly zero) is left out, and `np.maximum(values, 1e-17)` replaces any other exact zero by 10^{-17}, because a logarithmic axis cannot show zero.

```
dts = 2.0 / np.array(STEPS[:-1])  # the larger step of each pair
for (label, values), colour in zip(differences.items(), (RED, VIOLET)):
    axes[1].loglog(dts, values, "o-", color=colour, lw=1.6, label=label)
axes[1].loglog(dts, differences["extra time, start 0.2"][0] * (dts / dts[0]) ** 4,
               "--", color="black", lw=1.0, label="slope 4")
axes[1].set_xticks(dts, [f"{dt:g}" for dt in dts])  # the five steps as labels
axes[1].xaxis.set_minor_formatter(NullFormatter())  # no labels between them
```

The right panel: the differences against the larger step $\Delta\tau$ of each pair (0.04, 0.02, 0.01, 0.005 and 0.0025), on logarithmic axes, with a dashed reference line of slope 4; the five steps are written at the ticks, and the small ticks between them get no labels.

```
axes[1].set_xlabel("step $\\Delta\\tau$ of RK4")
axes[1].set_ylabel("difference of end states (step and half step)")
axes[1].set_title("RK4 is of order 4")
axes[1].legend(fontsize=8)
save_figure(fig, "accuracy",
            "The accuracy of the RK4 computation of free fall in the author's metric "
...
all_ratios = np.concatenate([d[1:-1] / d[2:] for d in differences.values()])
check(np.all((all_ratios > 14) & (all_ratios < 18)),
      "halving the RK4 step divides the error by 14 to 18: order 4")
```

Labels, title, legend; the figure is saved. For the check, the coarsest pair (where the error is not yet in its final form) is left out: `d[1:-1] / d[2:]` gives the last three ratios of each particle, $16.6, 16.3, 16.2$ and $16.7, 16.3, 16.2$, and all six must lie between 14 and 18 (`&` combines the two conditions element by element).

What Figure 03d.5 shows. Left: the conserved quantities drift by at most about 10^{-8} (the squared speed of the extra-time particle at the end, when its velocities have grown large), the 3-space quantities by less than 10^{-11}. Right: both sets of points lie on lines of slope 4: halving the step makes the error 16 times smaller. The computed paths are accurate far beyond the precision of any number quoted from them.

In [17], the last check.

```
figure_names = ["frame_velocities", "x4_velocity", "hidden_push", "quadratic_form",
                "accuracy"]
files = [output_file(f"{FIGURE_FOLDER}/03d_{n}_{name}.png")
         for n, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in files), "all five figure files exist")
all_checks_passed()
```

The five figure files must exist; the last line prints ALL 23 CHECKS PASSED (notebook 03d). The 23 checks are: 1 in In [3], 2 each in In [4] and In [5], 3 in In [6], 1 each in In [7], In [8] and In [9], 3 each in In [10] and In [11], and 1 each in In [12] to In [17].

3.36 What we proved, what we computed, what we assumed

PROVED in this chapter (each derivation written out line by line; every one is also confirmed by an exact check of a notebook, and where a Revision record states the same, the record and its check are named in the section):

- the line elements of the plane in polar coordinates and of the sphere; the inverse of a diagonal metric (Section 3.3);

- for the author's metric, written in the author's coordinates $x_0, \ldots, x_7$ with the two metric functions $a_4(x_4)$ and $b_4(x_4) > 0$: the signature (4,4) at every point of the patch, for every a_4 and every $b_4 > 0$; $\det g = b_4^3 \cos^2 z$ and $\sqrt{|\det g|} = b_4^{3/2} \cos z$, without a_4 (record `python-lovelock-report.json`, check `sqrt_abs_det_g`; `curvature.json`, key `sqrtAbsDetG`); the 7-volume density, which changes in time only through $b_4^{3/2}$, and the 7-volume $b_4^{3/2}/(6H)$ of the patch per unit transverse coordinate volume; $V_3 V_t = b_4^{3/2} \sin z$ (Sections 3.5 and 3.6);

- the scale factors and the diagonal vielbein (lead check `vielbein_reproduces_metric`); the expansion rates $\alpha = a_4'$ of 3-space and $\alpha_t = -a_4' + b_4'/(2b_4)$ of the extra times ($-a_4'$ for a constant b_4); the transverse product $b_4^{3/2} \sin z$ (Section 3.7);

- the hidden coordinate y: $dy = \cot z \, dx_0$ (lead check `ks_coordinate_jacobian`), $W = \sin^{1/6} z = e^{Hy}$, the warped form and the volume factor $b_4^{3/2} e^{6Hy}$, at $b_4 = 1$ those of the record `ks-theory.json`; the tip at infinite proper distance; the fraction e^{-6HL} beyond the tip cut-off (Section 3.9);

- the transformation rules of vectors, covectors and the metric; the invariance of contractions (Section 3.14); the covariant derivative of covectors and of tensors with two indices (one $+\Gamma$ term for every upper index, one $-\Gamma$ term for every lower index), in particular of the metric; the Christoffel formula as the only connection without torsion that is compatible with the metric; the four cases for a diagonal metric; the contracted symbol $\sum_a \Gamma^a{}_{ab} = \partial_b \ln \sqrt{|\det g|}$ (Section 3.15);

- along a geodesic the squared speed is constant, and a coordinate absent from a diagonal metric has a conserved momentum; the geodesic equations of the sphere; the equator is a geodesic and other circles of latitude are not; parallel transport around a circle of latitude turns a vector by $2\pi(1 - \cos\theta_0)$, the enclosed area divided by a^2 (Section 3.16);

- the commutator of covariant derivatives is the Riemann tensor (MTW convention); its antisymmetry in the last two indices and the first Bianchi identity; each diagonal entry of the Ricci tensor is the sum of the curvatures of the coordinate planes through that direction (Section 3.17);

- the plane is flat; the sphere has the Gaussian curvature $1/a^2$, $R = 2/a^2$, $K = 4/a^4$; two meridians approach as $a \cos(s/a) \Delta\varphi$ (Section 3.18);

- the 37 non-zero Christoffel symbols of the author's metric (25 with $b \le c$, record `curvature.json`, key `christoffelNonzero_b_le_c`); observers at rest fall freely with proper time x_4, for all a_4 and b_4 (Section 3.23);

- the curvatures $\sigma(a, b)$ of the 28 coordinate planes in the rates α and α_t, and what their signs mean (a shape only for two space-like directions, reversed for two time-like ones); for two observers at rest $d^2\xi/d\tau^2 = \sigma(x_1, x_4)\, \xi$ along 3-space and $\sigma(x_5, x_4)\, \xi$ along an extra time; the 156 non-zero components $R^{ab}{}_{cd}$ with 20 different values (record `lovelock-report.json`, check `riemann_antisymmetry`); their frame values do not depend on z (Section 3.24);

- $R^a{}_a$, $R = 6a_4'^2 - 3a_4' b_4'/b_4 + 3b_4''/b_4 - 42H^2$ and the Einstein tensor (record `curvature.json`, keys `ricciMixed`, `ricciScalar`, `einsteinMixed`); its only entries off the diagonal are $G^4{}_0 = \frac{3}{2} H \cot z \, b_4'/b_4$ and $G^0{}_4 = -\frac{3}{2} H \tan z \, b_4'/b_4$ (verifier of the metric with b_4, checks `off_diagonal_entries_x0_x4_only`, `off_diagonal_proportional_to_b4prime`), so the Ricci and

Einstein tensors are diagonal exactly for a constant b_4, when the three inflating and the three deflating directions cancel (with inflating extra times, $b_4 = e^{4a_4}$, they would not); at $b_4 = 1$, $G^4{}_4 - G^0{}_0 = 6(a_4'^2 + H^2) > 0$; for a constant b_4, $K = 12(7H^4 - 2H^2a_4'^2 + 7a_4'^4 + 2a_4''^2) \geq 576H^4/7 > 0$, so the metric is curved for every such history; the contracted Bianchi identity for all $a_4(x_4)$ and $b_4(x_4)$ (record `lovelock-report.json`, checks `k1_equals_minus_4_einstein`, `k1_divergence_free`) (Section 3.25);

- within Einstein's equations: a diagonal source requires a constant b_4, that is $b_4 = 1$; no empty spacetime has this metric; $\kappa(\rho + p_0) = -6(a_4'^2 + H^2) < 0$; along $a_4 = AHx_4$, $b_4 = 1$ the required source $\kappa\rho = -3H^2(7 + A^2) - \Lambda$, $\kappa p = 3H^2(5 - A^2) + \Lambda$, $\kappa(\rho + p) = -6H^2(A^2 + 1) < 0$ (record `a4-equations.json`, keys `einstein` and `linearMember`) (Section 3.26);

- in free fall: the six momenta and $g(u, u)$ are conserved; $\hat{u}^i = p_i e^{-Hy - a_4}$ (the momentum weight $\kappa(y, x_4)$ of `ks-theory.json`) and $\hat{u}^j = -p_j b_4^{-1/2} e^{a_4 - Hy}$, so, for a constant b_4, 3-space motion is redshifted and extra-time motion blueshifted; $d^2y/d\tau^2 = H(S - E)$; $du^4/d\tau = -a_4' S + \alpha_t E$; $(u^4)^2 = 1 + (\hat{u}^0)^2 + S - E$, which times m^2 is the quadratic form of the record's check `extra_time_growth_rates_unbounded`; without extra-time motion a particle never turns in x_4 (Section 3.31).

COMPUTED by the notebooks (each number in the cell named; where a Revision record is reproduced, its file and key or check):

- Notebook 03a: $g_{11} = 2.347679$ and $g_{55} = -0.317724$ at $z = 0.7$, $a_4 = 0.5$, $b_4 = 1$ (In [8]); the signs on a grid of 400 values of z, 13 of a_4 and 3 of b_4 (In [8]); the slices, $H = 1$, $A = 1$ and $L = 3$ (In [13]; `Revision/kohn_sham/results/parameters.json`); the growth and shrink factors $e^2 = 7.389056$ and $e^{-2} = 0.135335$ (In [14]); the cut-off fraction $e^{-18} = 1.5230 \times 10^{-8}$ and the cut-off angle 1.5230×10^{-8} radians (In [20]).

- Notebook 03c: the turning angles of 15 circles within 5.0×10^{-12} radians of the area formula (In [10]); three geodesics within 1.2×10^{-13}, 6.2×10^{-13} and 7.1×10^{-11} of their planes (In [11]); the deviation equation within 8.0×10^{-14} of two meridians (In [13]).

- Notebook 03b: the 512 Christoffel symbols by central differences, order 2.040, best error 5.7×10^{-11} at $h = 10^{-6}$ at the test point of the record's check `k1_brute_force_numeric` (with $b_4 = 1.37$, $b_4' = 0.31$; In [10], In [11]); all 310 recorded components equal to ours at the five test points of `python-lovelock-report.json` to the relative 2.96×10^{-31} with 30 digits (In [19]); K summed from the 156 components equal to the formula at 300 values of z, at $b_4 = 1$ (In [23]).

- Notebook 03d: along the prescribed history ($b_4 = 1$) with RK4 and the step 0.001, from $y = -1$: the particle at rest stays at rest (In [9]); the fastest 3-space particle at $\tau = 3$ has $x_4 = 3.3070$, $\hat{u}^1 = 0.014370$, $u^4 = 1.060733$, $y = -0.0643$ (In [10]); the extra-time particle turns at $\tau = 1.987$ with the largest $x_4 = 1.4864$, $\hat{u}^5 = 1.4013$, $\hat{u}^0 = -0.9817$ (In [11]); the push law within 3.4×10^{-6} (In [14]); RK4 ratios 16.2 to 17.2 (In [16]).

ASSUMED (used, not derived here):

- standard theorems quoted without proof: Sylvester's law of inertia (Section 3.4); the volume factor of a metric that is not diagonal (not needed); that the Christoffel symbols of two systems

of coordinates describe the same covariant derivative (Section 3.15); that a space with zero Riemann tensor has constant metrics locally (Section 3.17); the symmetries (S3) and (S4) and the contracted Bianchi identity for a general metric (Sections 3.17 and 3.25; for the author's metric all three are checked or proved); the uniqueness of solutions of ordinary differential equations (Section 3.16); the geodesic deviation equation of a general surface, and its form $d^2\xi/d\tau^2 = +\sigma\,\xi$ for free-fall paths along a time-like direction (Section 3.18; for the observers at rest in the author's metric it is proved in Section 3.24);

- from physics: that a body in free fall moves on a time-like geodesic, and that the bodies of Section 3.31 are test particles; the form of Einstein's field equations and the null energy condition as the mark of ordinary matter (Section 3.26; derived and discussed in Chapters 9 and 12);
- the history $a_4 = AHx_4$, $b_4 = 1$ with $A = 1$ and $H = 1$, used for every picture and every number along the history: a PRESCRIBED BACKGROUND, not a solution of the field equations with a source of this book (key `adiabaticity.historyStatus` of `Revision/kohn_sham/ks-theory.json`, and `Revision/field_equations_a4/reports/ks-source-conditions.json`); $b_4 = 1$ is the choice of the Revision record for every background (`Revision/SPEC.md`, section 1; Section 3.8). Every formula written with general $a_4(x_4)$ and $b_4(x_4)$ is exact without it.

HYPOTHESIS. None enters this chapter.

OPEN. Whether wave packets of the fields of the book follow the free-fall paths of Section 3.31 in the curved metric is not computed (Section 3.31).

This chapter says nothing about pairs of universes, their creation, or matter and antimatter; Chapters 18 to 21 treat these questions and state exactly what is and what is not proved about them.

3.37 Exercises

Exercise 1. In the plane, use the coordinates $u = x + y$ and $v = x - y$. Find the line element, the metric and its Christoffel symbols.

Answer. Solving for x and y: $x = (u+v)/2$ and $y = (u-v)/2$ (add and subtract the two definitions). So $dx = (du + dv)/2$ and $dy = (du - dv)/2$ (each coefficient is constant), and

$$ds^2 = dx^2 + dy^2 = \frac{(du+dv)^2 + (du-dv)^2}{4} = \frac{2\,du^2 + 2\,dv^2}{4} = \frac{du^2 + dv^2}{2}$$

(the squares of a sum and of a difference; the mixed terms $\pm 2\,du\,dv$ cancel). The metric is $\mathrm{diag}(1/2, 1/2)$. It is constant, so all its derivatives vanish and every Christoffel symbol is zero (Section 3.15): in these coordinates straight lines are again $d^2u/d\lambda^2 = d^2v/d\lambda^2 = 0$.

Exercise 2. Figure 03a.1 shows the author's metric at $z = \pi/4$, $a_4 = 0.5$, $b_4 = 1$ with the entries 1, 2.422 (three times), -1 and -0.328 (three times), in the order $x_0, \ldots, x_7$. Multiply them and compare with $\det g = b_4^3 \cos^2 z$. Then do the same exactly, and say how the product changes for $b_4 = 2$.

Answer. With the rounded numbers: $2.422 \times 0.328 = 0.794416$, and $(0.794416)^3 = 0.5013$; the product of the eight entries is $1 \cdot 2.422^3 \cdot (-1) \cdot (-0.328)^3 = (2.422 \times 0.328)^3 = 0.5013$ (an odd power

keeps the minus sign, and the two minus signs cancel). $b_4^3\cos^2(\pi/4) = 1/2$. Exactly: the entries are $e\,s$ and $-e^{-1}s$ with $s = (\sin\pi/4)^{1/3}$, so the product is $\cot^2(\pi/4)\cdot(e\,s)^3\cdot(-1)\cdot(-e^{-1}s)^3 = s^6 = \sin^2(\pi/4) = 1/2$ ($e^3e^{-3} = 1$; $\cot(\pi/4) = 1$). The difference 0.0013 comes only from rounding the entries to three decimals. For $b_4 = 2$ each of the three extra-time entries doubles, so the product is multiplied by $2^3 = 8$: $\det g = 4$, as $b_4^3\cos^2 z$ says.

Exercise 3. Compute ${\Gamma^{x_4}}_{x_5x_5}$ and ${\Gamma^{x_0}}_{x_5x_5}$ of the author's metric directly from the Christoffel formula, without the four cases.

Answer. The formula of Section 3.15 with $a = x_4$, $b = c = x_5$ keeps only $d = x_4$ (the metric is diagonal): ${\Gamma^4}_{55} = \frac{1}{2}g^{44}(\partial_5 g_{45} + \partial_5 g_{45} - \partial_4 g_{55}) = \frac{1}{2}(-1)(0 + 0 - \partial_4 g_{55}) = \frac{1}{2}\partial_4(-b_4e^{-2a_4}\sin^{1/3} z) = \frac{1}{2}(-b_4' + 2a_4'b_4)e^{-2a_4}\sin^{1/3} z = (a_4'b_4 - \frac{1}{2}b_4')e^{-2a_4}\sin^{1/3} z$ ($g_{45} = 0$; $g^{44} = -1$; the product rule for $b_4\cdot e^{-2a_4}$ and the chain rule, $\partial_4 e^{-2a_4} = -2a_4'e^{-2a_4}$). For ${\Gamma^0}_{55}$ the formula with $a = x_0$, $b = c = x_5$ keeps only $d = x_0$, and the two terms with $g_{05} = 0$ vanish: ${\Gamma^0}_{55} = -\frac{1}{2}g^{00}\partial_0 g_{55} = -\frac{1}{2}\tan^2 z\cdot(-b_4e^{-2a_4})\cdot\frac{1}{3}\sin^{-2/3} z\cos z\cdot 6H = H\tan^2 z\, b_4e^{-2a_4}\sin^{-2/3} z\cos z$ ($g^{00} = 1/\cot^2 z = \tan^2 z$; the power rule and the chain rule for $\sin^{1/3}(6Hx_0)$). Since $\tan^2 z\cos z\sin^{-2/3} z = \tan z\cdot\frac{\sin z}{\cos z}\cos z\sin^{-2/3} z = \tan z\sin^{1/3} z$, this is $H\tan z\, b_4e^{-2a_4}\sin^{1/3} z$. Both agree with the table of Section 3.23.

Exercise 4. (a) By what angle does a vector turn when it is carried once around the equator of a sphere? (b) Show that for a small circle around the pole, $\theta_0 \ll 1$, the turning angle is about $\pi\theta_0^2$, and explain this number.

Answer. (a) With $\theta_0 = \pi/2$, $\cos\theta_0 = 0$: the transport equations of Section 3.16 give $du/d\varphi = dw/d\varphi = 0$, so the vector does not turn at all relative to the south and east directions; the formula $2\pi(1 - \cos\theta_0) = 2\pi$ is one whole turn, the same direction. This fits: the cap is a hemisphere of area $2\pi a^2$, and the equator is a geodesic, along which a vector keeps its angle to the direction of travel. (b) For small θ_0, $\cos\theta_0 \approx 1 - \theta_0^2/2$ (Taylor's formula, Chapter 2), so $2\pi(1 - \cos\theta_0) \approx 2\pi\cdot\theta_0^2/2 = \pi\theta_0^2$. A small cap is almost a flat disc of radius $a\theta_0$ (the distance from the pole along the sphere), with the area $\pi a^2\theta_0^2$; times the curvature $1/a^2$ this is $\pi\theta_0^2$. For $\theta_0 = 0.1$ the exact angle is $2\pi(1-\cos 0.1) = 0.031390$ and the estimate 0.031416; Figure 03c.3 shows the first dot at this height.

Exercise 5. Show that the Einstein tensor of every surface (two dimensions) is zero.

Answer. By Section 3.17 a surface has ${R^1}_1 = {R^2}_2 = \sigma(1,2)$ and $R = 2\sigma(1,2)$. The off-diagonal entries vanish: ${R^1}_2 = \sum_c {R^{1c}}_{2c} = {R^{11}}_{21} + {R^{12}}_{22} = 0$ (antisymmetry in the upper pair and in the lower pair). So ${G^1}_1 = \sigma(1,2) - \frac{1}{2}\cdot 2\sigma(1,2) = 0$, likewise ${G^2}_2 = 0$, and ${G^1}_2 = {G^2}_1 = 0$. For the sphere, $1/a^2 - \frac{1}{2}\cdot 2/a^2 = 0$. In two dimensions the Einstein tensor says nothing about the curvature; this is why gravity needs more dimensions.

Exercise 6. For the canonical history $A = 1$ and $\Lambda = 0$, find $\kappa\rho$, κp and the ratio $w = p/\rho$ that Einstein's equations require. Which Λ would make $\rho = 0$, and what is then κp?

Answer. From Section 3.26: $\kappa\rho = -3H^2(7+1) - 0 = -24H^2$ and $\kappa p = 3H^2(5-1) + 0 = 12H^2$, so $w = p/\rho = 12/(-24) = -1/2$; the energy density is negative. $\rho = 0$ needs $\Lambda = -3H^2(7 + A^2) = -24H^2$, and then $\kappa p = 12H^2 - 24H^2 = -12H^2$. In both cases $\kappa(\rho + p) = -12H^2 < 0$, as Section 3.26 says for every Λ: the cosmological constant cancels from $\rho + p$.

Exercise 7. Find the smallest value of the Kretschmann scalar of the author's metric for histories with $a_4'' = 0$, and the slope A at which it is reached.

Answer. With $a_4'' = 0$ and $s = a_4'^2 \geq 0$, $K = 12(7s^2 - 2H^2s + 7H^4)$ (Section 3.25). Its derivative

with respect to s is $12(14s - 2H^2)$, zero at $s = H^2/7$; there $K = 12H^4(7/49 - 2/7 + 7) = 12H^4(1/7 - 2/7 + 49/7) = 12H^4 \cdot 48/7 = 576H^4/7 = 82.29H^4$, a minimum because the parabola $7s^2 - \dots$ opens upwards. With $a_4' = AH$: $A^2 = 1/7$, $A = 1/\sqrt{7} = 0.378$. This is the low point of the red curve of Figure 03b.6, and the value $576H^4/7$ printed by Notebook 03b, In [22].

Exercise 8. The extra-time particle of Notebook 03d starts at $y = -1$ with $\hat{u}^5 = 0.2$. (a) If it stayed at $y = -1$ and never moved along y, at which x_4 would it turn? (b) Use the printed turning-point values $x_4 = 1.4864$ and $\hat{u}^5 = 1.4013$ and the conserved momentum p_5 to find the height y of the turning point.

Answer. (a) At fixed y, $\hat{u}^5 = 0.2\,e^{a_4}$ (pure blueshift, Section 3.31, with $b_4 = 1$) and $\hat{u}^0 = 0$; the turning condition $(\hat{u}^5)^2 = 1 + (\hat{u}^0)^2$ becomes $0.2\,e^{a_4} = 1$, so $a_4 = \ln 5 = 1.609$, that is $x_4 = 1.609$ on the history $a_4 = x_4$. (b) From $\hat{u}^5 = -p_5 b_4^{-1/2} e^{a_4 - Hy}$ with $b_4 = 1$ and the start ($a_4 = 0$, $y = -1$, $H = 1$): $-p_5 = 0.2\,e^{-1}$, so $\hat{u}^5 = 0.2\,e^{a_4 - (y+1)}$. At the turning point $1.4013 = 0.2\,e^{1.4864 - (y+1)}$, so $1.4864 - (y + 1) = \ln 7.0065 = 1.9468$ and $y = -1.460$. The particle has sunk by 0.46 towards the tip, which raised its frame velocity by the factor $e^{0.46} = 1.585$ beyond the pure blueshift, and it turned earlier ($x_4 = 1.486$) than the estimate (a), although its motion along y, $\hat{u}^0 = -0.98$, made the turning condition harder to reach ($(\hat{u}^5)^2 = 1.96$ instead of 1). Figure 03d.3 shows the particle near $y = -1.46$ at $\tau \approx 2$.

Exercise 9. What fraction of the 7-volume of the patch, and at which angle z, would a tip cut-off $L = 2/H$ remove?

Answer. By Section 3.9 the fraction is $e^{-6HL} = e^{-12} = 6.144 \times 10^{-6}$, about 400 times more than the $e^{-18} = 1.523 \times 10^{-8}$ of the record's $L = 3/H$ ($e^6 = 403$). The cut-off lies at $\sin z = e^{6Hy} = e^{-12}$, so $z = \arcsin e^{-12} = 6.144 \times 10^{-6}$ (for small u, $\arcsin u \approx u$).

4 Clifford algebra Cl(4,4) and the author's T16

The field equations of this book contain eight real 16×16 matrices, the **gamma matrices** $\gamma^{(x_0)}, \gamma^{(x_1)}, \dots, \gamma^{(x_7)}$, one for each direction of the author's eight-dimensional space-time. This chapter explains from zero why such matrices are needed, why they must have at least 16 rows and 16 columns, how the author built his matrices (he calls them T16) in his Mathematica notebook, which rules they obey, and what all their products together make up: the **Clifford algebra** Cl(4,4). The chapter has four worked examples, each a complete notebook. Notebook 04a rebuilds T16 from the author's formulas with exact whole-number arithmetic and checks every rule. Notebook 04b follows the square-root idea from the matrices of Pauli and Dirac to the author's eight gammas and to the plane waves of the field. Notebook 04c forms all 256 products of the gammas and proves that they make up all real 16×16 matrices. Notebook 04d builds a second set of gammas from three 2×2 matrices and finds the one and only change of basis between the two sets. Everything in this chapter is the algebra of constant matrices; it makes no statement about the creation of universes or about matter and antimatter.

4.1 Why matrices, and why sixteen components

The length of an arrow in the plane with the components p and q is $\sqrt{p^2 + q^2}$ (Pythagoras). A square root is an awkward object in an equation: it is not linear, and it cannot be differentiated term

by term. A **linear expression** in some variables $p, q, \ldots$ is a sum of the variables, each multiplied by a fixed number (or, below, a fixed matrix), its **coefficient**: $\alpha p + \beta q$ is linear, while p^2, pq and $\sqrt{p^2+q^2}$ are not. A **quadratic form** is, in this book, a sum of the squares of the variables, each with a fixed sign + or −: $p^2 + q^2$ and $p^2 - q^2$ are quadratic forms. In 1928 Paul Dirac looked for an equation for the electron that contains only first derivatives and whose square is the relation $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2$ between the energy E, the mass m and the momentum (k_1, k_2, k_3) of a particle in special relativity; its right-hand side is a quadratic form in m, k_1, k_2, k_3. He found that a quadratic form can be written as the square of a linear expression, provided that its coefficients are matrices that **anticommute**: $\alpha\beta = -\beta\alpha$. Such matrices are called gamma matrices, and the rule they obey is the **Clifford relation**. Dirac needed four of them, for the time and the three directions of space, and the smallest ones are 4×4; that is why Dirac's electron field has four components.

The author's space-time has eight directions $x_0, x_1, \ldots, x_7$: a hidden space direction x_0, the three directions x_1, x_2, x_3 of ordinary space, the time x_4, and three **extra times** x_5, x_6, x_7, which deflate exponentially in the author's metric. Eight directions need eight gamma matrices, and Section 4.13 proves that eight such matrices must have at least 16×16 entries. This is why the fields dirac16complex and dirac16complex00 of this book have exactly sixteen components. The author's gamma matrices are **real**: every entry is −1, 0 or +1. Later chapters use this fact (Chapter 5 and Chapter 7); this chapter only proves it.

The chapter proceeds as follows.

- Section 4.2 collects the facts about matrices that the chapter uses, each with its proof.
- Section 4.3 solves the square-root problem and derives the Clifford relation.
- Section 4.4 describes the eight directions of the author's space-time and the signs η that tell space-like from time-like directions.
- Section 4.5 follows the author's construction of T16 step by step and proves its Clifford relation by hand; Notebook 04a (Sections 4.6 to 4.8) repeats the construction with the computer.
- Section 4.9 studies the square root of the 4+4 quadratic form and the plane waves of the field in flat 4+4 space, including what a momentum along an extra time does; Notebook 04b (Sections 4.10 to 4.12).
- Section 4.13 forms the 256 products of the gammas and proves that they are a basis of all real 16×16 matrices; Notebook 04c (Sections 4.14 to 4.16).
- Section 4.17 builds the gammas a second time, from 2×2 matrices, and proves that the two sets differ only by a renumbering of the sixteen components; Notebook 04d (Sections 4.18 to 4.20).
- Section 4.21 lists what was proved, computed and assumed, and Section 4.22 gives exercises with complete worked answers.

Every number of this chapter comes either from the Revision record or from the chapter's own notebooks, which reproduce the Revision record where they overlap. The Revision record files used here are:

- `Revision/algebra/gammas.json`: the eight gamma matrices of the author, written exactly, and the matrix B that Section 4.9 uses;
- `Revision/algebra/reports/wolfram-algebra.json`: the exact checks of the algebra computed with WolframScript (45 checks, all passed, as Notebook 04a reads and prints them);
- `Revision/algebra/reports/python-algebra.json`: the same algebra checked independently with Python (35 checks, all passed, as Notebook 04a prints them);
- `Revision/algebra/reports/python-gammas.json`: the gammas as rebuilt by the Python program;
- `Revision/theory/reports/python-field-theory.json` and `Revision/theory/reports/python-scope.json`, the theory reports from which Notebook 04b reproduces four checks about plane waves (each named where it is used).

Each statement carries a label: PROVED (exact, with the proof in the text and the record file and check that confirm it), COMPUTED (a floating-point computation with its measured accuracy), ASSUMED (taken as given), HYPOTHESIS or OPEN.

4.2 The matrix tools of this chapter

This section defines every word about matrices that the chapter uses and proves every rule.

Matrices and their entries. An $n \times n$ **matrix** M is a square table of numbers with n rows and n columns. M_{ij} is the **entry** in row i and column j. The notebooks count rows and columns from 0 (Python's convention), so a 16×16 matrix has the rows $0, 1, \ldots, 15$. The author's formulas for his 4×4 building blocks count from 1, as Mathematica does; where this chapter uses them it says so. A **column** u is a list of n numbers $u_0, \ldots, u_{n-1}$ written one below the other; the matrix acts on it by $(Mu)_i = \sum_j M_{ij} u_j$.

The product. The product of two $n \times n$ matrices is

$$(AB)_{ij} = \sum_k A_{ik} B_{kj},$$

row i of A times column j of B, entry by entry, added up. In Python it is written `A @ B`. Products are **associative**, $(AB)D = A(BD)$ (both sides are $\sum_{k,l} A_{ik} B_{kl} D_{lj}$), so brackets may be left out. They are not **commutative**: in general $AB \neq BA$. For example, with

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad B = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}: \qquad AB = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad BA = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = -AB.$$

The **identity matrix** I_n has 1 on the diagonal and 0 elsewhere, so $I_n M = M I_n = M$. A number c times a matrix multiplies every entry by c; cI_n is called a **multiple of the identity**. The **Kronecker delta** δ_{ij} is 1 if $i = j$ and 0 otherwise, so $(I_n)_{ij} = \delta_{ij}$.

Linear maps are matrices. A rule f that turns every column u of n numbers into a column $f(u)$ of n numbers is called a **map**; it is **linear** if $f(u + v) = f(u) + f(v)$ and $f(cu) = c\, f(u)$ for

all columns u, v and all numbers c. A matrix M gives a linear map, the one that sends u to Mu, because every entry $(Mu)_i = \sum_j M_{ij}u_j$ is a linear expression in the entries of u. Conversely, every linear map is a matrix. Proof, line by line, with the **unit columns** $e_1, \dots, e_n$ (e_j has 1 in place j and 0 elsewhere):

1. $u = \sum_j u_j e_j$ — in place i the right side is $\sum_j u_j \delta_{ij} = u_i$.
2. $f(u) = \sum_j u_j\, f(e_j)$ — the two rules of a linear map, used for each term of line 1.
3. $f(u)_i = \sum_j f(e_j)_i\, u_j = (Mu)_i$ with $M_{ij} = f(e_j)_i$ — entry i of line 2, and the definition of the product of a matrix and a column.

So f is the matrix M whose column j is the column $f(e_j)$: **the images of the unit columns are the columns of the matrix**. A **linear combination** of matrices (or of columns) is a sum of them, each multiplied by a number.

Commutator and anticommutator. For two matrices A and B,

$$[A, B] = AB - BA, \qquad \{A, B\} = AB + BA.$$

A and B **commute** if $[A, B] = 0$, that is $AB = BA$, and **anticommute** if $\{A, B\} = 0$, that is $AB = -BA$. The two matrices of the example above anticommute.

The transpose. The transpose M^T exchanges rows and columns: $(M^T)_{ij} = M_{ji}$. The transpose of a product is the product of the transposes in the opposite order, $(AB)^T = B^T A^T$. Proof, line by line:

1. $((AB)^T)_{ij} = (AB)_{ji}$ — definition of the transpose.
2. $(AB)_{ji} = \sum_k A_{jk} B_{ki}$ — definition of the product.
3. $\sum_k A_{jk} B_{ki} = \sum_k (B^T)_{ik} (A^T)_{kj}$ — each factor rewritten with the definition of the transpose, and the two numbers in each term exchanged (numbers commute).
4. $\sum_k (B^T)_{ik} (A^T)_{kj} = (B^T A^T)_{ij}$ — definition of the product.

M is **symmetric** if $M^T = M$ and **antisymmetric** if $M^T = -M$. An antisymmetric matrix has zeros on its diagonal, because $M_{ii} = -M_{ii}$.

Inverse and orthogonal matrices. The **inverse** M^{-1} of M, when it exists, satisfies $MM^{-1} = M^{-1}M = I_n$. A real matrix is **orthogonal** if $M^T M = I_n$; then $M^{-1} = M^T$.

Signed permutation matrices. A **signed permutation matrix** has exactly one nonzero entry in every row and in every column, and that entry is $+1$ or -1. Acting on a column it puts the components into a new order and changes some of their signs. We describe such a matrix by the **code** of each row: the code $+5$ in row 2 means that the only nonzero entry of row 2 is $+1$ in column 5, so $(Mu)_2 = +u_5$; the code -0 means $-u_0$. Every signed permutation matrix is orthogonal. Proof: $(M^T M)_{ij} = \sum_k (M^T)_{ik} M_{kj} = \sum_k M_{ki} M_{kj}$ (definitions of product and transpose). For $i \neq j$ no row k has nonzero entries in both columns i and j (a row has only one nonzero entry), so every term is

0. For $i = j$ exactly one row k has a nonzero entry in column i, and it contributes $(\pm 1)^2 = 1$. So $M^T M = I_n$.

Products and transposes of signed permutation matrices are again signed permutation matrices. The transpose exchanges rows and columns, so it still has exactly one entry ± 1 in every row and every column. For a product AB of two signed permutation matrices, line by line:

1. $(AB)_{il} = \sum_k A_{ik} B_{kl} = A_{ij} B_{jl}$ for every l, where j is the one column in which row i of A is nonzero — definition of the product; all other terms contain a zero A_{ik}.
2. So row i of AB is $A_{ij} = \pm 1$ times row j of B, which has exactly one entry ± 1 — line 1.
3. In the same way $(AB)_{il} = A_{ik} B_{kl}$ for every i, where k is the one row in which column l of B is nonzero, so column l of AB is ± 1 times column k of A, which has exactly one entry ± 1.

So AB has exactly one entry ± 1 in every row and every column.

Block matrices. A 16×16 matrix can be cut into four 8×8 **blocks** (upper left, upper right, lower left, lower right), and an 8×8 matrix into four 4×4 blocks. Block matrices multiply like 2×2 matrices whose entries are matrices, keeping the order of the factors:

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} E & F \\ K & L \end{pmatrix} = \begin{pmatrix} AE + BK & AF + BL \\ CE + DK & CF + DL \end{pmatrix}.$$

Proof: the entry in row i and column j of the product is a sum over all columns k of the first factor; split it into the sum over the columns of the left half and the sum over the columns of the right half. For a row i of the upper half and a column j of the left half, the first part is the entry of AE and the second the entry of BK; the other three positions work in the same way. In the same way the transpose of a block matrix transposes the pattern and every block:

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^T = \begin{pmatrix} A^T & C^T \\ B^T & D^T \end{pmatrix}.$$

A matrix whose two off-diagonal blocks are zero is **block diagonal**; one whose two diagonal blocks are zero is **block off-diagonal**. By the block rule, the product of two block off-diagonal matrices is block diagonal, and the product of a block diagonal and a block off-diagonal matrix is block off-diagonal. A block diagonal or block off-diagonal matrix whose two nonzero blocks are signed permutation matrices is itself a signed permutation matrix: each of its rows runs through exactly one nonzero block, where it has exactly one entry ± 1, and so does each of its columns.

The trace. The trace $\operatorname{tr} M$ is the sum of the diagonal entries. It has the **cyclic property** $\operatorname{tr}(AB) = \operatorname{tr}(BA)$. Proof: $\operatorname{tr}(AB) = \sum_i \sum_k A_{ik} B_{ki}$ (definitions), and exchanging the order of the two finite sums and of the two numbers in each term gives $\sum_k \sum_i B_{ki} A_{ik} = \operatorname{tr}(BA)$.

The permutation sign. For a list of different numbers, an **inversion** is a pair of positions in which the larger number stands first. The **permutation sign** of the list (Mathematica calls it *Signature*) is $+1$ if the number of inversions is even and -1 if it is odd; for a list in which a number occurs twice it is 0. Examples: $(1, 2, 3, 4)$ has no inversion, sign $+1$; $(2, 1, 3, 4)$ has one, the pair $(2, 1)$, sign -1; $(2, 3, 1, 4)$ has two, the pairs $(2, 1)$ and $(3, 1)$, sign $+1$; $(1, 1, 3, 4)$ has sign 0. **Exchanging**

two entries of a list flips its sign. Proof: exchanging two *neighbouring* entries changes only whether this one pair is an inversion (every other pair keeps its order), so the number of inversions changes by exactly one. Exchanging the entries at the positions $i < j$ can be done with neighbour exchanges: move the entry at position i to the right, past $j - i$ neighbours, to position j; then the entry that was at position j stands at position $j - 1$; move it to the left, past $j - i - 1$ neighbours, to position i. That is $2(j - i) - 1$ neighbour exchanges, an odd number, so the sign flips.

4.3 The square-root problem and the Clifford relation

Numbers are not enough. Can $\sqrt{p^2 + q^2}$ be written as $\alpha p + \beta q$ with fixed coefficients α and β, for all numbers p and q? Square the candidate, keeping $\alpha\beta$ and $\beta\alpha$ apart, because for matrices the order matters:

1. $(\alpha p + \beta q)^2 = (\alpha p + \beta q)(\alpha p + \beta q)$ — definition of the square.
2. $= \alpha p\, \alpha p + \alpha p\, \beta q + \beta q\, \alpha p + \beta q\, \beta q$ — multiplied out (distributive law).
3. $= \alpha^2 p^2 + (\alpha\beta + \beta\alpha)\, pq + \beta^2 q^2$ — the numbers p and q commute with everything and are moved to the right.

This must equal $p^2 + q^2$ for all p and q. With $p = 1$, $q = 0$ it gives $\alpha^2 = 1$; with $p = 0$, $q = 1$ it gives $\beta^2 = 1$; with $p = q = 1$ it gives $\alpha^2 + \beta^2 + \alpha\beta + \beta\alpha = 2$, hence $\alpha\beta + \beta\alpha = 0$. Conversely, these three conditions make line 3 equal to $p^2 + q^2$. For ordinary numbers $\alpha\beta + \beta\alpha = 2\alpha\beta$, and $2\alpha\beta = 0$ forces $\alpha = 0$ or $\beta = 0$, which contradicts $\alpha^2 = \beta^2 = 1$. So no two numbers solve the problem (status PROVED; Notebook 04b confirms with sympy that the three equations have no solution).

Matrices are enough. The two matrices of Section 4.2,

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

satisfy $\sigma_x^2 = \sigma_z^2 = I_2$ (multiply out) and anticommute ($\sigma_z\sigma_x = -\sigma_x\sigma_z$, computed in Section 4.2). By line 3, with the number 1 replaced by I_2: $(p\sigma_x + q\sigma_z)^2 = (p^2 + q^2)I_2$. Example: $p = 3$, $q = 4$ gives

$$3\sigma_x + 4\sigma_z = \begin{pmatrix} 4 & 3 \\ 3 & -4 \end{pmatrix}, \qquad \begin{pmatrix} 4 & 3 \\ 3 & -4 \end{pmatrix}^2 = \begin{pmatrix} 16 + 9 & 12 - 12 \\ 12 - 12 & 9 + 16 \end{pmatrix} = 25\, I_2,$$

a matrix square root of $25 = 3^2 + 4^2$. Space-time needs **minus signs** too, and a real matrix can square to $-I_2$:

$$N = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad N^2 = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = -I_2, \qquad \sigma_x N = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = -N\sigma_x.$$

So $(p\sigma_x + qN)^2 = p^2 I_2 + q^2 N^2 = (p^2 - q^2)I_2$: a real square root of a *difference* of squares.

The general rule. We want matrices $\gamma^1, \ldots, \gamma^n$ such that, for given signs $\eta^{aa} = \pm 1$ and for all numbers $p_1, \ldots, p_n$,

$$\Big(\sum_a p_a\gamma^a\Big)^2 = \Big(\sum_a \eta^{aa}p_a^2\Big)I.$$

The signs are collected in the diagonal matrix $\eta = \mathrm{diag}(\eta^{11},\dots,\eta^{nn})$; its off-diagonal entries are $\eta^{ab}=0$ for $a\neq b$. The left side, line by line:

1. $\big(\sum_a p_a\gamma^a\big)^2 = \big(\sum_a p_a\gamma^a\big)\big(\sum_b p_b\gamma^b\big)$ — definition of the square; the summation letter of the second factor is called b, which changes nothing.
2. $= \sum_{a,b} p_a p_b\,\gamma^a\gamma^b$ — multiplied out; the numbers p_ap_b are moved to the front.
3. $= \sum_{a,b} p_a p_b\,\gamma^b\gamma^a$ — the same sum with the two summation letters renamed (a called b and b called a), and $p_bp_a = p_ap_b$.
4. $= \frac{1}{2}\sum_{a,b} p_a p_b\,(\gamma^a\gamma^b+\gamma^b\gamma^a)$ — half the sum of lines 2 and 3, which are equal.

If the **Clifford relation**

$$\gamma^a\gamma^b+\gamma^b\gamma^a = 2\eta^{ab}I \qquad \text{for all } a,b$$

holds, line 4 becomes $\frac{1}{2}\sum_{a,b} p_a p_b\,2\eta^{ab}I = \sum_a \eta^{aa}p_a^2\,I$ (only $a=b$ survives), the wanted square. Conversely, if the square rule holds for all p: choose $p_a=1$ and all other p zero, then the left side is $(\gamma^a)^2$ and the right side $\eta^{aa}I$; choose $p_a=p_b=1$ for two different a,b and all other p zero, then the left side is $(\gamma^a+\gamma^b)^2 = (\gamma^a)^2+(\gamma^b)^2+\gamma^a\gamma^b+\gamma^b\gamma^a$ and the right side $(\eta^{aa}+\eta^{bb})I$, so $\gamma^a\gamma^b+\gamma^b\gamma^a=0$. So **the square-root rule and the Clifford relation say the same thing** (status PROVED). In words: each gamma matrix squares to $+I$ for a direction with sign $+1$ (a **space-like** direction) and to $-I$ for a direction with sign -1 (a **time-like** direction), and two different gamma matrices anticommute.

Pauli's three matrices. For three space directions (signs $+1,+1,+1$) a third 2×2 matrix is needed that squares to $+I_2$ and anticommutes with σ_x and σ_z. No real one exists (Exercise 1 of Section 4.22 shows what the real N gives instead), but a complex one does. With the imaginary unit i, $i^2=-1$, the three **Pauli matrices** (Wolfgang Pauli, 1927) are

$$\sigma_x = \begin{pmatrix}0&1\\1&0\end{pmatrix}, \qquad \sigma_y = \begin{pmatrix}0&-i\\i&0\end{pmatrix}, \qquad \sigma_z = \begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

For example $\sigma_x\sigma_y = \begin{pmatrix}i&0\\0&-i\end{pmatrix} = i\sigma_z$ and $\sigma_y\sigma_x = -i\sigma_z$, so they anticommute; and $\sigma_x\sigma_y\sigma_z = i\sigma_z\sigma_z = iI_2$.

Dirac's four matrices. Four anticommuting matrices do not fit into 2×2 matrices (Section 4.13 proves that four need at least 4×4). Dirac's choice, in the convention of particle physicists with the time first and the signs $(+1,-1,-1,-1)$, is made of 2×2 blocks (the letter D keeps these matrices apart from the author's):

$$\gamma^0_D = \begin{pmatrix}I_2&0\\0&-I_2\end{pmatrix}, \qquad \gamma^j_D = \begin{pmatrix}0&\sigma_j\\-\sigma_j&0\end{pmatrix} \quad (j=x,y,z).$$

By the block rule of Section 4.2: $(\gamma_D^0)^2 = \mathrm{diag}(I_2, I_2) = I_4$; $(\gamma_D^j)^2 = \mathrm{diag}(-\sigma_j^2, -\sigma_j^2) = -I_4$; $\gamma_D^0\gamma_D^j = \begin{pmatrix} 0 & \sigma_j \\ \sigma_j & 0 \end{pmatrix}$ and $\gamma_D^j\gamma_D^0 = \begin{pmatrix} 0 & -\sigma_j \\ -\sigma_j & 0 \end{pmatrix}$, which anticommute; and for $j \neq k$, $\gamma_D^j\gamma_D^k + \gamma_D^k\gamma_D^j = \mathrm{diag}(-\{\sigma_j, \sigma_k\}, -\{\sigma_j, \sigma_k\}) = 0$.

Dirac's equation contains the energy relation. For a plane wave $\psi = u\, e^{-i(Et - k_1x_1 - k_2x_2 - k_3x_3)}$ with a constant column u, Dirac's equation $i(\gamma_D^0\partial_t + \gamma_D^x\partial_1 + \gamma_D^y\partial_2 + \gamma_D^z\partial_3)\psi = m\psi$ becomes $(P - mI_4)u = 0$ with $P = E\gamma_D^0 - k_1\gamma_D^x - k_2\gamma_D^y - k_3\gamma_D^z$ (the derivative of e^{cx} is $c\,e^{cx}$; multiply by i; divide by the exponential, which is never zero). By the general rule with the signs $(+1, -1, -1, -1)$, $P^2 = (E^2 - k_1^2 - k_2^2 - k_3^2)I_4$. A nonzero u with $Pu = mu$ gives $P^2u = P(mu) = m^2u$, hence $(E^2 - k_1^2 - k_2^2 - k_3^2 - m^2)u = 0$, and because $u \neq 0$, $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2$: the energy relation of special relativity, the **mass shell**. Notebook 04b checks all of this exactly and shows it in pictures.

The Clifford algebra. Given n matrices with a Clifford relation, the set of all their real linear combinations of products is called the **Clifford algebra** of the signs η; with p signs $+1$ and q signs -1 it is written $\mathrm{Cl}(p, q)$. The author's space-time has four space-like and four time-like directions, so its Clifford algebra is Cl(4,4). Section 4.13 shows that it is the set of all real 16×16 matrices.

4.4 The eight directions of the author's space-time and their signs

The author's metric is the diagonal 8×8 matrix g that gives the squared length of a small step: a step dx_μ along the coordinate x_μ has the squared length $g_{\mu\mu}\,dx_\mu^2$. Its diagonal entries, in the order of the author's coordinates $x_0, \ldots, x_7$, are $\cot^2 z$, $e^{2a_4}\sin^{1/3} z$ three times, -1, and $-b_4e^{-2a_4}\sin^{1/3} z$ three times, where a_4 and $b_4 > 0$ are functions of the time x_4 (the metric functions; $b_4 = 1$ gives the metric used before 2026-10-14), $z = 6Hx_0$ lies between 0 and $\pi/2$, and $H > 0$ is the author's constant (Chapter 3 studies this metric in full). A direction with $g_{\mu\mu} > 0$ is **space-like**, one with $g_{\mu\mu} < 0$ is **time-like**. The **frame factor** of a direction is $\sqrt{|g_{\mu\mu}|}$: a coordinate step dx_μ is a step of the length $\sqrt{|g_{\mu\mu}|}\,|dx_\mu|$.

coordinate	**role**	**metric entry**	**frame factor**	**sign η**
x_0	the hidden space direction	$\cot^2 z$	$\cot z$	$+1$
x_1, x_2, x_3	ordinary 3-space, inflating	$e^{2a_4}\sin^{1/3} z$	$e^{a_4}\sin^{1/6} z$	$+1$
x_4	the time	-1	1	-1
x_5, x_6, x_7	the extra times, deflating exponentially	$-b_4e^{-2a_4}\sin^{1/3} z$	$b_4^{1/2}e^{-a_4}\sin^{1/6} z$	-1

When a_4 grows with the time x_4 (and b_4 stays constant), the frame factor e^{a_4} of 3-space grows (3-space **inflates**) and the frame factor $b_4^{1/2}e^{-a_4}$ of the extra times shrinks exponentially (the extra times **deflate**). Chapter 12 derives the equations that govern a_4 and b_4.

At every point one can choose eight perpendicular directions of unit length, one along each coordinate: a **frame**. Measured in the frame, the metric becomes the diagonal matrix of signs

$$\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1) \qquad (\text{order } x_0,\ldots,x_7):$$

four space-like directions (x_0,x_1,x_2,x_3) and four time-like ones (x_4,x_5,x_6,x_7), the **signature** (4,4). Because η is diagonal with entries ±1, the entries of η and of its inverse are the same numbers, $\eta^{ab}=\eta_{ab}$. The gamma matrices belong to the frame directions: $\gamma^{(x_a)}$ is the gamma matrix of the frame direction along x_a, and they satisfy the Clifford relation with this η. They are **constant**: the same matrices at every point and at every time. The inflation of 3-space and the deflation of the extra times reach the field equation only through the frame factors: the field equation contains $\gamma^{\mu}=\gamma^{(x_\mu)}/\sqrt{|g_{\mu\mu}|}$, for example $\gamma^{(x_5)}$ multiplied by $b_4^{-1/2}e^{a_4}\sin^{-1/6}z$, a factor that grows as the extra time x_5 deflates. The gamma matrices themselves never change.

The author's Mathematica notebook numbers the frame directions $A=0,\ldots,7$ in the order of his coordinates: $A=0$ is the hidden direction, $A=1,2,3$ are 3-space, $A=4$ is the time and $A=5,6,7$ are the extra times, and its matrix of signs is eta4488 $=\mathrm{diag}(1,1,1,1,-1,-1,-1,-1)$ (his input cell In[45]). The coordinate map of the Revision record:

coordinate	**index A of T16 in the author's notebook**	**sign η**
x_0 (hidden direction)	0	$+1$
x_1 (3-space)	1	$+1$
x_2 (3-space)	2	$+1$
x_3 (3-space)	3	$+1$
x_4 (the time)	4	-1
x_5 (extra time, deflating)	5	-1
x_6 (extra time, deflating)	6	-1
x_7 (extra time, deflating)	7	-1

So $\gamma^{(x_k)}=\mathrm{T16}[k]$ for $k=0,\ldots,7$: the index A of the author's notebook is the index of his coordinate, and the sign of each coordinate is the entry of eta4488 at that index. Status: ASSUMED (the metric and the coordinate roles are the author's input; the map is the one the Revision record uses and checks: `Revision/algebra/reports/wolfram-algebra.json`, checks `coordinate_map` and `eta_in_author_order`).

4.5 The author's construction of T16, step by step

The author builds his matrices in his Mathematica notebook, whose file name is

`Pair_Creation_of_Universes_WaveFunctionOfUniverse-4+4-Einstein-Lovelock-Nash.nb`

in four steps. The Revision record re-typed his formulas from the input cells In[45], In[46], In[294], In[300], In[301], In[338], In[351], In[370], In[371] and In[372] (the notebook itself is only read, never changed) and rebuilt the matrices twice, with WolframScript and with Python. This section follows the four steps and proves, by hand, every rule that the computer checks in Notebook 04a.

Step 1: six 4×4 blocks. For $h=1,2,3$ and $p,q=1,2,3,4$ (counted from 1, as in the author's formulas) the author defines two patterns (In[294]):

$$Q_a[h]_{pq} = \text{Signature}[\{h,p,q,4\}], \qquad Q_b[h]_{pq} = \delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4},$$

and from them the blocks $\text{s4}[h] = Q_a[h] - Q_b[h]$ (In[300]) and $\text{t4}[h] = Q_a[h] + Q_b[h]$ (In[301]). $Q_a[h]_{pq}$ is the permutation sign of the list $(h,p,q,4)$; it is nonzero only when $h,p,q,4$ are four different numbers. $Q_b[h]$ has exactly two nonzero entries: $+1$ in row 4, column h, and -1 in row h, column 4. A worked example for $h = 1$:

- row 1, column 4 of s4[1]: $Q_a = \text{Signature}[\{1,1,4,4\}] = 0$ (repeated numbers) and $Q_b = \delta_{14}\delta_{41} - \delta_{11}\delta_{44} = -1$, so the entry is $0 - (-1) = +1$;
- row 2, column 3: $Q_a = \text{Signature}[\{1,2,3,4\}] = +1$ and $Q_b = 0$, so the entry is $+1$;
- row 3, column 2: $Q_a = \text{Signature}[\{1,3,2,4\}] = -1$ (one inversion) and $Q_b = 0$, so the entry is -1;
- row 4, column 1: $Q_a = 0$ and $Q_b = \delta_{44}\delta_{11} = +1$, so the entry is $0 - 1 = -1$;
- every other entry is 0, because Q_a and Q_b vanish there.

All six blocks, computed in this way (Notebook 04a prints them and compares them with the six matrices that the author's notebook displays in its output Out[304]):

$$\text{s4}[1] = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}, \quad \text{s4}[2] = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}, \quad \text{s4}[3] = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix},$$

$$\text{t4}[1] = \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \text{t4}[2] = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad \text{t4}[3] = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

The blocks are antisymmetric. Exchanging p and q exchanges two entries of the list $(h,p,q,4)$, which flips its permutation sign (Section 4.2): $Q_a[h]_{qp} = -Q_a[h]_{pq}$. Exchanging p and q in Q_b turns $\delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4}$ into $\delta_{q4}\delta_{ph} - \delta_{qh}\delta_{p4}$, which is minus the original: $Q_b[h]_{qp} = -Q_b[h]_{pq}$. A sum or difference of antisymmetric matrices is antisymmetric, so s4[h] and t4[h] are antisymmetric.

The blocks are quaternion multiplications. A **quaternion** is $q = q_4 + q_1\mathbf{i} + q_2\mathbf{j} + q_3\mathbf{k}$ with four real numbers; we store it as the list (q_1, q_2, q_3, q_4), the real part last, to match the blocks. Quaternions are multiplied with Hamilton's rules $\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -1$, $\mathbf{ij} = \mathbf{k} = -\mathbf{ji}$, $\mathbf{jk} = \mathbf{i} = -\mathbf{kj}$, $\mathbf{ki} = \mathbf{j} = -\mathbf{ik}$, and their multiplication is associative. For a fixed quaternion u the **right multiplication** R_u maps q to $q\,u$ and the **left multiplication** L_u maps q to $u\,q$. Both are linear maps of the stored lists of four numbers: a product of quaternions is multiplied out term by term, so $(q + q')\,u = q\,u + q'\,u$ and $(cq)\,u = c\,(q\,u)$ for every real number c, and in the same way for L_u. By the rule "linear maps are matrices" of Section 4.2, each is therefore a 4×4 matrix whose column p holds the components of the image of the unit column e_p, where $e_1 = \mathbf{i}$, $e_2 = \mathbf{j}$, $e_3 = \mathbf{k}$, $e_4 = 1$ are stored as the four unit columns $(1,0,0,0)$, $(0,1,0,0)$, $(0,0,1,0)$, $(0,0,0,1)$: column p of R_u holds the components of $e_p u$, column p of L_u those of $u e_p$. Example: the columns of $R_{\mathbf{i}}$ are the components of $\mathbf{ii} = -1$, $\mathbf{ji} = -\mathbf{k}$,

$\mathbf{ki} = \mathbf{j}$ and $1\,\mathbf{i} = \mathbf{i}$, that is $(0,0,0,-1)$, $(0,0,-1,0)$, $(0,1,0,0)$ and $(1,0,0,0)$; these are exactly the four columns of s4[1] above. In the same way (Notebook 04a checks all six):

$$\text{s4}[h] = R_{u_h}, \qquad \text{t4}[h] = -L_{u_h}, \qquad u_1 = \mathbf{i},\ u_2 = \mathbf{j},\ u_3 = \mathbf{k}.$$

This explains every rule of the blocks. Line by line:

1. $R_u R_w = R_{wu}$ — because $R_u(R_w(q)) = (q\,w)\,u = q\,(w\,u)$ (associativity).
2. $L_u L_w = L_{uw}$ — because $L_u(L_w(q)) = u\,(w\,q) = (u\,w)\,q$.
3. $L_u R_w = R_w L_u$ — because $u\,(q\,w) = (u\,q)\,w$ (associativity).
4. $R_{-1} = L_{-1} = -I_4$ — multiplying by the number -1 changes every sign.
5. $\text{s4}[h]^2 = R_{u_h u_h} = R_{-1} = -I_4$ and $\text{t4}[h]^2 = (-1)^2 L_{u_h u_h} = -I_4$ — by lines 1, 2 and 4 and $\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -1$.
6. For $h \neq k$: $\text{s4}[h]\ \text{s4}[k] = R_{u_k u_h} = -R_{u_h u_k} = -\text{s4}[k]\ \text{s4}[h]$ — by line 1, because two different units anticommute ($u_k u_h = -u_h u_k$) and R is linear; t4 works in the same way with line 2.
7. $\text{s4}[h]\ \text{t4}[k] = -R_{u_h} L_{u_k} = -L_{u_k} R_{u_h} = \text{t4}[k]\ \text{s4}[h]$ — by line 3: every s-block commutes with every t-block.

So the s-blocks anticommute among themselves and square to $-I_4$, the t-blocks do the same, and every s-block commutes with every t-block: $\{\text{s4}[h], \text{s4}[k]\} = \{\text{t4}[h], \text{t4}[k]\} = -2\delta_{hk} I_4$ and $[\text{s4}[h], \text{t4}[k]] = 0$. Two further products are needed below. By lines 1 and 2, $\text{s4}[1]\ \text{s4}[2]\ \text{s4}[3] = R_{\mathbf{i}} R_{\mathbf{j}} R_{\mathbf{k}} = R_{\mathbf{kji}}$, and $\mathbf{kji} = (\mathbf{kj})\mathbf{i} = -\mathbf{ii} = 1$, so $\text{s4}[1]\ \text{s4}[2]\ \text{s4}[3] = I_4$; and $\text{t4}[3]\ \text{t4}[2]\ \text{t4}[1] = (-1)^3 L_{\mathbf{k}} L_{\mathbf{j}} L_{\mathbf{i}} = -L_{\mathbf{kji}} = -I_4$.

The author calls s4 *self-dual* and t4 *anti-self-dual*. The **dual** of an antisymmetric 4×4 matrix M is $(\star M)_{pq} = \frac{1}{2}\sum_{r,s} \epsilon_{pqrs} M_{rs}$, where the **Levi-Civita symbol** ϵ_{pqrs} is the permutation sign of (p,q,r,s). For an antisymmetric M the two surviving terms of each sum are equal; for example $(\star M)_{12} = \frac{1}{2}(\epsilon_{1234} M_{34} + \epsilon_{1243} M_{43}) = \frac{1}{2}(M_{34} + (-1)(-M_{34})) = M_{34}$. In the same way $(\star M)_{13} = -M_{24}$ and $(\star M)_{14} = M_{23}$, so M is self-dual ($\star M = M$) when $M_{12} = M_{34}$, $M_{13} = -M_{24}$ and $M_{14} = M_{23}$, and anti-self-dual ($\star M = -M$) when $M_{12} = -M_{34}$, $M_{13} = M_{24}$ and $M_{14} = -M_{23}$. Read off from the matrices above: s4[1] has $M_{12} = 0 = M_{34}$, $M_{13} = 0 = -M_{24}$, $M_{14} = 1 = M_{23}$ (self-dual), and t4[1] has $M_{14} = -1$, $M_{23} = 1$ (anti-self-dual).

Step 2: the 8×8 matrices. With 4×4 blocks (In[46], In[338], In[351]):

$$\sigma = \begin{pmatrix} 0 & I_4 \\ I_4 & 0 \end{pmatrix}, \quad \tau_0 = I_8, \quad \tau_h = \begin{pmatrix} 0 & \text{s4}[h] \\ \text{s4}[h] & 0 \end{pmatrix}, \quad \tau_{7-h} = \begin{pmatrix} 0 & \text{t4}[h] \\ -\text{t4}[h] & 0 \end{pmatrix} \quad (h = 1,2,3),$$

so τ_6 comes from t4[1], τ_5 from t4[2] and τ_4 from t4[3]; then $\tau_7 = \tau_1\tau_2\tau_3\tau_4\tau_5\tau_6$, $\bar\tau_0 = I_8$ and $\bar\tau_A = \sigma\,\tau_A^T\,\sigma$ for $A = 1, \ldots, 7$ (the author writes tau[A] and taubar[A]). The rules of these matrices follow from the block rule and Step 1, line by line:

1. $\sigma \begin{pmatrix} A & B \\ C & D \end{pmatrix} \sigma = \begin{pmatrix} D & C \\ B & A \end{pmatrix}$ — the block rule, applied twice: σ on the left exchanges the two block rows, on the right the two block columns.

2. $\tau_h^2 = \mathrm{diag}(\mathrm{s4}[h]^2, \mathrm{s4}[h]^2) = -I_8$ and $\tau_{7-h}^2 = \mathrm{diag}(-\mathrm{t4}[h]^2, -\mathrm{t4}[h]^2) = +I_8$ — block rule and Step 1, line 5.

3. $\tau_h\tau_k + \tau_k\tau_h = \mathrm{diag}(\{\mathrm{s4}[h], \mathrm{s4}[k]\}, \{\mathrm{s4}[h], \mathrm{s4}[k]\}) = 0$ for $h \neq k$, and in the same way $\tau_{7-h}\tau_{7-k} + \tau_{7-k}\tau_{7-h} = \mathrm{diag}(-\{\mathrm{t4}[h], \mathrm{t4}[k]\}, -\{\mathrm{t4}[h], \mathrm{t4}[k]\}) = 0$ — block rule and Step 1.

4. $\tau_h\tau_{7-k} + \tau_{7-k}\tau_h = \mathrm{diag}(-\mathrm{s4}[h]\mathrm{t4}[k] + \mathrm{t4}[k]\mathrm{s4}[h],\ \mathrm{s4}[h]\mathrm{t4}[k] - \mathrm{t4}[k]\mathrm{s4}[h]) = 0$ — block rule; the s-blocks commute with the t-blocks.

5. $\tau_1\tau_2\tau_3 = \begin{pmatrix} 0 & \mathrm{s4}[1]\mathrm{s4}[2]\mathrm{s4}[3] \\ \mathrm{s4}[1]\mathrm{s4}[2]\mathrm{s4}[3] & 0 \end{pmatrix} = \sigma$ — block rule twice, and s4[1] s4[2] s4[3] $= I_4$.

6. $\tau_4\tau_5\tau_6 = \begin{pmatrix} 0 & -\mathrm{t4}[3]\mathrm{t4}[2]\mathrm{t4}[1] \\ \mathrm{t4}[3]\mathrm{t4}[2]\mathrm{t4}[1] & 0 \end{pmatrix} = \begin{pmatrix} 0 & I_4 \\ -I_4 & 0 \end{pmatrix}$ — block rule twice, and t4[3] t4[2] t4[1] $= -I_4$.

7. $\tau_7 = (\tau_1\tau_2\tau_3)(\tau_4\tau_5\tau_6) = \begin{pmatrix} 0 & I_4 \\ I_4 & 0 \end{pmatrix} \begin{pmatrix} 0 & I_4 \\ -I_4 & 0 \end{pmatrix} = \begin{pmatrix} -I_4 & 0 \\ 0 & I_4 \end{pmatrix}$ — lines 5 and 6 and the block rule.

8. $\tau_7^2 = I_8$, and τ_7 anticommutes with $\tau_1, \ldots, \tau_6$ — τ_7 is diagonal with the blocks $-I_4$ and I_4; multiplying a block off-diagonal matrix by it from the left flips the sign of the upper-right block, from the right the sign of the lower-left block, so the two products differ by a sign.

9. $\tau_4\tau_5\tau_6\tau_7 = \begin{pmatrix} 0 & I_4 \\ -I_4 & 0 \end{pmatrix} \begin{pmatrix} -I_4 & 0 \\ 0 & I_4 \end{pmatrix} = \sigma$ and $\tau_1\tau_2\cdots\tau_7 = \tau_7\tau_7 = I_8$ — line 6, the block rule, and the definition $\tau_1\cdots\tau_6 = \tau_7$.

10. $\bar\tau_A = -\tau_A$ for $A = 1, \ldots, 7$ — for $A = h$: $\tau_h^T = \begin{pmatrix} 0 & \mathrm{s4}[h]^T \\ \mathrm{s4}[h]^T & 0 \end{pmatrix} = -\tau_h$ (block transpose, s4 antisymmetric), and by line 1 $\sigma\tau_h\sigma = \tau_h$, so $\bar\tau_h = -\tau_h$; for $A = 7 - h$: $\tau_{7-h}^T = \begin{pmatrix} 0 & -\mathrm{t4}[h]^T \\ \mathrm{t4}[h]^T & 0 \end{pmatrix} = \tau_{7-h}$, and by line 1 $\sigma\tau_{7-h}\sigma = \begin{pmatrix} 0 & -\mathrm{t4}[h] \\ \mathrm{t4}[h] & 0 \end{pmatrix} = -\tau_{7-h}$; for $A = 7$: τ_7 is symmetric and by line 1 $\sigma\tau_7\sigma = \mathrm{diag}(I_4, -I_4) = -\tau_7$.

Lines 2, 3, 4 and 8 together say that the seven matrices $\tau_1, \ldots, \tau_7$ satisfy a Clifford relation of their own: $\tau_A\tau_B + \tau_B\tau_A = -2\,\mathrm{eta4488}_{AB}\, I_8$ for $A, B = 1, \ldots, 7$ (τ_1, τ_2, τ_3 square to $-I_8$, $\tau_4, \ldots, \tau_7$ to $+I_8$). With line 10 this gives the **key rule** for all 64 pairs $A, B = 0, \ldots, 7$:

$$\tau_A\bar\tau_B + \tau_B\bar\tau_A = \bar\tau_A\tau_B + \bar\tau_B\tau_A = 2\,\mathrm{eta4488}_{AB}\, I_8.$$

Proof: for $A, B \geq 1$ both sides equal $-(\tau_A\tau_B + \tau_B\tau_A)$ by line 10, which is $2\,\mathrm{eta4488}_{AB} I_8$; for $A = 0$ and $B \geq 1$ the left side is $\bar\tau_B + \tau_B = 0 = 2\,\mathrm{eta4488}_{0B} I_8$; for $A = B = 0$ it is $2I_8$.

Step 3: the 16×16 matrices. The author puts $\bar\tau_A$ into the upper-right and τ_A into the lower-left 8×8 corner (In[371]) and multiplies the first eight (In[372]):

$$\mathrm{T16}[A] = \begin{pmatrix} 0 & \bar\tau_A \\ \tau_A & 0 \end{pmatrix} \quad (A = 0, \dots, 7), \qquad \mathrm{T16}[8] = \mathrm{T16}[0]\,\mathrm{T16}[1] \cdots \mathrm{T16}[7].$$

By the block rule, $\mathrm{T16}[A]\ \mathrm{T16}[B] = \mathrm{diag}(\bar\tau_A\tau_B, \tau_A\bar\tau_B)$. Adding the same with A and B exchanged and using the key rule:

$$\mathrm{T16}[A]\,\mathrm{T16}[B] + \mathrm{T16}[B]\,\mathrm{T16}[A] = \mathrm{diag}(\bar\tau_A\tau_B + \bar\tau_B\tau_A,\ \tau_A\bar\tau_B + \tau_B\bar\tau_A) = 2\,\mathrm{eta4488}_{AB}\, I_{16}.$$

This is the Clifford relation in the author's frame order. The product T16[8] is block diagonal (eight block off-diagonal factors). Its upper-left block is $\bar\tau_0\tau_1\,\bar\tau_2\tau_3\,\bar\tau_4\tau_5\,\bar\tau_6\tau_7 = \tau_1(-\tau_2)\tau_3(-\tau_4)\tau_5(-\tau_6)\tau_7 = -\tau_1\cdots\tau_7 = -I_8$ (pairs of factors multiplied with the block rule, line 10, line 9), and its lower-right block is $\tau_0\bar\tau_1\,\tau_2\bar\tau_3\,\tau_4\bar\tau_5\,\tau_6\bar\tau_7 = (+1)\tau_1\cdots\tau_7 = I_8$ (four minus signs). So $\mathrm{T16}[8] = \mathrm{diag}(-I_8, I_8)$, and $\mathrm{T16}[0]\ \mathrm{T16}[1]\ \cdots\ \mathrm{T16}[8] = \mathrm{T16}[8]^2 = I_{16}$. Chapter 5 calls this product the **chirality**; here it is only a product.

Step 4: the author's coordinates. With the map of Section 4.4, $\gamma^{(x_k)} = \mathrm{T16}[k]$ for $k = 0, \dots, 7$, and the signs are $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$, the same list as eta4488. Naming does not change a matrix, so

$$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I_{16} \qquad (a, b = x_0, \dots, x_7).$$

Three more properties follow. (i) Every γ^a is a **signed permutation matrix**, hence orthogonal: $(\gamma^a)^T = (\gamma^a)^{-1}$. Proof, line by line, with the rules of Section 4.2:

1. s4[h], t4[h], $-$t4[h] and I_4 are signed permutation matrices — read off from the six matrices of Step 1: each has exactly one entry ±1 in every row and every column.
2. σ, $\tau_0 = I_8$ and $\tau_1, \dots, \tau_6$ are signed permutation matrices — each is block diagonal or block off-diagonal with two blocks from line 1.
3. $\tau_7 = \tau_1\tau_2\cdots\tau_6$ is one — a product of signed permutation matrices.
4. $\bar\tau_0 = I_8$ and $\bar\tau_A = \sigma\,\tau_A^T\,\sigma$ are ones — a transpose and products of signed permutation matrices.
5. T16[A] is one — it is block off-diagonal with the two blocks $\bar\tau_A$ and τ_A of lines 2 to 4.

Renaming T16[A] as $\gamma^{(x_a)}$ changes no entry, so every γ^a is a signed permutation matrix, and Section 4.2 showed that such a matrix is orthogonal. (ii) **Reality**: every entry of every γ^a is -1, 0 or $+1$, by (i). (iii) The **symmetry pattern** $(\gamma^a)^T = \eta_{aa}\gamma^a$: symmetric for the space-like x_0, x_1, x_2, x_3, antisymmetric for the time-like $x_4, \dots, x_7$. Proof of (iii), line by line: $(\gamma^a)^2 = \eta_{aa} I_{16}$ (Clifford relation with $b = a$); multiplying by η_{aa} and using $\eta_{aa}^2 = 1$ gives $\gamma^a(\eta_{aa}\gamma^a) = I_{16}$, so $(\gamma^a)^{-1} = \eta_{aa}\gamma^a$; with (i), $(\gamma^a)^T = (\gamma^a)^{-1} = \eta_{aa}\gamma^a$.

Status. PROVED, by hand above, and exactly by the computer in two independent Revision programs. The table names, for each statement of this section, the checks that confirm it in the WolframScript report `Revision/algebra/reports/wolfram-algebra.json` and in the Python report `Revision/algebra/reports/python-algebra.json`.

the coordinate map and the signs η	coordinate_map, eta_in_author_order	coordinate_map
the Clifford relation for all 64 pairs	Clifford_relation	clifford_relation, clifford_relation_sympy
reality and signed permutations	reality, signed_permutation_matrices	reality_signed_permutations
the symmetry pattern	symmetry_pattern	symmetry_pattern
the stored gammas equal the rebuilt ones	fixture_round_trip	fixture_comparison_gammas_json

Notebook 04a reproduces every one of these 30 Revision checks (16 of the WolframScript report and 14 of the Python report) and compares all $8 \times 256 = 2048$ entries of the gammas with both Revision files: none differs.

The next three sections hold Notebook 04a: how to run it, its complete text, and the line-by-line walk-through.

4.6 How to run Notebook 04a

Step 1. What this notebook does and what it needs.

Notebook 04a (The author's gamma matrices T16 built from his formulas) is the file `Revision/textbook/notebooks/04a_t16_from_formulas.ipynb` of the repository Dirac_claude. It rebuilds, with exact integer arithmetic, the author's eight real 16 by 16 gamma matrices T16 from his own formulas (the 4 by 4 blocks s4 and t4, the 8 by 8 matrices sigma, tau and taubar), names them after the author's coordinates x0 to x7, checks the Clifford relation for all 64 pairs and every other property that the Revision record checks, compares every entry with the Revision record files, and draws six heat maps. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04a_t16_from_formulas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04a_t16_from_formulas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 04a_t16_from_formulas.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/04a.captions.json`
- `Revision/textbook/figures/04a_1_blocks_s4_t4.png`
- `Revision/textbook/figures/04a_2_tau_matrices.png`
- `Revision/textbook/figures/04a_3_block_form_of_t16.png`
- `Revision/textbook/figures/04a_4_gammas_x0_to_x7.png`
- `Revision/textbook/figures/04a_5_anticommutator_table.png`
- `Revision/textbook/figures/04a_6_symmetry_pattern.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 28 CHECKS PASSED (notebook 04a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/04a_t16_from_formulas.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.

- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 04a_t16_from_formulas.ipynb
python -m nbconvert --execute --inplace 04a_t16_from_formulas.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `Revision/algebra/gammas.json` or for a file in `Revision/algebra/reports`: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run `git status` in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

```
git checkout HEAD Revision/algebra
```

4.7 Notebook 04a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/04a_t16_from_formulas.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field equations of the theory contain eight real $16 \times 16$ matrices, the
```

gamma matrices $\gamma^{(x_0)}, \gamma^{(x_1)}, \dots, \gamma^{(x_7)}$, one for each direction $x_0, \dots, x_7$ of the author's 4+4 dimensional space-time. The author built them in his Mathematica notebook
'Pair_Creation_of_Universes_WaveFunctionOfUniverse-4+4-Einstein-Lovelock-Nash.nb'
from a few small building blocks, and he calls the finished 16×16 matrices T16. This notebook repeats his construction step by step, with exact integer arithmetic, and checks every property that the Revision record checks. It

- builds the six 4×4 blocks s4[h] and t4[h] (h = 1, 2, 3) from the author's formulas and compares them with the six matrices that his notebook displays;
- shows that these blocks are the multiplications of quaternions (a number system with four components), which explains their rules;
- builds the 8×8 matrices sigma, tau[A] and taubar[A] (A = 0, ..., 7) and checks their rules;
- assembles the 16×16 matrices T16[A] (A = 0, ..., 8);
- names them after the author's coordinates: $\gamma^{(x_k)}$ = T16[k] for k = 0, ..., 7;
- checks the Clifford relation $\gamma^a \gamma^b + \gamma^b \gamma^a = 2 \eta^{ab} I_{16}$ for all 64 pairs (a, b), and that every gamma matrix is real, a signed permutation matrix, and symmetric (space-like directions) or antisymmetric (time-like directions);
- compares every entry with the two Revision record files that hold the gammas;
- draws six figures (heat maps).

Every check prints a line that starts with PASS. When the Revision record made the same check, the lines below the PASS line name the record file and its check.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 04a (The author's gamma matrices T16 built from his formulas) is the file
'Revision/textbook/notebooks/04a_t16_from_formulas.ipynb' of the repository Dirac_claude.
It rebuilds, with exact integer arithmetic, the author's eight real 16 by 16 gamma
matrices T16 from his own formulas (the 4 by 4 blocks s4 and t4, the 8 by 8 matrices
sigma, tau and taubar), names them after the author's coordinates x0 to x7, checks the
Clifford relation for all 64 pairs and every other property that the Revision record
checks, compares every entry with the Revision record files, and draws six heat maps. It
needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
```

exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about

400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04a_t16_from_formulas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04a_t16_from_formulas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 04a_t16_from_formulas.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/04a.captions.json‘
- ‘Revision/textbook/figures/04a_1_blocks_s4_t4.png‘
- ‘Revision/textbook/figures/04a_2_tau_matrices.png‘
- ‘Revision/textbook/figures/04a_3_block_form_of_t16.png‘
- ‘Revision/textbook/figures/04a_4_gammas_x0_to_x7.png‘
- ‘Revision/textbook/figures/04a_5_anticommutator_table.png‘
- ‘Revision/textbook/figures/04a_6_symmetry_pattern.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 28 CHECKS PASSED (notebook 04a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/04a_t16_from_formulas.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 04a_t16_from_formulas.ipynb
  python -m nbconvert --execute --inplace 04a_t16_from_formulas.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.

- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘Revision/algebra/gammas.json‘ or for a file in ‘Revision/algebra/reports‘: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run ‘git status‘ in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

```
git checkout HEAD Revision/algebra
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 04a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 04a (The author's gamma matrices T16 built from his formulas) is the file
# Revision/textbook/notebooks/04a_t16_from_formulas.ipynb of the repository Dirac_claude.
# It rebuilds, with exact integer arithmetic, the author's eight real 16 by 16 gamma
# matrices T16 from his own formulas (the 4 by 4 blocks s4 and t4, the 8 by 8 matrices
# sigma, tau and taubar), names them after the author's coordinates x0 to x7, checks the
# Clifford relation for all 64 pairs and every other property that the Revision record
# checks, compares every entry with the Revision record files, and draws six heat maps.
# It needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
```

```
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
```

```
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 04a_t16_from_formulas.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
```

```
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 04a_t16_from_formulas.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 04a_t16_from_formulas.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/04a.captions.json
# - Revision/textbook/figures/04a_1_blocks_s4_t4.png
# - Revision/textbook/figures/04a_2_tau_matrices.png
# - Revision/textbook/figures/04a_3_block_form_of_t16.png
# - Revision/textbook/figures/04a_4_gammas_x0_to_x7.png
# - Revision/textbook/figures/04a_5_anticommutator_table.png
# - Revision/textbook/figures/04a_6_symmetry_pattern.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 28 CHECKS PASSED (notebook 04a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
```

```
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/04a_t16_from_formulas.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 04a_t16_from_formulas.ipynb
#     python -m nbconvert --execute --inplace 04a_t16_from_formulas.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or for a file in
#   Revision/algebra/reports: the notebook reads these Revision record files of the
#   repository; they are part of every complete clone. Run git status in the repository
#   folder: if it reports them as deleted, restore them with the command below and run
#   the notebook again.
#     git checkout HEAD Revision/algebra
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================

## 3. The words used in this notebook

- **Matrix**: a rectangular table of numbers. An $n \times n$ matrix has $n$ rows
  and $n$ columns; $M_{ij}$ is the *entry* in row $i$ and column $j$. numpy counts
  rows and columns from 0; the author's Mathematica notebook counts them from 1. This
  notebook counts from 0, except in the $4 \times 4$ blocks, whose formulas use the
  author's indices $p, q = 1, \dots, 4$ and $h = 1, 2, 3$.
- **Product of matrices**: $(AB)_{ij} = \sum_k A_{ik} B_{kj}$ (row $i$ of $A$ times
  column $j$ of $B$, entry by entry, added up). In Python it is written `A @ B`. The
  order matters: in general $AB \neq BA$.
- **Identity matrix** $I_n$: 1 on the diagonal, 0 elsewhere; $I_n M = M I_n = M$.
- **Transpose** $M^T$: rows and columns exchanged, $(M^T)_{ij} = M_{ji}$. $M$ is
  **symmetric** if $M^T = M$ and **antisymmetric** if $M^T = -M$.
- **Block matrix**: a big matrix cut into smaller matrices (blocks). For example
  $\begin{pmatrix} 0 & B \\ D & 0 \end{pmatrix}$ has the zero matrix as its upper-left
  and lower-right blocks.
- **Signed permutation matrix**: a matrix with exactly one nonzero entry, $+1$ or
  $-1$, in every row and every column. Acting on a column $u$ it reorders the
  components and flips some signs. We describe row $i$ by a short *code*: the code
  +5 in row 2 means $(Mu)_2 = +u_5$, and -0 means $-u_0$.
- **Permutation sign** (Mathematica's *Signature*): for a list of different numbers,
  $+1$ if the number of *inversions* (pairs of positions in which the larger number
  stands first) is even, $-1$ if it is odd; for a list with a repeated number, 0.
- **Kronecker delta** $\delta_{ij}$: 1 if $i = j$, otherwise 0.
- **Anticommutator** $\{A, B\} = AB + BA$; **commutator** $[A, B] = AB - BA$. Two
  matrices *anticommute* if $\{A, B\} = 0$ and *commute* if $[A, B] = 0$.
- **Frame metric** $\eta$: the diagonal matrix of signs that says which directions
  are space-like ($+1$) and which are time-like ($-1$); here, in the order
  $x_0, \dots, x_7$, $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$.
  Because $\eta$ is diagonal with entries $\pm 1$, $\eta^{ab} = \eta_{ab}$.
- **Clifford relation**: $\gamma^a \gamma^b + \gamma^b \gamma^a = 2 \eta^{ab} I_{16}$
  for all $a, b$: each gamma matrix squares to $+I_{16}$ (space-like direction) or
  $-I_{16}$ (time-like direction), and two different gamma matrices anticommute.
- **Heat map**: a picture of a matrix in which every entry is a small coloured
  square; in this notebook blue means $-1$, light grey $0$ and red $+1$.
- **Revision record**: the files under the folder `Revision` of the repository,
  computed by the Revision programs. A **report** is such a file that lists checks,
  each with a name and a verdict (PASS or FAIL).
```

Text cell:

4. The physical and mathematical situation

The author's space-time has eight coordinates $x_0, x_1, \dots, x_7$. In his metric (a diagonal 8×8 matrix g that measures lengths and durations, with the two metric functions $a_4(x_4)$ and $b_4(x_4) > 0$)

- x_0 is a hidden space direction, $z = 6 H x_0$ lies between 0 and $\pi/2$, and $g_{00} = \cot^2 z$;
- x_1, x_2, x_3 are ordinary 3-space; lengths along them carry the scale factor $e^{a_4} \sin^{1/6} z$, which grows (inflates) as a_4 grows;
- x_4 is the time, with $g_{44} = -1$;
- x_5, x_6, x_7 are three *extra times* (time-like, like x_4); they carry the scale factor $b_4^{1/2} e^{-a_4} \sin^{1/6} z$, so they **deflate exponentially** while 3-space inflates.

At every point one can choose eight perpendicular unit directions, a *frame*, one along each coordinate. In the frame the metric becomes the matrix of signs $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$: $+1$ for the space-like directions x_0, x_1, x_2, x_3 and -1 for the time-like directions x_4, x_5, x_6, x_7. Four of each kind: the signature is (4,4). The gamma matrices belong to these frame directions. They are constant matrices, the same at every point and at every time. The inflation of 3-space and the deflation of the extra times enter the field equations through the *frame factors* $\sqrt{|g_{\mu\mu}|}$ that convert coordinate directions into frame directions ($\cot z$ for x_0, $e^{a_4}\sin^{1/6} z$ for x_1, x_2, x_3, 1 for x_4 and $b_4^{1/2}e^{-a_4}\sin^{1/6} z$ for x_5, x_6, x_7), never through the gamma matrices.

The gamma matrices must satisfy the Clifford relation $\gamma^a \gamma^b + \gamma^b \gamma^a = 2 \eta^{ab} I_{16}$. The author builds them in four steps (his Mathematica input cells are named in brackets).

1. Two 4×4 patterns for h = 1, 2, 3 and p, q = 1, ..., 4 (In[294]):
   Qa[h]_pq = Signature[{h, p, q, 4}] and
   Qb[h]_pq = $\delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4}$; from them the blocks s4[h] = Qa[h] - Qb[h] (In[300]) and t4[h] = Qa[h] + Qb[h] (In[301]).
2. The 8×8 matrices (In[46], In[338], In[351]):
   sigma = $\begin{pmatrix} 0 & I_4 \\ I_4 & 0 \end{pmatrix}$;
   tau[0] = I_8;
   tau[h] = $\begin{pmatrix} 0 & s4[h] \\ s4[h] & 0 \end{pmatrix}$ and
   tau[7-h] = $\begin{pmatrix} 0 & t4[h] \\ -t4[h] & 0 \end{pmatrix}$ for h = 1, 2, 3;
   tau[7] = tau[1] tau[2] tau[3] tau[4] tau[5] tau[6];
   taubar[0] = I_8 and taubar[A] = sigma tau[A]^T sigma for A = 1, ..., 7.
3. The 16×16 matrices (In[371], In[372]):
   T16[A] = $\begin{pmatrix} 0 & \mathrm{taubar}[A] \\ \mathrm{tau}[A] & 0 \end{pmatrix}$ for A = 0, ..., 7, and T16[8] = T16[0] T16[1] ... T16[7].
4. The author's Mathematica notebook numbers its frame directions A = 0, ..., 7 in the order of his coordinates: A = 0 is the hidden direction x_0, A = 1, 2, 3 are 3-space, A = 4 is the time and A = 5, 6, 7 are the extra times; its frame metric is eta4488 = diag(1, 1, 1, 1, -1, -1, -1, -1) (In[45]). So $\gamma^{(x_k)}$ = T16[k] for k = 0, ..., 7: the frame index A is the index of the coordinate.

The Revision record re-typed these formulas from the author's notebook (the file

‘Revision/algebra/wolfram/RevisionAlgebra.wl‘), built the matrices twice, with WolframScript and with Python, and checked them exactly. This notebook builds them a third time, in a form a student can follow line by line.

```
## 5. Small tools

The next cell imports the packages and defines five small functions: the
permutation sign, the Kronecker delta, the anticommutator, the identity matrix and
the zero matrix. All matrices of this notebook hold whole numbers (numpy's type
‘int64‘); sums and products of whole numbers are computed exactly, without any
rounding, so every check below is exact. The check at the end tests the permutation
sign on four lists whose inversions are counted here by hand: (1, 2, 3, 4) has no
inversion, so its sign is $+1$; (2, 1, 3, 4) has one, the pair (2, 1), sign $-1$;
(2, 3, 1, 4) has two, the pairs (2, 1) and (3, 1), sign $+1$; and (1, 1, 3, 4)
repeats a number, sign 0.
```

In [2]:

```
import itertools  # loops over all pairs (or triples, ...) of indices
from fractions import Fraction  # exact fractions such as 1/2

import numpy as np  # integer matrices; their products are exact (no rounding)
import sympy as sp  # a second, independent engine for exact matrix algebra
from matplotlib.colors import BoundaryNorm, ListedColormap
from matplotlib.patches import Patch, Rectangle

def signature(numbers):
    """Mathematica's Signature: 0 if a number occurs twice; otherwise +1 for an even
    and -1 for an odd number of inversions (pairs of positions i < j with
    numbers[i] > numbers[j])."""
    if len(set(numbers)) != len(numbers):  # a set keeps each number only once
        return 0
    inversions = sum(1 for i, j in itertools.combinations(range(len(numbers)), 2)
                     if numbers[i] > numbers[j])
    return -1 if inversions % 2 else 1  # % 2 is the remainder after division by 2

def delta(i, j):
    """The Kronecker delta: 1 if i == j, otherwise 0."""
    return 1 if i == j else 0

def anticommutator(a, b):
    """{a, b} = a b + b a; the operator @ multiplies matrices."""
    return a @ b + b @ a

def identity(n):
    """The n x n identity matrix with whole-number entries."""
```

```
    return np.eye(n, dtype=np.int64)

def zeros(n):
    """The n x n zero matrix with whole-number entries."""
    return np.zeros((n, n), dtype=np.int64)

for numbers in ([1, 2, 3, 4], [2, 1, 3, 4], [2, 3, 1, 4], [1, 1, 3, 4]):
    say(f"the sign of {numbers} is {signature(numbers)}")
check(signature([1, 2, 3, 4]) == 1 and signature([2, 1, 3, 4]) == -1
      and signature([2, 3, 1, 4]) == 1 and signature([1, 1, 3, 4]) == 0,
      "the permutation sign agrees with the four examples worked out by hand")
```

Out [2]:

```
the sign of [1, 2, 3, 4] is 1
the sign of [2, 1, 3, 4] is -1
the sign of [2, 3, 1, 4] is 1
the sign of [1, 1, 3, 4] is 0
PASS the permutation sign agrees with the four examples worked out by hand
```

Text cell:

```
The next cell reads the two Revision reports of the algebra: the WolframScript
report (45 checks) and the Python report (35 checks). It keeps, for every check, its
verdict and its detail text. It then defines the function ‘check_record‘. It works
like ‘check‘, but it first makes sure that each named Revision check is recorded as
passed, and after the PASS line it prints, for each Revision check, the report file
(line "reproduces ...") and the check name (line "check ..."). So whenever this
notebook verifies a statement that the Revision record also verified, the output
says which record it reproduces.
```

In [3]:

```

Revision/algebra/reports/python-algebra.json: 35 checks recorded
```

Text cell:

```
The next cell defines the drawing tools of the figures. A matrix whose entries are
$-1$, $0$ and $+1$ is drawn as a heat map with three colours: blue for $-1$, light
grey for $0$ and red for $+1$. ‘draw_signs‘ draws one matrix into one panel (one pair
of axes) of a figure; with ‘numbers=True‘ it also writes every nonzero entry into its
square, and ‘first‘ is the number of the first row and column on the axes (1 for the
author’s 1-based $4 \times 4$ blocks, 0 otherwise). ‘sign_legend‘ adds the key of
the three colours below a figure.
```

In [4]:

```
# Three colours: entry -1 blue, entry 0 light grey, entry +1 red.
SIGN_COLOURS = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])
# The boundaries -1.5, -0.5, 0.5, 1.5 put -1, 0 and +1 into the three colours.
SIGN_NORM = BoundaryNorm([-1.5, -0.5, 0.5, 1.5], SIGN_COLOURS.N)

def draw_signs(ax, matrix, title, numbers=False, first=0):

    fig.legend(handles=handles, loc="outside lower center", ncol=3, fontsize=9,
            frameon=False)
```

Text cell:

```
## 6. Step 1: the six $4 \times 4$ blocks s4[h] and t4[h]

The author's two patterns, with $h = 1, 2, 3$ and $p, q = 1, 2, 3, 4$:

$$Q_a[h]_{pq} = \mathrm{Signature}[\{h, p, q, 4\}], \qquad
Q_b[h]_{pq} = \delta_{p4}\,\delta_{qh} - \delta_{ph}\,\delta_{q4}.$$

$Q_a[h]_{pq}$ is $\pm 1$ only when $h, p, q, 4$ are four different numbers, so it is
nonzero only in the rows and columns different from $h$ and 4. $Q_b[h]$ has exactly
two nonzero entries: $+1$ in row 4, column $h$ (there $\delta_{p4}\delta_{qh} = 1$)
and $-1$ in row $h$, column 4. The blocks are $s4[h] = Q_a[h] - Q_b[h]$ and
$t4[h] = Q_a[h] + Q_b[h]$.

A worked example by hand, $h = 1$:

- row 1, column 4 of s4[1]: $Q_a = \mathrm{Signature}[\{1, 1, 4, 4\}] = 0$ (repeated
  numbers) and $Q_b = \delta_{14}\delta_{41} - \delta_{11}\delta_{44} = 0 - 1 = -1$,
  so the entry is $0 - (-1) = +1$;
- row 2, column 3: $Q_a = \mathrm{Signature}[\{1, 2, 3, 4\}] = +1$ (no inversion)
  and $Q_b = 0$, so the entry is $+1$;
- row 3, column 2: $Q_a = \mathrm{Signature}[\{1, 3, 2, 4\}] = -1$ (one inversion,
  the pair 3, 2), so the entry is $-1$;
- row 4, column 1: $Q_a = 0$ and $Q_b = \delta_{44}\delta_{11} - 0 = +1$, so the
  entry is $0 - 1 = -1$.

So the first row of s4[1] is (0, 0, 0, 1) and its last row is (-1, 0, 0, 0). The next
cell computes all six blocks with these formulas and prints them next to each other.
```

In [5]:

```
def Qa(h, p, q):
    """The author's Qa[h, p, q] (In[294]); h, p, q count from 1, as in Mathematica."""

## 7. The rules of the blocks

The next cell checks four rules, for all h, k = 1, 2, 3:

1. every block is antisymmetric: $s4[h]^T = -s4[h]$ and $t4[h]^T = -t4[h]$;
2. every block squares to minus the identity: $s4[h]^2 = t4[h]^2 = -I_4$;
3. two different s-blocks anticommute, and so do two different t-blocks; together
```

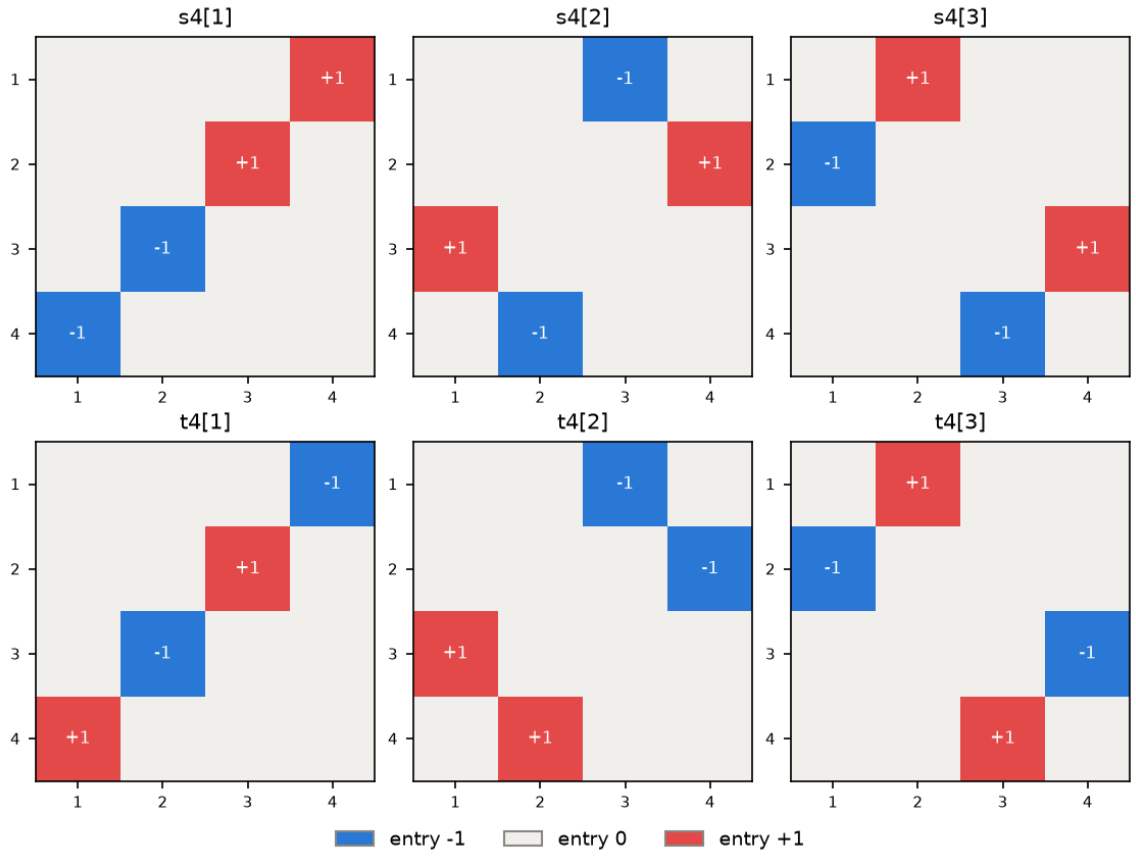

Figure 116: The six 4×4 building blocks of the author: s4 for h = 1, 2, 3 (upper row) and t4 for h = 1, 2, 3 (lower row), computed from Signature and Kronecker deltas; rows and columns numbered 1 to 4 as in his formulas; blue -1, grey 0, red $+1$. Every block has exactly one nonzero entry in each row and column and is antisymmetric: the square in row p, column q has the opposite colour of the square in row q, column p. (Notebook 04a, figure 1.)

```
   with rule 2 this is $\{s4[h], s4[k]\} = \{t4[h], t4[k]\} = -2\delta_{hk} I_4$;
4. every s-block commutes with every t-block: $s4[h]\,t4[k] = t4[k]\,s4[h]$.

Rules 2 and 3 are the rules of the imaginary units of the quaternions,
$\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -1$ and $\mathbf{ij} = -\mathbf{ji}$
(a later cell explains this). The Revision record checks them in both reports.
```

In [8]:

Text cell:

```
**Self-dual and anti-self-dual.** The author calls s4 *self-dual* and t4
*anti-self-dual*. The *dual* of a $4 \times 4$ matrix $M$ is the matrix
$(\star M)_{pq} = \tfrac12 \sum_{r,s} \epsilon_{pqrs} M_{rs}$, where the *Levi-Civita
symbol* $\epsilon_{pqrs}$ is the permutation sign of $(p, q, r, s)$. For an
antisymmetric $M$ only two terms survive in each sum, and they are equal; for example
$(\star M)_{12} = \tfrac12(\epsilon_{1234} M_{34} + \epsilon_{1243} M_{43})
= \tfrac12((+1) M_{34} + (-1)(-M_{34})) = M_{34}$, because exchanging the last two
numbers of (1, 2, 3, 4) flips the sign and $M_{43} = -M_{34}$. In the same way
$(\star M)_{13} = \epsilon_{1324} M_{24} = -M_{24}$ and
$(\star M)_{14} = \epsilon_{1423} M_{23} = M_{23}$. So $M$ is self-dual
($\star M = M$) when $M_{12} = M_{34}$, $M_{13} = -M_{24}$ and $M_{14} = M_{23}$.
For s4[1]: $M_{12} = 0 = M_{34}$, $M_{13} = 0 = -M_{24}$, $M_{14} = 1 = M_{23}$.

The next cell builds $\epsilon_{pqrs}$ for all 256 index lists (counting from 0 now;
the sign of a list does not depend on where the counting starts), computes the dual
```

```
of each block with numpy's `einsum` (which performs exactly the sum over $r$ and
$s$), and checks that every s4 is self-dual and every t4 anti-self-dual
($\star t4[h] = -t4[h]$).
```

```
**The blocks are quaternion multiplications.** A *quaternion* is
$q = q_4 + q_1\mathbf{i} + q_2\mathbf{j} + q_3\mathbf{k}$ with four real numbers; we
store it as the list $(q_1, q_2, q_3, q_4)$, real part last, to match the author's
blocks. Quaternions are multiplied with Hamilton's rules
$\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -1$,
$\mathbf{ij} = \mathbf{k} = -\mathbf{ji}$, $\mathbf{jk} = \mathbf{i} = -\mathbf{kj}$,
$\mathbf{ki} = \mathbf{j} = -\mathbf{ik}$; multiplying out $x\,y$ term by term with
these rules gives the four lines of `quaternion_product` below. For a fixed unit $u$
the maps $q \to q\,u$ (multiply on the right) and $q \to u\,q$ (multiply on the left)
are linear, so each is a $4 \times 4$ matrix: column $p$ of the matrix holds the
components of $e_p u$ (or $u e_p$), where $e_p$ is the quaternion with a 1 in
component $p$ and 0 elsewhere.
```

```
The next cell checks: s4[h] is the right multiplication by the unit
$\mathbf{i}, \mathbf{j}, \mathbf{k}$ (h = 1, 2, 3), and t4[h] is minus the left
multiplication by the same unit. This explains the rules above: the square of the
right multiplication by $\mathbf{i}$ is the right multiplication by
$\mathbf{i}^2 = -1$, which is $-I_4$; and multiplying on the left and on the right
can be done in either order, because $(u\,q)\,w = u\,(q\,w)$ for quaternions (their
multiplication is *associative*), which is why every s4 commutes with every t4.
```

Text cell:

8. Step 2: sigma and the eight matrices tau[A]

The next cell builds the 8×8 matrices of the author's step 2 exactly as the situation section states them: the frame metric eta4488 of his notebook, the matrix sigma (it exchanges the upper four and the lower four components of a column of eight), tau[0] = I_8, the three tau[h] made from s4[h], the three tau[7-h] made from t4[h] (so tau[6] comes from t4[1], tau[5] from t4[2] and tau[4] from t4[3]), tau[7] as the product of the first six, and taubar[A] = sigma tau[A]^T sigma. 'np.block' glues blocks into a big matrix, row of blocks by row of blocks. Then it prints the code of every row of tau[1], ..., tau[7] (the code +5 in row 2 means $(\tau u)_2 = +u_5$; all tau are signed permutation matrices, which the function 'codes' confirms row by row).

In [11]:

```
I8, Z4, Z8 = identity(8), zeros(4), zeros(8)
eta4488 = np.diag([1, 1, 1, 1, -1, -1, -1, -1])  # In[45]: frame order A = 0..7
sigma = np.block([[Z4, I4], [I4, Z4]])  # In[46]
tau = {0: I8}  # In[338]
for h in (1, 2, 3):

## 9. The rules of sigma and tau

The next cell checks, exactly, everything that the Revision record checks about
these matrices:

- sigma is symmetric, has trace 0 (the sum of its diagonal entries) and
  $\sigma^2 = I_8$;
- tau[7] = diag(-1, -1, -1, -1, 1, 1, 1, 1) and tau[1] tau[2] ... tau[7] = $I_8$;
- sigma = tau[1] tau[2] tau[3] = tau[4] tau[5] tau[6] tau[7], and
  sigma taubar[A] = (sigma tau[A])$^T$ for A = 0, ..., 7;
- taubar[A] = -tau[A] for A = 1, ..., 7;
- tau[A] tau[B] + tau[B] tau[A] = $-2\,$eta4488$_{AB} I_8$ for A, B = 1, ..., 7: the
  seven matrices tau[1], ..., tau[7] satisfy a Clifford relation of their own (three
  square to $-I_8$, four to $+I_8$);
- tau[A] taubar[B] + tau[B] taubar[A] = taubar[A] tau[B] + taubar[B] tau[A] =
  $2\,$eta4488$_{AB} I_8$ for A, B = 0, ..., 7 (64 pairs). This is the key rule:
  the next step turns it into the Clifford relation of the $16 \times 16$ matrices.
```

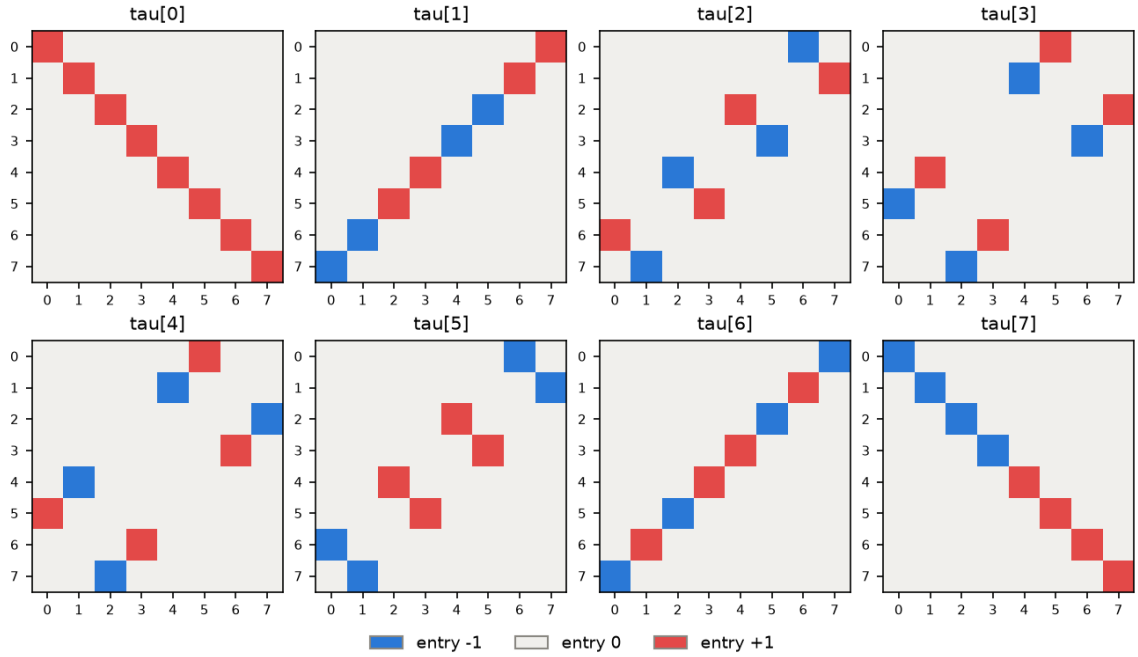

Figure 117: The author's eight 8×8 matrices tau for A = 0 to 7 (rows and columns numbered 0 to 7; blue -1, grey 0, red $+1$). tau 0 is the identity; tau 1 to tau 6 are made of two 4×4 blocks in the upper-right and lower-left corners (s4 for A = 1, 2, 3 and t4 for A = 6, 5, 4); tau 7, the product of the first six, is diagonal with four entries -1 and four entries $+1$. ## 10. Step 3: the $16 \times 16$ matrices T16[A]

The author puts taubar[A] into the upper-right and tau[A] into the lower-left
$8 \times 8$ corner of a $16 \times 16$ matrix (In[371]), and multiplies the first
eight in order to obtain T16[8] (In[372]). Why this works: by the rule for
multiplying block matrices (blocks multiply like the entries of $2 \times 2$
matrices, keeping their order),

$$\mathrm{T16}[A]\,\mathrm{T16}[B] =
\begin{pmatrix} 0 & \bar\tau_A \\ \tau_A & 0 \end{pmatrix}
\begin{pmatrix} 0 & \bar\tau_B \\ \tau_B & 0 \end{pmatrix} =
\begin{pmatrix} \bar\tau_A \tau_B & 0 \\ 0 & \tau_A \bar\tau_B \end{pmatrix},$$

where $\bar\tau$ stands for taubar. Adding the same with A and B exchanged gives the
two diagonal blocks taubar[A] tau[B] + taubar[B] tau[A] and tau[A] taubar[B] +
tau[B] taubar[A], which the previous cell found to be $2\,$eta4488$_{AB} I_8$ each.
So T16[A] T16[B] + T16[B] T16[A] = $2\,$eta4488$_{AB} I_{16}$: the Clifford relation
in the author's frame order. The next cell builds the nine matrices and checks the
block form, and checks two facts about T16[8] that the Revision record states: it is
the diagonal matrix diag(-1, ..., -1, 1, ..., 1) with eight entries of each sign, and
T16[0] T16[1] ... T16[8] = $I_{16}$ (this is T16[8] T16[8] = $I_{16}$). The meaning of
T16[8] (it is called the *chirality*) belongs to the study of the matrices built from
the gammas; here it is only a product.
```

In [15]:

```
T16 = {A: np.block([[Z8, taubar[A]], [tau[A], Z8]]) for A in range(8)}  # In[371]

## 11. Step 4: the author's coordinates x0, ..., x7

The next cell names the matrices after the author's coordinates. The list
'FRAME_INDEX' holds, for $x_0, \dots, x_7$ in this order, the index A of T16[A] in the
author's Mathematica notebook: 0, 1, 2, 3, 4, 5, 6, 7, because his frame directions
come in the order of his coordinates. The frame metric in the order
$x_0, \dots, x_7$ is read off from eta4488 through the same list. The cell prints one
line per coordinate and checks that $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1,
-1)$: space-like $x_0, x_1, x_2, x_3$ and time-like $x_4, x_5, x_6, x_7$, as the
author's metric requires. From here on, 'gamma[0]' is $\gamma^{(x_0)}$, ...,
'gamma[7]' is $\gamma^{(x_7)}$ (a Python list counts from 0, like the author's
coordinates).
```

## 13. Reality, signed permutations, symmetry

The next cell checks three more properties that the Revision record checks:

1. **reality**: every entry is $-1$, $0$ or $+1$ (in particular real);
2. every $\gamma^a$ is a **signed permutation matrix** (one nonzero entry in each row
   and in each column); such a matrix is *orthogonal*: $M^T M = I$;
3. the **symmetry pattern**: $\gamma^a$ is symmetric for the space-like directions
   $x_0, x_1, x_2, x_3$ and antisymmetric for the time-like directions
   $x_4, \dots, x_7$; in one formula $(\gamma^a)^T = \eta_{aa}\gamma^a$.

Point 3 follows from point 2 and the Clifford relation, line by line:
$(\gamma^a)^T = (\gamma^a)^{-1}$ (orthogonal); $(\gamma^a)^2 = \eta_{aa} I_{16}$
(Clifford relation with $b = a$), so $\gamma^a \cdot \eta_{aa}\gamma^a = I_{16}$
(multiply by $\eta_{aa}$ and use $\eta_{aa}^2 = 1$), that is
$(\gamma^a)^{-1} = \eta_{aa}\gamma^a$; together, $(\gamma^a)^T = \eta_{aa}\gamma^a$.
```

## 14. Comparison with the Revision record files

The Revision record stores the eight gammas in two files:
‘Revision/algebra/gammas.json‘ (written by the WolframScript verifier) and
‘Revision/algebra/reports/python-gammas.json‘ (written by the Python checker). In
‘gammas.json‘ every number is written exactly: a whole number as a JSON integer and a
```

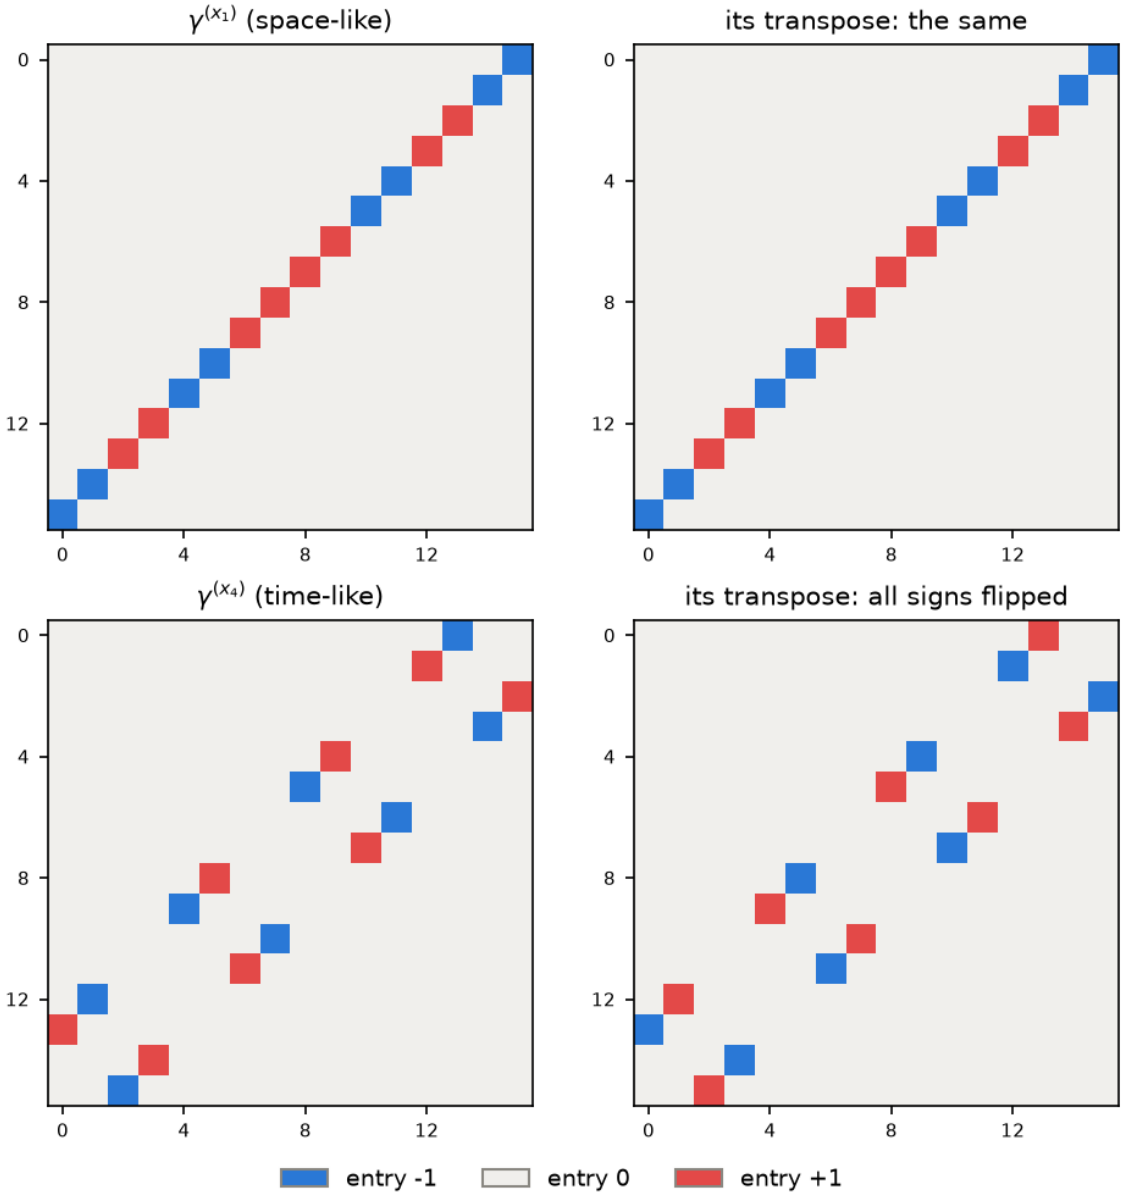

Figure 121: The symmetry pattern of the gammas (rows and columns numbered 0 to 15; blue -1, grey 0, red $+1$). Upper row: the space-like $\gamma^{(x_1)}$ and its transpose (rows and columns exchanged) are the same picture, so $\gamma^{(x_1)}$ is symmetric. Lower row: the transpose of the time-like $\gamma^{(x_4)}$ has every colour flipped, so $\gamma^{(x_4)}$ is antisymmetric. In general $(\gamma^a)^T = \eta_{aa}\gamma^a$. (Notebook 04a, figure 6.)

fraction as a text "p/q" (the function ‘exact‘ below reads both). The next cell reads both files, compares the coordinate names, the frame metric, the map to the author’s index A, and every one of the $8 \times 256 = 2048$ entries of the gammas with the matrices built above, and counts the entries that differ.

In [26]:

```
def exact(entry):
    """An exact number of gammas.json: a JSON integer, or a text "p/q"."""
    if isinstance(entry, int):
        return Fraction(entry)

ALL 28 CHECKS PASSED (notebook 04a)
```

Text cell:

```
## 16. What this notebook showed

- PROVED (exact integer arithmetic, this notebook; also in the Revision reports
  ‘Revision/algebra/reports/wolfram-algebra.json‘ and ‘python-algebra.json‘): the
  author’s formulas give six $4 \times 4$ blocks, exactly the ones his notebook
  displays; they are antisymmetric, square to $-I_4$, s4 is self-dual and t4
  anti-self-dual, and every s4 commutes with every t4. The blocks are the right
  (s4) and minus the left (t4) multiplications by the quaternion units
  $\mathbf{i}, \mathbf{j}, \mathbf{k}$, which explains these rules.
- PROVED: the $8 \times 8$ matrices satisfy sigma = tau[1] tau[2] tau[3] =
  tau[4] tau[5] tau[6] tau[7], tau[7] = diag(-I4, I4), taubar[A] = -tau[A]
  (A = 1, ..., 7), and the key rule tau[A] taubar[B] + tau[B] taubar[A] =
  $2\,$eta4488$_{AB} I_8$ for all 64 pairs.
- PROVED: the $16 \times 16$ matrices T16[A] = ((0, taubar[A]), (tau[A], 0)) satisfy
  the Clifford relation; named after the author’s coordinates
  ($\gamma^{(x_k)}$ = T16[k] for k = 0, ..., 7) they satisfy
  $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I_{16}$ with
  $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ for all 64 pairs (numpy and
  sympy); they are real signed permutation matrices, symmetric for $x_0, x_1, x_2,
  x_3$ and antisymmetric for the time $x_4$ and the deflating extra times
  $x_5, x_6, x_7$.
- The matrices agree entry by entry with the Revision record files
  ‘Revision/algebra/gammas.json‘ and ‘Revision/algebra/reports/python-gammas.json‘;
  the notebook reproduces 30 checks of the two Revision reports.
- ASSUMED: nothing beyond the author’s formulas. The gamma matrices are pure
  algebra: they make no physical claim. They are constant; the inflation of 3-space
  and the deflation of the extra times enter only later, through the frame factors
  of the metric.
```

4.8 Line-by-line walk-through of Notebook 04a

The notebook has 28 code cells, In [1] to In [28]. This section quotes every line of every one of them, in order, and explains what each line or small group of lines does. Only the long caption texts handed to `save_figure` are shortened here, to a line `...)` whose three dots stand for the caption text and whose bracket closes the call of `save_figure`, because each caption is printed in full under its figure in Section 4.7; every walk-through of this chapter does the same. Two kinds of lines are text for the reader and are not executed: a **comment** is everything after a `#` sign on a line, and a **docstring** is a text in triple quotes `"""..."""` directly below a `def` line, which says in words what the function does (Python stores it with the function and skips it when the function runs). They are quoted with the code they describe; the explanations below add what they do not already say.

In [1], the set-up cell. Its first part is the complete run instructions of Section 4.6 again, as **comment lines**: every line that starts with `#` is a comment, which Python skips; they are there so that the notebook file carries its own instructions. The code starts after the second line of `=` signs. This set-up cell is the same in every notebook of the book, except for the line that names the notebook.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json`, `os`, `textwrap` and `pathlib` come with Python; `from pathlib import Path` takes only the name `Path` out of `pathlib`. A `Path` is the address of a file or folder, written the same way on every operating system. The plotting package matplotlib is loaded, its drawing functions under the short name `plt`, and from IPython (the part of Jupyter that runs Python code) the two functions `Image` and `display`, which show a picture file below a cell.

```
NOTEBOOK_ID = "04a"  # this notebook: chapter 04, example a
```

A **variable** is a name for a value; this line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"04a"`. The figure files and the last printed line use it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` lists its parent folder, the parent of that, and so on; `[here, *here.parents]` is the list that starts with `here` and continues with all of them (the star unpacks the parents into the list). The `for` loop takes the folders one after the other; the operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none qualifies, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The line `REPO = find_repository_root()` calls the function and names the result `REPO`. As its comment says, it is never printed, because it differs from computer to computer while the printed output must not. The line that defines `OUTPUT_ROOT` chooses the folder below which files are written: `os.environ` holds the **environment variables** of the running program (named texts it receives from the computer), and `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and otherwise the default, the repository folder as a string. When you run the notebook the variable is not set, so the files go into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` gives the full path of a repository file, for reading a Revision record. `output_file("Revision/...")` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder that will hold it (and any missing folder above it) and does nothing if it exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters (the width of a page of the book); `textwrap.fill` breaks the text at blanks, and every continuation line starts with four blanks. `str(text)` turns any value into a string first.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings of matplotlib, so that personal settings on your computer cannot change the figures. `plt.rcParams.update({...})` then sets four settings for every figure: 7.0 by 4.2 inches, letters of 10 points, and a faint grid (30 per cent opaque) behind the curves. The braces `{...}` make a **dictionary**, a collection of pairs `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/04a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes the text `{}` (an empty JSON dictionary) and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` writes the same line end on every operating system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` saves and shows a figure, as its docstring says; `<id>` and `<k>` in the docstring stand for the notebook's name and the figure's number. `setdefault(name, value)` returns the number already stored for this figure name or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, and a cell run twice keeps its number. `fig.savefig` writes the PNG file with 150 dots per inch, cuts away the empty margin (`bbox_inches="tight"`) and stores no program name (`metadata={"Software": None}`), so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time. The caption is stored, the whole dictionary of captions is written to the captions file (`json.dumps` turns it into JSON text, one entry per line, keys sorted), `display(Image(...))` shows the saved picture, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection in square brackets). `check` is behind every check of the book. `condition` is either `True` or `False`; if it is false, `raise AssertionError(...)` stops the notebook with an error naming the check. (Python also has a statement `assert condition`, but the docstring explains why it is not used: Python started with the option `-O` skips every `assert`, while an `if` statement always runs.) Otherwise the name is appended to `PASSED` and `PASS name` is printed. `record=None` makes the third argument optional; when given, a second line names the Revision record that the check reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; the expression `(f" {unit}" if u nit else "")` adds a blank and the unit only when a unit is given. `all_checks_passed` prints the last line of the notebook with `len(PASSED)`, the number of checks that passed. The last statement prints the only output of In [1].

In [2], the small tools.

```
import itertools  # loops over all pairs (or triples, ...) of indices
from fractions import Fraction  # exact fractions such as 1/2

import numpy as np  # integer matrices; their products are exact (no rounding)
import sympy as sp  # a second, independent engine for exact matrix algebra
from matplotlib.colors import BoundaryNorm, ListedColormap
from matplotlib.patches import Patch, Rectangle
```

`itertools` makes all pairs, triples or lists of indices; `Fraction` (used in In [26]) holds exact fractions. numpy, under the short name `np`, stores matrices as arrays; all matrices of this notebook hold whole numbers (numpy's type `int64`), whose sums and products are exact, so every check is exact. sympy, as `sp`, is a second program for exact algebra, used in In [21] as an independent judge. `Boundary Norm` and `ListedColormap` make the three-colour heat maps; `Patch` draws the coloured squares of a legend and `Rectangle` a frame.

```
def signature(numbers):
    """Mathematica's Signature: 0 if a number occurs twice; otherwise +1 for an even
    and -1 for an odd number of inversions (pairs of positions i < j with
    numbers[i] > numbers[j])."""
    if len(set(numbers)) != len(numbers):  # a set keeps each number only once
        return 0
    inversions = sum(1 for i, j in itertools.combinations(range(len(numbers)), 2)
```

```
                    if numbers[i] > numbers[j])
    return -1 if inversions % 2 else 1  # % 2 is the remainder after division by 2
```

The permutation sign of Section 4.2. `set(numbers)` keeps each number once, so if it is shorter than the list a number is repeated and the sign is 0. `itertools.combinations(range(len(numbers)), 2)` lists every pair of positions $i < j$; the expression `sum(1 for ... if numbers[i] > numbers[j])` adds 1 for every pair in which the larger number stands first, that is it counts the inversions. `inversions % 2` is 1 for an odd and 0 for an even count, and Python reads 1 as true and 0 as false, so the function returns -1 for an odd and $+1$ for an even number of inversions.

```
def delta(i, j):
    """The Kronecker delta: 1 if i == j, otherwise 0."""
    return 1 if i == j else 0

def anticommutator(a, b):
    """{a, b} = a b + b a; the operator @ multiplies matrices."""
    return a @ b + b @ a

def identity(n):
    """The n x n identity matrix with whole-number entries."""
    return np.eye(n, dtype=np.int64)

def zeros(n):
    """The n x n zero matrix with whole-number entries."""
    return np.zeros((n, n), dtype=np.int64)
```

Four short functions, each with one line of code below its docstring: the Kronecker delta (1 if $i = j$, else 0; `==` tests equality); the anticommutator $\{a, b\} = ab + ba$, with `@` the matrix product; the $n \times n$ identity matrix with whole-number entries (`np.eye`); and the $n \times n$ zero matrix.

```
for numbers in ([1, 2, 3, 4], [2, 1, 3, 4], [2, 3, 1, 4], [1, 1, 3, 4]):
    say(f"the sign of {numbers} is {signature(numbers)}")
check(signature([1, 2, 3, 4]) == 1 and signature([2, 1, 3, 4]) == -1
      and signature([2, 3, 1, 4]) == 1 and signature([1, 1, 3, 4]) == 0,
      "the permutation sign agrees with the four examples worked out by hand")
```

The loop prints the sign of the four example lists of Section 4.2, and the check requires the values $+1$, -1, $+1$ and 0 found there by hand. `and` is true only when both sides are true. Output: four lines and the first PASS line.

In [3], the Revision reports.

```
WOLFRAM = "Revision/algebra/reports/wolfram-algebra.json"  # WolframScript report
PYTHON = "Revision/algebra/reports/python-algebra.json"  # Python report
RECORDED = {}  # report file -> {check name: the check (name, verdict, detail)}
for report_file in (WOLFRAM, PYTHON):
    text = repository_file(report_file).read_text(encoding="utf-8")
```

```
    RECORDED[report_file] = {entry["name"]: entry
                             for entry in json.loads(text)["checks"]}
    say(f"{report_file}: {len(RECORDED[report_file])} checks recorded")
REPRODUCED = set()  # the (report, check) pairs that this notebook reproduces
```

The two report files of the Revision record are named. For each, `read_text` reads the file and `json.loads` turns the JSON text into Python lists and dictionaries; the report holds a list `"checks"` of entries, each with a `"name"`, a `"verdict"` and a `"detail"`. The **dictionary comprehension** `{entry["name"]: entry for entry in ...}` makes a dictionary from check names to entries. The cell prints how many checks each report holds: 45 and 35. `REPRODUCED` starts as an empty **set** (a collection without repetitions).

```
def check_record(condition, name, *records):
    """check(condition, name) for a statement that the Revision record verified too.
    records: pairs (report file, check name); each must be recorded as passed."""
    for report_file, check_name in records:
        entry = RECORDED[report_file].get(check_name)
        if entry is None or entry["verdict"].upper() != "PASS":
            raise AssertionError(f"{report_file} has no passed check {check_name}")
    check(condition, name)
    for report_file, check_name in records:
        print(f"     reproduces {report_file}")
        print(f"          check {check_name}")
        REPRODUCED.add((report_file, check_name))
```

`check_record` is `check` for a statement that the Revision record also verified. `*records` collects any number of further arguments, each a pair (report file, check name). The first loop looks each check up (`.get` returns `None` for a missing name) and stops with an error if it is missing or not recorded as passed; `.upper()` makes the comparison work for both spellings, PASS in the WolframScript report and pass in the Python report. Then `check` tests the notebook's own condition and prints the PASS line, and the second loop prints, for each Revision check, the file and the check name and adds the pair to `REPRODUCED`.

In [4], the drawing tools.

```
# Three colours: entry -1 blue, entry 0 light grey, entry +1 red.
SIGN_COLOURS = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])
# The boundaries -1.5, -0.5, 0.5, 1.5 put -1, 0 and +1 into the three colours.
SIGN_NORM = BoundaryNorm([-1.5, -0.5, 0.5, 1.5], SIGN_COLOURS.N)
```

A colour such as `"#2a78d6"` is written as three two-digit hexadecimal numbers (base 16) for the amounts of red, green and blue. `ListedColormap` makes a list of three colours; `BoundaryNorm` with the boundaries $-1.5, -0.5, 0.5, 1.5$ assigns every value between two neighbouring boundaries to one colour, so -1 is blue, 0 light grey and $+1$ red. `SIGN_COLOURS.N` is the number of colours, 3.

```
def draw_signs(ax, matrix, title, numbers=False, first=0):
    """Draw a matrix with entries -1, 0, +1 as a heat map in the panel ax."""
    size = matrix.shape[0]
    ax.imshow(matrix, cmap=SIGN_COLOURS, norm=SIGN_NORM)
```

```
    ax.set_title(title, fontsize=10)
    step = 1 if size <= 8 else 4  # label every row (small) or every 4th (large)
    ticks = list(range(0, size, step))
    ax.set_xticks(ticks, [str(t + first) for t in ticks], fontsize=7)
    ax.set_yticks(ticks, [str(t + first) for t in ticks], fontsize=7)
    ax.grid(False)  # no grid lines on top of the coloured squares
    if numbers:
        for (row, column), value in np.ndenumerate(matrix):
            if value:
                ax.text(column, row, f"{value:+d}", ha="center", va="center",
                        color="white", fontsize=8)
```

`draw_signs` draws one matrix into one **panel** `ax` (a pair of axes) of a figure. `matrix.shape[0]` is its number of rows. `ax.imshow` paints every entry as a small coloured square, row 0 at the top. The axis labels mark every row of a small matrix and every fourth row of a large one; `range(0, size, step)` counts from 0 in steps of `step`, and `t + first` shifts the labels to start at 1 for the author's 4×4 blocks. With `numbers=True`, `np.ndenumerate` runs through all entries with their positions, and every nonzero entry is written into its square in white, with its sign (`{value:+d}` writes $+1$ or -1); `ha` and `va` centre the text.

```
def sign_legend(fig):
    """The key of the three colours, below the panels of the figure."""
    handles = [Patch(facecolor=SIGN_COLOURS(k), edgecolor="#898781", label=label)
               for k, label in enumerate(["entry -1", "entry 0", "entry +1"])]
    fig.legend(handles=handles, loc="outside lower center", ncol=3, fontsize=9,
               frameon=False)
```

`sign_legend` adds the key of the three colours below the panels. `enumerate` numbers the three labels 0, 1, 2; `SIGN_COLOURS(k)` is colour number `k`; each `Patch` is a small coloured square with its label, and `fig.legend` places the three in one row (`ncol=3`) below the figure, without a frame.

In [5], the six blocks.

```
def Qa(h, p, q):
    """The author's Qa[h, p, q] (In[294]); h, p, q count from 1, as in Mathematica."""
    return signature([h, p, q, 4])

def Qb(h, p, q):
    """The author's Qb[h, p, q] (In[294])."""
    return delta(p, 4) * delta(q, h) - delta(p, h) * delta(q, 4)
```

The author's two patterns of Section 4.5, letter for letter: $Q_a[h]_{pq} = \text{Signature}[\{h, p, q, 4\}]$ and $Q_b[h]_{pq} = \delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4}$, with h, p, q counted from 1; `*` multiplies numbers.

```
# s4[h] = Qa - Qb (In[300]) and t4[h] = Qa + Qb (In[301]). Row p, column q of the
# formula (1 to 4) is row p - 1, column q - 1 of the numpy array (0 to 3).
s4 = {h: np.array([[Qa(h, p, q) - Qb(h, p, q) for q in range(1, 5)]
                   for p in range(1, 5)]) for h in (1, 2, 3)}
t4 = {h: np.array([[Qa(h, p, q) + Qb(h, p, q) for q in range(1, 5)]
                   for p in range(1, 5)]) for h in (1, 2, 3)}
```

`range(1, 5)` is 1, 2, 3, 4. The inner **list comprehension** `[... for q in range(1, 5)]` makes one row (the four columns q), the outer one the four rows p, and `np.array` turns the list of rows into a matrix. Row p of the formula becomes row $p-1$ of the array, because numpy counts from 0. The dictionaries `s4` and `t4` hold the three blocks under the keys 1, 2, 3.

```
def side_by_side(matrices, labels):
    """Print square matrices next to each other, one printed line per row."""
    # ^11: centred in 11 characters; rstrip() removes the blanks at the end
    print("   ".join(f"{label:^11}" for label in labels).rstrip())
    for row in range(matrices[0].shape[0]):
        print("   ".join(" ".join(f"{x:2d}" for x in m[row]) for m in matrices))

side_by_side([s4[1], s4[2], s4[3]], ["s4[1]", "s4[2]", "s4[3]"])
print()
side_by_side([t4[1], t4[2], t4[3]], ["t4[1]", "t4[2]", "t4[3]"])
```

`side_by_side` prints several matrices next to each other. `" ".join(...)` glues texts together with three blanks between them; `{label:^11}` centres a title in 11 characters. For each row number, the inner `" ".join(f"{x:2d}" ...)` writes the entries of that row of one matrix, each two characters wide, and the outer join puts the rows of the three matrices next to each other. The output shows the six blocks, exactly the matrices of Section 4.5; `print()` prints the empty line between the two groups.

In [6], comparison with the author's display.

```
DISPLAYED_S4 = {  # Out[304] of the author's notebook: s4by4[1], s4by4[2], s4by4[3]
    1: [[0, 0, 0, 1], [0, 0, 1, 0], [0, -1, 0, 0], [-1, 0, 0, 0]],
    2: [[0, 0, -1, 0], [0, 0, 0, 1], [1, 0, 0, 0], [0, -1, 0, 0]],
    3: [[0, 1, 0, 0], [-1, 0, 0, 0], [0, 0, 0, 1], [0, 0, -1, 0]],
}
DISPLAYED_T4 = {  # Out[304]: t4by4[1], t4by4[2], t4by4[3]
    1: [[0, 0, 0, -1], [0, 0, 1, 0], [0, -1, 0, 0], [1, 0, 0, 0]],
    2: [[0, 0, -1, 0], [0, 0, 0, -1], [1, 0, 0, 0], [0, 1, 0, 0]],
    3: [[0, 1, 0, 0], [-1, 0, 0, 0], [0, 0, 0, -1], [0, 0, 1, 0]],
}
```

The six matrices that the author's notebook displays in its output Out[304], typed in row by row (the Revision Python checker types in the same six).

```
# .all() is True when the comparison holds for every entry.
same = all((s4[h] == np.array(DISPLAYED_S4[h])).all()
           and (t4[h] == np.array(DISPLAYED_T4[h])).all() for h in (1, 2, 3))
check_record(same, "the formulas give the six blocks that the author displays",
             (PYTHON, "notebook_blocks_s4_t4"),
             (WOLFRAM, "s4_t4_entries_from_Signature_and_deltas"))
```

Comparing two numpy arrays with `==` gives an array of `True`/`False`, one per entry; `.all()` is true when every entry agrees. `all(... for h in (1, 2, 3))` requires it for the three values of h. The check prints PASS and names the two Revision checks it reproduces.

In [7], figure 1.

```
fig, axes = plt.subplots(2, 3, figsize=(7.4, 5.6), layout="constrained")
for h in (1, 2, 3):
    draw_signs(axes[0, h - 1], s4[h], f"s4[{h}]", numbers=True, first=1)
    draw_signs(axes[1, h - 1], t4[h], f"t4[{h}]", numbers=True, first=1)
sign_legend(fig)
save_figure(fig, "blocks_s4_t4",
            ...)
```

(The caption is shortened here to the line `...)`: the three dots stand for the caption text, and the bracket closes the call of `save_figure`. The caption is printed in full in Section 4.7, written as several strings next to each other, which Python joins into one.) `plt.subplots(2, 3, ...)` makes a figure with two rows of three panels, 7.4 by 5.6 inches; `layout="constrained"` spaces the panels so that nothing overlaps. `axes[0, h - 1]` is the panel in row 0 and column $h-1$. The upper row shows s4[1], s4[2], s4[3], the lower row the t-blocks, each entry written into its square, rows and columns numbered 1 to 4. **What figure 1 shows and why:** every block has exactly one coloured square in each row and each column (a signed permutation), and the square in row p, column q has the opposite colour of the square in row q, column p, because every block is antisymmetric (Section 4.5).

In [8], the rules of the blocks.

```
I4 = identity(4)
blocks = [s4[1], s4[2], s4[3], t4[1], t4[2], t4[3]]
antisymmetric = all((m.T == -m).all() for m in blocks)
square_minus_one = all((m @ m == -I4).all() for m in blocks)
```

`m.T` is the transpose of `m`. `antisymmetric` is true when $m^T = -m$ for all six blocks, and `square_minus_one` when $m\,m = -I_4$ for all six.

```
anticommute = all((anticommutator(s4[h], s4[k]) == -2 * delta(h, k) * I4).all()
                  and (anticommutator(t4[h], t4[k]) == -2 * delta(h, k) * I4).all()
                  for h in (1, 2, 3) for k in (1, 2, 3))
s_t_commute = all((s4[h] @ t4[k] == t4[k] @ s4[h]).all()
                  for h in (1, 2, 3) for k in (1, 2, 3))
```

The two `for` parts run through all nine pairs (h, k). `anticommute` tests $\{\mathrm{s4}[h], \mathrm{s4}[k]\} = \{\mathrm{t4}[h], \mathrm{t4}[k]\} = -2\delta_{hk} I_4$, and `s_t_commute` tests that every s-block commutes with every t-block.

```
check_record(antisymmetric and square_minus_one and s_t_commute,
             "the blocks are antisymmetric, square to -I4, and s4 commutes with t4",
             (PYTHON, "blocks_antisymmetric_square_minus_one_commute"))
check_record(anticommute and s_t_commute and antisymmetric,
             "{s4[h], s4[k]} = {t4[h], t4[k]} = -2 delta_hk I4, [s4[h], t4[k]] = 0",
             (WOLFRAM, "s4_t4_quaternion_algebras"))
```

Two checks, each worded as the Revision check it reproduces: the Python check combines antisymmetry, squares and commuting, the WolframScript check the anticommutators, the commuting and the antisymmetry.

In [9], self-dual and anti-self-dual.

```
epsilon = np.zeros((4, 4, 4, 4), dtype=np.int64)
for p, q, r, s in itertools.product(range(4), repeat=4):  # all 4^4 = 256 lists
    epsilon[p, q, r, s] = signature([p, q, r, s])
```

`epsilon` is a table with four indices, each 0 to 3 (counting from 0 does not change a permutation sign). `itertools.product(range(4), repeat=4)` lists all $4^4 = 256$ lists (p, q, r, s), and each entry is set to the permutation sign: the Levi-Civita symbol of Section 4.5.

```
def dual(m):
    """(1/2) sum_rs epsilon_pqrs m_rs for every p, q (a 4 x 4 matrix)."""
    twice = np.einsum("pqrs,rs->pq", epsilon, m)  # the sum over r and s
    if (twice % 2).any():  # for an antisymmetric m every entry of twice is even
        raise ValueError("the dual is not a whole-number matrix")
    return twice // 2  # exact division by 2
```

`np.einsum("pqrs,rs->pq", epsilon, m)` computes, for every p and q, the sum $\sum_{r,s} \epsilon_{pqrs} m_{rs}$: the letters before the arrow name the indices of the two inputs, the letters after it the indices of the result, and every letter that does not appear after the arrow is summed over. That is twice the dual. For an antisymmetric matrix every entry of it is even (the two equal terms of Section 4.5); the `if` line stops with an error otherwise, and `//` divides exactly by 2.

```
for h in (1, 2, 3):
    say(f"h = {h}: dual(s4) == s4: {(dual(s4[h]) == s4[h]).all()},  "
        f"dual(t4) == -t4: {(dual(t4[h]) == -t4[h]).all()}")
check_record(all((dual(s4[h]) == s4[h]).all() and (dual(t4[h]) == -t4[h]).all()
                 for h in (1, 2, 3)),
             "every s4[h] is self-dual and every t4[h] anti-self-dual",
             (WOLFRAM, "s4_self_dual_t4_anti_self_dual"))
```

For each h one line reports $\star\mathrm{s4}[h] = \mathrm{s4}[h]$ and $\star\mathrm{t4}[h] = -\mathrm{t4}[h]$ (three lines, all True), and the check requires both for all three.

In [10], the quaternions.

```
def quaternion_product(x, y):
    """x y for quaternions stored as (q1, q2, q3, q4) = q4 + q1 i + q2 j + q3 k."""
    x1, x2, x3, x4 = x
    y1, y2, y3, y4 = y
    return (x4 * y1 + x1 * y4 + x2 * y3 - x3 * y2,  # the i component
            x4 * y2 + x2 * y4 + x3 * y1 - x1 * y3,  # the j component
            x4 * y3 + x3 * y4 + x1 * y2 - x2 * y1,  # the k component
            x4 * y4 - x1 * y1 - x2 * y2 - x3 * y3)  # the real component
```

The product of two quaternions stored as (q_1, q_2, q_3, q_4). The first two lines **unpack** the four components of each. The four returned lines come from multiplying $(x_4 + x_1\mathbf{i} + x_2\mathbf{j} + x_3\mathbf{k})(y_4 + y_1\mathbf{i} + y_2\mathbf{j} + y_3\mathbf{k})$ term by term with Hamilton's rules; for example the $\mathbf{i}$ component collects x_4y_1 (from $x_4 \cdot y_1\mathbf{i}$), x_1y_4, x_2y_3 (from $\mathbf{jk} = \mathbf{i}$) and $-x_3y_2$ (from $\mathbf{kj} = -\mathbf{i}$), and the real component $x_4y_4 - x_1y_1 - x_2y_2 - x_3y_3$ (from $\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -1$).

```
UNITS = {1: (1, 0, 0, 0), 2: (0, 1, 0, 0), 3: (0, 0, 1, 0)}  # i, j, k
BASIS = [(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1)]  # e_1, ..., e_4

def right_multiplication(u):
    """The 4 x 4 matrix of q -> q u: column p holds the components of e_p u."""
    return np.array([quaternion_product(e, u) for e in BASIS]).T

def left_multiplication(u):
    """The 4 x 4 matrix of q -> u q: column p holds the components of u e_p."""
    return np.array([quaternion_product(u, e) for e in BASIS]).T
```

`UNITS` holds $\mathbf{i}, \mathbf{j}, \mathbf{k}$ under the keys 1, 2, 3, and `BASIS` the four quaternions $e_1, \ldots, e_4$. `right_multiplication(u)` lists the products $e_p u$ as the rows of an array and transposes it with `.T`, so that they become the columns: the matrix R_u of Section 4.5. `left_multiplication(u)` does the same with ue_p: the matrix L_u.

```
say(f"i j = {quaternion_product(UNITS[1], UNITS[2])} (that is k), "
    f"j i = {quaternion_product(UNITS[2], UNITS[1])} (that is -k)")
check(quaternion_product(UNITS[1], UNITS[2]) == (0, 0, 1, 0)
      and quaternion_product(UNITS[1], UNITS[1]) == (0, 0, 0, -1),
      "the quaternion product follows Hamilton's rules i j = k and i i = -1")
check(all((s4[h] == right_multiplication(UNITS[h])).all()
          and (t4[h] == -left_multiplication(UNITS[h])).all() for h in (1, 2, 3)),
      "s4[h] is right and t4[h] minus left multiplication by i, j, k")
```

The printed line shows $\mathbf{ij} = (0, 0, 1, 0) = \mathbf{k}$ and $\mathbf{ji} = (0, 0, -1, 0) = -\mathbf{k}$. The first check confirms two of Hamilton's rules; the second confirms $\mathrm{s4}[h] = R_{u_h}$ and $\mathrm{t4}[h] = -L_{u_h}$ for $h = 1, 2, 3$, the fact from which Section 4.5 derived every rule of the blocks.

In [11], σ, τ and $\bar{\tau}$.

```
I8, Z4, Z8 = identity(8), zeros(4), zeros(8)
eta4488 = np.diag([1, 1, 1, 1, -1, -1, -1, -1])  # In[45]: frame order A = 0..7
sigma = np.block([[Z4, I4], [I4, Z4]])  # In[46]
```

Three matrices are named in one line (I_8 and the zero matrices of sizes 4 and 8). `np.diag(list)` makes the diagonal matrix with the listed diagonal: the author's eta4488. `np.block` glues blocks into a big matrix, row of blocks by row of blocks: $\sigma = \begin{pmatrix} 0 & I_4 \\ I_4 & 0 \end{pmatrix}$.

```
tau = {0: I8}  # In[338]
for h in (1, 2, 3):
    tau[h] = np.block([[Z4, s4[h]], [s4[h], Z4]])  # tau[1], tau[2], tau[3]
    tau[7 - h] = np.block([[Z4, t4[h]], [-t4[h], Z4]])  # tau[6], tau[5], tau[4]
tau[7] = tau[1] @ tau[2] @ tau[3] @ tau[4] @ tau[5] @ tau[6]  # In[338]
taubar = {0: I8}  # In[351]
for A in range(1, 8):
    taubar[A] = sigma @ tau[A].T @ sigma
```

The dictionary `tau` starts with $\tau_0 = I_8$; the loop adds τ_h from s4[h] and τ_{7-h} from t4[h] for $h = 1, 2, 3$; τ_7 is the product of the first six; and `taubar` holds $\bar{\tau}_0 = I_8$ and $\bar{\tau}_A = \sigma\tau_A^T\sigma$ for $A = 1, \ldots, 7$ (`range(1, 8)` is 1 to 7). These are the formulas of Step 2 in Section 4.5.

```
def codes(m):
    """The code of every row of a signed permutation matrix m: "+5" in row i means
    (m u)_i = +u_5. Stops with an error if a row has not exactly one nonzero."""
    result = []
    for row in m:
        columns = np.flatnonzero(row)  # the columns of the nonzero entries
        if len(columns) != 1 or abs(row[columns[0]]) != 1:
            raise ValueError("not a signed permutation matrix")
        column = int(columns[0])
        result.append(("+" if row[column] > 0 else "-") + str(column))
    return result
```

`codes` writes a signed permutation matrix in the code notation of Section 4.2. For every row, `np.flatnonzero(row)` lists the columns of its nonzero entries; if there is not exactly one, or it is not ± 1, the function stops with an error (so `codes` also checks that the matrix is a signed permutation matrix). Otherwise it appends the sign and the column number, for example `"+5"`.

```
labels = [f"tau[{A}]" for A in range(1, 8)]  # the column titles
print("row " + "".join(f"{label:>8}" for label in labels))
tau_codes = {A: codes(tau[A]) for A in range(1, 8)}
for i in range(8):
    print(f"{i:3d} " + "".join(f"{tau_codes[A][i]:>8}" for A in range(1, 8)))
```

The table of codes: one title line (`{label:>8}` writes each title right-aligned in 8 characters) and one line per row $i = 0, \ldots, 7$ with the code of row i of each of $\tau_1, \ldots, \tau_7$. In the output one reads, for example, that τ_7 has the codes $-0, -1, -2, -3, +4, +5, +6, +7$: it is $\mathrm{diag}(-I_4, I_4)$, as Step 2 proved.

In [12], figure 2.

```
fig, axes = plt.subplots(2, 4, figsize=(8.6, 5.0), layout="constrained")
for A in range(8):
    draw_signs(axes[A // 4, A % 4], tau[A], f"tau[{A}]")  # // and %: row, column
sign_legend(fig)
save_figure(fig, "tau_matrices",
            ...)
```

Two rows of four panels; matrix A goes into row $A//4$ (the whole part of $A/4$) and column $A\%4$ (the remainder). **What figure 2 shows and why:** τ_0 is the identity (red diagonal); τ_1 to τ_6 have their entries only in the upper-right and lower-left 4×4 corners, because they are made of the blocks s4 and t4 placed there; τ_7 is diagonal with four blue and four red entries, $\mathrm{diag}(-I_4, I_4)$.

In [13], the rules of σ and τ.

```
sigma_ok = (sigma.T == sigma).all() and np.trace(sigma) == 0 \
    and (sigma @ sigma == I8).all()
check_record(sigma_ok, "sigma is symmetric, traceless and squares to I8",
             (WOLFRAM, "sigma8_involution"))
```

A backslash at the end of a line continues the statement on the next line. σ must be symmetric, have trace 0 (`np.trace`) and square to I_8.

```
product_1_to_7 = I8
for A in range(1, 8):
    product_1_to_7 = product_1_to_7 @ tau[A]
check_record((tau[7] == np.diag([-1, -1, -1, -1, 1, 1, 1, 1])).all()
             and (product_1_to_7 == I8).all(),
             "tau[7] = diag(-I4, I4) and tau[1] tau[2] ... tau[7] = I8",
             (PYTHON, "tau7_and_product"))
```

The loop multiplies $\tau_1\tau_2\cdots\tau_7$ step by step, starting from I_8. The check requires $\tau_7 = \mathrm{diag}(-I_4, I_4)$ and $\tau_1\cdots\tau_7 = I_8$ (Step 2, lines 7 and 9).

```
sigma_products = (sigma == tau[1] @ tau[2] @ tau[3]).all() and \
    (sigma == tau[4] @ tau[5] @ tau[6] @ tau[7]).all()
sigma_transpose = all((sigma @ taubar[A] == (sigma @ tau[A]).T).all()
                      for A in range(8))
check_record(sigma_products and sigma_transpose,
             "sigma = tau1 tau2 tau3 = tau4 ... tau7 and sigma taubar = (sigma tau)^T",
             (WOLFRAM, "tau7_and_sigma_identities"),
             (PYTHON, "notebook_sigma_eq_tau1tau2tau3"))
```

Two identities that the author's notebook states: $\sigma = \tau_1\tau_2\tau_3 = \tau_4\tau_5\tau_6\tau_7$ (Step 2, lines 5 and 9), and $\sigma\bar{\tau}_A = (\sigma\tau_A)^T$ for all eight A (true because $(\sigma\tau_A)^T = \tau_A^T\sigma^T = \tau_A^T\sigma$, and $\sigma\bar{\tau}_A = \sigma\sigma\tau_A^T\sigma = \tau_A^T\sigma$ since $\sigma^2 = I_8$).

```
check_record(sigma_transpose and all((taubar[A] == -tau[A]).all()
                                     for A in range(1, 8)),
             "taubar[A] = -tau[A] for A = 1, ..., 7",
             (PYTHON, "taubar_relations"))
check_record(all((anticommutator(tau[A], tau[B]) == -2 * eta4488[A, B] * I8).all()
                 for A in range(1, 8) for B in range(1, 8)),
             "tau[A] tau[B] + tau[B] tau[A] = -2 eta4488_AB I8 for A, B = 1..7",
             (PYTHON, "notebook_tau_clifford"))
```

$\bar{\tau}_A = -\tau_A$ for $A = 1, \ldots, 7$ (Step 2, line 10), and the Clifford relation of the seven τ with the signs $-$eta4488, for all 49 pairs; `eta4488[A, B]` is the entry in row A, column B. Five PASS lines in all.

In [14], the key rule.

```
table = np.zeros((8, 8), dtype=np.int64)
multiples_of_identity = True
other_order = True
for A, B in itertools.product(range(8), repeat=2):  # all 64 pairs
    m = tau[A] @ taubar[B] + tau[B] @ taubar[A]
    table[A, B] = m[0, 0]  # the number that multiplies I8 (if it is a multiple)
    multiples_of_identity &= bool((m == table[A, B] * I8).all())
    other = taubar[A] @ tau[B] + taubar[B] @ tau[A]
    other_order &= bool((other == table[A, B] * I8).all())
```

For each of the 64 pairs the matrix $\tau_A\bar{\tau}_B + \tau_B\bar{\tau}_A$ is computed and its upper-left entry stored in `table`; if the matrix is a multiple of I_8, that entry is the multiple. `x &= y` means `x = x and y`: `multiples_of_identity` stays true only if every one of the 64 matrices equals its entry times I_8. The same is tested for the other order $\bar{\tau}_A\tau_B + \bar{\tau}_B\tau_A$. `bool(...)` turns numpy's truth value into Python's.

```
print("A\\B" + "".join(f"{B:4d}" for B in range(8)))
for A in range(8):
    print(f"{A:3d}" + "".join(f"{table[A, B]:4d}" for B in range(8)))
check_record(multiples_of_identity and other_order and (table == 2 * eta4488).all(),
             "tau[A] taubar[B] + tau[B] taubar[A] = 2 eta4488_AB I8, both orders",
             (WOLFRAM, "tau_taubar_Clifford_relation"),
             (PYTHON, "notebook_tau_taubar_clifford"))
```

The table is printed (`"A\\B"` prints `A\B`, the backslash written twice in the code because a single one has a special meaning in strings), row A, column B: 2 on the diagonal for $A = 0, 1, 2, 3$, -2 for $A = 4, \ldots, 7$, and 0 elsewhere. The check requires that it is twice eta4488: the key rule of Section 4.5.

In [15], the 16×16 matrices.

```
T16 = {A: np.block([[Z8, taubar[A]], [tau[A], Z8]]) for A in range(8)}  # In[371]
T16[8] = T16[0]
for A in range(1, 8):
    T16[8] = T16[8] @ T16[A]  # In[372]: T16[8] = T16[0] T16[1] ... T16[7]
I16 = identity(16)
```

T16$[A] = \begin{pmatrix} 0 & \bar{\tau}_A \\ \tau_A & 0 \end{pmatrix}$ for $A = 0, \ldots, 7$, then T16[8] as the product T16[0] T16[1] $\cdots$ T16[7], built up step by step, and I_{16}.

```
# [:8, 8:] means rows 0 to 7 and columns 8 to 15 (the upper-right corner), etc.
block_form = all((T16[A][:8, :8] == 0).all() and (T16[A][8:, 8:] == 0).all()
                 and (T16[A][:8, 8:] == taubar[A]).all()
                 and (T16[A][8:, :8] == tau[A]).all() for A in range(8))
check_record(block_form, "T16[A] = ((0, taubar[A]), (tau[A], 0)) for A = 0, ..., 7",
             (WOLFRAM, "T16_block_form"))
```

A **slice** `[:8, 8:]` picks rows 0 to 7 and columns 8 to 15 (`:8` means up to, not including, 8; `8:` from 8 to the end). The check confirms the four corners of every T16$[A]$.

```
say(f"diagonal of T16[8]: {list(int(x) for x in np.diag(T16[8]))}")
check_record((T16[8] == np.diag([-1] * 8 + [1] * 8)).all(),
             "T16[8] = T16[0] ... T16[7] = diag(-I8, I8)",
             (WOLFRAM, "Gamma_diag"), (PYTHON, "chirality_diag"))
```

`np.diag(matrix)` extracts the diagonal of a matrix (while `np.diag(list)` builds one); the line prints the 16 diagonal entries: eight -1, then eight $+1$. `[-1] * 8 + [1] * 8` is the list of eight -1 followed by eight 1. The check confirms T16[8] = diag$(-I_8, I_8)$, proved by hand in Step 3.

```
product_0_to_8 = I16
for A in range(9):
    product_0_to_8 = product_0_to_8 @ T16[A]
check_record((product_0_to_8 == I16).all(), "T16[0] T16[1] ... T16[8] = I16",
             (WOLFRAM, "notebook_product_identity"))
```

The product of all nine matrices T16[0] to T16[8] is I_{16}, an identity that the author's notebook states; it is $\mathrm{T16}[8]^2 = I_{16}$.

In [16], figure 3.

```
fig, ax = plt.subplots(figsize=(5.6, 5.6), layout="constrained")
draw_signs(ax, T16[4], "T16[4], the gamma matrix of the time $x_4$")
for left, top in ((-0.5, -0.5), (7.5, -0.5), (-0.5, 7.5), (7.5, 7.5)):
    ax.add_patch(Rectangle((left, top), 8, 8, fill=False, edgecolor="#0b0b0b",
                           linewidth=1.5))  # the frame of one 8 x 8 corner
```

One panel with T16[4]. In `imshow` the centre of the square of entry (i, j) lies at the point (j, i), so the square of entry $(0, 0)$ starts at -0.5; each `Rectangle((left, top), 8, 8, fill=False, ...)` draws an unfilled black frame of 8×8 squares around one corner.

```
labels = {(3.5, 3.5): "0", (11.5, 3.5): "taubar[4]", (3.5, 11.5): "tau[4]",
          (11.5, 11.5): "0"}
for (x, y), label in labels.items():
    ax.text(x, y, label, ha="center", va="center", fontsize=12, color="#0b0b0b",
            bbox={"facecolor": "white", "alpha": 0.85, "edgecolor": "none"})
sign_legend(fig)
save_figure(fig, "block_form_of_t16",
            ...)
```

The centres of the four corners get their names, each on a white, slightly transparent background (`bbox`). **What figure 3 shows and why:** the upper-left and lower-right corners are empty, because T16[4] is block off-diagonal; the upper-right corner is $\bar{\tau}_4$ and the lower-left τ_4, with one coloured square in each row.

In [17], the author's coordinates.

```
COORDINATES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
FRAME_INDEX = [0, 1, 2, 3, 4, 5, 6, 7]  # A of T16[A] for x0, ..., x7
ROLE = ["hidden direction", "3-space", "3-space", "3-space", "the time",
        "extra time (deflating)", "extra time (deflating)", "extra time (deflating)"]
gamma = [T16[A] for A in FRAME_INDEX]  # gamma[0] = gamma^(x0), ...
eta = np.array([eta4488[A, A] for A in FRAME_INDEX])  # signs in the order x0..x7
```

The coordinate map of Section 4.4: `FRAME_INDEX` lists, for $x_0, \ldots, x_7$, the index A of the author's T16[A]: the numbers 0 to 7 themselves. `gamma` is the list of the eight gamma matrices in the order of the coordinates (Python counts it from 0, as the author counts his coordinates: `gamma[0]` is $\gamma^{(x_0)}$, `gamma[7]` is $\gamma^{(x_7)}$), and `eta` the list of their signs, read off from the diagonal of eta4488 at the same indices.

```
for a in range(8):
    kind = "space-like" if eta[a] > 0 else "time-like"
    print(f"gamma^({COORDINATES[a]}) = T16[{FRAME_INDEX[a]}]   eta = {eta[a]:+d}   "
          f"{kind:10}   {ROLE[a]}")
```

One printed line per coordinate: its matrix, its sign, its kind and its role.

```
renamed = all(gamma[k] is T16[k] for k in range(8))
check_record(list(eta) == [1, 1, 1, 1, -1, -1, -1, -1] and renamed,
             "gamma^(xk) = T16[k] for k = 0..7, eta = diag(+,+,+,+,-,-,-,-)",
             (WOLFRAM, "coordinate_map"), (WOLFRAM, "eta_in_author_order"),
             (PYTHON, "coordinate_map"))
```

`is` tests that two names refer to the very same object (not only equal entries): `gamma[k]` is T16[k] itself for $k = 0, \ldots, 7$. The check requires these and $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$, reproducing three Revision checks.

In [18], the eight gammas in code notation.

```
gamma_codes = [codes(g) for g in gamma]
print("row" + "".join(f"{name:>6}" for name in COORDINATES))
for i in range(16):
    print(f"{i:3d}" + "".join(f"{gamma_codes[a][i]:>6}" for a in range(8)))
```

`codes` (which also confirms that each is a signed permutation matrix) is applied to all eight gammas, and the table prints, for each row $i = 0, \ldots, 15$, the code of row i of each gamma. This table is the complete content of the eight matrices: for example the column x4 starts with -13, so $(\gamma^{(x_4)}u)_0 = -u_{13}$, and the column x0 reads $+8, +9, \ldots, +15, +0, \ldots, +7$: $\gamma^{(x_0)}$ exchanges the upper and the lower eight components. Every code of rows 0 to 7 is a column 8 to 15 and vice versa: the block form.

In [19], figure 4.

```
fig, axes = plt.subplots(2, 4, figsize=(8.8, 5.0), layout="constrained")
for a in range(8):
    draw_signs(axes[a // 4, a % 4], gamma[a], f"$\\gamma^{{(x_{a})}}$")
sign_legend(fig)
save_figure(fig, "gammas_x0_to_x7",
            ...)
```

The eight gammas in two rows of four panels. In the f-string title, the doubled braces `{{` and `}}` print single braces and the doubled backslash prints one, so the title becomes the mathematical text $\gamma^{(x_0)}$, ..., $\gamma^{(x_7)}$. **What figure 4 shows and why:** each matrix has exactly one coloured square in every row and every column, all in the upper-right and lower-left 8×8 corners (signed permutations in block form); $\gamma^{(x_0)}$ consists of two red diagonal lines, because it is T16[0] $= \begin{pmatrix} 0 & I_8 \\ I_8 & 0 \end{pmatrix}$. These are the author's eight real 16×16 gamma matrices themselves.

In [20], the Clifford relation for all 64 pairs.

```
c = np.zeros((8, 8), dtype=np.int64)  # {gamma^a, gamma^b} = c[a, b] I16
all_multiples = True
for a, b in itertools.product(range(8), repeat=2):
    m = anticommutator(gamma[a], gamma[b])
    c[a, b] = m[0, 0]
    all_multiples &= bool((m == c[a, b] * I16).all())
```

As in In [14], now for the gammas: for all 64 ordered pairs (a, b) the anticommutator is computed, its upper-left entry stored as c_{ab}, and `all_multiples` stays true only if each anticommutator is exactly $c_{ab} I_{16}$.

```
print("a\\b" + "".join(f"{name:>5}" for name in COORDINATES))
for a in range(8):
    print(f"{COORDINATES[a]:>3}" + "".join(f"{c[a, b]:5d}" for b in range(8)))
squares = ", ".join(f"{COORDINATES[a]}:{c[a, a] // 2}" for a in range(8))
say(f"squares (gamma^a)^2 / I16: {squares}")
```

The table of the c_{ab} is printed; the string `squares` lists, for each coordinate, $c_{aa}/2$, the number in $(\gamma^a)^2 = (c_{aa}/2) I_{16}$, in the form `x0:1, x1:1, ...`.

```
recorded = RECORDED[WOLFRAM]["Clifford_relation"]["detail"]
check_record(all_multiples and (c == 2 * np.diag(eta)).all() and squares in recorded,
             "{gamma^a, gamma^b} = 2 eta^ab I16 for all 64 pairs a, b",
             (WOLFRAM, "Clifford_relation"), (PYTHON, "clifford_relation"))
```

`recorded` is the detail text of the WolframScript check `Clifford_relation`. The check requires every anticommutator to be a multiple of I_{16}, the table to be 2η, and the text `squares` to appear word for word in the Revision detail (`in` tests whether one string is part of another). The output shows the table: 2 on the diagonal for x_0, x_1, x_2, x_3, -2 for $x_4, \ldots, x_7$, 0 elsewhere.

In [21], the same with sympy.

```
sympy_gamma = [sp.Matrix(g.tolist()) for g in gamma]  # the same entries, in sympy
sympy_ok = all(
    sympy_gamma[a] * sympy_gamma[b] + sympy_gamma[b] * sympy_gamma[a]
    == 2 * int(eta[a] * delta(a, b)) * sp.eye(16)
    for a in range(8) for b in range(a, 8))
check_record(sympy_ok, "sympy confirms the 36 relations {gamma^a, gamma^b} = 2 eta^ab",
             (PYTHON, "clifford_relation_sympy"))
```

`g.tolist()` turns a numpy array into a list of rows, and `sp.Matrix` makes a sympy matrix of it; in sympy `*` is the matrix product and `sp.eye(16)` the identity. `range(a, 8)` makes b run from a to 7, so the 36 pairs with $a \le b$ are tested (the others follow, because $\{\gamma^a, \gamma^b\} = \{\gamma^b, \gamma^a\}$). $2\eta^{ab}$ is written as $2\,\eta_{aa}\delta_{ab}$, since η is diagonal.

In [22], one relation followed by hand.

```
def follow(m, row):
    """(m u)_row = sign * u_column for a signed permutation m: return (sign, column)."""
```

```
    column = int(np.flatnonzero(m[row])[0])
    return int(m[row, column]), column

def signed(sign, letter, index):
    """The text "+u_5" or "-u_5" for sign = +1 or -1, letter = "u", index = 5."""
    return ("+" if sign > 0 else "-") + letter + "_" + str(index)
```

`follow(m, row)` reads one row of a signed permutation matrix the way a student reads the code table: it returns the sign and the column of the single nonzero entry, so that $(mu)_{\text{row}} = \text{sign} \cdot u_{\text{column}}$. `signed` writes such a term as a text, for example `-u_13`.

```
g4, g0 = gamma[4], gamma[0]  # gamma^(x4) and gamma^(x0)
s1, c1 = follow(g4, 0)  # row 0 of gamma^(x4)
s2, c2 = follow(g4, c1)  # row c1 of gamma^(x4)
say(f"row 0 of gamma^(x4):  (gamma^(x4) v)_0 = {signed(s1, "v", c1)}")
say(f"row {c1} of gamma^(x4): (gamma^(x4) u)_{c1} = {signed(s2, "u", c2)}")
say(f"with v = gamma^(x4) u: (gamma^(x4) gamma^(x4) u)_0 = {signed(s1 * s2, "u", c2)}")
```

Row 0 of $\gamma^{(x_4)}$ gives $(\gamma^{(x_4)}v)_0 = -v_{13}$; row 13 gives $(\gamma^{(x_4)}u)_{13} = +u_0$. With $v = \gamma^{(x_4)}u$: $(\gamma^{(x_4)}\gamma^{(x_4)}u)_0 = -v_{13} = -u_0$, row 0 of $(\gamma^{(x_4)})^2 = -I_{16}$. (The f-strings contain double quotes inside their braces, such as `signed(s1, "v", c1)`; Python allows this from version 3.12 on, one reason why the book needs Python 3.12 or newer.)

```
t1, d1 = follow(g0, 0)  # row 0 of gamma^(x0) gamma^(x4): first gamma^(x0) ...
t2, d2 = follow(g4, d1)  # ... then row d1 of gamma^(x4)
r1, e1 = follow(g4, 0)  # row 0 of gamma^(x4) gamma^(x0): first gamma^(x4) ...
r2, e2 = follow(g0, e1)  # ... then row e1 of gamma^(x0)
say(f"(gamma^(x0) gamma^(x4) u)_0 = {signed(t1 * t2, "u", d2)};  "
    f"(gamma^(x4) gamma^(x0) u)_0 = {signed(r1 * r2, "u", e2)}")
check(s1 * s2 == -1 and c2 == 0, "by hand: row 0 of (gamma^(x4))^2 is -u_0")
check(d2 == e2 and t1 * t2 == -(r1 * r2),
      "by hand: row 0 of gamma^(x0) gamma^(x4) is minus that of gamma^(x4) gamma^(x0)")
```

The same for the two orders of $\gamma^{(x_0)}$ and $\gamma^{(x_4)}$: row 0 of $\gamma^{(x_0)}$ points to component 8, and row 8 of $\gamma^{(x_4)}$ to $+u_5$, so $(\gamma^{(x_0)}\gamma^{(x_4)}u)_0 = +u_5$; row 0 of $\gamma^{(x_4)}$ points to $-$component 13, and row 13 of $\gamma^{(x_0)}$ to $+u_5$, so $(\gamma^{(x_4)}\gamma^{(x_0)}u)_0 = -u_5$. The two checks require the hand results: $-u_0$, and the same component with opposite signs.

In [23], figure 5.

```
fig, ax = plt.subplots(figsize=(5.4, 4.9), layout="constrained")
colours = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])  # -2, 0, +2
ax.imshow(c, cmap=colours, norm=BoundaryNorm([-3, -1, 1, 3], 3))
for (a, b), value in np.ndenumerate(c):
    ax.text(b, a, f"{value:+d}" if value else "0", ha="center", va="center",
            color="white" if value else "#52514e", fontsize=10)
```

The 8×8 table c as a heat map with the boundaries $-3, -1, 1, 3$, so -2 is blue, 0 grey and $+2$ red; each number is written into its square (white on colour, dark grey on grey).

```
labels = [f"$x_{k}$" for k in range(8)]
ax.set_xticks(range(8), labels)
ax.set_yticks(range(8), labels)
ax.set_xlabel("direction $b$")
ax.set_ylabel("direction $a$")
ax.set_title("$\\gamma^a\\gamma^b + \\gamma^b\\gamma^a = c_{ab}\\, I_{16}$")
ax.grid(False)
save_figure(fig, "anticommutator_table",
            ...)
```

The rows and columns are labelled $x_0, \ldots, x_7$, the axes named, the title set, and the figure saved. **What figure 5 shows and why:** a diagonal of four red and four blue squares: $c_{ab} = 2\eta^{ab}$, red for the space-like x_0, x_1, x_2, x_3, blue for the time-like x_4 to x_7, and grey off the diagonal because different gammas anticommute. It is the Clifford relation in one picture.

In [24], reality, signed permutations and the symmetry pattern.

```
entries = sorted(set(int(x) for g in gamma for x in g.flatten()))
say(f"the different entries of the eight gamma matrices: {entries}")
rows_ok = all((np.count_nonzero(g, axis=1) == 1).all() for g in gamma)  # each row
columns_ok = all((np.count_nonzero(g, axis=0) == 1).all() for g in gamma)  # column
orthogonal = all((g.T @ g == I16).all() for g in gamma)
```

`g.flatten()` lists all 256 entries of a matrix; collecting them from all eight gammas in a set and sorting gives the different values: $[-1, 0, 1]$. `np.count_nonzero(g, axis=1)` counts the nonzero entries of each row (`axis=0`: of each column); each count must be 1. `orthogonal` tests $g^T g = I_{16}$.

```
check_record(entries == [-1, 0, 1], "every gamma^a is real with entries -1, 0, +1",
             (WOLFRAM, "reality"))
check_record(rows_ok and columns_ok and orthogonal,
             "every gamma^a is a signed permutation matrix, hence orthogonal",
             (WOLFRAM, "signed_permutation_matrices"),
             (PYTHON, "reality_signed_permutations"))
```

Two checks: reality (the entries are whole numbers $-1, 0, +1$, in particular real), and signed permutation matrices that are orthogonal.

```
symmetric = [COORDINATES[a] for a in range(8) if (gamma[a].T == gamma[a]).all()]
antisymmetric = [COORDINATES[a] for a in range(8) if (gamma[a].T == -gamma[a]).all()]
say("symmetric: " + ", ".join(symmetric) + ";  antisymmetric: "
    + ", ".join(antisymmetric))
check_record(symmetric == ["x0", "x1", "x2", "x3"]
             and antisymmetric == ["x4", "x5", "x6", "x7"]
             and all((gamma[a].T == eta[a] * gamma[a]).all() for a in range(8)),
             "(gamma^a)^T = eta_aa gamma^a: symmetric for x0, x1, x2, x3 only",
             (WOLFRAM, "symmetry_pattern"), (PYTHON, "symmetry_pattern"))
```

The lists of the symmetric and of the antisymmetric gammas are made and printed: x_0, x_1, x_2, x_3 and x_4, x_5, x_6, x_7. The check requires exactly these lists and $(\gamma^a)^T = \eta_{aa}\gamma^a$ for all eight: the symmetry pattern proved in Step 4 of Section 4.5.

In [25], figure 6.

```
fig, axes = plt.subplots(2, 2, figsize=(6.4, 6.6), layout="constrained")
draw_signs(axes[0, 0], gamma[1], "$\\gamma^{(x_1)}$ (space-like)")
draw_signs(axes[0, 1], gamma[1].T, "its transpose: the same")
draw_signs(axes[1, 0], gamma[4], "$\\gamma^{(x_4)}$ (time-like)")
draw_signs(axes[1, 1], gamma[4].T, "its transpose: all signs flipped")
sign_legend(fig)
save_figure(fig, "symmetry_pattern",
            ...)
```

Four panels: $\gamma^{(x_1)}$ and its transpose, $\gamma^{(x_4)}$ and its transpose. **What figure 6 shows and why:** the upper two pictures are identical (a symmetric matrix equals its transpose); in the lower two every red square has become blue and every blue square red at the same place, because the transpose of an antisymmetric matrix is minus the matrix.

In [26], comparison with the Revision record files.

```
def exact(entry):
    """An exact number of gammas.json: a JSON integer, or a text "p/q"."""
    if isinstance(entry, int):
        return Fraction(entry)
    if isinstance(entry, str) and "/" in entry:
        numerator, denominator = entry.split("/")
        return Fraction(int(numerator), int(denominator))
    raise ValueError(f"an entry of gammas.json that is not exact: {entry}")
```

The file `gammas.json` writes every number exactly: a whole number as a JSON integer, a fraction as a text such as `"1/2"`. `exact` reads both into an exact `Fraction`: `isinstance(entry, int)` tests whether the entry is a whole number; for a text containing `/`, `split("/")` cuts it into numerator and denominator. Anything else stops the notebook with an error, so no rounded number can slip in.

```
def differing(stored, ours):
    """How many entries of the stored matrix differ from our integer matrix."""
    return sum(1 for (i, j), x in np.ndenumerate(ours)
               if exact(stored[i][j]) != int(x))
```

`differing` counts the entries in which a stored matrix (a list of rows from the file) differs from the notebook's matrix: it runs through all positions (i, j) and adds 1 whenever the two numbers are not equal (`!=`).

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
python_gammas = json.loads(repository_file(
    "Revision/algebra/reports/python-gammas.json").read_text(encoding="utf-8"))
fixture_differ = [differing(fixture["gamma"][a], gamma[a]) for a in range(8)]
python_differ = [differing(python_gammas["gamma"][a], gamma[a]) for a in range(8)]
```

The two Revision files are read: `gammas.json`, written by the WolframScript program, and `python-gammas.json`, written by the independent Python program. For each of the eight gammas the number of differing entries is counted, for both files.

```
report("entries compared per file", 8 * 16 * 16)
report("differing entries, gammas.json, per x0..x7", fixture_differ)
report("differing entries, python-gammas.json, per x0..x7", python_differ)
```

Three RESULT lines: 2048 entries are compared per file, and the number of differing entries is 0 for every one of the eight gammas, in both files.

```
check_record(fixture["coordinates"] == COORDINATES and fixture["eta"] == list(eta)
             and fixture["notebookFrameIndex"] == FRAME_INDEX
             and sum(fixture_differ) == 0,
             "Revision/algebra/gammas.json holds exactly these eight gammas",
             (WOLFRAM, "fixture_round_trip"),
             (PYTHON, "fixture_comparison_gammas_json"))
python_map = python_gammas["map_coordinate_to_T16_index"]  # {"x0": 0, ...}
check(python_map == dict(zip(COORDINATES, FRAME_INDEX)) and sum(python_differ) == 0,
      "Revision/algebra/reports/python-gammas.json holds exactly these eight gammas")
```

The first check also compares the coordinate names, the signs and the coordinate map stored in `gammas.json` with the notebook's. The second compares the map stored in the Python file, a dictionary from coordinate names to indices, with the dictionary made from the notebook's two lists (`zip` pairs the two lists entry by entry, `dict` turns the pairs into a dictionary), and requires no differing entry.

In [27], the totals.

```
for report_file in (WOLFRAM, PYTHON):
    verdicts = [entry["verdict"].upper() for entry in RECORDED[report_file].values()]
    passed = verdicts.count("PASS")  # how many checks of the report passed
    mine = [name for f, name in REPRODUCED if f == report_file]
    report(f"{report_file} passed", f"{passed} of {len(verdicts)}")
    report("    of these checks, reproduced in this notebook", len(mine))
check(len(REPRODUCED) == 30, "this notebook reproduces 30 checks of the two reports")
```

For each report, the verdicts of all checks are collected (`.values()` gives the entries of a dictionary), and `count("PASS")` counts the passed ones; `mine` lists the checks of this report that the notebook reproduced. The output: the WolframScript report passed 45 of 45, of which this notebook reproduced 16; the Python report passed 35 of 35, of which it reproduced 14. The check requires 30 reproduced Revision checks in all.

In [28], the last check.

```
names = ["04a_1_blocks_s4_t4.png", "04a_2_tau_matrices.png",
         "04a_3_block_form_of_t16.png", "04a_4_gammas_x0_to_x7.png",
         "04a_5_anticommutator_table.png", "04a_6_symmetry_pattern.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in names),
      "all six figure files exist")
all_checks_passed()
```

The check confirms that the six figure files were written, and `all_checks_passed()` prints the last line, ALL 28 CHECKS PASSED (notebook 04a): one check in each of In [2], In [6], In [9], In [14], In [17], In [20], In [21], In [27] and In [28]; two in each of In [8], In [10], In [22] and In [26]; three in each of In [15] and In [24]; and five in In [13].

4.9 Square roots in 4+4 dimensions and the plane waves of the field

Section 4.3 showed that the Clifford relation is the same statement as the square-root rule. For the author's gammas, whose Clifford relation Section 4.5 proved, the rule reads

$$\Big(\sum_{a=0}^{7} p_a \gamma^{(x_a)}\Big)^2 = (p_0^2 + p_1^2 + p_2^2 + p_3^2 - p_4^2 - p_5^2 - p_6^2 - p_7^2)\, I_{16}$$

for all numbers $p_0, \ldots, p_7$: the author's eight matrices take the square root of the quadratic form of his space-time, with a plus sign for the hidden direction and 3-space and a minus sign for the time and the three extra times. (Status: PROVED; Notebook 04b confirms it with sympy for all values of the p_a, and with floating-point numbers for 300 random vectors.) This section uses the rule to find what the field equation says about waves, and what a momentum along an extra time does.

Complex numbers and the conjugate transpose. A **complex number** is $x + iy$ with real x, y and $i^2 = -1$; its **complex conjugate** is $x - iy$. The **conjugate transpose** $M^\dagger$ of a matrix transposes it and conjugates every entry. A matrix is **Hermitian** if $M^\dagger = M$; a real symmetric matrix is Hermitian. An **eigenvalue** of M is a number λ for which a nonzero column u (an **eigenvector**) has $Mu = \lambda u$. A Hermitian matrix has only real eigenvalues. Proof: from $Mu = \lambda u$ follows $u^\dagger M u = \lambda\, u^\dagger u$ (multiply from the left by the row $u^\dagger$); the number $u^\dagger M u$ equals its own complex conjugate, because its conjugate is $u^\dagger M^\dagger u = u^\dagger M u$, so it is real; and $u^\dagger u = \sum_i |u_i|^2$ is real and positive; so λ is a real number divided by a positive one. We also use a fact that Section 1.34 proved for **every** square matrix, Hermitian or not: an $n \times n$ matrix M has n eigenvalues, the n roots of its **characteristic polynomial** $\det(M - \lambda I_n)$, where a root that occurs several times is counted as often as it occurs (its **multiplicity**); and the sum of these n eigenvalues is the trace of M. (The proof there compares two ways of writing the characteristic polynomial; it rests on the fundamental theorem of algebra, which Chapter 1 assumes.) Finally, the **smallest singular value** of a square matrix M is the smallest length of Mu over all columns u of length 1; it is 0 exactly when some nonzero u has $Mu = 0$. numpy computes it, and Notebook 04b uses it to locate the energies at which waves exist.

The model: flat 4+4 space. The full field equation of the theory, $\gamma^\mu D_\mu \Psi = (m + U'(S))\Psi$, is derived in Chapter 7; it contains the frame factors of Section 4.4, the gravitational correction in D_μ, and a self-interaction $U'(S)$. This section studies the simplest equation with the same algebra,

$$\sum_{a=0}^{7} \gamma^{(x_a)}\, \partial_a \Psi = m\Psi,$$

in **flat 4+4 space**, where the metric is the constant η: no gravity, no inflation, no deflation and no self-interaction (∂_a is the derivative with respect to x_a). This is a model for the algebra only (status ASSUMED for this section): in the author's space-time the extra times deflate at every moment. What carries over is the algebra of the frame: in a region so small that the metric functions change

little across it, waves with **frame momenta** k_a obey the same matrix algebra; the Revision record uses this local plane-wave reading with the coefficients of the equation held fixed.

Plane waves, line by line. A **plane wave** is $\Psi = u\, e^{i(k_0x_0+k_1x_1+k_2x_2+k_3x_3+k_5x_5+k_6x_6+k_7x_7-Ex_4)}$ with a constant column u; E is its **energy** (its frequency in the time x_4) and the k_a are its **momenta**.

1. $\partial_a\Psi = ik_a\Psi$ for $a \neq 4$ and $\partial_4\Psi = -iE\Psi$ — the derivative of e^{cx} is $c\,e^{cx}$.
2. $-iE\gamma^{(x_4)}u + i\sum_{a\neq4} k_a\gamma^{(x_a)}u = mu$ — line 1 inserted into the equation, and both sides divided by the exponential, which is never zero.
3. $iEu + i\sum_{a\neq4} k_a\gamma^{(x_4)}\gamma^{(x_a)}u = m\gamma^{(x_4)}u$ — both sides multiplied from the left by $\gamma^{(x_4)}$, and $(\gamma^{(x_4)})^2 = -I_{16}$ (x_4 is time-like).
4. $Eu + \sum_{a\neq4} k_a\gamma^{(x_4)}\gamma^{(x_a)}u = -im\gamma^{(x_4)}u$ — both sides multiplied by $-i$, with $-i\cdot i = 1$.
5. $Eu = hu$ with $h = -im\gamma^{(x_4)} - \sum_{a\neq4} k_a\gamma^{(x_4)}\gamma^{(x_a)}$ — the sum moved to the right-hand side.

So a plane wave exists exactly when E is an eigenvalue of the 16×16 matrix h. Write $h = m\beta + \sum_{a\neq4} k_a\alpha_a$ with $\beta = -i\gamma^{(x_4)}$ and $\alpha_a = -\gamma^{(x_4)}\gamma^{(x_a)}$, and abbreviate $g_4 = \gamma^{(x_4)}$, $g_a = \gamma^{(x_a)}$. From the Clifford relation ($g_4^2 = -I$, $g_a^2 = \eta^{aa}I$, different gammas anticommute):

- $\beta^2 = (-i)^2 g_4^2 = (-1)(-1)I = I$ — numbers move to the front;
- $\alpha_a^2 = g_4g_ag_4g_a = -g_4g_4g_ag_a = -(-1)\eta^{aa}I = \eta^{aa}I$ — one exchange of the neighbours g_ag_4 gives the factor -1;
- $\beta\alpha_a = ig_4g_4g_a = -ig_a$ and $\alpha_a\beta = ig_4g_ag_4 = -ig_4g_4g_a = ig_a$ — so $\beta\alpha_a + \alpha_a\beta = 0$;
- for $a \neq b$: $\alpha_a\alpha_b = g_4g_ag_4g_b = -g_4g_4g_ag_b = g_ag_b$ and $\alpha_b\alpha_a = g_bg_a = -g_ag_b$ — so they anticommute.

So β and the seven α_a obey a Clifford relation with the signs $+1$ for β and η^{aa} for α_a, and the general rule of Section 4.3, applied with the numbers m and k_a, gives

$$h^2 = (m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2)\, I_{16}.$$

If $hu = Eu$ with $u \neq 0$, then $h^2u = E^2u$, so

$$E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2,$$

the **mass shell** of the flat 4+4 equation. Status: PROVED (here, and exactly with sympy in Notebook 04b); it reproduces `Revision/theory/reports/python-field-theory.json`, check `mode_hamiltonian_B_selfadjoint_dispersion` (that check also verifies a statement about a matrix B, which Chapter 10 needs and this chapter does not).

Without momentum along the extra times. When $k_5 = k_6 = k_7 = 0$ (the Revision record calls this the **good sector**), h is Hermitian, so its eigenvalues are real. Proof: the gammas are real with $(g_a)^T = \eta_{aa}g_a$ (Section 4.5). Then $\beta^\dagger = ig_4^T = -ig_4 = \beta$ (conjugating $-i$ gives i, and g_4

is antisymmetric). α_a is real with $\alpha_a^T = -g_a^T g_4^T = -(\eta_{aa} g_a)(-g_4) = \eta_{aa} g_a g_4 = -\eta_{aa} g_4 g_a = \eta_{aa}\alpha_a$: symmetric, hence Hermitian, for the space-like x_0, x_1, x_2, x_3 (and antisymmetric for the extra times, which is why they are left out here). With real momenta, h is then a sum of Hermitian matrices. The **example of the Revision record**: $m = 2$, $k_0 = 4$ and $(k_1, k_2, k_3) = (1, 2, 0)$ give $E^2 = 4 + 16 + 1 + 4 + 0 = 25$, so every eigenvalue is $+5$ or -5. How often each occurs follows from the trace: $\mathrm{tr}\, g_4 = 0$ (a block off-diagonal matrix has zeros on its diagonal) and $\mathrm{tr}(g_4 g_a) = -\mathrm{tr}(g_a g_4) = -\mathrm{tr}(g_4 g_a)$ (anticommuting, then the cyclic property), so $\mathrm{tr}(g_4 g_a) = 0$ and $\mathrm{tr}\, h = 0$. With n_+ eigenvalues $+5$ and n_- eigenvalues -5: $n_+ + n_- = 16$ and $5n_+ - 5n_- = \mathrm{tr}\, h = 0$ (the sum of the eigenvalues is the trace), so $n_+ = n_- = 8$: the energies $+5$ and -5, eight times each. Status: PROVED (this derivation) and COMPUTED (Notebook 04b finds the 16 eigenvalues numerically with deviations below 10^{-12}, and eight independent solutions u at each of the two energies). The Revision record `Revision/theory/reports/python-field-theory.json`, check `good_sector_spectrum_and_B_sectors`, states this result for all sixteen components in the words `h is Hermitian on the full 16-dim space with energies +-sqrt(m^2 + k0^2 + k1^2 + k2^2 + k3^2) (8 each)`, and Notebook 04b reproduces these words. The same check states its exact example in one half of the sixteen components, the subject of the next paragraph.

The record's exact example: the sector $B = +1$. The record uses the matrix $B = -i\,C g_4$, where $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ is the product of the four space-like gammas; the record file `Revision/algebra/gammas.json` stores both. Section 1.37 met B: it is Hermitian, $B^2 = I_{16}$, and its eigenvalues $+1$ and -1 occur eight times each (Chapter 5 studies C and B in full). Two rules move a gamma g_a through C, a product of four different gammas: if g_a is not one of the four factors, it anticommutes with each of them, so $g_a C = (-1)^4 C g_a = C g_a$; if g_a is one of them, it anticommutes with the other three and commutes with itself, so $g_a C = (-1)^3 C g_a = -C g_a$. In particular $g_4 C = C g_4$. Now, line by line:

1. $B\beta = (-i\,C g_4)(-i\,g_4) = -C g_4 g_4 = C$ — the numbers moved to the front, $(-i)^2 = -1$, and $g_4^2 = -I$.
2. $\beta B = (-i\,g_4)(-i\,C g_4) = -g_4 C g_4 = -C g_4 g_4 = C$ — the same steps and $g_4 C = C g_4$; so $B\beta = \beta B$.
3. $B\alpha_a = (-i\,C g_4)(-g_4 g_a) = i\,C g_4 g_4 g_a = -i\,C g_a$ — the numbers moved to the front, and $g_4^2 = -I$.
4. $\alpha_a B = (-g_4 g_a)(-i\,C g_4) = i\,g_4 g_a C g_4$ — the numbers moved to the front.
5. For the space-like $a = x_0, x_1, x_2, x_3$, which are factors of C: $\alpha_a B = -i\,g_4 C g_a g_4 = -i\,C g_4 g_a g_4 = -i\,C g_a = B\alpha_a$ — line 4 with $g_a C = -C g_a$, then $g_4 C = C g_4$, then $g_4 g_a g_4 = -g_a g_4 g_4 = g_a$, then line 3.
6. For the extra times $a = x_5, x_6, x_7$, which are not factors of C: $\alpha_a B = +i\,C g_4 g_a g_4 = i\,C g_a = -B\alpha_a$ — the same steps with $g_a C = +C g_a$.

So without extra-time momentum $h = m\beta + \sum_a k_a \alpha_a$ (with $a = x_0, x_1, x_2, x_3$) **commutes** with B: $Bh = hB$. A momentum along an extra time adds an α_a that **anticommutes** with B. The record states both, in the words `[B, h] = 0` and `B anticommutes with gamma^(4) gamma^(x5,x6,x7)` (the record writes `gamma^(4)` for $\gamma^{(x_4)}$, and $\gamma^{(x_4)}\gamma^{(x_a)} = -\alpha_a$). Call the columns u with $Bu = u$ the **sector** $B = +1$. If $Bu = u$, then $B(hu) = h(Bu) = hu$: without extra-time momentum, h maps the

sector into itself. Notebook 04b takes eight **orthonormal** columns of the sector (columns of length 1 with $u^\dagger v = 0$ for two different ones; numpy finds them as eigenvectors of B) as the columns of a 16×8 matrix V, and checks $VV^\dagger = P$ with $P = \frac{1}{2}(I_{16} + B)$, the matrix that keeps the $B = +1$ part of a column. Inside the sector h acts as the 8×8 matrix $h_+ = V^\dagger h V$ (that is, $hV = Vh_+$), and $h_+^2 = V^\dagger h V V^\dagger h V = V^\dagger h P h V = V^\dagger h h P V = 25\, V^\dagger V = 25\, I_8$, because $hP = Ph$, $PV = V$ and $V^\dagger V = I_8$. Its trace is $\operatorname{tr} h_+ = \operatorname{tr}(V^\dagger h V) = \operatorname{tr}(hVV^\dagger) = \operatorname{tr}(hP)$ (the cyclic property; its proof in Section 4.2 works unchanged for an 8×16 and a 16×8 factor), and $\operatorname{tr}(hP) = \frac{1}{2}(\operatorname{tr} h + \operatorname{tr}(hB)) = 0$: $\operatorname{tr} h = 0$ was shown above, and $hB = m\,\beta B + \sum_a k_a \alpha_a B = m\,C - i \sum_a k_a C g_a$ (lines 2, 3 and 5) is a combination of C, a product of four different gammas, and of Cg_a, which is $\pm$ a product of three different gammas, all of trace 0 by the trace lemma of Section 4.13. With n_+ eigenvalues $+5$ and n_- eigenvalues -5 of h_+: $n_+ + n_- = 8$ and $5n_+ - 5n_- = 0$, so the energies $+5$ and -5 occur **four times each** in the sector $B = +1$. Status: PROVED (by hand above; Notebook 04b confirms $Bh = hB$, the anticommutation for the extra times and $\operatorname{tr}(hP) = 0$ exactly with sympy, for all values of m, k_0, k_1, k_2, k_3) and COMPUTED (the eight eigenvalues of h_+ lie within 10^{-12} of ± 5, four of each); it reproduces `Revision/theory/reports/python-field-theory.json`, check `good_sector_spectrum_and_B_sectors`, whose words for its exact example are `m = 2, k0 = 4, (k1, k2, k3) = (1, 2, 0) on B = +1: +5 (4 times), -5 (4 times)`.

A momentum along an extra time. The extra times enter E^2 with a minus sign. Adding a momentum k_5 along x_5 to the example gives $E^2 = 25 - k_5^2$. For $k_5 < 5$ the energies $\pm\sqrt{25 - k_5^2}$ are real. For $k_5 > 5$ they are imaginary, $E = \pm i\kappa$ with $\kappa = \sqrt{k_5^2 - 25}$, and the factor e^{-iEx_4} of the wave becomes, for $E = i\kappa$, $e^{-i \cdot i\kappa\, x_4} = e^{\kappa x_4}$ (because $-i \cdot i = 1$): the wave **grows exponentially** in the time instead of oscillating, and the one with $E = -i\kappa$ shrinks. In general the growth rate is $\kappa = \sqrt{k_5^2 - m^2 - k_0^2 - k_1^2 - k_2^2 - k_3^2}$ whenever this is real; it has no upper bound as k_5 grows. Status: PROVED (the formula) and COMPUTED (Notebook 04b checks all 16 eigenvalues for 160 values of k_5 to 10^{-10}); it reproduces `Revision/theory/reports/python-scope.json`, check `extra_time_growth_rates_unbounded`. A problem of the kind "given the field at one time, find it at later times" is called **well posed** (in the sense of the mathematician Jacques Hadamard) when a solution exists, is unique, and changes only a little when the given data change a little. The Revision record draws from the missing upper bound the conclusion that the first-order equation is not well posed in this sense for data that depend on the extra times (`Revision/theory/reports/python-scope.json`, check `extra_time_growth_rates_unbounded`): a wave with a tiny amplitude but a large momentum k_5 grows like $e^{\kappa x_4}$ with an arbitrarily large κ, so arbitrarily small changes of the data cause large changes after any fixed time. Chapter 8 explains this. The record's smallest exact example is $m = 1$ with only $k_5 = 2$: $h^2 = (1 - 4)I_{16} = -3I_{16}$, so every eigenvalue has $E^2 = -3$, $E = +i\sqrt{3}$ or $-i\sqrt{3}$, eight times each (the trace argument again: $\operatorname{tr} h = 0$ also with the momentum k_5, and the sum of the eigenvalues is the trace for every square matrix, also for this h, which is not Hermitian), and the wave with $E = i\sqrt{3}$ grows like $e^{\sqrt{3}\, x_4}$. Status: PROVED (exactly, with sympy, in Notebook 04b); it reproduces `Revision/theory/reports/python-field-theory.json`, check `extra_time_modes_grow`.

Why the deflation matters here. In the author's space-time a wave with a fixed **coordinate** momentum k_{x_5} along x_5, a factor $e^{ik_{x_5}x_5}$, has a **frame** momentum that grows: the derivative along the frame direction is the coordinate derivative divided by the frame factor $b_4^{1/2} e^{-a_4} \sin^{1/6} z$ of x_5 (Section 4.4), so the frame momentum is $b_4^{-1/2} e^{a_4} \sin^{-1/6}(z)\, k_{x_5}$. As the extra times deflate (a_4 grows, b_4 constant; the record states it for $b_4 = 1$), this frame momentum grows like e^{a_4}. In the local plane-wave reading that the same Revision check `extra_time_modes_grow` states, every wave

along an extra time therefore reaches, sooner or later, the region where its energy is imaginary. Notebook 04b computes only the flat algebra behind this statement; the waves in the curved, deflating space-time are the subject of Chapter 8.

The next three sections hold Notebook 04b.

4.10 How to run Notebook 04b

Step 1. What this notebook does and what it needs.

Notebook 04b (Square roots of quadratic forms: from Pauli and Dirac to the author's gammas) is the file `Revision/textbook/notebooks/04b_square_roots.ipynb` of the repository Dirac_claude. It shows why the gamma matrices exist: a sum of squares with plus and minus signs has a linear square root only when the coefficients are anticommuting matrices. It checks this exactly for two 2 by 2 examples, the Pauli matrices, Dirac's 4 by 4 matrices and the author's eight 16 by 16 gammas, derives the plane-wave relation of the first-order equation in flat 4+4 dimensions, shows that a momentum along an extra time makes the energies imaginary (growing waves), reproduces the Revision record of these relations and of their exact examples, and draws six figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04b_square_roots.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04b_square_roots.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 04b_square_roots.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/04b.captions.json`
- `Revision/textbook/figures/04b_1_square_roots_2x2.png`
- `Revision/textbook/figures/04b_2_pauli_dirac_tables.png`
- `Revision/textbook/figures/04b_3_dirac_mass_shell.png`
- `Revision/textbook/figures/04b_4_square_root_8d.png`
- `Revision/textbook/figures/04b_5_mass_shell_4p4.png`
- `Revision/textbook/figures/04b_6_extra_time_momentum.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 19 CHECKS PASSED (notebook 04b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/04b_square_roots.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 04b_square_roots.ipynb
python -m nbconvert --execute --inplace 04b_square_roots.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `Revision/algebra/gammas.json` or `Revision/theory/reports/python-field-theory.json`: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run `git status` in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

```
git checkout HEAD Revision/algebra Revision/theory
```

4.11 Notebook 04b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/04b_square_roots.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The length of a vector is the square root of a sum of squares. Paul Dirac found in
1928 that such a square root can be written as a *linear* expression, provided the
coefficients are matrices that anticommute. This is the reason why gamma matrices
exist, and why the field of this book has 16 components. This notebook

- shows that ordinary numbers cannot do it;
- checks exactly (with sympy, for all values of the variables) the square roots of
  $p^2 + q^2$ and of $p^2 - q^2$ made from real $2 \times 2$ matrices, the three
  Pauli matrices (three directions), and Dirac's $4 \times 4$ matrices (time and
  three space directions);
- checks exactly that the author's eight $16 \times 16$ gammas give the square root
  of the quadratic form of his 4+4 dimensional space-time:
  $(\sum_a p_a\gamma^{(x_a)})^2 = (p_0^2 + p_1^2 + p_2^2 + p_3^2 - p_4^2 - p_5^2
  - p_6^2 - p_7^2)\, I_{16}$;
- derives, line by line, what the first-order field equation
  $\sum_a \gamma^{(x_a)} \partial_a \Psi = m\Psi$ says about plane waves in flat
  4+4 dimensions: $E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$,
  and reproduces the Revision record of this relation and of its exact example;
- shows that a momentum along an extra time enters $E^2$ with a minus sign and
  makes the energies imaginary (waves that grow in time) when it is large enough,
  and reproduces the Revision record of this growth;
- draws six figures.
```

Text cell:

```
## 2. How to run this notebook
```

Step 1. What this notebook does and what it needs.

Notebook 04b (Square roots of quadratic forms: from Pauli and Dirac to the author's gammas) is the file ‘Revision/textbook/notebooks/04b_square_roots.ipynb‘ of the repository Dirac_claude. It shows why the gamma matrices exist: a sum of squares with plus and minus signs has a linear square root only when the coefficients are anticommuting matrices. It checks this exactly for two 2 by 2 examples, the Pauli matrices, Dirac's 4 by 4 matrices and the author's eight 16 by 16 gammas, derives the plane-wave relation of the first-order equation in flat 4+4 dimensions, shows that a momentum along an extra time makes the energies imaginary (growing waves), reproduces the Revision record of these relations and of their exact examples, and draws six figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04b_square_roots.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04b_square_roots.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 04b_square_roots.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/04b.captions.json‘
- ‘Revision/textbook/figures/04b_1_square_roots_2x2.png‘
- ‘Revision/textbook/figures/04b_2_pauli_dirac_tables.png‘
- ‘Revision/textbook/figures/04b_3_dirac_mass_shell.png‘
- ‘Revision/textbook/figures/04b_4_square_root_8d.png‘
- ‘Revision/textbook/figures/04b_5_mass_shell_4p4.png‘
- ‘Revision/textbook/figures/04b_6_extra_time_momentum.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 19 CHECKS PASSED (notebook 04b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from

  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/04b_square_roots.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 04b_square_roots.ipynb
      python -m nbconvert --execute --inplace 04b_square_roots.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘Revision/algebra/gammas.json‘ or
  ‘Revision/theory/reports/python-field-theory.json‘: the notebook reads these Revision
  record files of the repository; they are part of every complete clone. Run ‘git status‘
  in the repository folder: if it reports them as deleted, restore them with the command
  below and run the notebook again.

      git checkout HEAD Revision/algebra Revision/theory

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 04b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 04b (Square roots of quadratic forms: from Pauli and Dirac to the author’s
# gammas) is the file Revision/textbook/notebooks/04b_square_roots.ipynb of the
# repository Dirac_claude. It shows why the gamma matrices exist: a sum of squares with
# plus and minus signs has a linear square root only when the coefficients are
```

```
# anticommuting matrices. It checks this exactly for two 2 by 2 examples, the Pauli
# matrices, Dirac's 4 by 4 matrices and the author's eight 16 by 16 gammas, derives the
# plane-wave relation of the first-order equation in flat 4+4 dimensions, shows that a
# momentum along an extra time makes the energies imaginary (growing waves), reproduces
# the Revision record of these relations and of their exact examples, and draws six
# figures. It needs a computer with Windows 11, macOS or Linux, an internet connection
# for the installation, the program Git, and Python 3.12 or newer (the notebooks were
# built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6,
# sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
# nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports
# numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and
# runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
```

```
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.

#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
```

```
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 04b_square_roots.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 04b_square_roots.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 04b_square_roots.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/04b.captions.json
```

```
# - Revision/textbook/figures/04b_1_square_roots_2x2.png
# - Revision/textbook/figures/04b_2_pauli_dirac_tables.png
# - Revision/textbook/figures/04b_3_dirac_mass_shell.png
# - Revision/textbook/figures/04b_4_square_root_8d.png
# - Revision/textbook/figures/04b_5_mass_shell_4p4.png
# - Revision/textbook/figures/04b_6_extra_time_momentum.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 19 CHECKS PASSED (notebook 04b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/04b_square_roots.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 04b_square_roots.ipynb
#     python -m nbconvert --execute --inplace 04b_square_roots.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
```

```
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or
#   Revision/theory/reports/python-field-theory.json: the notebook reads these Revision
#   record files of the repository; they are part of every complete clone. Run git status
#   in the repository folder: if it reports them as deleted, restore them with the
#   command below and run the notebook again.
#     git checkout HEAD Revision/algebra Revision/theory
#

## 3. The words used in this notebook

- **Quadratic form**: a sum of squares of variables, each with a plus or a minus
  sign, such as $p^2 + q^2$ (Pythagoras) or $p^2 - q^2$.
- **Square root of a quadratic form**: an expression $L$, linear in the variables,
  whose square is the quadratic form: $L^2 = p^2 + q^2$ (times the identity matrix
  when $L$ is a matrix).
- **Complex number**: $x + iy$ with real $x, y$ and $i^2 = -1$. A matrix may have
  complex entries.
- **Conjugate transpose** $M^\dagger$: transpose $M$ and replace every entry
  $x + iy$ by $x - iy$. A matrix is **Hermitian** if $M^\dagger = M$.
- **Anticommute**: $AB = -BA$, that is $\{A, B\} = AB + BA = 0$.
- **Clifford relation**: $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I$, with
  $\eta$ a diagonal matrix of signs $\pm 1$ (the *metric* of the directions).
- **Eigenvalue and eigenvector**: a number $\lambda$ and a nonzero column $u$ with
  $M u = \lambda u$.
- **Multiplicity, trace**: an $n \times n$ matrix $M$ has $n$ eigenvalues, the $n$
  roots of the polynomial $\det(M - \lambda I)$ (its *characteristic polynomial*);
```

```
  a root that occurs several times is counted with its *multiplicity*. The *trace*
  $\mathrm{tr}\, M$, the sum of the diagonal entries, equals the sum of these $n$
  eigenvalues, for every square matrix.
- **Orthonormal columns**: columns of length 1 with $u^\dagger v = 0$ for any two
  different ones.
- **Sector** of a Hermitian matrix $B$ with $B^2 = I$: the columns $u$ with
  $Bu = u$ (the sector $B = +1$), or those with $Bu = -u$ (the sector $B = -1$).
- **Smallest singular value** of a square matrix $M$: the smallest length of $Mu$
  over all columns $u$ of length 1. It is 0 exactly when some nonzero $u$ has
  $Mu = 0$. numpy computes it with `np.linalg.svd`.
- **Plane wave**: a solution of the form $u\, e^{i(k \cdot x - E x_4)}$, with a
  constant column $u$; $E$ is its *energy* (frequency in the time $x_4$) and the
  $k_a$ are its *momenta* (wave numbers in the other directions).
- **Mass shell** (or *dispersion relation*): the relation between $E$, the $k_a$
  and the mass $m$ that a plane wave must obey.
- **Flat 4+4 space**: space-time with the constant metric
  $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order
  $x_0, \dots, x_7$: no gravity, no inflation, no deflation.
- **sympy, symbol**: sympy computes with letters (symbols) such as $p$ and $q$ that
  stand for any number; an identity that sympy proves holds for every value.
- **Floating-point number**: a number stored with about 16 significant digits;
  numpy computes with them, so its results may differ from the exact ones in the
  last digits (rounding). **Random numbers with a seed**: numbers that look random
  but are the same in every run, because the generator starts from a fixed number.
```

Text cell:

```
## 4. The physical and mathematical situation

**The square-root problem.** Can $\sqrt{p^2 + q^2}$ be written as
$\alpha p + \beta q$? Squaring,
$(\alpha p + \beta q)^2 = \alpha^2 p^2 + (\alpha\beta + \beta\alpha) pq + \beta^2 q^2$
(multiply out; $\alpha\beta$ and $\beta\alpha$ are kept apart because for matrices
the order matters). This equals $p^2 + q^2$ for all $p, q$ exactly when
$\alpha^2 = 1$, $\beta^2 = 1$ and $\alpha\beta + \beta\alpha = 0$. For numbers,
$\alpha\beta + \beta\alpha = 2\alpha\beta = 0$ forces $\alpha = 0$ or $\beta = 0$,
which contradicts $\alpha^2 = \beta^2 = 1$. For matrices it is possible.

**The general rule.** For $n$ directions with signs $\eta^{aa} = \pm 1$ we want
$(\sum_a p_a \gamma^a)^2 = (\sum_a \eta^{aa} p_a^2) I$ for all numbers $p_a$.
Multiplying out, $(\sum_a p_a\gamma^a)^2 = \sum_{a,b} p_a p_b \gamma^a\gamma^b$; the
terms $(a, b)$ and $(b, a)$ have the same factor $p_a p_b$, so the sum equals
$\tfrac12 \sum_{a,b} p_a p_b (\gamma^a\gamma^b + \gamma^b\gamma^a)$. This is
$\sum_a \eta^{aa} p_a^2 I$ for all $p$ exactly when the Clifford relation
$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I$ holds.

**Why physics needs it.** In special relativity a particle of mass $m$, energy $E$
and momentum $k$ obeys $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2$. Dirac wanted a
first-order equation (only first derivatives) whose square is this relation; he
needed four anticommuting matrices, one with square $+1$ and three with square $-1$
in his sign convention, and found $4 \times 4$ ones.

**The author's 4+4 space-time.** It has eight directions: 3-space $x_1, x_2, x_3$
```

```
(space-like), the time $x_4$ and the three extra times $x_5, x_6, x_7$ (time-like;
in the author's metric they deflate exponentially, with the scale factor
$e^{-a_4}\sin^{1/6} z$), and the hidden space direction $x_0$. In a local frame the
signs are $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$, and the author's
eight real $16 \times 16$ matrices satisfy the Clifford relation with this $\eta$.
The field equation of the theory is $\gamma^\mu D_\mu\Psi = (m + U'(S))\Psi$, in which
$\gamma^\mu$ is $\gamma^{(x_\mu)}$ divided by the frame factor
$\sqrt{|g_{\mu\mu}|}$ of the direction $x_\mu$, $D_\mu$ is the derivative along
$x_\mu$ corrected by the gravitational field, and $U'(S)$ comes from the
self-interaction.

**What this notebook does with it.** It studies the equation
$\sum_a \gamma^{(x_a)} \partial_a\Psi = m\Psi$ in **flat** 4+4 space, where the
metric is the constant $\eta$: no gravity, no inflation and no deflation. It is a
model for the algebra only: in the author's space-time the extra times deflate at
every moment, and this notebook does not claim otherwise. What carries over is the
algebra of the frame: in a region so small that the metric functions change little
across it, plane waves with *frame momenta* $k_a$ obey the same matrix algebra (the
Revision record treats this local plane-wave analysis with the coefficients of the
equation held fixed). Nothing in this notebook depends on the curvature.
```

Text cell:

```
## 5. Numbers are not enough

The next cell asks sympy for all numbers $\alpha, \beta$ (real or complex) with
$\alpha^2 = 1$, $\beta^2 = 1$ and $\alpha\beta + \beta\alpha = 2\alpha\beta = 0$.
‘sp.solve‘ returns the list of all solutions; it must be empty.
```

In [2]:

```
import numpy as np  # floating-point arrays and linear algebra
import sympy as sp  # exact algebra with symbols

alpha, beta = sp.symbols("alpha beta")  # two unknown numbers
equations = [alpha**2 - 1, beta**2 - 1, 2 * alpha * beta]  # each must equal 0
solutions = sp.solve(equations, [alpha, beta], dict=True)  # ** is a power
say(f"number solutions of alpha^2 = 1, beta^2 = 1, 2 alpha beta = 0: {solutions}")
check(solutions == [], "no two numbers solve the square-root problem")
```

Out [2]:

```
number solutions of alpha^2 = 1, beta^2 = 1, 2 alpha beta = 0: []
PASS no two numbers solve the square-root problem
```

Text cell:

```
## 6. Two real $2 \times 2$ matrices
```

```
The matrices
$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and
$\sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ square to $I_2$ and
anticommute. So $(p\sigma_x + q\sigma_z)^2 = (p^2 + q^2) I_2$. A real matrix can also
square to $-I_2$: $N = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ has
$N^2 = -I_2$, and it anticommutes with $\sigma_x$; so
$(p\sigma_x + qN)^2 = (p^2 - q^2) I_2$, a square root of a *difference* of squares,
the kind that space and time need. The next cell checks both identities exactly
with the symbols $p$ and $q$, and prints the worked example $p = 3$, $q = 4$:
$3\sigma_x + 4\sigma_z = \begin{pmatrix} 4 & 3 \\ 3 & -4 \end{pmatrix}$, whose square
is $\begin{pmatrix} 16 + 9 & 12 - 12 \\ 12 - 12 & 9 + 16 \end{pmatrix} = 25 I_2$.
```

In [3]:

```
sigma_x = sp.Matrix([[0, 1], [1, 0]])
sigma_z = sp.Matrix([[1, 0], [0, -1]])
N = sp.Matrix([[0, 1], [-1, 0]])
I2 = sp.eye(2)  # the 2 x 2 identity matrix
p, q = sp.symbols("p q", real=True)  # two symbols that stand for any real numbers

euclidean = ((p * sigma_x + q * sigma_z) ** 2).expand()  # multiplied out
indefinite = ((p * sigma_x + q * N) ** 2).expand()
say(f"(p sigma_x + q sigma_z)^2 = {euclidean.tolist()}")
say(f"(p sigma_x + q N)^2 = {indefinite.tolist()}")
example = 3 * sigma_x + 4 * sigma_z
say(f"3 sigma_x + 4 sigma_z = {example.tolist()}, its square = "
    f"{(example * example).tolist()}")
check(euclidean == (p**2 + q**2) * I2 and (example * example) == 25 * I2,
      "(p sigma_x + q sigma_z)^2 = (p^2 + q^2) I2 for all p, q")
check(indefinite == (p**2 - q**2) * I2,
      "(p sigma_x + q N)^2 = (p^2 - q^2) I2 for all p, q")
```

Out [3]:

```
(p sigma_x + q sigma_z)^2 = [[p**2 + q**2, 0], [0, p**2 + q**2]]
(p sigma_x + q N)^2 = [[p**2 - q**2, 0], [0, p**2 - q**2]]
3 sigma_x + 4 sigma_z = [[4, 3], [3, -4]], its square = [[25, 0], [0, 25]]
PASS (p sigma_x + q sigma_z)^2 = (p^2 + q^2) I2 for all p, q
PASS (p sigma_x + q N)^2 = (p^2 - q^2) I2 for all p, q
```

Text cell:

```
A square root of a matrix multiple $c I_2$ has the eigenvalues $+\sqrt{c}$ and
$-\sqrt{c}$ (if $Mu = \lambda u$ then $M^2 u = \lambda^2 u = c\, u$, so
$\lambda^2 = c$). For $p^2 - q^2 < 0$ these are imaginary. The next cell computes
the eigenvalues numerically for $q = 1$ and 201 values of $p$ from $-3$ to $3$, checks
them against $\pm\sqrt{p^2 + 1}$ and $\pm\sqrt{p^2 - 1}$, and draws them: on the
left the Euclidean root (always real), on the right the real and imaginary parts of
the eigenvalues of the indefinite root (real for $|p| > 1$, imaginary for
$|p| < 1$).
```

In [4]:

```
p_values = np.linspace(-3.0, 3.0, 201)  # 201 equally spaced values of p
sx = np.array(sigma_x, dtype=float)  # the same matrices as numpy arrays
sz = np.array(sigma_z, dtype=float)
n_matrix = np.array(N, dtype=float)
euclid_eigen = np.array([np.sort(np.linalg.eigvals(pv * sx + sz).real)
                         for pv in p_values])  # q = 1

## 7. The Pauli matrices: three directions

A third real $2 \times 2$ matrix that anticommutes with $\sigma_x$ and $\sigma_z$ and
squares to $+I_2$ does not exist, but a complex one does:
$\sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$. The three **Pauli
matrices** (Wolfgang Pauli, 1927) satisfy the Clifford relation with
$\eta = \mathrm{diag}(+1, +1, +1)$. The next cell computes the table of numbers
$c_{ab}$ with $\{\sigma_a, \sigma_b\} = c_{ab} I_2$, checks that it is $2\delta_{ab}$,
and checks the products $\sigma_x\sigma_y = i\sigma_z$ and
$\sigma_x\sigma_y\sigma_z = i I_2$ (by hand:
$\sigma_x\sigma_y = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} = i\sigma_z$, then
$i\sigma_z\sigma_z = i I_2$). In sympy the imaginary unit is ‘sp.I‘.
```

In [5]:

```
sigma_y = sp.Matrix([[0, -sp.I], [sp.I, 0]])

## 8. Dirac's matrices: time and three space directions

$2 \times 2$ matrices are too small for four anticommuting matrices. Dirac's choice,
in the particle physicists' convention $\eta = \mathrm{diag}(+1, -1, -1, -1)$ (time
first, sign $+1$), is built from $2 \times 2$ blocks:
$\gamma_D^0 = \begin{pmatrix} I_2 & 0 \\ 0 & -I_2 \end{pmatrix}$ and
$\gamma_D^j = \begin{pmatrix} 0 & \sigma_j \\ -\sigma_j & 0 \end{pmatrix}$ for
$j = x, y, z$. (The letter D keeps them apart from the author's gammas.) By the
block rule, $(\gamma_D^j)^2 = \mathrm{diag}(-\sigma_j^2, -\sigma_j^2) = -I_4$ and
$\gamma_D^0\gamma_D^j = -\gamma_D^j\gamma_D^0$. The next cell builds them with sympy's
`sp.Matrix(sp.BlockMatrix(...))` and checks the whole $4 \times 4$ table.
```

In [6]:

```
Z2 = sp.zeros(2, 2)
dirac = [sp.Matrix(sp.BlockMatrix([[I2, Z2], [Z2, -I2]]))]  # gamma_D^0
for s in pauli:  # gamma_D^x, gamma_D^y, gamma_D^z
    dirac.append(sp.Matrix(sp.BlockMatrix([[Z2, s], [-s, Z2]])))
dirac_table = table_of(dirac, 4)
say(f"Dirac table c_ab: {dirac_table}")
check(dirac_table == [[2, 0, 0, 0], [0, -2, 0, 0], [0, 0, -2, 0], [0, 0, 0, -2]],
      "{gamma_D^a, gamma_D^b} = 2 diag(+1, -1, -1, -1)_ab I4")
```

Out [6]:

```

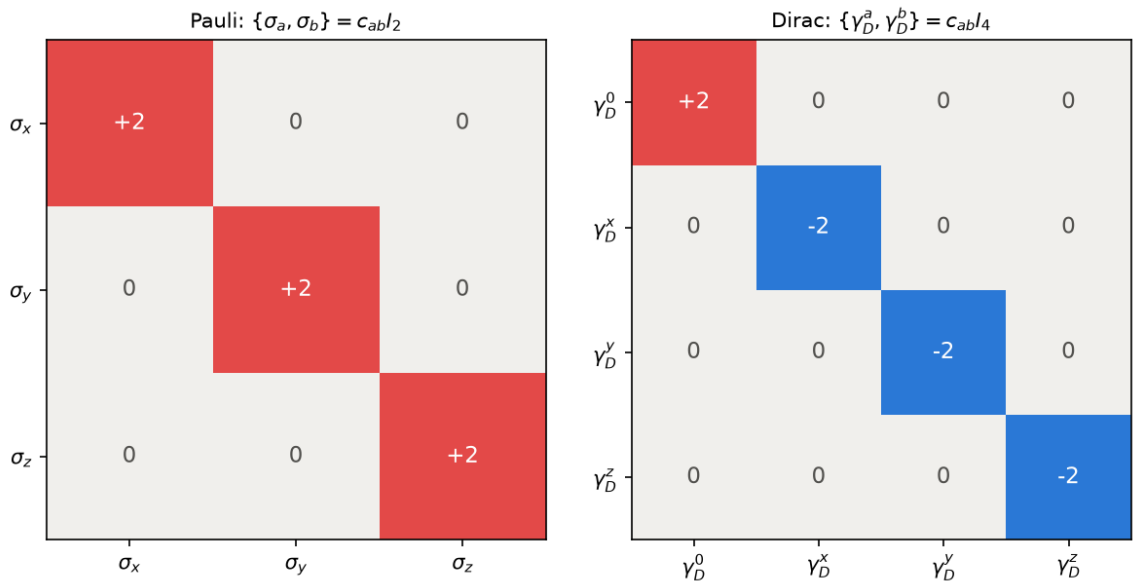

Figure 123: The Clifford relation of the Pauli matrices (left) and of Dirac's matrices (right): the number c_{ab} in $\{M_a, M_b\} = c_{ab} I$ for every pair, row a and column b (red $+2$, blue -2, grey 0). Off the diagonal every entry is 0: different matrices anticommute. On the diagonal stand twice the signs of the directions: $+2$ for the three space directions of Pauli, and $+2$ for Dirac's time and -2 for his three space directions. (Notebook 04b, figure 2.)

```
$\psi = u\,e^{-i(E t - k_1x_1 - k_2x_2 - k_3x_3)}$ the derivative $\partial_t$ gives the
factor $-iE$ and $\partial_j$ the factor $ik_j$; with the $i$ in front these become
$E$ and $-k_j$, so the plane wave solves the equation when
$(E\gamma_D^0 - k_1\gamma_D^x - k_2\gamma_D^y - k_3\gamma_D^z - m I_4)u = 0$. Call
$P = E\gamma_D^0 - k_1\gamma_D^x - k_2\gamma_D^y
- k_3\gamma_D^z$. By the general rule of the situation section, with the signs
$(+1, -1, -1, -1)$, $P^2 = (E^2 - k_1^2 - k_2^2 - k_3^2) I_4$. A nonzero $u$ with
$(P - m)u = 0$ satisfies $Pu = mu$, hence $P^2 u = m^2 u$, hence
$E^2 - k_1^2 - k_2^2 - k_3^2 = m^2$: the relativistic energy relation, the *mass
shell*. The next cell checks $P^2$ exactly with symbols, then takes $m = 3$ and
$k = (4, 0, 0)$, for which the mass shell is $E^2 = 9 + 16 = 25$, $E = \pm 5$, and
computes the smallest singular value of $P - m I_4$ for 801 energies from $-8$ to
$8$. It is zero exactly where a solution $u$ exists, and the check confirms that
this happens at $E = \pm 5$ and that there are two independent solutions there
(two singular values are zero).

## 10. Plane waves in flat 4+4 space

In flat 4+4 space the field equation without self-interaction is
$\sum_a \gamma^{(x_a)}\partial_a\Psi = m\Psi$ ($\partial_a$ is the derivative with
respect to $x_a$). Take a plane wave
$\Psi = u\,e^{i(k_1x_1 + k_2x_2 + k_3x_3 + k_5x_5 + k_6x_6 + k_7x_7 + k_0x_0 - Ex_4)}$
with a constant column $u$. Line by line:

1. $\partial_a\Psi = ik_a\Psi$ for $a \neq 4$ and $\partial_4\Psi = -iE\Psi$ (the
   derivative of $e^{cx}$ is $ce^{cx}$).
2. Inserting and dividing by the exponential (never zero):
   $-iE\gamma^{(x_4)}u + i\sum_{a\neq4}k_a\gamma^{(x_a)}u = mu$.
```

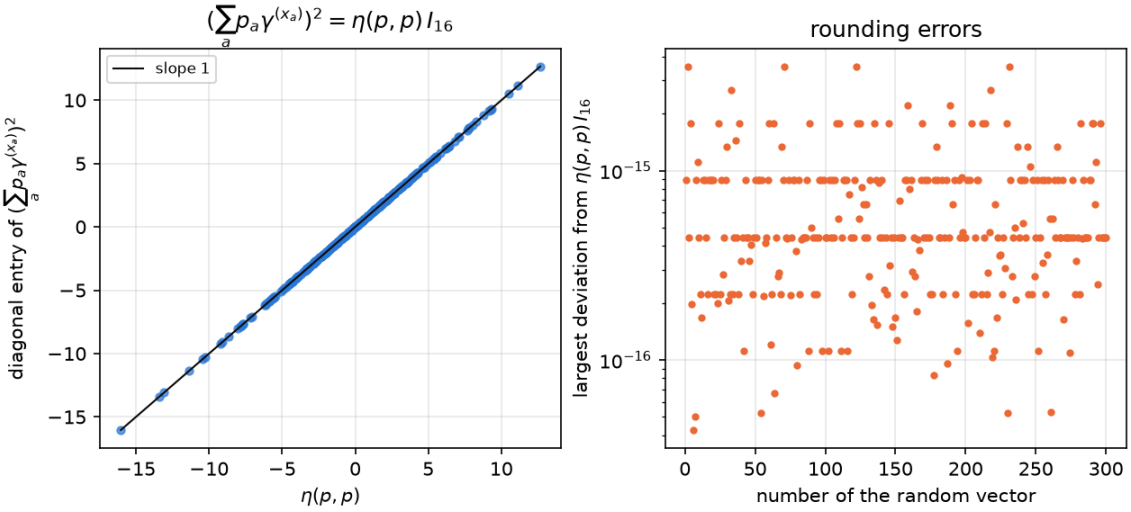

Figure 125: The author's gammas take the square root of the 4+4 quadratic form, tested with 300 random vectors p (pure numbers). Left: the diagonal entry of the matrix $(\sum_a p_a \gamma^{(x_a)})^2$ against $\eta(p,p) = p_0^2 + p_1^2 + p_2^2 + p_3^2 - p_4^2 - p_5^2 - p_6^2 - p_7^2$; all points lie on the line of slope 1, for positive and negative $\eta(p,p)$. Right: for each vector the largest deviation of an entry of this matrix from $\eta(p,p) I_{16}$, on a logarithmic scale; it is of the size of floating-point rounding, far below the tolerance 10^{-12} of the check (the exact identity is proved with symbols in the notebook). (Notebook 04b, figure 4.)

```
3. Multiplying from the left by $\gamma^{(x_4)}$ and using
   $(\gamma^{(x_4)})^2 = -I_{16}$ ($x_4$ is time-like):
   $iEu + i\sum_{a\neq4}k_a\gamma^{(x_4)}\gamma^{(x_a)}u = m\gamma^{(x_4)}u$.
4. Multiplying by $-i$ (and $-i \cdot i = 1$):
   $Eu + \sum_{a\neq4}k_a\gamma^{(x_4)}\gamma^{(x_a)}u = -im\gamma^{(x_4)}u$.
5. Moving the sum to the right-hand side:
   $Eu = hu$ with $h = -im\gamma^{(x_4)} - \sum_{a\neq4}k_a\gamma^{(x_4)}\gamma^{(x_a)}$.

So $E$ is an eigenvalue of the $16 \times 16$ matrix $h$. Write $h = m\beta +
\sum_{a\neq4}k_a\alpha_a$ with $\beta = -i\gamma^{(x_4)}$ and
$\alpha_a = -\gamma^{(x_4)}\gamma^{(x_a)}$. Then, from the Clifford relation
(write $g_4$ for $\gamma^{(x_4)}$ and $g_a$ for $\gamma^{(x_a)}$; $g_4^2 = -1$,
$g_a^2 = \eta^{aa}$, and different gammas anticommute):

- $\beta^2 = (-i)^2 g_4^2 = (-1)(-1) = 1$;
- $\alpha_a^2 = g_4 g_a g_4 g_a = -g_4 g_4 g_a g_a = -(-1)\eta^{aa} = \eta^{aa}$ (one
  exchange of $g_a$ and $g_4$ gives the minus sign);
- $\beta\alpha_a = i g_4 g_4 g_a = -i g_a$ and
  $\alpha_a\beta = i g_4 g_a g_4 = -i g_4 g_4 g_a = i g_a$: they anticommute;
- for $a \neq b$: $\alpha_a\alpha_b = g_4 g_a g_4 g_b = -g_4 g_4 g_a g_b = g_a g_b$,
  and $\alpha_b\alpha_a = g_b g_a = -g_a g_b$: they anticommute.

So $\beta$ and the $\alpha_a$ obey a Clifford relation, and by the general rule of
the situation section $h^2 = (m^2 + \sum_{a\neq4}\eta^{aa}k_a^2) I_{16}$, that is

$$h^2 = (m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2)\, I_{16},
\qquad E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2 .$$
```

The next cell checks the formula for h^2 exactly with symbols. The Revision record verified the same formula (‘Revision/theory/reports/python-field-theory.json‘, check ‘mode_hamiltonian_B_selfadjoint_dispersion‘; that check also verifies a statement about a matrix B that this notebook does not need). The cell reads the record and requires that its text contains the same h and the same formula for h^2, word for word: if the record ever says something else, the check fails.

```
**The example of the Revision record.** Without momentum along the extra
times ($k_5 = k_6 = k_7 = 0$; the Revision record calls this the *good sector*)
$h$ is Hermitian and its eigenvalues are real. The reason: the author’s gammas are
```

```
real with $(g_a)^T = \eta^{aa} g_a$ (symmetric for space-like, antisymmetric for
time-like directions). So $\beta^\dagger = i g_4^T = -i g_4 = \beta$, and
$\alpha_a$ is real with $\alpha_a^T = -g_a^T g_4^T = \eta^{aa} g_a g_4
= -\eta^{aa} g_4 g_a = \eta^{aa}\alpha_a$: Hermitian for the space-like
$a = x_0, x_1, x_2, x_3$ (and anti-Hermitian for the extra times, which is why
they are left out here). The record uses the example $m = 2$, $k_0 = 4$ and
$(k_1, k_2, k_3) = (1, 2, 0)$: $E^2 = 4 + 16 + 1 + 4 + 0 = 25$,
$E = \pm 5$. The 16 eigenvalues add up to the trace of $h$ (true for every square
matrix), which is 0 (every gamma product in $h$ has trace 0); with $n_+$ eigenvalues
$+5$ and $n_-$ eigenvalues $-5$, $n_+ + n_- = 16$ and $5n_+ - 5n_- = 0$, so $+5$
and $-5$ occur 8 times each. The record states exactly this for the full
16-dimensional space: $h$ is Hermitian there, with the energies
$\pm\sqrt{m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2}$, "8 each". The next cell computes
the eigenvalues numerically, counts the independent solutions $u$ at $E = +5$ and
at $E = -5$ (the number of singular values of $EI_{16} - h$ below $10^{-9}$), checks
them, and requires the record's words. It also computes, for 801 energies from
$-8$ to $8$, the smallest singular value of $EI_{16} - h$; for a Hermitian $h$ it is
the distance from $E$ to the nearest eigenvalue.
```

```
**The record's exact example lives in the sector $B = +1$.** The Revision record
states the spectrum of its example not on all 16 components but in a sector of the
matrix $B = -iC\gamma^{(x_4)}$, where
$C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ is the product of
the four space-like gammas; the record file `Revision/algebra/gammas.json` stores
$B$. $B$ is Hermitian with $B^2 = I_{16}$ and trace 0, so its eigenvalues are $+1$
and $-1$, 8 times each. Without extra-time momentum $B$ commutes with $h$:
$Bh = hB$. Then $h$ maps every column $u$ of the sector $B = +1$ into the same
sector, because $B(hu) = h(Bu) = hu$; inside the sector $h$ acts as an $8 \times 8$
matrix. A momentum along an extra time spoils this: $B$ anticommutes with
$\gamma^{(x_4)}\gamma^{(x_a)}$ for $a = x_5, x_6, x_7$, so such a momentum mixes the
two sectors.

The next cell first checks exactly (sympy, for all values of $m, k_0, k_1, k_2,
k_3$): $B$ built from the gammas equals the stored $B$; $B^\dagger = B$,
$B^2 = I_{16}$, $\mathrm{tr}\, B = 0$; $Bh = hB$ without extra-time momentum; $B$
anticommutes with $\gamma^{(x_4)}\gamma^{(x_a)}$ for the three extra times; and
$\mathrm{tr}(hP) = 0$ for $P = (I_{16} + B)/2$, the matrix that keeps the $B = +1$
part of a column. Then, with numbers, it takes the 8 orthonormal eigenvectors of
$B$ with eigenvalue $+1$ (from `np.linalg.eigh`) as the columns of a
$16 \times 8$ matrix $V$; then $VV^\dagger = P$, $hV = Vh_+$ with the $8 \times 8$
matrix $h_+ = V^\dagger h V$, and $h_+^2 = 25 I_8$. The 8 eigenvalues of $h_+$ add
up to $\mathrm{tr}\, h_+ = \mathrm{tr}(hVV^\dagger) = \mathrm{tr}(hP) = 0$ (the
trace does not change when the last factor $V^\dagger$ is moved to the front), so
$+5$ and $-5$ occur four times each, as the record states. The cell computes them
and requires the record's words for this example.

## 11. Momentum along an extra time

The extra times enter $E^2$ with a minus sign: $E^2 = 25 - k_5^2$ for the example
above with a momentum $k_5$ along the extra time $x_5$. For $k_5 < 5$ the energies
$\pm\sqrt{25 - k_5^2}$ are real; for $k_5 > 5$ they are imaginary, $E = \pm i
\sqrt{k_5^2 - 25}$, and the factor $e^{-iEx_4}$ of the plane wave then grows or
shrinks exponentially in the time $x_4$ instead of oscillating. This is the same
effect as in the right panel of the first figure, now in the author's 4+4
space-time; it is a fact about the flat equation, and the Revision record studies
its consequences separately. The next cell computes the 16 eigenvalues of $h$
numerically for 160 values of $k_5$ from 0.025 to 7.975 (the point $k_5 = 5$, where
both energies are 0, is left out), checks that 8 of them are
$+\sqrt{25 - k_5^2}$ and 8 are $-\sqrt{25 - k_5^2}$ (complex square root) to
$10^{-10}$, and draws their real and imaginary parts. For $k_5 > 5$ the imaginary
part $\sqrt{k_5^2 - 25} = \sqrt{k_5^2 - m^2 - k_0^2 - k_1^2 - k_2^2 - k_3^2}$ is the
*growth rate* of the wave; the Revision record states this formula
(`Revision/theory/reports/python-scope.json`, check
`extra_time_growth_rates_unbounded`). The cell first lets sympy write the formula
for $h^2$ of section 10 and, from it, the growth rate for a momentum $K$ along
$x_5$, and requires that the record's text contains both expressions exactly as
sympy writes them, and the words "no upper bound".

Text cell:

```
**The exact example of the Revision record.** The Revision record also works out
the smallest example exactly (‘Revision/theory/reports/python-field-theory.json‘,
check ‘extra_time_modes_grow‘): mass $m = 1$, no momentum except $k_5 = 2$ along
the extra time $x_5$. Then $h^2 = (m^2 - k_5^2) I_{16} = (1 - 4) I_{16} = -3 I_{16}$,
so every eigenvalue $E$ has $E^2 = -3$: $E = +i\sqrt3$ or $E = -i\sqrt3$. The plane
wave carries the factor $e^{-iEx_4}$; for $E = i\sqrt3$ this is
$e^{-i \cdot i\sqrt3\, x_4} = e^{\sqrt3\, x_4}$ (because $-i \cdot i = 1$), a wave
that grows exponentially in the time $x_4$. The next cell substitutes these numbers
into the exact $h$ of section 10, checks $h^2 = -3 I_{16}$, asks sympy for the
exact eigenvalues and their multiplicities (‘eigenvals‘ returns a dictionary
eigenvalue: multiplicity), and compares them with the eigenvalues that the record
prints.

**Why the deflation matters here.** In the author’s metric the extra times
```

```
deflate. A wave with a fixed *coordinate* momentum $k_{x_5}$ along $x_5$ has the
*frame* momentum $b_4^{-1/2}e^{a_4}\sin^{-1/6}(z)\, k_{x_5}$: the derivative along
the coordinate $x_5$ is divided by the frame factor $b_4^{1/2}e^{-a_4}\sin^{1/6} z$
of the direction $x_5$. As $a_4$ grows (with $b_4$ constant; the record states it at
$b_4 = 1$) this frame momentum grows like $e^{a_4}$, so,
in the local plane-wave reading that the same Revision check states, every wave
along an extra time eventually reaches the region where $E$ is imaginary. This
notebook computes only the flat algebra behind that statement.
```

```

Text cell:

```
## 13. What this notebook showed

- PROVED (exact, sympy): two numbers cannot take the square root of $p^2 + q^2$;
  anticommuting matrices can. $(p\sigma_x + q\sigma_z)^2 = (p^2 + q^2)I_2$ and
  $(p\sigma_x + qN)^2 = (p^2 - q^2)I_2$ with real $2 \times 2$ matrices; the Pauli
  matrices satisfy the Clifford relation for three space directions and Dirac's
  matrices for $\mathrm{diag}(+1, -1, -1, -1)$; Dirac's first-order equation
  contains $E^2 = m^2 + k^2$.
- PROVED (exact, sympy, with the gammas of the Revision record file
  `Revision/algebra/gammas.json`): $(\sum_a p_a\gamma^{(x_a)})^2 =
  (p_0^2 + p_1^2 + p_2^2 + p_3^2 - p_4^2 - p_5^2 - p_6^2 - p_7^2)I_{16}$ for all
  $p$: the author's gammas take the square root of the quadratic form of his
  space-time.
- PROVED (exact): plane waves of $\sum_a\gamma^{(x_a)}\partial_a\Psi = m\Psi$ in flat
  4+4 space obey $Eu = hu$ with $h^2 = (m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2
  - k_6^2 - k_7^2) I_{16}$; this reproduces the Revision record
  (`Revision/theory/reports/python-field-theory.json`, check
  `mode_hamiltonian_B_selfadjoint_dispersion`).
- PROVED (exact, sympy): the record's matrix $B = -iC\gamma^{(x_4)}$ is Hermitian
  with $B^2 = I_{16}$ and commutes with $h$ when there is no extra-time momentum;
  a momentum along an extra time mixes the sectors $B = +1$ and $B = -1$ (check
  `good_sector_spectrum_and_B_sectors`).
- COMPUTED (floating point; every deviation from the exact values is below
  $10^{-9}$): the record's example ($m = 2$, $k_0 = 4$,
  $(k_1, k_2, k_3) = (1, 2, 0)$) has the energies $+5$ and $-5$, eight each, with
  eight independent solutions each, on all 16 components, and four each in the
  sector $B = +1$ (both statements of
  check `good_sector_spectrum_and_B_sectors`); a momentum along an extra time
  makes the energies imaginary when
  $k_5^2 > m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2$, with the growth rate
  $\sqrt{k_5^2 - m^2 - k_0^2 - k_1^2 - k_2^2 - k_3^2}$
  (`Revision/theory/reports/python-scope.json`, check
  `extra_time_growth_rates_unbounded`). PROVED (exact, sympy): the record's example
  $m = 1$, $k_5 = 2$ has the energies $\pm i\sqrt3$, eight each (check
  `extra_time_modes_grow`); the wave with $E = i\sqrt3$ grows like
  $e^{\sqrt3\,x_4}$.
- ASSUMED: flat 4+4 space (constant metric $\eta$). The author's space-time is
  curved, 3-space inflates and the extra times deflate; these effects are not part
  of this notebook. The deflation multiplies the frame momentum of a wave along an
  extra time by $e^{a_4}$, so it pushes such waves towards the growing region; the
  Revision record states this as a local plane-wave statement.
```

4.12 Line-by-line walk-through of Notebook 04b

The notebook has 18 code cells, In [1] to In [18]. As in Section 4.8, every line is quoted except two things: the set-up cell In [1], which is the set-up cell of Notebook 04a explained line by line in Section 4.8 and differs from it only as said below, and the long caption texts handed to `save_figure`, which are shortened to a line `...)` (the dots stand for the caption, the bracket closes the call); each caption is printed in full under its figure in Section 4.11.

In [1], the set-up cell. It is the set-up cell of Notebook 04a, explained line by line in Section 4.8, with one difference: the line `NOTEBOOK_ID = "04b"` names this notebook, so its figures are numbered 04b.1, 04b.2, ..., and its comment lines hold the run instructions of Section 4.10. It prints one line, Set-up of notebook 04b complete: repository folder found, helpers defined.

In [2], numbers are not enough.

```
import numpy as np  # floating-point arrays and linear algebra
import sympy as sp  # exact algebra with symbols
```

numpy computes with floating-point numbers in this notebook (numbers with about 16 significant digits, so the last digits may be rounded); sympy computes exactly with **symbols**, letters that stand for any number, so an identity that sympy confirms holds for every value.

```
alpha, beta = sp.symbols("alpha beta")  # two unknown numbers
equations = [alpha**2 - 1, beta**2 - 1, 2 * alpha * beta]  # each must equal 0
solutions = sp.solve(equations, [alpha, beta], dict=True)  # ** is a power
say(f"number solutions of alpha^2 = 1, beta^2 = 1, 2 alpha beta = 0: {solutions}")
check(solutions == [], "no two numbers solve the square-root problem")
```

`sp.symbols("alpha beta")` makes two symbols. The list `equations` holds three expressions that must all be zero: $\alpha^2 - 1$, $\beta^2 - 1$ and $2\alpha\beta$ (in Python `**` is a power). `sp.solve` returns the list of all solutions, real or complex, each as a dictionary; it is the empty list `[]`, which the cell prints and the check requires. This confirms the first paragraph of Section 4.3.

In [3], two real 2×2 matrices.

```
sigma_x = sp.Matrix([[0, 1], [1, 0]])
sigma_z = sp.Matrix([[1, 0], [0, -1]])
N = sp.Matrix([[0, 1], [-1, 0]])
I2 = sp.eye(2)  # the 2 x 2 identity matrix
p, q = sp.symbols("p q", real=True)  # two symbols that stand for any real numbers
```

The three matrices σ_x, σ_z and N of Section 4.3 as sympy matrices (each given by the list of its rows), the identity I_2, and two real symbols p and q.

```
euclidean = ((p * sigma_x + q * sigma_z) ** 2).expand()  # multiplied out
indefinite = ((p * sigma_x + q * N) ** 2).expand()
say(f"(p sigma_x + q sigma_z)^2 = {euclidean.tolist()}")
say(f"(p sigma_x + q N)^2 = {indefinite.tolist()}")
```

`** 2` squares the sympy matrix (a matrix product), and `.expand()` multiplies out every entry. The two printed matrices are $(p^2+q^2)I_2$ and $(p^2-q^2)I_2$; `.tolist()` writes a matrix as a list of rows.

```
example = 3 * sigma_x + 4 * sigma_z
say(f"3 sigma_x + 4 sigma_z = {example.tolist()}, its square = "
    f"{(example * example).tolist()}")
check(euclidean == (p**2 + q**2) * I2 and (example * example) == 25 * I2,
      "(p sigma_x + q sigma_z)^2 = (p^2 + q^2) I2 for all p, q")
check(indefinite == (p**2 - q**2) * I2,
      "(p sigma_x + q N)^2 = (p^2 - q^2) I2 for all p, q")
```

The worked example of Section 4.3, $3\sigma_x + 4\sigma_z$ and its square $25I_2$, is printed; the two checks confirm both identities for all p and q (sympy compares the matrices of expressions exactly).

In [4], the eigenvalues of the two roots, and figure 1.

```
p_values = np.linspace(-3.0, 3.0, 201)  # 201 equally spaced values of p
sx = np.array(sigma_x, dtype=float)  # the same matrices as numpy arrays
sz = np.array(sigma_z, dtype=float)
n_matrix = np.array(N, dtype=float)
```

`np.linspace(-3.0, 3.0, 201)` makes 201 numbers from -3 to 3 in equal steps of 0.03. The sympy matrices are copied into numpy arrays of floating-point numbers.

```
euclid_eigen = np.array([np.sort(np.linalg.eigvals(pv * sx + sz).real)
                         for pv in p_values])  # q = 1
indef_eigen = np.array([np.linalg.eigvals(pv * sx + n_matrix) for pv in p_values])
root_euclid = np.sqrt(p_values**2 + 1.0)
root_indef = np.sqrt((p_values**2 - 1.0).astype(complex))  # complex square root
```

For every value `pv` of p (and $q = 1$), `np.linalg.eigvals` computes the two eigenvalues of $p\sigma_x + \sigma_z$ (`.real` keeps their real parts, `np.sort` puts them in increasing order) and of $p\sigma_x + N$ (complex numbers in general). A square root of $c\,I_2$ has the eigenvalues $\pm\sqrt{c}$ (if $Mu = \lambda u$, then $M^2u = \lambda^2 u = cu$), so they are compared with $\sqrt{p^2+1}$ and $\sqrt{p^2-1}$; `.astype(complex)` turns the numbers $p^2 - 1$ into complex numbers, so that the square root of a negative one is imaginary instead of an error.

```
errors = [np.max(np.abs(euclid_eigen[:, 1] - root_euclid)),
          np.max(np.abs(np.sort(np.abs(indef_eigen), axis=1)[:, 1]
                        - np.abs(root_indef)))]
check(max(errors) < 1e-12, "numpy eigenvalues equal +-sqrt(p^2 + 1), +-sqrt(p^2 - 1)")
```

`euclid_eigen[:, 1]` is the column of the larger eigenvalue; its largest distance from $\sqrt{p^2+1}$ is the first error. For the second root, `np.abs` takes the size of each complex eigenvalue, and the larger size is compared with the size of $\sqrt{p^2-1}$. The check allows a rounding error of 10^{-12}.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(8.4, 3.8), layout="constrained")
left.plot(p_values, root_euclid, color="#2a78d6", linewidth=2,
```

```
          label="$+\\sqrt{p^2+1}$")
left.plot(p_values, -root_euclid, color="#eb6834", linewidth=2,
          label="$-\\sqrt{p^2+1}$")
left.set_title("eigenvalues of $p\\,\\sigma_x + \\sigma_z$")
left.set_xlabel("$p$")
left.set_ylabel("eigenvalue")
left.legend(fontsize=8)
```

A figure with two panels side by side, named `left` and `right`. The left panel draws the two eigenvalues $\pm\sqrt{p^2+1}$ against p (blue and orange lines, two points wide), with a title, axis labels and a legend; `label=` is the name in the legend, and text between dollar signs is typeset as mathematics.

```
right.plot(p_values, np.abs(root_indef.real), color="#2a78d6", linewidth=2,
           label="real part of $+\\sqrt{p^2-1}$")
right.plot(p_values, np.abs(root_indef.imag), color="#1baf7a", linewidth=2,
           linestyle="--", label="imaginary part of $+\\sqrt{p^2-1}$")
right.set_title("eigenvalues of $p\\,\\sigma_x + N$")
right.set_xlabel("$p$")
right.set_ylabel("part of the eigenvalue")
right.legend(fontsize=8)
save_figure(fig, "square_roots_2x2",
            ...)
```

The right panel draws the real part (solid) and the imaginary part (dashed) of $\sqrt{p^2-1}$, and the figure is saved (its caption is printed in Section 4.11). **What figure 1 shows and why:** on the left two real curves that never meet, because $p^2+1>0$; on the right the solid curve is zero for $|p|<1$ and the dashed curve is zero for $|p|>1$: where the minus term of p^2-q^2 wins, the square root becomes imaginary. This is the two-dimensional picture of what a momentum along an extra time does in In [15].

In [5], the Pauli matrices.

```
sigma_y = sp.Matrix([[0, -sp.I], [sp.I, 0]])
pauli = [sigma_x, sigma_y, sigma_z]
```

σ_y with the imaginary unit, which sympy writes `sp.I`, and the list of the three Pauli matrices.

```
def table_of(matrices, size):
    """The numbers c_ab with {M_a, M_b} = c_ab I; None where it is not a multiple."""
    rows = []
    for ma in matrices:
        row = []
        for mb in matrices:
            m = (ma * mb + mb * ma).expand()
            row.append(m[0, 0] if m == m[0, 0] * sp.eye(size) else None)
        rows.append(row)
    return rows
```

`table_of` computes, for every pair of matrices of the list, the anticommutator; if it is a multiple of the identity, it stores the multiple (its upper-left entry), otherwise the special value `None`. The result is the table of the numbers c_{ab} in $\{M_a, M_b\} = c_{ab} I$, as a list of rows.

```
pauli_table = table_of(pauli, 2)
say(f"Pauli table c_ab: {pauli_table}")
check(pauli_table == [[2, 0, 0], [0, 2, 0], [0, 0, 2]],
      "{sigma_a, sigma_b} = 2 delta_ab I2 for the three Pauli matrices")
check(sigma_x * sigma_y == sp.I * sigma_z and sigma_x * sigma_y * sigma_z == sp.I * I2,
      "sigma_x sigma_y = i sigma_z and sigma_x sigma_y sigma_z = i I2")
```

The Pauli table is twice the identity table, $2\delta_{ab}$: the Clifford relation for three space directions. The second check confirms $\sigma_x\sigma_y = i\sigma_z$ and $\sigma_x\sigma_y\sigma_z = iI_2$, computed by hand in Section 4.3.

In [6], Dirac's matrices.

```
Z2 = sp.zeros(2, 2)
dirac = [sp.Matrix(sp.BlockMatrix([[I2, Z2], [Z2, -I2]]))]  # gamma_D^0
for s in pauli:  # gamma_D^x, gamma_D^y, gamma_D^z
    dirac.append(sp.Matrix(sp.BlockMatrix([[Z2, s], [-s, Z2]])))
dirac_table = table_of(dirac, 4)
say(f"Dirac table c_ab: {dirac_table}")
check(dirac_table == [[2, 0, 0, 0], [0, -2, 0, 0], [0, 0, -2, 0], [0, 0, 0, -2]],
      "{gamma_D^a, gamma_D^b} = 2 diag(+1, -1, -1, -1)_ab I4")
```

`sp.BlockMatrix` glues 2×2 blocks, and `sp.Matrix(...)` turns the result into an ordinary 4×4 matrix. The list `dirac` holds $\gamma_D^0 = \mathrm{diag}(I_2, -I_2)$ and, for each Pauli matrix s, $\gamma_D^j = \begin{pmatrix} 0 & s \\ -s & 0 \end{pmatrix}$ (`.append` adds an element to a list). Their table is $2\,\mathrm{diag}(+1, -1, -1, -1)$, which the check requires.

In [7], figure 2.

```
from matplotlib.colors import BoundaryNorm, ListedColormap

TABLE_COLOURS = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])  # -2, 0, +2
TABLE_NORM = BoundaryNorm([-3, -1, 1, 3], 3)
```

Three colours and the boundaries $-3, -1, 1, 3$: -2 blue, 0 grey, $+2$ red.

```
def draw_table(ax, table, labels, title):
    """Draw a table of the numbers c_ab as a heat map with the numbers written in."""
    values = np.array(table, dtype=float)
    ax.imshow(values, cmap=TABLE_COLOURS, norm=TABLE_NORM)
    for (a, b), value in np.ndenumerate(values):
        ax.text(b, a, f"{int(value):+d}" if value else "0", ha="center",
                va="center", color="white" if value else "#52514e", fontsize=11)
    ax.set_xticks(range(len(labels)), labels)
    ax.set_yticks(range(len(labels)), labels)
    ax.set_title(title, fontsize=10)
    ax.grid(False)
```

`draw_table` paints a table of the numbers c_{ab} as a heat map, writes each number into its square (with its sign, or 0), names the rows and columns with `labels`, and sets the title.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(8.0, 4.0), layout="constrained")
draw_table(left, pauli_table, ["$\\sigma_x$", "$\\sigma_y$", "$\\sigma_z$"],
           "Pauli: $\\{\\sigma_a, \\sigma_b\\} = c_{ab} I_2$")
draw_table(right, dirac_table, ["$\\gamma_D^0$", "$\\gamma_D^x$", "$\\gamma_D^y$",
                                "$\\gamma_D^z$"],
           "Dirac: $\\{\\gamma_D^a, \\gamma_D^b\\} = c_{ab} I_4$")
save_figure(fig, "pauli_dirac_tables",
            ...)
```

The Pauli table on the left, Dirac's on the right. **What figure 2 shows and why:** grey off the diagonal (different matrices anticommute) and twice the signs of the directions on the diagonal: three red squares for Pauli's three space directions; one red square for Dirac's time and three blue ones for his space directions, in his convention $(+1, -1, -1, -1)$.

In [8], Dirac's mass shell.

```
E, k1, k2, k3 = sp.symbols("E k1 k2 k3", real=True)
P = E * dirac[0] - k1 * dirac[1] - k2 * dirac[2] - k3 * dirac[3]
check((P * P).expand() == (E**2 - k1**2 - k2**2 - k3**2) * sp.eye(4),
      "(E gamma_D^0 - k . gamma_D)^2 = (E^2 - k^2) I4 for all E and k")
```

The matrix $P = E\gamma_D^0 - k_1\gamma_D^x - k_2\gamma_D^y - k_3\gamma_D^z$ of Section 4.3 with real symbols, and the exact check $P^2 = (E^2 - k_1^2 - k_2^2 - k_3^2)I_4$ for all values.

```
dirac_numeric = [np.array(g, dtype=complex) for g in dirac]  # numpy copies

def smallest_singular_value(matrix):
    """The smallest length of matrix @ u over all columns u of length 1."""
    return np.linalg.svd(matrix, compute_uv=False).min()
```

numpy copies of Dirac's matrices with complex entries. `np.linalg.svd(matrix, compute_uv=False)` computes the singular values of a matrix (the possible lengths of Mu along special directions, for columns u of length 1), and `.min()` takes the smallest.

```
mass, momentum = 3.0, (4.0, 0.0, 0.0)
energies = np.linspace(-8.0, 8.0, 801)  # steps of 0.02

def dirac_operator(energy):
    """P - m I4 for the energy energy and the fixed momentum and mass."""
    P_num = energy * dirac_numeric[0]
    for j in range(3):
        P_num = P_num - momentum[j] * dirac_numeric[j + 1]
    return P_num - mass * np.eye(4)
```

The example $m = 3$, $k = (4, 0, 0)$, for which the mass shell is $E^2 = 9 + 16 = 25$. `energies` holds 801 energies from -8 to 8 in steps of 0.02. `dirac_operator(energy)` builds the numeric matrix $P - mI_4$ for one energy.

```
dirac_svals = np.array([smallest_singular_value(dirac_operator(e))
                        for e in energies])
# The energies where it vanishes, rounded to 6 decimals, as plain Python numbers:
zeros_at = [float(x) for x in np.round(energies[dirac_svals < 1e-9], 6)]
report("energies where a Dirac plane wave exists", zeros_at)
kernel = np.sum(np.linalg.svd(dirac_operator(5.0), compute_uv=False) < 1e-9)
report("independent solutions u at E = 5", int(kernel))
check(zeros_at == [-5.0, 5.0] and kernel == 2,
      "Dirac plane waves exist exactly at E = +-sqrt(m^2 + k^2) = +-5")
```

The smallest singular value is computed at all 801 energies. `energies[dirac_svals < 1e-9]` keeps the energies at which it is below 10^{-9} (zero up to rounding): a **boolean mask**, an array of True/False that selects entries. `np.round(..., 6)` rounds them to six decimals. At $E = 5$ the number of singular values below 10^{-9} is the number of independent solutions u. The output: plane waves exist exactly at $E = -5$ and $E = 5$, with two independent solutions at $E = 5$; the check requires both.

In [9], figure 3.

```
fig, ax = plt.subplots(figsize=(7.0, 3.8), layout="constrained")
ax.plot(energies, dirac_svals, color="#2a78d6", linewidth=2)
for e in (-5.0, 5.0):
    ax.axvline(e, color="#898781", linewidth=1, linestyle=":")
ax.set_xlabel("energy $E$")
ax.set_ylabel("smallest singular value of $P - m I_4$")
ax.set_title("Dirac plane waves for $m = 3$, $k = (4, 0, 0)$")
save_figure(fig, "dirac_mass_shell",
            ...)
```

The smallest singular value against the energy, with dotted vertical lines (`axvline`) at $E = \pm 5$. **What figure 3 shows and why:** the curve touches zero only at the two dotted lines, the two solutions of $E^2 = m^2 + k^2 = 25$: the first-order matrix equation contains the energy relation of special relativity.

In [10], the square root in 4+4 dimensions.

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
eta = record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1] in the order x0..x7
for matrix in record["gamma"]:  # the entries must be whole numbers
    if not all(isinstance(x, int) for row in matrix for x in row):
        raise ValueError("a gamma matrix of gammas.json has an entry that is not "
                         "a whole number")
gamma = [np.array(matrix, dtype=np.int64) for matrix in record["gamma"]]
sympy_gamma = [sp.Matrix(matrix) for matrix in record["gamma"]]
say("coordinates " + ", ".join(record["coordinates"]) + f"; eta = {eta}")
```

The author's gammas are read from the Revision record file `gammas.json` (the same matrices that Notebook 04a built from his formulas). The loop makes sure that every entry is a whole number (`isinstance(x, int)`). Then the eight matrices are kept twice: as numpy arrays of whole numbers (`gamma`) and as sympy matrices (`sympy_gamma`). The printed line lists the coordinates and the signs.

```
p_symbols = sp.symbols("p0:8", real=True)  # p0, ..., p7: p_symbols[a] is p_a
p_slash = sp.zeros(16, 16)
for a in range(8):
    p_slash += p_symbols[a] * sympy_gamma[a]
quadratic_form = sum(eta[a] * p_symbols[a] ** 2 for a in range(8))
say(f"quadratic form: {quadratic_form}")
check((p_slash * p_slash).expand() == quadratic_form * sp.eye(16),
      "(sum_a p_a gamma^(xa))^2 = eta(p, p) I16 for all p (exact)")
```

`sp.symbols("p0:8")` makes the eight symbols $p_0, \ldots, p_7$, so that `p_symbols[a]` is p_a. The loop builds $\sum_a p_a \gamma^{(x_a)}$, read "p slash" (`+=` adds to a variable). `quadratic_form` is $\eta(p,p) = \sum_a \eta^{aa} p_a^2$, printed as `p0**2 + p1**2 + p2**2 + p3**2 - p4**2 - p5**2 - p6**2 - p7**2`. The check confirms exactly the square-root rule at the start of Section 4.9.

In [11], the same with 300 random vectors, and figure 4.

```
generator = np.random.default_rng(12345)  # the seed makes the numbers repeatable
vectors = generator.normal(size=(300, 8))  # 300 vectors p with 8 components
forms, diagonal, worst = [], [], []
```

A **random-number generator** started from the fixed number 12345 (its **seed**) produces the same numbers in every run. `normal(size=(300, 8))` draws 300×8 numbers from the normal (bell-shaped) distribution: 300 vectors p. Three empty lists are prepared.

```
for vector in vectors:
    slash = sum(vector[a] * gamma[a] for a in range(8))  # p slash, a 16 x 16 array
    square = slash @ slash
    form = sum(eta[a] * vector[a] ** 2 for a in range(8))  # eta(p, p)
    forms.append(form)
    diagonal.append(square[0, 0])
    worst.append(np.max(np.abs(square - form * np.eye(16))))
```

For each vector: the floating-point matrix $\sum_a p_a \gamma^{(x_a)}$, its square, and $\eta(p,p)$; the lists collect $\eta(p,p)$, the upper-left entry of the square, and the largest deviation of any entry of the square from $\eta(p,p) I_{16}$.

```
# The exact size of the rounding errors depends on the computer (its numerical
# library); the right panel of the figure shows them. The check only requires them
# to stay below 1e-12, so the printed lines are the same on every computer.
check(max(worst) < 1e-12, "(p slash)^2 = eta(p, p) I16 for 300 random vectors p")
say("every rounding error of the 300 tests is below 1e-12")
```

The check allows rounding errors up to 10^{-12}; as the comment says, the exact sizes of rounding errors differ between computers, so the notebook prints only that they are below the bound.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(8.4, 3.8), layout="constrained")
left.plot(forms, diagonal, "o", markersize=4, color="#2a78d6", alpha=0.7)
line = np.array([min(forms), max(forms)])
left.plot(line, line, color="#0b0b0b", linewidth=1, label="slope 1")
left.set_xlabel("$\\eta(p, p)$")
```

```
left.set_ylabel("diagonal entry of $(\\sum_a p_a\\gamma^{(x_a)})^2$")
left.set_title("$(\\sum_a p_a\\gamma^{(x_a)})^2 = \\eta(p,p)\\, I_{16}$")
left.legend(fontsize=8)
```

The left panel draws one dot (`"o"`, size 4, 70 per cent opaque) per vector, at $\eta(p,p)$ horizontally and the diagonal entry vertically, and the black line of slope 1 from the smallest to the largest $\eta(p,p)$.

```
right.semilogy(range(1, 301), np.maximum(worst, 1e-18), "o", markersize=3,
               color="#eb6834")
right.set_xlabel("number of the random vector")
right.set_ylabel("largest deviation from $\\eta(p,p)\\, I_{16}$")
right.set_title("rounding errors")
save_figure(fig, "square_root_8d",
            ...)
```

The right panel draws, on a **logarithmic** vertical axis (`semilogy`: equal distances for equal factors of ten), the largest deviation for each vector; `np.maximum(worst, 1e-18)` replaces a deviation of exactly 0 by 10^{-18}, because 0 has no logarithm. **What figure 4 shows and why:** on the left all 300 dots lie on the line of slope 1, for positive and for negative $\eta(p,p)$ (the minus signs of the time and the extra times make many values negative); on the right every deviation is of the size of floating-point rounding, that is, an error in about the sixteenth significant digit of entries whose size is between about 1 and 15, many powers of ten under the tolerance 10^{-12}. (This panel may look slightly different on another computer; the exact identity is the sympy check of In [10].)

In [12], the formula for h^2.

```
THEORY = "Revision/theory/reports/python-field-theory.json"
theory = json.loads(repository_file(THEORY).read_text(encoding="utf-8"))
theory_checks = {entry["name"]: entry for entry in theory["checks"]}
```

```
def recorded_detail(name):
    """The text (detail) of the named check of the theory report when its verdict
    is pass; otherwise an empty text, which contains none of the quoted words."""
    entry = theory_checks.get(name, {})
    passed = entry.get("verdict", "").upper() == "PASS"
    return entry.get("detail", "") if passed else ""
```

The theory report of the Revision record is read, and its checks are kept in a dictionary by name. Every check of the report has a name, a verdict and a **detail**, a text that says in words what was checked and found. `recorded_detail(name)` returns this text when the report holds the named check with the verdict pass, and otherwise the empty text `""`. The chained `.get(..., {})` and `.get("verdict", "")` return an empty dictionary or an empty text instead of an error when something is missing, `.upper()` writes the verdict in capital letters (the report writes `pass`), and `x if passed else ""` chooses between two values. The empty text contains no words at all, so every test "these words occur in the detail" fails when the check is missing or did not pass. The cells below use this function to compare the notebook's results with what the record **says**, not only with its verdict: if the record ever states a different formula or a different example, the check fails.

```
m, k = sp.symbols("m", real=True), sp.symbols("k0:8", real=True)  # k[a] is k_a
g4 = sympy_gamma[4]  # gamma^(x4)
h = -sp.I * m * g4
for a in range(8):
    if a != 4:  # every direction except the time x4
        h -= k[a] * g4 * sympy_gamma[a]
dispersion = m**2 + k[0]**2 + k[1]**2 + k[2]**2 + k[3]**2 \
    - k[5]**2 - k[6]**2 - k[7]**2
```

A real symbol m and the eight momentum symbols $k_0, \ldots, k_7$ (`k[a]` is k_a; k_4 is not used, because the time carries the energy). `h` is built exactly as in line 5 of Section 4.9: $-im\gamma^{(x_4)}$ minus $k_a\gamma^{(x_4)}\gamma^{(x_a)}$ for every a other than the time (`-=` subtracts from a variable). `dispersion` is $m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$.

```
# h and h^2 in the words of the record, quoted exactly as the record writes them
H_WORDS = "h = -i m gamma^(4) - sum_{a != x4} k_a gamma^(4) gamma^(a)"
H2_WORDS = "h^2 = (m^2 + k0^2 + k1^2 + k2^2 + k3^2 - k5^2 - k6^2 - k7^2) I16"
detail = recorded_detail("mode_hamiltonian_B_selfadjoint_dispersion")
check((h * h).expand() == dispersion * sp.eye(16)
      and H_WORDS in detail and H2_WORDS in detail, H2_WORDS)
print(f"     reproduces {THEORY}")
print("         check mode_hamiltonian_B_selfadjoint_dispersion (formula for h^2)")
```

`H_WORDS` and `H2_WORDS` are the record's own words for h (the record writes `gamma^(4)` for $\gamma^{(x_4)}$) and for h^2. `text in detail` is true when the text occurs, character for character, inside `detail`. The check confirms h^2 exactly, for all values of the symbols, and requires that the record states the same h and the same formula; the name of the check is the formula itself. The two printed lines name the record.

In [13], the good-sector example on all sixteen components.

```
gamma_complex = [g.astype(complex) for g in gamma]

def h_matrix(mass_value, momenta):
    """The numeric h for the mass and the eight momenta (momenta[4] is not used)."""
    result = -1j * mass_value * gamma_complex[4]
    for a in range(8):
        if a != 4:
            result = result - momenta[a] * gamma_complex[4] @ gamma_complex[a]
    return result
```

Complex copies of the gammas (Python writes the imaginary unit `1j`), and the function `h_matrix` that builds the numeric h for a mass and a list of eight momenta in the order $x_0, \ldots, x_7$ (`momenta[4]` is not used).

```
example = h_matrix(2.0, [4.0, 1.0, 2.0, 0.0, 0.0, 0.0, 0.0, 0.0])  # k0, k1, k2 = 4, 1, 2
hermitian = np.array_equal(example, example.conj().T)  # h^dagger = h, exactly
eigenvalues = np.linalg.eigvalsh(example)  # real eigenvalues, increasing order
rounded = [float(x) for x in np.round(eigenvalues, 9)]  # 9 decimals
```

```
multiplicities = {value: rounded.count(value) for value in sorted(set(rounded))}
report("eigenvalue: multiplicity of h for m = 2, k0 = 4, (k1, k2, k3) = (1, 2, 0)",
       multiplicities)
```

The record's example $m = 2$, $k_0 = 4$, $(k_1, k_2, k_3) = (1, 2, 0)$, the list of momenta $[4, 1, 2, 0, 0, 0, 0, 0]$. `example.conj().T` is the conjugate transpose, and `np.array_equal` compares exactly: h is Hermitian. `np.linalg.eigvalsh` computes the eigenvalues of a Hermitian matrix (real numbers, in increasing order, each listed as often as its multiplicity). They are rounded to nine decimals and counted: the RESULT line reads `{-5.0:  8, 5.0:  8}`.

```
solutions = [int(np.sum(np.linalg.svd(e * np.eye(16) - example, compute_uv=False)
                        < 1e-9)) for e in (5.0, -5.0)]  # singular values near 0
report("independent solutions u at E = +5 and at E = -5", solutions)
```

As for Dirac's matrices in In [8], the number of singular values of $EI_{16} - h$ below 10^{-9} is the number of independent solutions u of $hu = Eu$. The **list comprehension** `[... for e in (5.0, -5.0)]` computes this number once for $E = 5$ and once for $E = -5$ and collects the two results in a list; `int(...)` makes each a plain whole number. The RESULT line reads `[8, 8]`: eight independent solutions at each energy.

```
eight_each = np.allclose(eigenvalues[:8], -5.0, atol=1e-12) and \
    np.allclose(eigenvalues[8:], 5.0, atol=1e-12)
good = recorded_detail("good_sector_spectrum_and_B_sectors")
check(hermitian and eight_each and solutions == [8, 8]
      and "h is Hermitian on the full 16-dim space" in good
      and f"({multiplicities.get(5.0)} each)" in good,
      "good sector: h is Hermitian with energies +5 and -5, eight each")
print(f"     reproduces {THEORY}")
print("         check good_sector_spectrum_and_B_sectors (full space: 8 each)")
```

`np.allclose(x, value, atol=1e-12)` is true when every entry of `x` lies within 10^{-12} of `value`: the first eight eigenvalues are -5 and the last eight $+5$. `good` is the text of the record's check `good_sector_spectrum_and_B_sectors`. `multiplicities.get(5.0)` is the multiplicity 8 that the notebook found for the eigenvalue $+5$, so the f-string makes the text `(8 each)` from the notebook's own count. The check requires h to be Hermitian, eight eigenvalues -5 and eight $+5$, eight independent solutions at each energy, and the record's words for this statement about all sixteen components; the printed lines name the record and say which of its statements is reproduced.

```
energies_4p4 = np.linspace(-8.0, 8.0, 801)
svals_4p4 = np.array([smallest_singular_value(e * np.eye(16) - example)
                      for e in energies_4p4])
distance = np.minimum(np.abs(energies_4p4 - 5.0), np.abs(energies_4p4 + 5.0))
check(np.max(np.abs(svals_4p4 - distance)) < 1e-9,
      "smallest singular value of E - h = distance from E to +-5")
```

The smallest singular value of $EI_{16} - h$ at 801 energies from -8 to 8. For a Hermitian h it equals the distance from E to the nearest eigenvalue, here $\min(|E - 5|, |E + 5|)$ (`np.minimum` takes the smaller of two numbers, entry by entry); the check confirms this to 10^{-9}.

In [14], figure 5.

```
fig, ax = plt.subplots(figsize=(7.0, 3.8), layout="constrained")
ax.plot(energies_4p4, svals_4p4, color="#2a78d6", linewidth=2)
for e in (-5.0, 5.0):
    ax.axvline(e, color="#898781", linewidth=1, linestyle=":")
ax.set_xlabel("energy $E$")
ax.set_ylabel("smallest singular value of $E I_{16} - h$")
ax.set_title("plane waves in flat 4+4 space, $m = 2$, $k_0 = 4$, "
             "$(k_1, k_2, k_3) = (1, 2, 0)$")
save_figure(fig, "mass_shell_4p4",
            ...)
```

The same kind of figure as figure 3, now for the author's gammas. **What figure 5 shows and why:** a zigzag of straight lines, the distance from E to the nearer of ± 5, touching zero only at the dotted lines $E = \pm 5$, where $E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 = 25$; each of the two energies belongs to eight independent solutions (In [13] counted them). It has the shape of the Dirac curve: the same algebra in more directions.

In [15], the sector $B = +1$ and the record's exact example.

```
C_exact = sympy_gamma[0] * sympy_gamma[1] * sympy_gamma[2] * sympy_gamma[3]
B_exact = -sp.I * C_exact * g4  # B = -i C gamma^(x4)
B_stored = sp.Matrix(record["B"]["re"]) + sp.I * sp.Matrix(record["B"]["im"])
```

$C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ from the exact gammas (`sympy_gamma[a]` is $\gamma^{(x_a)}$), and $B = -iC\gamma^{(x_4)}$, exactly. `record` is the content of the record file `Revision/algebra/gammas.json`, read in In [10]; it stores B as two tables of whole numbers, its real part `"re"` and its imaginary part `"im"`, and `B_stored` puts them together as the real part plus i times the imaginary part.

```
h_good = h.subs({k[5]: 0, k[6]: 0, k[7]: 0})  # no momentum along an extra time
P_exact = (sp.eye(16) + B_exact) / 2  # keeps the B = +1 part of a column
mixes = all(B_exact * g4 * sympy_gamma[a] == -g4 * sympy_gamma[a] * B_exact
            for a in (5, 6, 7))  # anticommutes with gamma^(x4) gamma^(x5, x6, x7)
```

`h_good` is the exact h of In [12] with $k_5 = k_6 = k_7 = 0$ (the entries 5, 6 and 7 of the list `k`, counted from 0 like the coordinates); the symbols m, k_0, k_1, k_2, k_3 stay free, so everything checked with `h_good` holds for all their values. `P_exact` is $P = \frac{1}{2}(I_{16} + B)$: for a column with $Bu = u$ it gives $Pu = u$, for one with $Bu = -u$ it gives $Pu = 0$. `mixes` is true when $B\gamma^{(x_4)}\gamma^{(x_a)} = -\gamma^{(x_4)}\gamma^{(x_a)}B$ for $a = x_5, x_6, x_7$ (`sympy_gamma[5]` to `sympy_gamma[7]`); `all(...)` is true when the test holds for every value of `a` in the list.

```
check(B_exact == B_stored and B_exact.H == B_exact
      and B_exact * B_exact == sp.eye(16) and B_exact.trace() == 0
      and (B_exact * h_good - h_good * B_exact).expand() == sp.zeros(16, 16)
      and mixes and (h_good * P_exact).trace().expand() == 0
      and "[B, h] = 0" in good
      and "B anticommutes with gamma^(4) gamma^(x5,x6,x7)" in good,
      "B is Hermitian, B^2 = I16, B h = h B without extra-time momentum")
print(f"     reproduces {THEORY}")
print("         check good_sector_spectrum_and_B_sectors (B and h commute)")
```

The exact part of Section 4.9: the rebuilt B equals the stored one; `.H` is sympy's conjugate transpose, so `B_exact.H == B_exact` says $B^\dagger = B$; $B^2 = I_{16}$ and $\operatorname{tr} B = 0$ (`.trace()` is the trace); $Bh - hB$, multiplied out, is the zero matrix `sp.zeros(16, 16)` for all values of the symbols; B anticommutes with $\gamma^{(x_4)}\gamma^{(x_a)}$ for the three extra times; $\operatorname{tr}(hP) = 0$, again for all values; and the record states the commutation and the anticommutation in these words.

```
B_numeric = np.array(B_exact.tolist(), dtype=complex)
b_values, b_vectors = np.linalg.eigh(B_numeric)  # B is Hermitian: eigh applies
V = b_vectors[:, b_values > 0]  # the 8 orthonormal columns u with B u = u
h_plus = V.conj().T @ example @ V  # h inside the sector B = +1, 8 x 8
```

A numpy copy of B (`tolist()` turns the sympy matrix into a list of rows). `np.linalg.eigh` returns, for a Hermitian matrix, its eigenvalues in increasing order and a matrix whose columns are orthonormal eigenvectors, one for each eigenvalue in the same order. `b_vectors[:, b_values > 0]` keeps all rows (`:`) of the columns whose eigenvalue is positive, that is $+1$: the 16×8 matrix V of Section 4.9. `h_plus` is $h_+ = V^\dagger h V$ for the example h of In [13].

```
plus_values = np.linalg.eigvalsh(h_plus)  # its eigenvalues, increasing order
plus_rounded = [float(x) for x in np.round(plus_values, 9)]  # 9 decimals
plus_counts = {value: plus_rounded.count(value)
               for value in sorted(set(plus_rounded))}
report("eigenvalue: multiplicity of h in the sector B = +1", plus_counts)
```

The eight eigenvalues of h_+, rounded and counted as in In [13]: the RESULT line reads `{-5.0:  4, 5.0:  4}`.

```
sector_words = (f"m = 2, k0 = 4, (k1, k2, k3) = (1, 2, 0) on B = +1: +5 "
                f"({plus_counts.get(5.0)} times), -5 ({plus_counts.get(-5.0)} times)")
check(V.shape == (16, 8)
      and np.allclose(V @ V.conj().T, (np.eye(16) + B_numeric) / 2, atol=1e-12)
      and np.allclose(example @ V, V @ h_plus, atol=1e-12)
      and np.allclose(h_plus @ h_plus, 25.0 * np.eye(8), atol=1e-12)
      and np.allclose(plus_values, [-5.0] * 4 + [5.0] * 4, atol=1e-12)
      and sector_words in good,
      "sector B = +1: h has the energies +5 and -5, four times each")
print(f"     reproduces {THEORY}")
print("         check good_sector_spectrum_and_B_sectors (its exact example)")
```

`sector_words` writes the record's sentence for its exact example with the counts that the notebook found (two texts written next to each other inside round brackets are joined into one). The check requires: V has 16 rows and 8 columns (`V.shape`); $VV^\dagger = P$; $hV = Vh_+$, so h maps the sector into itself; $h_+^2 = 25 I_8$; the eight eigenvalues are four times -5 and four times $+5$ (`[-5.0] * 4 + [5.0] * 4` is the list of four -5 followed by four $+5$), all within 10^{-12}; and the record's text contains `m = 2, k0 = 4, (k1, k2, k3) = (1, 2, 0) on B = +1:  +5 (4 times), -5 (4 times)`. This reproduces the record's exact example as the record states it.

In [16], a momentum along an extra time, and figure 6.

```
SCOPE = "Revision/theory/reports/python-scope.json"
scope = json.loads(repository_file(SCOPE).read_text(encoding="utf-8"))
scope_checks = {entry["name"]: entry for entry in scope["checks"]}
scope_entry = scope_checks.get("extra_time_growth_rates_unbounded", {})
scope_passed = scope_entry.get("verdict", "").upper() == "PASS"
scope_detail = scope_entry.get("detail", "") if scope_passed else ""
```

The scope report of the Revision record is read. `scope_detail` is the text of its check `extra_time_growth_rates_unbounded` when that check passed, and otherwise the empty text: the same rule as `recorded_detail` in In [12], for the other report.

```
K = sp.symbols("K", positive=True)  # a momentum K along the extra time x5
rate = sp.sqrt(-dispersion.subs({k[5]: K, k[6]: 0, k[7]: 0}))  # Im E if E^2 < 0
say(f"h^2 = ({dispersion}) I16")
say(f"growth rate for k5 = K: Im E = {rate}")
scope_ok = (f"h_k^2 = ({dispersion}) I16" in scope_detail
            and f"Im E = {rate}" in scope_detail
            and "no upper bound" in scope_detail)  # the record's words
```

A positive symbol K for the momentum along x_5. With $k_5 = K$ and $k_6 = k_7 = 0$, `dispersion` is E^2; when $E^2 < 0$, $E = \pm i\sqrt{-E^2}$, so the imaginary part of the growing energy, the growth rate, is $\sqrt{-E^2}$: `rate`. sympy writes the two expressions in its own order, and the two printed lines show them: `h^2 = (k0**2 + k1**2 + k2**2 + k3**2 - k5**2 - k6**2 - k7**2 + m**2) I16` and `growth rate for k5 = K: Im E = sqrt(K**2 - k0**2 - k1**2 - k2**2 - k3**2 - m**2)`, where `**` is a power. `scope_ok` is true when the record's text contains both expressions exactly as sympy writes them, and the words `no upper bound`.

```
k5_values = np.linspace(0.025, 7.975, 160)  # steps of 0.05, avoiding k5 = 5
real_parts, imaginary_parts, deviations, counts_ok = [], [], [], True
for k5 in k5_values:
    values = np.linalg.eigvals(h_matrix(2.0, [4.0, 1.0, 2.0, 0.0, 0.0, k5, 0.0, 0.0]))
    root = np.sqrt(complex(25.0 - k5**2))  # +sqrt(25 - k5^2), complex if needed
    to_plus, to_minus = np.abs(values - root), np.abs(values + root)
    deviations.append(np.max(np.minimum(to_plus, to_minus)))
    counts_ok &= bool(np.sum(to_plus < to_minus) == 8)  # eight near +root
    real_parts.append(np.sort(values.real))
    imaginary_parts.append(np.sort(values.imag))
```

160 values of k_5 from 0.025 to 7.975 in steps of 0.05 (the value $k_5 = 5$, where both energies are 0, is skipped). For each, the 16 eigenvalues of h with the momentum k_5 added (in position 5 of the list, the direction x_5; h is no longer Hermitian, so the general `eigvals` is used); `root` is $\sqrt{25 - k_5^2}$, imaginary when $k_5 > 5$. For each eigenvalue its distance to +root and to −root is computed; the largest of the smaller distances is stored, and `counts_ok` stays true only if exactly eight eigenvalues lie nearer to +root. The sorted real and imaginary parts are kept for the figure.

```
# As above, the size of the deviations depends on the computer; the check requires
# every one of the 160 x 16 eigenvalues to lie within 1e-10 of its exact value.
check(max(deviations) < 1e-10 and counts_ok and scope_ok,
      "with momentum k5: eight energies +sqrt(25 - k5^2), eight -sqrt(25 - k5^2)")
```

```
print(f"     reproduces {SCOPE}")
print("         check extra_time_growth_rates_unbounded (growth rate formula)")
```

The check requires all 160×16 eigenvalues within 10^{-10} of $\pm\sqrt{25 - k_5^2}$, eight of each, and the record's words (`scope_ok`).

```
real_parts, imaginary_parts = np.array(real_parts), np.array(imaginary_parts)
fig, (left, right) = plt.subplots(1, 2, figsize=(8.4, 3.8), layout="constrained")
for column in range(16):  # the 16 eigenvalues; they lie on two curves
    left.plot(k5_values, real_parts[:, column], ".", markersize=3, color="#2a78d6")
    right.plot(k5_values, imaginary_parts[:, column], ".", markersize=3,
               color="#1baf7a")
```

The lists become arrays with one row per k_5 and one column per eigenvalue; each column is drawn as small dots, real parts on the left, imaginary parts on the right.

```
for ax, part in ((left, "real"), (right, "imaginary")):
    ax.axvline(5.0, color="#898781", linewidth=1, linestyle=":")
    ax.set_xlabel("momentum $k_5$ along the extra time $x_5$")
    ax.set_ylabel(f"{part} part of the energy $E$")
left.set_title("real parts: $\\pm\\sqrt{25 - k_5^2}$ for $k_5 < 5$")
right.set_title("imaginary parts: $\\pm\\sqrt{k_5^2 - 25}$ for $k_5 > 5$")
save_figure(fig, "extra_time_momentum",
            ...)
```

Both panels get a dotted line at $k_5 = 5$ and axis labels, then titles, and the figure is saved. **What figure 6 shows and why:** on the left the real parts follow the upper and the lower half of a circle of radius 5, $\pm\sqrt{25 - k_5^2}$, reach zero at $k_5 = 5$ and stay zero beyond; on the right the imaginary parts are zero up to $k_5 = 5$ and then open up as $\pm\sqrt{k_5^2 - 25}$, growing without bound. Because the extra times enter the quadratic form with a minus sign, a large enough momentum along an extra time turns oscillating waves into growing and shrinking ones.

In [17], the exact example with growing modes.

```
example_values = {m: 1, k[0]: 0, k[1]: 0, k[2]: 0, k[3]: 0, k[5]: 2, k[6]: 0,
                  k[7]: 0}  # mass 1, momentum 2 along x5, nothing else
h_example = h.subs(example_values)  # the exact 16 x 16 matrix h for these numbers
exact_eigenvalues = h_example.eigenvals()  # {eigenvalue: multiplicity}
```

`h.subs(...)` substitutes the numbers of the record's example ($m = 1$, $k_5 = 2$, all other momenta 0) into the exact matrix h of In [12]. `eigenvals()` returns the exact eigenvalues as a dictionary eigenvalue: multiplicity, the multiplicity being the number of times the eigenvalue occurs as a root of the characteristic polynomial.

```
names = sorted(str(value) for value in exact_eigenvalues)  # as sympy writes them
# printed in sorted order, so that every run prints the same line
listed = ", ".join(f"{value} ({count} times)" for value, count in
                   sorted(exact_eigenvalues.items(), key=lambda item: str(item[0])))
say(f"h^2 = -3 I16: {h_example * h_example == -3 * sp.eye(16)}; exact eigenvalues: "
    f"{listed}")
```

`names` lists the eigenvalues as sympy writes them, sorted. `listed` writes each eigenvalue with its multiplicity; `sorted(..., key=lambda item:  str(item[0]))` sorts the pairs by the text of the eigenvalue (a `lambda` is a one-line function without a name), so that every run prints the same order. The printed line: $h^2 = -3I_{16}$ is True, and the eigenvalues are `-sqrt(3)*I` and `sqrt(3)*I`, eight times each.

```
detail = recorded_detail("extra_time_modes_grow")
check(h_example * h_example == -3 * sp.eye(16)
      and exact_eigenvalues == {sp.sqrt(3) * sp.I: 8, -sp.sqrt(3) * sp.I: 8}
      and "m = 1, k5 = 2" in detail and str(names) in detail,
      "m = 1, k5 = 2: E = +i sqrt(3) and -i sqrt(3), eight each (growing modes)")
print(f"     reproduces {THEORY}")
print("         check extra_time_modes_grow (its exact example)")
```

`detail` is the text of the Revision check `extra_time_modes_grow` (the empty text if the check did not pass, by the rule of In [12]). The check requires $h^2 = -3I_{16}$, the eigenvalues $\pm i\sqrt{3}$ with multiplicity 8 each, and the record's text to contain the example and the same list of eigenvalues word for word.

In [18], the last check.

```
names = ["04b_1_square_roots_2x2.png", "04b_2_pauli_dirac_tables.png",
         "04b_3_dirac_mass_shell.png", "04b_4_square_root_8d.png",
         "04b_5_mass_shell_4p4.png", "04b_6_extra_time_momentum.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in names),
      "all six figure files exist")
all_checks_passed()
```

The six figure files must exist; the last line reads ALL 19 CHECKS PASSED (notebook 04b): one check in each of In [2], In [4], In [6], In [10], In [11], In [12], In [16], In [17] and In [18], and two in each of In [3], In [5], In [8], In [13] and In [15].

4.13 The 256 products: Cl(4,4) is all real 16 by 16 matrices

The Clifford algebra Cl(4,4) is the set of all real combinations of products of the eight gammas (Section 4.3). This section proves that it is the set of **all** real 16×16 matrices, and that sixteen is the smallest size eight such matrices can have. Everything follows from the Clifford relation alone.

Sets and how to count them. A **set** is a collection of different objects, written in braces, for example $A = \{x_2, x_5\}$; the **empty set** $\{\}$ has no element. A **subset** of a set S is a set whose elements all belong to S. A set of eight directions has $2^8 = 256$ subsets, because each of the eight directions is either in a subset or not (two choices, eight times). The **binomial coefficient** $\binom{n}{k}$ ("n choose k") is the number of subsets with k elements of a set with n elements. With the **factorial** $n! = 1 \cdot 2 \cdots n$ and $0! = 1$ it is $\binom{n}{k} = \frac{n!}{k!\,(n-k)!}$: k different elements can be picked one after the other in $n(n-1)\cdots(n-k+1) = n!/(n-k)!$ ways, and every subset of k elements arises in this way $k!$ times, once for each order of its elements. For $n = 8$ the numbers for $k = 0, 1, \ldots, 8$ are $1, 8, 28, 56, 70, 56, 28, 8, 1$ (for example $\binom{8}{2} = 8 \cdot 7/2 = 28$). Exactly half of the 256 subsets have an even number of elements. Proof: the rule "add x_1 if it is missing, remove it if it is present" turns

every subset into another one, changes the number of elements by one (so it turns even into odd and odd into even), and applied twice gives the subset back; so it pairs every even subset with exactly one odd subset, and there are 128 of each.

The products. For a set A of directions write γ_A for the product of their gammas in increasing order, for example $\gamma_{\{x_2,x_5\}} = \gamma^{(x_2)}\gamma^{(x_5)}$, and $\gamma_{\{\}} = I_{16}$. The number k of factors is the **degree** of γ_A; the product is **even** if k is even and **odd** if k is odd. There are 256 products, $\binom{8}{k}$ of degree k, 128 even and 128 odd. The **symmetric difference** $A \triangle B$ is the set of the directions that lie in exactly one of A and B. Three rules follow from the Clifford relation.

Rule R1: products multiply into products. $\gamma_A\gamma_B = s(A,B)\,\gamma_{A\triangle B}$ with the sign $s(A,B) = (-1)^{N(A,B)} \prod_{c\in A\cap B} \eta^{cc}$, where $N(A,B)$ is the number of pairs (a,b) with a in A, b in B and a later than b in the order $x_0,\dots,x_7$, and $A\cap B$ is the set of the directions in both. Proof, step by step: in $\gamma_A\gamma_B$, take the factors of γ_B one after the other, the earliest direction first, and move each to the left until it stands in increasing order. A factor γ^b passes exactly the factors γ^a of A with a later than b (the factors of B moved before it are earlier than b and stay on its left); each of them is a different gamma, so each exchange gives a factor -1 (anticommutation). If b also lies in A, γ^b then stands next to its partner γ^b, and the two give $(\gamma^b)^2 = \eta^{bb} I_{16}$ and disappear. What remains is the product, in increasing order, of the directions in exactly one of A and B, and the collected signs are $(-1)^{N(A,B)}$ and one η^{cc} for each common direction.

Rule R2: squares. With $B = A$ the common directions are all of A, and $N(A,A)$ is the number of pairs in A with the later one first, $k(k-1)/2$ for a product of degree k (every pair of different elements of A counts once). So

$$\gamma_A\gamma_A = (-1)^{k(k-1)/2} \prod_{a\in A} \eta^{aa}\; I_{16}\,:$$

every product squares to $+I_{16}$ or to $-I_{16}$, and its inverse is $\gamma_A^{-1} = \pm\gamma_A$ with the same sign. For example a product of two gammas has $(\gamma^a\gamma^b)^2 = (-1)^1\eta^{aa}\eta^{bb} I_{16} = -\eta^{aa}\eta^{bb} I_{16}$.

Rule R3: passing one gamma. Moving γ^b from the left of γ_A to its right passes each of the k factors once: $\gamma^b\gamma_A = (-1)^k\gamma_A\gamma^b$ if b is not in A (all k factors are different from γ^b), and $\gamma^b\gamma_A = (-1)^{k-1}\gamma_A\gamma^b$ if b is in A (passing γ^b itself gives no sign).

The trace lemma. Every product other than I_{16} has trace 0. Proof, line by line, for a product γ_A of degree $k \geq 1$:

1. If k is odd, then $k \leq 7$, so some direction b is not in A, and R3 gives $\gamma^b\gamma_A = (-1)^k\gamma_A\gamma^b = -\gamma_A\gamma^b$.
2. If k is even, take b in A; R3 gives $\gamma^b\gamma_A = (-1)^{k-1}\gamma_A\gamma^b = -\gamma_A\gamma^b$.
3. In both cases multiply from the left by $(\gamma^b)^{-1} = \eta^{bb}\gamma^b$: $\gamma_A = -(\gamma^b)^{-1}\gamma_A\gamma^b$.
4. Take the trace and use the cyclic property with the two factors $(\gamma^b)^{-1}$ and $\gamma_A\gamma^b$: $\operatorname{tr}\gamma_A = -\operatorname{tr}(\gamma_A\gamma^b(\gamma^b)^{-1}) = -\operatorname{tr}\gamma_A$.
5. A number equal to its own negative is 0.

Line 1 needs an even number of directions: with an odd number, the product of all of them has odd degree and no direction outside it.

The products are perpendicular and independent. Each γ_A is a product of orthogonal matrices, hence orthogonal ($(MN)^T(MN) = N^T M^T MN = N^T N = I$), so $\gamma_A^T = \gamma_A^{-1} = \pm\gamma_A$ (R2). Then, line by line:

1. $\gamma_A^T \gamma_B = \pm\gamma_A \gamma_B = \pm\gamma_{A\triangle B}$ — the last remark and R1.
2. $\mathrm{tr}(\gamma_A^T \gamma_B) = 0$ for $A \neq B$ — then $A\triangle B$ is not empty, and the trace lemma applies.
3. $\mathrm{tr}(\gamma_A^T \gamma_A) = \mathrm{tr}\, I_{16} = 16$ — γ_A is orthogonal.

The 256 numbers $\mathrm{tr}(\gamma_A^T \gamma_B)$ therefore form the table $16\,\delta_{AB}$; this table is called the **Gram matrix**. Now suppose a combination vanishes, $\sum_B c_B \gamma_B = 0$. Multiplying from the left by γ_A^T and taking the trace gives $\sum_B c_B \,\mathrm{tr}(\gamma_A^T \gamma_B) = 16\, c_A = 0$, so every coefficient is 0: the 256 products are **linearly independent** (no combination of them with coefficients not all zero gives the zero matrix).

They are a basis of all real 16×16 **matrices.** The real 16×16 matrices form a space of **dimension** 256: every matrix is in exactly one way a combination $\sum_{i,j} M_{ij} E_{ij}$ of the 256 matrices E_{ij} that have a single 1 in row i and column j. We quote a fact of linear algebra: in a space of dimension m, any m independent elements form a **basis**, that is, every element of the space is exactly one combination of them. So every real 16×16 matrix M is a combination $M = \sum_A c_A \gamma_A$, and multiplying by γ_A^T and taking the trace gives the coefficients:

$$c_A = \tfrac{1}{16}\,\mathrm{tr}(\gamma_A^T M).$$

Cl(4,4) is the set of all real 16×16 **matrices** (status PROVED; reproduced exactly by Notebook 04c, which finds the **rank** 256 of the 256 products, the rank of a list of matrices being the largest number of independent matrices among them; `Revision/algebra/reports/wolfram-algebra.json`, check `Clifford_basis_spans_full_matrix_algebra`, and `Revision/algebra/reports/python-algebra.json`, check `clifford_products_span_M16`).

Which products are symmetric. A product is symmetric exactly when it squares to $+I_{16}$, because $\gamma_A^T = \gamma_A^{-1}$ and $\gamma_A^{-1} = \pm\gamma_A$ with the sign of the square; it is antisymmetric when it squares to $-I_{16}$. The symmetric 16×16 matrices form a space of dimension $16 \cdot 17/2 = 136$ (the free entries on and above the diagonal) and the antisymmetric ones a space of dimension $16 \cdot 15/2 = 120$ (the free entries above the diagonal). The symmetric products are independent, so there are at most 136 of them; the antisymmetric ones at most 120; together there are $256 = 136 + 120$. So there are exactly 136 symmetric and 120 antisymmetric products (status PROVED; Notebook 04c counts them by degree).

Even products are block diagonal, odd products block off-diagonal. Every gamma is block off-diagonal (Section 4.5). By the block rule (Section 4.2), a product of an even number of block off-diagonal matrices is block diagonal and a product of an odd number is block off-diagonal. The block diagonal real matrices form a space of dimension $64 + 64 = 128$, and the 128 even products are independent block diagonal matrices, so by the quoted fact they are a basis of all block diagonal matrices; in the same way the 128 odd products are a basis of all block off-diagonal matrices. Status PROVED; `Revision/algebra/reports/wolfram-algebra`

`.json`, check `even_subalgebra_dimension`, and `Revision/algebra/reports/python-algebra.json`, check `even_products_span_M8_plus_M8`.

How big must the matrices be? The argument above works for any even number n of $d \times d$ matrices with a Clifford relation, real or complex, if γ_A^{-1} is used in place of γ_A^T: the 2^n products are independent, and independent matrices cannot be more numerous than the dimension d^2 of the space of all $d \times d$ matrices. So $d^2 \geq 2^n$. For Dirac's $n = 4$: $d \geq 4$, and his 4×4 matrices are the smallest possible. For the author's $n = 8$: $d^2 \geq 256$, so $d \geq 16$. **A field on which eight gamma matrices act has at least sixteen components; the author's fields have exactly sixteen** (status PROVED). For an odd number of matrices the trace lemma fails, and fewer components suffice: the author's seven 8×8 matrices $\tau_1, \ldots, \tau_7$ satisfy a Clifford relation (Section 4.5), yet $8^2 = 64 < 2^7 = 128$. The reason is that their product is $\tau_1 \cdots \tau_7 = I_8$ (Section 4.5, Step 2, line 9): multiplying the product τ_A of a set A by the product $\tau_{A'}$ of the remaining directions gives $\pm\tau_1 \cdots \tau_7 = \pm I_8$ (R1), so $\tau_{A'} = \pm\tau_A^{-1} = \pm\tau_A$ (R2), and the 128 products come in pairs that are equal up to sign. Notebook 04c finds that exactly $64 = 8^2$ of them are independent.

The 28 products of two gammas and the matrices S^{ab}. The products of degree 2, $\gamma^a\gamma^b$ with a before b, are $\binom{8}{2} = 28$ matrices. The Revision record names the matrices

$$S^{ab} = \tfrac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a) = \tfrac{1}{4}[\gamma^a, \gamma^b].$$

Line by line, for $a \neq b$: $\gamma^b\gamma^a = -\gamma^a\gamma^b$ (different gammas anticommute); so $\gamma^a\gamma^b - \gamma^b\gamma^a = 2\gamma^a\gamma^b$; so $S^{ab} = \frac{1}{4} \cdot 2\gamma^a\gamma^b = \frac{1}{2}\gamma^a\gamma^b$. For $a = b$ the two terms cancel: $S^{aa} = 0$. Exchanging a and b changes the sign: $S^{ba} = -S^{ab}$. So the 64 matrices S^{ab} are the 28 products of degree 2, halved, their 28 negatives, and 8 zero matrices; their entries are 0 and $\pm\frac{1}{2}$. By R2, $(\gamma^a\gamma^b)^2 = -\eta^{aa}\eta^{bb}I_{16}$. Two directions of the same kind (both space-like or both time-like) have $\eta^{aa}\eta^{bb} = +1$, so their product squares to $-I_{16}$, like the imaginary unit; there are $\binom{4}{2} + \binom{4}{2} = 12$ such pairs, the planes of **rotations**. A space-like and a time-like direction have $\eta^{aa}\eta^{bb} = -1$, so their product squares to $+I_{16}$; there are $4 \cdot 4 = 16$ such pairs, the planes of **boosts** (the transformations that, in special relativity, change the velocity of an observer). All 28 are even products, hence block diagonal. The S^{ab} are the **generators** of the rotations and boosts of the 16-component field: a generator is a matrix from which a whole family of transformations is built, the transformation by a small angle ϵ being $I_{16} + \epsilon S^{ab}$ up to terms with ϵ^2 (Chapter 5 makes this precise). The Revision record checks that they obey the rules of the rotations and boosts of the 4+4 space-time (`Revision/algebra/reports/wolfram-algebra.json`, checks `S_gamma_commutator` and `S_Lorentz_algebra`), and Chapter 5 shows how they generate the groups Spin(4,4) and, with the gammas themselves, Pin(4,4). Status of this paragraph: PROVED; `Revision/algebra/reports/python-algebra.json`, check `S_definition`; `Revision/algebra/reports/wolfram-algebra.json`, checks `S_half_product` and `S_real_entries_in_half_integers`; Notebook 04c compares all 64 matrices S^{ab} entry by entry with the matrices stored in `Revision/algebra/gammas.json` and finds them equal.

The next three sections hold Notebook 04c.

4.14 How to run Notebook 04c

Step 1. What this notebook does and what it needs.

Notebook 04c (The 256 products of the author's gammas: Cl(4,4) is all real 16 by 16 matrices) is the

file `Revision/textbook/notebooks/04c_256_products.ipynb` of the repository Dirac_claude. It forms the 256 ordered products of the author's eight gammas, checks exactly the three rules by which they multiply, their squares and symmetry (136 symmetric, 120 antisymmetric), the trace lemma and their orthogonality, proves that they are linearly independent (exact rank 256), so that the Clifford algebra Cl(4,4) is the set of all real 16 by 16 matrices, writes any matrix as a combination of them, shows that the 128 even products fill the two diagonal 8 by 8 blocks, explains why 16 is the smallest possible size, reproduces the Revision record of these facts, checks that half of each product of two different gammas is the matrix S of the Revision record, and draws eight figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04c_256_products.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04c_256_products.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 04c_256_products.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/04c.captions.json`
- `Revision/textbook/figures/04c_1_products_by_degree.png`
- `Revision/textbook/figures/04c_2_multiplication_table.png`
- `Revision/textbook/figures/04c_3_squares_by_degree.png`
- `Revision/textbook/figures/04c_4_trace_products.png`
- `Revision/textbook/figures/04c_5_coefficients.png`
- `Revision/textbook/figures/04c_6_even_odd_blocks.png`
- `Revision/textbook/figures/04c_7_how_big.png`
- `Revision/textbook/figures/04c_8_two_gamma_products.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all eight figure files exist
ALL 19 CHECKS PASSED (notebook 04c)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/04c_256_products.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 04c_256_products.ipynb
python -m nbconvert --execute --inplace 04c_256_products.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `Revision/algebra/gammas.json` or for a file in `Revision/algebra/reports`: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run `git status` in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

```
git checkout HEAD Revision/algebra
```

4.15 Notebook 04c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/04c_256_products.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The *Clifford algebra* Cl(4,4) of the author's space-time is the set of all real
linear combinations of products of his eight gamma matrices
$\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$. This notebook shows, exactly, that it is the
set of ALL real $16 \times 16$ matrices, and why 16 is the smallest size that eight
such matrices can have. It

- forms the 256 ordered products $\gamma_A$, one for each set $A$ of directions, and
  counts them by their number of factors;
- checks the three rules by which the products multiply, square and pass each other,
  for all pairs; draws the multiplication table of the 16 products of the first
  four gammas;
- finds which products square to $+I_{16}$ (136, the symmetric ones) and which to
  $-I_{16}$ (120, the antisymmetric ones);
- checks the *trace lemma* (every product except $I_{16}$ has trace 0) and that the
  256 products are perpendicular to each other in the trace sense;
- proves that they are linearly independent (exact rank 256 = $16^2$) and writes
  any matrix as a combination of them;
- shows that the 128 even products fill the two diagonal $8 \times 8$ blocks and the
  128 odd ones the two other blocks;
- compares four examples to show why the matrices must be at least $16 \times 16$;
- shows the 28 products of two different gammas, half of which are the matrices
  $S^{ab}$ of the Revision record, and compares them entry by entry with the record;
- reproduces the Revision record of these facts and draws eight figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 04c (The 256 products of the author's gammas: Cl(4,4) is all real 16 by 16
matrices) is the file 'Revision/textbook/notebooks/04c_256_products.ipynb' of the
repository Dirac_claude. It forms the 256 ordered products of the author's eight gammas,
checks exactly the three rules by which they multiply, their squares and symmetry (136
symmetric, 120 antisymmetric), the trace lemma and their orthogonality, proves that they
are linearly independent (exact rank 256), so that the Clifford algebra Cl(4,4) is the
set of all real 16 by 16 matrices, writes any matrix as a combination of them, shows that
the 128 even products fill the two diagonal 8 by 8 blocks, explains why 16 is the
smallest possible size, reproduces the Revision record of these facts, checks that half
```

of each product of two different gammas is the matrix S of the Revision record, and draws eight figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04c_256_products.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04c_256_products.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 04c_256_products.ipynb‘ (in the same folder, without running the cells again) to read the

printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/04c.captions.json‘
- ‘Revision/textbook/figures/04c_1_products_by_degree.png‘
- ‘Revision/textbook/figures/04c_2_multiplication_table.png‘
- ‘Revision/textbook/figures/04c_3_squares_by_degree.png‘
- ‘Revision/textbook/figures/04c_4_trace_products.png‘
- ‘Revision/textbook/figures/04c_5_coefficients.png‘
- ‘Revision/textbook/figures/04c_6_even_odd_blocks.png‘
- ‘Revision/textbook/figures/04c_7_how_big.png‘
- ‘Revision/textbook/figures/04c_8_two_gamma_products.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all eight figure files exist
ALL 19 CHECKS PASSED (notebook 04c)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/04c_256_products.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 04c_256_products.ipynb
      python -m nbconvert --execute --inplace 04c_256_products.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘Revision/algebra/gammas.json‘ or for a file in ‘Revision/algebra/reports‘: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run ‘git status‘ in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

      git checkout HEAD Revision/algebra

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 04c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 04c (The 256 products of the author’s gammas: Cl(4,4) is all real 16 by 16
# matrices) is the file Revision/textbook/notebooks/04c_256_products.ipynb of the
# repository Dirac_claude. It forms the 256 ordered products of the author’s eight
# gammas, checks exactly the three rules by which they multiply, their squares and
# symmetry (136 symmetric, 120 antisymmetric), the trace lemma and their orthogonality,
# proves that they are linearly independent (exact rank 256), so that the Clifford
# algebra Cl(4,4) is the set of all real 16 by 16 matrices, writes any matrix as a
# combination of them, shows that the 128 even products fill the two diagonal 8 by 8
# blocks, explains why 16 is the smallest possible size, reproduces the Revision record
# of these facts, checks that half of each product of two different gammas is the matrix
# S of the Revision record, and draws eight figures. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
```

```
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
```

```
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 04c_256_products.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 04c_256_products.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 04c_256_products.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/04c.captions.json
# - Revision/textbook/figures/04c_1_products_by_degree.png
# - Revision/textbook/figures/04c_2_multiplication_table.png
# - Revision/textbook/figures/04c_3_squares_by_degree.png
# - Revision/textbook/figures/04c_4_trace_products.png
# - Revision/textbook/figures/04c_5_coefficients.png
# - Revision/textbook/figures/04c_6_even_odd_blocks.png
# - Revision/textbook/figures/04c_7_how_big.png
```

```
# - Revision/textbook/figures/04c_8_two_gamma_products.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all eight figure files exist
#     ALL 19 CHECKS PASSED (notebook 04c)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/04c_256_products.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 04c_256_products.ipynb
#     python -m nbconvert --execute --inplace 04c_256_products.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
```

```
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for Revision/algebra/gammas.json or for a file in
#   Revision/algebra/reports: the notebook reads these Revision record files of the
#   repository; they are part of every complete clone. Run git status in the repository
#   folder: if it reports them as deleted, restore them with the command below and run
#   the notebook again.
#     git checkout HEAD Revision/algebra
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Set, subset**: a set is a collection of different objects, written in braces,
  for example $A = \{x_2, x_5\}$; a *subset* of a set $S$ is a set whose elements all
  belong to $S$. The empty set $\{\}$ has no element.
- **Binomial coefficient** $\binom{n}{k}$ ("n choose k"): the number of subsets with
  $k$ elements of a set with $n$ elements; $\binom{n}{k} = \frac{n!}{k!(n-k)!}$ with
  $n! = 1 \cdot 2 \cdots n$ and $0! = 1$. For example $\binom{8}{2} = 28$.
- **Product** $\gamma_A$: for a set $A$ of directions, the product of their gamma
  matrices in increasing order, for example
  $\gamma_{\{x_2, x_5\}} = \gamma^{(x_2)}\gamma^{(x_5)}$; for the empty set,
  $\gamma_{\{\}} = I_{16}$. Its **degree** is the number $k$ of factors; the product
  is **even** if $k$ is even and **odd** if $k$ is odd.
- **Symmetric difference** $A \triangle B$: the directions that lie in exactly one of
  the sets $A$ and $B$.
- **Linear combination**: $c_1 M_1 + c_2 M_2 + \dots$ with numbers $c_j$. Matrices
  are **linearly independent** if the only combination that gives the zero matrix
  has all $c_j = 0$. The **span** of a list of matrices is the set of all their
  combinations; a **basis** of a space is an independent list that spans it, and the
  number of its elements is the **dimension** of the space. All real $16 \times 16$
  matrices form a space of dimension $16 \times 16 = 256$ (one number per entry).
- **Rank** of a list of matrices: the largest number of independent matrices in it,
  which is the dimension of its span. sympy computes it exactly with fractions.
```

```
- **Trace** $\mathrm{tr}\,M$: the sum of the diagonal entries. It has the *cyclic
  property* $\mathrm{tr}(MN) = \mathrm{tr}(NM)$, because both are
  $\sum_{i,j} M_{ij}N_{ji}$.
- **Orthogonal matrix**: $M^T M = I$, so $M^{-1} = M^T$.
- **Block diagonal**: a $16 \times 16$ matrix whose upper-right and lower-left
  $8 \times 8$ blocks are zero; **block off-diagonal**: one whose upper-left and
  lower-right blocks are zero.
- **Clifford algebra** Cl(4,4): the set of all real combinations of products of
  eight matrices that satisfy the Clifford relation with four signs $+1$ and four
  signs $-1$.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's gammas satisfy the Clifford relation
$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}I_{16}$ with
$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order of his coordinates
$x_0, \dots, x_7$: space-like hidden direction $x_0$ and 3-space $x_1, x_2, x_3$,
time-like time $x_4$ and extra times $x_5, x_6, x_7$ (the extra times deflate
exponentially in his metric; the gammas, which belong to the local frame, are
constant). Everything below follows from this relation alone; the computer checks
each rule for the author's matrices.

**Rule R1 (products multiply into products).** Two different gammas anticommute and
$\gamma^a\gamma^a = \eta^{aa}I_{16}$. To multiply $\gamma_A\gamma_B$, move each factor
of $\gamma_B$ to the left until it reaches its place in increasing order. Passing a
different gamma gives a factor $-1$; meeting the same gamma gives $\eta^{aa}$. So
$\gamma_A\gamma_B = s(A,B)\,\gamma_{A\triangle B}$ with the sign
$s(A,B) = (-1)^{N(A,B)}\prod_{c \in A\cap B}\eta^{cc}$, where $N(A,B)$ is the number of
pairs $(a, b)$ with $a$ in $A$, $b$ in $B$ and $a$ later than $b$.

**Rule R2 (squares).** By R1 with $B = A$:
$\gamma_A\gamma_A = (-1)^{k(k-1)/2}\prod_{a\in A}\eta^{aa}\,I_{16}$ for a product of
degree $k$ (here $N(A,A) = k(k-1)/2$, the number of pairs in $A$).

**Rule R3 (passing one gamma).** Moving $\gamma^b$ from the left of $\gamma_A$ to its
right passes each of the $k$ factors once: $\gamma^b\gamma_A = (-1)^k\gamma_A\gamma^b$
if $b$ is not in $A$ and $(-1)^{k-1}\gamma_A\gamma^b$ if it is.

**The trace lemma.** For eight gammas (an even number) every $\gamma_A$ with $A$ not
empty has trace 0. Proof, line by line: if $k$ is odd, then $k \le 7$, so some $b$ is
not in $A$, and R3 gives $\gamma^b\gamma_A = -\gamma_A\gamma^b$; if $k$ is even, take
$b$ in $A$, and R3 gives again $\gamma^b\gamma_A = -\gamma_A\gamma^b$. Multiply from
the left by $(\gamma^b)^{-1} = \eta^{bb}\gamma^b$:
$\gamma_A = -(\gamma^b)^{-1}\gamma_A\gamma^b$. Take the trace and use the cyclic
property: $\mathrm{tr}\,\gamma_A = -\mathrm{tr}(\gamma_A\gamma^b(\gamma^b)^{-1})
= -\mathrm{tr}\,\gamma_A$. A number equal to its negative is 0.

**Independence.** Each $\gamma_A$ is a product of orthogonal matrices, hence
orthogonal: $\gamma_A^T = \gamma_A^{-1} = \pm\gamma_A$ (the sign of R2). So
$\gamma_A^T\gamma_B = \pm\gamma_A\gamma_B = \pm\gamma_{A\triangle B}$ (R1), whose trace
is 0 unless $A = B$ (trace lemma), and $\mathrm{tr}(\gamma_A^T\gamma_A) =
```

```
\mathrm{tr}\,I_{16} = 16$. If $\sum_B c_B\gamma_B = 0$, multiply by $\gamma_A^T$ and
take the trace: $16\,c_A = 0$. So all coefficients vanish: the 256 products are
independent. Since the real $16 \times 16$ matrices form a space of dimension
$256$, the products are a basis of it: **Cl(4,4) is all real $16 \times 16$
matrices**, and every matrix $M$ is $\sum_A c_A\gamma_A$ with
$c_A = \mathrm{tr}(\gamma_A^T M)/16$.

**How big.** The same argument works for any even number $n$ of $d \times d$ matrices
with a Clifford relation, real or complex, if $\gamma_A^{-1}$ is used in place of
$\gamma_A^T$: by R2 every product squares to $\pm 1$, so $\gamma_A^{-1} = \pm\gamma_A$,
and $\mathrm{tr}(\gamma_A^{-1}\gamma_B)$ is 0 for $A \neq B$ and $d$ for $A = B$. So
the $2^n$ products are independent and must fit into the space of all $d \times d$
matrices, of dimension $d^2$: $d^2 \ge 2^n$. For $n = 8$: $d \ge 16$. A field on
which eight gammas act therefore has at least 16 components; the author's field
has exactly 16.
```

Text cell:

```
## 5. The 256 products

The next cell reads the gammas from the Revision record file
‘Revision/algebra/gammas.json‘ (eight matrices in the order $x_0, \dots, x_7$, whole
numbers), then forms the 256 products. ‘itertools.combinations(range(8), k)‘ lists the
sets of $k$ directions in increasing order (direction index 0 is $x_0$, ..., 7 is
$x_7$), for $k = 0, 1, \dots, 8$, which is also the order of the Revision verifier.
The products are kept in one numpy array ‘products‘ of shape (256, 16, 16): product
number $i$ is ‘products[i]‘. The cell then counts the products of each degree and
compares with the binomial coefficients $\binom{8}{k}$.
```

In [2]:

```

## 6. Rule R1: the products multiply into products

The next cell multiplies every product with every product (256 times 256 = 65536
multiplications; `products[i] @ products` multiplies product $i$ with all 256 at
once) and checks that each result is $+\gamma_{A\triangle B}$ or
$-\gamma_{A\triangle B}$, with exactly the sign $s(A,B)$ of rule R1. It also checks
that every product is a signed permutation matrix (one entry $\pm 1$ in each row and
column), hence orthogonal.
```

In [4]:

```
def sign_formula(A, B):

## 7. Rule R2: the squares, and which products are symmetric

The next cell checks rule R2 for all 256 products, counts how many square to
$+I_{16}$ and how many to $-I_{16}$, and checks that a product is symmetric exactly
when its square is $+I_{16}$ (and antisymmetric when it is $-I_{16}$). The reason:
$\gamma_A^T = \gamma_A^{-1}$ (orthogonal), and $\gamma_A^{-1} = \pm\gamma_A$ with the
sign of the square. The symmetric $16 \times 16$ matrices form a space of dimension
$16 \cdot 17/2 = 136$ (the free entries on and above the diagonal) and the
antisymmetric ones a space of dimension $16 \cdot 15/2 = 120$; the counts below fill
both spaces exactly.
```

In [6]:

## 8. The trace lemma and the trace products

The next cell checks the trace lemma for the 255 products other than $I_{16}$, and
computes the $256 \times 256$ table of *trace products*
$G_{AB} = \mathrm{tr}(\gamma_A^T\gamma_B)$ (it is called the Gram matrix). The
situation section proved $G = 16\,I_{256}$: every product is perpendicular to every
other one. numpy computes all 65536 entries at once: ‘flat‘ holds each product as one
row of 256 numbers, and $\mathrm{tr}(\gamma_A^T\gamma_B) = \sum_{ij}(\gamma_A)_{ij}
(\gamma_B)_{ij}$ is the product of row $A$ of ‘flat‘ with row $B$, so
‘flat @ flat.T‘ is the whole table. The cell also computes the table without the
transpose, $\mathrm{tr}(\gamma_A\gamma_B)$, which is $16$ times the sign of the
square on the diagonal and 0 elsewhere.
```

In [8]:

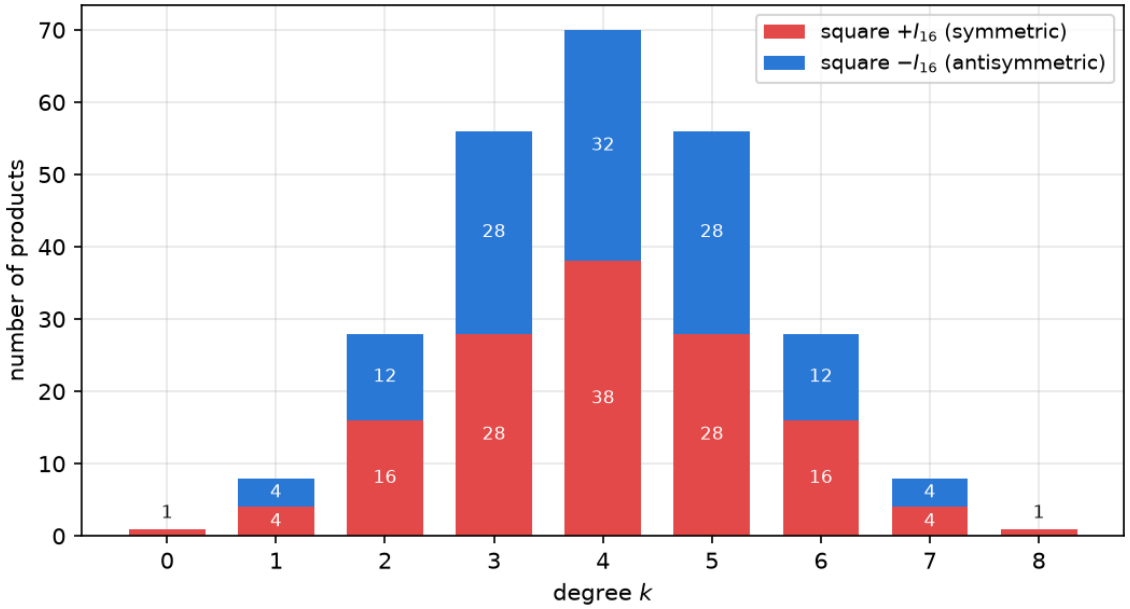

Figure 130: The squares of the 256 products by degree k (horizontal axis): red, the number of products γ_A with $\gamma_A^2 = +I_{16}$, which are exactly the symmetric ones; blue, the number with $\gamma_A^2 = -I_{16}$, the antisymmetric ones. The sign follows rule R2: $(-1)^{k(k-1)/2}$ times the signs η of the directions in A. In total $136 = 16 \cdot 17/2$ symmetric and $120 = 16 \cdot 15/2$ antisymmetric products, exactly the dimensions of the symmetric and antisymmetric 16×16 matrices. (Notebook 04c, figure 3.)

```
traces = np.array([np.trace(m) for m in products])

## 10. Every matrix is a combination of the products

Because the products are a basis, every real $16 \times 16$ matrix $M$ equals
$\sum_A c_A\gamma_A$, and the trace products give the coefficients:
$c_A = \mathrm{tr}(\gamma_A^T M)/16$ (multiply $M = \sum_B c_B\gamma_B$ by
$\gamma_A^T$ and take the trace). The next cell does this for two examples: the
matrix $E_{00}$ with a single 1 in row 0 and column 0, and a matrix of random whole
numbers between $-3$ and $3$ (seed 12345). It computes $16\,c_A$ (whole numbers, so
the arithmetic stays exact), rebuilds $16M = \sum_A (16c_A)\gamma_A$ and checks that
it is exactly $16M$. For $E_{00}$ only 16 coefficients are nonzero, each $\pm 1/16$:
they belong to the 16 products that are diagonal matrices.
```

In [11]:

```
e00 = np.zeros((16, 16), dtype=np.int64)
e00[0, 0] = 1

## 11. Even products fill the diagonal blocks, odd products the others

Every gamma has zero upper-left and lower-right $8 \times 8$ blocks (it is block
off-diagonal). By the block rule a product of two block off-diagonal matrices is
block diagonal, and a product of a block diagonal and a block off-diagonal matrix is
block off-diagonal. So every even product is block diagonal and every odd one block
off-diagonal. The block diagonal real matrices form a space of dimension
$64 + 64 = 128$ and so do the block off-diagonal ones; the 128 even products are
independent (they are part of the 256), so they span all block diagonal matrices
(Mat(8) + Mat(8)), and the odd ones all block off-diagonal matrices. The next cell
checks the block forms and the two exact ranks, reproduces the Revision record, and
counts at every position $(i, j)$ how many even (and odd) products have a nonzero
entry there.
```

## 12. How big must the matrices be?

The next cell compares four examples of matrices with a Clifford relation:

- $n = 2$: the real $2 \times 2$ matrices $\sigma_x$ and $N$ (signs $+1, -1$);
- $n = 4$: Dirac's complex $4 \times 4$ matrices (rebuilt here in three lines);
- $n = 7$: the author's seven $8 \times 8$ matrices tau[1], ..., tau[7], which are the
  lower-left $8 \times 8$ blocks of $\gamma^{(x_1)}, \dots, \gamma^{(x_7)}$ (his
  construction puts tau[k] there);
```

```
- $n = 8$: the author's gammas.

For each it computes the number $2^n$ of products, their exact rank and the
dimension $d^2$ of the space of all $d \times d$ matrices. For the even $n$ the rank
is $2^n = d^2$: the products fill everything, and $d$ is as small as possible. For
the odd $n = 7$ the trace lemma fails: the product of all seven taus is $I_8$, so the
products come in pairs that are equal up to sign, and only $64 = 8^2$ of the 128 are
independent. This is why seven anticommuting matrices fit into $8 \times 8$ matrices
but eight need $16 \times 16$.
```

```
## 13. The 28 products of two different gammas

The products of degree 2, $\gamma^a\gamma^b$ with $a$ before $b$ in the order
$x_0, \dots, x_7$, are $\binom{8}{2} = 28$ matrices. Half of each of them is a matrix
that the Revision record names $S^{ab}$:
$S^{ab} = \tfrac14(\gamma^a\gamma^b - \gamma^b\gamma^a)$. Line by line, for
$a \neq b$: $\gamma^b\gamma^a = -\gamma^a\gamma^b$ (two different gammas
anticommute), so $\gamma^a\gamma^b - \gamma^b\gamma^a = 2\gamma^a\gamma^b$, and
$S^{ab} = \tfrac14 \cdot 2\gamma^a\gamma^b = \tfrac12\gamma^a\gamma^b$. For $a = b$
the two terms cancel and $S^{aa} = 0$. The matrices $S^{ab}$ are the generators of
the rotations and boosts of the 16-component field (the record checks that they
obey the rules of the rotations and boosts of the 4+4 space-time).

By rule R2 with $k = 2$, $(\gamma^a\gamma^b)^2 = -\eta^{aa}\eta^{bb} I_{16}$. Two
directions of the same kind (both space-like or both time-like) have
$\eta^{aa}\eta^{bb} = +1$, so their product squares to $-I_{16}$, like the
imaginary unit $i$ of the complex numbers: there are
$\binom{4}{2} + \binom{4}{2} = 12$ such pairs, the planes of *rotations*. A
space-like and a time-like direction have $\eta^{aa}\eta^{bb} = -1$, so their
product squares to $+I_{16}$: there are $4 \cdot 4 = 16$ such pairs, the planes of
*boosts*.

The next cell checks, exactly: $\tfrac14(\gamma^a\gamma^b - \gamma^b\gamma^a)$ is
$\tfrac12\gamma^a\gamma^b$ for $a \neq b$ and 0 for $a = b$; it compares all
$8 \times 8 = 64$ matrices $S^{ab}$ (16384 entries) with the matrices that the
```

Revision record file ‘Revision/algebra/gammas.json‘ stores under the key S (their
entries are 0 and the fractions $\pm 1/2$, written as texts "1/2" and "-1/2");
and it checks the squares and the 12 + 16 count. All arithmetic is exact: the
fractions are Python ‘Fraction‘ numbers.

```
PASS all eight figure files exist
ALL 19 CHECKS PASSED (notebook 04c)
```

Text cell:

```
## 15. What this notebook showed

- PROVED (exact integer arithmetic, all pairs checked): the 256 ordered products of
  the author’s gammas multiply by rule R1,
  $\gamma_A\gamma_B = s(A,B)\gamma_{A\triangle B}$; they square to $\pm I_{16}$ by
  rule R2; 136 are symmetric (square $+I_{16}$) and 120 antisymmetric (square
  $-I_{16}$); every product other than $I_{16}$ has trace 0, and
  $\mathrm{tr}(\gamma_A^T\gamma_B) = 16\delta_{AB}$.
```

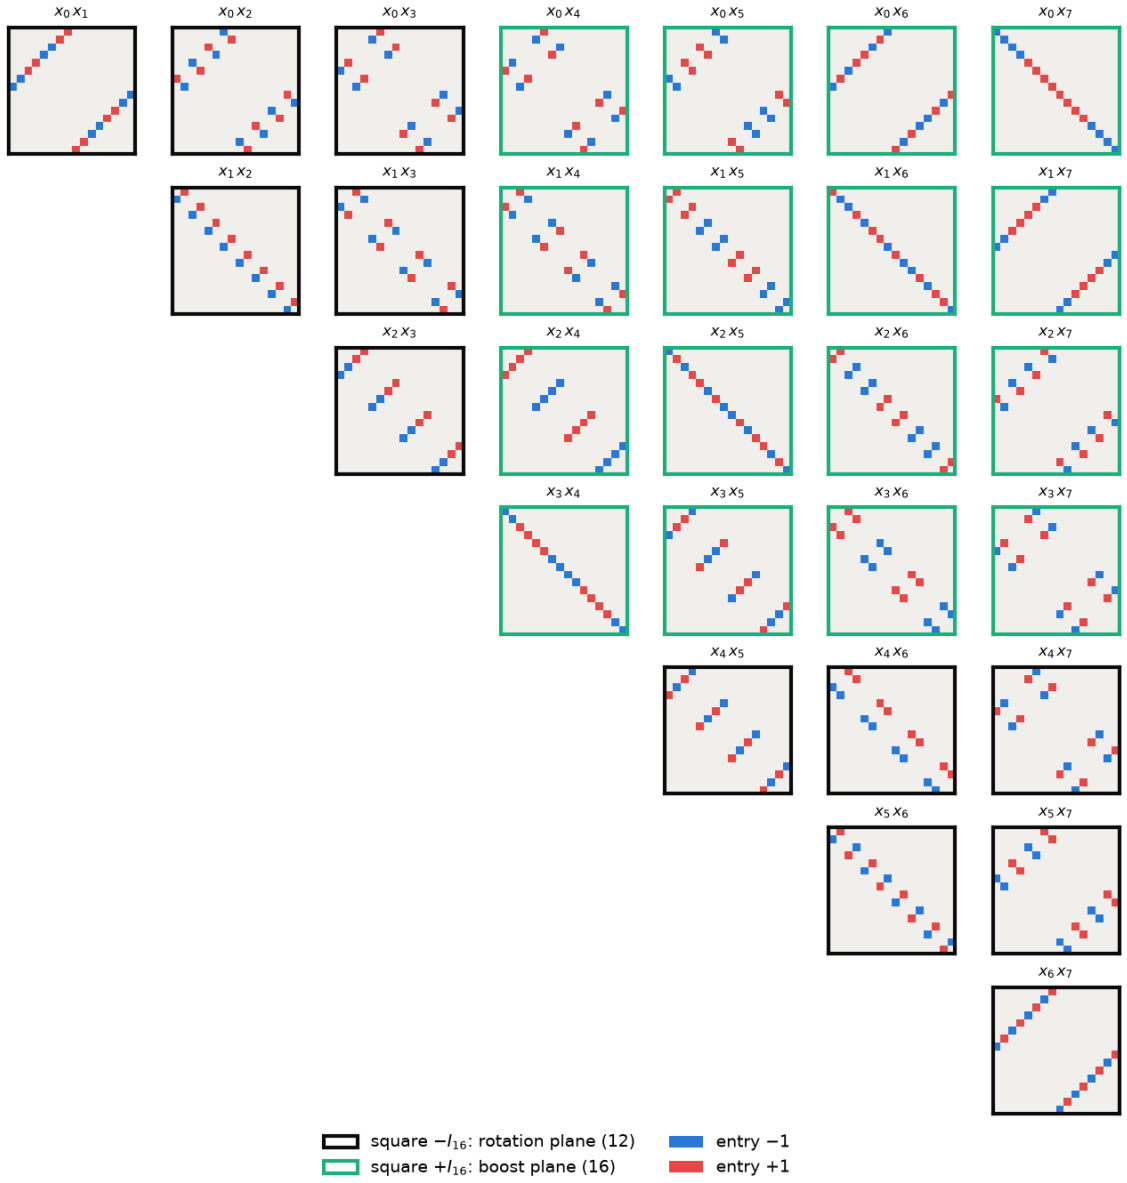

Figure 135: The 28 products $\gamma^a \gamma^b$ of two different gammas of the author, each drawn as a 16×16 heat map (blue -1, grey 0, red $+1$); the panel titled $x_a x_b$ shows $\gamma^a \gamma^b$, with x_a before x_b in the order x_0 to x_7. Every product is block diagonal, with its 16 nonzero entries in the two diagonal 8×8 blocks. Black frames mark the 12 products that square to $-I_{16}$ (two directions of the same kind: rotation planes), green frames the 16 that square to $+I_{16}$ (one space-like and one time-like direction: boost planes). Half of each product is the matrix S^{ab} of the Revision record. (Notebook 04c, figure 8.)

```
- PROVED (exact rank over the rational numbers; reproduces
  ‘Revision/algebra/reports/wolfram-algebra.json‘, check
  ‘Clifford_basis_spans_full_matrix_algebra‘, and ‘python-algebra.json‘, check
  ‘clifford_products_span_M16‘): the 256 products are independent, so the Clifford
  algebra Cl(4,4) of the author’s gammas is the set of all real $16 \times 16$
  matrices, and every matrix is $\sum_A c_A\gamma_A$ with
  $c_A = \mathrm{tr}(\gamma_A^T M)/16$.
- PROVED (reproduces the checks ‘even_subalgebra_dimension‘ and
  ‘even_products_span_M8_plus_M8‘): the 128 even products are block diagonal and
  span all block diagonal matrices (dimension 128); the 128 odd products span the
  block off-diagonal ones.
- PROVED: eight $d \times d$ matrices with a Clifford relation have $d \ge 16$
  ($d^2 \ge 2^8$); the author’s field has exactly 16 components. Seven such
  matrices fit into $8 \times 8$ (the author’s tau matrices, whose product is
  $I_8$; reproduces check ‘tau7_and_product‘).
- PROVED (exact fractions; reproduces ‘python-algebra.json‘, check ‘S_definition‘,
  and ‘wolfram-algebra.json‘, checks ‘S_half_product‘ and
  ‘S_real_entries_in_half_integers‘, and agrees entry by entry with the matrices S
  of ‘Revision/algebra/gammas.json‘): $S^{ab} = \tfrac14(\gamma^a\gamma^b -
  \gamma^b\gamma^a) = \tfrac12\gamma^a\gamma^b$ for $a \neq b$, with entries
  $0, \pm\tfrac12$. The 28 products of two gammas are block diagonal; 12 square to
  $-I_{16}$ (rotation planes) and 16 to $+I_{16}$ (boost planes).
- ASSUMED: nothing beyond the Clifford relation of the author’s gammas, which the
  Revision record verified exactly. These are statements of algebra; they make no
  physical claim.
```

4.16 Line-by-line walk-through of Notebook 04c

The notebook has 19 code cells, In [1] to In [19]. As in Section 4.8, every line is quoted except two things: the set-up cell In [1], which is the set-up cell of Notebook 04a explained line by line in Section 4.8 and differs from it only as said below, and the long caption texts handed to `save_figure`, which are shortened to a line `...)` (the dots stand for the caption, the bracket closes the call); each caption is printed in full under its figure in Section 4.15.

In [1], the set-up cell. It is the set-up cell of Notebook 04a, explained line by line in Section 4.8, except for the line `NOTEBOOK_ID = "04c"` and the run instructions of Section 4.14 in its comment lines. It prints one line.

In [2], the 256 products.

```
import itertools  # all subsets of a given size
from math import comb  # comb(n, k) is the binomial coefficient n choose k

import numpy as np
import sympy as sp
from matplotlib.colors import BoundaryNorm, ListedColormap
from sympy.polys.matrices import DomainMatrix  # exact matrices for the rank
```

`comb(n, k)` computes $\binom{n}{k}$. `DomainMatrix` is sympy’s fast matrix type for exact linear algebra with whole numbers and fractions, used for the ranks in In [10], In [13] and In [15]. The other imports are as in Notebook 04a.

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
eta = record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1] in the order x0..x7
gamma = [np.array(matrix, dtype=np.int64) for matrix in record["gamma"]]
I16 = np.eye(16, dtype=np.int64)
```

The author's eight gammas and their signs are read from the Revision record file `gammas.json` (Notebook 04a showed that they are exactly the matrices built from his formulas), as whole-number arrays.

```
SETS = [s for k in range(9) for s in itertools.combinations(range(8), k)]
INDEX = {s: i for i, s in enumerate(SETS)}  # set -> its number in the list
```

`itertools.combinations(range(8), k)` lists the sets of k directions as tuples of increasing numbers (0 stands for x_0, ..., 7 for x_7); the list comprehension collects them for $k = 0, 1, \ldots, 8$, so `SETS` holds the 256 sets ordered by degree, starting with the empty tuple `()`. `INDEX` gives the number of each set in this list.

```
products = np.zeros((256, 16, 16), dtype=np.int64)
for i, s in enumerate(SETS):
    matrix = I16
    for a in s:  # multiply the gammas of the set in increasing order
        matrix = matrix @ gamma[a]
    products[i] = matrix
DEGREE = np.array([len(s) for s in SETS])  # the number of factors of each product
```

`products` is one array of shape (256, 16, 16): product number i is `products[i]`, a 16×16 matrix. For each set the gammas are multiplied in increasing order, starting from I_{16} (so the empty set gives I_{16}). `DEGREE` holds the degree of every product.

```
def label(s):
    """A short name of a set: its coordinate numbers, e.g. (1, 4) -> "14"."""
    return "".join(str(a) for a in s) if s else "I"
```

`label` writes a short name of a set: the coordinate numbers glued together, for example the set $\{x_1, x_4\}$, stored as `(1, 4)`, becomes `"14"`; the empty set (which Python reads as false) becomes `"I"`.

```
counts = [int(np.sum(DEGREE == k)) for k in range(9)]
report("number of products of degree 0, 1, ..., 8", counts)
report("even and odd products", (sum(counts[0::2]), sum(counts[1::2])))
check(counts == [comb(8, k) for k in range(9)] and sum(counts) == 256
      and sum(counts[0::2]) == 128,
      "the products by degree are 1, 8, 28, 56, 70, 56, 28, 8, 1 (128 even)")
```

`np.sum(DEGREE == k)` counts the products of degree k (True counts as 1). `counts[0::2]` takes every second entry starting with the first (the even degrees), `counts[1::2]` the others. The RESULT

lines show $1, 8, 28, 56, 70, 56, 28, 8, 1$ and $(128, 128)$, and the check compares them with the binomial coefficients.

In [3], figure 1.

```
fig, ax = plt.subplots(figsize=(7.0, 3.8), layout="constrained")
ax.set_axisbelow(True)  # grid lines behind the bars
colours = ["#2a78d6" if k % 2 == 0 else "#eb6834" for k in range(9)]
bars = ax.bar(range(9), counts, color=colours, width=0.7)
ax.bar_label(bars, labels=[str(n) for n in counts], padding=2, fontsize=9)
ax.set_xticks(range(9))
ax.set_xlabel("degree $k$ (number of gamma factors)")
ax.set_ylabel("number of products")
ax.set_ylim(0, 80)
ax.legend(handles=[bars[0], bars[1]], labels=["even degree (128 in all)",
                                              "odd degree (128 in all)"], fontsize=9)
save_figure(fig, "products_by_degree",
            ...)
```

A bar chart: `ax.bar` draws one bar per degree, blue for even and orange for odd degrees; `ax.bar_label` writes each count above its bar; the vertical axis runs from 0 to 80; the legend uses the first two bars (degree 0, blue, and degree 1, orange) as samples of the two colours. **What figure 1 shows and why:** the counts rise from 1 to 70 at degree 4 and fall back to 1, symmetric about the middle because choosing k directions is the same as leaving out $8 - k$; the blue bars add up to 128, the orange ones to 128.

In [4], rule R1 for all pairs.

```
def sign_formula(A, B):
    """s(A, B) of rule R1: (-1)^N(A, B) times the signs eta of the common directions."""
    later_pairs = sum(1 for a in A for b in B if a > b)  # N(A, B)
    sign = (-1) ** later_pairs
    for c in set(A) & set(B):  # & : the directions in both sets
        sign *= eta[c]
    return sign
```

`sign_formula` computes the sign $s(A, B)$ of rule R1: `later_pairs` counts the pairs with a in A, b in B and a later than b; the sign starts as (-1) to that power and is multiplied (`*=`) by η^{cc} for every common direction (`set(A) & set(B)` is the set of the directions in both).

```
rule_r1 = True
SIGN = np.zeros((256, 256), dtype=np.int64)  # SIGN[i, j] = s(A_i, A_j)
for i, A in enumerate(SETS):
    row = products[i] @ products  # gamma_A times each of the 256 products
    for j, B in enumerate(SETS):
        target = products[INDEX[tuple(sorted(set(A) ^ set(B)))]]  # ^ : symmetric diff.
        SIGN[i, j] = sign_formula(A, B)
        rule_r1 &= bool((row[j] == SIGN[i, j] * target).all())
```

For every product γ_A, `products[i] @ products` multiplies it with all 256 products at once (numpy applies `@` to each of the 256 matrices in turn). For every B, `set(A) ^ set(B)` is the symmetric

difference; `sorted` puts it in increasing order and `tuple` makes it a key of `INDEX`, which finds the product $\gamma_{A \triangle B}$. `rule_r1` stays true only if every one of the 65536 products equals $s(A,B)\,\gamma_{A \triangle B}$.

```
report("pairs with sign +1 and with sign -1",
       (int(np.sum(SIGN == 1)), int(np.sum(SIGN == -1))))
check(rule_r1, "gamma_A gamma_B = s(A,B) gamma_(A sym. diff. B) for all 65536 pairs")
```

The RESULT line counts the pairs with sign $+1$ and -1: $(33024, 32512)$. These two numbers depend on the order in which the directions are numbered, because γ_A is the product in increasing order and $N(A,B)$ counts pairs in that order: with the hidden direction numbered last instead of first, the same rule gives $(33280, 32256)$. The rule itself holds in every numbering, and the check confirms it for all pairs.

```
signed_permutations = all(
    (np.count_nonzero(m, axis=0) == 1).all() and (np.count_nonzero(m, axis=1) == 1).all()
    and set(np.unique(m)) <= {-1, 0, 1} for m in products[1:])  # <= : subset
check(signed_permutations and all((m.T @ m == I16).all() for m in products),
      "every product is a signed permutation matrix, hence orthogonal")
```

For the products after I_{16} (`products[1:]` skips the first; I_{16} obviously qualifies), every column and every row must have exactly one nonzero entry, and the different values (`np.unique`) must form a subset of $\{-1, 0, 1\}$ (`<=` tests "is a subset of" for sets). The check also confirms $\gamma_A^T \gamma_A = I_{16}$ for all 256.

In [5], figure 2.

```
four = [s for s in SETS if set(s) <= {1, 2, 3, 4}]  # the 16 sets inside x1..x4
table = np.array([[SIGN[INDEX[A], INDEX[B]] for B in four] for A in four])
fig, ax = plt.subplots(figsize=(7.4, 7.0), layout="constrained")
ax.imshow(table, cmap=ListedColormap(["#2a78d6", "#e34948"]),
          norm=BoundaryNorm([-2, 0, 2], 2))
```

`four` keeps the 16 sets made only of x_1, x_2, x_3, x_4 (direction numbers 1 to 4; `set(s) <= {1, 2, 3, 4}` tests "is a subset of"). `table` is the 16×16 table of their signs $s(A,B)$, painted with two colours: blue for -1, red for $+1$.

```
for r, A in enumerate(four):
    for c_, B in enumerate(four):
        name = label(tuple(sorted(set(A) ^ set(B))))
        ax.text(c_, r, ("+" if table[r, c_] > 0 else "-") + name, ha="center",
                va="center", color="white", fontsize=7)
names = [label(s) for s in four]
ax.set_xticks(range(16), names, fontsize=8)
ax.set_yticks(range(16), names, fontsize=8)
ax.set_xlabel("second factor $\\gamma_B$ (coordinate numbers of $B$)")
ax.set_ylabel("first factor $\\gamma_A$")
ax.grid(False)
save_figure(fig, "multiplication_table",
            ...)
```

Every square gets the sign and the name of $A \triangle B$, so that it reads, for example, -14 for $\gamma_A \gamma_B = -\gamma^{(x_1)}\gamma^{(x_4)}$; rows and columns are labelled with the names of the 16 sets. **What figure 2 shows and why:** every product of two of these 16 matrices is again one of them, up to sign (rule R1): they form the Clifford algebra of four directions, the algebra of Dirac's matrices. The diagonal holds the squares, +I or −I as rule R2 predicts (for example the square of $\gamma^{(x_4)}$ is −I, because x_4 is time-like).

In [6], rule R2, and the symmetric products.

```
rule_r2 = True
square_sign = np.zeros(256, dtype=np.int64)
for i, s in enumerate(SETS):
    k = len(s)
    predicted = (-1) ** (k * (k - 1) // 2)  # // : division without remainder
    for a in s:
        predicted *= eta[a]
    square_sign[i] = predicted
    rule_r2 &= bool((products[i] @ products[i] == predicted * I16).all())
```

For every product the sign of rule R2, $(-1)^{k(k-1)/2} \prod_{a \in A} \eta^{aa}$, is computed and stored in `square_sign`, and `rule_r2` stays true only if every square equals that sign times I_{16}.

```
symmetric = np.array([(m.T == m).all() for m in products])
antisymmetric = np.array([(m.T == -m).all() for m in products])
plus, minus = int(np.sum(square_sign == 1)), int(np.sum(square_sign == -1))
report("products with square +I16 and with square -I16", (plus, minus))
check(rule_r2, "gamma_A^2 = (-1)^(k(k-1)/2) prod(eta) I16 for all 256 products")
check(plus == 136 == 16 * 17 // 2 and minus == 120 == 16 * 15 // 2
      and (symmetric == (square_sign == 1)).all()
      and (antisymmetric == (square_sign == -1)).all(),
      "136 products are symmetric (square +I16), 120 antisymmetric (square -I16)")
```

Two True/False arrays record which products are symmetric and which antisymmetric; `plus` and `minus` count the squares $+I_{16}$ and $-I_{16}$: $(136, 120)$. The first check confirms R2; the second confirms the counts (Python allows the chain `plus == 136 == 16 * 17 // 2`, meaning both equalities) and that a product is symmetric exactly when its square is $+I_{16}$.

In [7], figure 3.

```
plus_by_degree = [int(np.sum((DEGREE == k) & (square_sign == 1))) for k in range(9)]
minus_by_degree = [int(np.sum((DEGREE == k) & (square_sign == -1))) for k in range(9)]
fig, ax = plt.subplots(figsize=(7.0, 3.8), layout="constrained")
ax.set_axisbelow(True)  # grid lines behind the bars
low = ax.bar(range(9), plus_by_degree, color="#e34948", width=0.7,
             label="square $+I_{16}$ (symmetric)")
high = ax.bar(range(9), minus_by_degree, bottom=plus_by_degree, color="#2a78d6",
              width=0.7, label="square $-I_{16}$ (antisymmetric)")
```

For each degree the products with square $+I_{16}$ and with square $-I_{16}$ are counted (`&` combines two True/False arrays entry by entry). The red bars show the first counts; the blue bars are stacked on top of them (`bottom=`).

```
# numbers inside the bars that are tall enough, above the two bars of height 1
ax.bar_label(low, labels=[str(n) if n > 2 else "" for n in plus_by_degree],
             label_type="center", color="white", fontsize=8)
ax.bar_label(high, labels=[str(n) if n else "" for n in minus_by_degree],
             label_type="center", color="white", fontsize=8)
for k in (0, 8):
    ax.text(k, plus_by_degree[k] + 1.5, str(plus_by_degree[k]), ha="center",
            fontsize=8, color="#0b0b0b")
ax.set_xticks(range(9))
ax.set_xlabel("degree $k$")
ax.set_ylabel("number of products")
ax.legend(fontsize=9)
save_figure(fig, "squares_by_degree",
            ...)
```

The counts are written into the middle of the bars that are tall enough; for degrees 0 and 8, whose bars have height 1, the number is written above the bar instead. **What figure 3 shows and why:** the red counts per degree are $1, 4, 16, 28, 38, 28, 16, 4, 1$ and the blue ones $0, 4, 12, 28, 32, 28, 12, 4, 0$; for example among the 28 products of degree 2, the 16 boost planes square to $+I_{16}$ and the 12 rotation planes to $-I_{16}$ (Section 4.13). The totals are 136 and 120, the dimensions of the symmetric and of the antisymmetric matrices.

In [8], the trace lemma and the Gram matrix.

```
traces = np.array([np.trace(m) for m in products])
check(traces[0] == 16 and (traces[1:] == 0).all(),
      "trace lemma: tr gamma_A = 0 for all 255 products other than I16")
```

The trace of every product: 16 for I_{16} and 0 for the 255 others, as the trace lemma says.

```
flat = products.reshape(256, 256)  # each product as one row of 256 entries
gram = flat @ flat.T  # gram[A, B] = tr(gamma_A^T gamma_B), exact whole numbers
# tr(gamma_A gamma_B) = sum_ij (gamma_A)_ij (gamma_B^T)_ij: the same with the
# transposed products in the second factor.
flat_transposed = products.transpose(0, 2, 1).reshape(256, 256)
without_transpose = flat @ flat_transposed.T
```

`reshape(256, 256)` writes each 16×16 product as one row of 256 numbers (row by row). Because $\mathrm{tr}(X^T Y) = \sum_{i,j} X_{ij} Y_{ij}$ (the definitions of trace, product and transpose), the trace product of two products is the product of their two rows, and `flat @ flat.T` computes all 256×256 of them at once: the Gram matrix. `products.transpose(0, 2, 1)` transposes every product (it exchanges the last two indices), and the same trick gives the table of $\mathrm{tr}(\gamma_A \gamma_B)$.

```
check((gram == 16 * np.eye(256, dtype=np.int64)).all(),
      "tr(gamma_A^T gamma_B) = 16 for A = B and 0 otherwise (all 65536 pairs)")
check((without_transpose == 16 * np.diag(square_sign)).all(),
      "tr(gamma_A gamma_B) = 16 times the sign of the square for A = B, else 0")
```

The Gram matrix is $16 I_{256}$, as Section 4.13 proved; and $\mathrm{tr}(\gamma_A \gamma_B)$ is 16 times the sign of the square of γ_A for $A = B$ and 0 otherwise.

In [9], figure 4.

```
starts = [int(np.argmax(DEGREE == k)) for k in range(9)]  # first product of degree k
three = ListedColormap(["#2a78d6", "#f0efec", "#e34948"])  # -1, 0, +1
three_norm = BoundaryNorm([-1.5, -0.5, 0.5, 1.5], 3)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 4.8), layout="constrained")
```

`np.argmax` of a True/False array gives the position of the first True: `starts[k]` is the number of the first product of degree k (0, 1, 9, 37, ...). The three colours and boundaries of the sign heat maps, and a figure with two panels.

```
left.imshow(gram // 16, cmap=three, norm=three_norm, interpolation="nearest")
left.set_xticks(range(0, 256, 64))
left.set_yticks(range(0, 256, 64))
left.set_xlabel("number of the product $\\gamma_B$")
left.set_ylabel("number of the product $\\gamma_A$")
left.set_title("$\\mathrm{tr}(\\gamma_A^T\\gamma_B)/16$, all 256 products")
left.grid(False)
```

The left panel paints the Gram matrix divided by 16 (`interpolation="nearest"` draws every entry as a sharp square).

```
corner = starts[3]  # 37: the products of degree 0, 1 and 2
right.imshow(without_transpose[:corner, :corner] // 16, cmap=three, norm=three_norm)
names = [label(s) for s in SETS[:corner]]
right.set_xticks(range(corner), names, fontsize=5, rotation=90)
right.set_yticks(range(corner), names, fontsize=5)
right.set_title("$\\mathrm{tr}(\\gamma_A\\gamma_B)/16$, degrees 0, 1, 2")
right.grid(False)
save_figure(fig, "trace_products",
            ...)
```

The right panel magnifies the corner of the table $\mathrm{tr}(\gamma_A\gamma_B)/16$ for the first 37 products ($1+8+28$, degrees 0, 1 and 2), labelled with their names (the column labels turned by 90 degrees). **What figure 4 shows and why:** on the left a single red diagonal line on grey: every product is perpendicular to every other, which is why they are independent. On the right the diagonal is red for I and for $\gamma^{(x_0)}, \gamma^{(x_1)}, \gamma^{(x_2)}, \gamma^{(x_3)}$ (squares $+I_{16}$), blue for $\gamma^{(x_4)}, \ldots, \gamma^{(x_7)}$ (squares $-I_{16}$), and for the products of two gammas red for the 16 boost planes and blue for the 12 rotation planes, $-\eta^{aa}\eta^{bb}$ by rule R2.

In [10], the exact rank.

```
WOLFRAM = "Revision/algebra/reports/wolfram-algebra.json"
PYTHON = "Revision/algebra/reports/python-algebra.json"
RECORDED = {}
for report_file in (WOLFRAM, PYTHON):
    text = repository_file(report_file).read_text(encoding="utf-8")
    RECORDED[report_file] = {e["name"]: e for e in json.loads(text)["checks"]}
```

The two algebra reports of the Revision record are read, as in Notebook 04a.

```
def recorded(report_file, name):
    """The detail text of a Revision check; it must be recorded as passed."""
    entry = RECORDED[report_file][name]
    if entry["verdict"].upper() != "PASS":
        raise AssertionError(f"{report_file}: {name} is not recorded as passed")
    return entry["detail"]
```

`recorded` returns the detail text of a Revision check after making sure that it is recorded as passed.

```
def exact_rank(rows):
    """The exact rank of a list of rows of whole numbers (fractions, over QQ)."""
    matrix = DomainMatrix([[sp.ZZ(int(x)) for x in row] for row in rows],
                          (len(rows), len(rows[0])), sp.ZZ)
    return matrix.convert_to(sp.QQ).rank()
```

The **rank** of a list of rows is the largest number of independent rows among them. `exact_rank` builds a `DomainMatrix` of whole numbers (`sp.ZZ`, with its numbers of rows and columns), converts it to the rational numbers `sp.QQ` (exact fractions) and computes its rank by exact elimination, without any rounding.

```
rank_all = exact_rank(flat.tolist())
report("exact rank of the 256 products", rank_all)
check(rank_all == 256
      and f"span dimension {rank_all} = 16^2" in recorded(
          WOLFRAM, "Clifford_basis_spans_full_matrix_algebra")
      and f"{rank_all} (sympy DomainMatrix over QQ)" in recorded(
          PYTHON, "clifford_products_span_M16"),
      "the 256 products are independent: Cl(4,4) is all real 16 x 16 matrices")
print(f"     reproduces {WOLFRAM}")
print("         check Clifford_basis_spans_full_matrix_algebra")
print(f"     reproduces {PYTHON}")
print("         check clifford_products_span_M16")
```

The 256 products, as 256 rows of 256 numbers, have the exact rank 256. The check also requires that both Revision checks state this rank in their own words (the texts are built with the computed rank, so they must contain 256). The printed lines name the two records.

In [11], every matrix is a combination of the products.

```
e00 = np.zeros((16, 16), dtype=np.int64)
e00[0, 0] = 1
generator = np.random.default_rng(12345)
random_matrix = generator.integers(-3, 4, size=(16, 16))  # whole numbers -3..3
coefficients = {}
```

Two example matrices: E_{00}, with a single 1 in row 0 and column 0, and a 16×16 matrix of random whole numbers from -3 to 3 (the upper limit 4 of `integers` is not included), from a generator with the fixed seed 12345.

```
for name, matrix in (("E00", e00), ("random", random_matrix)):
    sixteen_c = flat @ matrix.reshape(256)  # 16 c_A = tr(gamma_A^T M) for all A
    rebuilt = np.einsum("a,aij->ij", sixteen_c, products)  # sum_A (16 c_A) gamma_A
    coefficients[name] = sixteen_c / 16.0
    check((rebuilt == 16 * matrix).all(),
          f"the matrix {name} equals sum_A c_A gamma_A with c_A = tr(gamma_A^T M)/16")
```

For each example, `flat @ matrix.reshape(256)` computes the 256 numbers $\mathrm{tr}(\gamma_A^T M) = 16c_A$ (whole numbers, so the arithmetic stays exact). `np.einsum("a,aij->ij", ...)` forms $\sum_A (16c_A)\gamma_A$ (the letter `a`, missing after the arrow, is summed). The check requires that this is exactly $16M$; the coefficients c_A are stored for the figure. Two PASS lines.

```
nonzero = [label(SETS[i]) for i in np.flatnonzero(coefficients["E00"])]
diagonal = [label(s) for i, s in enumerate(SETS)
            if (products[i] == np.diag(np.diag(products[i]))).all()]
say("the nonzero coefficients of E00 belong to: " + ", ".join(nonzero))
check(nonzero == diagonal and len(nonzero) == 16
      and set(np.abs(coefficients["E00"][np.flatnonzero(coefficients["E00"])]))
      == {1 / 16},
      "E00 has 16 coefficients +-1/16, on the 16 diagonal products")
```

`nonzero` names the products with a nonzero coefficient in E_{00}; `diagonal` names the products that are diagonal matrices (a matrix equals the diagonal matrix of its own diagonal exactly when it is diagonal). The printed list is I, 07, 16, 25, 34, 0167, 0257, 0347, 1256, 1346, 2345, 012567, 013467, 023457, 123456, 01234567: exactly the 16 sets made of whole pairs (x_1, x_6), (x_2, x_5), (x_3, x_4), (x_0, x_7), each pair either in or out, a pattern that Section 4.17 explains. The check requires that the two lists agree, that there are 16, and that every nonzero coefficient is $\pm 1/16$. (The reason: $c_A = \mathrm{tr}(\gamma_A^T E_{00})/16 = (\gamma_A)_{00}/16$, which is nonzero only when row 0 of the signed permutation γ_A points to column 0.)

In [12], figure 5.

```
fig, (top, bottom) = plt.subplots(2, 1, figsize=(8.0, 5.6), layout="constrained",
                                  sharex=True)
for ax, name, colour in ((top, "E00", "#2a78d6"), (bottom, "random", "#eb6834")):
    ax.bar(range(256), coefficients[name], color=colour, width=0.8)
    ax.axhline(0.0, color="#898781", linewidth=0.8)
    ax.set_ylabel("coefficient $c_A$")
    for start in starts[1:]:
        ax.axvline(start - 0.5, color="#c3c2b7", linewidth=0.6, linestyle=":")
top.set_title("$E_{00}$ (a single 1 in row 0, column 0)")
bottom.set_title("a matrix of random whole numbers from $-3$ to $3$")
bottom.set_xlabel("number of the product $\\gamma_A$ (dotted lines: degree changes)")
save_figure(fig, "coefficients",
            ...)
```

Two panels one above the other, sharing the horizontal axis (`sharex=True`): one bar per product with its coefficient, a grey zero line, and dotted lines where the degree changes. **What figure 5 shows and why:** for E_{00} only 16 bars, all of height $\pm 1/16$, at the diagonal products; for the

random matrix nearly every one of the 256 bars is nonzero. Every matrix, however special or random, is a combination of the 256 products.

In [13], even and odd products.

```
even, odd = flat[DEGREE % 2 == 0], flat[DEGREE % 2 == 1]  # rows of 256 numbers
even_blocks = all((m[:8, 8:] == 0).all() and (m[8:, :8] == 0).all()
                  for m in products[DEGREE % 2 == 0])
odd_blocks = all((m[:8, :8] == 0).all() and (m[8:, 8:] == 0).all()
                 for m in products[DEGREE % 2 == 1])
rank_even, rank_odd = exact_rank(even.tolist()), exact_rank(odd.tolist())
report("exact ranks of the even and of the odd products", (rank_even, rank_odd))
```

The masks `DEGREE % 2 == 0` and `== 1` select the even and the odd products. `even_blocks` requires every even product to be block diagonal (zero upper-right and lower-left blocks), `odd_blocks` every odd one to be block off-diagonal. Both exact ranks are 128.

```
check(even_blocks and odd_blocks and rank_even == 128 and rank_odd == 128
      and f"dimension {rank_even} = 2 x 8^2" in recorded(
          WOLFRAM, "even_subalgebra_dimension")
      and f"rank {rank_even} (Fraction), {rank_even} (sympy)" in recorded(
          PYTHON, "even_products_span_M8_plus_M8"),
      "even products block diagonal, odd block off-diagonal, ranks 128 and 128")
print(f"     reproduces {WOLFRAM}")
print("         check even_subalgebra_dimension")
print(f"     reproduces {PYTHON}")
print("         check even_products_span_M8_plus_M8")
```

The check combines the block forms, the two ranks and the statements of the two Revision checks.

```
support_even = np.sum(products[DEGREE % 2 == 0] != 0, axis=0)  # count per entry
support_odd = np.sum(products[DEGREE % 2 == 1] != 0, axis=0)
report("even products nonzero at each position (values found)",
       sorted(set(int(x) for x in support_even.flatten())))
```

For each position (i, j), `support_even` counts how many even products have a nonzero entry there (`axis=0` adds over the 128 products), and `support_odd` the same for the odd ones. The RESULT line shows that the even counts take only the values 0 and 16.

```
upper = np.arange(16) < 8  # True for the rows (and columns) 0 to 7
# in_diagonal_blocks[i, j] is True when row i and column j lie in the same half;
# ~ turns True into False and back.
in_diagonal_blocks = np.equal.outer(upper, upper)
check((support_even[in_diagonal_blocks] == 16).all()
      and (support_even[~in_diagonal_blocks] == 0).all()
      and (support_odd[~in_diagonal_blocks] == 16).all()
      and (support_odd[in_diagonal_blocks] == 0).all(),
      "each position of its blocks is covered by exactly 16 even (or odd) products")
```

`upper` marks the upper half of the rows; `np.equal.outer(upper, upper)` is the 16×16 table that is True where row and column lie in the same half (the two diagonal blocks). The check requires 16 even products at every position of the diagonal blocks and none elsewhere, and the opposite for the odd products.

In [14], figure 6.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(8.4, 4.2), layout="constrained")
cover = ListedColormap(["#f0efec", "#1c5cab"])  # 0 products, 16 products
for ax, values, title in ((left, support_even, "128 even products"),
                          (right, support_odd, "128 odd products")):
    ax.imshow(values, cmap=cover, norm=BoundaryNorm([-1, 8, 17], 2))
    ax.set_xticks(range(0, 16, 4))
    ax.set_yticks(range(0, 16, 4))
    ax.set_title(title)
    ax.set_xlabel("column")
    ax.set_ylabel("row")
    ax.axhline(7.5, color="#0b0b0b", linewidth=1)
    ax.axvline(7.5, color="#0b0b0b", linewidth=1)
    ax.grid(False)
save_figure(fig, "even_odd_blocks",
            ...)
```

Two heat maps of the counts, light grey for 0 and dark blue for 16, with black lines between the blocks. **What figure 6 shows and why:** the even products fill exactly the two diagonal 8×8 blocks, and the odd ones exactly the two others, because every gamma is block off-diagonal (Section 4.13).

In [15], how big must the matrices be?

```
def all_products(generators):
    """The 2^n ordered products of a list of square sympy matrices."""
    size = generators[0].shape[0]
    result = []
    for k in range(len(generators) + 1):
        for s in itertools.combinations(range(len(generators)), k):
            matrix = sp.eye(size)
            for a in s:
                matrix = matrix * generators[a]
            result.append(matrix)
    return result
```

`all_products` forms the 2^n ordered products of a list of n sympy matrices, exactly as In [2] did for the gammas.

```
sigma_x, sigma_y = sp.Matrix([[0, 1], [1, 0]]), sp.Matrix([[0, -sp.I], [sp.I, 0]])
sigma_z, N_matrix = sp.Matrix([[1, 0], [0, -1]]), sp.Matrix([[0, 1], [-1, 0]])
Z2, I2 = sp.zeros(2, 2), sp.eye(2)
dirac = [sp.Matrix(sp.BlockMatrix([[I2, Z2], [Z2, -I2]]))] + [
    sp.Matrix(sp.BlockMatrix([[Z2, s], [-s, Z2]])) for s in (sigma_x, sigma_y, sigma_z)]
taus = [sp.Matrix(gamma[a][8:, :8].tolist()) for a in range(1, 8)]  # tau[1..7]
```

The Pauli matrices, N, and Dirac's four matrices (Section 4.3), rebuilt in three lines. `taus` takes the lower-left 8×8 blocks of $\gamma^{(x_1)}, \ldots, \gamma^{(x_7)}$; by the author's construction these are $\tau_1, \ldots, \tau_7$ (Section 4.5).

```
examples = {"n = 2, real 2 x 2": [sigma_x, N_matrix], "n = 4, Dirac 4 x 4": dirac,
            "n = 7, tau 8 x 8": taus, "n = 8, gammas 16 x 16":
                [sp.Matrix(g.tolist()) for g in gamma]}
rows = []
for name, generators in examples.items():
    prods = all_products(generators)
    d = generators[0].shape[0]
    flat_rows = sp.Matrix([list(m) for m in prods])  # one row per product
    # exact rank; from_Matrix chooses exact numbers (Gaussian integers for Dirac)
    rank = DomainMatrix.from_Matrix(flat_rows).rank()
    rows.append((name, len(prods), rank, d * d))
    print(f"{name:24} products {len(prods):4d}   rank {rank:4d}   d^2 {d * d:4d}")
```

Four examples, each a list of matrices with a Clifford relation: σ_x and N (signs $+1, -1$), Dirac's matrices, the seven τ, and the eight gammas. For each, all 2^n products are formed; `list(m)` lists the entries of a sympy matrix row by row, so `flat_rows` has one row per product; `DomainMatrix.fro m_Matrix` chooses an exact number system (for Dirac's matrices the **Gaussian integers**, whole numbers plus whole multiples of i), and `.rank()` computes the exact rank. One line per example is printed: products 4, 16, 128, 256; ranks 4, 16, 64, 256; d^2 4, 16, 64, 256.

```
tau_product = sp.eye(8)
for t in taus:
    tau_product = tau_product * t
check([r[2] for r in rows] == [4, 16, 64, 256] and [r[1] for r in rows]
      == [4, 16, 128, 256], "ranks 4, 16, 64, 256: products fill d^2 for even n")
check(tau_product == sp.eye(8) and taus[6] == sp.diag(-1, -1, -1, -1, 1, 1, 1, 1)
      and "tau[7] = diag(-I4, I4) and tau[1]...tau[7] = ID8"
      in recorded(PYTHON, "tau7_and_product"),
      "tau[1] tau[2] ... tau[7] = I8 and tau[7] = diag(-I4, I4)")
print(f"     reproduces {PYTHON}")
print("         check tau7_and_product")
```

The product of the seven τ is computed. The first check requires the ranks and the numbers of products of the table; the second that $\tau_1 \cdots \tau_7 = I_8$ and $\tau_7 = \mathrm{diag}(-I_4, I_4)$, the reason why only 64 of the 128 products of the seven τ are independent (Section 4.13).

In [16], figure 7.

```
fig, ax = plt.subplots(figsize=(7.6, 4.0), layout="constrained")
ax.set_axisbelow(True)  # grid lines behind the bars
positions = np.arange(len(rows))
for offset, column, colour, name in ((-0.25, 1, "#2a78d6", "number of products $2^n$"),
                                     (0.0, 2, "#eb6834", "exact rank"),
                                     (0.25, 3, "#1baf7a", "$d^2$ (all matrices)")):
    values = [r[column] for r in rows]
    bars = ax.bar(positions + offset, values, width=0.24, color=colour, label=name)
```

```
    ax.bar_label(bars, labels=[str(v) for v in values], fontsize=8, padding=1)
ax.set_yscale("log", base=2)
ax.set_ylim(1, 1024)
ax.set_xticks(positions, [r[0] for r in rows], fontsize=9)
ax.set_ylabel("count (logarithmic scale)")
ax.legend(fontsize=8, loc="upper left")
save_figure(fig, "how_big",
            ...)
```

For each of the four examples three bars side by side (shifted by -0.25, 0 and $+0.25$): the number of products, the exact rank and d^2, each labelled with its value; the vertical axis is logarithmic with base 2, from 1 to 1024. **What figure 7 shows and why:** for $n = 2$, 4 and 8 the three bars of each group have the same height, $2^n = d^2$: the products fill all $d \times d$ matrices, so no smaller d is possible. For $n = 7$ the first bar (128) is taller than the other two (64): seven matrices fit into 8×8, but eight need 16×16.

In [17], the 28 products of two gammas and the matrices S^{ab}.

```
from fractions import Fraction  # exact fractions such as 1/2

def exact(entry):
    """A number of gammas.json: a JSON integer or a text "p/q", as a Fraction."""
    if isinstance(entry, int):
        return Fraction(entry)
    numerator, denominator = entry.split("/")
    return Fraction(int(numerator), int(denominator))
```

`exact` reads a number of `gammas.json` (a whole number, or a text "p/q") as an exact fraction, as in Notebook 04a.

```
PAIRS_AB = [(a, b) for a in range(8) for b in range(a + 1, 8)]  # the 28 pairs
two = {(a, b): products[INDEX[(a, b)]] for a, b in PAIRS_AB}  # gamma^a gamma^b
half_ok, record_ok, values = True, True, set()
```

`PAIRS_AB` lists the 28 pairs $a < b$, and `two` looks up their products $\gamma^a\gamma^b$ among the 256 products. Three variables start: two truth values and an empty set of the entries found.

```
for a, b in itertools.product(range(8), repeat=2):  # all 64 ordered pairs
    ab, ba = gamma[a] @ gamma[b], gamma[b] @ gamma[a]
    commutator = ab - ba  # 4 S^ab, a whole-number matrix
    if a != b:
        half_ok &= bool((commutator == 2 * ab).all())  # 4 S^ab = 2 gamma^a gamma^b
    else:
        half_ok &= not commutator.any()  # S^aa = 0
```

For all 64 ordered pairs the commutator $\gamma^a\gamma^b - \gamma^b\gamma^a = 4S^{ab}$ is computed with whole numbers. For $a \neq b$ it must equal $2\gamma^a\gamma^b$ (so $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$); for $a = b$ it must vanish (`.any()` is true when some entry is nonzero, `not` reverses it).

```
    stored = record["S"][a][b]  # the record's S^ab: 16 rows of exact numbers
    for i, j in itertools.product(range(16), repeat=2):
        ours = Fraction(int(commutator[i, j]), 4)  # S^ab entry, exact
        values.add(ours)
        record_ok &= exact(stored[i][j]) == ours
```

Still inside the loop: the record file stores S^{ab} under the key `"S"`; every one of its 256 entries is compared with the exact fraction (commutator entry)/4, and the entry is added to the set `values`.

```
report("the different entries of the 64 matrices S^ab",
       [str(v) for v in sorted(values)])
check(half_ok and record_ok and sorted(values) == [Fraction(-1, 2), 0,
                                                   Fraction(1, 2)]
      and "(1/2) gamma^a gamma^b for a != b" in recorded(PYTHON, "S_definition")
      and "S^ab = (1/2) gamma^a gamma^b" in recorded(WOLFRAM, "S_half_product")
      and "{-1/2, 0, 1/2}" in recorded(WOLFRAM, "S_real_entries_in_half_integers"),
      "S^ab = (1/4)(g^a g^b - g^b g^a) = (1/2) g^a g^b = the record's S, entry by entry")
print(f"     reproduces {PYTHON}")
print("         check S_definition")
print(f"     reproduces {WOLFRAM}")
print("         checks S_half_product, S_real_entries_in_half_integers")
```

The RESULT line lists the entries found, $-1/2$, 0 and $1/2$. The check combines: $S^{ab} = \frac{1}{2}\gamma^a\gamma^b$ and $S^{aa} = 0$; all $64 \times 256 = 16384$ entries equal to the record's; the entries are exactly $-\frac{1}{2}, 0, \frac{1}{2}$; and the statements of the three Revision checks.

```
square_of = {pair: int((m @ m)[0, 0]) for pair, m in two.items()}  # +1 or -1
rotations = [pair for pair in PAIRS_AB if square_of[pair] == -1]
boosts = [pair for pair in PAIRS_AB if square_of[pair] == 1]
report("pairs whose product squares to -I16 (rotations), to +I16 (boosts)",
       (len(rotations), len(boosts)))
check(all((m @ m == square_of[(a, b)] * I16).all()
          and square_of[(a, b)] == -eta[a] * eta[b]
          and not m[:8, 8:].any() and not m[8:, :8].any()
          for (a, b), m in two.items())
      and len(rotations) == 12 and len(boosts) == 16,
      "(g^a g^b)^2 = -eta^aa eta^bb I16; 12 rotation, 16 boost planes; block diagonal")
```

For each of the 28 products the sign of its square is read off its upper-left entry; the pairs are sorted into rotation planes (square $-I_{16}$) and boost planes (square $+I_{16}$): $(12, 16)$. The check requires, for every pair, that the square is exactly that sign times I_{16}, that the sign is $-\eta^{aa}\eta^{bb}$, and that the product is block diagonal; and the counts 12 and 16.

In [18], figure 8.

```
from matplotlib.patches import Patch  # coloured squares for the key

FRAME = {-1: "#0b0b0b", 1: "#1baf7a"}  # square -I16: black, square +I16: green
fig, axes = plt.subplots(7, 7, figsize=(8.6, 8.9), layout="constrained")
```

The frame colours: black for a rotation plane, green for a boost plane. The figure has a grid of 7×7 panels.

```
for r, c_ in itertools.product(range(7), repeat=2):
    ax = axes[r, c_]
    a, b = r, c_ + 1  # row: first factor x_a; column: second factor x_b
    if b <= a:
        ax.axis("off")  # no panel below the diagonal of the grid (c_ < r)
        continue
    ax.imshow(two[(a, b)], cmap=three, norm=three_norm)
    ax.set_xticks([])
    ax.set_yticks([])
    for spine in ax.spines.values():  # the frame of the panel
        spine.set_edgecolor(FRAME[square_of[(a, b)]])
        spine.set_linewidth(2.0)
    ax.set_title(f"$x_{a}\\,x_{b}$", fontsize=8)
```

Panel (r, c) shows the product of the directions $a = r$ and $b = c + 1$ (rows x_0 to x_6, columns x_1 to x_7). The panels on the diagonal of the grid ($c = r$, that is $b = a + 1$) show the neighbouring pairs $x_0x_1, x_1x_2, \ldots, x_6x_7$. The panels below the diagonal ($c < r$, that is $b \leq a$) would repeat a pair or pair a direction with itself; they are switched off, and `continue` jumps to the next panel. Each remaining panel shows $\gamma^a\gamma^b$ as a heat map without tick marks; its four border lines (`spines`) get the colour of its plane, two points wide, and its title names the two directions.

```
key = [Patch(facecolor="white", edgecolor=FRAME[-1], linewidth=2,
             label="square $-I_{16}$: rotation plane (12)"),
       Patch(facecolor="white", edgecolor=FRAME[1], linewidth=2,
             label="square $+I_{16}$: boost plane (16)"),
       Patch(facecolor="#2a78d6", label="entry $-1$"),
       Patch(facecolor="#e34948", label="entry $+1$")]
fig.legend(handles=key, loc="outside lower center", ncol=2, fontsize=9,
           frameon=False)
save_figure(fig, "two_gamma_products",
            ...)
```

The key below the figure explains the two frame colours and the two entry colours. **What figure 8 shows and why:** a triangle of 28 small heat maps, the products of two of the author's real gammas, each block diagonal with 16 nonzero entries (two of every four quadrants are empty), because each is an even product. The black frames sit where both directions are of the same kind (among x_0, x_1, x_2, x_3, or among $x_4, \ldots, x_7$), the green ones where one is space-like and one time-like. Four panels are diagonal matrices: x_0x_7, x_1x_6, x_2x_5 and x_3x_4 (Section 4.17 explains why exactly these). Half of each product is the matrix S^{ab} of the Revision record.

In [19], the last check.

```
names = ["04c_1_products_by_degree.png", "04c_2_multiplication_table.png",
         "04c_3_squares_by_degree.png", "04c_4_trace_products.png",
         "04c_5_coefficients.png", "04c_6_even_odd_blocks.png", "04c_7_how_big.png",
         "04c_8_two_gamma_products.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in names),
```

```
     "all eight figure files exist")
all_checks_passed()
```

The eight figure files must exist; the last line reads ALL 19 CHECKS PASSED (notebook 04c): one check in each of In [2], In [10] and In [19]; two in each of In [4], In [6], In [13], In [15] and In [17]; and three in each of In [8] and In [11].

4.17 A second set of gammas and the one change of basis

The author's gammas are one solution of the Clifford relation. Are they special? This section builds a second set of eight real 16×16 gammas from three 2×2 matrices, with a recipe that needs nothing from the author's notebook, and proves that the two sets differ only by a renumbering of the sixteen components and some signs. It also proves that this renumbering is the only change of basis between them, and that only the multiples of I_{16} commute with all eight gammas.

Three 2×2 matrices.

$$P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad N = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad G = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

(P and G are the σ_x and σ_z of Section 4.3). They are real; P and G are symmetric and N is antisymmetric; $P^2 = G^2 = I_2$ and $N^2 = -I_2$; and any two of them anticommute: $PN = -G = -NP$, $PG = -N = -GP$, $NG = -P = -GN$. Each of these is one 2×2 multiplication; for example $PG = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = -N$ and $GP = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = N$.

The Kronecker product. For a 2×2 matrix A and an $m \times m$ matrix B, the **Kronecker product** (or tensor product) $A \otimes B$ is the $2m \times 2m$ matrix of four blocks whose block in position (i, j) is $A_{ij}B$; in indices, $(A \otimes B)_{im+k,\ jm+l} = A_{ij}B_{kl}$. For example

$$P \otimes G = \begin{pmatrix} 0 \cdot G & 1 \cdot G \\ 1 \cdot G & 0 \cdot G \end{pmatrix} = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}.$$

The **mixed-product rule** $(A \otimes B)(C \otimes D) = (AC) \otimes (BD)$ holds. Proof, line by line, for the entry in row $im + k$ and column $jm + l$:

1. $\big((A \otimes B)(C \otimes D)\big)_{im+k,\,jm+l} = \sum_{r,s} (A \otimes B)_{im+k,\,rm+s}\,(C \otimes D)_{rm+s,\,jm+l}$ — the product rule, summing over all columns $rm + s$ of the first factor.
2. $= \sum_{r,s} A_{ir}B_{ks}C_{rj}D_{sl}$ — the index formula, twice.
3. $= \big(\sum_r A_{ir}C_{rj}\big)\big(\sum_s B_{ks}D_{sl}\big)$ — the double sum of products splits into a product of two sums.
4. $= (AC)_{ij}(BD)_{kl} = \big((AC) \otimes (BD)\big)_{im+k,\,jm+l}$ — the product rule and the index formula.

In the same way $(A \otimes B)^T = A^T \otimes B^T$ (exchange i with j and k with l in the index formula). A product of four 2×2 matrices, $M_1 \otimes M_2 \otimes M_3 \otimes M_4$, is a 16×16 matrix; M_1 stands in **slot** 1, ..., M_4 in slot 4, and products are computed slot by slot. The 16 components are numbered $j = 8b_1 + 4b_2 + 2b_3 + b_4$ by four binary digits (**bits**) $b_1, \ldots, b_4$, each 0 or 1, one per slot; for example $j = 5$ has the bits 0101.

The recipe. For a slot k and $M = P$ or N, put G into the slots before k, M into slot k and I_2 into the slots after k. Every space-like direction gets a P, every time-like direction an N, and each slot is shared by one space-like and one time-like direction. With the pairs (x_1, x_6) in slot 1, (x_2, x_5) in slot 2, (x_3, x_4) in slot 3 and (x_0, x_7) in slot 4 (why exactly these pairs is explained below):

direction	**slot 1**	**slot 2**	**slot 3**	**slot 4**
$\hat{\gamma}^{(x_1)}$	P	I_2	I_2	I_2
$\hat{\gamma}^{(x_6)}$	N	I_2	I_2	I_2
$\hat{\gamma}^{(x_2)}$	G	P	I_2	I_2
$\hat{\gamma}^{(x_5)}$	G	N	I_2	I_2
$\hat{\gamma}^{(x_3)}$	G	G	P	I_2
$\hat{\gamma}^{(x_4)}$	G	G	N	I_2
$\hat{\gamma}^{(x_0)}$	G	G	G	P
$\hat{\gamma}^{(x_7)}$	G	G	G	N

for example $\hat{\gamma}^{(x_5)} = G \otimes N \otimes I_2 \otimes I_2$ (read "gamma hat").

The recipe satisfies the Clifford relation. By the mixed-product rule every product is computed slot by slot.

1. Squares: every slot is squared; $G^2 = I_2^2 = P^2 = I_2$ and $N^2 = -I_2$, so a matrix with P squares to $+I_{16}$ (space-like) and one with N to $-I_{16}$ (time-like).

2. The two matrices of the same slot k: their two products agree in every slot except slot k, which holds PN in one order and $NP = -PN$ in the other; so they anticommute.

3. Two matrices of different slots $k < l$: compare the two orders slot by slot. Before k both have G ($GG = GG$); in slot k the first has P or N and the second G, which anticommute (one factor -1); between k and l the first has I_2 and the second G, which commute; in slot l the first has I_2, which commutes with everything; after l both have I_2. Exactly one factor -1: they anticommute.

Each $\hat{\gamma}$ is a signed permutation matrix (a Kronecker product of signed permutation matrices is one: each row combines one row of each factor and so holds one nonzero product), and it has the author's symmetry pattern $(\hat{\gamma}^{(x_a)})^T = \eta_{aa}\hat{\gamma}^{(x_a)}$, because P, G and I_2 are symmetric, N is antisymmetric and the transpose works slot by slot. By Section 4.13 its 256 products are a basis of all real 16×16 matrices.

The product of all eight, in both sets. The product of the two matrices of slot k is, slot by slot, $GG = I_2$ before k, $PN = -G$ in slot k and I_2 after k: minus the matrix with G in slot k and I_2 elsewhere. The product of all eight hat gammas in the author's order, $\hat{\Gamma} = \hat{\gamma}^{(x_0)}\hat{\gamma}^{(x_1)}\hat{\gamma}^{(x_2)} \ldots \hat{\gamma}^{(x_7)}$, can be reordered into the pairs $(x_1, x_6), (x_2, x_5), (x_3, x_4), (x_0, x_7)$; each exchange of two neighbouring (anticommuting) factors gives a factor -1 and changes the number of inversions by one, so the

reordering multiplies the product by the permutation sign of the reordering, which is $+1$ (Notebook 04d counts the 12 inversions). The four pair products then give $(-1)^4\, G\otimes G\otimes G\otimes G = G\otimes G\otimes G\otimes G$. Since $G = \mathrm{diag}(+1,-1)$, its diagonal entry in row j is $(-1)^{b_1+b_2+b_3+b_4}$: -1 in the eight rows $1,2,4,7,8,11,13,14$, whose bits contain an odd number of ones. The author's product is $\mathrm{diag}(-I_8, I_8)$ (Section 4.5). Both have eight entries of each sign, in different rows.

The change of basis, line by line. Let γ_A and $\hat\gamma_A$ be the products of the two sets for the 256 sets A (Section 4.13). For any 16×16 matrix M define

$$S = \sum_A \gamma_A\, M\, \hat\gamma_A^T.$$

1. Fix a direction b. By R1, $\gamma^{(b)}\gamma_A = \epsilon\,\gamma_{A'}$ with $A' = A\triangle\{b\}$ (b added to A, or removed if it was in A) and a sign $\epsilon = \pm 1$ that depends only on b, A and η. The hat gammas obey the same Clifford relation, so $\hat\gamma^{(b)}\hat\gamma_A = \epsilon\,\hat\gamma_{A'}$ with the SAME sign.
2. Both sets are signed permutation matrices, hence orthogonal: $(\hat\gamma^{(b)})^{-1} = (\hat\gamma^{(b)})^T$. From line 1, $\hat\gamma_A = \epsilon\,(\hat\gamma^{(b)})^T\hat\gamma_{A'}$, and transposing (Section 4.2), $\hat\gamma_A^T = \epsilon\,\hat\gamma_{A'}^T\hat\gamma^{(b)}$.
3. Therefore $\gamma^{(b)}S = \sum_A \epsilon\,\gamma_{A'}\, M\,\epsilon\,\hat\gamma_{A'}^T\hat\gamma^{(b)} = \big(\sum_A \gamma_{A'} M\hat\gamma_{A'}^T\big)\hat\gamma^{(b)}$ — lines 1 and 2 inserted, and $\epsilon^2 = 1$.
4. As A runs through all 256 sets, $A' = A\triangle\{b\}$ runs through all 256 sets too, each exactly once (doing it twice gives A back). So the sum is S again: $\gamma^{(b)}S = S\hat\gamma^{(b)}$ for every b.

A matrix X with $\gamma^{(b)}X = X\hat\gamma^{(b)}$ for every b is called an **intertwiner**; S is one, for every M.

S is orthogonal up to a factor. Transposing $\gamma^{(b)}S = S\hat\gamma^{(b)}$ gives $S^T(\gamma^{(b)})^T = (\hat\gamma^{(b)})^T S^T$; both sets have the same symmetry pattern, so after dividing by $\eta_{bb} = \pm 1$: $S^T\gamma^{(b)} = \hat\gamma^{(b)}S^T$. Then $(S^TS)\hat\gamma^{(b)} = S^T\gamma^{(b)}S = \hat\gamma^{(b)}(S^TS)$: the matrix S^TS commutes with all eight hat gammas.

Only multiples of the identity commute with all gammas. Suppose X commutes with every $\hat\gamma^{(b)}$. Then it commutes with every product $\hat\gamma_A$ and with every combination of them, that is (Section 4.13) with every real 16×16 matrix, in particular with E_{ij}, the matrix with a single 1 in row i and column j. The entry in row k, column j of XE_{ij} is X_{ki}; that of $E_{ij}X$ is X_{jj} if $k = i$ and 0 otherwise. So $X_{ki} = 0$ for $k \neq i$, and $X_{ii} = X_{jj}$: $X = c\,I_{16}$. The same holds for the author's gammas. Applied to S^TS: $S^TS = c\,I_{16}$, with $c > 0$ when $S \neq 0$ (the diagonal entries of S^TS are sums of squares of the columns of S). Then $Q = S/\sqrt{c}$ satisfies $Q^TQ = I_{16}$ and

$$\gamma^{(x_a)} = Q\,\hat\gamma^{(x_a)}\,Q^T \qquad \text{for all eight directions.}$$

Unique up to a factor. If X is any intertwiner, then $Q\hat\gamma^{(b)}Q^TX = X\hat\gamma^{(b)}$; multiplying from the left by Q^T gives $\hat\gamma^{(b)}(Q^TX) = (Q^TX)\hat\gamma^{(b)}$, so Q^TX commutes with every hat gamma, $Q^TX = cI_{16}$, and $X = cQ$.

What Notebook 04d finds. With $M = E_{08}$ (the first choice that gives a nonzero S), $S = 16\,Q$ with a **signed permutation matrix** Q ($c = 256$). Its codes, rows 0 to 15, are $+8,+4,+2,-14,-7,+11,-13,-1,-9,-5,-3,+15,-6,+10,-12,-0$; the code $+8$ in row 0 means that $(Q\chi)_0 = +\chi_8$: component 0 of the author's basis is component 8 of the tensor basis. **The**

author's T16 are the tensor-product gammas with the sixteen components renumbered and some of their signs flipped. The first eight rows pick the eight tensor components with an odd number of ones in their bits, where $\hat{\Gamma} = -1$, which is why the author's product of all eight gammas is $\mathrm{diag}(-I_8, I_8)$. Status: PROVED (exact integer arithmetic; Notebook 04d checks $\gamma_A = Q\hat{\gamma}_A Q^T$ for all 256 products).

What it means for the field equation. In flat 4+4 space write $\Psi = Q\chi$. Then $\gamma^{(x_a)}\partial_a\Psi = Q\hat{\gamma}^{(x_a)}Q^TQ\,\partial_a\chi = Q\,\hat{\gamma}^{(x_a)}\partial_a\chi$, so $\sum_a \gamma^{(x_a)}\partial_a\Psi = m\Psi$ becomes $Q(\sum_a \hat{\gamma}^{(x_a)}\partial_a\chi - m\chi) = 0$, and, since Q is invertible, $\sum_a \hat{\gamma}^{(x_a)}\partial_a\chi = m\chi$: the same equation in the other basis. The same argument applies to every equation of the book that is written with products of the gammas and numbers, because all 256 products transform with Q (Notebook 04d checks them all). The choice between the two sets is a choice of how to number the sixteen components, not a choice of physics.

Why these pairs of directions. A signed permutation Q turns a diagonal matrix D into a diagonal matrix QDQ^T (it only renumbers the diagonal entries and multiplies each by $(\pm1)^2 = 1$). So if $\gamma_A = Q\hat{\gamma}_A Q^T$ with a signed permutation Q, then γ_A is diagonal exactly when $\hat{\gamma}_A$ is: both sets must have their diagonal products for the same sets A. The author's 16 diagonal products belong to the sets made of whole pairs (x_1, x_6), (x_2, x_5), (x_3, x_4), (x_0, x_7) (Notebook 04c, In [11]); the diagonal products of the hat set belong to the sets made of whole slot pairs (the pair product of a slot is $-G$ in that slot, a diagonal matrix). So the slot pairs must be the author's pairs. With other pairs, for example $(x_1, x_4), (x_2, x_5), (x_3, x_6), (x_0, x_7)$, the Clifford relation still holds and a change of basis still exists (the argument above did not use the pairs), but it cannot be a signed permutation: Notebook 04d finds Q_2 with two entries $\pm1/\sqrt{2}$ in every row, which mixes the components two by two.

How strongly the equations reject every other matrix. The equations $\gamma^{(x_a)}X - X\hat{\gamma}^{(x_a)} = 0$ for the eight directions $x_a = x_0, \ldots, x_7$ are $8 \times 256 = 2048$ linear equations for the 256 entries of X. Write A for this system as a 2048×256 matrix, so that the sum of the squares of all 2048 left-hand sides is v^TKv with $K = A^TA$, where v lists the entries of X. K has the exact eigenvectors $X_B = Q\hat{\gamma}_B$ for the 256 sets B. Line by line:

1. Write $L_a(X) = \gamma^{(a)}X - X\hat{\gamma}^{(a)}$ for the left-hand side of equation block a; A is the stack of the eight blocks L_a, and $K = \sum_a L_a^T L_a$ (the product of a stack with its transpose adds up the products of the blocks).

2. The transpose of the block L_a is the map $Y \to (\gamma^{(a)})^TY - Y(\hat{\gamma}^{(a)})^T$ (the rows of the system become its columns). Both sets have $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$ and $(\hat{\gamma}^{(a)})^T = \eta_{aa}\hat{\gamma}^{(a)}$, so $L_a^T = \eta_{aa}L_a$ and $K = \sum_a \eta_{aa}L_aL_a$.

3. $L_a(X_B) = Q\hat{\gamma}^{(a)}Q^TQ\hat{\gamma}_B - Q\hat{\gamma}_B\hat{\gamma}^{(a)} = Q(\hat{\gamma}^{(a)}\hat{\gamma}_B - \hat{\gamma}_B\hat{\gamma}^{(a)})$ — insert $\gamma^{(a)} = Q\hat{\gamma}^{(a)}Q^T$ and $Q^TQ = I_{16}$. By R3 this is 0 when $\hat{\gamma}^{(a)}$ commutes with $\hat{\gamma}_B$, and $2Q\hat{\gamma}^{(a)}\hat{\gamma}_B$ when it anticommutes.

4. In the anticommuting case apply L_a once more: $L_a(2Q\hat{\gamma}^{(a)}\hat{\gamma}_B) = 2Q(\hat{\gamma}^{(a)}\hat{\gamma}^{(a)}\hat{\gamma}_B - \hat{\gamma}^{(a)}\hat{\gamma}_B\hat{\gamma}^{(a)}) = 2Q(\eta_{aa}\hat{\gamma}_B + \eta_{aa}\hat{\gamma}_B) = 4\eta_{aa}X_B$ — the square is η_{aa}, and $\hat{\gamma}_B\hat{\gamma}^{(a)} = -\hat{\gamma}^{(a)}\hat{\gamma}_B$. Multiplied by the η_{aa} of line 2 it gives $4X_B$, because $\eta_{aa}^2 = 1$.

5. Adding over a: $KX_B = 4n_BX_B$, where n_B is the number of directions whose gamma anticommutes with $\hat{\gamma}_B$; by R3 these are the k directions in B for an even degree k, and the $8 - k$ directions outside B for an odd k.

So the eigenvalues of K are $0, 4, 8, \ldots, 32$, with the multiplicities $\binom{8}{0}, \binom{8}{1}, \ldots, \binom{8}{8}$, and the eigenvalue 0, which means "solves all 2048 equations", belongs only to $B = \{\}$, that is to $X = Q$. Because the

256 eigenvectors X_B are perpendicular to each other (Section 4.13), every matrix X is a combination of them, and the part of X perpendicular to Q raises the sum of the squared equations by at least 4 times its squared size (the sum of the squares of its entries).

Status. PROVED (exact integer arithmetic and exact ranks in Notebook 04d): the hat gammas satisfy the Clifford relation with the author's η and symmetry pattern; their 256 products have rank 256; $\gamma_A = Q\hat{\gamma}_A Q^T$ for all 256 products with the signed permutation Q; the intertwiners form a space of dimension 1 (the system has the exact rank 255); and only the multiples of I_{16} commute with all eight of the author's gammas, which reproduces `Revision/algebra/reports/python-algebra.json`, check `pin_commutant_dimension_1`, and `Revision/algebra/reports/wolfram-algebra.json`, check `Pin44_irreducible_commutant_dim_1`. Chapter 5 explains what this last statement means for the group Pin(4,4): the sixteen components cannot be split into smaller pieces that the reflections and rotations of the 4+4 space-time keep apart.

The next three sections hold Notebook 04d.

4.18 How to run Notebook 04d

Step 1. What this notebook does and what it needs.

Notebook 04d (A second set of gammas from tensor products, and the change of basis to the author's T16) is the file `Revision/textbook/notebooks/04d_tensor_gammas.ipynb` of the repository Dirac_claude. It builds a second set of eight real 16 by 16 gamma matrices for the author's 4+4 directions from three 2 by 2 matrices with Kronecker (tensor) products, checks exactly that they satisfy the same Clifford relation, and constructs the change of basis that turns them into the author's gammas: a signed permutation matrix Q with gamma = Q times the tensor gamma times the transpose of Q for all eight directions. It proves exactly that this change of basis is unique up to a factor (the solution space has dimension 1; the commutant of the author's gammas has dimension 1, as the Revision record found), shows what changes when the 2 by 2 blocks are distributed differently, and draws six figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
```

```
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04d_tensor_gammas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04d_tensor_gammas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 04d_tensor_gammas.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/04d.captions.json`
- `Revision/textbook/figures/04d_1_slot_pattern.png`
- `Revision/textbook/figures/04d_2_tensor_gammas.png`
- `Revision/textbook/figures/04d_3_chirality_diagonals.png`
- `Revision/textbook/figures/04d_4_change_of_basis.png`
- `Revision/textbook/figures/04d_5_penalty_spectrum.png`
- `Revision/textbook/figures/04d_6_two_assignments.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 18 CHECKS PASSED (notebook 04d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/04d_tensor_gammas.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 04d_tensor_gammas.ipynb
python -m nbconvert --execute --inplace 04d_tensor_gammas.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `Revision/algebra/gammas.json` or for a file in `Revision/algebra/reports`: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run `git status` in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

```
git checkout HEAD Revision/algebra
```

4.19 Notebook 04d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/04d_tensor_gammas.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The author's eight gamma matrices are ONE solution of the Clifford relation
$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I_{16}$ with
$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order of his
coordinates $x_0, \dots, x_7$. Are they special? This notebook answers the question
exactly. It

- builds a second set of eight real $16 \times 16$ matrices $\hat\gamma^{(x_a)}$
  ("gamma hat") from three $2 \times 2$ matrices P, N and G with the *Kronecker
  product*, a recipe that needs no notebook of the author at all;
- checks exactly that the new set satisfies the same Clifford relation, has the same
  symmetry pattern, and that its 256 products are independent;
- compares the products of all eight gammas in both sets (the *chirality product*);
- constructs, with one formula, the change of basis that turns the new set into the
  author's: a $16 \times 16$ signed permutation matrix $Q$ with
  $\gamma^{(x_a)} = Q\,\hat\gamma^{(x_a)}\,Q^T$ for all eight directions, so the
  author's matrices are the new ones with the 16 components renumbered and some of
```

```
  their signs flipped;
- proves exactly that this change of basis is unique up to a factor, and reproduces
  the Revision record's result that only multiples of the identity commute with all
  eight of the author's gammas;
- distributes the $2 \times 2$ blocks in another way and shows that a change of
  basis still exists but is no longer a signed permutation, and why;
- draws six figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 04d (A second set of gammas from tensor products, and the change of basis to the
author's T16) is the file `Revision/textbook/notebooks/04d_tensor_gammas.ipynb` of the
repository Dirac_claude. It builds a second set of eight real 16 by 16 gamma matrices for
the author's 4+4 directions from three 2 by 2 matrices with Kronecker (tensor) products,
checks exactly that they satisfy the same Clifford relation, and constructs the change of
basis that turns them into the author's gammas: a signed permutation matrix Q with gamma
= Q times the tensor gamma times the transpose of Q for all eight directions. It proves
exactly that this change of basis is unique up to a factor (the solution space has
dimension 1; the commutant of the author's gammas has dimension 1, as the Revision record
found), shows what changes when the 2 by 2 blocks are distributed differently, and draws
six figures. It needs a computer with Windows 11, macOS or Linux, an internet connection
for the installation, the program Git, and Python 3.12 or newer (the notebooks were built
with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:
```

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 04d_tensor_gammas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,

copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 04d_tensor_gammas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 04d_tensor_gammas.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/04d.captions.json‘
- ‘Revision/textbook/figures/04d_1_slot_pattern.png‘
- ‘Revision/textbook/figures/04d_2_tensor_gammas.png‘
- ‘Revision/textbook/figures/04d_3_chirality_diagonals.png‘
- ‘Revision/textbook/figures/04d_4_change_of_basis.png‘
- ‘Revision/textbook/figures/04d_5_penalty_spectrum.png‘
- ‘Revision/textbook/figures/04d_6_two_assignments.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 18 CHECKS PASSED (notebook 04d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/04d_tensor_gammas.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 04d_tensor_gammas.ipynb
      python -m nbconvert --execute --inplace 04d_tensor_gammas.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘Revision/algebra/gammas.json‘ or for a file in ‘Revision/algebra/reports‘: the notebook reads these Revision record files of the repository; they are part of every complete clone. Run ‘git status‘ in the repository folder: if it reports them as deleted, restore them with the command below and run the notebook again.

      git checkout HEAD Revision/algebra

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a

check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 04d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 04d (A second set of gammas from tensor products, and the change of basis to
# the author's T16) is the file Revision/textbook/notebooks/04d_tensor_gammas.ipynb of
# the repository Dirac_claude. It builds a second set of eight real 16 by 16 gamma
# matrices for the author's 4+4 directions from three 2 by 2 matrices with Kronecker
# (tensor) products, checks exactly that they satisfy the same Clifford relation, and
# constructs the change of basis that turns them into the author's gammas: a signed
# permutation matrix Q with gamma = Q times the tensor gamma times the transpose of Q for
# all eight directions. It proves exactly that this change of basis is unique up to a
# factor (the solution space has dimension 1; the commutant of the author's gammas has
# dimension 1, as the Revision record found), shows what changes when the 2 by 2 blocks
# are distributed differently, and draws six figures. It needs a computer with Windows
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
```

```
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 04d_tensor_gammas.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
```

```
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 04d_tensor_gammas.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 04d_tensor_gammas.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/04d.captions.json
# - Revision/textbook/figures/04d_1_slot_pattern.png
# - Revision/textbook/figures/04d_2_tensor_gammas.png
# - Revision/textbook/figures/04d_3_chirality_diagonals.png
# - Revision/textbook/figures/04d_4_change_of_basis.png
# - Revision/textbook/figures/04d_5_penalty_spectrum.png
# - Revision/textbook/figures/04d_6_two_assignments.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 18 CHECKS PASSED (notebook 04d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/04d_tensor_gammas.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
```

```
