```
## 8. The fundamental lemma, seen with narrow bumps
```

```
Take the parabola, whose $E(t) = -2 - t^2$ is not zero, and a bump of half-width
$w$ centred at $t_0$:

$$\xi(t) = \cos^2\Big(\frac{\pi(t - t_0)}{2w}\Big)\ \text{for}\ |t - t_0| < w,
\qquad \xi(t) = 0\ \text{otherwise}.$$

The ratio $\int E\xi\,dt / \int\xi\,dt$ is an average of $E$ over the bump. As the
bump becomes narrower it tends to $E(t_0)$; so if $\int E\xi\,dt$ were zero for
every bump, $E(t_0)$ would be zero at every $t_0$. For this $E$ the error of the
average is exactly proportional to $w^2$: halving $w$ divides it by 4 (an average
over a symmetric bump removes the linear part of $E$ around $t_0$, and the
quadratic part leaves a term of size $w^2$). The next cell computes the integrals
with the trapezoidal rule on 200001 points (fine enough that its own error does not
matter), for $t_0 = 0.3, 0.5, 0.7$ and $w = 0.2, 0.1, 0.05, 0.025$, checks the
factor 4, and draws Figure 3.
```

```
## 9. The action on a grid

A computer stores a path as its values $q_0, q_1, \dots, q_N$ at the grid times
```

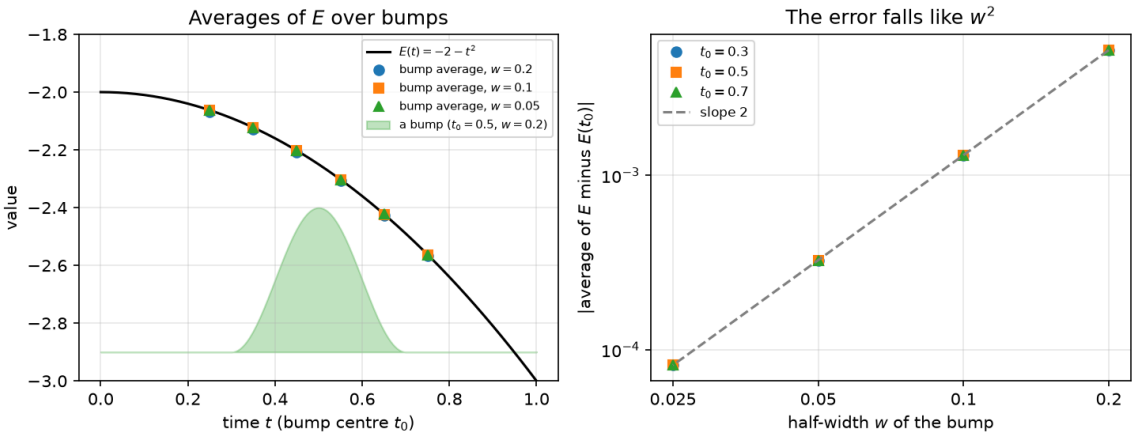

Figure 206: The fundamental lemma made visible, for the parabola path with $E(t) = -2 - t^2$ (black line). Left: the average of E over a bump $\cos^2(\pi(t - t_0)/(2w))$ of half-width w (one bump is shaded green at the bottom), plotted at its centre t_0 for $w = 0.2$, 0.1, 0.05; the averages approach the curve as the bumps narrow. Right: the distance of the average from $E(t_0)$ against w on logarithmic axes for three centres; the points lie on a line of slope 2 (dashed): the error is proportional to w^2. A function whose integral against every bump vanishes must therefore vanish everywhere. (Notebook 07d, figure 3.)

```
$t_n = nh$, $h = T/N$, and replaces the integral by a sum. With the velocity on
each step written as a difference quotient and the potential energy averaged over
the two ends of the step,

$$S_N = \sum_{n=0}^{N-1} h\Big[\frac12\Big(\frac{q_{n+1} - q_n}{h}\Big)^2 -
\frac{\omega^2}{4}\big(q_n^2 + q_{n+1}^2\big)\Big].$$

An inner value $q_n$ ($0 < n < N$) appears in two terms of the sum, the step that
ends at $t_n$ and the step that starts there. Differentiating, line by line:

$$\frac{\partial S_N}{\partial q_n} = h\Big[\frac{q_n - q_{n-1}}{h^2} -
\frac{q_{n+1} - q_n}{h^2} - \frac{\omega^2}{2}q_n - \frac{\omega^2}{2}q_n\Big]
= h\Big[-\frac{q_{n+1} - 2q_n + q_{n-1}}{h^2} - \omega^2q_n\Big].$$

The first equality takes the derivative of the two squares (chain rule: $\frac12
\cdot 2\cdot(q_n - q_{n-1})/h \cdot 1/h$ and $\frac12\cdot 2\cdot(q_{n+1} -
q_n)/h\cdot(-1/h)$) and of the two potential terms; the second collects. The
bracket is $E = -\ddot q - \omega^2q$ with $\ddot q$ replaced by the second
difference quotient. So "the action on the grid is stationary" means "the grid
version of the Euler-Lagrange equation holds at every inner point". The next cell
checks the derivative with sympy for $N = 5$ (symbols $h$, $\omega$, $q_0, \dots,
q_5$).
```

In [8]:

```
N5 = 5
h, w_sym = sp.symbols("h omega", positive=True)

```

Out [8]:

```
PASS dS_N/dq_n = h (-(q_(n+1) - 2 q_n + q_(n-1))/h^2 - omega^2 q_n) for every inner n
```

Text cell:

```
Setting all inner derivatives to zero gives $N - 1$ linear equations for the $N - 1$
inner values (the end values $q_0 = 0$ and $q_N = 1$ are fixed). The next cell
solves them with numpy for $N = 4, 8, \dots, 256$ and measures the largest
difference from the true path $\sin t/\sin 1$ at the grid times. Each doubling of
$N$ should divide the error by about 4: the error is proportional to $h^2$ (order
2), because the second difference quotient differs from $\ddot q$ by a term of
size $h^2$. The cell prints the errors and the observed orders
$\log_2(\text{error}_N/\text{error}_{2N})$, and draws Figure 4.

## 10. Energy is constant on the true path

The energy is $H = \dot q\,\partial L/\partial\dot q - L$; for the oscillator $H =
\dot q^2 - (\frac12\dot q^2 - \frac12\omega^2q^2) = \frac12\dot q^2 +
\frac12\omega^2q^2$, kinetic plus potential energy. Its time derivative, line by
line, for any path:
```

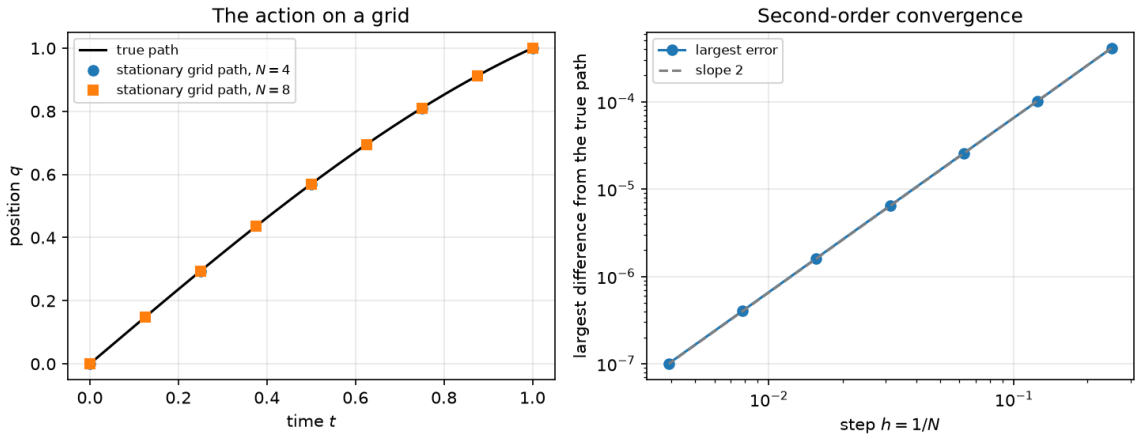

Figure 207: The action on a grid of times. Left: the path that makes the grid action S_N stationary, for $N = 4$ (circles) and $N = 8$ (squares) steps, and the true path $\sin t/\sin 1$ (black line), against the time t (pure numbers); already four steps follow the true path closely. Right: the largest difference between the grid path and the true path against the step $h = 1/N$, for $N = 4$ to 256, on logarithmic axes; the points lie on a line of slope 2 (dashed): halving the step divides the error by 4. (Notebook 07d, figure 4.)

```
$$\frac{dH}{dt} = \ddot q\,\dot q + \omega^2q\,\dot q = \dot q\,(\ddot q +
\omega^2q) = -\dot q\,E .$$

The first equality is the chain rule; the second takes out the common factor
$\dot q$; the third uses $E = -\ddot q - \omega^2q$. So $H$ is constant on every
solution of $E = 0$ and changes on a path where $E \neq 0$ (unless $\dot q = 0$).
The next cell checks the identity for a general path, computes $dH/dt$ on the three
paths and draws Figure 5.
```

## 11. A total derivative changes nothing

Add to $L$ the total derivative of a function $F(q, t)$, here $F = t\,q^3$:

$$L' = L + \frac{d}{dt}F(q(t), t) = L + q^3 + 3t\,q^2\dot q .$$

The action changes by $\int_0^1 \frac{dF}{dt}\,dt = F(q(1), 1) - F(q(0), 0)$, the
same number for every path with the given end values (here $1\cdot 1^3 - 0 = 1$).
A change that is the same for every path cannot change which path is stationary,
so $L'$ has the same Euler-Lagrange equation as $L$. In particular a Lagrangian
that is ONLY a total derivative, such as $\frac{d}{dt}(q^2) = 2q\dot q$, has the
Euler-Lagrange expression $2\dot q - \frac{d}{dt}(2q) = 0$ for every path: it
gives no equation at all. (Notebook 07c meets exactly this in the author's own
Lagrangian for a real anticommuting field.) The next cell checks all three
statements.
```

In [11]:

```
F = t * q**3  # F(q, t)

## 12. First-order Lagrangians

The Lagrangians of the two fields of this book contain the derivatives only to the
first power. Two small examples show what such Lagrangians do.

**Example A: two real variables.** $L_A = \frac12(q_0\dot q_1 - q_1\dot q_0) -
\frac12\omega(q_0^2 + q_1^2)$. For $q_0$: $\partial L_A/\partial q_0 = \frac12\dot
q_1 - \omega q_0$ and $\partial L_A/\partial\dot q_0 = -\frac12 q_1$, whose time
derivative is $-\frac12\dot q_1$; so $E_0 = \frac12\dot q_1 - \omega q_0 + \frac12
\dot q_1 = \dot q_1 - \omega q_0$. In the same way $E_1 = -\dot q_0 - \omega q_1$.
The equations $\dot q_1 = \omega q_0$, $\dot q_0 = -\omega q_1$ are of FIRST order:
the starting values alone fix the motion, $q_0 = \cos\omega t$, $q_1 = \sin\omega t$
for $q_0(0) = 1$, $q_1(0) = 0$, a rotation. The kinetic part is antisymmetric in
$(q_0, q_1)$ but not a total derivative for ordinary numbers; for anticommuting
numbers it would be one (Notebook 07a, section 17).

**Example B: one complex variable.** $\psi = (q_0 + iq_1)/\sqrt2$ and

$$L_B = \frac{i}{2}\big(\psi^*\dot\psi - \dot\psi^*\psi\big) - \omega\,\psi^*\psi .$$

Multiplying out with $\psi^* = (q_0 - iq_1)/\sqrt2$ gives $\psi^*\psi = \frac12(q_0^2
+ q_1^2)$ and $\psi^*\dot\psi - \dot\psi^*\psi = i(q_0\dot q_1 - q_1\dot q_0)$, so
$L_B = \frac12(q_1\dot q_0 - q_0\dot q_1) - \frac12\omega(q_0^2 + q_1^2)$: Example A
with the sense of rotation reversed. The two complex combinations can be varied AS
IF they were independent, because $(q_0, q_1) \to (\psi, \psi^*)$ is an invertible
linear change of variables; the Euler-Lagrange expressions combine in the same way,
$E_{\psi^*} = (E_{q_0} + iE_{q_1})/\sqrt2$. Varying $\psi^*$: $\partial L_B/\partial
\psi^* = \frac{i}{2}\dot\psi - \omega\psi$ and $\partial L_B/\partial\dot\psi^* =
-\frac{i}{2}\psi$, so $E_{\psi^*} = i\dot\psi - \omega\psi$ and $i\dot\psi =
\omega\psi$, with the solution $\psi = e^{-i\omega t}\psi(0)$. The Lagrangian of
the fields of this book has exactly this structure: $\psi$ becomes the column
$\Psi$, $\psi^*$ the row $\bar\Psi = \Psi^\dagger C$, and $\omega$ a matrix of
```

```
derivatives. The next cell checks every statement of the two examples, with
$\omega$ as a symbol.
```

## 13. A field of one space direction and time

A field $\phi(x_1, x_4)$ of a 3-space coordinate $x_1$ and the time $x_4$ has, in
the flat version of the author's signature ($\eta_{11} = +1$, $\eta_{44} = -1$),
the Lagrangian density

$$\mathcal{L} = -\frac12\big(\eta^{11}(\partial_1\phi)^2 + \eta^{44}(\partial_4
\phi)^2\big) - \frac12 m^2\phi^2 = \frac12(\partial_4\phi)^2 - \frac12(\partial_1
\phi)^2 - \frac12 m^2\phi^2,$$

kinetic minus potential energy again, with a gradient energy along $x_1$. The
Euler-Lagrange expression has one derivative term per coordinate, line by line:

$$E = \frac{\partial\mathcal{L}}{\partial\phi} - \partial_1\frac{\partial
\mathcal{L}}{\partial(\partial_1\phi)} - \partial_4\frac{\partial\mathcal{L}}
{\partial(\partial_4\phi)} = -m^2\phi - \partial_1(-\partial_1\phi) -
\partial_4(\partial_4\phi) = \partial_1^2\phi - \partial_4^2\phi - m^2\phi .$$

The first equality is the field version of section 4 (one integration by parts per
coordinate); the second inserts the three partial derivatives of $\mathcal{L}$;
the third simplifies. So $\partial_4^2\phi = \partial_1^2\phi - m^2\phi$, the wave
equation with a mass (the Klein-Gordon equation). A plane wave $\cos(kx_1)\cos(
\omega x_4)$ solves it exactly when $\omega^2 = m^2 + k^2$: it oscillates in time.

The next cell defines `field_euler_lagrange` (the same recipe as `euler_lagrange`,
with one derivative symbol per coordinate), checks the equation and the plane
wave, and checks the grid version: on a grid with steps $h_1$, $h_4$ the field
action is a sum over cells, and its derivative with respect to an inner value
```

```
$\phi_{ij}$ is $h_1h_4$ times the grid Euler-Lagrange expression (second difference
quotients in place of $\partial_1^2$ and $\partial_4^2$). The derivative is computed
numerically by the central difference $(S(\phi_{ij} + \delta) - S(\phi_{ij} -
\delta))/(2\delta)$, which is exact (up to rounding) for an action that is quadratic
in $\phi$, for a field of random values (fixed seed) on a grid of 7 by 6 points.
```

In [14]:

## 14. A field of one EXTRA time and time

Now replace the space coordinate $x_1$ by the extra time $x_5$. The author's
signature makes $x_5$ time-like, $\eta_{55} = -1$, and the same recipe gives

$$\mathcal{L} = \frac12(\partial_4\phi)^2 + \frac12(\partial_5\phi)^2 - \frac12
m^2\phi^2,\qquad E = -\partial_5^2\phi - \partial_4^2\phi - m^2\phi .$$

The only change is the sign of the $x_5$ term. Try $\phi = \cos(kx_5)\,P(x_4)$:
then $\partial_5^2\phi = -k^2\phi$, and $E = 0$ becomes

$$P'' = (k^2 - m^2)\,P .$$

For $k < m$ the solutions oscillate, but for $k > m$ they are $\cosh(\kappa x_4)$
and $\sinh(\kappa x_4)$ with $\kappa = \sqrt{k^2 - m^2}$: they GROW exponentially,
at a rate that becomes as large as we like when $k$ grows. A wave along a space
direction lowers nothing (its $\omega^2 = m^2 + k^2$); a wave along an extra time
lowers $\omega^2 = m^2 - k^2$ below zero.
```

The fields of this book obey a first-order equation; in flat space, multiplying it by the same operator once more gives this second-order equation for every one of the 16 components, because $(\gamma^{(a)}k_a)^2 = (\eta^{ab}k_ak_b)\,I_{16}$ (the Clifford relation). The Revision record finds the same growth rate for the 16-component field. The next cell checks the extra-time field equation and its growing solution, checks the Clifford square with the author's gammas, and reads the growth-rate formula from the Revision scope record and compares it, for a momentum along x_5 only, with $\kappa = \sqrt{k^2 - m^2}$.

## 15. The last check

The last cell checks that the eight figure files exist and prints the number of
checks that passed.
```

In [17]:

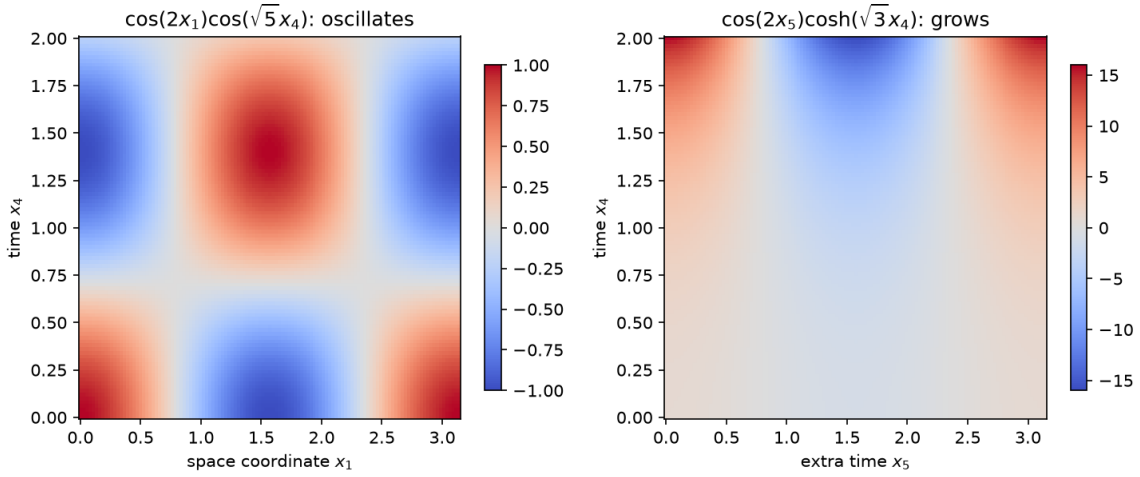

Figure 210: Two exact solutions of the field equation with mass $m = 1$ and wave number $k = 2$, as colour maps over one wavelength of a coordinate (horizontal) and the time x_4 from 0 to 2 (vertical), pure numbers; red positive, blue negative. Left: a wave along the space direction x_1, $\cos(2x_1)\cos(\sqrt{5}x_4)$, which oscillates in time between -1 and 1. Right: a wave along the extra time x_5, $\cos(2x_5)\cosh(\sqrt{3}x_4)$, which grows; its colour scale reaches $\cosh(2\sqrt{3}) \approx 16$. The only difference in the Lagrangian is the sign of the term of the second coordinate. (Notebook 07d, figure 7.)

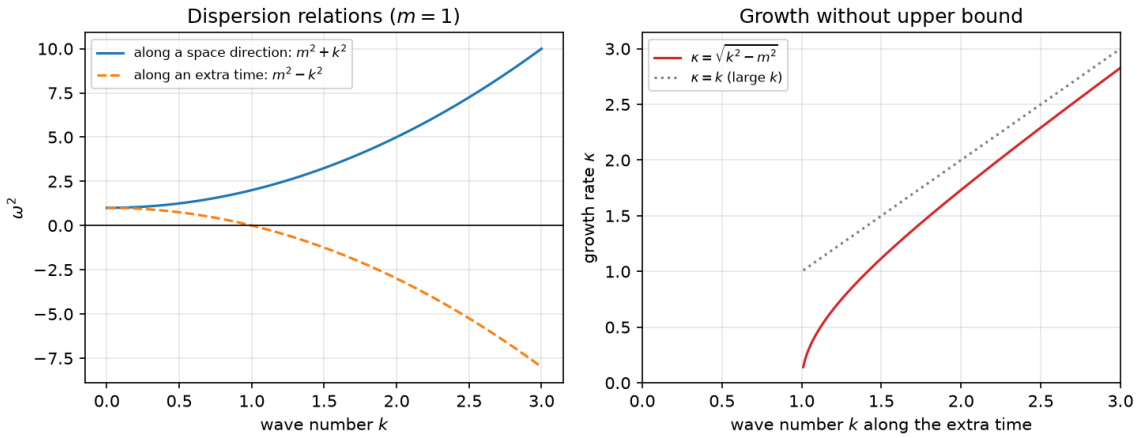

Figure 211: Left: the square ω^2 of the angular frequency of a plane wave against its wave number k (pure numbers, mass $m = 1$), for a wave along a space direction ($m^2 + k^2$, always positive: oscillation) and along an extra time ($m^2 - k^2$, negative for $k > m$). Right: for $k > m$ the wave grows like $e^{\kappa x_4}$ with the rate $\kappa = \sqrt{k^2 - m^2}$ (red), which approaches k (dotted) and has no upper bound; the Revision record finds the same rate for the 16-component field. (Notebook 07d, figure 8.)

## 16. What this notebook showed

- The action $S[q] = \int L\,dt$ of a path changed by $\epsilon\xi$ is, for the
  oscillator, a quadratic polynomial in $\epsilon$; its slope at $\epsilon = 0$ is
  exactly zero for the true path $\sin t/\sin 1$ and not zero for the wrong paths
  $t$ and $t^2$. For short times the true path is a minimum, for times longer than
  $\pi/\omega$ only a saddle: the principle is one of STATIONARY action.
- Integration by parts turns the slope into $\int E\,\xi\,dt$ with the
  Euler-Lagrange expression $E = \partial L/\partial q - \frac{d}{dt}\partial L/
  \partial\dot q$, plus a boundary term that vanishes when $\xi$ vanishes at the
  ends; narrow bumps show that $\int E\xi\,dt = 0$ for all $\xi$ forces $E = 0$.
- On a grid of times the stationary action gives the grid Euler-Lagrange equation,
  and its solution approaches the true path with an error proportional to $h^2$.
- The energy $\frac12\dot q^2 + \frac12\omega^2q^2$ is constant exactly on the
  solutions ($dH/dt = -\dot q\,E$).
- A total derivative added to $L$ changes no equation, and a Lagrangian that is a
  total derivative gives none.
- First-order Lagrangians give first-order equations; a complex variable and its
  conjugate may be varied as if independent, and $\frac{i}{2}(\psi^*\dot\psi -
  \dot\psi^*\psi) - \omega\psi^*\psi$ gives $i\dot\psi = \omega\psi$: the structure
  of the Lagrangians of the fields of this book.
- For fields, one derivative term per coordinate appears; along a space direction
  the field oscillates ($\omega^2 = m^2 + k^2$), along an extra time it grows at the
  rate $\sqrt{k^2 - m^2}$, without upper bound: the same rate as in the Revision
  record for the 16-component field.
```

7.9 Line-by-line walk-through of Notebook 07d

The notebook has 17 code cells, In [1] to In [17]. This section explains every line of every one of them, in order. A line that starts with `#` is a **comment**: Python skips it; it is there for the reader. A text in triple quotes directly below a `def` line is a **docstring**, a description that Python stores but does not run. In the quoted code a line `...)` stands for the remaining lines of a long figure caption; every caption is printed in full under its figure in Section 7.8, and the paragraph "What Figure 07d.k shows" after the code says what to look for.

In [1], the set-up cell. Its first 237 lines are the complete run instructions of Section 7.7 again, as comment lines, so that the notebook file carries its own instructions. The code starts below the line THE SET-UP between two lines of = signs. This part is the same in every notebook of the book except for one line (the notebook's name); we explain it here once, and the walk-throughs of Notebooks 07a, 07b and 07c refer back to this explanation.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json` reads and writes the text format JSON, in which the Revision record stores its results; `os` gives access to the computer's environment; `textwrap` breaks long text into lines; `from pathlib import Path` takes the single name `Path` out of the module `pathlib`. A `Path` is the address of a file or a folder, written the same way on every operating system. The next three lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell.

```
NOTEBOOK_ID = "07d"  # this notebook: chapter 07, example d
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"07d"`. It is the only line of the set-up code that differs between notebooks.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. `Path.cwd()` is the folder in which the notebook runs and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with all of them. The `for` loop takes these folders one after the other; the operator `/` joins a folder and a name into a longer path; `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

`REPO` is the repository folder. `os.environ` holds the **environment variables** of the running program (named texts that the computer hands to it); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and otherwise the default, the repository folder written as a string. When you run the notebook the variable is not set, so the notebook writes into the repository; the book's checking tool sets it to a scratch folder, so that a check run does not change the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` gives the full path of a repository file, for reading. `output_file("Revision/...")` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder that will hold it (and any missing folder above it) and does nothing if it exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters; `textwrap.fill` breaks it at blanks, and every line after the first starts with four blanks. `str(text)` turns any value into a string first.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to matplotlib's built-in settings, so that a personal settings file cannot change the figures. `plt.rcParams.update({...})` then sets, for every figure of the notebook, the size (7.0 by 4.2 inches), the size of the letters (10 points) and a faint grid (30 per cent opaque). The braces make a **dictionary**: pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
```

```
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/07d.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
```

`save_figure` is called after a figure has been drawn. `setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, ..., and a cell that is run twice keeps its numbers. The file name joins the notebook id, the number and the name, for example `07d_1_action_versus_epsilon.png`.

```
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`fig.savefig` writes the PNG file with 150 dots per inch, without an empty margin and without the program's name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory. The caption is stored, and the whole dictionary of captions is written into the captions file (`json.dumps` turns it into JSON text with sorted keys and one blank of indentation). `display(Image(...))` shows the saved picture below the cell; its `metadata` tells the book's tools which file it is. The last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order
```

```
def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection, written with square brackets) that collects the names of the checks that pass. `check(condition, name, record=None)` is the notebook's test: `record=None` makes the third argument optional. If `condition` is false, `raise AssertionError(...)` stops the notebook with a message that names the failed check. An `if` statement is used instead of Python's `assert`, because `python -O` would skip an `assert`. Otherwise the name is appended to `PASSED` and a line `PASS <name>` is printed; when the check reproduces a Revision record, a second line `reproduces <record>` follows.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")
```

`report` prints a key number as a line `RESULT <label> = <value> <unit>`; the expression `(f" {unit}" if unit else "")` adds the unit only when one is given. `all_checks_passed` prints the last line of the notebook with the number of passed checks, `len(PASSED)`.

```
say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

The cell ends by printing one line. Two strings written next to each other inside the parentheses are joined into one by Python. **Out [1]:** `Set-up of notebook 07d complete:  repository folder found, helpers defined.`

In [2]: helpers, and the first variation of nine varied paths.

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)
import re  # regular expressions: read a formula from a check's detail text

import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
```

Three modules of Python: `contextlib` can send printed text somewhere else, `io` provides an in-memory text file, `re` reads patterns in text (**regular expressions**). Then the two packages of the computation: numpy (arrays of numbers, under the short name `np`) and sympy (exact algebra with symbols, `sp`).

```
check_of_the_setup = check  # the helper check of the set-up cell

def check(condition, name, record=None):
    """The set-up cell's check, with its PASS line and its "reproduces" line
    printed by ONE print call, so that Jupyter delivers them together."""
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # collect what check prints
        check_of_the_setup(condition, name, record)
    print(buffer.getvalue(), end="")  # and print it in one piece
```

The first line keeps the set-up cell's `check` under a second name. The new `check` of the same name calls the old one while `contextlib.redirect_stdout(buffer)` sends everything it prints into the in-memory file `buffer`; then it prints the collected text with one single `print` (`end=""` adds no extra line end, because the collected text already ends with one). The reason: Jupyter delivers printed text in pieces, and the book's tools must see a PASS line and the "reproduces" line that may follow it as one piece.

```
def revision_check(report, name):
    """The check called name of a Revision report (a JSON file): its dictionary
    (name, verdict, detail); stops if it is missing or its verdict is not PASS."""
    data = json.loads(repository_file(report).read_text(encoding="utf-8"))
    found = [item for item in data["checks"] if item["name"] == name]
    if len(found) != 1 or found[0]["verdict"].upper() != "PASS":
        raise ValueError(f"{name} is not a passing check of {report}")
    return found[0]

def reproduces(report, name):
    """The text "<report>, check <name>" after making sure the check passes."""
    revision_check(report, name)
    return f"{report}, check {name}"
```

`revision_check(report, name)` reads a Revision report (a JSON file) with `json.loads` and returns the entry of the check called `name` (a dictionary with the keys name, verdict and detail). The square brackets `[item for item in data["checks"] if ...]` form a **list comprehension**: the list of all entries whose name is `name`. If there is not exactly one, or its verdict, written in capitals with `.upper()`, is not PASS, the notebook stops with a `ValueError`. `reproduces(repor t, name)` makes sure that the check passes and returns the text that a PASS line prints after the word reproduces.

```
t, eps = sp.symbols("t epsilon", real=True)  # the time and the size of the change
omega, T_end = sp.Integer(1), sp.Integer(1)  # omega = 1 and the end time T = 1
```

```
def lagrangian(q, q_dot):
    """The oscillator: kinetic energy minus potential energy."""
    return q_dot**2 / 2 - omega**2 * q**2 / 2
```

`sp.symbols("t epsilon", real=True)` makes two sympy symbols, the time t and the size ϵ of the change, both real numbers. `sp.Integer(1)` is the exact number 1; here it is $\omega = 1$ and the end time $T = 1$ (called `T_end`, because the name `T` is used later for a symbol). The function `lagrangian(q, q_dot)` returns $\frac{1}{2}\dot{q}^2 - \frac{1}{2}\omega^2 q^2$; in Python `**` is the power and `/` the division.

```
PATHS = {"true path": sp.sin(t) / sp.sin(1), "line": t, "parabola": t**2}
SHAPES = {n: sp.sin(n * sp.pi * t) for n in (1, 2, 3)}  # xi_n, zero at t = 0, 1
```

`PATHS` is a dictionary from the names of the three paths to their formulas: the true path $\sin t/\sin 1$, the line t and the parabola t^2. `SHAPES` is a **dictionary comprehension**: for $n = 1, 2, 3$ it stores the shape $\xi_n = \sin(n\pi t)$ under the key n; `sp.pi` is the exact number π.

```
def action_polynomial(path, shape):
    """S[path + eps shape] as a polynomial in eps (exact)."""
    varied = path + eps * shape
    integrand = sp.expand(lagrangian(varied, sp.diff(varied, t)))
    return sp.Poly(sp.integrate(integrand, (t, 0, T_end)), eps)
```

`action_polynomial(path, shape)` forms the varied path $q + \epsilon\xi$, differentiates it with `sp.diff(varied, t)`, puts both into the Lagrangian, multiplies out with `sp.expand`, integrates exactly from 0 to T with `sp.integrate(integrand, (t, 0, T_end))` and returns the result as a polynomial in ϵ (`sp.Poly(..., eps)`), the $S_0 + S_1\epsilon + S_2\epsilon^2$ of Section 7.2.

```
S1 = {}  # the first variations, S1[(path name, n)]
S2 = {}  # the coefficients of eps^2
for name, path in PATHS.items():
    for n, shape in SHAPES.items():
        polynomial = action_polynomial(path, shape)
        S1[(name, n)] = sp.simplify(polynomial.coeff_monomial(eps))
        S2[(name, n)] = sp.simplify(polynomial.coeff_monomial(eps**2))
        say(f"{name:9s} n = {n}: S1 = {S1[(name, n)]} = "
            f"{float(S1[(name, n)]):+.6f}")
```

Two empty dictionaries collect the coefficients. The two nested loops go over the three paths and the three shapes (`PATHS.items()` gives the pairs name, formula). For each of the nine combinations the polynomial is computed; `coeff_monomial(eps)` takes the coefficient of ϵ and `coeff_monomial(eps**2)` that of ϵ^2, and `sp.simplify` brings each to its simplest form. The key `(name, n)` is a **tuple**, a fixed pair of values. The `say` line prints the name in a field of 9 characters (`{name:9s}`), the exact coefficient, and its decimal value with sign and six decimals (`{...:+.6f}`; `float` turns the exact number into a decimal one). **Out [2]:** nine lines. For the true path $S_1 = 0$ for all three shapes; for the line $-1/\pi$, $1/(2\pi)$ and $-1/(3\pi)$; for the parabola $-5/\pi + 4/\pi^3 = -1.462543$, $1/(2\pi)$ and $(4 - 45\pi^2)/(27\pi^3)$. The value $-1/\pi = -0.318310$ is the one computed by hand in Section 7.2.

In [3]: the checks of the table.

```
check(all(S1[("true path", n)] == 0 for n in SHAPES),
      "the true path: the first variation is exactly 0 for xi_1, xi_2, xi_3")
check(all(S1[(name, n)] != 0 for name in ("line", "parabola") for n in SHAPES),
      "the line and the parabola: the first variation is not 0")
check(all(S2[(name, n)] == S2[("true path", n)] for name in PATHS for n in SHAPES),
      "the coefficient of eps^2 is the same for every path")
for n in SHAPES:
    coefficient = S2[("true path", n)]  # the same for every path
    report(f"S2 for xi_{n}", f"{coefficient} = {float(coefficient):.6f}")
```

The first check uses `all(...)` over the three shapes: it is true when $S_1 = 0$ exactly for every shape of the true path. The second checks $S_1 \neq 0$ for all six combinations of a wrong path and a shape (a **generator expression** with two `for` parts goes over all of them). The third checks that S_2 is the same for every path, as Section 7.2 proved. The loop prints S_2 for each shape, exactly and to six decimals. **Out [3]:** three PASS lines and `RESULT S2 for xi_1 = -1/4 + pi**2/4 = 2.217401`, and the same for ξ_2 (9.619604) and ξ_3 (21.956610).

In [4]: minimum or saddle, and Figure 07d.1.

```
T = sp.Symbol("T", positive=True)
xi_T = sp.sin(sp.pi * t / T)  # the shape xi_1 on the interval from 0 to T
S2_general = sp.integrate(sp.diff(xi_T, t) ** 2 / 2 - omega**2 * xi_T**2 / 2,
                          (t, 0, T))
say(f"S2(T) = {sp.simplify(S2_general)}")
check(sp.simplify(S2_general - T / 4 * (sp.pi**2 / T**2 - omega**2)) == 0,
      "S2 = (T/4)(pi^2/T^2 - omega^2) for the shape xi_1 on (0, T)")
check(S2_general.subs(T, 1) > 0 and S2_general.subs(T, 4) < 0,
      "S2 > 0 for T = 1 (a minimum), S2 < 0 for T = 4 > pi (a saddle)")
```

`sp.Symbol("T", positive=True)` is the length of the interval as a positive symbol. `xi_T` is the shape $\sin(\pi t/T)$, and `S2_general` the exact integral $\int_0^T (\frac{1}{2}\dot{\xi}^2 - \frac{1}{2}\omega^2\xi^2)\,dt$. The `say` line prints it (sympy writes it as `(-T**2 + pi**2)/(4*T)`, which is $\frac{T}{4}(\frac{\pi^2}{T^2} - 1)$ with $\omega = 1$). The first check compares it with the formula of Section 7.2: the difference simplifies to 0. The second evaluates it with `.subs(T, 1)` and `.subs(T, 4)` and checks the signs: positive at $T = 1$ (minimum), negative at $T = 4 > \pi$ (saddle).

```
epsilons = np.linspace(-0.6, 0.6, 121)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
for name, style in (("true path", "-"), ("line", "--"), ("parabola", ":")):
    polynomial = action_polynomial(PATHS[name], SHAPES[1])
    values = sp.lambdify(eps, polynomial.as_expr() - polynomial.coeff_monomial(1))
    left.plot(epsilons, values(epsilons), style, label=name)
    slope = float(S1[(name, 1)])
    left.plot(epsilons, slope * epsilons, style, color="grey", linewidth=0.8)
left.axvline(0.0, color="black", linewidth=0.8)
left.set_xlabel("size of the change $\\epsilon$")
left.set_ylabel("$S[q + \\epsilon\\xi_1] - S[q]$")
left.set_title("Only the true path has slope 0")
left.legend(fontsize=8)
```

`np.linspace(-0.6, 0.6, 121)` is 121 equally spaced values of ϵ. `plt.subplots(1, 2, figsize=(9.8, 3.9))` makes a figure with one row of two panels, `left` and `right`. For each path with its line style (solid `"-"`, dashed, written as two minus signs, and dotted `":"`), the polynomial with the shape ξ_1 is computed again; `polynomial.as_expr() - polynomial.coeff_monomial(1)` is $S - S_0 = S_1\epsilon + S_2\epsilon^2$; `sp.lambdify(eps, ...)` turns this formula into a numerical function, which `values(epsilons)` evaluates at all 121 values at once. The curve is drawn with its label, and its tangent at $\epsilon = 0$, the straight line $S_1\epsilon$, is drawn thin and grey. `axvline(0.0)` draws a vertical line at $\epsilon = 0$. The axis labels use LaTeX inside `$...$`; in a Python string a backslash is written twice. `legend` draws the key of the line styles.

```
lengths = np.linspace(0.3, 6.0, 300)
S2_values = sp.lambdify(T, S2_general)(lengths)
right.plot(lengths, S2_values)
right.axhline(0.0, color="black", linewidth=0.8)
right.axvline(np.pi, color="red", linestyle="--", label="$T = \\pi/\\omega$")
right.set_ylim(-2.0, 4.0)
right.set_xlabel("length of the time interval $T$")
right.set_ylabel("coefficient $S_2$ of $\\epsilon^2$")
right.set_title("Minimum for $T < \\pi$, saddle for $T > \\pi$")
right.legend(fontsize=8)
fig.tight_layout()
```

The right panel: 300 interval lengths from 0.3 to 6.0, the coefficient $S_2(T)$ evaluated on them, a black line at 0 and a red dashed vertical line at $T = \pi$ (`np.pi`), the place where S_2 changes sign. `set_ylim(-2.0, 4.0)` fixes the vertical range. `fig.tight_layout()` arranges the panels so that nothing overlaps.

```
save_figure(fig, "action_versus_epsilon",
            "Left: the change of the action of the oscillator ($\\omega = 1$, from "
            ...)
```

`save_figure` saves and shows the figure with its caption. **Out [4]:** `S2(T) = (-T**2 + pi**2)/(4*T)`, two PASS lines, the figure and the line `Figure 07d.1 saved as Revision/textbook/figures/07d_1_action_versus_epsilon.png`.

What Figure 07d.1 shows. In the left panel the solid curve of the true path touches its horizontal tangent at $\epsilon = 0$: changing the true path a little changes its action only to second order. The dashed and dotted curves of the line and the parabola cross $\epsilon = 0$ with a slope (their grey tangents are tilted): their action changes to first order, so they are not stationary. All three curves are parabolas of the same shape, shifted, because S_2 is the same for every path. In the right panel S_2 is positive for short intervals and changes sign at $T = \pi$ (red line): beyond it the true path is a saddle, not a minimum.

In [5]: the Euler-Lagrange expression and the integration by parts.

```
from sympy.calculus.euler import euler_equations  # sympy's own Euler-Lagrange
```

This line imports sympy's own function `euler_equations`, used below as an independent comparison.

```
def euler_lagrange(L, functions, variable):
    """The Euler-Lagrange expressions dL/dq - d/dt dL/d(q') of the Lagrangian L
    for each function q of the list functions of the variable."""
    values = [sp.Symbol(f"Q{i}") for i in range(len(functions))]  # stand for q
    speeds = [sp.Symbol(f"V{i}") for i in range(len(functions))]  # stand for q'
    plain = L
    for function, speed in zip(functions, speeds):
        plain = plain.subs(sp.diff(function, variable), speed)  # q' -> V first
    for function, value in zip(functions, values):
        plain = plain.subs(function, value)  # then q -> Q
    back = {**{s: sp.diff(f, variable) for f, s in zip(functions, speeds)},
            **{v: f for f, v in zip(functions, values)}}  # Q -> q, V -> q'
    return [sp.expand(sp.diff(plain, value).subs(back)
                      - sp.diff(sp.diff(plain, speed).subs(back), variable))
            for value, speed in zip(values, speeds)]
```

`euler_lagrange(L, functions, variable)` computes $\partial L/\partial q - \frac{d}{dt}\partial L/\partial \dot{q}$ for each function q in the list `functions`, exactly as Section 7.3 says. A partial derivative with respect to q must hold $\dot{q}$ fixed, but in sympy $q(t)$ and its derivative are tied together. So the function first replaces them by plain symbols: `values` are symbols `Q0`, `Q1`, ... standing for the functions and `speeds` are `V0`, `V1`, ... standing for their derivatives (`range(len(functions))` counts the functions; `zip` walks through two lists side by side). The first loop replaces each derivative $\dot{q}$ by its speed symbol (this must come first, because $\dot{q}$ contains q); the second replaces each q by its value symbol. The dictionary `back` undoes both replacements (the notation `{**a, **b}` merges two dictionaries). The returned list holds, for each function, the derivative of the plain Lagrangian with respect to its value symbol, put back into functions, minus the time derivative of the derivative with respect to its speed symbol, also put back; `sp.expand` multiplies out.

```
q = sp.Function("q")(t)  # a general path
E_general = euler_lagrange(lagrangian(q, sp.diff(q, t)), [q], t)[0]
say(f"E for the oscillator: {E_general}")
sympy_E = euler_equations(lagrangian(q, sp.diff(q, t)), [q], t)[0]
check(sp.simplify(E_general - (sympy_E.lhs - sympy_E.rhs)) == 0
      and sp.simplify(E_general + sp.diff(q, t, 2) + omega**2 * q) == 0,
      "euler_lagrange gives E = -q'' - omega^2 q, as sympy's euler_equations")
```

`sp.Function("q")(t)` is an unknown function $q(t)$, a general path. `E_general` is its Euler-Lagrange expression for the oscillator. `euler_equations` returns sympy's own equation in the form left side = right side (`lhs`, `rhs`); the check requires that the two results agree and that `E_general` equals $-\ddot{q} - \omega^2 q$ (`sp.diff(q, t, 2)` is the second derivative).

```
def E_of(path):
    """E(t) of a given path (insert the path into E_general)."""
    return sp.simplify(E_general.subs(q, path).doit())

for name, path in PATHS.items():
    say(f"{name:9s}: E(t) = {E_of(path)}")
check(E_of(PATHS["true path"]) == 0, "the true path solves E = 0")
```

`E_of(path)` puts a given path into `E_general` (`.subs(q, path)` replaces the unknown function, `.doit()` carries out the derivatives) and simplifies. The loop prints $E(t)$ for the three paths, and the check confirms that the true path gives exactly 0.

```
by_parts = all(sp.simplify(S1[(name, n)]
                           - sp.integrate(E_of(PATHS[name]) * SHAPES[n], (t, 0, 1)))
               == 0 for name in ("line", "parabola") for n in SHAPES)
check(by_parts, "S1 = integral of E xi_n from 0 to 1 for both wrong paths and n = 1, "
      "2, 3")
```

`by_parts` is true when, for both wrong paths and all three shapes, the first variation S_1 of In [2] equals the exact integral $\int_0^1 E\,\xi_n\,dt$: Line 3 of Section 7.3 for shapes that vanish at both ends.

```
boundary_ok = True
xi_open = t  # a shape with xi(0) = 0 but xi(1) = 1
for name in ("line", "parabola"):
    path = PATHS[name]
    first = action_polynomial(path, xi_open).coeff_monomial(eps)  # its S1
    inside = sp.integrate(E_of(path) * xi_open, (t, 0, 1))
    p_xi = sp.diff(path, t) * xi_open  # (dL/dq') xi = q' xi for the oscillator
    boundary = p_xi.subs(t, 1) - p_xi.subs(t, 0)  # [q' xi] from 0 to 1
    say(f"{name}, xi = t: S1 = {sp.simplify(first)}, integral = "
        f"{sp.simplify(inside)}, boundary term = {boundary}")
    boundary_ok = boundary_ok and sp.simplify(first - inside - boundary) == 0
check(boundary_ok, "for xi = t (not zero at t = 1): S1 = integral of E xi + "
      "boundary term q'(1) xi(1)")
```

Now the shape $\xi = t$, which is 1 at $t = 1$. For each wrong path: `first` is its S_1 (the coefficient of ϵ), `inside` is $\int_0^1 E\xi\,dt$, `p_xi` is $\dot{q}\,\xi$ (because $\partial L/\partial\dot{q} = \dot{q}$ for the oscillator), and `boundary` is $[\dot{q}\,\xi]_0^1$, the value at 1 minus the value at 0. The line printed shows the three numbers; `boundary_ok` stays true only if S_1 equals the integral plus the boundary term for both paths. **Out [5]:** `E for th e oscillator:  -q(t) - Derivative(q(t), (t, 2))`, the expressions 0, $-t$ and $-t^2 - 2$ of the three paths, the lines `line, xi = t:  S1 = 2/3, integral = -1/3, boundary term = 1` and `parabola, xi = t:  S1 = 3/4, integral = -5/4, boundary term = 2`, and four PASS lines.

In [6]: Figure 07d.2.

```
times = np.linspace(0.0, 1.0, 201)
styles = {"true path": "-", "line": "--", "parabola": ":"}
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
for name, path in PATHS.items():
    left.plot(times, sp.lambdify(t, path)(times) * np.ones_like(times),
              styles[name], label=name)
    residual = sp.lambdify(t, E_of(path))(times) * np.ones_like(times)
    right.plot(times, residual, styles[name], label=name)
left.set_xlabel("time $t$")
left.set_ylabel("position $q(t)$")
left.set_title("Three paths with $q(0) = 0$, $q(1) = 1$")
left.legend(fontsize=8)
right.axhline(0.0, color="black", linewidth=0.8)
```

```
right.set_xlabel("time $t$")
right.set_ylabel("$E(t) = -\\ddot q - q$")
right.set_title("Euler-Lagrange expression")
right.legend(fontsize=8)
fig.tight_layout()
```

201 times from 0 to 1 and a dictionary of line styles. For each path the left panel draws $q(t)$ and the right panel $E(t)$; `sp.lambdify(t, ...)` makes numerical functions of the formulas. The factor `np.ones_like(times)`, an array of ones of the same length, turns a constant result (the 0 of the true path, which `lambdify` returns as the single number 0) into an array that can be drawn. Labels, titles, a black zero line and the legends follow.

```
save_figure(fig, "paths_and_residuals",
            "Left: three paths of the oscillator with the same end values $q(0) = "
            ...)
```

Out [6]: the figure and its saved file `07d_2_paths_and_residuals.png`. **What Figure 07d.2 shows.** The three paths in the left panel look alike; nothing in their shapes shows which one is the true motion. The right panel tells them apart at once: $E(t)$, the amount by which Newton's law $\ddot q = -q$ fails at time t, is zero at every time only for the true path, $-t$ for the line and $-2 - t^2$ for the parabola.

In [7]: narrow bumps and Figure 07d.3.

```
grid = np.linspace(0.0, 1.0, 200001)  # fine grid for the integrals

def E_parabola(times_):
    return -2.0 - times_**2  # E(t) of the parabola path

def bump(times_, centre, width):
    """cos^2 bump of half-width width around centre, zero outside."""
    inside = np.abs(times_ - centre) < width
    return np.where(inside, np.cos(np.pi * (times_ - centre) / (2 * width)) ** 2, 0.0)
```

`grid` is 200001 equally spaced times from 0 to 1, fine enough that the integrals below are accurate to far more digits than are printed. `E_parabola` is $E(t) = -2 - t^2$ of the parabola path, for an array of times. `bump(times_, centre, width)` is the shape $\cos^2(\pi(t - t_0)/(2w))$ inside $|t - t_0| < w$ and 0 outside: `inside` is an array of true and false values, and `np.where(inside, a, b)` takes `a` where it is true and `b` elsewhere.

```
widths = [0.2, 0.1, 0.05, 0.025]
centres = [0.3, 0.5, 0.7]
errors = {}
for centre in centres:
    errors[centre] = []
    for width in widths:
        weight = bump(grid, centre, width)
```

```
        average = (np.trapezoid(E_parabola(grid) * weight, grid)
                   / np.trapezoid(weight, grid))
        errors[centre].append(average - E_parabola(centre))
    ratios = [errors[centre][i] / errors[centre][i + 1] for i in range(3)]
    say(f"t0 = {centre}: errors " + ", ".join(f"{e:+.3e}" for e in errors[centre])
        + "; ratios " + ", ".join(f"{r:.4f}" for r in ratios))
check(all(abs(errors[c][i] / errors[c][i + 1] - 4.0) < 1e-6
          for c in centres for i in range(3)),
      "the average of E over the bump tends to E(t0); halving w divides the error by 4")
```

Four half-widths and three centres. For each centre and width, `weight` is the bump on the grid and `average` is $\int E\xi\,dt / \int \xi\,dt$; `np.trapezoid(f, grid)` computes an integral with the trapezoidal rule (Chapter 2). The error, the average minus $E(t_0)$, is appended to a list. `ratios` divides each error by the next one (half the width). The `say` line prints the errors in **scientific notation** (`{e:+.3e}` gives three decimals and a power of ten) and the ratios with four decimals; `", ".join(...)` joins the texts with commas. The check requires that every ratio equals 4 within 10^{-6}. **Out [7]:** for each of the three centres the errors -5.228×10^{-3}, -1.307×10^{-3}, -3.267×10^{-4}, -8.168×10^{-5} and the ratios 4.0000, 4.0000, 4.0000, then the PASS line. These are exactly $-0.130691\,w^2$ (Section 7.3), the same for every centre because $E'' = -2$ is the same everywhere.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
left.plot(times, E_parabola(times), color="black", label="$E(t) = -2 - t^2$")
for width, marker in zip(widths[:3], ["o", "s", "^"]):
    points = np.linspace(0.25, 0.75, 6)
    averages = [np.trapezoid(E_parabola(grid) * bump(grid, c, width), grid)
                / np.trapezoid(bump(grid, c, width), grid) for c in points]
    left.plot(points, averages, marker, label=f"bump average, $w = {width}$")
shown = bump(times, 0.5, 0.2)
left.fill_between(times, -2.9, -2.9 + 0.5 * shown, color="tab:green", alpha=0.3,
                  label="a bump ($t_0 = 0.5$, $w = 0.2$)")
left.set_ylim(-3.0, -1.8)
left.set_xlabel("time $t$ (bump centre $t_0$)")
left.set_ylabel("value")
left.set_title("Averages of $E$ over bumps")
left.legend(fontsize=7, loc="upper right")
```

The left panel draws $E(t)$ in black and, for the three larger widths with three marker shapes (`zip(widths[:3], ["o", "s", "^"])` pairs each width with circles, squares or triangles), the bump averages at six centres between 0.25 and 0.75. One bump ($t_0 = 0.5$, $w = 0.2$) is shown as a green shaded area near the bottom: `fill_between(times, -2.9, -2.9 + 0.5 * shown, ...)` fills the area between the level -2.9 and a curve that rises by half the bump's height, `alpha=0.3` makes it transparent.

```
for centre, marker in zip(centres, ["o", "s", "^"]):
    right.loglog(widths, np.abs(errors[centre]), marker, label=f"$t_0 = {centre}$")
reference = np.abs(errors[0.5][0]) * (np.array(widths) / widths[0]) ** 2
right.loglog(widths, reference, "--", color="grey", label="slope 2")
right.set_xticks(widths, [str(width) for width in widths])  # plain tick labels
right.minorticks_off()  # no unlabelled minor ticks
right.set_xlabel("half-width $w$ of the bump")
```

```
right.set_ylabel("|average of $E$ minus $E(t_0)$|")
right.set_title("The error falls like $w^2$")
right.legend(fontsize=8)
fig.tight_layout()
```

The right panel draws the size of the errors (`np.abs`) against the width on **logarithmic axes** (`loglog`), one marker shape per centre, and a grey dashed reference line proportional to w^2, which on these axes is a straight line of slope 2. `set_xticks` writes the four widths as plain numbers under the axis, and `minorticks_off()` removes the unlabelled small ticks.

```
save_figure(fig, "bump_lemma",
            "The fundamental lemma made visible, for the parabola path with $E(t) = "
            ...)
```

What Figure 07d.3 shows. In the left panel the markers move onto the black curve as the bumps narrow: averaging E over a narrower and narrower bump recovers its value at the centre. In the right panel the points of all three centres lie on one line of slope 2: the distance falls like w^2. So if $\int E\xi\,dt$ vanished for every bump, every average would be 0, and so would E at every point: the fundamental lemma.

In [8]: the derivative of the grid action.

```
N5 = 5
h, w_sym = sp.symbols("h omega", positive=True)
qs = sp.symbols(f"q0:{N5 + 1}", real=True)  # q_0 .. q_5
S_grid = sum(h * (((qs[n + 1] - qs[n]) / h) ** 2 / 2
                  - w_sym**2 * (qs[n] ** 2 + qs[n + 1] ** 2) / 4) for n in range(N5))
grid_E = [h * (-(qs[n + 1] - 2 * qs[n] + qs[n - 1]) / h**2 - w_sym**2 * qs[n])
          for n in range(1, N5)]
check(all(sp.simplify(sp.diff(S_grid, qs[n]) - grid_E[n - 1]) == 0
          for n in range(1, N5)),
      "dS_N/dq_n = h (-(q_(n+1) - 2 q_n + q_(n-1))/h^2 - omega^2 q_n) for every "
      "inner n")
```

$N = 5$ steps. `h` and `w_sym` are positive symbols for the step and for ω; `sp.symbols(f"q0:{N5 + 1}", real=True)` makes the six symbols `q0` to `q5` (the notation `q0:6` means "q0 up to but not including q6"). `S_grid` is the grid action S_N of Section 7.3, a sum over the five steps. `grid_E` is the list of the expected derivatives $h[-(q_{n+1} - 2q_n + q_{n-1})/h^2 - \omega^2 q_n]$ for the inner points $n = 1, \ldots, 4$. The check differentiates `S_grid` with respect to each inner value and compares. **Out [8]:** one PASS line.

In [9]: solving the grid equations, and Figure 07d.4.

```
def grid_path(N):
    """Solve the grid equations: returns the grid times and q_0 .. q_N."""
    step = 1.0 / N
    A = np.zeros((N - 1, N - 1))  # one row per inner point n = 1 .. N-1
    b = np.zeros(N - 1)
    for i in range(N - 1):
```

```
        A[i, i] = 2.0 / step**2 - 1.0  # from -(-2 q_n)/h^2 - omega^2 q_n
        if i > 0:
            A[i, i - 1] = -1.0 / step**2  # the neighbour q_(n-1)
        if i < N - 2:
            A[i, i + 1] = -1.0 / step**2  # the neighbour q_(n+1)
    b[-1] = 1.0 / step**2  # the known end value q_N = 1 moved to the right side
    inner = np.linalg.solve(A, b)
    return np.linspace(0.0, 1.0, N + 1), np.concatenate([[0.0], inner, [1.0]])
```

`grid_path(N)` solves the $N-1$ linear equations "the bracket is zero at every inner point" for $\omega = 1$, $T = 1$, $q_0 = 0$, $q_N = 1$. Multiplying the bracket by -1, the equation at the inner point n is $-q_{n-1}/h^2 + (2/h^2 - 1)q_n - q_{n+1}/h^2 = 0$. The matrix `A` holds these coefficients: row `i` belongs to the inner point $n = i + 1$; its diagonal entry is $2/h^2 - 1$ and its neighbours $-1/h^2$ (the `if` lines leave out neighbours that are end points). The known end value $q_N = 1$ appears only in the last row, as $-1/h^2$ times 1; moved to the right side it gives `b[-1] = 1.0 / step**2` (the index `-1` means the last entry). `np.linalg.solve(A, b)` solves the equations, and the function returns the $N+1$ grid times and the values with the two end values added in front and behind (`np.concatenate`).

```
sizes = [4, 8, 16, 32, 64, 128, 256]
grid_errors = []
for N in sizes:
    nodes, values = grid_path(N)
    grid_errors.append(np.abs(values - np.sin(nodes) / np.sin(1.0)).max())
orders = [np.log2(grid_errors[i] / grid_errors[i + 1]) for i in range(len(sizes) - 1)]
say("largest errors: " + ", ".join(f"N = {N}: {e:.3e}"
                                   for N, e in zip(sizes, grid_errors)))
say("observed orders: " + ", ".join(f"{p:.3f}" for p in orders))
check(all(1.9 < p < 2.1 for p in orders),
      "the stationary grid path converges to the true path with order 2")
```

For $N = 4, 8, \ldots, 256$ the largest distance between the grid path and the true path $\sin t / \sin 1$ at the grid times is stored. `np.log2(e_N/e_{2N})` is the observed order: if the error is Ch^p, halving h divides it by 2^p, and the logarithm to base 2 of the ratio is p (Chapter 2). The check requires every observed order between 1.9 and 2.1. **Out [9]:** the errors 4.089×10^{-4} ($N = 4$), 1.017×10^{-4}, 2.582×10^{-5}, 6.452×10^{-6}, 1.613×10^{-6}, 4.032×10^{-7}, 1.008×10^{-7} ($N = 256$), the orders 2.007, 1.978, 2.001, 2.000, 2.000, 2.000 and the PASS line.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
left.plot(times, np.sin(times) / np.sin(1.0), color="black", label="true path")
for N, marker in ((4, "o"), (8, "s")):
    nodes, values = grid_path(N)
    left.plot(nodes, values, marker, label=f"stationary grid path, $N = {N}$")
left.set_xlabel("time $t$")
left.set_ylabel("position $q$")
left.set_title("The action on a grid")
left.legend(fontsize=8)
steps = 1.0 / np.array(sizes)
right.loglog(steps, grid_errors, "o-", label="largest error")
right.loglog(steps, grid_errors[0] * (steps / steps[0]) ** 2, "--", color="grey",
             label="slope 2")
```

```
right.set_xlabel("step $h = 1/N$")
right.set_ylabel("largest difference from the true path")
right.set_title("Second-order convergence")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "action_on_a_grid",
...)
```

The left panel draws the true path as a black line and, for $N = 4$ (circles) and $N = 8$ (squares), the points of the stationary grid path, computed again with `grid_path`. For the right panel `steps` is the array of the steps $h = 1/N$ (`np.array` turns the list of sizes into an array, so that `1.0 /` divides every entry); the largest errors are drawn against the steps on logarithmic axes, as dots joined by lines, and the grey dashed reference line is the first error times $(h/h_0)^2$, a line of slope 2 through the first point. Labels, titles and legends follow, and `save_figure` saves the figure.

What Figure 07d.4 shows. Already four steps give a grid path whose points lie on the true path to the eye. On the right the errors lie on a line parallel to the slope-2 guide: halving the step divides the error by 4. So the principle of stationary action can be used directly on a computer, and the grid solution converges to the true motion.

In [10]: the energy, and Figure 07d.5.

```
def energy(path):
    """H = (1/2) q'^2 + (1/2) omega^2 q^2 of a path."""
    return sp.diff(path, t) ** 2 / 2 + omega**2 * path**2 / 2

check(sp.simplify(sp.diff(energy(q), t) + sp.diff(q, t) * E_general) == 0,
      "dH/dt = -q' E for every path")
for name, path in PATHS.items():
    say(f"{name:9s}: dH/dt = {sp.simplify(sp.diff(energy(path), t))}")
check(sp.simplify(sp.diff(energy(PATHS["true path"]), t)) == 0
      and all(sp.simplify(sp.diff(energy(PATHS[name]), t)) != 0
              for name in ("line", "parabola")),
      "H is constant on the true path and changes on the two wrong paths")
true_energy = sp.simplify(energy(PATHS["true path"]))
report("energy of the true path", f"{true_energy} = {float(true_energy):.6f}")
```

`energy(path)` is $H = \frac{1}{2}\dot{q}^2 + \frac{1}{2}\omega^2 q^2$. The first check is the identity $dH/dt = -\dot{q}\,E$ of Section 7.4 for a general path (the sum $dH/dt + \dot{q}E$ simplifies to 0). The loop prints dH/dt on the three paths; the second check requires 0 for the true path and a nonzero result for the two wrong ones. `report` prints the energy of the true path exactly and as a decimal. **Out [10]:** two PASS lines, `true path:  dH/dt = 0`, `line:  dH/dt = t`, `parabola:  dH/dt = 2*t*(t**2 + 2)` and `RESULT energy of the true path = 1/(2*sin(1)**2) = 0.706141`.

```
fig, ax = plt.subplots()
for name, path in PATHS.items():
    values = sp.lambdify(t, energy(path))(times) * np.ones_like(times)
    ax.plot(times, values, styles[name], label=name)
ax.set_xlabel("time $t$")
ax.set_ylabel("$H = \\frac{1}{2}\\dot q^2 + \\frac{1}{2}q^2$")
```

```
ax.set_title("The energy along the three paths")
ax.legend(fontsize=8)
save_figure(fig, "energy_along_paths",
...)
```

One panel: the energy along each path against the time. **What Figure 07d.5 shows.** The solid line of the true path is flat at $1/(2\sin^2 1) \approx 0.706$; the energies of the line and the parabola change, because their E is not zero.

In [11]: a total derivative changes nothing.

```
F = t * q**3  # F(q, t)
L = lagrangian(q, sp.diff(q, t))
E_changed = euler_lagrange(L + sp.diff(F, t), [q], t)[0]
check(sp.simplify(E_changed - E_general) == 0,
      "L + dF/dt with F = t q^3 has the same Euler-Lagrange expression as L")
E_pure = euler_lagrange(sp.diff(q**2, t), [q], t)[0]
check(E_pure == 0, "the pure total derivative d(q^2)/dt gives E = 0 for every path")
differences = [sp.simplify(sp.integrate(sp.diff(F.subs(q, path), t), (t, 0, 1)))
               for path in PATHS.values()]
say(f"S'[path] - S[path] for the three paths: {differences}")
check(all(d == 1 for d in differences),
      "the action changes by F(q(1), 1) - F(q(0), 0) = 1 for every path")
```

`F` is $F(q,t) = t\,q^3$ for the general path `q` of In [5]. `E_changed` is the Euler-Lagrange expression of $L + dF/dt$ (`sp.diff(F, t)` is the total derivative along the path, because `q` is a function of `t`); the first check requires it to equal that of L. `E_pure` is the expression of the pure total derivative $\frac{d}{dt}q^2$; the second check requires it to be 0. `differences` holds, for each of the three paths, the change $\int_0^1 \frac{dF}{dt}\,dt$ of the action; it is printed, and the third check requires it to be 1 for every path. **Out [11]:** three PASS lines and `S'[path] - S[path] for the three paths:  [1, 1, 1]`.

In [12]: the two first-order Lagrangians.

```
w = sp.Symbol("omega", positive=True)
q0, q1 = sp.Function("q0")(t), sp.Function("q1")(t)
L_A = (q0 * sp.diff(q1, t) - q1 * sp.diff(q0, t)) / 2 - w * (q0**2 + q1**2) / 2
E_A = euler_lagrange(L_A, [q0, q1], t)
say(f"Example A: E_0 = {E_A[0]},  E_1 = {E_A[1]}")
check(sp.simplify(E_A[0] - (sp.diff(q1, t) - w * q0)) == 0
      and sp.simplify(E_A[1] - (-sp.diff(q0, t) - w * q1)) == 0,
      "Example A: E_0 = q1' - omega q0, E_1 = -q0' - omega q1")
rotation = {q0: sp.cos(w * t), q1: sp.sin(w * t)}
check(all(sp.simplify(e.subs(rotation).doit()) == 0 for e in E_A),
      "Example A: q0 = cos(omega t), q1 = sin(omega t) solves both equations")
```

`w` is ω as a positive symbol and `q0`, `q1` are two unknown functions of t. `L_A` is Example A of Section 7.4, and `E_A` the list of its two Euler-Lagrange expressions (the function `euler_lagrange` of In [5] works for several functions at once). The first check compares them with $\dot q_1 - \omega q_0$ and $-\dot q_0 - \omega q_1$, the second puts in the rotation $q_0 = \cos\omega t$, $q_1 = \sin\omega t$ and requires both to vanish.

```
psi, psi_star = sp.Function("psi")(t), sp.Function("psistar")(t)
L_B = (sp.I / 2 * (psi_star * sp.diff(psi, t) - sp.diff(psi_star, t) * psi)
       - w * psi_star * psi)
E_B = euler_lagrange(L_B, [psi_star, psi], t)  # vary psi* first, then psi
say(f"Example B: E_psi* = {E_B[0]},  E_psi = {E_B[1]}")
complex_form = {psi: (q0 + sp.I * q1) / sp.sqrt(2), psi_star: (q0 - sp.I * q1)
                / sp.sqrt(2)}
L_B_real = (q1 * sp.diff(q0, t) - q0 * sp.diff(q1, t)) / 2 - w * (q0**2 + q1**2) / 2
check(sp.simplify(sp.expand(L_B.subs(complex_form).doit() - L_B_real)) == 0,
      "Example B in real variables is Example A with the rotation reversed")
```

`psi` and `psi_star` are two unknown functions ψ and ψ^*, varied as independent functions; `sp.I` is the imaginary unit i. `L_B` is Example B. `E_B` lists the expressions for ψ^* (first) and ψ. `complex_form` is the dictionary that writes ψ and ψ^* in terms of q_0 and q_1, and `L_B_real` is the real form of Section 7.4; the check requires `L_B` with the substitution to equal it.

```
E_real = euler_lagrange(L_B_real, [q0, q1], t)
combined = E_B[0].subs(complex_form).doit() - (E_real[0] + sp.I * E_real[1]) / sp.sqrt(2)
check(sp.simplify(sp.expand(combined)) == 0,
      "E_psi* = (E_q0 + i E_q1)/sqrt(2): varying psi* is varying q0 and q1")
check(sp.simplify(E_B[0] - (sp.I * sp.diff(psi, t) - w * psi)) == 0
      and sp.simplify(E_B[0].subs(psi, sp.exp(-sp.I * w * t)).doit()) == 0,
      "Example B: i psi' = omega psi, solved by psi = exp(-i omega t)")
```

`E_real` are the expressions of the real form. `combined` is E_{ψ^*} written in q_0, q_1 minus $(E_{q_0} + iE_{q_1})/\sqrt{2}$; the check requires it to vanish: varying ψ^* is the same as varying q_0 and q_1. The last check compares E_{ψ^*} with $i\dot{\psi} - \omega\psi$ and puts in $\psi = e^{-i\omega t}$. **Out [12]:** the four expressions and five PASS lines.

In [13]: Figure 07d.6.

```
turn = np.linspace(0.0, 1.5 * np.pi, 200)  # times up to three quarters of a turn
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 4.2))
for sense, label, style, colour in ((1.0, "Example A", "-", "tab:blue"),
                                    (-1.0, "Example B", "--", "tab:orange")):
    x, y = np.cos(turn), sense * np.sin(turn)
    left.plot(x, y, style, color=colour, label=label)
    for i in (30, 150):  # arrows that show the sense of the motion
        left.annotate("", xy=(x[i + 4], y[i + 4]), xytext=(x[i], y[i]),
                      arrowprops={"arrowstyle": "->", "lw": 1.5, "color": colour})
left.plot([1.0], [0.0], "ko")
left.text(1.05, 0.05, "start")
left.set_aspect("equal")
left.set_xlim(-1.4, 1.4)
left.set_ylim(-1.4, 1.4)
left.set_xlabel("$q_0$")
left.set_ylabel("$q_1$")
left.set_title("First-order motion: a rotation")
left.legend(fontsize=8, loc="lower left")
```

`turn` holds 200 times from 0 to 1.5π, three quarters of a turn for $\omega = 1$. The loop draws both motions in the plane (q_0, q_1): `sense` is $+1$ for Example A ($q_1 = \sin t$) and -1 for Example B ($q_1 = -\sin t$).

For each, two arrows show the sense of motion: `annotate("", xy=..., xytext=...)` draws an arrow from the point at index `i` to the point four indices later, with the arrow style given in `arrowprops`. A black dot marks the start $(1, 0)$; `set_aspect("equal")` makes one unit equally long on both axes, so the circle looks round.

```
psi_values = np.exp(-1j * turn) / np.sqrt(2)  # psi(t) = exp(-i t) psi(0)
right.plot(turn, psi_values.real, label="real part of $\\psi$")
right.plot(turn, psi_values.imag, "--", label="imaginary part of $\\psi$")
right.plot(turn, np.abs(psi_values) ** 2, ":", color="black",
           label="$|\\psi|^2 = \\frac{1}{2}$")
right.set_xlabel("time $t$")
right.set_ylabel("value")
right.set_ylim(-0.85, 1.15)  # room for the legend above the curves
right.set_title("$\\psi(t) = e^{-it}\\psi(0)$")
right.legend(fontsize=7, loc="upper center", ncol=3)
fig.tight_layout()
save_figure(fig, "first_order_rotation",
...)
```

The right panel draws $\psi(t) = e^{-it}/\sqrt{2}$ (`1j` is Python's imaginary unit; `.real` and `.imag` are the real and imaginary parts) and $|\psi|^2$. **What Figure 07d.6 shows.** Both first-order motions run on the unit circle; Example A turns counterclockwise and Example B, whose kinetic term has the opposite sign, clockwise. On the right the real and imaginary parts of ψ oscillate a quarter period apart while $|\psi|^2 = \frac{1}{2}$ stays constant.

In [14]: a field of a space direction and time.

```
x1, x4, x5 = sp.symbols("x1 x4 x5", real=True)
m = sp.Symbol("m", positive=True)
```

Three real coordinate symbols x_1, x_4, x_5 and the mass m as a positive symbol.

```
def field_euler_lagrange(L, field, coordinates):
    """dL/dphi - sum over the coordinates of d/dx dL/d(dphi/dx)."""
    value = sp.Symbol("P")  # stands for phi
    slopes = [sp.Symbol(f"D{i}") for i in range(len(coordinates))]  # dphi/dx
    plain = L
    for x, slope in zip(coordinates, slopes):
        plain = plain.subs(sp.diff(field, x), slope)
    plain = plain.subs(field, value)
    back = {**{s: sp.diff(field, x) for x, s in zip(coordinates, slopes)},
            value: field}
    result = sp.diff(plain, value).subs(back)
    for x, slope in zip(coordinates, slopes):
        result -= sp.diff(sp.diff(plain, slope).subs(back), x)
    return sp.expand(result)
```

`field_euler_lagrange(L, field, coordinates)` is the recipe of Section 7.5: like `euler_lagrange` of In [5], it replaces the field's derivatives by the symbols `D0`, `D1`, ... (one per coordinate) and then the field by `P`; it differentiates with respect to `P`, puts the functions back, and subtracts

for each coordinate the derivative along that coordinate of the derivative with respect to its slope symbol.

```
ETA = {x1: 1, x4: -1, x5: -1}  # the author's signs: x1 space-like, x4, x5 time-like
phi = sp.Function("phi")(x1, x4)
L_space = (-(ETA[x1] * sp.diff(phi, x1) ** 2 + ETA[x4] * sp.diff(phi, x4) ** 2) / 2
           - m**2 * phi**2 / 2)
E_space = field_euler_lagrange(L_space, phi, [x1, x4])
say(f"E = {E_space}")
check(sp.simplify(E_space - (sp.diff(phi, x1, 2) - sp.diff(phi, x4, 2)
                             - m**2 * phi)) == 0,
      "space and time: E = d1^2 phi - d4^2 phi - m^2 phi (Klein-Gordon)")
k, frequency = sp.symbols("k omega_k", positive=True)
wave = sp.cos(k * x1) * sp.cos(frequency * x4)
on_wave = E_space.subs(phi, wave).doit()
check(sp.simplify(on_wave.subs(frequency, sp.sqrt(m**2 + k**2))) == 0
      and sp.simplify(on_wave.subs(frequency, k)) != 0,
      "cos(k x1) cos(omega x4) solves it exactly when omega^2 = m^2 + k^2")
```

`ETA` holds the author's signs for the three coordinates used: $+1$ for x_1, -1 for x_4 and x_5. `phi` is an unknown field $\phi(x_1, x_4)$, and `L_space` the Lagrangian density of Section 7.5. The first check compares the Euler-Lagrange expression with $\partial_1^2\phi - \partial_4^2\phi - m^2\phi$. For the plane wave $\cos(kx_1)\cos(\omega x_4)$, the second check requires $E = 0$ when $\omega = \sqrt{m^2 + k^2}$ and $E \neq 0$ for the wrong value $\omega = k$.

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed
h1, h4, mass = 0.3, 0.2, 1.5  # grid steps and the mass
field_values = rng.normal(size=(7, 6))  # phi_ij: i along x1, j along x4

def grid_action(f):
    """The field action on the grid: a sum over the cells."""
    d4 = (f[:-1, 1:] - f[:-1, :-1]) / h4  # time differences
    d1 = (f[1:, :-1] - f[:-1, :-1]) / h1  # space differences
    return h1 * h4 * np.sum(d4**2 / 2 - d1**2 / 2 - mass**2 * f[:-1, :-1] ** 2 / 2)
```

Now the same on a grid of 7 by 6 points with steps $h_1 = 0.3$ and $h_4 = 0.2$ and mass 1.5. `rng` is a random-number generator with a fixed **seed** 12345, so that every run draws the same numbers; `rng.normal(size=(7, 6))` gives a table of random field values ϕ_{ij}. `grid_action(f)` is the action on the grid: in each cell the time difference `d4` and the space difference `d1` (array slices such as `f[:-1, 1:]` take all rows but the last and all columns but the first), and the sum of $h_1 h_4[\frac{1}{2}d_4^2 - \frac{1}{2}d_1^2 - \frac{1}{2}m^2\phi^2]$.

```
largest = 0.0
delta = 1e-3
for i in range(1, 6):
    for j in range(1, 5):
        plus, minus = field_values.copy(), field_values.copy()
        plus[i, j] += delta
        minus[i, j] -= delta
        numeric = (grid_action(plus) - grid_action(minus)) / (2 * delta)
        f_ = field_values  # a short name for the formula below
```

```
        expected = h1 * h4 * (
            (f_[i + 1, j] - 2 * f_[i, j] + f_[i - 1, j]) / h1**2  # space part
            - (f_[i, j + 1] - 2 * f_[i, j] + f_[i, j - 1]) / h4**2  # time part
            - mass**2 * f_[i, j])
        largest = max(largest, abs(numeric - expected))
say("largest difference over the 20 inner points is below 1e-9: "
    f"{largest < 1e-9}")
check(largest < 1e-9, "on the grid: dS/dphi_ij = h1 h4 times the grid "
      "Euler-Lagrange expression at every inner point")
```

For each of the 20 inner points, the derivative of the grid action with respect to ϕ_{ij} is computed numerically by the **central difference** $(S(\phi_{ij}+\delta) - S(\phi_{ij}-\delta))/(2\delta)$ with $\delta = 10^{-3}$ (`.copy()` makes independent copies of the table, so that only one entry is changed). For an action that is quadratic in ϕ this is exact up to rounding. `expected` is $h_1 h_4$ times the grid Euler-Lagrange expression (second difference quotients in place of ∂_1^2 and ∂_4^2). The largest difference is printed as a true or false statement and checked to be below 10^{-9}. **Out [14]:** the expression `E = -m**2*phi(x1, x4) + Derivative(...)  - Derivative(...)`, the PASS lines and `largest difference over the 20 inner points is below 1e-9:  True`.

In [15]: a field of an extra time and time, and the record's growth rate.

```
phi5 = sp.Function("phi")(x5, x4)
L_extra = (-(ETA[x5] * sp.diff(phi5, x5) ** 2 + ETA[x4] * sp.diff(phi5, x4) ** 2) / 2
           - m**2 * phi5**2 / 2)
E_extra = field_euler_lagrange(L_extra, phi5, [x5, x4])
say(f"E = {E_extra}")
check(sp.simplify(E_extra - (-sp.diff(phi5, x5, 2) - sp.diff(phi5, x4, 2)
                             - m**2 * phi5)) == 0,
      "extra time and time: E = -d5^2 phi - d4^2 phi - m^2 phi")
kappa = sp.Symbol("kappa", positive=True)
growing = sp.cos(k * x5) * sp.cosh(kappa * x4)
check(sp.simplify(E_extra.subs(phi5, growing).doit()
                  .subs(kappa, sp.sqrt(k**2 - m**2))) == 0,
      "cos(k x5) cosh(kappa x4) solves it with kappa^2 = k^2 - m^2: growth for k > m")
```

`phi5` is an unknown field $\phi(x_5, x_4)$ and `L_extra` its Lagrangian density with the sign $\eta_{55} = -1$. The first check compares the expression with $-\partial_5^2\phi - \partial_4^2\phi - m^2\phi$; the second puts in $\cos(kx_5)\cosh(\kappa x_4)$ and requires $E = 0$ when $\kappa = \sqrt{k^2 - m^2}$.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))

norm = sum(signs[a] * ks[a] ** 2 for a in range(8))  # eta^ab k_a k_b
check((slash * slash - norm * sp.eye(16)).applyfunc(sp.expand) == sp.zeros(16, 16),
      "(gamma^a k_a)^2 = (k0^2 + k1^2 + k2^2 + k3^2 - k4^2 - k5^2 - k6^2 - k7^2) I16",
      record=reproduces("Revision/theory/reports/python-field-theory.json",
                        "clifford_relations"))
```

The notebook now reads the author's gammas from the Revision record `Revision/algebra/gammas.json` (the key `"gamma"` holds the eight 16×16 integer matrices in the order $x_0, \ldots, x_7$) and turns them into exact sympy matrices. `signs` is η in the same order, `ks` eight real symbols $k_0, \ldots, k_7$. `slash` is $\sum_a k_a \gamma^{(a)}$ (the sum starts from the zero matrix `sp.zeros(16, 16)`), and `norm` is $\sum_a \eta^{aa} k_a^2$. The check multiplies out `slash * slash - norm * I16` entry by entry (`applyfunc(sp.expand)`) and requires the zero matrix; its second line names the Revision check it reproduces.

```
SCOPE = "Revision/theory/reports/python-scope.json"
detail = revision_check(SCOPE, "extra_time_growth_rates_unbounded")["detail"]
formula = re.search(r"Im E = (sqrt\([^)]*\))", detail).group(1)  # the record's rate
say(f"growth rate in the record: {formula}")
K = sp.Symbol("K", positive=True)
rate = sp.sympify(formula, locals={"K": K, "m": m,
                                   **{f"k{i}": sp.Symbol(f"k{i}") for i in range(8)}})
along_x5 = rate.subs({sp.Symbol(f"k{i}"): 0 for i in (0, 1, 2, 3)}).subs(K, k)
check(sp.simplify(along_x5 - sp.sqrt(k**2 - m**2)) == 0,
      "the record's rate for a momentum along x5 only is sqrt(k^2 - m^2) = kappa",
      record=reproduces(SCOPE, "extra_time_growth_rates_unbounded"))
```

`detail` is the detail text of the scope record's check `extra_time_growth_rates_unbounded`. `re.search(r"Im E = (sqrt\([^)]*\))", detail)` finds in it the text that follows "Im E = ", a `sqrt(...)` up to the first closing parenthesis; `.group(1)` is that text, printed as `sqrt(K**2 - k0**2 - k1**2 - k2**2 - k3**2 - m**2)` ($k_0, \ldots, k_3$ are the momenta along the space-like directions $x_0, \ldots, x_3$, K the size of the momentum along the extra times). `sp.sympify` turns it into a formula (the dictionary `locals` tells sympy which names are which symbols). Setting $k_0 = k_1 = k_2 = k_3 = 0$ and $K = k$ gives the rate for a momentum along x_5 alone, and the check compares it with $\sqrt{k^2 - m^2}$. **Out [15]:** the expression, four PASS lines, two of them with the "reproduces" line, and the formula of the record.

In [16]: Figures 07d.7 and 07d.8.

```
coordinate = np.linspace(0.0, 2 * np.pi / 2.0, 121)  # one wavelength for k = 2
clock = np.linspace(0.0, 2.0, 101)  # the time x4 from 0 to 2
X, Y = np.meshgrid(coordinate, clock)
space_wave = np.cos(2.0 * X) * np.cos(np.sqrt(5.0) * Y)
extra_wave = np.cos(2.0 * X) * np.cosh(np.sqrt(3.0) * Y)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 4.2))
image = left.pcolormesh(X, Y, space_wave, cmap="coolwarm", vmin=-1, vmax=1,
                        shading="auto")
fig.colorbar(image, ax=left, shrink=0.85)
left.set_xlabel("space coordinate $x_1$")
left.set_ylabel("time $x_4$")
left.set_title("$\\cos(2x_1)\\cos(\\sqrt{5}x_4)$: oscillates")
limit = float(np.cosh(np.sqrt(3.0) * 2.0))
image = right.pcolormesh(X, Y, extra_wave, cmap="coolwarm", vmin=-limit, vmax=limit,
                         shading="auto")
fig.colorbar(image, ax=right, shrink=0.85)
right.set_xlabel("extra time $x_5$")
right.set_ylabel("time $x_4$")
right.set_title("$\\cos(2x_5)\\cosh(\\sqrt{3}x_4)$: grows")
for ax in (left, right):
    ax.grid(False)
```

`coordinate` is one wavelength $2\pi/k = \pi$ of a coordinate for $k = 2$, `clock` the time from 0 to 2. `np.meshgrid` makes two tables `X`, `Y` that hold the coordinate and the time at every point of a 121 by 101 grid. `space_wave` is $\cos(2x_1)\cos(\sqrt{5}x_4)$ (for $m = 1$, $k = 2$: $\omega = \sqrt{1+4}$), `extra_wave` is $\cos(2x_5)\cosh(\sqrt{3}x_4)$ ($\kappa = \sqrt{4-1}$). `pcolormesh` draws each table as a colour map (red positive, blue negative in the colour scheme `coolwarm`); `colorbar` adds the colour scale. The right panel's scale reaches $\cosh(2\sqrt{3}) \approx 16$ (`limit`). `ax.grid(False)` switches the grid lines off over the colour maps.

```
fig.tight_layout()
save_figure(fig, "space_and_extra_time",
            "Two exact solutions of the field equation with mass $m = 1$ and wave "
            ...)
```

What Figure 07d.7 shows. On the left the colours repeat in time: the wave along the space direction oscillates between -1 and 1. On the right the colours grow stronger with time: the wave along the extra time grows like $\cosh(\sqrt{3}x_4)$. The two Lagrangians differ only by the sign of one term.

```
numbers = np.linspace(0.0, 3.0, 301)  # the wave number k, with m = 1
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
left.plot(numbers, 1.0 + numbers**2, label="along a space direction: $m^2 + k^2$")
left.plot(numbers, 1.0 - numbers**2, "--",
          label="along an extra time: $m^2 - k^2$")
left.axhline(0.0, color="black", linewidth=0.8)
left.set_xlabel("wave number $k$")
left.set_ylabel("$\\omega^2$")
left.set_title("Dispersion relations ($m = 1$)")
left.legend(fontsize=8)
above = numbers[numbers > 1.0]
right.plot(above, np.sqrt(above**2 - 1.0), color="tab:red",
           label="$\\kappa = \\sqrt{k^2 - m^2}$")
right.plot(above, above, ":", color="grey", label="$\\kappa = k$ (large $k$)")
right.set_xlim(0.0, 3.0)
right.set_xlabel("wave number $k$ along the extra time")
right.set_ylabel("growth rate $\\kappa$")
right.set_title("Growth without upper bound")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "dispersion",
...)
```

The second figure: on the left $\omega^2 = 1 + k^2$ and $\omega^2 = 1 - k^2$ against the wave number k from 0 to 3; on the right, for $k > 1$ (`numbers[numbers > 1.0]` keeps only those values), the growth rate $\kappa = \sqrt{k^2 - 1}$ and the dotted line $\kappa = k$ that it approaches. **Out [16]:** the two figures and their saved files.

What Figure 07d.8 shows. Along a space direction ω^2 is always positive (oscillation); along an extra time it falls below zero for $k > m$, and then the wave grows at the rate κ, which keeps growing with k and has no upper bound: the same rate as in the Revision record for the 16-component field.

In [17]: the last check.

```
names = ["action_versus_epsilon", "paths_and_residuals", "bump_lemma",
         "action_on_a_grid", "energy_along_paths", "first_order_rotation",
         "space_and_extra_time", "dispersion"]
files = [f"{FIGURE_FOLDER}/07d_{k_}_{name}.png" for k_, name in enumerate(names, 1)]
check(all(output_file(path).is_file() for path in files),
      "all 8 figure files of this notebook exist")
all_checks_passed()
```

The list of the eight figure names, and the list of their file paths built with `enumerate(names, 1)`, which numbers them from 1. The check requires that every file exists in the output folder; `all_checks_passed()` prints the last line. **Out [17]:** `PASS all 8 figure files of this notebook exist` and `ALL 30 CHECKS PASSED (notebook 07d)`.

7.10 Grassmann numbers from zero

Why anticommuting numbers. Electrons, and the quanta of the field dirac16complex, are **fermions**: two of them never occupy the same state (the Pauli principle). In the quantum theory this is expressed by field operators that **anticommute**, $XY = -YX$ (Chapter 10). The classical field from which such operators are obtained is therefore given values that anticommute: the Revision record defines the components of dirac16complex in this way (ASSUMED here as the definition of the field; Revision/SPEC.md, section 3). Such values are not measured; they are bookkeeping symbols with exact rules, and every statement about them is a statement about these rules.

Generators and the defining rule. Take n symbols $\theta_0, \theta_1, \ldots, \theta_{n-1}$, called **generators**. The one rule is

$$\theta_i \theta_j = -\theta_j \theta_i \qquad \text{for all } i, j.$$

Ordinary numbers are allowed as factors and commute with everything. Setting $j = i$ in the rule gives $\theta_i\theta_i = -\theta_i\theta_i$, that is $2\theta_i\theta_i = 0$ (add $\theta_i\theta_i$ to both sides), so

$$\theta_i^2 = 0.$$

A generator times itself is zero. This is the algebraic form of the Pauli principle.

Monomials and the sign of a reordering. A product of generators can be put into increasing order of the indices by exchanging neighbours that stand in the wrong order, one pair at a time; every exchange costs a factor -1 by the defining rule. Example: $\theta_2\theta_0\theta_1$. Exchange θ_2 and θ_0: $-\theta_0\theta_2\theta_1$. Exchange θ_2 and θ_1: $+\theta_0\theta_1\theta_2$. Two exchanges, sign $+1$. Another: $\theta_1\theta_0 = -\theta_0\theta_1$, one exchange, sign -1. If a generator occurs twice, the two copies can be brought next to each other, and the product is 0. A product of different generators in increasing order, such as $\theta_0\theta_2\theta_5$, is called a **monomial**; the empty product is the number 1; the number of generators in a monomial is its **degree**. Every product of generators is therefore 0, or $+1$ or -1 times exactly one monomial. The sign does not depend on the order in which the exchanges are made: every way of sorting a list by exchanging neighbours uses a number of exchanges of the same parity (even or odd), because each exchange of two neighbours changes the number of pairs that stand in the wrong order by exactly one. (Notebook 07a, In [2], computes the sign by sorting, and In [3] by counting the pairs in the wrong order; the two agree on 2000 random examples.)

The Grassmann algebra. The **Grassmann algebra** of the n generators is the set of all sums of ordinary numbers times monomials, with the defining rule. Its elements are called **Grassmann numbers**, and the ordinary numbers in front of the monomials are their **coefficients**. Two elements are added by adding the coefficients of equal monomials, and multiplied by multiplying every term of the first with every term of the second, each product of monomials being reordered with its sign. Example with two generators: for $F = a + b\theta_0 + c\theta_1 + d\theta_0\theta_1$ and $F' = a' + b'\theta_0 + c'\theta_1 + d'\theta_0\theta_1$,

$$FF' = aa' + (ab' + ba')\theta_0 + (ac' + ca')\theta_1 + (ad' + da' + bc' - cb')\,\theta_0\theta_1.$$

Rule for each term: $b\theta_0\, c'\theta_1 = bc'\,\theta_0\theta_1$ (already in order); $c\theta_1\, b'\theta_0 = cb'\,\theta_1\theta_0 = -cb'\,\theta_0\theta_1$ (one exchange); every product with a repeated generator, such as $b\theta_0\, b'\theta_0$ or $b\theta_0\, d'\theta_0\theta_1$, vanishes. (PROVED; Notebook 07a, In [5].)

How big is a Grassmann algebra? The product $(1+\theta_0)(1+\theta_1)\cdots(1+\theta_{n-1})$, multiplied out, contains every monomial exactly once, with coefficient $+1$: from each bracket we take either 1 or θ_i, and the chosen generators come out in increasing order, so no reordering is needed. So the number of monomials, called the **dimension** of the algebra, is 2^n (each generator is either in a monomial or not: two choices, n times). The number of monomials of degree k is the number of ways to choose k of the n generators, the **binomial coefficient** $\binom{n}{k} = \frac{n!}{k!(n-k)!}$, where $n! = 1\cdot 2\cdots n$ is the **factorial** ($0! = 1$). For $n = 8$ these are 1, 8, 28, 56, 70, 56, 28, 8, 1, which add up to $2^8 = 256$ (PROVED; Notebook 07a counts the monomials for $n = 0$ to 12, In [6], Figure 07a.1). For ordinary commuting symbols there would be infinitely many monomials ($q, q^2, q^3, \ldots$ are all different); anticommuting symbols give a finite algebra.

The multiplication table of three generators. With three generators the eight monomials are $1, \theta_0, \theta_1, \theta_2, \theta_0\theta_1, \theta_0\theta_2, \theta_1\theta_2, \theta_0\theta_1\theta_2$. A product of two of them is nonzero exactly when each of the three generators is in the left factor, in the right factor, or in neither (in both would repeat it): three possibilities for each of three generators, $3^3 = 27$ nonzero products among the $8 \times 8 = 64$ (PROVED; Notebook 07a, In [7], Figure 07a.2).

7.11 Even and odd elements, conjugation and derivatives

Even and odd. Moving a monomial X of degree k past a monomial Y of degree l (with no common generator) moves each of the k generators of X past each of the l generators of Y: kl exchanges. So

$$YX = (-1)^{kl}\, XY.$$

An element is **even** if all its monomials have even degree, **odd** if all have odd degree. If k or l is even, kl is even and the sign is $+1$: an even element commutes with everything. If both are odd, the sign is -1: two odd elements anticommute (PROVED; Notebook 07a measures the sign for $k, l = 0$ to 4, In [8], Figure 07a.3). The Lagrangian of dirac16complex contains the components in pairs, so it is even and behaves like an ordinary number in the order of factors. One more consequence: every odd element squares to zero. For example $(3\theta_0+5\theta_1)^2 = 9\theta_0^2+15\theta_0\theta_1+15\theta_1\theta_0+25\theta_1^2 = 15\theta_0\theta_1-15\theta_0\theta_1 = 0$ (Notebook 07a, In [5]).

Complex Grassmann numbers and conjugation. The components of dirac16complex are complex, and complex numbers have conjugates. For complex Grassmann numbers the generators

come in pairs, θ_k and its **conjugate** $\bar\theta_k = \theta_k^*$, two different generators. The **conjugation** $F \mapsto F^*$ of the algebra is defined by three rules: it exchanges the two members of every pair ($\theta_k^* = \bar\theta_k$, $\bar\theta_k^* = \theta_k$), it replaces every coefficient by its complex conjugate, and it REVERSES the order of every product:

$$(FG)^* = G^* F^*, \qquad \text{for example} \qquad (\theta_1\theta_2)^* = \theta_2^*\theta_1^* = \bar\theta_2\bar\theta_1.$$

Why reverse? With this rule the product of a generator with its conjugate is real: $(\bar\theta\theta)^* = \theta^*\bar\theta^* = \bar\theta\theta$. Without the reversal we would get $\bar\theta^*\theta^* = \theta\bar\theta = -\bar\theta\theta$, and the analogue of $|z|^2 = z^*z$ would not be real. An element with $F^* = F$ is called **real**. Applying the conjugation twice gives back F (the order is reversed twice, the pairs exchanged twice, the coefficients conjugated twice). (PROVED; Notebook 07a checks these rules on the test algebra of the Wolfram verifier and on the 32 generators of a 16-component field, In [9]; they reproduce `Revision/theory/reports/wolfram-field-theory.json`, check `grassmann_algebra_structure`, and `Revision/theory/reports/python-field-theory.json`, check `superalgebra_axioms`.)

Left and right derivatives. To vary a Lagrangian we must differentiate with respect to a generator. Because the order matters, there are two derivatives. The **left derivative** $\partial_L F/\partial\theta_k$: in every monomial that contains θ_k, move θ_k to the far left, collecting a -1 for every generator it passes, and then delete it; monomials without θ_k give nothing. The **right derivative** $\partial_R F/\partial\theta_k$ moves θ_k to the far right instead. In a sorted monomial of degree n in which θ_k stands at position p (counting from 0), moving it left passes p generators and moving it right passes $n-1-p$. Worked by hand for $F = \theta_0\theta_1$:

$$\frac{\partial_L F}{\partial\theta_0} = \theta_1, \qquad \frac{\partial_L F}{\partial\theta_1} = -\theta_0, \qquad \frac{\partial_R F}{\partial\theta_1} = \theta_0, \qquad \frac{\partial_R F}{\partial\theta_0} = -\theta_1.$$

(The second: write $F = -\theta_1\theta_0$, then delete θ_1. The fourth: $F = -\theta_1\theta_0$ has θ_0 on the right.) For an EVEN monomial the two signs differ by $(-1)^{(n-1-p)-p} = (-1)^{n-1}\cdot(-1)^{-2p} = (-1)^{n-1} = -1$, because $n-1$ is odd. So $\partial_R F = -\partial_L F$ for every even F (PROVED; Notebook 07a, In [10], also checks the derivative rules of the sympy record and reproduces its check `superalgebra_axioms`).

7.12 Bilinear forms, real columns and the powers of S

When is $\Psi^\dagger M\Psi$ real? Take a column Ψ of n complex Grassmann components with generators $\psi_A = \Psi_A$ and the conjugate row $\Psi^\dagger$ with generators $\chi_A = \psi_A^*$ (the **dagger** $\dagger$ means transpose and conjugate). For a matrix M of ordinary numbers the **bilinear form** $\Psi^\dagger M\Psi = \sum_{A,B}\chi_A M_{AB}\psi_B$ contains one factor from $\Psi^\dagger$ and one from Ψ in every term. Its conjugate, line by line:

$$\left(\Psi^\dagger M\Psi\right)^* = \sum_{A,B}\left(\chi_A M_{AB}\psi_B\right)^*$$

(the conjugate of a sum is the sum of the conjugates);

$$= \sum_{A,B} M_{AB}^*\,\psi_B^*\chi_A^* = \sum_{A,B} M_{AB}^*\,\chi_B\psi_A$$

(the conjugation reverses the order of the two factors and conjugates the coefficient; then $\psi_B^* = \chi_B$ and $\chi_A^* = \psi_A$);

$$= \sum_{B,A} \chi_B \, (M^\dagger)_{BA} \, \psi_A = \Psi^\dagger M^\dagger \Psi$$

(the coefficient is an ordinary number and may stand anywhere; $(M^\dagger)_{BA} = M^*_{AB}$ by the definition of the dagger; the names of the two summation indices are exchanged). So the form is real exactly when M is **Hermitian**, $M^\dagger = M$. For ordinary complex numbers the same result holds for the opposite reason: there nothing is reordered, because ordinary numbers commute. The reversal of the order built into the conjugation is what makes the two cases come out the same (PROVED; Notebook 07a checks it for $n = 4$ with a random Hermitian and a random non-Hermitian matrix, In [11]).

Real columns keep opposite halves of a matrix. Now take a REAL column $\Theta = (\theta_0, \ldots, \theta_{15})^T$ of 16 real Grassmann generators (no conjugates at all) and the form $\Theta^T M \Theta = \sum_{A,B} \theta_A M_{AB} \theta_B$, where ^{T} is the **transpose** (rows and columns exchanged). Exchanging the two odd factors and renaming the indices, line by line:

$$\Theta^T M \Theta = \sum_{A,B} \theta_A M_{AB} \theta_B = - \sum_{A,B} \theta_B M_{AB} \theta_A$$

(the anticommutation of θ_A and θ_B; for $A = B$ both sides are 0);

$$= - \sum_{A,B} \theta_A M_{BA} \theta_B = - \sum_{A,B} \theta_A (M^T)_{AB} \theta_B = -\Theta^T M^T \Theta$$

(the names A and B exchanged; then $(M^T)_{AB} = M_{BA}$). Write M as the sum of its **symmetric part** $\frac{1}{2}(M + M^T)$ and its **antisymmetric part** $\frac{1}{2}(M - M^T)$. The identity says that the symmetric part gives zero. So: **for a real Grassmann column only the antisymmetric part of M survives, and $\Theta^T M \Theta = 0$ for every symmetric M.** For a real column q of ordinary numbers it is the other way round: there $q^T M q = q^T M^T q$ (no sign when the factors are exchanged), so only the symmetric part survives and $q^T M q = 0$ for every antisymmetric M (PROVED).

The author's matrix C. The author's 16×16 matrix $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ (his σ_{16}; Chapter 5) is real and symmetric with $C^2 = 1$, and every $C\gamma^{(a)}$ is real and antisymmetric (`Revision /theory/reports/python-field-theory.json`, check `C_properties`). By the rule just proved: for a real Grassmann column $\Theta^T C \Theta = 0$, while every $\Theta^T C \gamma^{(a)} \Theta$ survives; for real ordinary numbers $q^T C q$ survives and every $q^T C \gamma^{(a)} q = 0$. Notebook 07a computes the nine forms with $M = C$ and $M = C\gamma^{(a)}$ for both kinds of numbers and counts the surviving monomials: $[0, 8, 8, 8, 8, 8, 8, 8, 8]$ for real Grassmann numbers and $[8, 0, 0, 0, 0, 0, 0, 0, 0]$ for real ordinary numbers (In [12] and In [13], Figures 07a.4 and 07a.5; the Grassmann statement is part of `Revision/theory/reports/wolfram-field-theory.json`, check `Majorana_Lg_total_derivative_grassmann`, the commuting one part of its check `Majorana_Lg_commuting_control`). Each of the 8 surviving monomials of $\Theta^T C \gamma^{(a)} \Theta$ has the coefficient ± 2: every row of the signed permutation matrix $C\gamma^{(a)}$ has one entry ± 1, and the two mirror entries $M_{AB} = -M_{BA}$ give $\theta_A M_{AB} \theta_B + \theta_B M_{BA} \theta_A = M_{AB}(\theta_A \theta_B - \theta_B \theta_A) = 2 M_{AB} \theta_A \theta_B$.

The scalar density and its powers. At one point, the field dirac16complex consists of 16 complex Grassmann numbers: 32 generators $\chi_A = \Psi_A^*$ and $\psi_A = \Psi_A$. The **scalar density** is

$$S = \Psi^\dagger C \Psi = \sum_{A,B} \chi_A C_{AB} \psi_B.$$

C is a **signed permutation matrix**: every row and every column has exactly one nonzero entry, ± 1 (Chapter 5). If row A has its entry in column $\pi(A)$, then

$$S = \sum_A C_{A\pi(A)}\, P_A, \qquad P_A = \chi_A \psi_{\pi(A)},$$

a sum of 16 **pairs** that share no generator (different rows give different χ's, and different columns different ψ's). Each pair is even, so the pairs commute with each other, and $P_A^2 = \chi_A \psi_{\pi(A)} \chi_A \psi_{\pi(A)} = 0$ (the generator χ_A repeats). Now take the k-th power. Multiplying out $S^k = S \cdot S \cdots S$ gives a sum over all ordered choices of k pairs, one from each factor. A choice with a repeated pair gives 0. A choice of k different pairs gives the product of those pairs, and since the pairs commute, all $k!$ orders of the same k pairs give the same product. Each such product is ± 1 times one monomial of degree $2k$, and different sets of pairs give different monomials. So

$$S^k = k! \sum_{\{A_1 < \cdots < A_k\}} C_{A_1\pi(A_1)} \cdots C_{A_k\pi(A_k)}\, P_{A_1} \cdots P_{A_k} :$$

S^k has $\binom{16}{k}$ monomials, each with the coefficient $\pm k!$; S^{16} is a single monomial (all 32 generators), and $S^{17} = 0$, because 17 different pairs do not exist (PROVED; Notebook 07a computes all 17 powers with its program: 16, 120, 560, 1820, 4368, 8008, 11440, 12870, 11440, 8008, 4368, 1820, 560, 120, 16, 1, 0 monomials, In [14], Figure 07a.6). Consequence for the Lagrangian: every function of S is a polynomial of degree at most 16, so the potential $U(S) = \frac{\lambda}{2} S^2$ is a choice among finitely many possible terms. For ordinary commuting components the same S has powers that never vanish; there S^k has $\binom{16+k-1}{k}$ monomials (the number of ways to choose k of the 16 pairs when a pair may be chosen several times): 16, 136, 816 for $k = 1, 2, 3$ (Notebook 07a checks these three with sympy, In [14]). The difference $136 - 120 = 16$ for $k = 2$ will reappear in Section 7.20: it is the number of squares P_A^2 that vanish for Grassmann numbers.

The test algebra of the Revision record. The Wolfram verifier of the Revision record does not give every component its own generators. It uses a Grassmann algebra with only two generators θ_1, θ_2 and their conjugates $\bar\theta_1, \bar\theta_2$, and writes each component as $\Psi_A = c_{A1}\theta_1 + c_{A2}\theta_2$ with ordinary complex coefficients c_{Ak} (which may depend on the coordinates). This keeps the computation small and is still a genuine Grassmann field. Then $\Psi_A^* = c_{A1}^* \bar\theta_1 + c_{A2}^* \bar\theta_2$ (a single generator is not reordered), and

$$S = \sum_{A,B} \Psi_A^* C_{AB} \Psi_B = \sum_{k,l} \bar\theta_k \theta_l \Big(\sum_{A,B} c_{Ak}^* C_{AB} c_{Bl} \Big)$$

(multiply out and collect by the pair of generators). So S lives on the four monomials $\bar\theta_k \theta_l$ (it is even), S^2 only on the one monomial that contains all four generators, and $S^3 = 0$, because it would need six different generators out of four. Hence in this test algebra the most general

potential is $U = u_1 S + \frac{\lambda}{2} S^2$ (PROVED; Notebook 07a checks it with random coefficients, In [16], and reproduces `Revision/theory/reports/wolfram-field-theory.json`, check `grassmann_algebra_structure`).

7.13 Field equations with Grassmann numbers

Jets. A field depends on coordinates. To vary a Lagrangian we treat the value of the field and its derivatives at one point as independent symbols; such a set of symbols is called a **jet**. For a Grassmann field each of them is a generator. The **total derivative** d/dx acts on a jet by raising each generator to its derivative ($\theta \to \theta'$, $\theta' \to \theta''$) in each place in turn, with the product rule; d/dx is even (it does not change the number of odd factors), so it needs no extra sign, but the raised generator may have to be sorted back into place.

The Grassmann oscillator. Take one complex Grassmann field $\theta(t)$ of one variable t and the Lagrangian

$$L = \tfrac{i}{2}(\bar\theta\theta' - \bar\theta'\theta) - \omega\,\bar\theta\theta,$$

the Grassmann copy of Example B of Section 7.4 (a prime is d/dt). It is real: $(\bar\theta\theta')^* = \theta'^*\bar\theta^* = \bar\theta'\theta$, so the bracket is $X - X^*$ with $X = \bar\theta\theta'$, and $\big(\tfrac{i}{2}(X - X^*)\big)^* = -\tfrac{i}{2}(X^* - X) = \tfrac{i}{2}(X - X^*)$ (the conjugate of i is $-i$); and $(\bar\theta\theta)^* = \bar\theta\theta$. Varying $\bar\theta$ with LEFT derivatives:

$$\mathcal{E} = \frac{\partial_L L}{\partial\bar\theta} - \frac{d}{dt}\frac{\partial_L L}{\partial\bar\theta'} = \Big(\tfrac{i}{2}\theta' - \omega\theta\Big) - \frac{d}{dt}\Big(-\tfrac{i}{2}\theta\Big) = i\theta' - \omega\theta.$$

The first term: $\bar\theta$ already stands on the left in $\bar\theta\theta'$ and $\bar\theta\theta$, so deleting it costs no sign. The second: $\bar\theta'$ stands on the left in $-\tfrac{i}{2}\bar\theta'\theta$, its left derivative is $-\tfrac{i}{2}\theta$, whose d/dt is $-\tfrac{i}{2}\theta'$. The field equation $i\theta' = \omega\theta$ has the same form as for an ordinary complex oscillator (PROVED; Notebook 07a, In [17]). Its solution is $\theta(t) = e^{-i\omega t}\theta_0$ with a constant generator θ_0: an ordinary complex function times a fixed generator (In [18], Figure 07a.7). The anticommuting nature sits in θ_0, not in the time dependence. The lesson, used again in Section 7.21: if every conjugate factor is written on the left of every non-conjugate factor, and left derivatives are taken with respect to the conjugates, field equations with Grassmann numbers keep their ordinary form.

A first-order kinetic term of REAL Grassmann fields gives no equation. Now two real Grassmann fields $\theta_0(x)$, $\theta_1(x)$ of one coordinate x, and the first-order kinetic term with the antisymmetric matrix $A = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$:

$$K_A = \theta^T A\,\theta' = \theta_0\theta_1' - \theta_1\theta_0'.$$

Line by line:

$$K_A = \theta_0\theta_1' + \theta_0'\theta_1$$

(in the second term $\theta_1\theta_0' = -\theta_0'\theta_1$, one exchange of two odd factors);

$$= (\theta_0\theta_1)'$$

(the product rule read backwards); and $\theta^T A\theta = \theta_0\theta_1 - \theta_1\theta_0 = 2\theta_0\theta_1$, so

$$K_A = \tfrac{1}{2}(\theta^T A\theta)',$$

a **total derivative**. By Section 7.4 it gives no field equation: both Euler-Lagrange expressions vanish identically. With the symmetric identity matrix instead, $K_I = \theta_0\theta_0' + \theta_1\theta_1'$ is not a total derivative ($(\theta_0\theta_0)' = 0$ because $\theta_0^2 = 0$), and its Euler-Lagrange expression for θ_0 is $\theta_0' - \frac{d}{dx}(-\theta_0) = 2\theta_0'$ (the left derivative of $\theta_0\theta_0'$ with respect to θ_0' passes θ_0, hence the $-\theta_0$). For ORDINARY numbers q_0, q_1 the roles are exchanged: $K_A = q_0q_1' - q_1q_0'$ gives the nonzero expressions $E_0 = q_1' - \frac{d}{dx}(-q_1) = 2q_1'$ and $E_1 = -q_0' - \frac{d}{dx}q_0 = -2q_0'$ (PROVED; Notebook 07a, In [19]). This is the one-dimensional model of the negative control of Section 7.28: a real anticommuting field whose kinetic matrices $C\gamma^\mu$ are antisymmetric has no field equation at all. That is why the Lagrangian of dirac16complex is written for a COMPLEX field, with the row $\bar\Psi = \Psi^\dagger C$ in place of a transpose.

7.14 Example: Notebook 07a builds a Grassmann algebra by hand

Notebook 07a builds the algebra of Sections 7.10 to 7.13 from nothing but its rules, in a few lines of plain Python: a sorting function that returns the sign of a reordering, a faster sign rule for the product of two sorted monomials, and a class `Grassmann` whose elements are dictionaries from monomials to coefficients. It checks the defining rules and the product of two general elements, counts the 2^n monomials, draws the multiplication table of three generators and the commutation signs $(-1)^{kl}$, builds the conjugation and the two derivatives, checks the reality rule for bilinear forms, shows with the author's matrix C (read from the Revision record) which bilinear forms survive for real columns of the two kinds of numbers, computes all powers of the scalar density of a 16-component field up to $S^{17} = 0$, checks the test algebra of the Wolfram verifier, derives the Grassmann oscillator and shows that the first-order kinetic term of real Grassmann fields is a total derivative. It draws seven figures and ends with the line ALL 38 CHECKS PASSED (notebook 07a).

7.15 How to run Notebook 07a

Step 1. What this notebook does and what it needs.

Notebook 07a (A Grassmann algebra by hand) is the file `Revision/textbook/notebooks/07a_grassmann_algebra.ipynb` of the repository Dirac_claude. It builds a Grassmann algebra (numbers that anticommute) from its rules in a few lines of plain Python, checks the rules, the order-reversing conjugation and the left and right derivatives, shows which bilinear forms of a real anticommuting column survive with the author's charge matrix C, counts the monomials of every power of the scalar density S of a 16-component complex Grassmann field (the 17th power is zero), reproduces the Grassmann-algebra facts of the Revision record, derives two Euler-Lagrange equations with Grassmann variables and draws seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6,

sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 07a_grassmann_algebra.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 07a_grassmann_algebra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 07a_grassmann_algebra.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/07a.captions.json`
- `Revision/textbook/figures/07a_1_dimension_and_degrees.png`
- `Revision/textbook/figures/07a_2_multiplication_signs.png`
- `Revision/textbook/figures/07a_3_commutation_signs.png`
- `Revision/textbook/figures/07a_4_bilinear_survivors.png`
- `Revision/textbook/figures/07a_5_symmetric_antisymmetric.png`
- `Revision/textbook/figures/07a_6_powers_of_s.png`
- `Revision/textbook/figures/07a_7_oscillator_solution.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 7 figure files of this notebook exist
ALL 38 CHECKS PASSED (notebook 07a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/07a_grassmann_algebra.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 07a_grassmann_algebra.ipynb
python -m nbconvert --execute --inplace 07a_grassmann_algebra.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory/reports Revision/algebra
```

7.16 Notebook 07a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/07a_grassmann_algebra.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field dirac16complex of this book has 16 components that **anticommute**: for
two of its components $\Psi_A \Psi_B = -\Psi_B \Psi_A$. Ordinary numbers cannot do
that. This notebook builds, from nothing but its rules, the algebra of such numbers
(a **Grassmann algebra**) in a few lines of plain Python, and then uses it. It

- writes a program that multiplies anticommuting symbols and checks the rules
  $\theta_i \theta_j = -\theta_j \theta_i$ and $\theta_i^2 = 0$;
- counts how many independent products a Grassmann algebra has ($2^n$ for $n$
  symbols) and draws the multiplication table of three symbols;
- shows which elements commute and which anticommute (even and odd elements);
- builds the **conjugation**, which reverses the order of a product, and the
  **left and right derivatives**;
- shows that a bilinear form $\Psi^\dagger M \Psi$ is real exactly when the matrix
  $M$ is Hermitian, for anticommuting components as for ordinary numbers;
- shows, with the author's matrix $C$ read from the Revision record, that for a
  REAL anticommuting column the form $\Theta^T C \Theta$ is zero while every
  $\Theta^T C \gamma^{(a)} \Theta$ survives, and that for real ordinary numbers it is
  the other way round;
- computes every power of the scalar density $S = \bar\Psi \Psi = \Psi^\dagger C
  \Psi$ of a 16-component complex anticommuting field: $S^k$ has
  $\binom{16}{k}$ monomials, each with coefficient $\pm k!$, and $S^{17} = 0$;
- reproduces the Grassmann-algebra facts that the Revision record verifies
  (Revision/theory/reports/python-field-theory.json and
  Revision/theory/reports/wolfram-field-theory.json);
- derives the Euler-Lagrange equation of a small anticommuting oscillator, and
  shows that a first-order kinetic term of REAL anticommuting fields gives no
  field equation at all.

Every result is checked by a line that starts with PASS; the last line counts the
checks. Seven figures are drawn and saved.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 07a (A Grassmann algebra by hand) is the file
‘Revision/textbook/notebooks/07a_grassmann_algebra.ipynb‘ of the repository Dirac_claude.
It builds a Grassmann algebra (numbers that anticommute) from its rules in a few lines of
plain Python, checks the rules, the order-reversing conjugation and the left and right
derivatives, shows which bilinear forms of a real anticommuting column survive with the
author's charge matrix C, counts the monomials of every power of the scalar density S of
a 16-component complex Grassmann field (the 17th power is zero), reproduces the
Grassmann-algebra facts of the Revision record, derives two Euler-Lagrange equations with
Grassmann variables and draws seven teaching plots. It needs a computer with Windows 11,
macOS or Linux, an internet connection for the installation, the program Git, and Python
3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
```

Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then

needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 07a_grassmann_algebra.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 07a_grassmann_algebra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 07a_grassmann_algebra.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/07a.captions.json‘

- ‘Revision/textbook/figures/07a_1_dimension_and_degrees.png‘
- ‘Revision/textbook/figures/07a_2_multiplication_signs.png‘
- ‘Revision/textbook/figures/07a_3_commutation_signs.png‘
- ‘Revision/textbook/figures/07a_4_bilinear_survivors.png‘
- ‘Revision/textbook/figures/07a_5_symmetric_antisymmetric.png‘
- ‘Revision/textbook/figures/07a_6_powers_of_s.png‘
- ‘Revision/textbook/figures/07a_7_oscillator_solution.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 7 figure files of this notebook exist
ALL 38 CHECKS PASSED (notebook 07a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/07a_grassmann_algebra.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command

below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 07a_grassmann_algebra.ipynb
python -m nbconvert --execute --inplace 07a_grassmann_algebra.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory/reports Revision/algebra
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 07a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 07a (A Grassmann algebra by hand) is the file
# Revision/textbook/notebooks/07a_grassmann_algebra.ipynb of the repository Dirac_claude.
# It builds a Grassmann algebra (numbers that anticommute) from its rules in a few lines
# of plain Python, checks the rules, the order-reversing conjugation and the left and
# right derivatives, shows which bilinear forms of a real anticommuting column survive
# with the author’s charge matrix C, counts the monomials of every power of the scalar
# density S of a 16-component complex Grassmann field (the 17th power is zero),
# reproduces the Grassmann-algebra facts of the Revision record, derives two
# Euler-Lagrange equations with Grassmann variables and draws seven teaching plots. It
# needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
```

```
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
```

```
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
```

```
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 07a_grassmann_algebra.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 07a_grassmann_algebra.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 07a_grassmann_algebra.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/07a.captions.json
# - Revision/textbook/figures/07a_1_dimension_and_degrees.png
# - Revision/textbook/figures/07a_2_multiplication_signs.png
# - Revision/textbook/figures/07a_3_commutation_signs.png
# - Revision/textbook/figures/07a_4_bilinear_survivors.png
# - Revision/textbook/figures/07a_5_symmetric_antisymmetric.png
# - Revision/textbook/figures/07a_6_powers_of_s.png
# - Revision/textbook/figures/07a_7_oscillator_solution.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
```

```
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 7 figure files of this notebook exist
#     ALL 38 CHECKS PASSED (notebook 07a)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/07a_grassmann_algebra.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 07a_grassmann_algebra.ipynb
#     python -m nbconvert --execute --inplace 07a_grassmann_algebra.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "ValueError: ... is not a passing check of Revision/theory/reports/...": the Revision
#   record files of your copy of the repository differ from the committed ones; restore
#   them with the command below (run in the repository folder) and run the notebook
#   again.
#     git restore Revision/theory/reports Revision/algebra
#
# ------------------------------------------------------------------------------------
```

```
# ============================================================================

## 3. The words used in this notebook

- **Generator**: one of the anticommuting symbols $\theta_0, \theta_1, \dots,
  \theta_{n-1}$ from which everything is built. In the program a generator is
  named by its number $0, 1, \dots, n-1$.
- **Anticommute**: $xy = -yx$. Two different generators anticommute; a generator
  times itself is zero, because $\theta\theta = -\theta\theta$ means
  $2\theta\theta = 0$.
- **Monomial**: a product of different generators written in increasing order,
  such as $\theta_0 \theta_2 \theta_5$; the empty product is the number 1. Its
  **degree** is the number of generators in it.
- **Grassmann algebra**: all sums of ordinary numbers times monomials, with the
  rules above. An element of it is called a **Grassmann number**. The ordinary
  numbers in front of the monomials are the **coefficients**.
- **Sign of a reordering**: putting the factors of a product into increasing order
  by exchanging neighbours; every exchange of two generators gives a factor $-1$.
  The total factor is $+1$ for an even and $-1$ for an odd number of exchanges.
- **Even, odd**: an element is even if all its monomials have even degree, odd if
  all have odd degree. Even elements commute with everything.
- **Conjugation**: the rule that turns an element $F$ into $F^*$. For complex
  Grassmann numbers the generators come in pairs $\theta$ and $\bar\theta =
  \theta^*$; the conjugation exchanges the two members of every pair, replaces
  every coefficient by its complex conjugate and REVERSES the order of every
  product: $(FG)^* = G^* F^*$. An element with $F^* = F$ is called **real**.
- **Left (right) derivative** $\partial_L F / \partial \theta_k$
  ($\partial_R F / \partial \theta_k$): move $\theta_k$ to the far left (right)
  of every monomial that contains it, collecting a $-1$ for every generator it
  passes, and then delete it.
- **Matrix, transpose, symmetric, antisymmetric, Hermitian**: a table of numbers;
  $M^T$ has rows and columns exchanged; $M$ is symmetric if $M^T = M$,
  antisymmetric if $M^T = -M$, Hermitian if $M^\dagger = M$, where $M^\dagger$ is
  the transpose with every entry complex-conjugated.
- **Bilinear form**: an expression $\sum_{A,B} x_A M_{AB} y_B$ that contains one
  factor from the column $x$ and one from the column $y$ in every term.
```

- **The matrix C**: the author's 16×16 matrix $C = \gamma^{(x_0)} \gamma^{(x_1)} \gamma^{(x_2)} \gamma^{(x_3)}$ (his σ_{16}), read from the Revision file Revision/algebra/gammas.json together with the eight gamma matrices $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$.
- **Scalar density** $S = \bar\Psi\Psi = \Psi^\dagger C \Psi$: the bilinear that the mass term and the potential of the Lagrangian contain.
- **Euler-Lagrange equation**: the field equation obtained from a Lagrangian L by requiring that the action does not change, to first order, when the field is changed a little.
- **Python dictionary**: a table that maps keys to values; here monomials (tuples of generator numbers) to coefficients.

Text cell:

```
## 4. The physical and mathematical situation

**Why anticommuting numbers.** Electrons and the quanta of the field dirac16complex
are fermions: two of them never occupy the same state (the Pauli principle). In the
quantum theory this is expressed by field operators that anticommute. The
classical field from which such operators are obtained is therefore given values
that anticommute: the Revision record defines the components of dirac16complex as
Grassmann numbers (Revision/SPEC.md, section 3). Grassmann numbers are not
measured; they are bookkeeping symbols with exact rules, and every statement of
this notebook is a statement about those rules.

**The two fields of the book.** dirac16complex is a column $\Psi$ of 16 complex
Grassmann numbers $\Psi_1, \dots, \Psi_{16}$ (one complex generator pair per
component and point); dirac16complex00 is a column of 16 ordinary complex numbers.
Both have the same Lagrangian,

$$L = \sqrt{|g|}\,\Big[\tfrac12\big(\bar\Psi\gamma^\mu D_\mu\Psi -
(D_\mu\bar\Psi)\gamma^\mu\Psi\big) - m S - \tfrac{\lambda}{2} S^2\Big],
\qquad S = \bar\Psi\Psi,\quad \bar\Psi = \Psi^\dagger C,$$

(Notebook 07b derives its field equations). The difference between the two fields
is only the kind of numbers, and this notebook shows where that difference
matters: in products of a symbol with itself ($\theta^2 = 0$), in the order of
factors, in which bilinear forms vanish, and in the powers of $S$.

**Rules.** For generators $\theta_0, \dots, \theta_{n-1}$:

$$\theta_i \theta_j = -\theta_j \theta_i \quad\text{for all } i, j,
\qquad\text{hence}\qquad \theta_i \theta_i = 0 .$$

Ordinary numbers commute with every generator. Every product of generators can be
reordered into increasing order; each exchange of two neighbours gives a factor
$-1$. So every element is a unique sum of numbers times the $2^n$ monomials
$\theta_{i_1}\theta_{i_2}\cdots\theta_{i_k}$ with $i_1 < i_2 < \dots < i_k$.
This is exactly how the program stores an element: a dictionary from sorted
tuples $(i_1, \dots, i_k)$ to coefficients.
```

Text cell:

5. The sign of a reordering

The next cell imports the packages and wraps the set-up cell's ‘check‘ so that a PASS line and the line "reproduces ..." that may follow it are printed by one single ‘print‘ call (Jupyter sends printed text in pieces; two separate prints can arrive in two pieces, and the book's tools then do not see that the two lines belong together). Then it defines the function ‘sort_with_sign‘. It sorts a list of generator numbers by exchanging neighbours that stand in the wrong order (the method called bubble sort), counts the exchanges, and returns the sign $(-1)^{\text{exchanges}}$ together with the sorted tuple. If a generator occurs twice, the product contains $\theta_i\theta_i = 0$ and the sign is 0. The cell prints six examples and checks three of them by hand:
$\theta_1\theta_0 = -\theta_0\theta_1$ (one exchange),
$\theta_2\theta_0\theta_1 = +\theta_0\theta_1\theta_2$ (two exchanges) and
$\theta_0\theta_0 = 0$.

## 6. A Grassmann algebra in a few lines of Python

Multiplying two monomials means writing one after the other and sorting. Both are
already sorted, so there is a faster way to get the sign: when the left monomial
is placed before the right one, every pair ($x$ from the left, $y$ from the right)
with $x > y$ is in the wrong order and needs exactly one exchange to be repaired.
So the sign is $(-1)^N$ with $N$ the number of such pairs. The function
‘shuffle_sign‘ counts them with ‘bisect_right‘ (which finds how many entries of a
sorted tuple are at most $y$). The next cell defines it and compares it with the
slow ‘sort_with_sign‘ on 2000 random pairs of monomials.
```

In [3]:

```
def shuffle_sign(left, right):
    """The sign of the product of the sorted monomials left and right: 0 if they
    share a generator, otherwise (-1)**N with N the number of pairs (x in left,
    y in right) with x > y, which is the number of neighbour exchanges needed."""
    if set(left) & set(right):  # a common generator: the product holds theta^2
        return 0
    # len(left) - bisect_right(left, y) entries of left are larger than y
    pairs = sum(len(left) - bisect_right(left, y) for y in right)
    return -1 if pairs % 2 else 1

rng = np.random.default_rng(12345)  # random numbers with a fixed seed: same every run
agree = 0
for trial in range(2000):
```

```
    # two random sorted monomials with generators from 0 .. 9
    left = tuple(sorted(rng.choice(10, size=rng.integers(0, 5), replace=False)))
    right = tuple(sorted(rng.choice(10, size=rng.integers(0, 5), replace=False)))
    agree += shuffle_sign(left, right) == sort_with_sign(left + right)[0]

```

Text cell:

```
Now the algebra itself. An element is stored as a dictionary ‘terms‘ that maps
every monomial (a sorted tuple; ‘()‘ is the number 1) to its coefficient. Adding
two elements adds the coefficients of equal monomials; multiplying multiplies every
term of the first by every term of the second, with the sign of ‘shuffle_sign‘.
A coefficient that becomes zero is deleted, so an element is zero exactly when its
dictionary is empty. The coefficients may be integers or exact sympy numbers and
expressions; a sympy coefficient is multiplied out (‘sp.expand‘) whenever it
changes, so that terms that are equal also look equal and cancel.
```

In [4]:

```
class Grassmann:
    """An element of a Grassmann algebra: self.terms maps every monomial (a sorted
    tuple of generator numbers; () is the number 1) to its coefficient."""

Text cell:

```
The next cell checks the two defining rules and one consequence: every odd element
squares to zero, for example $(3\theta_0 + 5\theta_1)^2 = 15\,\theta_0\theta_1 +
15\,\theta_1\theta_0 = 0$. Then it multiplies two general elements of the algebra
with two generators, $F = a + b\theta_0 + c\theta_1 + d\theta_0\theta_1$ and
$F' = a' + b'\theta_0 + c'\theta_1 + d'\theta_0\theta_1$ (the primes are written
a2, b2, c2, d2 in the code), and compares with the product worked out by hand:

$$FF' = aa' + (ab' + ba')\theta_0 + (ac' + ca')\theta_1 + (ad' + da' + bc' -
cb')\,\theta_0\theta_1 .$$

The term $-cb'$ comes from $c\theta_1\, b'\theta_0 = cb'\,\theta_1\theta_0 =
-cb'\,\theta_0\theta_1$; every product with a repeated generator vanishes.
```

## 7. How big is a Grassmann algebra?

The product $(1 + \theta_0)(1 + \theta_1)\cdots(1 + \theta_{n-1})$ contains every
monomial exactly once, with coefficient $+1$: from each bracket we take either 1 or
$\theta_i$, and the factors come out in increasing order. So the number of its
terms is the number of monomials, the **dimension** of the algebra, which should be
$2^n$ (each generator is either in a monomial or not). The number of monomials of
degree $k$ should be the binomial coefficient $\binom{n}{k}$, the number of ways to
choose $k$ of the $n$ generators. The next cell computes the product for
$n = 0, 1, \dots, 12$, checks both counts, and draws them (Figure 1). For ordinary
commuting symbols there would be infinitely many monomials ($q^2, q^3, \dots$ are
all different); anticommuting symbols give a finite algebra.
```

## 8. The multiplication table of three generators

With three generators the algebra has the eight monomials $1, \theta_0, \theta_1,
\theta_2, \theta_0\theta_1, \theta_0\theta_2, \theta_1\theta_2,
\theta_0\theta_1\theta_2$. The next cell computes the sign of the product of every
monomial (row) with every monomial (column): $+1$, $-1$, or 0 when they share a
generator. A product is nonzero when each of the three generators is in the row
monomial, in the column monomial, or in neither: $3^3 = 27$ possibilities. The
cell checks this count and draws the table as a heat map (Figure 2).
```

In [7]:

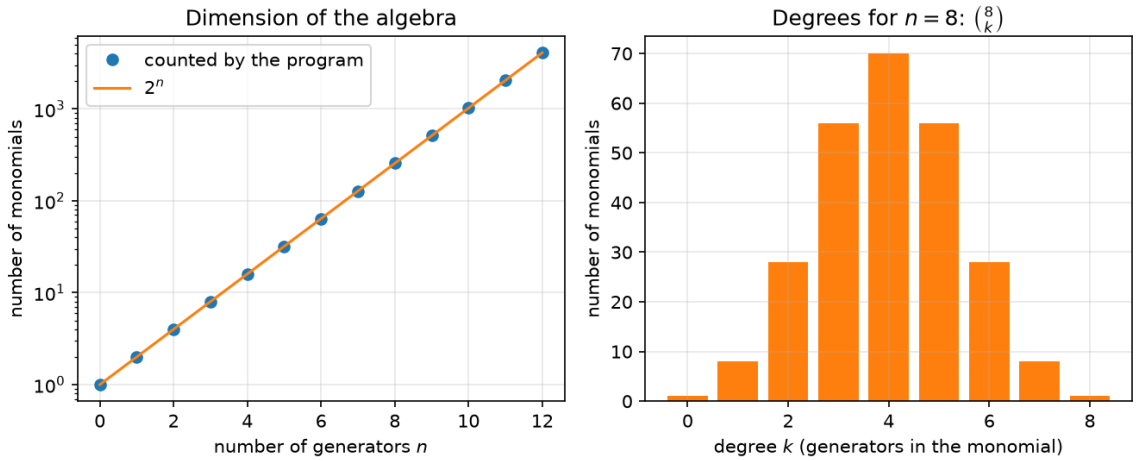

Figure 212: Left: the number of monomials of a Grassmann algebra with n generators, counted by the program (dots), and the formula 2^n (line), for $n = 0$ to 12; horizontal axis n, vertical axis the count on a logarithmic scale, on which 2^n is a straight line. Right: for $n = 8$ the number of monomials of each degree k, the binomial coefficients 1, 8, 28, 56, 70, 56, 28, 8, 1, which add up to $2^8 = 256$. The algebra is finite because no generator can occur twice in a nonzero product. (Notebook 07a, figure 1.)

## 9. Even and odd elements

Moving a monomial $X$ of degree $k$ past a monomial $Y$ of degree $l$ (with no
common generator) moves each of the $k$ generators past each of the $l$ others:
$kl$ exchanges. So

$$YX = (-1)^{kl}\, XY .$$

If $k$ or $l$ is even, the sign is $+1$: an even element commutes with everything.
If both are odd, the sign is $-1$: odd elements anticommute. The next cell measures
the sign for $k, l = 0, \dots, 4$ with $X = \theta_0\cdots\theta_{k-1}$ and $Y =
\theta_5\cdots\theta_{5+l-1}$, checks it against $(-1)^{kl}$ and draws Figure 3.
This is why the Lagrangian of dirac16complex, which contains the components in
pairs (it is even), behaves like an ordinary number in the order of factors.
```

## 10. Conjugation reverses the order

For complex Grassmann numbers the generators come in pairs, $\theta_k$ and
$\bar\theta_k = \theta_k^*$. The conjugation exchanges the members of every pair,
conjugates every coefficient, and reverses every product:

$$(\theta_1\theta_2)^* = \theta_2^*\theta_1^* = \bar\theta_2\bar\theta_1 .$$

Why reverse? With this rule the conjugate of $\bar\theta\theta$ is
$\theta^*\bar\theta^* = \bar\theta\theta$: the product of a complex Grassmann
number with its conjugate is real, as for ordinary numbers. The function
‘conjugate‘ below takes a list ‘partner‘, with ‘partner[g]‘ the generator that
the conjugation assigns to generator ‘g‘, reverses each monomial, replaces each
generator by its partner, sorts back with ‘sort_with_sign‘ and conjugates the
coefficient with sympy.

The cell first defines the helper ‘reproduces(report, name)‘: it reads the Revision
report (a JSON file), makes sure that it contains the check ‘name‘ with the verdict
PASS, and returns the text that the PASS line prints after "reproduces". The cell
then checks the rules that the Revision record checks for its own algebras. For
the Wolfram test algebra (generators $\theta_1, \theta_2$ and
$\bar\theta_1, \bar\theta_2$, numbered 0, 1, 2, 3 here): anticommutation,
$\theta_i^2 = 0$, $(\theta_1\theta_2)^* = \bar\theta_2\bar\theta_1$ and
$(F^*)^* = F$. For the jet super-algebra of the sympy record, with 16 complex
components $\psi_A$ and their conjugates $\chi_A = \psi_A^*$ (numbered $A$ and
$16 + A$ here): $\psi\psi = 0$, $\psi_A\psi_B = -\psi_B\psi_A$,
$(\chi_A\psi_B)^* = \chi_B\psi_A$ (order reversal) and $(i\chi_A\psi_A)^* =
-i\chi_A\psi_A$.
```

## 11. Left and right derivatives

The left derivative $\partial_L F/\partial\theta_k$ moves $\theta_k$ to the far
left of each monomial that contains it (a $-1$ for every generator passed) and
deletes it; the right derivative moves it to the far right. In a sorted monomial
$\theta_k$ stands at a position $p$ (counting from 0); moving it left passes $p$
generators, moving it right passes $\text{degree} - 1 - p$. Examples worked by
hand for $F = \theta_0\theta_1$: $\partial_L F/\partial\theta_0 = \theta_1$,
$\partial_L F/\partial\theta_1 = -\theta_0$ (write $F = -\theta_1\theta_0$),
```

$\partial_R F/\partial\theta_1 = \theta_0$, $\partial_R F/\partial\theta_0 =
-\theta_1$.

For an EVEN monomial of degree n the two signs differ by
$(-1)^{(n-1-p) - p} = (-1)^{n-1} = -1$, so $\partial_R F = -\partial_L F$ for
every even F. The next cell defines both derivatives, checks the four examples,
the rule for even elements on a random even element, and the derivative rules of
the sympy record: for $x = \chi_0$, $a = \psi_0$, $y = \psi_1$ and $p = xay$:
$\partial_L p/\partial y = \partial_R p/\partial y = xa$ and $\partial_L
p/\partial a = \partial_R p/\partial a = -xy$; for $q = xa$: $\partial_L
q/\partial a = -x$ and $\partial_R q/\partial a = +x$.

## 12. Bilinear forms: when is $\Psi^\dagger M \Psi$ real?

Take a column $\Psi$ of $n$ complex Grassmann numbers (generators $\psi_A$, numbered
$A$) and its conjugate row $\Psi^\dagger$ (generators $\chi_A = \psi_A^*$, numbered
$n + A$). For a matrix $M$ of ordinary numbers the conjugation rules give, in two
lines,

$$\big(\Psi^\dagger M \Psi\big)^* = \sum_{A,B} \big(\chi_A M_{AB} \psi_B\big)^*
= \sum_{A,B} M_{AB}^*\, \chi_B \psi_A = \Psi^\dagger M^\dagger \Psi .$$

The first equality is the definition of the bilinear form; the second is the
conjugation rule $(\chi_A\psi_B)^* = \psi_B^*\chi_A^* = \chi_B\psi_A$ (order
reversed, partners exchanged) with the conjugated coefficient; the third renames
the summation indices and uses $(M^\dagger)_{BA} = M_{AB}^*$. So the form is real
exactly when $M$ is Hermitian, the same rule as for ordinary complex numbers. The
reversal of the order is what makes the rule come out the same. The next cell
checks this with $n = 4$ for a random Hermitian $M$ (real) and a random
non-Hermitian $M$ (not real).
```

In [11]:

```
def bilinear(row, M, column):
    """sum over A, B of row[A] M[A, B] column[B] (one factor from each side)."""
    total = Grassmann()

## 13. Real Grassmann columns and the author's matrix $C$

Now take a REAL column $\Theta = (\theta_0, \dots, \theta_{15})^T$ of 16 real
Grassmann generators (no conjugates at all) and the form $\Theta^T M \Theta =
\sum_{A,B} \theta_A M_{AB} \theta_B$. Exchanging the two odd factors and renaming
the indices gives, line by line,

$$\Theta^T M \Theta = \sum_{A,B} \theta_A M_{AB} \theta_B = -\sum_{A,B} \theta_B
M_{AB} \theta_A = -\sum_{A,B} \theta_A (M^T)_{AB} \theta_B = -\Theta^T M^T \Theta .$$

The second step is the anticommutation of $\theta_A$ and $\theta_B$; the third
renames $A \leftrightarrow B$ and uses $(M^T)_{AB} = M_{BA}$. Hence the symmetric
part of $M$ drops out: **for a real Grassmann column only the antisymmetric part of
$M$ survives, and $\Theta^T M \Theta = 0$ for every symmetric $M$.** For a real
column $q$ of ordinary numbers it is the other way round: $q^T M q = q^T M^T q$, so
only the symmetric part survives and $q^T M q = 0$ for every antisymmetric $M$.

The author's matrix $C$ is symmetric and each $C\gamma^{(a)}$ is antisymmetric.
The next cell reads $C$ and the eight gamma matrices from the Revision record
Revision/algebra/gammas.json, checks these two properties, and computes the nine
forms $\Theta^T C \Theta$ and $\Theta^T C \gamma^{(a)} \Theta$ ($a = x_0, \dots,
x_7$) both for real Grassmann $\Theta$ (with the program) and for real ordinary
numbers $q$ (with sympy), counting the monomials that survive.
```

In [12]:

## 14. The scalar density $S$ of a 16-component field and its powers

At one point the field dirac16complex consists of 16 complex Grassmann numbers. We
use 32 generators: $\chi_A = \Psi_A^*$ (numbers 0 to 15) and $\psi_A = \Psi_A$
(numbers 16 to 31). The scalar density is

$$S = \Psi^\dagger C \Psi = \sum_{A,B} \chi_A C_{AB} \psi_B .$$

Every row of $C$ has exactly one entry $\pm1$, in the column $\pi(A)$, so $S =
\sum_A C_{A\pi(A)}\, P_A$ is a sum of 16 pairs $P_A = \chi_A\psi_{\pi(A)}$ that
share no generator. Each pair is even, so the pairs commute with each other, and
$P_A^2 = 0$. In $S^k$ only products of $k$ DIFFERENT pairs survive, and each such
product appears $k!$ times (once for every order of its factors). Hence $S^k$ has
$\binom{16}{k}$ monomials with coefficients $\pm k!$, $S^{16}$ is a single
monomial, and $S^{17} = 0$. Consequence for the Lagrangian: every function of $S$
is a polynomial of degree at most 16, so the potential $U(S) = \frac{\lambda}{2}
S^2$ is a choice among finitely many terms. For ordinary commuting numbers the
same $S$ has powers that never vanish; $S^k$ then has $\binom{16 + k - 1}{k}$
monomials (the number of ways to choose $k$ pairs with repetition).

The next cell computes $S, S^2, \dots, S^{17}$ with the program (about one second),
checks the counts and the coefficients, checks the commuting counts with sympy for
$k \le 3$, and draws Figure 6.

## 15. The Revision test algebra with two generators
```

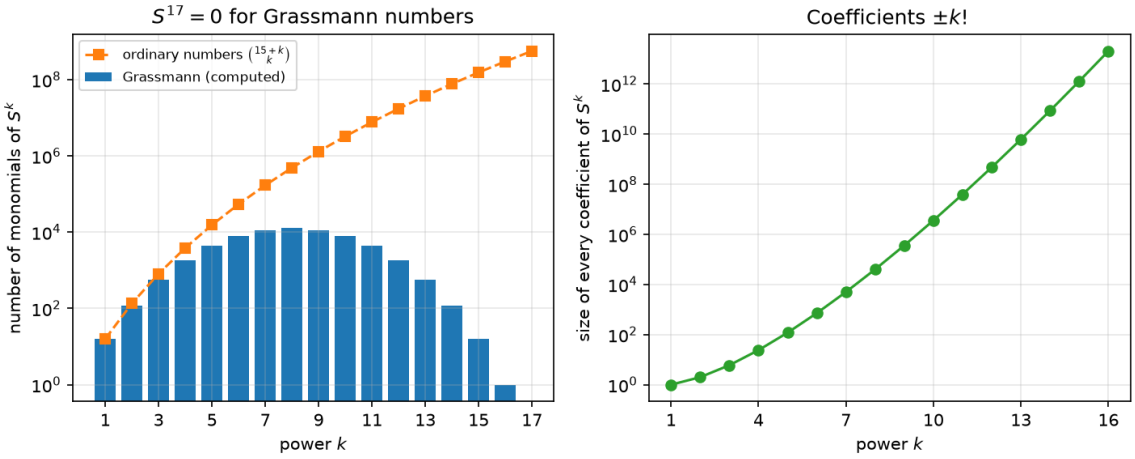

Figure 217: Left: the number of monomials of S^k, the k-th power of the scalar density $S = \Psi^\dagger C \Psi$ of a 16-component field at one point, for $k = 1$ to 17 (logarithmic vertical axis). Blue bars: complex Grassmann components, computed by the program; the counts rise and fall as $\binom{16}{k}$ and $S^{17} = 0$ (no bar). Orange squares: ordinary commuting components, $\binom{15+k}{k}$, which grow without end. Right: every coefficient of S^k is $\pm k!$, from 1 to 16! $\approx 2.1 \times 10^{13}$. (Notebook 07a, figure 6.)

```
The Wolfram verifier of the Revision record does not give every component its own
generator. It uses an algebra with only two generators $\theta_1, \theta_2$ and
their conjugates $\bar\theta_1, \bar\theta_2$, and writes each component as
$\Psi_A = c_{A1}\theta_1 + c_{A2}\theta_2$ with ordinary complex coefficients. That
keeps the computation small and is still a genuine Grassmann field. Then

$$S = \Psi^\dagger C \Psi = \sum_{k,l} \bar\theta_k\theta_l\, \big(c_k^\dagger C
c_l\big),$$

so $S$ lives only on the four monomials $\bar\theta_k\theta_l$ (it is even),
$S^2$ only on $\theta_1\theta_2\bar\theta_1\bar\theta_2$, and $S^3 = 0$ because it
would need six different generators out of four. Hence in this test algebra the
most general potential is $U = u_1 S + \frac{\lambda}{2} S^2$. The next cell
builds such a field with random Gaussian-integer coefficients (fixed seed) and
checks all of this, and that $S$ is real ($C$ is real and symmetric, hence
Hermitian).

## 16. Field equations with Grassmann numbers: the oscillator

A field depends on a coordinate. To vary a Lagrangian we treat the value of a
variable and its derivative at one point as independent symbols (they are called
**jets**). Here the variable is a complex Grassmann number $\theta(t)$ of one
variable $t$; the generators are $\bar\theta$ (number 0), $\theta$ (1),
$\bar\theta'$ (2), $\theta'$ (3), and the second derivatives
$\bar\theta^{\prime\prime}$ (4), $\theta^{\prime\prime}$ (5); the prime is $d/dt$.
The **total derivative** $d/dt$ raises each generator by 2 (from $\theta$ to
$\theta'$, from $\theta'$ to $\theta^{\prime\prime}$) in each place, with the
product rule; it is even, so it needs no extra sign, but the raised generator may
have to be sorted back into place.

The Lagrangian of the oscillator,

$$L = \tfrac{i}{2}\big(\bar\theta\theta' - \bar\theta'\theta\big) -
\omega\,\bar\theta\theta ,$$

is real. Varying $\bar\theta$ from the left gives the Euler-Lagrange expression

$$\mathcal{E} = \frac{\partial_L L}{\partial\bar\theta} - \frac{d}{dt}\,
\frac{\partial_L L}{\partial\bar\theta'}
= \Big(\tfrac{i}{2}\theta' - \omega\theta\Big) - \frac{d}{dt}\Big(-\tfrac{i}{2}
\theta\Big) = i\theta' - \omega\theta .$$

The first term: $\bar\theta$ already stands on the left of $\bar\theta\theta'$
and $\bar\theta\theta$; the second: $-\frac{i}{2}\bar\theta'\theta$ has
$\bar\theta'$ on the left, its derivative is $-\frac{i}{2}\theta$, whose $d/dt$ is
$-\frac{i}{2}\theta'$. The field equation $i\theta' = \omega\theta$ has the same
form as for an ordinary complex oscillator. The next cell computes $\mathcal{E}$
with the program and checks that $L$ is real.
```

In [17]:

```
def total_derivative(element, step):
    """d/dt on jets: every generator g in every place becomes g + step (from a
```

```
    variable to its derivative), with the product rule; the raised monomial is
    sorted back with its sign."""
    result = Grassmann()
    for monomial, coefficient in element.terms.items():
        for place, g in enumerate(monomial):
            raised = monomial[:place] + (g + step,) + monomial[place + 1:]
            sign, ordered = sort_with_sign(raised)

## 17. A first-order kinetic term of real Grassmann fields

Now two REAL Grassmann fields $\theta_0(x)$, $\theta_1(x)$ of one coordinate $x$
(generators: $\theta_0$ = 0, $\theta_1$ = 1, $\theta_0'$ = 2, $\theta_1'$ = 3,
$\theta_0^{\prime\prime}$ = 4, $\theta_1^{\prime\prime}$ = 5) and the first-order
kinetic term with the antisymmetric matrix $A = \begin{pmatrix} 0 & 1 \\ -1 & 0
\end{pmatrix}$:

$$K_A = \theta^T A\, \theta' = \theta_0\theta_1' - \theta_1\theta_0' .$$

Moving $\theta_0'$ to the left in the second term (one exchange) gives
$K_A = \theta_0\theta_1' + \theta_0'\theta_1 = (\theta_0\theta_1)'$ by the
product rule, and $\theta^T A\theta = \theta_0\theta_1 - \theta_1\theta_0 =
2\theta_0\theta_1$. So $K_A = \frac12(\theta^T A\theta)'$ is a **total
derivative**, and a total derivative gives no field equation: both
Euler-Lagrange expressions vanish identically. With the symmetric identity matrix
instead, $K_I = \theta_0\theta_0' + \theta_1\theta_1'$ is not a derivative and its
Euler-Lagrange expression for $\theta_0$ is $\theta_0' - \frac{d}{dx}(-\theta_0) =
2\theta_0'$. For ORDINARY numbers $q_0, q_1$ the roles are exchanged: $K_A$ gives
the nonzero expressions $2q_1'$ and $-2q_0'$. This is the one-dimensional model of
the Majorana-type negative control of the Revision record (a real anticommuting
field with the antisymmetric kinetic matrices $C\gamma^\mu$ has no field equation),
which Notebook 07c computes in the author's metric. The next cell checks all of
it, with sympy for the ordinary numbers.
```

In [19]:

```
th0, th1_, th0_d, th1_d = theta(0), theta(1), theta(2), theta(3)

```
## 19. What this notebook showed

- A Grassmann algebra is completely fixed by $\theta_i\theta_j = -\theta_j\theta_i$:
  a product is the sorted monomial times the sign $(-1)^{\text{exchanges}}$, or 0
  when a generator repeats. With $n$ generators there are exactly $2^n$
  monomials, $\binom{n}{k}$ of degree $k$.
- Even elements commute with everything, odd ones anticommute
  ($YX = (-1)^{kl}XY$); the Lagrangian, which contains the field in pairs, is even.
- The conjugation reverses the order of products; with that rule a bilinear form
  $\Psi^\dagger M\Psi$ is real exactly when $M$ is Hermitian, for Grassmann and for
  ordinary numbers alike. For even elements the right derivative is minus the left
```

```
  derivative.
- For a REAL column the two kinds of numbers keep opposite halves of a matrix: real
  Grassmann numbers keep the antisymmetric part ($\Theta^T C\Theta = 0$, every
  $\Theta^T C\gamma^{(a)}\Theta$ survives), real ordinary numbers the symmetric
  part.
- The scalar density $S$ of the 16-component complex Grassmann field satisfies
  $S^{17} = 0$; $S^k$ has $\binom{16}{k}$ monomials with coefficients $\pm k!$. In
  the two-generator test algebra of the Revision record $S^3 = 0$ already.
- With Grassmann numbers written with every conjugate on the left, field equations
  keep their ordinary form (the oscillator gives $i\theta' = \omega\theta$); but a
  first-order kinetic term of REAL Grassmann fields with an antisymmetric matrix is
  a total derivative and gives no field equation. This is why the Lagrangian of
  dirac16complex uses the complex field with $\bar\Psi = \Psi^\dagger C$.
- The rules reproduce the Grassmann-algebra checks of the Revision record
  (superalgebra_axioms, grassmann_algebra_structure, C_properties, and the parts of
  Majorana_Lg_total_derivative_grassmann and Majorana_Lg_commuting_control that
  concern the bilinear forms).
```

7.17 Line-by-line walk-through of Notebook 07a

The notebook has 20 code cells, In [1] to In [20]. This section explains every line of every one of them, with the conventions of Section 7.9 (comments, docstrings, and `...`) for the rest of a long caption, which is printed in full under its figure in Section 7.16).

In [1], the set-up cell. It is the set-up cell of Notebook 07d with one difference: the line `NOTEBOOK_ID = "07a"`. Its first part repeats the complete run instructions of Section 7.15 as comment lines; its code is explained line by line in Section 7.9. **Out [1]:** `Set-up of notebook 07a complete: repository folder found, helpers defined.`

In [2]: the sign of a reordering.

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)
import math  # factorials and binomial coefficients
from bisect import bisect_right  # counts the entries of a sorted tuple that are <= y
from collections import Counter  # counts how often each value occurs

import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
```

The modules used by the notebook: `contextlib` and `io` for the combined printing of a PASS line (explained below), `math` for factorials and binomial coefficients, `bisect_right` from the module `bisect` (it finds how many entries of a sorted tuple are at most a given number), `Counter` from `collections` (it counts how often each value occurs), numpy and sympy.

```
check_of_the_setup = check  # the helper check of the set-up cell

def check(condition, name, record=None):
    """The set-up cell's check, with its PASS line and its "reproduces" line
    printed by ONE print call, so that Jupyter delivers them together."""
```

```
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # collect what check prints
        check_of_the_setup(condition, name, record)
    print(buffer.getvalue(), end="")  # and print it in one piece
```

The same wrapper of `check` as in Notebook 07d (Section 7.9, In [2]): the set-up cell's check runs while its printed text is collected in `buffer`, and the collected text is then printed in one piece, so that a PASS line and its "reproduces" line reach the book's tools together.

```
def sort_with_sign(generators):

            if items[i] > items[i + 1]:  # a pair in the wrong order:
                items[i], items[i + 1] = items[i + 1], items[i]  # exchange it,
                sign = -sign  # which costs one factor -1
    if any(items[i] == items[i + 1] for i in range(len(items) - 1)):
        return 0, tuple(items)  # a repeated generator: theta_i theta_i = 0
    return sign, tuple(items)
```

`sort_with_sign(generators)` sorts a list of generator numbers by the method called **bubble sort** and counts the exchanges. `items` is a copy of the input that may be reordered, and `sign` starts at +1. The outer loop makes passes over shorter and shorter beginnings of the list (`range(len(items) - 1, 0, -1)` counts down from the last position to 1); in each pass the inner loop looks at every neighbour pair, and when a pair stands in the wrong order it is exchanged (`items[i], items[i + 1] = items[i + 1], items[i]` swaps two entries in one line) and the sign is reversed. After a pass the largest remaining number has bubbled to the end, so the list is sorted after the last pass. If two equal neighbours remain, a generator occurs twice and the function returns the sign 0 (the product contains $\theta_i\theta_i = 0$); otherwise it returns the sign and the sorted tuple.

```
for example in [(0, 1), (1, 0), (2, 0, 1), (2, 1, 0), (0, 0), (3, 1, 2, 0)]:
    sign, ordered = sort_with_sign(example)
    say(f"generators {example} -> sign {sign:+d}, sorted {ordered}")
check(sort_with_sign((1, 0)) == (-1, (0, 1)), "theta_1 theta_0 = -theta_0 theta_1")
check(sort_with_sign((2, 0, 1)) == (1, (0, 1, 2)),
      "theta_2 theta_0 theta_1 = +theta_0 theta_1 theta_2 (two exchanges)")
check(sort_with_sign((0, 0))[0] == 0, "theta_0 theta_0 = 0")
```

Six examples are sorted and printed (`{sign:+d}` prints a whole number with its sign). The three checks are the examples of Section 7.10: one exchange for $\theta_1\theta_0$, two for $\theta_2\theta_0\theta_1$, and 0 for $\theta_0\theta_0$. **Out [2]:** six lines such as `generators (2, 0, 1) -> sign +1, sorted (0, 1, 2)` and `generators (3, 1, 2, 0) -> sign -1, sorted (0, 1, 2, 3)` (five exchanges), and three PASS lines.

In [3]: a faster sign rule.

```
def shuffle_sign(left, right):
    """The sign of the product of the sorted monomials left and right: 0 if they
    share a generator, otherwise (-1)**N with N the number of pairs (x in left,
    y in right) with x > y, which is the number of neighbour exchanges needed."""
    if set(left) & set(right):  # a common generator: the product holds theta^2
        return 0
    # len(left) - bisect_right(left, y) entries of left are larger than y
    pairs = sum(len(left) - bisect_right(left, y) for y in right)
    return -1 if pairs % 2 else 1
```

`shuffle_sign(left, right)` gives the sign of the product of two monomials that are already sorted. `set(left) & set(right)` is the set of the generators that both contain; if it is not empty, the product holds a square and the sign is 0. Otherwise, placing `left` before `right`, each pair (x from the left, y from the right) with $x > y$ stands in the wrong order and needs exactly one exchange, and no other pair does. For each y of the right factor, `bisect_right(left, y)` is the number of entries of `left` that are at most y, so `len(left) - bisect_right(left, y)` is the number larger than y. Their total `pairs` decides the sign: -1 if it is odd (`pairs % 2` is the remainder after division by 2), $+1$ if even.

```
rng = np.random.default_rng(12345)  # random numbers with a fixed seed: same every run
agree = 0
for trial in range(2000):
    # two random sorted monomials with generators from 0 .. 9
    left = tuple(sorted(rng.choice(10, size=rng.integers(0, 5), replace=False)))
    right = tuple(sorted(rng.choice(10, size=rng.integers(0, 5), replace=False)))
    agree += shuffle_sign(left, right) == sort_with_sign(left + right)[0]
report("random pairs of monomials on which the two sign rules agree", f"{agree} of 2000")
check(agree == 2000, "shuffle_sign equals sort_with_sign on 2000 random pairs")
```

A random-number generator with the fixed seed 12345. In each of 2000 trials two random sorted monomials are drawn: `rng.integers(0, 5)` is a random degree from 0 to 4 and `rng.choice(10, size=..., replace=False)` that many different generators out of 0 to 9; `sorted` and `tuple` put them in increasing order. `agree` counts the trials in which the fast rule gives the same sign as sorting the joined list (`left + right` joins two tuples; a true comparison counts as 1). **Out [3]:** `RESULT random pairs of monomials on which the two sign rules agree = 2000 of 2000` and the PASS line.

In [4]: the algebra itself.

```
class Grassmann:
    """An element of a Grassmann algebra: self.terms maps every monomial (a sorted
    tuple of generator numbers; () is the number 1) to its coefficient."""

    def __init__(self, terms=None):
        self.terms = {}
        for monomial, coefficient in (terms or {}).items():
            self.add(monomial, coefficient)
```

A **class** is a recipe for a new kind of object. Every object of the class `Grassmann` holds a dictionary `self.terms` from monomials (sorted tuples; `()` is the number 1) to coefficients. `__init__` is the

function that runs when an object is made: it starts with an empty dictionary and adds the given terms one by one (`terms or {}` uses an empty dictionary when none is given).

```
    def add(self, monomial, coefficient):
        """Add coefficient times monomial to this element (in place)."""
        total = self.terms.get(monomial, 0) + coefficient
        if isinstance(total, sp.Basic):  # an exact sympy number or expression:
            total = sp.expand(total)  # multiply out, so that equal terms cancel
        if total == 0:
            self.terms.pop(monomial, None)  # a zero coefficient is not stored
        else:
            self.terms[monomial] = total
```

`add` adds a coefficient times a monomial to the object itself. `self.terms.get(monomial, 0)` is the stored coefficient or 0. If the sum is an exact sympy expression (`isinstance(total, sp.Basic)`), it is multiplied out with `sp.expand`, so that terms that are equal also look equal and cancel. A coefficient that has become zero is removed (`pop(monomial, None)` removes the key if it is there), so an element is zero exactly when its dictionary is empty.

```
    def __add__(self, other):  # self + other
        result = Grassmann(self.terms)
        for monomial, coefficient in other.terms.items():
            result.add(monomial, coefficient)
        return result

    def scaled(self, factor):  # factor * self, factor an ordinary number
        return Grassmann({m: factor * c for m, c in self.terms.items()})

    def __sub__(self, other):  # self - other
        return self + other.scaled(-1)
```

`__add__` defines what `+` does for two elements: a copy of the first with every term of the second added. `scaled(factor)` multiplies every coefficient by an ordinary number. `__sub__` defines `-` as adding the second element multiplied by -1.

```
    def __mul__(self, other):  # self * other: every term times every term
        result = Grassmann()
        for left, a in self.terms.items():
            for right, b in other.terms.items():
                sign = shuffle_sign(left, right)
                if sign != 0:
                    result.add(tuple(sorted(left + right)), sign * a * b)
        return result

    def is_zero(self):
        return not self.terms  # True when no monomial is left
```

`__mul__` defines `*`: every term of the first element times every term of the second. For two monomials `left` and `right` the sign comes from `shuffle_sign`; if it is not 0, the joined and sorted monomial gets the product of the two coefficients times the sign. `is_zero` is true when no monomial is left.

```
def number(value):
    """The ordinary number value as an element of the algebra."""
    return Grassmann({(): value})

def theta(i):
    """The generator number i."""
    return Grassmann({(i,): 1})

say("The class Grassmann and the helpers number and theta are defined.")
```

Two helpers: `number(value)` is an ordinary number as an element (the monomial `()` with that coefficient), and `theta(i)` is the generator number `i` (the monomial `(i,)` with coefficient 1; the comma makes a tuple of one entry). **Out [4]:** `The class Grassmann and the helpers number and theta are defined.`

In [5]: the defining rules and a product worked by hand.

```
t0, t1, t2 = theta(0), theta(1), theta(2)
check((t0 * t1 + t1 * t0).is_zero(), "theta_0 theta_1 + theta_1 theta_0 = 0")
check((t0 * t0).is_zero() and (t2 * t2).is_zero(), "a generator squares to zero")
odd = t0.scaled(3) + t1.scaled(5)  # the odd element 3 theta_0 + 5 theta_1
check((odd * odd).is_zero(), "(3 theta_0 + 5 theta_1)^2 = 0")
```

`t0`, `t1`, `t2` are the generators $\theta_0, \theta_1, \theta_2$. The three checks: $\theta_0\theta_1 + \theta_1\theta_0 = 0$; $\theta_0^2 = \theta_2^2 = 0$; and $(3\theta_0 + 5\theta_1)^2 = 0$ (Section 7.11).

```
a, b, c, d, a2, b2, c2, d2 = sp.symbols("a b c d a2 b2 c2 d2")  # 8 ordinary numbers
F = number(a) + t0.scaled(b) + t1.scaled(c) + (t0 * t1).scaled(d)
F2 = number(a2) + t0.scaled(b2) + t1.scaled(c2) + (t0 * t1).scaled(d2)
by_hand = {(): a * a2, (0,): a * b2 + b * a2, (1,): a * c2 + c * a2,
           (0, 1): a * d2 + d * a2 + b * c2 - c * b2}
product = F * F2
same = sorted(product.terms) == sorted(by_hand) and all(
    sp.expand(product.terms[key] - value) == 0 for key, value in by_hand.items())
say(f"coefficient of theta_0 theta_1 in F F': {product.terms[(0, 1)]}")
check(same, "the product of two general elements of a 2-generator algebra")
```

Eight ordinary sympy symbols for the coefficients of F and F' (the primes are written a2, b2, c2, d2). `F` and `F2` are the two general elements of Section 7.10, `by_hand` the dictionary of the product worked out there. `same` is true when the computed product has exactly the same monomials (`sorted(product.terms)` lists them in order) and every coefficient agrees after multiplying out. **Out [5]:** four PASS lines and the coefficient `a*d2 + a2*d + b*c2 - b2*c` of $\theta_0\theta_1$, with the minus sign of the exchange.

In [6]: the dimension, and Figure 07a.1.

```
sizes = []  # the number of monomials for n = 0, 1, ..., 12
for n in range(13):
```

```
    everything = number(1)
    for i in range(n):
        everything = everything * (number(1) + theta(i))  # (1 + theta_i)
    sizes.append(len(everything.terms))
    if n == 8:
        degrees8 = Counter(len(monomial) for monomial in everything.terms)
        ones8 = all(value == 1 for value in everything.terms.values())
report("number of monomials for n = 12 generators", sizes[12])
check(sizes == [2 ** n for n in range(13)], "a Grassmann algebra with n generators "
      "has 2^n monomials (n = 0 to 12)")
check(ones8 and all(degrees8[k] == math.comb(8, k) for k in range(9)),
      "for n = 8 there are binom(8, k) monomials of degree k, each coefficient +1")
```

For $n = 0$ to 12 the product $(1+\theta_0)\cdots(1+\theta_{n-1})$ is computed, starting from the number 1, and the number of its monomials is stored. For $n = 8$, `Counter(len(monomial) ...)` counts the monomials of each degree and `ones8` records whether every coefficient is $+1$. The first check compares the counts with 2^n, the second the degrees with `math.comb(8, k)` $= \binom{8}{k}$. **Out [6]:** `RESULT number of monomials for n = 12 generators = 4096` and two PASS lines.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
left.semilogy(range(13), sizes, "o", label="counted by the program")
left.semilogy(range(13), [2 ** n for n in range(13)], "-", label="$2^n$")
left.set_xlabel("number of generators $n$")
left.set_ylabel("number of monomials")
left.set_title("Dimension of the algebra")
left.legend()
right.bar(range(9), [degrees8[k] for k in range(9)], color="tab:orange")
right.set_xlabel("degree $k$ (generators in the monomial)")
right.set_ylabel("number of monomials")
right.set_title("Degrees for $n = 8$: $\\binom{8}{k}$")
fig.tight_layout()
save_figure(fig, "dimension_and_degrees",
...)
```

Left: the counts as dots and 2^n as a line on a logarithmic vertical axis (`semilogy`). Right: a bar chart (`bar`) of the number of monomials of each degree for $n = 8$. **What Figure 07a.1 shows.** On the logarithmic axis 2^n is a straight line and the dots lie on it: each new generator doubles the algebra. The bars are the binomial coefficients 1, 8, 28, 56, 70, 56, 28, 8, 1, symmetric around degree 4.

In [7]: the multiplication table, and Figure 07a.2.

```
basis3 = [(), (0,), (1,), (2,), (0, 1), (0, 2), (1, 2), (0, 1, 2)]
names3 = ["$1$"] + ["$" + "".join(f"\\theta_{i}" for i in m) + "$" for m in basis3[1:]]
table = np.array([[shuffle_sign(row, column) for column in basis3] for row in basis3])
nonzero = int(np.count_nonzero(table))
report("nonzero products among the 64 products of the 8 monomials", nonzero)
check(nonzero == 27, "27 = 3^3 of the 64 products of monomials of 3 generators are "
      "nonzero")
check(np.array_equal(table[1:4, 1:4], -table[1:4, 1:4].T),
      "the table of the three generators is antisymmetric")
```

`basis3` lists the eight monomials of three generators, `names3` their labels for the plot (`"".join( ...)` joins the texts θ_i of one monomial; a doubled backslash in a Python string is one backslash for LaTeX). `table` is the 8×8 array of the signs of all products, row = left factor, column = right factor. `np.count_nonzero` counts the nonzero entries. The first check requires 27; the second checks that the block of the three single generators (rows and columns 1 to 3; `table[1:4, 1:4]`) is antisymmetric. **Out [7]:** `RESULT nonzero products among the 64 products of the 8 monomials = 27` and two PASS lines.

```
fig, ax = plt.subplots(figsize=(6.4, 5.4))
image = ax.imshow(table, cmap="coolwarm", vmin=-1, vmax=1)
for i in range(8):
    for j in range(8):
        ax.text(j, i, {1: "+", -1: "-", 0: "0"}[int(table[i, j])], ha="center",
                va="center", fontsize=12)
ax.set_xticks(range(8), names3, rotation=45)
ax.set_yticks(range(8), names3)
ax.set_xlabel("right factor")
ax.set_ylabel("left factor")
ax.set_title("Sign of (left factor) times (right factor)")
ax.grid(False)
fig.colorbar(image, ax=ax, ticks=[-1, 0, 1], shrink=0.8)
save_figure(fig, "multiplication_signs",
...)
```

`imshow` draws the table as a **heat map**, one coloured square per entry (red $+1$, blue -1, grey 0), and the two loops write $+$, $-$ or 0 into each square (`ha` and `va` centre the text). The ticks carry the monomial names, rotated by 45 degrees under the horizontal axis. **What Figure 07a.2 shows.** The first row and column (the factor 1) are all $+$; every product with a shared generator is grey; the 3×3 block of single generators has $+$ above and $-$ below the grey diagonal: $\theta_i\theta_j = -\theta_j\theta_i$.

In [8]: even and odd, and Figure 07a.3.

```
signs = np.zeros((5, 5), dtype=int)
for k in range(5):
    for l in range(5):
        X = number(1)
        for i in range(k):
            X = X * theta(i)  # theta_0 ... theta_(k-1)
        Y = number(1)
        for i in range(l):
            Y = Y * theta(5 + i)  # theta_5 ... theta_(4+l)
        XY, YX = X * Y, Y * X
        (monomial, value), = XY.terms.items()  # XY is one monomial
        signs[k, l] = YX.terms[monomial] // value  # +1 or -1
expected = np.array([[(-1) ** (k * l) for l in range(5)] for k in range(5)])
check(np.array_equal(signs, expected), "YX = (-1)^(k l) XY for degrees k, l = 0 .. 4")
```

For degrees $k, l = 0$ to 4, `X` is the monomial $\theta_0 \cdots \theta_{k-1}$ and `Y` the monomial $\theta_5 \cdots \theta_{4+l}$ (no common generator). Both products `X * Y` and `Y * X` are formed. `(monomial, value), = XY.terms.it ems()` unpacks the single term of `XY` (the trailing comma says "exactly one item"), and the sign

is the coefficient of the same monomial in `YX` divided by `value` (`//` divides whole numbers). The check compares the table of signs with $(-1)^{kl}$. **Out [8]:** one PASS line.

```
fig, ax = plt.subplots(figsize=(5.6, 4.6))
image = ax.imshow(signs, cmap="coolwarm", vmin=-1, vmax=1)
for k in range(5):
    for l in range(5):
        ax.text(l, k, f"{signs[k, l]:+d}", ha="center", va="center", fontsize=12)
ax.set_xticks(range(5))
ax.set_yticks(range(5))
ax.set_xlabel("degree $l$ of $Y$")
ax.set_ylabel("degree $k$ of $X$")
ax.set_title("$YX = (\\pm 1)\\, XY$")
ax.grid(False)
fig.colorbar(image, ax=ax, ticks=[-1, 1], shrink=0.8)
save_figure(fig, "commutation_signs",
...)
```

A heat map of the 5×5 signs with the numbers written in. **What Figure 07a.3 shows.** Only the squares where both degrees are odd (1 and 3) are blue: two odd monomials anticommute. Every row and column of even degree is red: an even monomial commutes with everything.

In [9]: the conjugation.

```
def reproduces(report, name):
    """The text "<report>, check <name>" for a PASS line, after making sure that
    the Revision report (a JSON file) contains the check name with verdict PASS."""
    data = json.loads(repository_file(report).read_text(encoding="utf-8"))
    found = [item for item in data["checks"] if item["name"] == name]
    if len(found) != 1 or found[0]["verdict"].upper() != "PASS":
        raise ValueError(f"{name} is not a passing check of {report}")
    return f"{report}, check {name}"

WLREP = "Revision/theory/reports/wolfram-field-theory.json"
PYREP = "Revision/theory/reports/python-field-theory.json"
```

`reproduces(report, name)` reads a Revision report, makes sure that it holds exactly one check of that name with the verdict PASS, and returns the text that a PASS line prints after "reproduces" (the same helper as in Notebook 07d). `WLREP` and `PYREP` are the paths of the Wolfram and the sympy field-theory reports.

```
def conjugate(element, partner):
    """The conjugate of element: generator g -> partner[g], the order of every
    product reversed, every coefficient complex-conjugated."""
    result = Grassmann()
    for monomial, coefficient in element.terms.items():
        images = [partner[g] for g in reversed(monomial)]  # reversed order
        sign, ordered = sort_with_sign(images)  # back to increasing order
        if sign != 0:
            result.add(ordered, sign * sp.conjugate(coefficient))
    return result
```

`conjugate(element, partner)` implements the three rules of Section 7.11. For every term, `reversed(monomial)` runs through the generators in reverse order and `partner[g]` replaces each by its partner; `sort_with_sign` sorts the result back and gives its sign; the coefficient is conjugated with `sp.conjugate`.

```
# the Wolfram test algebra: 0 = theta_1, 1 = theta_2, 2 = thetabar_1, 3 = thetabar_2
PAIR4 = [2, 3, 0, 1]
th1, th2, tb1, tb2 = theta(0), theta(1), theta(2), theta(3)
general = (number(sp.Rational(1, 2) + 2 * sp.I) + th1.scaled(3 - sp.I)
           + (th2 * tb1).scaled(-4 * sp.I) + (th1 * th2 * tb2).scaled(7))
check((th1 * th2 + th2 * th1).is_zero() and (th1 * th1).is_zero()
      and (conjugate(th1 * th2, PAIR4) - tb2 * tb1).is_zero()
      and (conjugate(conjugate(general, PAIR4), PAIR4) - general).is_zero(),
      "anticommutation, theta^2 = 0, (theta_1 theta_2)* = thetabar_2 thetabar_1, "
      "(F*)* = F",
      record=reproduces(WLREP, "grassmann_algebra_structure"))
```

The test algebra of the Wolfram verifier: generators 0 and 1 are θ_1, θ_2 and 2 and 3 are $\bar{\theta}_1, \bar{\theta}_2$, so the list `PAIR4 = [2, 3, 0, 1]` gives each generator its partner. `general` is an element with complex coefficients ($\frac{1}{2} + 2i$, $3 - i$, $-4i$, 7; `sp.Rational(1, 2)` is the exact fraction $\frac{1}{2}$). The check combines four statements with `and`: anticommutation, $\theta_1^2 = 0$, $(\theta_1\theta_2)^* = \bar{\theta}_2\bar{\theta}_1$, and $(F^*)^* = F$.

```
# the jet super-algebra of the sympy record: psi_A = generator A, chi_A = 16 + A
PAIR32 = [16 + A for A in range(16)] + list(range(16))
psi = [theta(A) for A in range(16)]
chi = [theta(16 + A) for A in range(16)]
rules = ((psi[0] * psi[0]).is_zero() and (psi[0] * psi[1] + psi[1] * psi[0]).is_zero()
         and (conjugate(chi[0] * psi[1], PAIR32) - chi[1] * psi[0]).is_zero()
         and (conjugate((chi[0] * psi[0]).scaled(sp.I), PAIR32)
              + (chi[0] * psi[0]).scaled(sp.I)).is_zero())
check(rules, "psi psi = 0, psi_A psi_B = -psi_B psi_A, (chi_A psi_B)* = chi_B "
      "psi_A, (i chi_A psi_A)* = -i chi_A psi_A",
      record=reproduces(PYREP, "superalgebra_axioms"))
check((conjugate(chi[3] * psi[3], PAIR32) - chi[3] * psi[3]).is_zero(),
      "chi_A psi_A (a component times its conjugate) is real")
```

The jet algebra of the sympy record for one point of a 16-component field: ψ_A is generator A (0 to 15) and $\chi_A = \psi_A^*$ is generator $16 + A$, so `PAIR32` sends A to $16 + A$ and back. `rules` combines the four rules of the record's check `superalgebra_axioms`: $\psi\psi = 0$, $\psi_A\psi_B = -\psi_B\psi_A$, $(\chi_A\psi_B)^* = \chi_B\psi_A$ (order reversal) and $(i\chi_A\psi_A)^* = -i\chi_A\psi_A$. The last check: $\chi_A\psi_A$ is real. **Out [9]:** three PASS lines; the first two each followed by a "reproduces" line naming `wolfram-field-theory.json`, check `grassmann_algebra_structure`, and `python-field-theory.json`, check `superalgebra_axioms`.

In [10]: left and right derivatives.

```
def left_derivative(element, k):
    """d_L element / d theta_k: move theta_k to the far left, then delete it."""
    result = Grassmann()
    for monomial, coefficient in element.terms.items():
        if k in monomial:
```

```
            p = monomial.index(k)  # the number of generators to its left
            result.add(monomial[:p] + monomial[p + 1:], (-1) ** p * coefficient)
    return result

def right_derivative(element, k):
    """d_R element / d theta_k: move theta_k to the far right, then delete it."""
    result = Grassmann()
    for monomial, coefficient in element.terms.items():
        if k in monomial:
            p = monomial.index(k)
            passed = len(monomial) - 1 - p  # generators to its right
            result.add(monomial[:p] + monomial[p + 1:], (-1) ** passed * coefficient)
    return result
```

`left_derivative(element, k)`: for every monomial that contains generator `k`, `monomial.index(k)` is its position `p`, which is the number of generators to its left; the generator is deleted (`monomial[:p] + monomial[p + 1:]` joins the parts before and after it) and the coefficient multiplied by $(-1)^p$. `right_derivative` does the same with the number of generators to its right, `len(monomial) - 1 - p`.

```
F = t0 * t1
check((left_derivative(F, 0) - t1).is_zero() and (left_derivative(F, 1) + t0).is_zero()
      and (right_derivative(F, 1) - t0).is_zero()
      and (right_derivative(F, 0) + t1).is_zero(),
      "the four derivatives of theta_0 theta_1 worked by hand")
even = Grassmann()
for trial in range(40):  # a random even element of the algebra of 8 generators
    size = 2 * int(rng.integers(1, 4))  # degree 2, 4 or 6
    monomial = tuple(sorted(rng.choice(8, size=size, replace=False)))
    even.add(monomial, int(rng.integers(-9, 10)))
check(all((right_derivative(even, k) + left_derivative(even, k)).is_zero()
          for k in range(8)), "d_R F = -d_L F for a random even element F")
```

The four derivatives of $\theta_0\theta_1$ worked by hand in Section 7.11 are checked. Then a random even element of the algebra of 8 generators is built from 40 random monomials of degree 2, 4 or 6 (`2 * int(rng.integers(1, 4))`) with random whole coefficients from -9 to 9 (`rng.integers(-9, 10)`; a repeated monomial simply adds up); the check requires $\partial_R F = -\partial_L F$ for all 8 generators.

```
x, a_, y = chi[0], psi[0], psi[1]  # x = chi_0 (generator 16), a = psi_0, y = psi_1
p_, q_ = x * a_ * y, x * a_
rules = ((left_derivative(p_, 1) - x * a_).is_zero()
         and (right_derivative(p_, 1) - x * a_).is_zero()
         and (left_derivative(p_, 0) + x * y).is_zero()
         and (right_derivative(p_, 0) + x * y).is_zero()
         and (left_derivative(q_, 0) + x).is_zero()
         and (right_derivative(q_, 0) - x).is_zero())
check(rules, "left and right derivatives with the Grassmann signs",
      record=reproduces(PYREP, "superalgebra_axioms"))
```

The derivative rules of the sympy record, with $x = \chi_0$, $a = \psi_0$, $y = \psi_1$ and $p = xay$, $q = xa$:

$\partial_L p/\partial y = \partial_R p/\partial y = xa$, $\partial_L p/\partial a = \partial_R p/\partial a = -xy$, $\partial_L q/\partial a = -x$ and $\partial_R q/\partial a = +x$ (generators 1 and 0 are y and a). **Out [10]:** three PASS lines, the last with its "reproduces" line.

In [11]: when is a bilinear form real?

```
def bilinear(row, M, column):
    """sum over A, B of row[A] M[A, B] column[B] (one factor from each side)."""
    total = Grassmann()
    for A in range(len(row)):
        for B in range(len(column)):
            if M[A, B] != 0:
                total = total + (row[A] * column[B]).scaled(M[A, B])
    return total
```

`bilinear(row, M, column)` forms $\sum_{A,B} \mathrm{row}_A M_{AB} \mathrm{column}_B$, skipping the zero entries of M.

```
n4 = 4
psi4 = [theta(A) for A in range(n4)]  # psi_A: generators 0 .. 3
chi4 = [theta(n4 + A) for A in range(n4)]  # chi_A = psi_A*: generators 4 .. 7
PAIR8 = [n4 + A for A in range(n4)] + list(range(n4))
random_matrix = sp.Matrix(n4, n4, lambda i, j: int(rng.integers(-3, 4))
                          + sp.I * int(rng.integers(-3, 4)))
hermitian = random_matrix + random_matrix.H  # M + M^dagger is Hermitian
form_h = bilinear(chi4, hermitian, psi4)
form_n = bilinear(chi4, random_matrix, psi4)
check((conjugate(form_h, PAIR8) - form_h).is_zero(),
      "Psi^dagger M Psi is real for a Hermitian M")
not_hermitian = random_matrix.H != random_matrix  # True: M^dagger differs from M
check(not_hermitian and not (conjugate(form_n, PAIR8) - form_n).is_zero(),
      "Psi^dagger M Psi is not real for a non-Hermitian M")
```

$n = 4$: the ψ_A are generators 0 to 3, the χ_A generators 4 to 7, and `PAIR8` pairs them. `random_matrix` is a 4×4 sympy matrix with random **Gaussian integers** (whole numbers $a + bi$ with a, b from -3 to 3; the `lambda i, j: ...` is a small unnamed function that gives the entry in row `i` and column `j`). `random_matrix.H` is its conjugate transpose $M^\dagger$, so `hermitian` $= M + M^\dagger$ is Hermitian. The first check: $\Psi^\dagger M \Psi$ with the Hermitian matrix equals its conjugate. The second: the random matrix is not Hermitian, and its form is not real. **Out [11]:** two PASS lines.

In [12]: the author's C and the real columns.

```
gammas_file = "Revision/algebra/gammas.json"
fixture = json.loads(repository_file(gammas_file).read_text(encoding="utf-8"))
G = [np.array(g, dtype=int) for g in fixture["gamma"]]  # gamma^(x0) .. gamma^(x7)
C = np.array(fixture["C"], dtype=int)  # C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
check(np.array_equal(C, G[0] @ G[1] @ G[2] @ G[3]), "C = gamma^(x0) gamma^(x1) "
      "gamma^(x2) gamma^(x3) (read from Revision/algebra/gammas.json)")
check(np.array_equal(C.T, C) and np.array_equal(C @ C, np.eye(16, dtype=int))
      and all(np.array_equal((C @ g).T, -(C @ g)) for g in G),
      "C is symmetric, C^2 = 1, and every C gamma^(a) is antisymmetric",
      record=reproduces(PYREP, "C_properties"))
```

The notebook reads the Revision record `Revision/algebra/gammas.json`: `G` holds the eight gammas $\gamma^{(x_0)}, \ldots, \gamma^{(x_7)}$ as integer arrays (`G[k]` is $\gamma^{(x_k)}$: `G[0]` is $\gamma^{(x_0)}$, `G[7]` is $\gamma^{(x_7)}$) and `C` the matrix C. The first check recomputes $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ (`@` is the matrix product of numpy). The second checks that C is symmetric (`C.T` is the transpose), $C^2 = 1$ (`np.eye(16)` is the identity), and every $C\gamma^{(a)}$ is antisymmetric; it names the record's check `C_properties`.

```
Theta = [theta(A) for A in range(16)]  # a real Grassmann column
q = sp.Matrix(sp.symbols("q0:16"))  # a real column of ordinary numbers
labels = ["$C$"] + [f"$C\\gamma^{{(x_{a})}}$" for a in range(8)]
matrices = [sp.Matrix(C)] + [sp.Matrix(C @ g) for g in G]  # exact sympy matrices
grassmann_counts, commuting_counts = [], []
for M in matrices:
    grassmann_counts.append(len(bilinear(Theta, M, Theta).terms))
    form = sp.expand((q.T * M * q)[0, 0])
    commuting_counts.append(0 if form == 0 else len(sp.Add.make_args(form)))
say(f"monomials, real Grassmann: {grassmann_counts}")
say(f"monomials, real commuting: {commuting_counts}")
```

`Theta` is a real Grassmann column of 16 generators, `q` a column of 16 ordinary sympy symbols. `labels` are the plot labels of the nine matrices (in an f-string a doubled brace `{{` prints one brace). `matrices` holds C and the eight $C\gamma^{(a)}$ as exact sympy matrices. For each, the number of surviving monomials is counted: for Grassmann numbers with the class `Grassmann`, for ordinary numbers by expanding the sympy expression $q^T M q$ and counting its terms (`sp.Add.make_args` splits a sum into its terms; a zero form has no terms). **Out [12]:** two PASS lines (the second followed by its "reproduces" line, which names the check `C_properties`), and `monomials, real Grassmann: [0, 8, 8, 8, 8, 8, 8, 8, 8]`, `monomials, real commuting: [8, 0, 0, 0, 0, 0, 0, 0, 0]`.

In [13]: the pattern and its figures.

```
two = all(abs(value) == 2 for M in matrices[1:]
          for value in bilinear(Theta, M, Theta).terms.values())
check(grassmann_counts == [0] + [8] * 8 and two, "real Grassmann: Theta^T C Theta "
      "= 0; each Theta^T C gamma^(a) Theta has 8 monomials with coefficients +-2",
      record=reproduces(WLREP, "Majorana_Lg_total_derivative_grassmann"))
check(commuting_counts == [8] + [0] * 8, "real commuting: q^T C q has 8 monomials, "
      "every q^T C gamma^(a) q is 0",
      record=reproduces(WLREP, "Majorana_Lg_commuting_control"))
```

`two` is true when every coefficient of every surviving Grassmann form is ± 2. The first check requires the counts $[0, 8, \ldots, 8]$ and the coefficients ± 2 and names the Wolfram check `Majorana_Lg_total_derivative_grassmann`, of which this is the part about the bilinear forms; the second requires the commuting counts $[8, 0, \ldots, 0]$ and names the Wolfram check `Majorana_Lg_commuting_control`. **Out [13]:** two PASS lines with their "reproduces" lines, and two figures.

```
fig, ax = plt.subplots(figsize=(8.4, 4.0))
positions = np.arange(len(labels))
ax.bar(positions - 0.2, grassmann_counts, width=0.4, label="real Grassmann column")
ax.bar(positions + 0.2, commuting_counts, width=0.4, label="real ordinary numbers")
ax.set_xticks(positions, labels)
```

```
ax.set_ylabel("surviving monomials")
ax.set_ylim(0, 10.5)  # room for the legend above the bars
ax.set_title("Which bilinear forms survive for a real column")
ax.legend(loc="upper center", ncol=2)
save_figure(fig, "bilinear_survivors",
...)
```

Two bars per matrix, shifted left and right by 0.2 (`positions - 0.2`, `positions + 0.2`), for the two kinds of numbers. **What Figure 07a.4 shows.** The blue bars (real Grassmann columns) are zero for C and 8 for every $C\gamma^{(a)}$; the orange bars (real ordinary numbers) are 8 for C and zero for every $C\gamma^{(a)}$. The two kinds of numbers keep opposite halves of a matrix.

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.2))
for ax, M, title in zip(axes, [C, C @ G[1]],
                        ["$C$ (symmetric)", "$C\\gamma^{(x_1)}$ (antisymmetric)"]):
    image = ax.imshow(M, cmap="coolwarm", vmin=-1, vmax=1)
    ax.set_xticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
    ax.set_yticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
    ax.set_xlabel("column $B$")
    ax.set_ylabel("row $A$")
    ax.set_title(title)
    ax.grid(False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8)
save_figure(fig, "symmetric_antisymmetric",
...)
```

Heat maps of C and $C\gamma^{(x_1)}$ (`C @ G[1]`), with ticks every three rows labelled 1, 4, 7, ... (rows and columns counted from 1, as in the book), and one common colour scale for both panels (`fig.colorbar(image, ax=axes, ...)`). **What Figure 07a.5 shows.** Each row of both matrices has exactly one coloured square. Mirroring C in its diagonal gives the same colours (symmetric); mirroring $C\gamma^{(x_1)}$ turns every red square into blue and every blue into red (antisymmetric).

In [14]: the powers of the scalar density.

```
S = Grassmann()
for A in range(16):
    for B in range(16):
        if C[A, B] != 0:
            S = S + (theta(A) * theta(16 + B)).scaled(int(C[A, B]))  # chi_A C psi_B
```

$S = \sum_{A,B} \chi_A C_{AB} \psi_B$ is built from the 16 nonzero entries of C; here the χ_A are generators 0 to 15 and the ψ_B generators 16 to 31.

```
power = number(1)
counts, sizes_ok = [], True
for k in range(1, 18):
    power = power * S  # S^k
    counts.append(len(power.terms))
    sizes_ok = sizes_ok and all(abs(value) == math.factorial(k)
                                for value in power.terms.values())
```

```
report("monomials of S^k for k = 1 .. 8", counts[:8])
report("monomials of S^k for k = 9 .. 17", counts[8:])
check(counts[:16] == [math.comb(16, k) for k in range(1, 17)] and sizes_ok,
      "S^k has binom(16, k) monomials with coefficients +-k! (k = 1 .. 16)")
check(counts[16] == 0, "S^17 = 0: every function of S is a polynomial of degree <= 16")
```

`power` starts at 1 and is multiplied by S seventeen times. After each multiplication the number of monomials is stored, and `sizes_ok` stays true only while every coefficient of S^k has the size $k!$ (`math.factorial(k)`). The two `report` lines print the counts; `counts[:8]` is the first eight entries and `counts[8:]` the rest. The first check compares the counts for $k = 1$ to 16 with $\binom{16}{k}$, the second requires $S^{17} = 0$. The computation takes about one second.

```
# ordinary (commuting) stand-ins for the 16 chi_A and the 16 psi_A
chi_c, psi_c = sp.symbols("chi0:16"), sp.symbols("psi0:16")
S_commuting = sum(int(C[A, B]) * chi_c[A] * psi_c[B]
                  for A in range(16) for B in range(16) if C[A, B] != 0)
commuting = [len(sp.Add.make_args(sp.expand(S_commuting ** k))) for k in (1, 2, 3)]
check(commuting == [math.comb(16 + k - 1, k) for k in (1, 2, 3)],
      "commuting numbers: S^k has binom(15 + k, k) monomials (k = 1, 2, 3)")
```

The same S with 32 ordinary sympy symbols `chi0` to `chi15` and `psi0` to `psi15` in place of the generators. Its powers $k = 1, 2, 3$ are multiplied out and their terms counted; the check compares with $\binom{15+k}{k}$. **Out [14]:** `RESULT monomials of S^k for k = 1 ..  8 = [16, 120, 560, 1820, 4368, 8008, 11440, 12870]`, `RESULT monomials of S^k for k = 9 ..  17 = [11440, 8008, 4368, 1820, 560, 120, 16, 1, 0]` and three PASS lines.

In [15]: Figure 07a.6.

```
ks = np.arange(1, 18)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 4.0))
left.bar(ks[:16], counts[:16], color="tab:blue", label="Grassmann (computed)")
left.plot(ks, [math.comb(15 + k, k) for k in ks], "s--", color="tab:orange",
          label="ordinary numbers $\\binom{15+k}{k}$")
left.set_yscale("log")
left.set_xticks(range(1, 18, 2))
left.set_xlabel("power $k$")
left.set_ylabel("number of monomials of $S^k$")
left.set_title("$S^{17} = 0$ for Grassmann numbers")
left.legend(fontsize=8)
right.semilogy(ks[:16], [math.factorial(k) for k in ks[:16]], "o-", color="tab:green")
right.set_xticks(range(1, 17, 3))
right.set_xlabel("power $k$")
right.set_ylabel("size of every coefficient of $S^k$")
right.set_title("Coefficients $\\pm k!$")
fig.tight_layout()
save_figure(fig, "powers_of_s",
...)
```

Left: blue bars of the Grassmann counts for $k = 1$ to 16 and orange squares joined by a dashed line for the commuting counts $\binom{15+k}{k}$ for $k = 1$ to 17, on a logarithmic axis (`set_yscale("log")`).

Right: the size $k!$ of the coefficients. **What Figure 07a.6 shows.** The Grassmann counts rise to 12870 at $k = 8$ and fall back symmetrically to 1 at $k = 16$, with no bar at $k = 17$; the commuting counts keep growing. On the right, the coefficients grow from 1 to 16! $\approx 2.1 \times 10^{13}$.

In [16]: the test algebra with two generators.

```
coefficients = [[int(rng.integers(-3, 4)) + sp.I * int(rng.integers(-3, 4))
                 for k in range(2)] for A in range(16)]
Psi = [th1.scaled(coefficients[A][0]) + th2.scaled(coefficients[A][1])
       for A in range(16)]
Psi_dagger = [conjugate(component, PAIR4) for component in Psi]
S2 = bilinear(Psi_dagger, sp.Matrix(C), Psi)  # S in the test algebra
shapes = sorted(S2.terms)
say(f"monomials of S (generator numbers): {shapes}")
say(f"monomials of S^2: {sorted((S2 * S2).terms)}")
check(all(len(m) == 2 and m[0] in (0, 1) and m[1] in (2, 3) for m in shapes)
      and (conjugate(S2, PAIR4) - S2).is_zero(),
      "S is a real even element on the monomials thetabar_k theta_l")
check(sorted((S2 * S2).terms) == [(0, 1, 2, 3)] and (S2 * S2 * S2).is_zero(),
      "S^2 != 0 lives on theta_1 theta_2 thetabar_1 thetabar_2 and S^3 = 0",
      record=reproduces(WLREP, "grassmann_algebra_structure"))
```

`coefficients` holds, for each of the 16 components, two random Gaussian integers c_{A1}, c_{A2}; `Psi` is the column of the components $c_{A1}\theta_1 + c_{A2}\theta_2$ (generators 0 and 1 of the test algebra of In [9]), and `Psi_dagger` the conjugates. `S2` is $S = \Psi^\dagger C \Psi$ in this algebra (the name says "S of the two-generator algebra"). The two `say` lines print the monomials of S and of S^2 as tuples of generator numbers. The first check: every monomial of S holds exactly one generator θ_l (number 0 or 1) and one conjugate $\bar{\theta}_k$ (number 2 or 3), which sorting puts second, and S is real. The second: S^2 lives on the single monomial (0, 1, 2, 3) and $S^3 = 0$. **Out [16]:** `monomials of S (generator numbers): [(0, 2), (0, 3), (1, 2), (1, 3)]`, `monomials of S^2: [(0, 1, 2, 3)]` and two PASS lines, the second with its "reproduces" line.

In [17]: the Grassmann oscillator.

```
def total_derivative(element, step):
    """d/dt on jets: every generator g in every place becomes g + step (from a
    variable to its derivative), with the product rule; the raised monomial is
    sorted back with its sign."""
    result = Grassmann()
    for monomial, coefficient in element.terms.items():
        for place, g in enumerate(monomial):
            raised = monomial[:place] + (g + step,) + monomial[place + 1:]
            sign, ordered = sort_with_sign(raised)
            if sign != 0:
                result.add(ordered, sign * coefficient)
    return result
```

`total_derivative(element, step)` is d/dt on jets. In the numbering of this cell the generators of the value come first and their derivatives have numbers larger by `step` (here 2), so raising a generator `g` to its derivative means replacing it by `g + step`. For every monomial and every place in it, the raised monomial is formed, sorted back with its sign, and added (the product rule adds one term per place).

```
omega = sp.Symbol("omega", positive=True)  # the angular frequency
bar, th, bar_d, th_d = theta(0), theta(1), theta(2), theta(3)
L_osc = ((bar * th_d - bar_d * th).scaled(sp.I / 2) - (bar * th).scaled(omega))
E_osc = left_derivative(L_osc, 0) - total_derivative(left_derivative(L_osc, 2), 2)
PAIR6 = [1, 0, 3, 2, 5, 4]  # theta-bar <-> theta for the value and two derivatives
say(f"Euler-Lagrange expression (monomial: coefficient): {E_osc.terms}")
check((E_osc - (th_d.scaled(sp.I) - th.scaled(omega))).is_zero(),
      "the oscillator's Euler-Lagrange expression is i theta' - omega theta")
check((conjugate(L_osc, PAIR6) - L_osc).is_zero(), "the oscillator Lagrangian is real")
```

`omega` is a positive symbol. The generators are $\bar\theta$ (0), θ (1), $\bar\theta'$ (2), θ' (3); `L_osc` is the Lagrangian of Section 7.13. `E_osc` is the Euler-Lagrange expression with left derivatives: the left derivative with respect to $\bar\theta$ minus the total derivative of the left derivative with respect to $\bar\theta'$. `PAIR6` pairs $\bar\theta \leftrightarrow \theta$ for the value and two derivatives (generators 4 and 5 are the second derivatives). The `say` line prints the expression as its dictionary of terms; the checks compare it with $i\theta' - \omega\theta$ and test that L is real. **Out [17]:** `Euler-Lagrange expression (monomial: coefficient): {(3,): I, (1, ): -omega}` (that is $i\theta' - \omega\theta$) and two PASS lines.

In [18]: the solution, and Figure 07a.7.

```
t = sp.Symbol("t", real=True)
solution = sp.exp(-sp.I * omega * t)  # theta(t) = solution * theta_0
residual = sp.simplify(sp.I * sp.diff(solution, t) - omega * solution)
check(residual == 0, "theta(t) = exp(-i omega t) theta_0 solves i theta' = omega theta")
```

The coefficient function $e^{-i\omega t}$ of the solution $\theta(t) = e^{-i\omega t}\theta_0$; the residual $i\frac{d}{dt}e^{-i\omega t} - \omega e^{-i\omega t}$ simplifies to 0 (the generator θ_0 is a common factor and drops out).

```
times = np.linspace(0.0, 2.0 * np.pi, 400)
values = np.exp(-2.0j * times)  # omega = 2
fig, ax = plt.subplots()
ax.plot(times, values.real, label="real part $\\cos 2t$")
ax.plot(times, values.imag, "--", label="imaginary part $-\\sin 2t$")
ax.plot(times, np.abs(values), ":", color="black", label="absolute value 1")
ax.set_xlabel("time $t$")
ax.set_ylabel("coefficient of $\\theta_0$")
ax.set_title("$\\theta(t) = e^{-2it}\\,\\theta_0$")
ax.set_ylim(-1.75, 1.25)  # room for the legend below the curves
ax.legend(loc="lower center", ncol=3, fontsize=9)
save_figure(fig, "oscillator_solution",
...)
```

400 times from 0 to 2π, the values of e^{-2it} ($\omega = 2$), and one panel with the real part, the imaginary part and the absolute value; `set_ylim(-1.75, 1.25)` leaves room for the legend below the curves. **What Figure 07a.7 shows.** The function in front of θ_0 is an ordinary complex function of absolute value 1 that turns with angular frequency 2: its real part is $\cos 2t$ and its imaginary part $-\sin 2t$. The anticommuting nature of the solution sits entirely in the constant generator θ_0.

In [19]: the first-order kinetic term of real fields.

```
th0, th1_, th0_d, th1_d = theta(0), theta(1), theta(2), theta(3)
K_A = th0 * th1_d - th1_ * th0_d  # theta^T A theta' with A = ((0, 1), (-1, 0))
K_I = th0 * th0_d + th1_ * th1_d  # theta^T I theta'
```

Four generators: θ_0 (0), θ_1 (1), θ_0' (2), θ_1' (3); the variable names `th1_` and `th0_d`, `th1_d` avoid clashing with names used earlier. `K_A` $= \theta^T A \theta'$ and `K_I` $= \theta^T \theta'$ of Section 7.13.

```
def euler_lagrange(L, field):
    """dL/d(field) - d/dx dL/d(field') with left derivatives (field = 0 or 1)."""
    return left_derivative(L, field) - total_derivative(left_derivative(L, field + 2), 2)
```

`euler_lagrange(L, field)` is the Euler-Lagrange expression of field 0 or 1 with left derivatives; the derivative of field `field` is generator `field + 2`.

```
check((K_A - total_derivative((th0 * th1_ - th1_ * th0).scaled(sp.Rational(1, 2)),
                              2)).is_zero(),
      "K_A = (1/2) d/dx (theta^T A theta): a total derivative")
check(euler_lagrange(K_A, 0).is_zero() and euler_lagrange(K_A, 1).is_zero(),
      "real Grassmann fields: both Euler-Lagrange expressions of K_A vanish")
check((euler_lagrange(K_I, 0) - th0_d.scaled(2)).is_zero(),
      "real Grassmann fields: K_I gives the expression 2 theta_0'")
```

Three checks: K_A equals $\frac{1}{2}\frac{d}{dx}(\theta^T A \theta)$ with $\theta^T A \theta = \theta_0\theta_1 - \theta_1\theta_0$; both Euler-Lagrange expressions of K_A vanish; the expression of K_I for θ_0 is $2\theta_0'$.

```
from sympy.calculus.euler import euler_equations  # sympy's Euler-Lagrange

xs = sp.Symbol("x", real=True)
q0, q1 = sp.Function("q0")(xs), sp.Function("q1")(xs)  # two ordinary functions
K_A_commuting = q0 * sp.diff(q1, xs) - q1 * sp.diff(q0, xs)
equations = euler_equations(K_A_commuting, [q0, q1], xs)
expressions = [sp.simplify(equation.lhs - equation.rhs) for equation in equations]
say(f"ordinary numbers, Euler-Lagrange expressions of K_A: {expressions}")
check(sp.simplify(expressions[0] - 2 * sp.diff(q1, xs)) == 0
      and sp.simplify(expressions[1] + 2 * sp.diff(q0, xs)) == 0,
      "ordinary numbers: K_A gives the nonzero expressions 2 q1' and -2 q0'")
```

The same kinetic term for two ordinary functions $q_0(x)$, $q_1(x)$, with sympy's `euler_equations`; the list `expressions` holds left side minus right side of each equation. The check requires $2q_1'$ and $-2q_0'$.
Out [19]: four PASS lines and `ordinary numbers, Euler-Lagrange expressions of K_A: [2* Derivative(q1(x), x), -2*Derivative(q0(x), x)]`.

In [20]: the last check.

```
names = ["dimension_and_degrees", "multiplication_signs", "commutation_signs",
         "bilinear_survivors", "symmetric_antisymmetric", "powers_of_s",
         "oscillator_solution"]
files = [f"{FIGURE_FOLDER}/07a_{k}_{name}.png" for k, name in enumerate(names, 1)]
check(all(output_file(path).is_file() for path in files),
      "all 7 figure files of this notebook exist")
all_checks_passed()
```

The seven figure files are listed and checked, and the last line is printed. **Out [20]:** `PASS all 7 figure files of this notebook exist` and `ALL 38 CHECKS PASSED (notebook 07a)`.

7.18 The geometry the fields live in

The Lagrangian of the two fields uses five geometric objects of the author's metric: the frame, the volume factor, the coordinate gammas, the Christoffel symbols and the spin connection. Chapter 3 introduced the first four and Chapter 6 treats the spin connection in full; this section collects what the field equations need, with the derivations that Notebook 07b repeats exactly.

The frame and the volume factor. The author's metric is diagonal, $g_{aa} = \eta_{aa} f_a^2$ (no sum), with the frame metric $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order $x_0, \ldots, x_7$ and the **frame factors**

$$f_0 = \cot z, \qquad f_1 = f_2 = f_3 = e^{a_4} \sin^{1/6} z, \qquad f_4 = 1, \qquad f_5 = f_6 = f_7 = e^{-a_4} b_4^{1/2} \sin^{1/6} z.$$

Here $b_4(x_4) > 0$ is the second function of the author's metric (Chapter 3); the backgrounds of the record have $b_4 = 1$. The **diagonal frame** (or **vielbein**, "many legs") $e^a{}_\mu = f_a \delta^a_\mu$ is a set of eight local unit directions, one along each coordinate; a column of numbers written in this frame, such as the 16 components of a spinor, is measured with these unit directions. For a diagonal metric $|\det g|$ is the product of the $|g_{aa}| = f_a^2$, so the **volume factor** is

$$\sqrt{|g|} = f_0 \cdot f_1 f_2 f_3 \cdot f_4 \cdot f_5 f_6 f_7 = \frac{\cos z}{\sin z} \cdot e^{3a_4} \sin^{1/2} z \cdot 1 \cdot e^{-3a_4} b_4^{3/2} \sin^{1/2} z = b_4^{3/2} \cos z$$

(insert the factors; $e^{3a_4} e^{-3a_4} = 1$; $\sin^{1/2} z \sin^{1/2} z = \sin z$ cancels against $1/\sin z$). It depends on the time only through $b_4^{3/2}$: the inflation e^{3a_4} of 3-space and the deflation e^{-3a_4} of the extra times compensate exactly, and on the backgrounds $b_4 = 1$ the volume factor $\cos z$ does not depend on the time at all (PROVED; Notebook 07b, In [4]; the table at the end of this section names the Revision checks of this and the following statements).

Exact bookkeeping with a few symbols. Notebook 07b writes every coefficient with the symbols $E = e^{a_4}$, $s = \sin^{1/6} z$, $c = \cos z$, $A_1 = a_4'$, $A_2 = a_4''$, $A_3 = a_4'''$, b_4 and its derivatives b_4', b_4'', b_4''', and H, m, λ (a prime is d/dx_4). Then $f_0 = c/s^6$ (because $\sin z = s^6$), $f_{1,2,3} = Es$ and $f_{5,6,7} = s\sqrt{b_4}/E$. Their derivatives follow from the chain rule: $\partial_4 E = EA_1$, $\partial_4 b_4 = b_4'$; $\partial_0 s = \frac{1}{6} \sin^{-5/6} z \cdot \cos z \cdot 6H = Hc/s^5$ (the power rule, the derivative $\cos z$ of $\sin z$, then $dz/dx_0 = 6H$); $\partial_0 c = -\sin z \cdot 6H = -6Hs^6$; nothing depends on $x_1, x_2, x_3, x_5, x_6, x_7$. Because $\cos^2 z + \sin^2 z = 1$, the symbols obey $c^2 = 1 - s^{12}$; replacing c^2 by $1 - s^{12}$ decides exactly whether an expression is zero.

The coordinate gammas. The author's eight frame gammas $\gamma^{(x_0)}, \ldots, \gamma^{(x_7)}$ (Chapter 4) obey $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}$. The **coordinate gammas** are $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (the frame gamma of the same direction divided by its frame factor); they obey $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}$ with the inverse metric $g^{\mu\mu} = \eta_{\mu\mu}/f_\mu^2$.

The Christoffel symbols. The **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$ say how the coordinate directions turn from point to point (Chapter 3). For a diagonal metric the general formula keeps only a few terms:

$$\Gamma^{\lambda}{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}\big(\delta_{\lambda\nu}\,\partial_\mu g_{\lambda\lambda} + \delta_{\lambda\mu}\,\partial_\nu g_{\lambda\lambda} - \delta_{\mu\nu}\,\partial_\lambda g_{\mu\mu}\big).$$

Four examples, each in one line. $\Gamma^{x_1}{}_{x_1x_4} = \partial_4 g_{11}/(2g_{11}) = \partial_4(E^2s^2)/(2E^2s^2) = 2E^2A_1s^2/(2E^2s^2) = a_4'$: 3-space stretches at the rate a_4'. $\Gamma^{x_5}{}_{x_4x_5} = \partial_4 g_{55}/(2g_{55})$ with $g_{55} = -b_4s^2/E^2$, and $\partial_4(-b_4s^2E^{-2}) = -s^2E^{-2}(b_4' - 2A_1b_4)$, so $\Gamma^{x_5}{}_{x_4x_5} = (b_4' - 2A_1b_4)/(2b_4) = -a_4' + b_4'/(2b_4)$: the extra times shrink at this rate, which is $-a_4'$, the rate of 3-space with the opposite sign, at $b_4 = 1$. We write $\alpha_t = -a_4' + b_4'/(2b_4)$ for it. $\Gamma^{x_1}{}_{x_0x_1} = \partial_0(E^2s^2)/(2E^2s^2) = \partial_0 s/s = Hc/s^6 = H\cot z$. $\Gamma^{x_0}{}_{x_0x_0} = \frac{1}{2}\partial_0 \ln g_{00}$ with $g_{00} = c^2/s^{12}$, so $\frac{1}{2}(2\partial_0 c/c - 12\,\partial_0 s/s) = -6Hs^6/c - 6Hc/s^6 = -6H(s^{12}+c^2)/(cs^6) = -6H/(\sin z\cos z)$. The metric has 25 independent nonzero Christoffel symbols (COMPUTED exactly by Notebook 07b, In [7], and compared there with the formula records `Revision/theory/field-theory-b4.json` and, at $b_4 = 1$, `Revision/theory/field-theory.json`).

Why a spinor needs a connection. The 16 components of a spinor are measured in the local frame. Because the frame turns from point to point (that is what the Christoffel symbols describe), the plain derivative $\partial_\mu\Psi$ compares components measured in two different frames, and an equation built from it would depend on the arbitrary choice of frames. The **canonical spin connection** $\omega_\mu{}^a{}_b$ records how the frame turns; it is fixed by the **vielbein postulate** $\partial_\mu e^a{}_\nu - \Gamma^\lambda{}_{\mu\nu}e^a{}_\lambda + \omega_\mu{}^a{}_b\,e^b{}_\nu = 0$ (the frame is carried along consistently with the metric). For the diagonal frame its solution is

$$\omega_\mu{}^a{}_b = f_a\Big(\delta_{ab}\,\partial_\mu\frac{1}{f_b} + \frac{\Gamma^a{}_{\mu b}}{f_b}\Big), \qquad \omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b,$$

and the lowered $\omega_{\mu ab}$ is antisymmetric in a, b. For $a \neq b$ it is $\eta_{aa}f_a\Gamma^a{}_{\mu b}/f_b$. Two examples: $\omega_{x_1(x_1)(x_4)} = (+1)\cdot Es\cdot a_4'/1 = a_4'e^{a_4}\sin^{1/6} z$, and $\omega_{x_5(x_4)(x_5)} = (-1)\cdot 1\cdot\Gamma^{x_4}{}_{x_5x_5}/f_5$ with $\Gamma^{x_4}{}_{x_5x_5} = -\partial_4 g_{55}/(2g_{44}) = -f_5^2\alpha_t$, which gives $f_5^2\alpha_t/f_5 = \alpha_t f_5 = -(a_4' - \frac{b_4'}{2b_4})e^{-a_4}b_4^{1/2}\sin^{1/6} z$. Exactly 12 components with $a < b$ are nonzero (COMPUTED exactly by Notebook 07b, In [8]):

$$\begin{aligned}
&\omega_{x_i(x_i)(x_4)} = a_4'e^{a_4}\sin^{1/6} z, && \omega_{x_i(x_0)(x_i)} = -He^{a_4}\sin^{1/6} z,\\
&\omega_{x_t(x_4)(x_t)} = -\Big(a_4' - \frac{b_4'}{2b_4}\Big)e^{-a_4}b_4^{1/2}\sin^{1/6} z, && \omega_{x_t(x_0)(x_t)} = He^{-a_4}b_4^{1/2}\sin^{1/6} z,
\end{aligned}$$

for $i = 1,2,3$ and $t = 5,6,7$. Each is a rate (a_4', $a_4' - b_4'/(2b_4)$ or H) times a factor that never vanishes for $0 < z < \pi/2$.

The spinor connection and the covariant derivatives. With the **spin generators** $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$, which equal $\frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ for $a \neq b$ (the two products differ only in sign) and 0 for $a = b$ (Chapter 5), the **spinor connection** is

$$\Omega_\mu = \tfrac{1}{2}\,\omega_{\mu ab}S^{ab} = \sum_{a<b}\omega_{\mu ab}S^{ab}$$

(the two halves of the double sum are equal, because both $\omega_{\mu ab}$ and S^{ab} change sign when a and b are exchanged). The **covariant derivatives** of a column and of a row are

$$D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi, \qquad D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\,\Omega_\mu.$$

In the author's metric $\Omega_{x_0} = \Omega_{x_4} = 0$, and for $i = 1, 2, 3$ and $t = 5, 6, 7$, with $r = a_4' - b_4'/(2b_4) = -\alpha_t$:

$$\Omega_{x_i} = \tfrac{1}{2} e^{a_4} \sin^{1/6} z \, \big(a_4' \gamma^{(x_i)} \gamma^{(x_4)} + H \gamma^{(x_i)} \gamma^{(x_0)}\big),$$
$$\Omega_{x_t} = -\tfrac{1}{2} e^{-a_4} b_4^{1/2} \sin^{1/6} z \, \big(r \, \gamma^{(x_4)} \gamma^{(x_t)} + H \gamma^{(x_t)} \gamma^{(x_0)}\big).$$

The term $\gamma^\mu \Omega_\mu$, direction by direction. The field equation will contain the matrix $\gamma^\mu \Omega_\mu$ (summed over μ). For an inflating direction x_i:

$$\gamma^{x_i} \Omega_{x_i} = \frac{\gamma^{(x_i)}}{e^{a_4} \sin^{1/6} z} \cdot \tfrac{1}{2} e^{a_4} \sin^{1/6} z \, \big(a_4' \gamma^{(x_i)} \gamma^{(x_4)} + H \gamma^{(x_i)} \gamma^{(x_0)}\big) = \tfrac{1}{2} \big(a_4' \gamma^{(x_4)} + H \gamma^{(x_0)}\big)$$

(the frame factors cancel; then $\gamma^{(x_i)} \gamma^{(x_i)} = \eta_{ii} = +1$). For a deflating extra time x_t:

$$\begin{aligned} \gamma^{x_t} \Omega_{x_t} &= \frac{\gamma^{(x_t)}}{f_t} \cdot \Big(-\tfrac{1}{2} f_t \Big) \big(r \, \gamma^{(x_4)} \gamma^{(x_t)} + H \gamma^{(x_t)} \gamma^{(x_0)}\big) \\ &= -\tfrac{1}{2} \big(r \, \gamma^{(x_t)} \gamma^{(x_4)} \gamma^{(x_t)} + H \gamma^{(x_t)} \gamma^{(x_t)} \gamma^{(x_0)}\big) \end{aligned}$$

(the frame factors cancel), and $\gamma^{(x_t)} \gamma^{(x_4)} \gamma^{(x_t)} = -\gamma^{(x_4)} \gamma^{(x_t)} \gamma^{(x_t)} = -\gamma^{(x_4)} \cdot (-1) = \gamma^{(x_4)}$ (exchange two different gammas, then $\gamma^{(x_t)} \gamma^{(x_t)} = \eta_{tt} = -1$), and $\gamma^{(x_t)} \gamma^{(x_t)} \gamma^{(x_0)} = -\gamma^{(x_0)}$; so

$$\gamma^{x_t} \Omega_{x_t} = -\tfrac{1}{2} \big(r \, \gamma^{(x_4)} - H \gamma^{(x_0)}\big) = -\tfrac{1}{2} \Big(a_4' - \frac{b_4'}{2b_4}\Big) \gamma^{(x_4)} + \tfrac{1}{2} H \gamma^{(x_0)}.$$

Summing over the three inflating directions, the three deflating extra times and the two directions x_0, x_4 (which give 0):

$$\gamma^\mu \Omega_\mu = 3 \cdot \tfrac{1}{2} a_4' \gamma^{(x_4)} - 3 \cdot \tfrac{1}{2} \Big(a_4' - \frac{b_4'}{2b_4}\Big) \gamma^{(x_4)} + 6 \cdot \tfrac{1}{2} H \gamma^{(x_0)} = 3H \gamma^{(x_0)} + \frac{3}{4} \frac{b_4'}{b_4} \gamma^{(x_4)}.$$

The a_4' terms of the three inflating directions and the three deflating extra times cancel exactly, because 3-space inflates at the rate at which the extra times deflate; the extra times leave the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ of their factor $b_4^{1/2}$; the hidden-direction terms of all six directions add up. The result does not contain a_4 at all, for every function $a_4(x_4)$; on the backgrounds $b_4 = 1$ (and for every constant b_4) it is $3H\gamma^{(x_0)}$ (PROVED; Notebook 07b, In [9], Figure 07b.2). We call $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ the **gravitational term**.

Two more facts about Ω_μ. (i) For each direction separately, γ^μ and Ω_μ anticommute: $\gamma^\mu \Omega_\mu + \Omega_\mu \gamma^\mu = 0$ (no sum). The reason: Ω_μ contains only products $\gamma^{(\mu)} \gamma^{(b)}$ that share the index μ with $\gamma^{(\mu)}$, and $\gamma^{(\mu)} \gamma^{(\mu)} \gamma^{(b)} = \eta_{\mu\mu} \gamma^{(b)}$ while $\gamma^{(\mu)} \gamma^{(b)} \gamma^{(\mu)} = -\gamma^{(\mu)} \gamma^{(\mu)} \gamma^{(b)} = -\eta_{\mu\mu} \gamma^{(b)}$; the two add to 0. (ii) The same matrix is a derivative of the volume factor and the coordinate gammas:

$$\begin{aligned} \frac{1}{2\sqrt{|g|}} \, \partial_\mu \big(\sqrt{|g|} \, \gamma^\mu\big) &= \frac{1}{2 b_4^{3/2} \cos z} \Big[\partial_0 \Big(b_4^{3/2} \cos z \cdot \frac{\sin z}{\cos z} \Big) \gamma^{(x_0)} + \partial_4 \big(b_4^{3/2} \cos z\big) \gamma^{(x_4)} \Big] \\ &= 3H \gamma^{(x_0)} + \frac{3}{4} \frac{b_4'}{b_4} \gamma^{(x_4)} = \gamma^\mu \Omega_\mu. \end{aligned}$$

The first equality: $\sqrt{|g|}\gamma^\mu = b_4^{3/2}\cos z\,\gamma^{(\mu)}/f_\mu$ depends only on x_4 and x_0, so only $\mu = x_0$ (with $1/f_0 = \tan z = \sin z/\cos z$) and $\mu = x_4$ (with $f_4 = 1$) contribute. The second: $\cos z \cdot \sin z/\cos z = \sin z$, whose derivative along x_0 is $6H\cos z$, which gives $6Hb_4^{3/2}\cos z/(2b_4^{3/2}\cos z) = 3H$; and $\partial_4 b_4^{3/2} = \frac{3}{2}b_4^{1/2}b_4'$, which gives $\frac{3}{2}b_4^{1/2}b_4'/(2b_4^{3/2}) = \frac{3}{4}b_4'/b_4$. So $\partial_\mu(\sqrt{|g|}\gamma^\mu) = 2\sqrt{|g|}\,\gamma^\mu\Omega_\mu$ in this metric (PROVED; Notebook 07b, In [11]). Both facts are used in the next three sections.

Where the statements of this section are verified. The reports are named by their file names; the theory reports lie in the folder `Revision/theory/reports`. The formula records are `Revision/theory/field-theory-b4.json` (the metric with b_4) and `Revision/theory/field-theory.json` (the metric at $b_4 = 1$); the reports without "b4" in their name check the metric at $b_4 = 1$.

statement	status	where it is verified

7.19 The two fields and their common Lagrangian

Why the row contains C. A Lagrangian must not depend on the choice of the local frames, so it must be built from combinations of the field that do not change when the frames are turned. Under a turning of the frames the column changes as $\Psi \to R\Psi$ with a real 16×16 **spin transformation** R (Chapter 5). The simplest number, $\Psi^\dagger\Psi = \sum_A |\Psi_A|^2$, becomes $\Psi^\dagger R^T R \Psi$, which equals $\Psi^\dagger\Psi$ only if $R^T R = 1$: true for rotations, false for boosts (Chapter 5). The author's matrix C cures this: every spin generator satisfies $(S^{ab})^T C = -C S^{ab}$ (`python-field-theory.json`, check `S_definition_and_C_S_antisymmetric`), and therefore $R^T C R = C$ for every spin transformation (Chapter 5), so

$$\Psi^\dagger C \Psi \to \Psi^\dagger R^T C R\, \Psi = \Psi^\dagger C \Psi.$$

The row $\bar\Psi = \Psi^\dagger C$ is called the **Dirac adjoint** of Ψ, and $S = \bar\Psi\Psi$ the **scalar density**. In the same way the eight numbers $\bar\Psi\gamma^{(a)}\Psi$ change like the components of a vector under the turnings, and contracted with a covariant derivative they give the frame-independent combination $\bar\Psi\gamma^\mu D_\mu \Psi$.

The Lagrangian. For both fields the Revision record uses the same Lagrangian density (Revision/SPEC.md, section 3; ASSUMED as the definition of the two theories):

$$\mathcal{L} = \sqrt{|g|}\,\Big[\tfrac{1}{2}(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi) - m\,S - U(S)\Big], \qquad \bar\Psi = \Psi^\dagger C, \quad S = \bar\Psi\Psi, \quad U(S) = \tfrac{\lambda}{2}S^2,$$

with a sum over $\mu = x_0, \ldots, x_7$. Read term by term:

- $\sqrt{|g|} = b_4^{3/2}\cos z$ turns the coordinate volume into proper volume, so that the action does not depend on the coordinates.
- The **kinetic term** $K = \frac{1}{2}(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi)$ contains each derivative to the first power, like the first-order Lagrangians of Section 7.4. It is **symmetrised**: the derivative acts once on Ψ and once on $\bar\Psi$, with opposite signs (Section 7.20 shows why).
- The **mass term** $-mS = -m\bar\Psi\Psi$ is linear in the mass m (a real number) and quadratic in the field: every term contains one component of $\Psi^\dagger$ and one of Ψ.
- The **interaction** $-U(S) = -\frac{\lambda}{2}S^2$ with a real coupling λ is quartic in the field. For dirac16complex it must be a polynomial in S (Section 7.12: $S^{17} = 0$); for dirac16complex00 any real function of S would be allowed, and the record keeps the same U so that the two theories differ only in the statistics. We write $V = m + U'(S) = m + \lambda S$, the **effective mass**.
- Gravity enters through $\sqrt{|g|}$, through the coordinate gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$, and through the spinor connection in D_μ.

The structure is that of Example B of Section 7.4: Ψ plays the role of ψ, the row $\bar\Psi$ that of ψ^*, and the kinetic term is symmetrised in the same way. The factor i of Example B is not needed, because the matrices $C\gamma^{(a)}$ are antisymmetric (next section).

The two statistics. For dirac16complex the 16 components Ψ_A and the 16 conjugates Ψ_A^* are 32 Grassmann generators at each point, with the rules of Sections 7.10 and 7.11; for dirac16complex00 they are ordinary complex numbers. Every term of $\mathcal{L}$ is written with all factors of $\Psi^\dagger$ (or of its derivatives) to the LEFT of all factors of Ψ, so the formula can be read for both kinds of numbers without any reordering.

7.20 Reality, the total divergence, and the connection that drops out of $\mathcal{L}$

The lemma for two columns. For two columns Ψ and Φ (for example $\Phi = D_\mu\Psi$), both commuting or both Grassmann, and a matrix M of ordinary numbers,

$$\big(\Psi^\dagger M\Phi\big)^* = \Phi^\dagger M^\dagger\Psi.$$

The proof is the three-line computation of Section 7.12 with Φ in place of the second Ψ: for Grassmann components the conjugation reverses the order of the two factors; for commuting components nothing needs reordering (PROVED).

The Lagrangian is real. Call $K_u = \bar\Psi\gamma^\mu D_\mu\Psi = \Psi^\dagger(C\gamma^\mu)(D_\mu\Psi)$ the **unsymmetrised** kinetic term. Line by line:

$$K_u^* = (D_\mu\Psi)^\dagger (C\gamma^\mu)^\dagger \Psi$$

(the lemma with $M = C\gamma^\mu$ and $\Phi = D_\mu\Psi$);

$$= -(D_\mu\Psi)^\dagger C\gamma^\mu \Psi$$

($C\gamma^\mu = C\gamma^{(\mu)}/f_\mu$ is real and antisymmetric, so its dagger is its transpose, which is minus itself);

$$= -(D_\mu\bar\Psi)\gamma^\mu\Psi$$

(because $(D_\mu\Psi)^\dagger C = \partial_\mu\Psi^\dagger C + \Psi^\dagger\Omega_\mu^T C = \partial_\mu\bar\Psi - \Psi^\dagger C\Omega_\mu = D_\mu\bar\Psi$: the matrix Ω_μ is real, and $\Omega_\mu^T C = -C\Omega_\mu$ since Ω_μ is a combination of the S^{ab} with real coefficients and $(S^{ab})^T C = -CS^{ab}$). So the kinetic term $K = \frac{1}{2}(K_u - (D_\mu\bar\Psi)\gamma^\mu\Psi) = \frac{1}{2}(K_u + K_u^*)$ is real. Next $S^* = \Psi^\dagger C^\dagger\Psi = S$, because C is real and symmetric (the lemma with $M = C$). For Grassmann components S is even, so $(S^2)^* = S^*S^* = S^2$, and $U(S) = \frac{\lambda}{2}S^2$ is real; for commuting components S is a real number. Finally m, λ and $\sqrt{|g|}$ are real. Hence $\mathcal{L}^* = \mathcal{L}$ for both statistics (PROVED; Notebook 07b, In [15]; `python-field-theory.json`, checks `grassmann_lagrangian_real` and `commuting_lagrangian_real`; `wolfram-field-theory.json`, checks `L_real_G` and `L_real_C`). The unsymmetrised form $\sqrt{|g|}\,[K_u - mS - U]$ is NOT real: its imaginary part is the difference $K_u - K_u^*$, which is not zero for a general field (checks `grassmann_controls_not_vacuous` and `commuting_controls_not_vacuous`); this control shows that the reality test is not empty. A real Lagrangian matters: the equations obtained by varying $\Psi^\dagger$ and by varying Ψ are then conjugates of each other (Section 7.21), so there are exactly as many equations as unknown components.

The two forms differ by a total divergence. The product rule along x_μ, applied to the three factors of $\sqrt{|g|}\,\bar\Psi\gamma^\mu\Psi$ (with the matrix $\sqrt{|g|}\gamma^\mu$ as one factor), gives

$$\partial_\mu(\sqrt{|g|}\,\bar\Psi\gamma^\mu\Psi) = \sqrt{|g|}\,(\partial_\mu\bar\Psi)\gamma^\mu\Psi + \bar\Psi\,\partial_\mu(\sqrt{|g|}\gamma^\mu)\Psi + \sqrt{|g|}\,\bar\Psi\gamma^\mu\partial_\mu\Psi$$

(for Grassmann components the derivative is even and needs no sign; the order of the factors is kept);

$$= \sqrt{|g|}\,[(\partial_\mu\bar\Psi)\gamma^\mu\Psi + 2\bar\Psi\gamma^\mu\Omega_\mu\Psi + \bar\Psi\gamma^\mu\partial_\mu\Psi]$$

(the identity $\partial_\mu(\sqrt{|g|}\gamma^\mu) = 2\sqrt{|g|}\gamma^\mu\Omega_\mu$ of Section 7.18);

$$= \sqrt{|g|}\,[(\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu)\gamma^\mu\Psi + \bar\Psi\gamma^\mu(\partial_\mu\Psi + \Omega_\mu\Psi)] = \sqrt{|g|}\,[(D_\mu\bar\Psi)\gamma^\mu\Psi + \bar\Psi\gamma^\mu D_\mu\Psi]$$

(split $2\gamma^\mu\Omega_\mu = \gamma^\mu\Omega_\mu - \Omega_\mu\gamma^\mu$, using $\gamma^\mu\Omega_\mu = -\Omega_\mu\gamma^\mu$ for each μ; then the definitions of the covariant derivatives). Now $K = \frac{1}{2}(K_u - (D_\mu\bar\Psi)\gamma^\mu\Psi) = K_u - \frac{1}{2}(K_u + (D_\mu\bar\Psi)\gamma^\mu\Psi)$, so

$$\mathcal{L} = \sqrt{|g|}\,[\bar\Psi\gamma^\mu D_\mu\Psi - mS - U(S)] - \tfrac{1}{2}\,\partial_\mu(\sqrt{|g|}\,\bar\Psi\gamma^\mu\Psi).$$

The two forms differ by a total divergence (the field version of the total derivative of Section 7.4) and give the same field equations; only the symmetrised one is real (PROVED; Notebook 07b, In

[15]; checks `grassmann_total_divergence_relation` and `commuting_total_divergence_relation`; Wolfram `L_total_divergence_to_unsymmetrised_G` and `_C`).

The spin connection drops out of $\mathcal{L}$ in this metric. The terms of K that contain Ω_μ are $\frac{1}{2}\bar{\Psi}\gamma^\mu\Omega_\mu\Psi$ from the first half and $-\frac{1}{2}(-\bar{\Psi}\Omega_\mu)\gamma^\mu\Psi = +\frac{1}{2}\bar{\Psi}\Omega_\mu\gamma^\mu\Psi$ from the second, together

$$\tfrac{1}{2}\,\bar{\Psi}\big(\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu\big)\Psi = 0,$$

because γ^μ and Ω_μ anticommute for each μ (Section 7.18). So in the author's metric

$$\mathcal{L} = b_4^{3/2}\cos z\,\Big[\tfrac{1}{2}\sum_{a=0}^{7}\frac{1}{f_a}\big(\bar{\Psi}\gamma^{(a)}\partial_a\Psi - \partial_a\bar{\Psi}\,\gamma^{(a)}\Psi\big) - mS - U(S)\Big]$$

contains no spin connection at all (PROVED; Notebook 07b, In [15]; Wolfram checks `L_spin_connection_drops_out_G` and `L_spin_connection_drops_out_C`). Gravity is still present in $\mathcal{L}$, through $b_4^{3/2}\cos z$ and the frame factors $1/f_a$. Section 7.21 shows that the connection comes back in the field equation, through the derivative of $\sqrt{|g|}\gamma^\mu$.

Counting the terms of $\mathcal{L}$ at one point. Written in the jet symbols of Section 7.13 (the 16 components, their 16 conjugates and their first derivatives at one point), the Lagrangian is a sum of monomials. Every $C\gamma^{(a)}$ is a signed permutation matrix, so in each of the 8 directions $\bar{\Psi}\gamma^{(a)}\partial_a\Psi$ gives 16 monomials $\Psi_A^*\,\partial_a\Psi_B$ and $\partial_a\bar{\Psi}\gamma^{(a)}\Psi$ another 16: $8\times 32 = 256$ kinetic monomials. The mass term gives 16 (one for each nonzero entry of C). The quartic term $\frac{\lambda}{2}S^2$ is $\frac{\lambda}{2}\big(\sum_A c_A P_A\big)^2$ with the 16 pairs P_A of Section 7.12: the $\binom{16}{2} = 120$ products of two different pairs survive for both statistics, while the 16 squares P_A^2 survive only for commuting numbers. So $\mathcal{L}$ has $256 + 16 + 120 = 392$ monomials for dirac16complex and $256 + 16 + 136 = 408$ for dirac16complex00 (COMPUTED by Notebook 07b, In [13] and In [14], Figure 07b.3; the counts reproduce those written in `python-field-theory.json`, checks `grassmann_lagrangian_real` and `commuting_lagrangian_real`).

7.21 The Euler-Lagrange equations of both fields

The derivation by hand, for the commuting field. Write $V = m + \lambda S$ and, with $\chi_A = \Psi_A^*$ the components of $\Psi^\dagger$,

$$\frac{\mathcal{L}}{\sqrt{|g|}} = \tfrac{1}{2}\,\chi C\gamma^\mu\big(\partial_\mu\Psi + \Omega_\mu\Psi\big) - \tfrac{1}{2}\big(\partial_\mu\chi\,C - \chi C\Omega_\mu\big)\gamma^\mu\Psi - m\,\chi C\Psi - \tfrac{\lambda}{2}\big(\chi C\Psi\big)^2,$$

where χ is the row $\Psi^\dagger$. Vary the component χ_A; by Section 7.4 the components and their conjugates may be varied as if they were independent. The Euler-Lagrange expression of a field (Section 7.5) needs two partial derivatives.

- Step 1. $\partial\mathcal{L}/\partial\chi_A = \sqrt{|g|}\,\big[\frac{1}{2}(C\gamma^\mu D_\mu\Psi)_A + \frac{1}{2}(C\Omega_\mu\gamma^\mu\Psi)_A - V(C\Psi)_A\big]$. Rule: a term χX with a column X has the derivative X_A with respect to χ_A; the second half contributes through its part $+\frac{1}{2}\chi C\Omega_\mu\gamma^\mu\Psi$; and the chain rule gives $\partial\big(\frac{\lambda}{2}S^2\big)/\partial\chi_A = \lambda S\,(C\Psi)_A$.
- Step 2. $\partial\mathcal{L}/\partial(\partial_\mu\chi_A) = -\frac{1}{2}\sqrt{|g|}\,(C\gamma^\mu\Psi)_A$. Rule: only the second half contains $\partial_\mu\chi$.

- Step 3. The Euler-Lagrange expression is Step 1 minus ∂_μ of Step 2, that is Step 1 plus $\frac{1}{2}\partial_\mu(\sqrt{|g|}\,C\gamma^\mu\Psi)_A$.
- Step 4. By the product rule and Section 7.18, $\partial_\mu(\sqrt{|g|}\gamma^\mu\Psi) = \partial_\mu(\sqrt{|g|}\gamma^\mu)\Psi + \sqrt{|g|}\gamma^\mu\partial_\mu\Psi = 2\sqrt{|g|}\,\gamma^\mu\Omega_\mu\Psi + \sqrt{|g|}\,\gamma^\mu\partial_\mu\Psi$ (C is constant and comes out of the derivative).
- Step 5. Add: the expression is $\sqrt{|g|}\,\big(C\,[\frac{1}{2}\gamma^\mu D_\mu\Psi + \frac{1}{2}\Omega_\mu\gamma^\mu\Psi + \gamma^\mu\Omega_\mu\Psi + \frac{1}{2}\gamma^\mu\partial_\mu\Psi - V\Psi]\big)_A$. With $\Omega_\mu\gamma^\mu = -\gamma^\mu\Omega_\mu$ the second and third terms give $\frac{1}{2}\gamma^\mu\Omega_\mu\Psi$, and $\frac{1}{2}\gamma^\mu\Omega_\mu\Psi + \frac{1}{2}\gamma^\mu\partial_\mu\Psi = \frac{1}{2}\gamma^\mu D_\mu\Psi$. So the expression is $\sqrt{|g|}\,\big(C\,(\gamma^\mu D_\mu\Psi - V\Psi)\big)_A$.
- Step 6. $\sqrt{|g|} = b_4^{3/2}\cos z \neq 0$ and C is invertible ($C^2 = 1$), so the 16 expressions vanish exactly when

$$\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi.$$

This is the **field equation** of both fields (for a general potential, $m + U'(S)$ in place of $m + \lambda S$). The spin connection, which was absent from $\mathcal{L}$, is present in it: Step 4 brought it back through $\partial_\mu(\sqrt{|g|}\gamma^\mu)$.

Grassmann components. For dirac16complex the LEFT derivative with respect to χ_A is used (Section 7.11). In every term of $\mathcal{L}$ the factor χ (or $\partial_\mu\chi$) stands on the far left, so moving it there costs no sign, and S is even, so the chain rule of Step 1 holds unchanged. Steps 1 to 6 go through word for word: the field equation is the same for both statistics (PROVED; Notebook 07b, In [16], with the control that the comparison with m replaced by $-m$ fails).

The adjoint equation. Varying Ψ instead (for Grassmann components with RIGHT derivatives, because Ψ stands on the far right) gives in the same way

$$(D_\mu\bar\Psi)\gamma^\mu = -(m + \lambda S)\bar\Psi.$$

It is not a new equation: it is the **Dirac conjugate** of the field equation. With the residual $\mathcal{E} = \gamma^\mu D_\mu\Psi - V\Psi$, line by line:

$$\mathcal{E}^\dagger C = (D_\mu\Psi)^\dagger(\gamma^\mu)^T C - V\Psi^\dagger C$$

(the dagger of a product reverses it; γ^μ and V are real; for Grassmann components the conjugation reverses the order as well);

$$= -(D_\mu\Psi)^\dagger C\gamma^\mu - V\bar\Psi = -(D_\mu\bar\Psi)\gamma^\mu - V\bar\Psi$$

($(\gamma^\mu)^T C = -C\gamma^\mu$, because $C\gamma^\mu$ is antisymmetric and C symmetric; then $(D_\mu\Psi)^\dagger C = D_\mu\bar\Psi$ as in Section 7.20). So $\mathcal{E}^\dagger C = -\big[(D_\mu\bar\Psi)\gamma^\mu + V\bar\Psi\big]$: the residual of the adjoint equation is minus the Dirac conjugate of the residual of the field equation. One equation holds exactly when the other does, and the two form one system (PROVED; Notebook 07b, In [16]).

Where the statements of this section are verified (in the folder `Revision/theory/reports`; the sympy names start with `grassmann_` or `commuting_` for the two statistics, the Wolfram names end in `_G` or `_C`):

7.22 The equations in the author's metric: explicit, block and evolution forms

The explicit form. Since $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and $\gamma^\mu \Omega_\mu = M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ (Section 7.18), the Dirac operator is $\gamma^\mu D_\mu \Psi = \sum_a \frac{1}{f_a}\gamma^{(a)}\partial_a \Psi + M\Psi$, and the field equation in the author's metric reads

$$\tan z\, \gamma^{(x_0)}\partial_0 \Psi + \frac{1}{e^{a_4}\sin^{1/6} z}\sum_{i=1}^{3}\gamma^{(x_i)}\partial_i\Psi + \gamma^{(x_4)}\partial_4\Psi + \frac{e^{a_4}}{b_4^{1/2}\sin^{1/6} z}\sum_{t=5}^{7}\gamma^{(x_t)}\partial_t\Psi + 3H\gamma^{(x_0)}\Psi + \frac{3}{4}\frac{b_4'}{b_4}\gamma^{(x_4)}\Psi = (m+\lambda S)\Psi$$

(PROVED; Notebook 07b, In [17]; `wolfram-field-theory-b4.json`, checks `Dirac_operator_explicit_G` and `Dirac_operator_explicit_C`; formula records, key `field_equation`; at $b_4 = 1$ the same checks of `wolfram-field-theory.json`). The coefficient $e^{a_4} b_4^{-1/2}\sin^{-1/6} z$ of the extra-time derivatives GROWS as the extra times deflate, while that of the 3-space derivatives shrinks.

One component equation, read off the gamma tables. Every frame gamma is a signed permutation matrix: row 1 of $\gamma^{(x_0)}, \gamma^{(x_1)}, \ldots, \gamma^{(x_7)}$ has its single entry in the columns $+9, -16, +15, -14, -14, +15, +16, +9$ (the sign of the entry and its column; the tables of Chapter 5, read from the record `Revision/algebra/gammas.json`). So the first of the 16 component equations is

$$\tan z\, \partial_0 \Psi_9 + \frac{-\partial_1 \Psi_{16} + \partial_2 \Psi_{15} - \partial_3 \Psi_{14}}{e^{a_4} \sin^{1/6} z} - \partial_4 \Psi_{14} + \frac{e^{a_4}(\partial_5 \Psi_{15} + \partial_6 \Psi_{16} + \partial_7 \Psi_9)}{b_4^{1/2} \sin^{1/6} z} + 3H\Psi_9 - \frac{3}{4}\frac{b_4'}{b_4}\Psi_{14} = (m + \lambda S)\Psi_1.$$

Notebook 07b prints this equation in its own symbols and the same equation read from the formula record (`Revision/theory/field-theory-b4.json`, key `field_equation_components`), and checks that all 16 equations agree term by term with it and, at $b_4 = 1$, with the record `Revision/theory/field-theory.json` (In [17]). Each equation contains four components, each with derivatives along two directions (here Ψ_9 along x_0 and x_7, Ψ_{16} along x_1 and x_6, Ψ_{15} along x_2 and x_5, Ψ_{14} along x_3 and x_4), and the gravitational term $3H\Psi_B$ stands next to the hidden-direction derivative $\tan z\, \partial_0 \Psi_B$ of the same component, the term $-\frac{3}{4}(b_4'/b_4)\Psi_B$ next to the time derivative $-\partial_4 \Psi_B$ (Figure 07b.4).

The chiral block form. Split Ψ into its upper half ψ_- (components 1 to 8, where the chirality matrix $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)} \cdots \gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$ is -1; Chapter 5) and its lower half ψ_+ (components 9 to 16, $\Gamma = +1$). Every frame gamma anticommutes with Γ, and therefore has the block form

$$\gamma^{(a)} = \begin{pmatrix} 0 & \bar{\tau}_a \\ \tau_a & 0 \end{pmatrix}$$

with 8×8 blocks $\bar{\tau}_a$ (upper right) and τ_a (lower left); for the hidden direction $\bar{\tau}_{x_0} = \tau_{x_0} = I_8$. (Why: write $\gamma^{(a)}$ in 8×8 blocks P, Q, R, T; then $\Gamma\gamma^{(a)} = \begin{pmatrix} -P & -Q \\ R & T \end{pmatrix}$ and $\gamma^{(a)}\Gamma = \begin{pmatrix} -P & Q \\ -R & T \end{pmatrix}$, and $\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$ forces $P = 0$ and $T = 0$.) A block matrix times the column (ψ_-, ψ_+) gives $(\bar{\tau}_a\psi_+, \tau_a\psi_-)$: the upper rows see only the lower half. The term $V\Psi$ keeps each half in its own rows. So the field equation is the pair

$$\sum_a \frac{1}{f_a}\bar{\tau}_a\, \partial_a \psi_+ + 3H\psi_+ + \tfrac{3}{4}\tfrac{b_4'}{b_4}\bar{\tau}_{x_4}\psi_+ = V\psi_-, \qquad \sum_a \frac{1}{f_a}\tau_a\, \partial_a \psi_- + 3H\psi_- + \tfrac{3}{4}\tfrac{b_4'}{b_4}\tau_{x_4}\psi_- = V\psi_+ :$$

the derivatives and the gravitational term of one half are balanced by the mass term of the other half (PROVED; Notebook 07b, In [19]; Wolfram check `block_form`; formula record key `field_equation_blocks`).

The evolution form. Write the explicit equation with the x_4 term separately ($f_4 = 1$), with the gravitational term $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$, and solve it for $\partial_4\Psi$, line by line:

$$\gamma^{(x_4)}\partial_4\Psi + \sum_{a \neq x_4} \frac{1}{f_a}\gamma^{(a)}\partial_a\Psi + M\Psi = V\Psi$$

(the field equation);

$$\gamma^{(x_4)}\partial_4\Psi = V\Psi - \sum_{a\neq x_4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi - M\Psi$$

(every other term moved to the right side);

$$\partial_4\Psi = -\gamma^{(x_4)}\Big[V\Psi - \sum_{a\neq x_4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi - M\Psi\Big]$$

(multiplied from the left by $-\gamma^{(x_4)}$, using $-\gamma^{(x_4)}\gamma^{(x_4)} = 1$ because $(\gamma^{(x_4)})^2 = \eta_{44} = -1$). So the time derivative of every component is fixed by the field and its derivatives along the other seven directions at the same time x_4: the slices $x_4 = \text{const}$ are **non-characteristic** (PROVED; Notebook 07b, In [19]; `wolfram-field-theory-b4.json`, checks `evolution_form_G` and `evolution_form_C`; the part $\frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ of M gives $-\frac{3}{4}(b_4'/b_4)\Psi$ on the right, formula record key `evolution_form`). Scope, from the Revision scope record: this does NOT make the initial-value problem well posed. For data that depend on the extra times the growth rates of the modes have no upper bound (Section 7.5; `Revision/theory/reports/python-scope.json`, check `extra_time_growth_rates_unbounded`), so small changes of the data can grow without limit in any time; Chapter 8 treats this.

7.23 Non-triviality [1] and [2], their exact scope, and an exact family of solutions

The author's requirement. The author asked that the Lagrangians of both fields be **non-trivial**: their Euler-Lagrange equations must always contain nonzero contributions from gravity through the canonical spin connection, unless space-time is flat 4+4 space ([1] for dirac16complex, [2] for dirac16complex00), and must be self-consistent.

What "self-consistent" means for field equations. Here the word has a meaning of its own, different from its meaning for a Kohn-Sham state in Chapters 13 to 15 (there a state is self-consistent when the potential computed from the density of its orbitals is the potential that produced them, a fixed point). Field equations are **self-consistent** when they do not contradict one another or the geometry in which they live: the equations obtained by varying different fields form one system, and the further equations that follow from them (by differentiating them, or by combining them with identities of the metric) hold without any extra condition on the field or on the metric (this plain-word summary is the book's; the exact content is the list of senses below). The specification of the Revision record (`Revision/SPEC.md`, section 3) names three parts: the integrability of the field equations, the conserved current and the Bianchi-type identity of the energy-momentum tensor. The record itself (`Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`, section 8, "Self-consistency") states six exact senses. This book treats them as follows. The record proves (iii), (v) and (vi) for the metric at $b_4 = 1$; for a general b_4 the record contains (i), (ii) and the local law of (iv), while the Noether identities of (v), the Lichnerowicz identity of (iii) and the exact solutions of (vi) were NOT recomputed for a general b_4 (`Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`; `claude_failures.md`, C1).

(i) One system. The adjoint equation, obtained by varying Ψ, is the Dirac conjugate of the field equation, obtained by varying $\Psi^\dagger$ (PROVED in Section 7.21; Notebook 07b, In [16]; checks `adjoint_equation_is_Dirac_conjugate_G` and `grassmann_adjoint_equation_is_conjugate`).

(ii) An evolution form, but no well-posed initial-value problem. The field equation can be

solved for the time derivative $\partial_4\Psi$, so the slices $x_4 = \text{const}$ are non-characteristic (PROVED in Section 7.22; check `evolution_form_G`), and the Heisenberg equation of the quantised field reproduces this evolution form (Section 10.12; checks `Heisenberg_equation_reproduces_field_equation` and `hamiltonian_form_and_heisenberg_equation`). For data that depend on the extra times the initial-value problem is NOT well posed (Section 7.5 and Sections 8.16 to 8.18; check `extra_time_growth_rates_unbounded`).

(iii) Integrability. A first-order equation implies a second-order one. Take $U = 0$, so that the right side is $m\Psi$ with a constant number m. Line by line: $\gamma^\nu D_\nu(\gamma^\mu D_\mu\Psi) = \gamma^\nu D_\nu(m\Psi)$ (apply the operator $\gamma^\nu D_\nu$ to both sides of the field equation); $= m\,\gamma^\nu D_\nu\Psi$ (the number m is constant, and D_ν is linear); $= m^2\Psi$ (the field equation once more). So every solution obeys $(\gamma^\mu D_\mu)^2\Psi = m^2\Psi$. The Revision record proves the **Lichnerowicz identity** for the square of the Dirac operator in the author's metric, for every Ψ, solution or not:

$$(\gamma^\mu D_\mu)^2\Psi = g^{\mu\nu}\big(D_\mu D_\nu\Psi - \Gamma^\lambda{}_{\mu\nu} D_\lambda\Psi\big) - \frac{R}{4}\Psi, \qquad R = 6\big((a_4')^2 - 7H^2\big) \text{ at } b_4 = 1.$$

Here $D_\mu D_\nu\Psi$ is D_μ applied to the column $D_\nu\Psi$; the term with the Christoffel symbols $\Gamma^\lambda{}_{\mu\nu}$ (Section 3.15; not the matrix Γ) corrects for the index ν, as for the covariant derivative of a vector; the sum with the inverse metric $g^{\mu\nu}$ makes the whole first term the curved-space form of the wave operator; and R is the Ricci scalar of the author's metric (Section 3.17; its value is derived in Sections 3.25 and 8.7; with b_4 it is $R = 6a_4'^2 - 3a_4'b_4'/b_4 + 3b_4''/b_4 - 42H^2$, formula record key `ricci_scalar`). In flat 4+4 space with Cartesian coordinates ($D_\mu = \partial_\mu$, no Christoffel symbols, $R = 0$) the identity reads $(\gamma^{(a)}\partial_a)^2 = \sum_a \eta^{aa}\partial_a^2$, the operator form of the Clifford square of Section 7.5. Combined with the line above, every solution obeys the second-order equation $g^{\mu\nu}(D_\mu D_\nu\Psi - \Gamma^\lambda{}_{\mu\nu}D_\lambda\Psi) - \frac{R}{4}\Psi = m^2\Psi$, in which the curvature appears only as the term $-\frac{R}{4}\Psi$; in the record's words, the second-order consequence of the field equations is consistent with the curvature. Status: the identity is PROVED in the Revision record for the metric at $b_4 = 1$ (checks `Lichnerowicz_identity_G` of `wolfram-field-theory.json`, `lichnerowicz_identity_on_fields` and `lichnerowicz_contraction` of `python-field-theory.json`); it is quoted here and NOT derived in this book. It is a general identity of the square of the Dirac operator, but the record has not checked it for the metric with a changing b_4.

(iv) A conserved current. The phase change $\Psi \to e^{i\alpha}\Psi$ leaves the Lagrangian unchanged, and the quantity that belongs to this symmetry is the **current** $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, whose time component is the charge density (Section 7.28). It is real and obeys the local law $\nabla_\mu J^\mu = 0$, that is $\sum_\mu \partial_\mu(\sqrt{|g|}\,J^\mu) = 0$ with $\sqrt{|g|} = b_4^{3/2}\cos z$, on every solution (PROVED; derived line by line in Section 21.17; checks `current_conservation_identity_G` and `grassmann_current_conservation` at $b_4 = 1$, and `u1_noether_matrix_identity_b4` of `python-field-theory-b4.json` for every b_4). The total charge of a slice of constant x_4 is constant only if no charge flows through the brane $z = \pi/2$; this no-flux condition is ASSUMED, not derived (Sections 21.17 and 21.18).

(v) The Bianchi-type identity of the energy-momentum tensor. The invariance of the action under changes of coordinates and under local frame rotations gives identities that hold for every field, solution or not (like the Bianchi identity of the curvature, Section 3.17); on every solution they make the energy-momentum tensor symmetric and conserved, $\nabla_\mu T^\mu{}_\nu = 0$ (PROVED in the Revision record for the metric at $b_4 = 1$, checks `Noether_identity_diffeomorphisms_G`, `Noether_identity_local_Lorentz_G` and `conservation_on_shell_general`; Chapter 9 uses it without its proof and derives what it says for a diagonal tensor, Sections 9.9 to 9.11).

(vi) Exact solutions as test points. The exact family derived at the end of this section solves the field equation for every a_4 and every constant b_4 (PROVED here; Notebook 07b, In [21]); the record also verifies that T and J are conserved exactly at these solutions, and states the scope of this test: there the pressures vanish, so the general proof is the pair of identities of (v) (checks `exact_solution_x4_x0_G` and `exact_solution_family_x4_x0`).

The non-triviality theorem below answers the first half of the author's requirement, (i) to (vi) the second half. Self-consistency in these senses is a property of the equations: it does not make the initial-value problem well posed (ii), and it imposes no boundary condition at $z = \pi/2$ (iv).

Theorem (non-triviality [1] and [2] in the diagonal frame). Hypotheses: the author's metric with $H > 0$ and $0 < z < \pi/2$; any function $a_4(x_4)$, a constant one included; a constant $b_4 > 0$ (as on the backgrounds $b_4 = 1$; a changing b_4 is treated after the proof); real m and λ; the diagonal frame and its canonical spin connection; a field Ψ of either statistics that is not identically zero. Then the field-equation residual computed with the spin connection minus the one computed with $\Omega_\mu = 0$ is

$$\gamma^\mu \Omega_\mu \Psi = 3H\gamma^{(x_0)}\Psi \neq 0.$$

Proof. The difference is $\gamma^\mu(D_\mu - \partial_\mu)\Psi = \gamma^\mu\Omega_\mu\Psi$ by the definition of D_μ, and $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ for a constant b_4 by Section 7.18. The matrix $\gamma^{(x_0)}$ is a signed permutation matrix with $(\gamma^{(x_0)})^2 = 1$, so every component of $\gamma^{(x_0)}\Psi$ is $\pm$ a component of Ψ, and $3H\gamma^{(x_0)}\Psi = 0$ forces $\Psi = 0$ when $H > 0$. $\square$ (PROVED; Notebook 07b, In [20], checks the difference in all 16 components for both statistics.) Moreover, Ω_μ vanishes for all μ only if $H = 0$, because six of its 12 nonzero components are H times a factor that never vanishes (and the other six are a_4' or $a_4' - b_4'/(2b_4)$ times such a factor); $H = 0$ is not a member of the author's family (it is a degenerate limit in which g_{11} and g_{55} go to 0 and g_{00} to infinity), and the metric is curved for every $H > 0$, since $R^{x_0}{}_{x_0} = -6H^2$ (the checks are listed in the table at the end of this section).

A changing b_4. Then the difference is $M\Psi$ with $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$. Because $\gamma^{(x_0)}$ and $\gamma^{(x_4)}$ anticommute and $(\gamma^{(x_0)})^2 = 1$, $(\gamma^{(x_4)})^2 = -1$, the cross terms cancel and $MM = (9H^2 - \frac{9}{16}(b_4'/b_4)^2)1$. So $M\Psi = 0$ forces $\Psi = 0$ at every time where $|b_4'/b_4| \neq 4H$; at a time where $|b_4'/b_4| = 4H$ the matrix M has rank 8 and $M\Psi$ vanishes for the fields in its null space (PROVED; `python-field-theory-b4.json`, check `gravity_term_square_b4`; Notebook 07b, In [20], checks the difference $M\Psi$ in all 16 components). The theorem, as the record states it, is the case of a constant b_4.

The exact scope of the theorem. The value $3H\gamma^{(x_0)}$ belongs to the diagonal frame and to the field variables Ψ; read without these hypotheses the theorem would overstate [1] and [2]. The Revision record states, and its scope reports verify exactly:

- In another frame of the same metric, boosted in the (x_4, x_0) plane with the rapidity $6Hx_4 + b_0$, the term $\gamma^\mu\Omega_\mu$ vanishes identically (for a constant b_4; Section 6.16).
- Within the diagonal frame the rescaling $\Psi = \sin^{-1/2} z\, \chi$ removes it (derived below for a constant b_4; for a changing b_4 the rescaling $\Psi = \sin^{-1/2} z\, b_4^{-3/4}\chi$ removes all of M, Section 6.18).
- The deflation contributes nothing to $\gamma^\mu\Omega_\mu$: a_4 enters the field equation only through the frame factors $e^{-a_4}\sin^{-1/6} z$ and $e^{a_4}b_4^{-1/2}\sin^{-1/6} z$ of the derivative terms. And since the connection

drops out of $\mathcal{L}$ (Section 7.20), the Euler-Lagrange equations are those of the connection-free symmetric Lagrangian; $M = \frac{1}{2\sqrt{|g|}}\partial_\mu(\sqrt{|g|}\gamma^\mu)$ is its volume-and-frame term.

- What is frame-independent: Ω_μ itself vanishes in no frame, because its curvature is the Riemann tensor of the metric, which is not zero; and the frame factors enter every derivative term. In this qualified sense [1] and [2] hold; Chapter 8 discusses the frame dependence further.

The rescaling, line by line. Put $\Psi = \sin^{-1/2} z\,\chi$. Take b_4 constant. Only the x_0 term of the Dirac operator acts on the factor $\sin^{-1/2} z$, so by the product rule

$$\gamma^\mu D_\mu \Psi = \sin^{-1/2} z\,\gamma^\mu D_\mu \chi + \tan z\,\gamma^{(x_0)}\big(\partial_0 \sin^{-1/2} z\big)\chi.$$

The derivative is $\partial_0 \sin^{-1/2} z = -\frac{1}{2}\sin^{-3/2} z\cos z \cdot 6H$ (the power rule and the chain rule with $dz/dx_0 = 6H$), so the last term is

$$\frac{\sin z}{\cos z}\cdot\big(-3H\sin^{-3/2} z\cos z\big)\gamma^{(x_0)}\chi = -3H\sin^{-1/2} z\,\gamma^{(x_0)}\chi.$$

And $\gamma^\mu D_\mu\chi = \gamma^\mu\partial_\mu\chi + 3H\gamma^{(x_0)}\chi$. The two $3H$ terms cancel:

$$\gamma^\mu D_\mu \Psi = \sin^{-1/2} z\,\gamma^\mu\partial_\mu\chi.$$

For $U = 0$ the equation for χ therefore has no spin-connection term. For $U = \frac{\lambda}{2}S^2$ the scalar density is $S[\Psi] = S[\chi]/\sin z$ (the factor is real), and the term becomes the x_0-dependent coupling $\lambda S[\chi]/\sin z$ in $\gamma^\mu\partial_\mu\chi = (m + \lambda S[\chi]/\sin z)\chi$.

An exact family of solutions. Look for solutions that depend only on the time x_4 and the hidden direction x_0, of the form $\Psi = \sin^\alpha z\,P(x_4)\,\chi_0$ with a constant column χ_0, a number α and a 16×16 matrix function P. Take $\lambda = 0$. Line by line:

$$\gamma^{(x_4)}\partial_4\Psi + \tan z\,\gamma^{(x_0)}\partial_0\Psi + 3H\gamma^{(x_0)}\Psi = m\Psi$$

(the explicit equation for a constant b_4; the derivatives along the other six directions vanish, which is why the result holds for EVERY a_4);

$$\sin^\alpha z\,\big[\gamma^{(x_4)}P' + (6H\alpha + 3H)\gamma^{(x_0)}P\big]\chi_0 = m\sin^\alpha z\,P\chi_0$$

(because $\tan z\,\partial_0\sin^\alpha z = \frac{\sin z}{\cos z}\,\alpha\sin^{\alpha-1} z\cos z\cdot 6H = 6H\alpha\sin^\alpha z$);

$$P' = -\gamma^{(x_4)}\big(m - 3H(2\alpha+1)\gamma^{(x_0)}\big)P = MP, \qquad M = -m\gamma^{(x_4)} + 3H(2\alpha+1)\gamma^{(x_4)}\gamma^{(x_0)}$$

(divide by $\sin^\alpha z$, require the bracket for every χ_0, and multiply by $-\gamma^{(x_4)}$, using $(\gamma^{(x_4)})^2 = -1$). The matrix M squares to a number: with $\beta = 3H(2\alpha+1)$,

$$M^2 = m^2(\gamma^{(x_4)})^2 - m\beta\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)} + \gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_4)}\big) + \beta^2\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)} = -m^2 + 0 + \beta^2 = k^2$$

with $k^2 = 9H^2(2\alpha+1)^2 - m^2$ (the middle bracket is $-\gamma^{(x_0)} + \gamma^{(x_0)} = 0$, because $\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_4)} = -\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)} = \gamma^{(x_0)}$; the last product is $-\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_0)} = -(-1)(1) = 1$). Therefore

$$P(x_4) = \cosh(kx_4) + \frac{\sinh(kx_4)}{k} M$$

solves $P' = MP$ with $P(0) = 1$: $P' = k\sinh(kx_4) + \cosh(kx_4)M$ and $MP = \cosh(kx_4)M + \frac{\sinh(kx_4)}{k}k^2$, the same. Moreover $M^TC + CM = 0$ (from $(\gamma^{(x_4)})^TC = -C\gamma^{(x_4)}$ and $\gamma^{(x_4)}C = C\gamma^{(x_4)}$, $\gamma^{(x_0)}C = -C\gamma^{(x_0)}$), which gives $\frac{d}{dx_4}(P^TCP) = P^T(M^TC + CM)P = 0$, so $P^TCP = C$ and the scalar density $S = \sin^{2\alpha} z\, \chi_0^\dagger C\chi_0$ does not change with x_4 (P is real) (PROVED; Notebook 07b, In [21]). Two members, with the illustration values $H = 1$, $m = 2$, $\chi_0 = e_1 + e_5$ (components 1 and 5 equal to 1):

- $\alpha = 0$: $k^2 = 9 - 4 = 5$, and P grows like $e^{\sqrt{5}x_4}$. This is an x_0-independent growing mode, which exists without a boundary condition at $z = \pi/2$ whenever $m^2 < 9H^2$ (the scope record, table below). Its scalar density is $\chi_0^T C\chi_0 = 2C_{1,5} = -2$.
- $\alpha = -\frac{1}{2}$: $2\alpha + 1 = 0$, $M = -m\gamma^{(x_4)}$, $k^2 = -m^2 = -4$, so $\cosh(kx_4) = \cos 2x_4$ and $\sinh(kx_4)/k = \sin(2x_4)/2$: the solution oscillates. This is the rescaling $\Psi = \sin^{-1/2} z\, \chi$ above, in which the $3H$ term disappears. Its scalar density at $z = \pi/4$ is $-2/\sin z = -2\sqrt{2} = -2.828427$.

Notebook 07b evaluates both members at $z = \pi/4$ for x_4 from 0 to 2 and finds $S = -2.000000$ and -2.828427, constant along x_4 (In [22], Figure 07b.5; COMPUTED). Put into the equation WITHOUT the term $3H\gamma^{(x_0)}\Psi$, the growing solution leaves the residual $3H\gamma^{(x_0)}\Psi$, whose largest component is $3H$ times the largest component of Ψ (In [24], Figure 07b.6): the gravitational term is needed for the solution. These solutions are test points; at them the pressures vanish, so they are a weak test of the energy-momentum tensor, whose conservation is proved in general in Chapter 9.

Where the statements of this section are verified (the reports in the folder `Revision/theory/reports`):

statement	status	where it is verified
the gravitational term $3H\gamma^{(x_0)}\Psi$ of the field equation is nonzero for a constant b_4, both statistics	PROVED; Notebook 07b, In [20]	`wolfram-field-theory.json`, checks `nontriviality_1_dirac16complex` and `nontriviality_2_dirac16complex00` (at $b_4 = 1$)
with a changing b_4: $MM = (9H^2 - \frac{9}{16}(b_4'/b_4)^2)1$, so $M\Psi \neq 0$ unless $\lvert b_4'/b_4\rvert = 4H$	PROVED	`python-field-theory-b4.json`, check `gravity_term_square_b4`

statement	status	where it is verified
$\Omega_\mu = 0$ only for $a_4' = 0$ and $H = 0$ (at $b_4 = 1$); $H = 0$ degenerate; curved for every $H > 0$	PROVED	`python-field-theory.json`, check `nontriviality_Omega_zero_iff_flat`; `wolfram-field-theory.json`, checks `Omega_vanishes_iff_a4prime_and_H_vanish`, `degenerate_at_H_0` and `never_flat_for_H_positive`
the boosted frame removes $\gamma^\mu \Omega_\mu$ (constant b_4)	PROVED (quoted)	`wolfram-scope.json` and `python-scope.json`, check `boosted_frame_gammaOmega_vanishes`
the rescaling $\Psi = \sin^{-1/2} z\, \chi$ removes it; the coupling $\lambda S[\chi]/\sin z$ (constant b_4; with b_4 see Section 6.18)	PROVED here	scope reports, checks `rescaling_removes_the_connection_term` and `rescaled_equation_quadratic_potential`
$\gamma^\mu \Omega_\mu$ does not see the deflation; the equations are those of the connection-free Lagrangian	PROVED (quoted)	scope reports, checks `gammaOmega_blind_to_the_deflation` and `connection_free_lagrangian_same_equations`
Ω_μ vanishes in no frame	PROVED (quoted)	`wolfram-scope.json`, check `boosted_frame_curvature_nonzero`; `wolfram-field-theory.json`, check `spin_curvature_equals_Riemann`
the exact family of solutions, $M^2 = k^2$, $M^T C + C M = 0$	PROVED; In [21]	`python-field-theory.json`, check `exact_solution_family_x4_x0`
growing x_0-independent modes without a boundary condition at $z = \pi/2$ when $m^2 < 9H^2$	PROVED (quoted); In [21]	`python-scope.json`, check `good_sector_x0_independent_modes_without_boundary_condition`
self-consistency (ii): the Heisenberg equation reproduces the evolution form	PROVED (quoted; derived in Section 10.12)	`wolfram-field-theory.json`, check `Heisenberg_equation_reproduces_field_equation`; `python-field-theory.json`, check `hamiltonian_form_and_heisenberg_equation`

statement	status	where it is verified
self-consistency (iii): the Lichnerowicz identity, $R = 6((a_4')^2 - 7H^2)$ (at $b_4 = 1$)	PROVED in the record at $b_4 = 1$, quoted, NOT derived in this book (R derived in Sections 3.25 and 8.7)	`wolfram-field-theory.json`, check `Lichnerowicz_identity_G`; `python-field-theory.json`, checks `lichnerowicz_identity_on_fields` and `lichnerowicz_contraction`
self-consistency (iv): the local law $\nabla_\mu J^\mu = 0$	PROVED (derived in Section 21.17)	`wolfram-field-theory.json`, check `current_conservation_identity_G`; `python-field-theory.json`, check `grassman_current_conservation`
self-consistency (v): the Noether identities; T symmetric and conserved on shell	PROVED in the record, quoted (used in Chapter 9)	`wolfram-field-theory.json`, checks `Noether_identity_diffeomorphisms_G`, `Noether_identity_local_Lorentz_G` and `conservation_on_shell_general`
self-consistency (vi): T and J conserved at the exact solutions	PROVED (quoted)	`wolfram-field-theory.json`, check `exact_solution_x4_x0_G`

7.24 Example: Notebook 07b derives the field equations in the author's metric

Notebook 07b derives everything of Sections 7.18 to 7.23 exactly, with the computer doing every step of algebra that a person would do by hand. It reads the author's gammas and C from the Revision record; builds the metric from its frame and checks $\sqrt{|g|} = \cos z$; computes the 25 Christoffel symbols, the 12 components of the spin connection and $\gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ direction by direction; writes the Lagrangian of both fields in an exact jet algebra (392 and 408 monomials); proves its reality, the total divergence and the absence of the connection; derives the 16 Euler-Lagrange equations of both statistics and compares them term by term with the formula record; checks the block and evolution forms, non-triviality, and the exact family of solutions. Every result that the Revision record also contains is checked against it. It draws six figures and ends with the line ALL 47 CHECKS PASSED (notebook 07b).

7.25 How to run Notebook 07b

Step 1. What this notebook does and what it needs.

Notebook 07b (The Euler-Lagrange equations in the author's metric) is the file `Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb` of the repository Dirac_claude. It builds the author's primordial metric, its diagonal frame, Christoffel symbols and canonical spin connection from the Revision gamma matrices with exact computer algebra, shows that the spin-connection term of the field equation is 3 H gamma^(x0) because the time terms of the three inflating and the three deflating directions cancel, writes the Lagrangian of both fields in an exact jet algebra

(392 monomials for dirac16complex, 408 for dirac16complex00), proves that it is real, derives the 16 Euler-Lagrange equations for both statistics, compares them term by term with the Revision formula record, checks their chiral block form and their evolution form, verifies an exact family of solutions, and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 07b_euler_lagrange_metric.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 07b_euler_lagrange_metric.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 07b_euler_lagrange_metric.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/07b.captions.json`
- `Revision/textbook/figures/07b_1_scale_factors.png`
- `Revision/textbook/figures/07b_2_gamma_omega_per_direction.png`
- `Revision/textbook/figures/07b_3_lagrangian_monomials.png`
- `Revision/textbook/figures/07b_4_coupling_map.png`
- `Revision/textbook/figures/07b_5_exact_solutions.png`
- `Revision/textbook/figures/07b_6_residuals.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 47 CHECKS PASSED (notebook 07b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 07b_euler_lagrange_metric.ipynb
python -m nbconvert --execute --inplace 07b_euler_lagrange_metric.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/..." or a check that names Revision/theory/field-theory.json fails: the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory Revision/algebra
```

7.26 Notebook 07b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the

cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook derives the field equations of the two fields of the book in the
author's primordial gravitational field, exactly, with the computer doing every
step of algebra that a person would do by hand. It

- reads the author's gamma matrices and the matrix $C$ from the Revision record and
  checks the Clifford relation;
- builds the author's metric from its diagonal frame (vielbein), checks that the
  volume factor is $\sqrt{|g|} = \cos z$, and plots the scale factors of 3-space
  and of the three deflating extra times;
- computes the 25 nonzero Christoffel symbols, the 12 nonzero components of the
  canonical spin connection and the spinor connection $\Omega_\mu$;
- shows that the spin-connection term of the field equation is
  $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$: the time terms of the three inflating
  and the three deflating directions cancel, the hidden-direction terms add up;
- writes the Lagrangian of both fields in an exact "jet" algebra: 392 monomials
  for dirac16complex (anticommuting) and 408 for dirac16complex00 (commuting), the
  difference being 16 squares $(\bar\Psi_A\Psi_B)^2$ that vanish for Grassmann
  numbers;
- proves that the Lagrangian is real, that it differs from the unsymmetrised form
  by a total divergence, and that the spin connection drops out of it in this
  metric;
- derives the 16 Euler-Lagrange equations for both statistics and shows that they
  are the same: $\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$;
- writes them out in the author's metric and compares every one of the 16 component
  equations term by term with the Revision formula record
  Revision/theory/field-theory.json;
- checks two more forms of the same equations: the chiral block form (each
  equation relates the two halves of $\Psi$) and the evolution form, which gives
  the time derivative $\partial_4\Psi$ from the field at one time;
- verifies an exact family of solutions and shows numerically that it fails when
  the spin-connection term $3H\gamma^{(x_0)}$ is left out.

Every result that the Revision record also contains is checked against it; such a
PASS line is followed by a line "reproduces <record file>, check <name>".
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 07b (The Euler-Lagrange equations in the author's metric) is the file
`Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb` of the repository
Dirac_claude. It builds the author's primordial metric, its diagonal frame, Christoffel
symbols and canonical spin connection from the Revision gamma matrices with exact
computer algebra, shows that the spin-connection term of the field equation is 3 H
```

gamma^(x0) because the time terms of the three inflating and the three deflating directions cancel, writes the Lagrangian of both fields in an exact jet algebra (392 monomials for dirac16complex, 408 for dirac16complex00), proves that it is real, derives the 16 Euler-Lagrange equations for both statistics, compares them term by term with the Revision formula record, checks their chiral block form and their evolution form, verifies an exact family of solutions, and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of

‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 07b_euler_lagrange_metric.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 30 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.

**Step 6. Or run the notebook without a browser (headless).**

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 07b_euler_lagrange_metric.ipynb

This runs every cell from the top to the bottom and saves the results into the notebook
```

file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 07b_euler_lagrange_metric.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/07b.captions.json‘
- ‘Revision/textbook/figures/07b_1_scale_factors.png‘
- ‘Revision/textbook/figures/07b_2_gamma_omega_per_direction.png‘
- ‘Revision/textbook/figures/07b_3_lagrangian_monomials.png‘
- ‘Revision/textbook/figures/07b_4_coupling_map.png‘
- ‘Revision/textbook/figures/07b_5_exact_solutions.png‘
- ‘Revision/textbook/figures/07b_6_residuals.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 47 CHECKS PASSED (notebook 07b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with

  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 07b_euler_lagrange_metric.ipynb
python -m nbconvert --execute --inplace 07b_euler_lagrange_metric.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/theory/reports/..." or a check that names Revision/theory/field-theory.json fails: the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory Revision/algebra
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 07b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 07b (The Euler-Lagrange equations in the author's metric) is the file
# Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb of the repository
# Dirac_claude. It builds the author's primordial metric, its diagonal frame, Christoffel
# symbols and canonical spin connection from the Revision gamma matrices with exact
# computer algebra, shows that the spin-connection term of the field equation is 3 H
# gamma^(x0) because the time terms of the three inflating and the three deflating
# directions cancel, writes the Lagrangian of both fields in an exact jet algebra (392
# monomials for dirac16complex, 408 for dirac16complex00), proves that it is real,
# derives the 16 Euler-Lagrange equations for both statistics, compares them term by term
# with the Revision formula record, checks their chiral block form and their evolution
```

```
# form, verifies an exact family of solutions, and draws six teaching plots. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
```

```
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
```

```
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 07b_euler_lagrange_metric.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 07b_euler_lagrange_metric.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 07b_euler_lagrange_metric.ipynb (in the same folder, without running the cells again)
# to read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/07b.captions.json
# - Revision/textbook/figures/07b_1_scale_factors.png
# - Revision/textbook/figures/07b_2_gamma_omega_per_direction.png
# - Revision/textbook/figures/07b_3_lagrangian_monomials.png
# - Revision/textbook/figures/07b_4_coupling_map.png
```

```
# - Revision/textbook/figures/07b_5_exact_solutions.png
# - Revision/textbook/figures/07b_6_residuals.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 47 CHECKS PASSED (notebook 07b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/07b_euler_lagrange_metric.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 07b_euler_lagrange_metric.ipynb
#     python -m nbconvert --execute --inplace 07b_euler_lagrange_metric.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
```

```
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "ValueError: ... is not a passing check of Revision/theory/reports/..." or a check
#   that names Revision/theory/field-theory.json fails: the Revision record files of your
#   copy of the repository differ from the committed ones; restore them with the command
#   below (run in the repository folder) and run the notebook again.
#     git restore Revision/theory Revision/algebra
#

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$, named as the author names them: $x_1, x_2,
  x_3$ ordinary 3-space; $x_4$ the time; $x_5, x_6, x_7$ the three **extra
  times** (time-like directions that shrink, "deflate", as $a_4$ grows); $x_0$ the
  **hidden** space direction. In the program they are list positions 0 to 7.
- **Metric** $g_{\mu\nu}$: the table that gives lengths and time intervals,
  $ds^2 = \sum g_{\mu\nu} dx_\mu dx_\nu$. The author's metric is diagonal. Its
  **signature** (4,4): four space-like directions ($x_0, x_1, x_2, x_3$, positive
  entries) and four time-like ones ($x_4, \dots, x_7$, negative entries).
- $z = 6Hx_0$, with the author's constant $H > 0$ and $0 < z < \pi/2$; $a_4(x_4)$ is
  the free function of time in the metric; $a_4' = da_4/dx_4$.
- **Scale factor**: the number by which a coordinate distance is multiplied to give
  a real (proper) distance: $e^{a_4}\sin^{1/6}z$ for 3-space, $e^{-a_4}\sin^{1/6}z$
  for the extra times. When $a_4$ grows, 3-space inflates and the extra times
  deflate.
- **Vielbein (frame)** $e^a{}_\mu = f_a\delta^a_\mu$: a set of eight local unit
  directions; here simply the square roots $f_a = \sqrt{|g_{aa}|}$.
- **Frame gamma matrices** $\gamma^{(a)}$: the author's eight real $16\times16$
  matrices with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}$,
  $\eta = \mathrm{diag}(1,1,1,1,-1,-1,-1,-1)$ (in the order $x_0, \dots, x_7$).
  **Coordinate gammas** $\gamma^\mu =
```

```
  \gamma^{(\mu)}/f_\mu$.
- **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$: the numbers that say how the
  coordinate directions turn from point to point.
- **Canonical spin connection** $\omega_{\mu ab}$ and **spinor connection**
  $\Omega_\mu = \frac12\omega_{\mu ab}S^{ab}$, $S^{ab} = \frac14[\gamma^{(a)},
  \gamma^{(b)}]$: they say how the frame turns, and how a spinor must be turned
  with it. **Covariant derivative** $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$.
- **Lagrangian density** $L$: the function whose integral (the action) must not
  change to first order when the field is varied; that requirement is the
  **Euler-Lagrange equation**, the field equation.
- **Statistics**: whether the components commute (dirac16complex00) or
  anticommute (dirac16complex, Grassmann numbers).
- **Jet**: the value of a field component and its derivatives at one point,
  treated as independent symbols ($\psi_A$, $\partial_\mu\psi_A$, ...). The
  **total derivative** $d/dx_\mu$ acts on jets by raising the derivative order.
- **Coefficient ring**: the symbols $E = e^{a_4}$, $s = \sin^{1/6}z$, $c = \cos z$,
  $A_1 = a_4'$ and the second and third derivatives $A_2 = a_4^{\prime\prime}$,
  $A_3 = a_4^{\prime\prime\prime}$, together with $H$, $m$, $\lambda$, in which
  every coefficient is written; with the rule $c^2 = 1 - s^{12}$ it allows an
  exact test whether an expression is zero.
- **Monomial**: a product of jets with a coefficient, such as
  $E\,s\,\chi_3\,\partial_1\psi_7$.
- **On shell**: on solutions of the field equation.
```

Text cell:

```
## 4. The physical and mathematical situation

**The author's metric** (Revision/SPEC.md, section 1), $z = 6Hx_0 \in (0,
\pi/2)$:

$$ds^2 = e^{2a_4}\sin^{1/3}z\,(dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2
- e^{-2a_4}\sin^{1/3}z\,(dx_5^2 + dx_6^2 + dx_7^2) + \cot^2 z\, dx_0^2 .$$

3-space ($x_1, x_2, x_3$) has the scale factor $e^{a_4}\sin^{1/6}z$, the three
extra times ($x_5, x_6, x_7$) the scale factor $e^{-a_4}\sin^{1/6}z$: when $a_4$
increases, 3-space inflates and the extra times DEFLATE exponentially. Every
equation of this notebook holds for every function $a_4(x_4)$. Only the plots use a
definite history, the linear member $a_4 = AHx_4$ with $A = 1$ and $H = 1$; this
history is prescribed (a choice made for the picture, deflation being the choice of
sign $A > 0$), not a result.

**The two fields** have the same Lagrangian (Revision/SPEC.md, section 3):

$$L = \sqrt{|g|}\,\Big[\tfrac12\big(\bar\Psi\gamma^\mu D_\mu\Psi -
(D_\mu\bar\Psi)\gamma^\mu\Psi\big) - mS - \tfrac{\lambda}{2}S^2\Big],\quad
\bar\Psi = \Psi^\dagger C,\quad S = \bar\Psi\Psi,\quad D_\mu\bar\Psi =
\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu .$$

For dirac16complex the 16 components are complex Grassmann numbers, for
dirac16complex00 ordinary complex numbers.

**What we expect.** Varying $\Psi^\dagger$ should give the field equation
```

```
$\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$ for both statistics, and in the
author's metric

$$e^{-a_4}\sin^{-1/6}z\sum_{i=1}^{3}\gamma^{(x_i)}\partial_i\Psi
+ \gamma^{(x_4)}\partial_4\Psi + e^{a_4}\sin^{-1/6}z\sum_{t=5}^{7}
\gamma^{(x_t)}\partial_t\Psi + \tan z\,\gamma^{(x_0)}\partial_0\Psi
+ 3H\gamma^{(x_0)}\Psi = (m + \lambda S)\Psi .$$

**How the computer proves it.** Every coefficient is written with the symbols of
the coefficient ring; derivatives along $x_4$ and $x_0$ follow fixed rules
(section 6); and a coefficient is exactly zero when its numerator vanishes after
$c^2$ is replaced by $1 - s^{12}$. The field components and their derivatives at a
point are the generators of a jet algebra that can be commuting or anticommuting
(section 12). Nothing is approximated, except in the two numerical plots at the end.
```

Text cell:

```
## 5. The gamma matrices and $C$ from the Revision record

The next cell imports the packages and wraps the set-up cell's 'check' so that a
PASS line and the line "reproduces ..." that follows it are printed by one single
'print' call (Jupyter sends printed text in pieces; two separate prints can arrive
in two pieces, and the book's tools then do not see that the two lines belong
together). It then reads the eight frame gamma matrices
$\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$ and the matrix $C = \gamma^{(x_0)}
\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ from Revision/algebra/gammas.json as
exact sympy matrices, builds the 28 spin generators $S^{ab} = \frac14(\gamma^{(a)}
\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$, and defines a helper that looks up a
check of a Revision report and makes sure that its verdict is PASS. It then checks
the Clifford relation for all 64 pairs and the properties of $C$.
```

In [2]:

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)

## 6. Exact symbols for the metric functions (the coefficient ring)

Every coefficient will be written with the symbols $E = e^{a_4(x_4)}$, $s =
\sin^{1/6}z$, $c = \cos z$, $A_1 = a_4'$, $A_2 = a_4^{\prime\prime}$, $A_3 =
a_4^{\prime\prime\prime}$, the second function of the metric $b_4(x_4) > 0$ and its
derivatives (the symbols `b4`, `b4p`, `b4pp`, `b4ppp`), $H$, $m$ and $\lambda$.
Their derivatives follow from the chain rule, line by line:

- $\partial_4 E = e^{a_4}a_4' = E A_1$, $\partial_4 A_1 = A_2$, $\partial_4 A_2 =
  A_3$ (the derivative of $e^{a_4(x_4)}$ is $e^{a_4}$ times the derivative of the
  exponent); $\partial_4 b_4 = b_4'$, $\partial_4 b_4' = b_4''$, $\partial_4 b_4''
  = b_4^{\prime\prime\prime}$;
- $\partial_0 s = \frac16\sin^{-5/6}z\,\cos z \cdot 6H = H c/s^5$ (the power rule,
  then the derivative $\cos z$ of $\sin z$, then $dz/dx_0 = 6H$, and finally
  $\sin^{-5/6}z = s^{-5}$);
- $\partial_0 c = -\sin z \cdot 6H = -6Hs^6$ (because $\sin z = s^6$);
- no symbol depends on $x_1, x_2, x_3, x_5, x_6, x_7$.

The function `cd(expression, mu)` applies these rules (the product and chain rules
are done by sympy's `diff`). Since $\cos^2z + \sin^2z = 1$, the symbols obey
$c^2 = 1 - s^{12}$; the function `is_zero` brings an expression to one fraction and
replaces $c^2$ by $1 - s^{12}$ in its numerator (by polynomial division), which
decides exactly whether it is zero. The function `to_physical` turns ring
expressions back into functions of $x_4$ and $x_0$. The cell checks the derivative
rules against sympy's own derivatives of the physical functions.
```

In [3]:

```
E, s, c = sp.symbols("E s c", positive=True)  # e^a4, sin(z)^(1/6), cos z

## 7. The metric, its frame and the volume factor

The diagonal frame has $f_0 = c/s^6 = \cot z$, $f_1 = f_2 = f_3 = Es$, $f_4 = 1$,
$f_5 = f_6 = f_7 = s\sqrt{b_4}/E$, and the metric is $g_{aa} = \eta_{aa}f_a^2$. The
volume factor is the product of the $f_a$, worked out line by line:

$$\sqrt{|g|} = f_0 \cdot f_1 f_2 f_3 \cdot f_4 \cdot f_5 f_6 f_7
= \frac{c}{s^6} \cdot E^3s^3 \cdot 1 \cdot \frac{s^3b_4^{3/2}}{E^3} = b_4^{3/2}c
= b_4^{3/2}\cos z .$$

The first equality: for a diagonal metric $|\det g|$ is the product of the
$f_a^2$; the second inserts the $f_a$; the third cancels $E^3$ against $E^{-3}$
and $s^6$ against $s^{-6}$. The inflation $E^3$ of 3-space and the deflation
$E^{-3}$ of the extra times compensate: the 7-volume depends on the time only
through $b_4^{3/2}$, and not at all on the backgrounds $b_4 = 1$. The next cell
checks that the frame gives the author's metric entry by entry and that
$\sqrt{|g|} = b_4^{3/2}\cos z$, which is $\cos z$ at $b_4 = 1$.
```

In [4]:

```
f = [c / s**6] + [E * s] * 3 + [sp.Integer(1)] + [s * sp.sqrt(b4) / E] * 3  # frame
g = [ETA[a] * f[a] ** 2 for a in range(8)]  # the diagonal metric entries
sqrt_g = sp.prod(f)  # the volume factor
third = sp.sin(z) ** sp.Rational(1, 3)
author = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * third] * 3 + [-1]
          + [-sp.exp(-2 * a4) * b4f * third] * 3)  # the author's metric with b4

```

Text cell:

```
The formula record Revision/theory/field-theory.json stores the formulas of the
Wolfram verifier as text in the Wolfram Language (for example
‘E^a4[x4]*Sin[6*H*x0]^(1/6)‘). The next cell defines a small translator: it
rewrites such a text into sympy syntax (square brackets to round ones, ‘^‘ to
‘**‘, ‘Sin‘ to ‘sin‘, ‘a4[x4]‘, ‘b4[x4]‘ and their derivatives to symbols), lets
sympy read it, and then puts it into the ring: $a_4 \to \ln E$ (so $e^{a_4} \to
E$), $b_4$ and its derivatives to ‘b4‘, ‘b4p‘, ‘b4pp‘, $\sin z \to s^6$, $\cos z
\to c$, $\tan z \to s^6/c$, $\cot z \to c/s^6$, $\sec z \to 1/c$, $\csc z \to
1/s^6$ and $\csc 2z \to 1/(2s^6c)$ (from $\sin 2z = 2\sin z\cos z$). Then a record
formula and our own result can be compared with ‘is_zero‘. Two formula records are
read: ‘record‘ (the metric at $b_4 = 1$, Revision/theory/field-theory.json) and
‘record_b4‘ (the metric with $b_4$, Revision/theory/field-theory-b4.json). A result
of this notebook is compared with the first after ‘.subs(AT_B4_1)‘, which puts
$b_4 = 1$ and $b_4' = b_4'' = b_4^{\prime\prime\prime} = 0$. The cell compares the
frame and the
volume factor with the record of $b_4 = 1$.

## 8. The Christoffel symbols
```

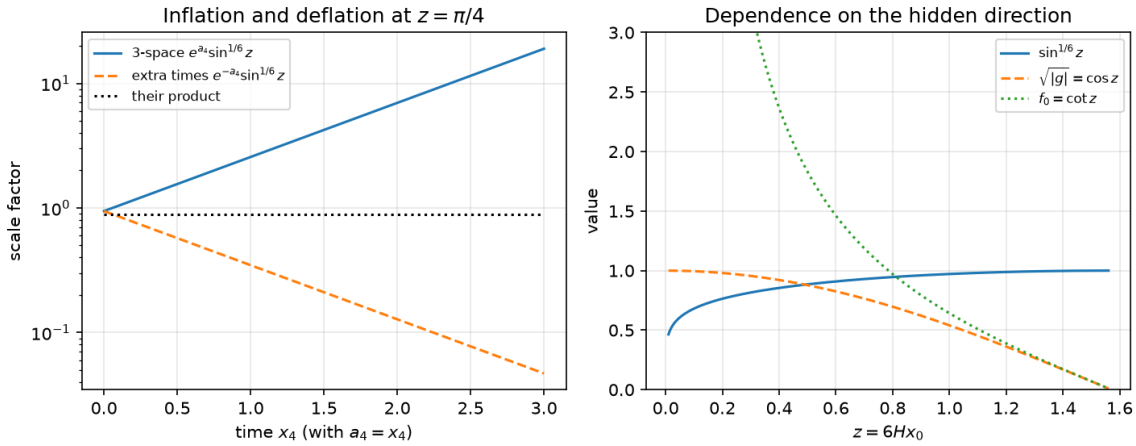

Figure 219: The author's metric along the deflating history $a_4 = AHx_4$ with the illustration values $A = 1$, $H = 1$ on the background $b_4 = 1$ (a prescribed history, not a result). Left, at $z = \pi/4$, against the time x_4 (logarithmic vertical axis, pure numbers): the scale factor of 3-space $e^{a_4} \sin^{1/6} z$ grows, that of the three extra times $e^{-a_4} \sin^{1/6} z$ shrinks exponentially, and their product stays constant. Right, at $x_4 = 0$, against $z = 6Hx_0$ from 0 to $\pi/2$: the common warp $\sin^{1/6} z$, the volume factor $\sqrt{|g|} = \cos z$ and the frame factor $\cot z$ of the hidden direction. (Notebook 07b, figure 1.)

```
For a metric that is diagonal, the general formula $\Gamma^\lambda{}_{\mu\nu} =
\frac12 g^{\lambda\rho}(\partial_\mu g_{\rho\nu} + \partial_\nu g_{\rho\mu} -
\partial_\rho g_{\mu\nu})$ keeps only $\rho = \lambda$, because $g^{\lambda\rho} =
0$ otherwise; then $\partial_\mu g_{\lambda\nu}$ is nonzero only for $\nu =
\lambda$, $\partial_\nu g_{\lambda\mu}$ only for $\mu = \lambda$, and
$\partial_\lambda g_{\mu\nu}$ only for $\mu = \nu$. So

$$\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}\big(\delta_{\lambda\nu}
\partial_\mu g_{\lambda\lambda} + \delta_{\lambda\mu}\partial_\nu g_{\lambda\lambda}
- \delta_{\mu\nu}\partial_\lambda g_{\mu\mu}\big),$$

which the next cell evaluates for all $8^3$ index triples. It counts the
independent nonzero symbols ($\mu \le \nu$), compares all of them with both formula
records, and prints four of them in the ring: $\Gamma^{x_1}{}_{x_1x_4} = a_4'$
(3-space stretches with time), $\Gamma^{x_5}{}_{x_4x_5} = -a_4' + b_4'/(2b_4)$ (the
extra times shrink; $-a_4'$ at $b_4 = 1$), $\Gamma^{x_1}{}_{x_0x_1} = H\cot z$ and
$\Gamma^{x_0}{}_{x_0x_0}$.
```

## 9. The canonical spin connection

The canonical spin connection is fixed by the **vielbein postulate**
$\partial_\mu e^a{}_\nu - \Gamma^\lambda{}_{\mu\nu}e^a{}_\lambda +
\omega_\mu{}^a{}_b\,e^b{}_\nu = 0$ (the frame is carried along consistently with
the metric). Its solution is $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu
e_b{}^\nu + \Gamma^\nu{}_{\mu\lambda}e_b{}^\lambda)$ with the inverse frame
$e_b{}^\nu = \delta_b^\nu/f_b$; for our diagonal frame this is
```

```
$$\omega_\mu{}^a{}_b = f_a\Big(\delta_{ab}\,\partial_\mu\frac{1}{f_b} +
\frac{\Gamma^a{}_{\mu b}}{f_b}\Big),\qquad \omega_{\mu ab} =
\eta_{aa}\,\omega_\mu{}^a{}_b .$$

The next cell computes it, checks that $\omega_{\mu ab} = -\omega_{\mu ba}$ and that
the vielbein postulate holds in all 512 components, counts the nonzero components
with $a < b$ (there should be 12), compares them with the formula record and prints
them.

vanishes. Six of them are $H$ times such a factor: the connection never vanishes,
because $H = 0$ is not a member of the author's family.
```

Text cell:

```
## 10. The spinor connection and the term $\gamma^\mu\Omega_\mu$

The spinor connection is $\Omega_\mu = \frac12\omega_{\mu ab}S^{ab} =
\sum_{a<b}\omega_{\mu ab}S^{ab}$ (the two halves of the double sum are equal
because both $\omega_{\mu ab}$ and $S^{ab}$ change sign when $a$ and $b$ are
exchanged). The coordinate gammas are $\gamma^\mu = \gamma^{(\mu)}/f_\mu$. The next
cell computes, for every direction $\mu$ separately (no sum), the matrix
$\gamma^\mu\Omega_\mu$ and writes it as $\alpha_\mu\gamma^{(x_4)} +
\beta_\mu\gamma^{(x_0)}$. The two numbers are found with traces, because
$\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_4)}) = -16$, $\mathrm{tr}(\gamma^{(x_0)}
\gamma^{(x_0)}) = 16$ and $\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_0)}) = 0$; the cell
checks that nothing else is left over. The hand calculation for an inflating
direction $i$, line by line:

$$\gamma^{x_i}\Omega_{x_i} = \frac{\gamma^{(i)}}{Es}\cdot\frac{Es}{2}\big(A_1
\gamma^{(i)}\gamma^{(x_4)} + H\gamma^{(i)}\gamma^{(x_0)}\big) = \frac12\big(A_1
\gamma^{(x_4)} + H\gamma^{(x_0)}\big),$$

where the factors $Es$ cancel and $(\gamma^{(i)})^2 = +1$. For a deflating extra
time $t$ the frame factor is $f_t = s\sqrt{b_4}/E$ and its rate is $\alpha_t =
\partial_4 f_t/f_t = -A_1 + b_4'/(2b_4)$; $\Omega_{x_t} = \frac{f_t}{2}(\alpha_t
\gamma^{(x_4)}\gamma^{(t)} - H\gamma^{(t)}\gamma^{(x_0)})$, and with
$(\gamma^{(t)})^2 = -1$ and $\gamma^{(t)}\gamma^{(x_4)}\gamma^{(t)} =
+\gamma^{(x_4)}$ one gets $\gamma^{x_t}\Omega_{x_t} = \frac12(\alpha_t\gamma^{(x_4)}
+ H\gamma^{(x_0)})$, which is $\frac12(-A_1\gamma^{(x_4)} + H\gamma^{(x_0)})$ at
$b_4 = 1$. The record with $b_4$ stores only the sum; the cell compares the eight
terms at $b_4 = 1$ with the record of $b_4 = 1$.

## 11. Why the connection drops out of $L$ but not out of the field equation

$\Omega_\mu$ contains only generators $S^{(\mu)b}$ that share the index $\mu$ with
$\gamma^{(\mu)}$, and $\gamma^{(\mu)}$ anticommutes with such an $S^{(\mu)b}$. So
$\{\gamma^\mu, \Omega_\mu\} = 0$ for each $\mu$ separately. The connection enters
the symmetrised kinetic term only as $\frac12\bar\Psi\{\gamma^\mu,\Omega_\mu\}\Psi$
(the $\Omega$ parts of the two halves of $K$), so it drops out of $L$ in this
metric. It comes back through the variation: the derivative of $\sqrt{|g|}
\gamma^\mu$ appears when the action is varied (section 15), and

$$\frac{1}{2\sqrt{|g|}}\,\partial_\mu\big(\sqrt{|g|}\,\gamma^\mu\big)
= \frac{1}{2b_4^{3/2}c}\Big[\partial_0\Big(b_4^{3/2}c\,\frac{s^6}{c}\Big)\gamma^{(x_0)}
+ \partial_4\big(b_4^{3/2}c\big)\gamma^{(x_4)}\Big]
= 3H\gamma^{(x_0)} + \frac34\,\frac{b_4'}{b_4}\,\gamma^{(x_4)} .$$

The first equality: only $\mu = x_0$ and $\mu = x_4$ contribute, because nothing
depends on the other six coordinates; $\gamma^{x_0} = \gamma^{(x_0)}/f_0 =
(s^6/c)\gamma^{(x_0)}$ and $\gamma^{x_4} = \gamma^{(x_4)}$. The second:
```

```
$c\cdot s^6/c = s^6 = \sin z$ and $\partial_0\sin z = 6H\cos z$, so the first term
is $6Hb_4^{3/2}c/(2b_4^{3/2}c) = 3H$; and $\partial_4 b_4^{3/2} = \frac32
b_4^{1/2}b_4'$, so the second is $\frac34 b_4'/b_4$ (zero at $b_4 = 1$). This
equals $\gamma^\mu\Omega_\mu$: the surviving term is the half-density (volume and
frame divergence) term. The next cell checks both statements.
```

## 12. Fields at one point: a jet algebra for both statistics

To vary the Lagrangian we need the field components and their derivatives at one
point as symbols. A **generator** is a triple `(kind, A, derivatives)`: `kind` 0
for a component $\chi_A = \Psi_A^*$ of $\Psi^\dagger$, `kind` 1 for a component
$\psi_A = \Psi_A$ of $\Psi$; `A` = 0 to 15; `derivatives` a sorted tuple of
coordinate positions (empty for the value itself, `(4,)` for $\partial_4$). An
element is a dictionary from sorted tuples of generators (monomials) to ring
coefficients, as in Notebook 07a, with one switch: `odd = True` makes the
generators anticommute (dirac16complex), `odd = False` makes them commute
(dirac16complex00).

- Products sort the generators; for odd generators every exchange gives $-1$ and a
  repeated generator gives 0; for even ones nothing changes sign.
- The conjugation reverses each product, exchanges $\chi_A \leftrightarrow \psi_A$
  (keeping the derivatives) and replaces $i$ by $-i$.
- The left (right) derivative with respect to a generator moves it to the far left
  (right) with the Grassmann signs; for commuting generators both are the ordinary
  partial derivative ($x^n \to n x^{n-1}$).
- The total derivative $d/dx_\mu$ differentiates the coefficient with `cd` and
  raises the derivative tuple of each generator in turn (product rule).
```

The next cell defines the class ‘Jet‘ and the vector helpers.

## 13. The Lagrangian of both fields

The next cell builds, for each statistics, the jets $\psi = \Psi$, $\chi =
\Psi^\dagger$, the row $\bar\Psi = \chi C$, the covariant derivatives $D_\mu\psi =
\partial_\mu\psi + \Omega_\mu\psi$ and $D_\mu\bar\Psi = \partial_\mu\bar\Psi -
\bar\Psi\Omega_\mu$, the kinetic term $K = \frac12\sum_\mu(\bar\Psi\gamma^\mu
```

```
D_\mu\psi - D_\mu\bar\Psi\gamma^\mu\psi)$, $S = \bar\Psi\psi$, and

$$L = \sqrt{|g|}\,\big(K - mS - \tfrac{\lambda}{2}S^2\big).$$

It also builds the unsymmetrised form $L_u = \sqrt{|g|}(\bar\Psi\gamma^\mu
D_\mu\psi - mS - \frac{\lambda}{2}S^2)$ and the residual of the expected field
equation, $\mathcal{E} = \gamma^\mu D_\mu\psi - (m + \lambda S)\psi$, and counts
the monomials of $L$ by type: kinetic ($8 \times 32 = 256$: in each direction 16
terms $\chi\,\partial\psi$ and 16 terms $\partial\chi\,\psi$), mass (16, one for
each nonzero entry of $C$), and quartic. In the quartic term $S^2 = \sum_{A,B}
P_AP_B$ with the 16 pairs $P_A = \chi_A C_{A\pi(A)}\psi_{\pi(A)}$: for commuting
numbers the 16 squares $P_A^2$ and the $\binom{16}{2} = 120$ products of two
different pairs survive (136), for Grassmann numbers the squares vanish (120).
```

In [13]:

## 14. Reality, the total divergence, and the connection that drops out

Three exact statements, for both statistics:

1. $L^* = L$: the Lagrangian is real. The proof by hand uses that $C\gamma^{(a)}$
   is real and antisymmetric (so the two halves of $K$ are complex conjugates of
   each other) and that $C$ is real and symmetric (so $S^* = S$). The control: the
   unsymmetrised $L_u$ is NOT real, so the test is not empty.
2. $L = L_u - \frac12\partial_\mu\big(\sqrt{|g|}\,\bar\Psi\gamma^\mu\Psi\big)$:
   the two forms differ by a total divergence and give the same field equations.
3. In this metric $L$ computed with $\Omega_\mu$ equals $L$ computed with
   $\Omega_\mu$ set to zero (section 11).

The next cell checks all three and names the Revision checks that state them.
```

## 15. The Euler-Lagrange equations

**The derivation by hand** (commuting field; the Grassmann case follows below).
Write $V = m + \lambda S$ and $L/\sqrt{|g|} = \frac12\Psi^\dagger C\gamma^\mu(
\partial_\mu\Psi + \Omega_\mu\Psi) - \frac12(\partial_\mu\Psi^\dagger C -
\Psi^\dagger C\Omega_\mu)\gamma^\mu\Psi - m\Psi^\dagger C\Psi -
\frac{\lambda}{2}(\Psi^\dagger C\Psi)^2$. Vary the component $\Psi_A^* = \chi_A$.

- Step 1. $\partial L/\partial\chi_A = \sqrt{|g|}\big[\frac12(C\gamma^\mu
  D_\mu\Psi)_A + \frac12(C\Omega_\mu\gamma^\mu\Psi)_A - V(C\Psi)_A\big]$ (every
  term with an undifferentiated $\chi$ contributes its column entry $A$; the chain
  rule gives $\partial(\frac{\lambda}{2}S^2)/\partial\chi_A = \lambda S(C\Psi)_A$).
- Step 2. $\partial L/\partial(\partial_\mu\chi_A) = -\frac12\sqrt{|g|}\,
  (C\gamma^\mu\Psi)_A$ (only the second term contains $\partial_\mu\chi$).
- Step 3. The Euler-Lagrange expression is Step 1 minus $\partial_\mu$ of Step 2,
  that is Step 1 plus $\frac12\partial_\mu(\sqrt{|g|}\,C\gamma^\mu\Psi)_A$.
- Step 4. By the product rule and section 11, $\partial_\mu(\sqrt{|g|}\gamma^\mu
  \Psi) = 2\sqrt{|g|}\gamma^\mu\Omega_\mu\Psi + \sqrt{|g|}\gamma^\mu\partial_\mu
  \Psi$, and $\gamma^\mu\Omega_\mu = -\Omega_\mu\gamma^\mu$ for each $\mu$.
- Step 5. Adding: the terms $\pm\frac12 C\Omega_\mu\gamma^\mu\Psi$ cancel, and
  $\frac12C\gamma^\mu D_\mu\Psi + \frac12 C\gamma^\mu\Omega_\mu\Psi + \frac12
  C\gamma^\mu\partial_\mu\Psi = C\gamma^\mu D_\mu\Psi$. So the expression is
  $\sqrt{|g|}\,\big(C(\gamma^\mu D_\mu\Psi - V\Psi)\big)_A$.
- Step 6. $\sqrt{|g|} = b_4^{3/2}\cos z \ne 0$ and $C$ is invertible ($C^2 = 1$), so the
  16 expressions vanish exactly when $\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$.

**Grassmann components.** The left derivative with respect to $\chi_A$ is used. In
every term of $L$ the factor $\chi$ (or $\partial_\mu\chi$) stands on the far left,
so moving it there costs no sign, and $S$ is even; Steps 1 to 6 go through word for
word. Varying $\psi_B$ with the right derivative gives the adjoint equation
$D_\mu\bar\Psi\gamma^\mu = -(m + \lambda S)\bar\Psi$, which is the Dirac conjugate
of the first one.

The next cell lets the computer do all of this: for every $A$ it computes
$\partial_L L/\partial\chi_A - \sum_\mu \frac{d}{dx_\mu}\partial_L L/\partial(
\partial_\mu\chi_A)$ and compares it with $\sqrt{|g|}(C\mathcal{E})_A$; as a control
it repeats the comparison with $m$ replaced by $-m$, which must fail.

## 16. The equations written out in the author's metric

Since $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and $\gamma^\mu\Omega_\mu = 3H
\gamma^{(x_0)} + \frac34(b_4'/b_4)\gamma^{(x_4)}$, the Dirac operator is

$$\gamma^\mu D_\mu\Psi = \sum_{a=0}^{7}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi +
3H\gamma^{(x_0)}\Psi + \frac34\frac{b_4'}{b_4}\gamma^{(x_4)}\Psi,$$
$$\frac{1}{f_a} = \frac{s^6}{c} = \tan z\ (x_0),\ \frac{1}{Es}\ (x_1, x_2, x_3),\
1\ (x_4),\ \frac{E}{s\sqrt{b_4}}\ (x_5, x_6, x_7).$$

The coefficient of the extra-time derivatives, $e^{a_4}b_4^{-1/2}\sin^{-1/6}z$,
grows as the extra times deflate. The next cell checks this form for both
statistics, then turns each of our 16 component equations into an ordinary sympy
expression in the symbols `d<a>_<B>` (for $\partial_a\Psi_B$, with $a = 0, \dots,
7$ for $x_0, \dots, x_7$) and `P<B>` (for $\Psi_B$), and compares it with the
corresponding equation of both formula records (key `field_equation_components`,
left-hand sides), term by term: as it is with the record with $b_4$, and at
$b_4 = 1$ with the record of $b_4 = 1$. It prints the first equation in both
forms.

Figure 4 shows which components are coupled. Every frame gamma is a signed
permutation matrix, so each equation contains one derivative term per direction. A
square of the map (row $A$ = equation, column $B$ = component) is coloured by the
number of derivatives $\partial_a\Psi_B$ in equation $A$ and labelled with the
directions $a$. Each equation contains only four components, each with two
directions, and the equations of rows 1 to 8 (chirality $\Gamma = -1$) contain only
components 9 to 16 ($\Gamma = +1$) and back: every gamma is block off-diagonal in
the chiral split. The term $3H\gamma^{(x_0)}\Psi$ sits in the squares labelled
with 0, next to $\tan z\,\partial_0$ of the same component, and the term
$\frac34(b_4'/b_4)\gamma^{(x_4)}\Psi$ in the squares labelled with 4.

Text cell:

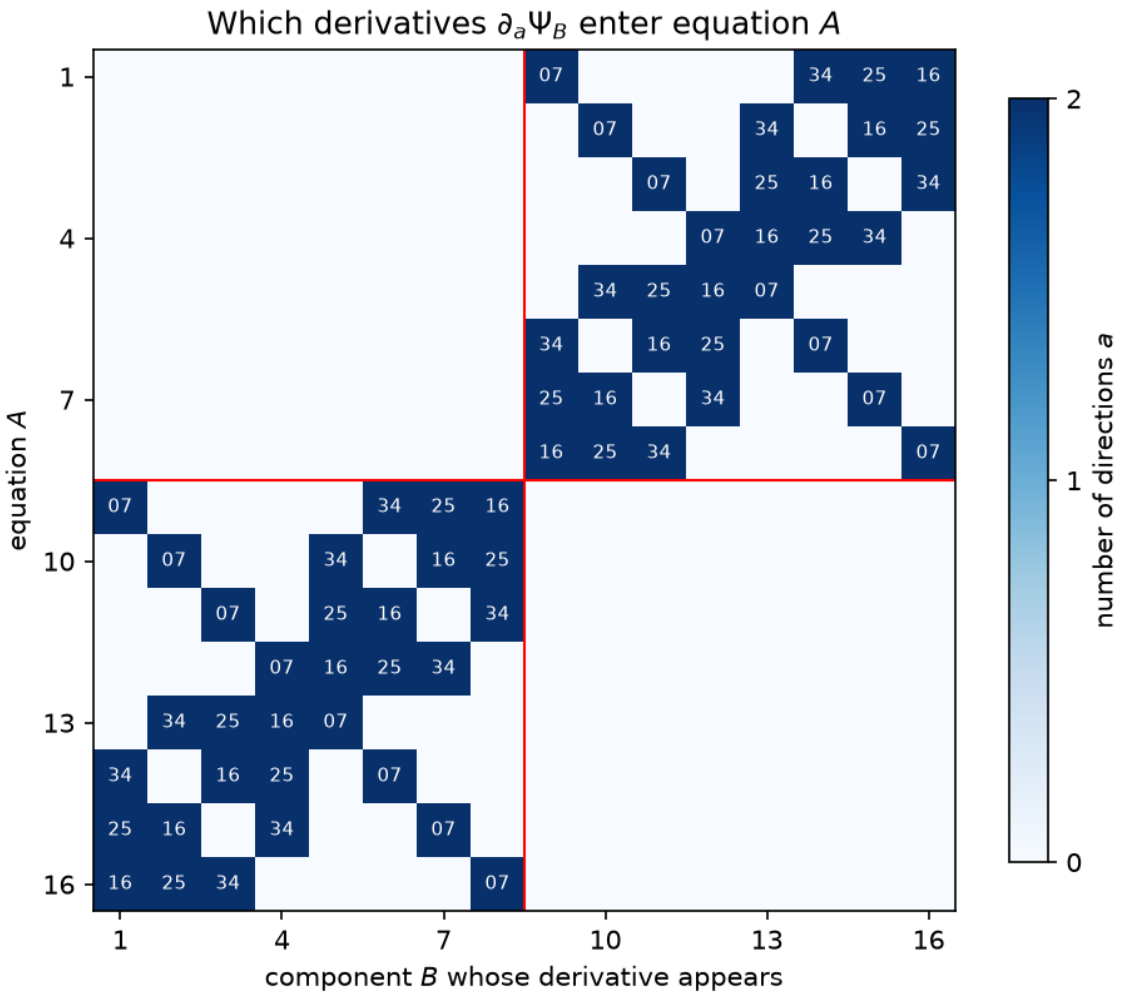

Figure 222: The coupling map of the 16 component field equations in the author's metric: row A is the equation $(\gamma^\mu D_\mu \Psi)_A = V \Psi_A$, column B a component; a square is coloured by the number of directions a whose derivative $\partial_a \Psi_B$ appears in equation A, and the digits name those directions (k for x_k). Every equation contains 4 components with 2 directions each. The red lines separate the chiral halves: rows 1 to 8 involve only components 9 to 16 and rows 9 to 16 only components 1 to 8. The term $3H\gamma^{(x_0)}\Psi$ appears in the squares that contain the digit 0, the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}\Psi$ in those that contain the digit 4. (Notebook 07b, figure 4.)

17. The chiral blocks and the evolution form

Two more ways of writing the same 16 equations; both are stated in the Revision formula record.

The chiral blocks. Split Ψ into its upper half ψ_- (components 1 to 8, where the chirality matrix $\Gamma = \mathrm{diag}(-I_8, I_8)$ is -1) and its lower half ψ_+ (components 9 to 16, where $\Gamma = +1$). Every frame gamma is block off-diagonal,

$$\gamma^{(a)} = \begin{pmatrix} 0 & \bar\tau_a \\ \tau_a & 0 \end{pmatrix},$$

with 8×8 blocks $\bar\tau_a$ (upper right) and τ_a (lower left), and $\bar\tau_{x_0} = \tau_{x_0} = I_8$. Multiplying a block matrix by the column (ψ_-, ψ_+) gives $(\bar\tau_a\psi_+, \tau_a\psi_-)$: the upper rows see only the lower half and the lower rows only the upper half. The mass term $V\Psi$, $V = m + \lambda S$, keeps each half in its own rows. So the field equation is the pair

$$\sum_a\frac{1}{f_a}\bar\tau_a\partial_a\psi_+ + 3H\bar\tau_{x_0}\psi_+ + \tfrac34\tfrac{b_4'}{b_4}\bar\tau_{x_4}\psi_+ = V\psi_-,\qquad \sum_a\frac{1}{f_a}\tau_a\partial_a\psi_- + 3H\tau_{x_0}\psi_- + \tfrac34\tfrac{b_4'}{b_4}\tau_{x_4}\psi_- = V\psi_+ .$$

The derivatives and the gravitational term of one half are balanced by the mass term of the other half: the mass term and the gravitational term both couple the two chiral halves (the coupling map of Figure 4 shows the same fact).

The evolution form. Write the explicit equation of section 16 with the x_4 term separately ($f_4 = 1$), write $M = 3H\gamma^{(x_0)} + \frac34(b_4'/b_4)\gamma^{(x_4)}$ for the gravitational term, and solve for $\partial_4\Psi$, line by line:

$$\gamma^{(x_4)}\partial_4\Psi + \sum_{a\neq4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi + M\Psi = V\Psi$$
$$\gamma^{(x_4)}\partial_4\Psi = V\Psi - \sum_{a\neq4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi - M\Psi$$
$$\partial_4\Psi = -\gamma^{(x_4)}\Big[V\Psi - \sum_{a\neq4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi - M\Psi\Big] .$$

(The part $\frac34(b_4'/b_4)\gamma^{(x_4)}$ of M gives $-\frac34(b_4'/b_4)\Psi$ on the right, as in the record's ‘evolution_form‘.)

The second line moves every other term to the right side; the third multiplies from the left by $-\gamma^{(x_4)}$ and uses $-\gamma^{(x_4)}\gamma^{(x_4)} = 1$ (because $(\gamma^{(x_4)})^2 = -1$). So the time derivative of every component is fixed by the field and its derivatives along the other seven directions at the same time x_4: the slices $x_4 = $ const are **non-characteristic** (the coefficient $\gamma^{(x_4)}$ of ∂_4 is invertible; $g^{44} = -1 \neq 0$). Scope, from the Revision scope record: this does NOT make the initial-value problem well posed. For data that depend on the extra times the growth rates of the modes have no upper bound (check extra_time_growth_rates_unbounded of Revision/theory/reports/python-scope.json).

```
The next cell reads the blocks from the formula record and compares them with the
gammas, checks $\Gamma = \mathrm{diag}(-I_8, I_8)$, and verifies the evolution form
exactly for both statistics: with $R$ the right side of the third line,
$\gamma^{(x_4)}(\partial_4\Psi - R)$ must equal the field-equation residual
$\mathcal{E} = \gamma^\mu D_\mu\Psi - (m + \lambda S)\Psi$ in all 16 components.
```

## 18. Non-triviality: the gravitational term in the field equation

The difference between the field-equation residual computed with the canonical
spin connection and the one computed with $\Omega_\mu = 0$ is $\gamma^\mu\Omega_\mu
\Psi = M\Psi$, $M = 3H\gamma^{(x_0)} + \frac34(b_4'/b_4)\gamma^{(x_4)}$. Because
$\gamma^{(x_0)}$ and $\gamma^{(x_4)}$ anticommute, $MM = (9H^2 - \frac{9}{16}
(b_4'/b_4)^2)\,1$: $M\Psi$ vanishes only for $\Psi = 0$, except at times where
$|b_4'/b_4| = 4H$ (the check ‘gravity_term_square_b4‘ of
Revision/theory/reports/python-field-theory-b4.json). For a constant $b_4$, as on
the backgrounds $b_4 = 1$, $M = 3H\gamma^{(x_0)}$, a signed permutation matrix with
$(\gamma^{(x_0)})^2 = 1$, and $M\Psi$ vanishes only for $\Psi = 0$ when $H > 0$.
So in the diagonal frame and in the variables $\Psi$ the Euler-Lagrange equations
of both fields always contain a gravitational term through the spin connection (the
Revision record’s non-triviality tests [1] and [2]). Its exact scope, stated in the
Revision record: the value $3H\gamma^{(x_0)}$ belongs to this frame and these
variables (it vanishes in a frame boosted in the $(x_4, x_0)$ plane, and the
rescaling $\Psi = \sin^{-1/2}z\,\chi$ removes it), while the frame-independent
facts are that $\Omega_\mu$ itself vanishes in no frame (the metric is curved for
$H > 0$) and that the frame factors $1/f_a$ enter every derivative term. The next
cell checks the difference for both statistics.

## 19. An exact family of solutions

Look for solutions that depend only on the time $x_4$ and the hidden direction
$x_0$: $\Psi = \sin^\alpha z\,P(x_4)\,\chi_0$ with a constant column $\chi_0$ and a
number $\alpha$, for a constant $b_4$ (as on the backgrounds $b_4 = 1$; a changing
$b_4$ adds the term $\frac34(b_4'/b_4)\gamma^{(x_4)}\Psi$ and changes the family).
With $U = 0$ ($\lambda = 0$) the field equation becomes, line by line,

$$\gamma^{(x_4)}\partial_4\Psi + \tan z\,\gamma^{(x_0)}\partial_0\Psi + 3H
\gamma^{(x_0)}\Psi = m\Psi$$
$$\sin^\alpha z\,\big[\gamma^{(x_4)}P' + (6H\alpha + 3H)\gamma^{(x_0)}P\big]\chi_0
= m\sin^\alpha z\,P\chi_0$$
$$P' = -\gamma^{(x_4)}\big(m - 3H(2\alpha + 1)\gamma^{(x_0)}\big)P = MP,\qquad M =
-m\gamma^{(x_4)} + 3H(2\alpha + 1)\gamma^{(x_4)}\gamma^{(x_0)} .$$

The first line keeps the terms that act on a function of $x_4$ and $x_0$ (the other
derivatives vanish, which is why the result holds for EVERY $a_4$ and every
constant $b_4$). The second uses
$\tan z\,\partial_0\sin^\alpha z = \frac{\sin z}{\cos z}\,\alpha\sin^{\alpha-1}z
\cos z\cdot 6H = 6H\alpha\sin^\alpha z$. The third multiplies by
$-\gamma^{(x_4)}$ (since $(\gamma^{(x_4)})^2 = -1$). Because $\gamma^{(x_4)}$ and
$\gamma^{(x_0)}$ anticommute, $M^2 = k^2$ with $k^2 = 9H^2(2\alpha + 1)^2 - m^2$, so

$$P(x_4) = \cosh(kx_4) + \frac{\sinh(kx_4)}{k}M$$

solves $P' = MP$ with $P(0) = 1$. Moreover $M^TC + CM = 0$, so $S = \Psi^\dagger C
\Psi = \sin^{2\alpha}z\,\chi_0^\dagger C\chi_0$ does not change with $x_4$. The
next cell verifies the family exactly, writing $\cosh(kx_4)$ and $\sinh(kx_4)$ as
symbols ‘ch‘, ‘sh‘ with $\partial_4\,\mathrm{ch} = k\,\mathrm{sh}$, $\partial_4\,
\mathrm{sh} = k\,\mathrm{ch}$, and $\sin^\alpha z = s^{6\alpha}$; then it checks the
matrix identity behind the growing modes of the Revision scope record.

            "$a_4(x_4)$.")
```

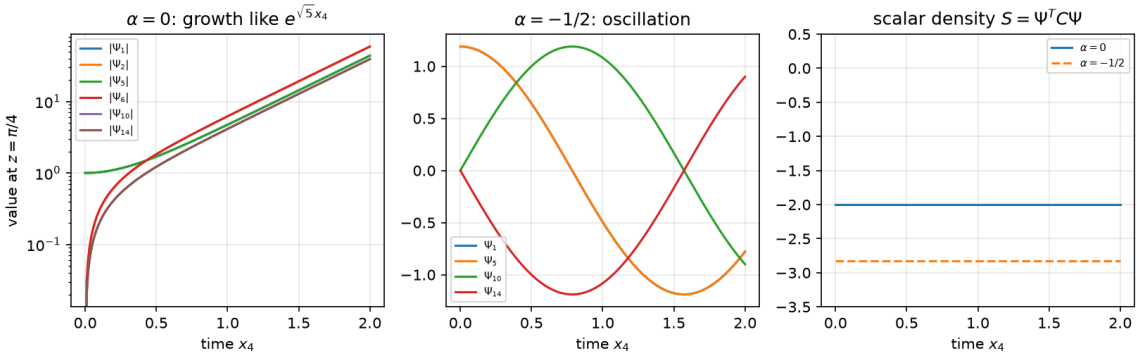

Figure 223: Two exact solutions $\Psi = \sin^\alpha z\,(\cosh kx_4 + \sinh(kx_4)/k\,M)\chi_0$ of the field equation with $\lambda = 0$, for the illustration values $H = 1$, $m = 2$, $\chi_0 = e_1 + e_5$, at $z = \pi/4$, against the time x_4 from 0 to 2 (pure numbers). Left: $\alpha = 0$, $k = \sqrt{5}$; the nonzero components grow exponentially (logarithmic axis), the growing mode that exists without a boundary condition at $z = \pi/2$ when $m^2 < 9H^2$. Middle: $\alpha = -1/2$, $k = 2i$; the components oscillate. Right: the scalar density S of both stays exactly constant (-2 and $-2/\sin z$), because $M^TC + CM = 0$. The solutions hold for every $a_4(x_4)$. (Notebook 07b, figure 5.)

## 21. What this notebook showed

- The diagonal frame $f = (\cot z,\ e^{a_4}\sin^{1/6}z\ (\times3),\ 1,\
  e^{-a_4}b_4^{1/2}\sin^{1/6}z\ (\times3))$ gives exactly the author's metric with
  $b_4$, with $\sqrt{|g|} = b_4^{3/2}\cos z$: the inflation of 3-space and the
  deflation of the extra times compensate, and at $b_4 = 1$ the volume factor
  $\cos z$ does not depend on time.
- The metric has 25 independent nonzero Christoffel symbols; the canonical spin
  connection has 12 nonzero components, each a rate ($a_4'$, $a_4' -
  b_4'/(2b_4)$ or $H$) times a nonvanishing factor. Both agree with the formula
  record with $b_4$ and, at $b_4 = 1$, with the record of $b_4 = 1$.
- Direction by direction, $\gamma^\mu\Omega_\mu$ has a time part $\pm\frac12a_4'
  \gamma^{(x_4)}$ that cancels between the three inflating and the three deflating
  directions (the extra times leave $\frac34(b_4'/b_4)\gamma^{(x_4)}$), and a hidden
  part $\frac12H\gamma^{(x_0)}$ that adds up: $\gamma^\mu\Omega_\mu =
  3H\gamma^{(x_0)} + \frac34(b_4'/b_4)\gamma^{(x_4)}$, which is $3H\gamma^{(x_0)}$
  for every $a_4$ at $b_4 = 1$.
- The Lagrangian of both fields is real, differs from the unsymmetrised form by a
  total divergence, and in this metric does not contain the spin connection at all
  ($\{\gamma^\mu, \Omega_\mu\} = 0$); written in jets it has 392 monomials for
  dirac16complex and 408 for dirac16complex00, the difference being the 16 squares
  that vanish for Grassmann numbers.
- Its Euler-Lagrange equations are the same for both statistics:
  $\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$ and its Dirac conjugate. In the
  author's metric the 16 component equations contain the frame factors $\tan z$,
  $e^{-a_4}\sin^{-1/6}z$, $1$, $e^{a_4}b_4^{-1/2}\sin^{-1/6}z$ and the
  gravitational term $M\Psi$, $M = 3H\gamma^{(x_0)} +
  \frac34(b_4'/b_4)\gamma^{(x_4)}$; they agree term by term with the Revision
  formula record with $b_4$, and at $b_4 = 1$ with the record of $b_4 = 1$. Each
  equation couples four components across the chiral halves: every gamma is block
  off-diagonal, and the mass term and the gravitational term both couple the halves
  $\psi_-$ and $\psi_+$. $M\Psi$ vanishes only for $\Psi = 0$, except at times
```

```
  where $|b_4'/b_4| = 4H$; for a constant $b_4$ never.
- Solved for the time derivative, $\partial_4\Psi = -\gamma^{(x_4)}[V\Psi -
  \sum_{a\neq4}f_a^{-1}\gamma^{(a)}\partial_a\Psi - M\Psi]$: the slices $x_4 = $
  const are non-characteristic, which does not by itself make the initial-value
  problem well posed (the extra-time growth rates are unbounded).
- The family $\Psi = \sin^\alpha z(\cosh kx_4 + \sinh(kx_4)/k\,M)\chi_0$ solves the
  equations exactly for every $a_4$ and every constant $b_4$, with constant $S$; for
  $\alpha = 0$ and $m^2
  < 9H^2$ it grows exponentially, and it fails the equation from which the
  spin-connection term is removed.
- Every statement that the Revision record also contains was reproduced; the scope
  of the gravitational term (frame and variable dependence) is the one stated in
  the Revision record.
```

7.27 Line-by-line walk-through of Notebook 07b

The notebook has 25 code cells, In [1] to In [25]. This section explains every line of every one of them, with the conventions of Section 7.9; every caption is printed in full under its figure in Section 7.26.

In [1], the set-up cell. It is the set-up cell of Notebook 07d with the one line `NOTEBOOK_ID = "07b"`; its first part repeats the complete run instructions of Section 7.25 as comment lines, and its code is explained line by line in Section 7.9. **Out [1]:** `Set-up of notebook 07b complete: repository folder found, helpers defined.`

In [2]: the gammas and C from the Revision record.

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)
import re  # regular expressions: used to read the Wolfram formula record

import numpy as np  # numbers for the plots
import sympy as sp  # exact algebra

check_of_the_setup = check  # the helper check of the set-up cell

def check(condition, name, record=None):
    """The set-up cell's check, with its PASS line and its "reproduces" line
    printed by ONE print call, so that Jupyter delivers them together."""
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # collect what check prints
        check_of_the_setup(condition, name, record)
    print(buffer.getvalue(), end="")  # and print it in one piece
```

The modules (as in Notebook 07d; `re` is used here to read formulas and numbers from the record's texts) and the same wrapper of `check` that prints a PASS line and its "reproduces" line in one piece (Section 7.9, In [2]).

```
GAMMAS = "Revision/algebra/gammas.json"
FORMULAS = "Revision/theory/field-theory.json"  # the formulas at b4 = 1
```

```
FORMULAS_B4 = "Revision/theory/field-theory-b4.json"  # the formulas with b4(x4)
PYREP_B4 = "Revision/theory/reports/python-field-theory-b4.json"
PYREP = "Revision/theory/reports/python-field-theory.json"
WLREP = "Revision/theory/reports/wolfram-field-theory.json"
SCOPE = "Revision/theory/reports/python-scope.json"
```

The repository paths of the five Revision files the notebook reads: the gammas, the formula record of the Wolfram verifier, the sympy and the Wolfram field-theory reports, and the sympy scope report.

```
def revision_check(report, name):
    """The check called name of the Revision report (a JSON file): a dictionary
    with its name, verdict and detail; stops if it is missing or not PASS."""
    data = json.loads(repository_file(report).read_text(encoding="utf-8"))
    found = [item for item in data["checks"] if item["name"] == name]
    if len(found) != 1 or found[0]["verdict"].upper() != "PASS":
        raise ValueError(f"{name} is not a passing check of {report}")
    return found[0]

def reproduces(report, name):
    """The text "<report>, check <name>" for a PASS line, after making sure that
    the Revision report contains the check name with the verdict PASS."""
    revision_check(report, name)
    return f"{report}, check {name}"
```

`revision_check` returns the entry of a named check of a report and stops if it is missing or does not pass; `reproduces` uses it and returns the text for the "reproduces" line. Both are explained in Section 7.9 (In [2] of Notebook 07d).

```
fixture = json.loads(repository_file(GAMMAS).read_text(encoding="utf-8"))
G = [sp.Matrix(g) for g in fixture["gamma"]]  # gamma^(x0) .. gamma^(x7), integers
C = sp.Matrix(fixture["C"])  # the author's sigma16
ETA = [1, 1, 1, 1, -1, -1, -1, -1]  # eta in the order x0 .. x7
I16, Z16 = sp.eye(16), sp.zeros(16, 16)
SAB = [[(G[a] * G[b] - G[b] * G[a]) / 4 for b in range(8)] for a in range(8)]
X0, X4 = 0, 4  # list positions of the hidden direction x0 and of the time x4
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
```

The gammas are read as exact sympy matrices: `G[0]` to `G[7]` are $\gamma^{(x_0)}$ to $\gamma^{(x_7)}$, `C` is C. `ETA` is η in the order $x_0, \ldots, x_7$; `I16` and `Z16` are the 16×16 identity and zero matrices. `SAB[a][b]` is the spin generator $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$, built for all 64 pairs with a nested list comprehension. `X0, X4 = 0, 4` are the list positions of x_0 and x_4 (positions count from 0, so position k is the direction x_k), and `NAMES` the printed names of the eight coordinates. `FORMULAS_B4` and `PYREP_B4` name the formula record and the sympy report of the metric with b_4.

```
clifford = all(G[a] * G[b] + G[b] * G[a] == 2 * (ETA[a] if a == b else 0) * I16
               for a in range(8) for b in range(8))
check(clifford, "{gamma^a, gamma^b} = 2 eta^ab I16 for all 64 pairs",
```

```
      record=reproduces(PYREP, "clifford_relations"))
c_ok = (C == G[0] * G[1] * G[2] * G[3] and C.T == C and C * C == I16
        and all((C * g).T == -(C * g) for g in G))
check(c_ok, "C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3), symmetric, C^2 = 1, "
      "every C gamma^a antisymmetric", record=reproduces(PYREP, "C_properties"))
```

`clifford` is true when $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab} I_{16}$ for all 64 pairs (the expression `(ETA[a] if a == b else 0)` is η^{ab}). `c_ok` checks $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, $C^T = C$, $C^2 = 1$ and that every $C\gamma^{(a)}$ is antisymmetric. **Out [2]:** two PASS lines with their "reproduces" lines (`clifford_relations` and `C_properties` of the sympy report).

In [3]: the coefficient ring.

```
E, s, c = sp.symbols("E s c", positive=True)  # e^a4, sin(z)^(1/6), cos z
A1, A2, A3 = sp.symbols("A1 A2 A3", real=True)  # 1st, 2nd, 3rd derivative of a4
b4 = sp.Symbol("b4", positive=True)  # the function b4(x4) > 0 of the metric
b4p, b4pp, b4ppp = sp.symbols("b4p b4pp b4ppp", real=True)  # its 1st to 3rd derivative
AT_B4_1 = {b4: 1, b4p: 0, b4pp: 0, b4ppp: 0}  # the background b4 = 1
H = sp.Symbol("H", positive=True)  # the author's constant
m, lam = sp.symbols("m lambda", real=True)  # the mass and the coupling
```

The symbols of Section 7.18: `E`, `s`, `c` (positive), `A1`, `A2`, `A3` (the first three derivatives of a_4), `b4` (positive) and `b4p`, `b4pp`, `b4ppp` (the first three derivatives of b_4), `H` (positive), and `m`, `lam` (λ; the name `lambda` is reserved in Python). `AT_B4_1` is the substitution that puts in the background $b_4 = 1$: with `.subs(AT_B4_1)` a result for a general b_4 becomes the result at $b_4 = 1$, which is compared with the record of $b_4 = 1$.

```
def cd(expression, mu):
    """The derivative of a ring expression along coordinate mu (0 .. 7)."""
    expression = sp.sympify(expression)
    if mu == X4:
        return (sp.diff(expression, E) * E * A1 + sp.diff(expression, A1) * A2
                + sp.diff(expression, A2) * A3 + sp.diff(expression, b4) * b4p
                + sp.diff(expression, b4p) * b4pp + sp.diff(expression, b4pp) * b4ppp)
    if mu == X0:
        return (sp.diff(expression, s) * H * c / s**5
                + sp.diff(expression, c) * (-6 * H * s**6))
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7
```

`cd(expression, mu)` differentiates a ring expression along the coordinate at list position `mu`. Along x_4: by the chain rule, through E ($\partial_4 E = EA_1$), through A_1 ($\partial_4 A_1 = A_2$), through A_2 ($\partial_4 A_2 = A_3$), and in the same way through b_4, b_4' and b_4''. Along x_0: through s ($\partial_0 s = Hc/s^5$) and through c ($\partial_0 c = -6Hs^6$). Along every other coordinate: 0.

```
def is_zero(expression):
    """Exact test: the numerator vanishes after c^2 -> 1 - s^12."""
    numerator, _ = sp.fraction(sp.together(sp.sympify(expression)))
    numerator = sp.expand(numerator)
    if numerator == 0:
```

```
        return True
    remainder = sp.rem(sp.Poly(numerator, c), sp.Poly(c**2 - 1 + s**12, c))
    return sp.expand(remainder.as_expr()) == 0
```

`is_zero(expression)` decides exactly whether a ring expression is zero. `sp.together` brings it to one fraction and `sp.fraction` returns its numerator and denominator; the numerator is multiplied out. If it is not already 0, it is divided as a polynomial in c by $c^2 - 1 + s^{12}$ (`sp.rem` gives the remainder of the division); the remainder no longer contains c^2, and it vanishes exactly when the expression is zero.

```
x4, x0 = sp.symbols("x4 x0", real=True)
a4 = sp.Function("a4")(x4)  # the free function of the metric
b4f = sp.Function("b4")(x4)  # the second function of the metric
z = 6 * H * x0

def to_physical(expression):
    """Ring symbols -> the functions they stand for."""
    return sp.sympify(expression).subs(
        {E: sp.exp(a4), s: sp.sin(z) ** sp.Rational(1, 6), c: sp.cos(z),
         A1: a4.diff(x4), A2: a4.diff(x4, 2), A3: a4.diff(x4, 3),
         b4: b4f, b4p: b4f.diff(x4), b4pp: b4f.diff(x4, 2), b4ppp: b4f.diff(x4, 3)})
```

The physical variables: `x4`, `x0`, the unknown functions $a_4(x_4)$ and $b_4(x_4)$ (`b4f`) and $z = 6Hx_0$. `to_physical` replaces the ring symbols by the functions they stand for.

```
rules_ok = all(
    sp.simplify(to_physical(cd(v, mu)) - sp.diff(to_physical(v), variable)) == 0
    for v in (E, s, c, A1, A2, b4, b4p, b4pp)
    for mu, variable in ((X4, x4), (X0, x0)))
check(rules_ok, "the derivative rules of the ring agree with sympy's derivatives")
check(is_zero(c**2 + s**12 - 1) and not is_zero(c) and not is_zero(s - c),
      "the exact zero test: c^2 + s^12 - 1 is zero, c and s - c are not")
```

The first check compares, for the five symbols E, s, c, A_1, A_2 and the two coordinates, the ring derivative put back into functions with sympy's own derivative of the functions. The second checks the zero test on three examples: $c^2 + s^{12} - 1$ is zero, c and $s - c$ are not. **Out [3]:** two PASS lines.

In [4]: the metric and the volume factor.

```
f = [c / s**6] + [E * s] * 3 + [sp.Integer(1)] + [s * sp.sqrt(b4) / E] * 3  # frame
g = [ETA[a] * f[a] ** 2 for a in range(8)]  # the diagonal metric entries
sqrt_g = sp.prod(f)  # the volume factor
third = sp.sin(z) ** sp.Rational(1, 3)
author = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * third] * 3 + [-1]
          + [-sp.exp(-2 * a4) * b4f * third] * 3)  # the author's metric with b4
check(all(sp.simplify(to_physical(g[a]) - author[a]) == 0 for a in range(8)),
      "the diagonal frame reproduces the author's metric with b4 entry by entry",
      record=reproduces(PYREP, "metric_from_vielbein_equals_SPEC") + " (at b4 = 1)")
say(f"sqrt|g| = {sqrt_g} (ring) = {to_physical(sqrt_g)}")
```

```
check(sqrt_g == b4 ** sp.Rational(3, 2) * c and sqrt_g.subs(AT_B4_1) == c,
      "sqrt|g| = b4^(3/2) cos z; cos z, independent of x4, at b4 = 1",
      record=reproduces(WLREP, "sqrt_det_g_is_cos_z") + " (at b4 = 1)")
```

`f` is the list of the eight frame factors in the order $x_0, \dots, x_7$ (`[E * s] * 3` repeats a one-entry list three times), `g` the diagonal metric entries $\eta_{aa} f_a^2$, and `sqrt_g` their product $\sqrt{|g|}$ (`sp.prod`). `author` is the author's metric with b_4, typed from the author's notebook `Dirac_Einstein-Lovelock_4+4_Nash.nb` (Chapter 3). The first check compares the eight entries; the `say` line prints the volume factor in the ring and as a function; the second check requires it to be $b_4^{3/2} c$, and c at $b_4 = 1$. **Out [4]:** two PASS lines with "reproduces" lines and `sqrt|g| = b4**(3/2)*c (ring) = b4(x4)**(3/2)*cos(6*H*x0)`.

In [5]: reading the formula record.

```
record = {item["key"]: item["wl"] for item in
          json.loads(repository_file(FORMULAS).read_text(encoding="utf-8"))["formulas"]}
record_b4 = {item["key"]: item["wl"] for item in json.loads(
    repository_file(FORMULAS_B4).read_text(encoding="utf-8"))["formulas"]}
a4x, A1w = sp.symbols("a4x A1w", real=True)  # a4(x4) and a4'(x4) in the record
b4x = sp.Symbol("b4x", positive=True)  # b4(x4) in the record
B1w, B2w = sp.symbols("B1w B2w", real=True)  # b4'(x4) and b4''(x4) in the record
```

`record` is a dictionary from the keys of the formula record `Revision/theory/field-theory.json` (the metric at $b_4 = 1$) to their Wolfram-language texts (the field `wl` of each entry), and `record_b4` the same for `Revision/theory/field-theory-b4.json` (the metric with b_4). `a4x` and `A1w` are symbols for $a_4(x_4)$ and $a_4'(x_4)$ as they appear in those texts, `b4x`, `B1w` and `B2w` for $b_4(x_4)$, $b_4'(x_4)$ and $b_4''(x_4)$.

```
def from_wolfram(text):
    """Read a Wolfram InputForm text of the formula record into sympy."""
    t = text.replace("Derivative[1][a4][x4]", "A1w").replace("a4[x4]", "a4x")
    t = t.replace("Derivative[1][b4][x4]", "B1w").replace("Derivative[2][b4][x4]", "B2w")
    t = t.replace("b4[x4]", "b4x")
    t = re.sub(r'dd\["x(\d)",\s*Psi\[(\d+)\]\]', r"d\1_\2", t)  # d_a Psi_B
    t = re.sub(r"Psi\[(\d+)\]", r"P\1", t)  # Psi_B
    for name in ("Sin", "Cos", "Tan", "Cot", "Sec", "Csc", "Sqrt"):
        t = t.replace(name + "[", name.lower() + "(")
    t = t.replace("[", "(").replace("]", ")").replace("{", "[").replace("}", "]")
    t = t.replace("^", "**")
    names = {"E": sp.E, "H": H, "x0": x0, "a4x": a4x, "A1w": A1w, "b4x": b4x,
             "B1w": B1w, "B2w": B2w}
    for symbol in set(re.findall(r"\b(d\d_\d+|P\d+)\b", t)):
        names[symbol] = sp.Symbol(symbol)
    return sp.sympify(t, locals=names)
```

`from_wolfram(text)` turns a Wolfram-language text into a sympy expression in five steps: the derivatives and the functions a_4 and b_4 are replaced by the symbols `A1w`, `a4x`, `B1w`, `B2w` and `b4x`; a regular expression replaces each derivative `dd["x5", Psi[15]]` by the name `d5_15` (the pattern `(\d)` captures a digit and `\1`, `\2` put the captured parts back); each `Psi[9]` becomes `P9`; the

function names `Sin` ... `Csc` and `Sqrt` become `sin` ... `csc` and `sqrt`; square brackets become round ones, braces (Wolfram lists) square ones (Python lists), and `^` becomes `**`. The dictionary `names` tells sympy what each name means; the loop adds a plain symbol for every derivative name and component name found in the text (`set(...)` removes repetitions). `sp.sympify` reads the result.

```
RING = {sp.sin(z): s**6, sp.cos(z): c, sp.tan(z): s**6 / c, sp.cot(z): c / s**6,
        sp.sec(z): 1 / c, sp.csc(z): 1 / s**6, sp.csc(2 * z): 1 / (2 * s**6 * c)}

def to_ring(expression):
    """A record formula in the ring symbols E, s, c, A1, b4, b4p, b4pp."""
    return (sp.sympify(expression).subs(a4x, sp.log(E)).subs(A1w, A1)
            .subs({b4x: b4, B1w: b4p, B2w: b4pp}).subs(RING))
```

`RING` replaces the trigonometric functions of z by ring expressions: $\sin z = s^6$, $\cos z = c$, $\tan z = s^6/c$, $\cot z = c/s^6$, $\sec z = 1/c$, $\csc z = 1/s^6$ and $\csc 2z = 1/(2s^6c)$ (because $\sin 2z = 2\sin z \cos z$). `to_ring` puts a record formula into the ring: $a_4 \to \ln E$ (so $e^{a_4} \to E$), $a_4' \to A_1$, and the replacements of `RING`.

```
frame_record = from_wolfram(record["vielbein_diagonal"])
say(f"record vielbein_diagonal in the ring: {[to_ring(v) for v in frame_record]}")
check(all(is_zero(to_ring(v) - f[a].subs(AT_B4_1)) for a, v in enumerate(frame_record))
      and is_zero(to_ring(from_wolfram(record["sqrt_det_g"])) - sqrt_g.subs(AT_B4_1)),
      "at b4 = 1 the frame factors and sqrt|g| equal the formula record",
      record=f"{FORMULAS}, formulas vielbein_diagonal and sqrt_det_g")
```

The record's frame factors (key `vielbein_diagonal`, a record of $b_4 = 1$) are put into the ring and printed; the check compares each with our `f[a]` at $b_4 = 1$ and the record's volume factor with ours. The `record=` text names the record file and the two formula keys. **Out [5]:** `record vielbein_diagonal in the ring: [c/s**6, E*s, E*s, E*s, 1, s/E, s/E, s/E]` and the PASS line with its "reproduces" line.

In [6]: Figure 07b.1.

```
times = np.linspace(0.0, 3.0, 301)  # x4 from 0 to 3 (H = 1, A = 1: a4 = x4)
warp = np.sin(np.pi / 4) ** (1 / 6)  # sin^(1/6) z at z = pi/4
angles = np.linspace(0.01, np.pi / 2 - 0.01, 300)  # z inside (0, pi/2)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9))
left.semilogy(times, np.exp(times) * warp, label="3-space $e^{a_4}\\sin^{1/6}z$")
left.semilogy(times, np.exp(-times) * warp, "--",
              label="extra times $e^{-a_4}\\sin^{1/6}z$")
left.semilogy(times, np.exp(times) * np.exp(-times) * warp**2, ":", color="black",
              label="their product")
left.set_xlabel("time $x_4$ (with $a_4 = x_4$)")
left.set_ylabel("scale factor")
left.set_title("Inflation and deflation at $z = \\pi/4$")
left.legend(fontsize=8)
right.plot(angles, np.sin(angles) ** (1 / 6), label="$\\sin^{1/6}z$")
right.plot(angles, np.cos(angles), "--", label="$\\sqrt{|g|} = \\cos z$")
right.plot(angles, 1 / np.tan(angles), ":", label="$f_0 = \\cot z$")
```

```
right.set_ylim(0, 3)
right.set_xlabel("$z = 6Hx_0$")
right.set_ylabel("value")
right.set_title("Dependence on the hidden direction")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "scale_factors",
...)
```

`times` is x_4 from 0 to 3 (with $H = 1$, $A = 1$ the history is $a_4 = x_4$); `warp` is $\sin^{1/6} z$ at $z = \pi/4$; `angles` is z from just above 0 to just below $\pi/2$. The left panel draws, on a logarithmic axis, the scale factor of 3-space $e^{x_4} \sin^{1/6} z$, that of the extra times $e^{-x_4} \sin^{1/6} z$ and their product; the right panel draws $\sin^{1/6} z$, $\cos z$ and $\cot z$ against z, with the vertical range cut at 3 because $\cot z$ grows without bound near $z = 0$. **What Figure 07b.1 shows.** On the logarithmic axis the 3-space factor is a rising straight line and the extra-time factor a falling one: exponential inflation and exponential deflation, with a constant product. On the right, $\sin^{1/6} z$ rises steeply near the tip $z = 0$ and is almost 1 elsewhere; the volume factor $\cos z$ falls to 0 at $z = \pi/2$, where the frame factor $\cot z$ of the hidden direction also vanishes. The history $a_4 = x_4$ is an illustration chosen for the picture, not a result: every equation of the notebook holds for every $a_4(x_4)$.

In [7]: the Christoffel symbols.

```
Gam = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]  # Gam[l][mu][nu]
for l in range(8):
    for mu in range(8):
        for nu in range(8):
            value = 0
            if l == nu:
                value += cd(g[l], mu)
            if l == mu:
                value += cd(g[l], nu)
            if mu == nu:
                value -= cd(g[mu], l)
            if value != 0:
                Gam[l][mu][nu] = sp.expand(value / (2 * g[l]))
```

`Gam[l][mu][nu]` is $\Gamma^{\lambda}{}_{\mu\nu}$, a three-index table of zeros to start with (`[sp.Integer(0)] * 8` is a list of eight zeros; the underscore `_` is a loop variable whose value is not used). The three `if` lines add the three terms of the diagonal formula of Section 7.18, and a nonzero result is divided by $2g_{\lambda\lambda}$ and multiplied out.

```
nonzero = [(l, mu, nu) for l in range(8) for mu in range(8) for nu in range(mu, 8)
           if not is_zero(Gam[l][mu][nu])]
report("independent nonzero Christoffel symbols", len(nonzero))
for l, mu, nu in [(1, 1, 4), (5, 4, 5), (1, 0, 1), (0, 0, 0)]:
    say(f"Gamma^{NAMES[l]}_{NAMES[mu]}{NAMES[nu]} = {sp.factor(Gam[l][mu][nu])}")
```

`nonzero` lists the index triples with $\mu \le \nu$ (the symbols are symmetric in μ and ν) whose symbol is not zero; its length is reported. Four of them are printed, factored with `sp.factor`.

```
recorded = int(re.search(r"(\d+) independent nonzero",
                         revision_check(PYREP, "christoffel_symmetric_metric_"
                                               "compatible")["detail"]).group(1))
check(len(nonzero) == recorded == 25, "25 independent nonzero Christoffel symbols",
      record=reproduces(PYREP, "christoffel_symmetric_metric_compatible"))
# the records number the directions from 1 in the order x0 .. x7: subtract 1
listed = from_wolfram(record_b4["christoffel_nonzero"])
listed_1 = from_wolfram(record["christoffel_nonzero"])
check(len(listed) == len(listed_1) == 25
      and all(is_zero(to_ring(v) - Gam[l - 1][mu - 1][nu - 1])
              for l, mu, nu, v in listed)
      and all(is_zero(to_ring(v) - Gam[l - 1][mu - 1][nu - 1].subs(AT_B4_1))
              for l, mu, nu, v in listed_1),
      "every Christoffel symbol equals the formula record with b4, and at b4 = 1 "
      "the record of b4 = 1",
      record=f"{FORMULAS_B4} and {FORMULAS}, formula christoffel_nonzero")
```

`recorded` is the number that the detail text of the sympy check `christoffel_symmetric_metric_compatible` states ("25 independent nonzero"), read with a regular expression (`(\d+)` captures the digits) and turned into a whole number with `int`. The first check requires our count to equal it and 25. `listed` is the list of all nonzero symbols of the record with b_4 (key `christoffel_nonzero`), `listed_1` that of the record of $b_4 = 1$, each entry a list λ, μ, ν, value with the directions counted from 1 in the order $x_0, \ldots, x_7$; the second check compares each value of the first with ours and each value of the second with ours at $b_4 = 1$ (`Gam[l - 1][mu - 1][nu - 1]` shifts to positions counted from 0). **Out [7]:** `RESULT independent nonzero Christoffel symbols = 25`, the four symbols `Gamma^x1_x1x4 = A1`, `Gamma^x5_x4x5 = -(2*A1*b4 - b4p)/(2*b4)`, `Gamma^x1_x0x1 = H*c/s**6`, `Gamma^x0_x0x0 = -6*H*(c**2 + s**12)/(c*s**6)` (the values derived in Section 7.18; with $c^2 + s^{12} = 1$ the last is $-6H/(\sin z \cos z)$), and two PASS lines with their "reproduces" lines.

In [8]: the canonical spin connection.

```
om = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]  # om[mu][a][b]
for mu in range(8):
    for a in range(8):
        for b in range(8):
            mixed = f[a] * ((cd(1 / f[b], mu) if a == b else 0) + Gam[a][mu][b] / f[b])
            om[mu][a][b] = sp.expand(ETA[a] * mixed)  # lowered with eta_aa
```

`om[mu][a][b]` is $\omega_{\mu ab}$: the formula $f_a(\delta_{ab}\partial_\mu(1/f_b) + \Gamma^a{}_{\mu b}/f_b)$ of Section 7.18 for the mixed connection, lowered with η_{aa}.

```
antisymmetric = all(is_zero(om[mu][a][b] + om[mu][b][a])
                    for mu in range(8) for a in range(8) for b in range(8))
postulate = all(is_zero((cd(f[a], mu) if a == nu else 0) - Gam[a][mu][nu] * f[a]
                        + ETA[a] * om[mu][a][nu] * f[nu])
                for mu in range(8) for a in range(8) for nu in range(8))
check(antisymmetric and postulate, "omega_mu ab = -omega_mu ba and the vielbein "
      "postulate holds in all 512 components",
      record=reproduces(PYREP, "vielbein_postulate"))
```

`antisymmetric` checks $\omega_{\mu ab} + \omega_{\mu ba} = 0$ for all 512 index triples. `postulate` checks the vielbein postulate for the diagonal frame in all 512 components: $\partial_\mu e^a{}_\nu$ (nonzero only for $\nu = a$, where it is $\partial_\mu f_a$), minus $\Gamma^a{}_{\mu\nu} f_a$, plus $\omega_\mu{}^a{}_\nu f_\nu$ with $\omega_\mu{}^a{}_\nu = \eta_{aa}\omega_{\mu a\nu}$.

```
pairs = [(mu, a, b) for mu in range(8) for a in range(8) for b in range(a + 1, 8)
         if not is_zero(om[mu][a][b])]
for mu, a, b in pairs:
    say(f"omega_{NAMES[mu]} ({NAMES[a]})({NAMES[b]}) = {sp.factor(om[mu][a][b])}")
listed = from_wolfram(record_b4["omega_nonzero"])
listed_1 = from_wolfram(record["omega_nonzero"])
check(len(pairs) == 12 and len(listed) == len(listed_1) == 12
      and all(is_zero(to_ring(v) - om[mu - 1][a - 1][b - 1])
              for mu, a, b, v in listed)
      and all(is_zero(to_ring(v) - om[mu - 1][a - 1][b - 1].subs(AT_B4_1))
              for mu, a, b, v in listed_1),
      "exactly 12 nonzero components, equal to the formula record with b4, and at "
      "b4 = 1 to the record of b4 = 1", record=f"{FORMULAS_B4}, formula "
      "omega_nonzero; " + reproduces(WLREP, "omega_components") + " (at b4 = 1)")
```

`pairs` lists the nonzero components with $a < b$, which are printed. `listed` and `listed_1` are the lists of the two records (key `omega_nonzero`); the check requires exactly 12 components, equal to those of the record with b_4, and at $b_4 = 1$ to those of the record of $b_4 = 1$. **Out [8]:** a PASS line with its "reproduces" line, the twelve components (for example `omega_x1 (x1)(x4) = A1*E*s` and `omega_x5 (x4)(x5) = -s*(2*A1*b4 - b4p)/(2*E*sqrt(b4))`), and a second PASS line with its "reproduces" line (the formula record with b_4 and the Wolfram check `omega_components`).

In [9]: the spinor connection and $\gamma^\mu\Omega_\mu$.

```
Om = []  # Omega_mu, mu = x0 .. x7
for mu in range(8):
    M = sp.zeros(16, 16)
    for a in range(8):
        for b in range(a + 1, 8):
            if om[mu][a][b] != 0:
                M += om[mu][a][b] * SAB[a][b]
    Om.append(M.applyfunc(sp.expand))
```

`Om[mu]` is $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$, a 16×16 matrix, built for each of the eight directions and multiplied out entry by entry.

```
gam = [G[a] / f[a] for a in range(8)]  # the coordinate gammas gamma^mu
alpha, beta, rest_zero = [], [], True
for mu in range(8):
    M = (gam[mu] * Om[mu]).applyfunc(sp.expand)  # gamma^mu Omega_mu, no sum
    alpha.append(sp.expand(-(M * G[X4]).trace() / 16))  # coefficient of gamma^(x4)
    beta.append(sp.expand((M * G[X0]).trace() / 16))  # coefficient of gamma^(x0)
    rest_zero = rest_zero and all(
        is_zero(v) for v in (M - alpha[-1] * G[X4] - beta[-1] * G[X0]))
```

`gam` holds the coordinate gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$. For each direction separately (no sum), `M` is $\gamma^\mu\Omega_\mu$, and it is written as $\alpha_\mu\gamma^{(x_4)} + \beta_\mu\gamma^{(x_0)}$. The two numbers come from **traces** (the trace of a

matrix is the sum of its diagonal entries): because $\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_4)}) = -16$, $\mathrm{tr}(\gamma^{(x_0)}\gamma^{(x_0)}) = 16$ and $\mathrm{tr}(\gamma^{(x_4)}\gamma^{(x_0)}) = 0$, the trace of $M\gamma^{(x_4)}$ is $-16\alpha_\mu$ and the trace of $M\gamma^{(x_0)}$ is $16\beta_\mu$. `rest_zero` stays true only if nothing else is left over: every entry of $M - \alpha_\mu\gamma^{(x_4)} - \beta_\mu\gamma^{(x_0)}$ is zero.

```
for mu in range(8):
    say(f"gamma^{NAMES[mu]} Omega_{NAMES[mu]} = ({alpha[mu]}) gamma^(x4) + "
        f"({beta[mu]}) gamma^(x0)")
listed = from_wolfram(record["gammaOmega_per_direction"])
check(rest_zero and all(is_zero(to_ring(al) - alpha[mu - 1].subs(AT_B4_1))
                        and is_zero(to_ring(be) - beta[mu - 1].subs(AT_B4_1))
                        for mu, al, be in listed),
      "per direction gamma^mu Omega_mu = alpha gamma^(x4) + beta gamma^(x0); at "
      "b4 = 1 equal to the formula record",
      record=f"{FORMULAS}, formula gammaOmega_per_direction")
```

The eight decompositions are printed. The check compares each pair (α_μ, β_μ) at $b_4 = 1$ with the list of the record of $b_4 = 1$ (key `gammaOmega_per_direction`; the record with b_4 stores only the sum).

```
total = sum((gam[mu] * Om[mu] for mu in range(8)), Z16)
GRAV = 3 * H * G[X0] + 3 * b4p / (4 * b4) * G[X4]  # the gravitational term
check(all(is_zero(v) for v in (total - GRAV))
      and all(is_zero(v) for v in (total.subs(AT_B4_1) - 3 * H * G[X0])),
      "gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4) (summed over "
      "mu); 3 H gamma^(x0) at b4 = 1",
      record=reproduces(PYREP_B4, "gammaOmega_total") + "; "
      + reproduces(PYREP, "gamma_mu_Omega_mu_equals_3H_gamma_x0") + " (at b4 = 1)")
check(sp.expand(sum(alpha[1:4])) == sp.Rational(3, 2) * A1
      and sp.expand(sum(alpha[5:8]) + sp.Rational(3, 2) * A1
                    - sp.Rational(3, 4) * b4p / b4) == 0
      and sp.expand(sum(alpha[5:8]).subs(AT_B4_1)) == -sp.Rational(3, 2) * A1
      and sp.expand(sum(beta)) == 3 * H,
      "the a4' terms cancel (+3 A1/2 inflating, -3 A1/2 deflating; the extra times "
      "leave (3/4) b4'/b4, zero at b4 = 1), the six x0 terms add to 3 H",
      record=reproduces(PYREP, "time_terms_cancel_hidden_term_survives")
      + " (at b4 = 1)")
```

`total` is the sum over μ and `GRAV` the gravitational term $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$; the first check requires `total` to be M, and $3H\gamma^{(x_0)}$ at $b_4 = 1$. The second checks the cancellation: the α of the three inflating directions (positions 1 to 3, `alpha[1:4]`) add to $\frac{3}{2}A_1$, those of the three extra times (positions 5 to 7, `alpha[5:8]`) to $-\frac{3}{2}A_1 + \frac{3}{4}b_4'/b_4$, which is $-\frac{3}{2}A_1$ at $b_4 = 1$, and all β add to $3H$. **Out [9]:** the eight lines `gamma^x0 Omega_x0 = (0) gamma^(x4) + (0) gamma^(x0)`, `gamma^x1 Omega_x1 = (A1/2) gamma^(x4) + (H/2) gamma^(x0) ...` `gamma^x5 Omega_x5 = (-A1/2 + b4p/(4*b4)) gamma^(x4) + (H/2) gamma^(x0) ...`, with zeros for x_0 and x_4, and three PASS lines with their "reproduces" lines.

In [10]: Figure 07b.2.

```
a_units = [float(sp.expand(v.subs(AT_B4_1) / A1)) if v != 0 else 0.0
           for v in alpha]  # in units of a4', at b4 = 1
b_units = [float(sp.expand(v / H)) if v != 0 else 0.0 for v in beta]  # H units
```

```
positions = np.arange(8)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9), sharey=True)
for ax, values, unit, title in [
        (left, a_units, "$a_4'$", "coefficient of $\\gamma^{(x_4)}$"),
        (right, b_units, "$H$", "coefficient of $\\gamma^{(x_0)}$")]:
    ax.bar(positions, values, color=["grey"] + ["tab:blue"] * 3 + ["grey"]
           + ["tab:red"] * 3, label="one direction")
    ax.plot(positions, np.cumsum(values), "ko-", label="running sum")
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xticks(positions, [f"$x_{k}$" for k in range(8)])
    ax.set_xlabel("direction $\\mu$ (blue 3-space, red extra times)")
    ax.set_title(f"{title} (units of {unit})")
    ax.legend(fontsize=8, loc="upper left")
left.set_ylabel("coefficient")
fig.tight_layout()
save_figure(fig, "gamma_omega_per_direction",
...)
```

`a_units` and `b_units` are the coefficients in units of a_4' (at $b_4 = 1$) and of H (the zeros of x_0 and x_4 become 0.0). Two panels with a shared vertical axis (`sharey=True`); the loop draws in each a bar chart with grey bars for x_0 and x_4, blue for 3-space and red for the extra times, and the **running sum** (`np.cumsum`, the sum of the first one, two, three, ... values) as black dots joined by lines. **What Figure 07b.2 shows.** On the left the bars are $+\frac{1}{2}$ (blue) and $-\frac{1}{2}$ (red): the running sum climbs to $\frac{3}{2}$ and falls back to 0, the time terms cancel. On the right all six bars are $+\frac{1}{2}$ and the running sum ends at 3: $\gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ at $b_4 = 1$.

In [11]: why the connection drops out of $\mathcal{L}$ but not out of the equation.

```
anti = all(all(is_zero(v) for v in (gam[mu] * Om[mu] + Om[mu] * gam[mu]))
           for mu in range(8))
check(anti, "{gamma^mu, Omega_mu} = 0 for each mu: the connection drops out of L",
      record=reproduces(PYREP, "anticommutator_gamma_Omega_vanishes"))
divergence = sum((((sqrt_g * gam[mu]).applyfunc(lambda v: cd(v, mu)))
                  for mu in range(8)), Z16) / (2 * sqrt_g)
check(all(is_zero(v) for v in (divergence - GRAV)),
      "(1/(2 sqrt|g|)) d_mu (sqrt|g| gamma^mu) = 3 H gamma^(x0) + (3/4)(b4'/b4) "
      "gamma^(x4)", record=reproduces(PYREP, "divergence_of_sqrtg_gamma")
      + " (at b4 = 1)")
```

`anti` checks $\gamma^\mu \Omega_\mu + \Omega_\mu \gamma^\mu = 0$ for each direction. `divergence` is $\frac{1}{2\sqrt{|g|}} \sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)$: `applyfun c(lambda v: cd(v, mu))` differentiates every entry of the matrix $\sqrt{|g|}\gamma^\mu$ along x_μ. The second check requires $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$. **Out [11]:** two PASS lines with their "reproduces" lines.

In [12]: a jet algebra for both statistics.

```
CHI, PSI = 0, 1  # the two kinds: components of Psi^dagger and of Psi

def gen(kind, A, derivatives=()):
    """The generator: component A of chi (kind 0) or psi (kind 1), differentiated
```

```
    along the coordinate positions in derivatives."""
    return (kind, A, tuple(sorted(derivatives)))
```

A generator of the jet algebra is a triple `(kind, A, derivatives)`: kind 0 for a component $\chi_A = \Psi^*_A$ of $\Psi^\dagger$, kind 1 for a component ψ_A of Ψ; `A` from 0 to 15; `derivatives` a sorted tuple of coordinate positions (empty for the value itself, `(4,)` for ∂_4). `gen` builds such a triple.

```
def sort_sign(keys, odd):
    """Sorted tuple of generators and the sign; (None, 0) for a zero product."""
    items, sign = list(keys), 1
    for end in range(len(items) - 1, 0, -1):  # bubble sort, counting exchanges
        for i in range(end):
            if items[i] > items[i + 1]:
                items[i], items[i + 1] = items[i + 1], items[i]
                sign = -sign
    if not odd:
        return tuple(items), 1  # commuting generators: no signs, squares allowed
    if any(items[i] == items[i + 1] for i in range(len(items) - 1)):
        return None, 0  # a repeated Grassmann generator: the product is zero
    return tuple(items), sign
```

`sort_sign(keys, odd)` sorts a tuple of generators with the bubble sort of Notebook 07a and counts the exchanges (Python compares triples entry by entry, so the order is first by kind, then by component, then by derivatives). For commuting generators (`odd` false) there is no sign and squares are allowed; for Grassmann generators a repeated generator gives the zero product, `(None, 0)`.

```
class Jet:
    """An element of the jet algebra: self.terms maps monomials to coefficients."""

    def __init__(self, odd, terms=None):
        self.odd, self.terms = odd, {}
        for monomial, coefficient in (terms or {}).items():
            self.add(monomial, coefficient)

    def add(self, monomial, coefficient):
        total = sp.expand(self.terms.get(monomial, 0) + coefficient)
        if total == 0:
            self.terms.pop(monomial, None)
        else:
            self.terms[monomial] = total
```

The class `Jet`: an element remembers whether its generators are odd and holds a dictionary from monomials to ring coefficients. `add` adds a coefficient to a monomial, multiplies out and removes zeros, as in Notebook 07a.

```
    def __add__(self, other):
        result = Jet(self.odd, self.terms)
        for monomial, coefficient in other.terms.items():
            result.add(monomial, coefficient)
        return result
```

```
    def __sub__(self, other):
        return self + other.times(-1)

    def times(self, factor):  # an ordinary (ring) factor
        return Jet(self.odd, {k: factor * v for k, v in self.terms.items()})
```

Addition, subtraction, and `times(factor)`, the multiplication by an ordinary ring factor.

```
    def __mul__(self, other):
        result = Jet(self.odd)
        for k1, v1 in self.terms.items():
            for k2, v2 in other.terms.items():
                monomial, sign = sort_sign(k1 + k2, self.odd)
                if monomial is not None:
                    result.add(monomial, sign * v1 * v2)
        return result
```

The product: every term times every term, the joined monomial sorted with its sign.

```
    def conj(self):
        result = Jet(self.odd)
        for monomial, coefficient in self.terms.items():
            images = [(1 - kind, A, d) for kind, A, d in reversed(monomial)]
            ordered, sign = sort_sign(images, self.odd)
            if ordered is not None:
                result.add(ordered, sign * sp.sympify(coefficient).subs(sp.I, -sp.I))
        return result
```

`conj` is the conjugation of Section 7.11: the monomial is reversed, each generator's kind is exchanged ($\chi_A \leftrightarrow \psi_A$, `1 - kind`) while its component and derivatives are kept, the result is sorted with its sign (for commuting generators no sign), and i is replaced by $-i$ in the coefficient (all other symbols are real).

```
    def lderiv(self, key):
        result = Jet(self.odd)
        for monomial, coefficient in self.terms.items():
            if key in monomial:
                p = monomial.index(key)
                factor = (-1) ** p if self.odd else monomial.count(key)
                result.add(monomial[:p] + monomial[p + 1:], factor * coefficient)
        return result

    def rderiv(self, key):
        if not self.odd:
            return self.lderiv(key)
        result = Jet(self.odd)
        for monomial, coefficient in self.terms.items():
            if key in monomial:
                p = monomial.index(key)
```

```
                factor = (-1) ** (len(monomial) - 1 - p)
                result.add(monomial[:p] + monomial[p + 1:], factor * coefficient)
        return result
```

`lderiv(key)` is the left derivative: for Grassmann generators the sign $(-1)^p$ of the position; for commuting generators the ordinary derivative, which brings down the power (`monomial.count(key)` is the number of times the generator occurs, the n of $x^n \to nx^{n-1}$). `rderiv(key)` is the right derivative; for commuting generators it is the same as the left one.

```
    def total(self, mu):
        result = Jet(self.odd)
        for monomial, coefficient in self.terms.items():
            derivative = cd(coefficient, mu)
            if derivative != 0:
                result.add(monomial, derivative)
            for p, (kind, A, d) in enumerate(monomial):
                raised = (kind, A, tuple(sorted(d + (mu,))))
                ordered, sign = sort_sign(monomial[:p] + (raised,) + monomial[p + 1:],
                                          self.odd)
                if ordered is not None:
                    result.add(ordered, sign * coefficient)
        return result

    def is_zero(self):
        return all(is_zero(v) for v in self.terms.values())
```

`total(mu)` is the total derivative d/dx_μ on jets: the coefficient is differentiated with `cd` (the explicit dependence on x_4 and x_0), and every generator of the monomial in turn gets the additional derivative μ (its derivative tuple grows by `mu`), with the product rule and the sign of sorting back. `is_zero` uses the exact zero test of In [3] on every coefficient.

```
def column(odd, kind, derivatives=()):
    """The 16 generators of chi or psi (or of one of their derivatives)."""
    return [Jet(odd, {(gen(kind, A, derivatives),): 1}) for A in range(16)]

def matvec(M, v, odd):
    """The column M v."""
    out = [Jet(odd) for _ in range(16)]
    for i in range(16):
        for j in range(16):
            if M[i, j] != 0:
                out[i] = out[i] + v[j].times(M[i, j])
    return out

def vecmat(v, M, odd):
    """The row v M."""
    out = [Jet(odd) for _ in range(16)]
    for i in range(16):
        for j in range(16):
```

```
            if M[i, j] != 0:
                out[j] = out[j] + v[i].times(M[i, j])
    return out

def dot(row, col, odd):
    """The number row col (row first)."""
    result = Jet(odd)
    for x, y in zip(row, col):
        result = result + x * y
    return result

say("The jet algebra and the vector helpers are defined.")
```

Vector helpers: `column(odd, kind, derivatives)` is the list of the 16 generators of χ or ψ (or of one of their derivatives) as elements; `matvec(M, v, odd)` is the column Mv, `vecmat(v, M, odd)` the row vM (each skips the zero entries of the matrix), and `dot(row, col, odd)` the number $\sum_A \mathrm{row}_A \mathrm{col}_A$ with the row factor first. **Out [12]:** `The jet algebra and the vector helpers are defined.`

In [13]: the Lagrangian of both fields.

```
def build(odd, connection):
    """Lagrangian, unsymmetrised Lagrangian, field-equation residual and pieces
    for one statistics (odd True: Grassmann) and one spinor connection."""
    psi, chi = column(odd, PSI), column(odd, CHI)
    psibar = vecmat(chi, C, odd)  # Psibar = Psi^dagger C
    Dpsi = [[x + y for x, y in zip(column(odd, PSI, (mu,)),
                                   matvec(connection[mu], psi, odd))]
            for mu in range(8)]
    Dpsibar = [[x - y for x, y in zip(vecmat(column(odd, CHI, (mu,)), C, odd),
                                      vecmat(psibar, connection[mu], odd))]
               for mu in range(8)]
```

`build(odd, connection)` builds everything for one statistics and one spinor connection (a list of eight matrices). `psi` and `chi` are the columns of generators; `psibar` is the row $\bar\Psi = \chi C$. `Dpsi[mu]` is $D_\mu\psi = \partial_\mu\psi + \Omega_\mu\psi$ and `Dpsibar[mu]` is $D_\mu\bar\Psi = \partial_\mu\chi\, C - \bar\Psi\Omega_\mu$, each a list of 16 elements.

```
    K, Ku = Jet(odd), Jet(odd)
    for mu in range(8):
        forward = dot(psibar, matvec(gam[mu], Dpsi[mu], odd), odd)
        K = K + forward - dot(vecmat(Dpsibar[mu], gam[mu], odd), psi, odd)
        Ku = Ku + forward
    S = dot(psibar, psi, odd)
    potential = S.times(m) + (S * S).times(lam / 2)  # m S + (lambda/2) S^2
    L = (K.times(sp.Rational(1, 2)) - potential).times(sqrt_g)
    Lu = (Ku - potential).times(sqrt_g)
```

`K` collects $\sum_\mu(\bar\Psi\gamma^\mu D_\mu\psi - D_\mu\bar\Psi\gamma^\mu\psi)$ and `Ku` the unsymmetrised $\sum_\mu \bar\Psi\gamma^\mu D_\mu\psi$ (`forward` is the first product, computed once). `S` is $\bar\Psi\psi$, `potential` is $mS + \frac{\lambda}{2}S^2$. `L` is $\sqrt{|g|}(\frac{1}{2}K - mS - \frac{\lambda}{2}S^2)$, `Lu` the unsymmetrised form.

```
    dirac = [Jet(odd) for _ in range(16)]  # gamma^mu D_mu psi
    for mu in range(8):
        dirac = [x + y for x, y in zip(dirac, matvec(gam[mu], Dpsi[mu], odd))]
    V = Jet(odd, {(): m}) + S.times(lam)  # m + lambda S
    residual = [dirac[A] - V * psi[A] for A in range(16)]
    bar_residual = [Jet(odd)] * 16  # -(D_mu Psibar gamma^mu + V Psibar)
    for mu in range(8):
        bar_residual = [x - y for x, y in zip(bar_residual,
                                              vecmat(Dpsibar[mu], gam[mu], odd))]
    bar_residual = [x - V * y for x, y in zip(bar_residual, psibar)]
    return {"L": L, "Lu": Lu, "E": residual, "Ebar": bar_residual, "S": S,
            "psi": psi, "psibar": psibar, "dirac": dirac}
```

`dirac` is the column $\gamma^\mu D_\mu \psi$; `V` is the element $m + \lambda S$; `residual` is the column $\mathcal{E} = \gamma^\mu D_\mu \psi - V\psi$. `bar_residual` is the row $-(D_\mu \bar{\Psi}\gamma^\mu + V\bar{\Psi})$. The function returns all pieces in a dictionary.

```
STATS = {"grassmann": True, "commuting": False}  # statistics -> odd
fields = {name: build(odd, Om) for name, odd in STATS.items()}
kinds = {}
for name, data in fields.items():
    monomials = data["L"].terms
    kinetic = sum(1 for k in monomials if any(d for (_, _, d) in k))
    quartic = sum(1 for k in monomials if len(k) == 4)
    kinds[name] = (kinetic, len(monomials) - kinetic - quartic, quartic)
    report(f"monomials of L, {name}", f"{len(monomials)} = {kinetic} kinetic + "
           f"{kinds[name][1]} mass + {quartic} quartic")
```

`STATS` maps the two names to the switch `odd`. `fields` holds the pieces for both statistics with the canonical connection `Om`. For each, the monomials of $\mathcal{L}$ are sorted by type: kinetic if some generator carries a derivative (`any(d for (_, _, d) in k)` is true when a derivative tuple is not empty), quartic if the monomial has four generators, and mass otherwise. **Out [13]:** `RESULT monomials of L, grassmann = 392 = 256 kinetic + 16 mass + 120 quartic` and `RESULT monomials of L, commuting = 408 = 256 kinetic + 16 mass + 136 quartic`.

In [14]: the counts against the record, and Figure 07b.3.

```
for name in STATS:
    detail = revision_check(PYREP, f"{name}_lagrangian_real")["detail"]
    recorded = int(re.search(r"\((\d+) monomials", detail).group(1))
    check(len(fields[name]["L"].terms) == recorded,
          f"{name}: L has {recorded} monomials, as recorded",
          record=reproduces(PYREP, f"{name}_lagrangian_real"))
check(kinds["grassmann"] == (256, 16, 120) and kinds["commuting"] == (256, 16, 136),
      "the difference is the 16 squares of the pairs in S^2 (136 - 120)")
```

For each statistics the number of monomials is read from the detail text of the record's reality check ("(392 monomials" and "(408 monomials") and compared. The last check is the difference of Section 7.20: 136 minus 120 quartic monomials, the 16 squares of the pairs.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
labels = ["dirac16complex\n(Grassmann)", "dirac16complex00\n(commuting)"]
```

```
bottoms = np.zeros(2)
for index, (part, colour) in enumerate([("kinetic", "tab:blue"), ("mass", "tab:green"),
                                        ("quartic", "tab:orange")]):
    values = np.array([kinds["grassmann"][index], kinds["commuting"][index]])
    ax.bar(labels, values, bottom=bottoms, color=colour, label=part, width=0.5)
    for x, (value, bottom) in enumerate(zip(values, bottoms)):
        ax.text(x, bottom + value / 2, str(value), ha="center", va="center")
    bottoms = bottoms + values
for x, total in enumerate(bottoms):
    ax.text(x, total + 6, f"total {int(total)}", ha="center")
ax.set_ylim(0, 520)  # room above the bars for the legend
ax.set_ylabel("number of monomials of $L$")
ax.set_title("The Lagrangian at one point, by type of term")
ax.legend(loc="upper center", ncol=3, fontsize=8)
save_figure(fig, "lagrangian_monomials",
...)
```

A **stacked bar chart**: for each field the bars of the three types are drawn on top of each other (`bottom=bottoms` starts each new bar where the previous one ended), the counts are written into the bars and the totals above them (`"\n"` in a label is a line break). **Out [14]:** three PASS lines (the first two with "reproduces" lines) and the figure. **What Figure 07b.3 shows.** The kinetic (blue) and mass (green) parts are equal for the two fields; the only difference is the quartic part (orange), 120 against 136: the 16 squares $(\bar{\Psi}_A \Psi_B)^2$ vanish for Grassmann numbers.

In [15]: reality, the total divergence and the connection that drops out.

```
no_connection = [Z16] * 8  # Omega_mu = 0
for name, odd in STATS.items():
    data = fields[name]
    L, Lu = data["L"], data["Lu"]
    check((L.conj() - L).is_zero() and not (Lu.conj() - Lu).is_zero(),
          f"{name}: L is real, the unsymmetrised L_u is not",
          record=reproduces(PYREP, f"{name}_controls_not_vacuous"))
    current = Jet(odd)
    for mu in range(8):
        current = current + dot(data["psibar"], matvec(gam[mu], data["psi"], odd),
                                odd).times(sqrt_g).total(mu)
    check((L - Lu + current.times(sp.Rational(1, 2))).is_zero(),
          f"{name}: L = L_u - (1/2) d_mu (sqrt|g| Psibar gamma^mu Psi)",
          record=reproduces(PYREP, f"{name}_total_divergence_relation"))
    flat_connection = build(odd, no_connection)["L"]
    tag = "G" if odd else "C"
    check((L - flat_connection).is_zero(),
          f"{name}: L with Omega equals L with Omega = 0 in this metric",
          record=reproduces(WLREP, f"L_spin_connection_drops_out_{tag}"))
```

`no_connection` is the list of eight zero matrices ($\Omega_\mu = 0$). For each statistics: the first check requires $\mathcal{L}^* = \mathcal{L}$ and that the unsymmetrised form is not real (the control). `current` is $\sum_\mu \frac{d}{dx_\mu}(\sqrt{|g|}\,\bar{\Psi}\gamma^\mu\psi)$, built with the total derivative of the jet algebra; the second check is the relation $\mathcal{L} = \mathcal{L}_u - \frac{1}{2}\cdot$ current of Section 7.20. `flat_connection` is the Lagrangian built with $\Omega_\mu = 0$; the third check requires it to equal $\mathcal{L}$. `tag` is `"G"` or `"C"`, the ending of the Wolfram check names. **Out [15]:** six PASS lines, each with its "reproduces" line.

In [16]: the Euler-Lagrange equations.

```
def euler_lagrange_chi(L, A):
    """dL/dchi_A - d_mu dL/d(d_mu chi_A), left derivatives."""
    result = L.lderiv(gen(CHI, A))
    for mu in range(8):
        result = result - L.lderiv(gen(CHI, A, (mu,))).total(mu)
    return result

def euler_lagrange_psi(L, B):
    """dL/dpsi_B - d_mu dL/d(d_mu psi_B), right derivatives."""
    result = L.rderiv(gen(PSI, B))
    for mu in range(8):
        result = result - L.rderiv(gen(PSI, B, (mu,))).total(mu)
    return result
```

`euler_lagrange_chi(L, A)` is $\partial_L \mathcal{L}/\partial\chi_A - \sum_\mu \frac{d}{dx_\mu}\partial_L \mathcal{L}/\partial(\partial_\mu \chi_A)$ with left derivatives; `euler_lagrange_psi(L, B)` is the same for ψ_B with right derivatives.

```
for name, odd in STATS.items():
    data = fields[name]
    L, residual, psi = data["L"], data["E"], data["psi"]
    expected = matvec(C, residual, odd)  # C times the residual
    ok = all((euler_lagrange_chi(L, A) - expected[A].times(sqrt_g)).is_zero()
             for A in range(16))
    wrong = matvec(C, [residual[B] + psi[B].times(2 * m) for B in range(16)], odd)
    control = not (euler_lagrange_chi(L, 0) - wrong[0].times(sqrt_g)).is_zero()
    check(ok and control, f"{name}: varying Psi^dagger gives gamma^mu D_mu Psi = "
          "(m + lambda S) Psi in all 16 components (control m -> -m fails)",
          record=reproduces(PYREP, f"{name}_euler_lagrange_psibar_variation"))
    ok = all((euler_lagrange_psi(L, B) - data["Ebar"][B].times(sqrt_g)).is_zero()
             for B in range(16))
    check(ok, f"{name}: varying Psi gives D_mu Psibar gamma^mu = -(m + lambda S) "
          "Psibar", record=reproduces(PYREP, f"{name}_euler_lagrange_psi_variation"))
    conjugate_row = vecmat([x.conj() for x in residual], C, odd)
    check(all((conjugate_row[B] - data["Ebar"][B]).is_zero() for B in range(16)),
          f"{name}: the adjoint equation is the Dirac conjugate of the field equation",
          record=reproduces(PYREP, f"{name}_adjoint_equation_is_conjugate"))
```

For each statistics: `expected` is the column $C\mathcal{E}$; the first check requires the Euler-Lagrange expression of every χ_A to equal $\sqrt{|g|}(C\mathcal{E})_A$ (Steps 1 to 6 of Section 7.21), and, as a control, that the comparison with m replaced by $-m$ fails (`wrong` adds $2m\psi$ to the residual; only component 0 is tested, which suffices to show the failure). The second check: the expressions for ψ_B equal $\sqrt{|g|}$ times the adjoint residual. The third: the conjugate of the residual, as a row times C (`conjugate_row`), equals the adjoint residual. **Out [16]:** six PASS lines, each with its "reproduces" line.

In [17]: the equations written out in the author's metric.

```
for name, odd in STATS.items():
    data = fields[name]
```

```
    explicit = matvec(GRAV, data["psi"], odd)  # (3 H gamma^(x0) + ...) psi
    for a in range(8):
        explicit = [x + y for x, y in zip(explicit, matvec(
            G[a] / f[a], column(odd, PSI, (a,)), odd))]
    tag = "G" if odd else "C"
    check(all((data["dirac"][A] - explicit[A]).is_zero() for A in range(16)),
          f"{name}: gamma^mu D_mu Psi = sum_a (1/f_a) gamma^(a) d_a Psi + 3 H "
          "gamma^(x0) Psi + (3/4)(b4'/b4) gamma^(x4) Psi",
          record=reproduces(WLREP, f"Dirac_operator_explicit_{tag}") + " (at b4 = 1)")
```

For each statistics `explicit` is the column $M\psi + \sum_a \frac{1}{f_a}\gamma^{(a)}\partial_a\psi$ (`GRAV` is M); the check requires it to equal $\gamma^\mu D_\mu\psi$ in all 16 components.

```
def as_sympy(element):
    """A linear jet element as a sympy expression in d<a>_<B> and P<B>."""
    total = 0
    for ((kind, B, d),), coefficient in element.terms.items():
        symbol = f"d{d[0]}_{B + 1}" if d else f"P{B + 1}"  # d0 .. d7: x0 .. x7
        total += coefficient * sp.Symbol(symbol)
    return total
```

`as_sympy(element)` turns a linear jet element into an ordinary sympy expression: each monomial has exactly one generator (the unpacking `((kind, B, d),)` requires this), which becomes the symbol `d<a>_<B>` for $\partial_a\Psi_B$ or `P<B>` for Ψ_B, counted from 1 like the record.

```
ours = [as_sympy(x) for x in fields["grassmann"]["dirac"]]
theirs = [to_ring(from_wolfram(text.split("==")[0]))
          for text in record_b4["field_equation_components"]]
theirs_1 = [to_ring(from_wolfram(text.split("==")[0]))
            for text in record["field_equation_components"]]
say(f"equation 1, this notebook: {ours[0]} = V P1")
say(f"equation 1, formula record: {theirs[0]} = V P1")
check(len(theirs) == len(theirs_1) == 16
      and all(is_zero(x - y) for x, y in zip(ours, theirs))
      and all(is_zero(x.subs(AT_B4_1) - y) for x, y in zip(ours, theirs_1)),
      "all 16 component equations equal the formula record with b4 term by term, "
      "and at b4 = 1 the record of b4 = 1",
      record=f"{FORMULAS_B4} and {FORMULAS}, formula field_equation_components")
```

`as_sympy` names the derivative of component B along the direction at position a `d<a>_<B>` (so `d0_9` is $\partial_0\Psi_9$, as in the records). `ours` are our 16 Dirac-operator components, `theirs` and `theirs_1` the left sides of the 16 component equations of the record with b_4 and of the record of $b_4 = 1$ (each text is split at `==` and its first part translated and put into the ring). The first equation is printed in both forms, and the check compares all 16 with the exact zero test: ours with the first record, and ours at $b_4 = 1$ with the second. **Out [17]:** two PASS lines with their "reproduces" lines, the first equation twice (identical, the equation of Section 7.22 in ring symbols), and the third PASS line. The first equation is printed as

```
equation 1, this notebook: E*d5_15/(sqrt(b4)*s) + E*d6_16/(sqrt(b4)*s) +
    E*d7_9/(sqrt(b4)*s) + 3*H*P9 - 3*P14*b4p/(4*b4) - d4_14 + d0_9*s**6/c - d1_16/(E*s) +
    d2_15/(E*s) - d3_14/(E*s) = V P1
```

In [18]: the coupling map, Figure 07b.4.

```
counts = np.zeros((16, 16), dtype=int)
tags = [["" for _ in range(16)] for _ in range(16)]
for a in range(8):
    for A in range(16):
        for B in range(16):
            if G[a][A, B] != 0:
                counts[A, B] += 1
                tags[A][B] += str(a)  # the digit k names the direction xk
four_twos = all(np.count_nonzero(counts[A]) == 4 and counts[A].max() == 2
                for A in range(16))  # 4 components, each with 2 directions
check(four_twos and int(counts.sum()) == 128
      and not counts[:8, :8].any() and not counts[8:, 8:].any(),
      "each equation couples 4 components with 2 directions each, across the chiral "
      "halves")
```

`counts[A, B]` counts the directions a whose gamma has a nonzero entry in row A, column B, that is the directions whose derivative of Ψ_B appears in equation A; `tags[A][B]` collects their numbers as a text. The check: every row has 4 nonzero entries, each 2; 128 derivative terms in total (8×16); and the two diagonal 8×8 blocks are empty (`counts[:8, :8]` is the upper left block): every equation couples the two chiral halves.

```
fig, ax = plt.subplots(figsize=(7.4, 6.6))
image = ax.imshow(counts, cmap="Blues", vmin=0, vmax=2)
for A in range(16):
    for B in range(16):
        if tags[A][B]:
            ax.text(B, A, tags[A][B], ha="center", va="center", fontsize=7,
                    color="white" if counts[A, B] == 2 else "black")
ax.axhline(7.5, color="red", linewidth=1)
ax.axvline(7.5, color="red", linewidth=1)
ax.set_xticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
ax.set_yticks(range(0, 16, 3), [str(k + 1) for k in range(0, 16, 3)])
ax.set_xlabel("component $B$ whose derivative appears")
ax.set_ylabel("equation $A$")
ax.set_title("Which derivatives $\\partial_a\\Psi_B$ enter equation $A$")
ax.grid(False)
fig.colorbar(image, ax=ax, ticks=[0, 1, 2], shrink=0.8,
             label="number of directions $a$")
save_figure(fig, "coupling_map",
...)
```

A heat map of `counts` in shades of blue, with the direction numbers written in (white on the darker squares) and red lines between rows 8 and 9 and columns 8 and 9 (`axhline(7.5)` lies between positions 7 and 8). **What Figure 07b.4 shows.** Each row has four coloured squares, each labelled with two direction numbers; the upper left and lower right quarters are empty: the equations of the upper half contain only the lower half of the field, and the other way round. The digit 0 marks the components that carry both $\tan z\,\partial_0$ and the term $3H$, the digit 4 those that carry ∂_4 and the term $\frac{3}{4}(b_4'/b_4)$ (each digit k names the direction x_k).

In [19]: the chiral blocks and the evolution form.

```
blocks = {}  # direction name -> (tau-bar_a, tau_a)
for text in record["field_equation_blocks"]:
    # the Wolfram list {"x1", {{...}}, {{...}}} is the JSON list ["x1", [[...]], [[...]]]
    name, upper, lower = json.loads(text.replace("{", "[").replace("}", "]"))
    blocks[name] = (sp.Matrix(upper), sp.Matrix(lower))
GAMMA = sp.Matrix(fixture["Gamma"])  # the chirality matrix of Revision/algebra
Z8 = sp.zeros(8, 8)
blocks_ok = sorted(blocks) == NAMES and GAMMA == sp.diag(*([-1] * 8 + [1] * 8))
for a in range(8):
    upper, lower = blocks[NAMES[a]]
    blocks_ok = (blocks_ok and G[a][:8, :8] == Z8 and G[a][8:, 8:] == Z8  # zero
                 and G[a][:8, 8:] == upper and G[a][8:, :8] == lower)  # the blocks
blocks_ok = blocks_ok and blocks["x0"][0] == sp.eye(8) and blocks["x0"][1] == sp.eye(8)
check(blocks_ok, "Gamma = diag(-I8, I8); every gamma^(a) is block off-diagonal with the "
      "blocks of the formula record; tau-bar_x0 = tau_x0 = I8",
      record=reproduces(WLREP, "block_form"))
```

The record's key `field_equation_blocks` holds, for each direction, its name and its two 8×8 blocks as a Wolfram list; replacing braces by square brackets makes it a JSON list, which `json.loads` reads. `GAMMA` is the chirality matrix of the record, `Z8` the 8×8 zero matrix. The check requires: the eight direction names; $\Gamma = \mathrm{diag}(-I_8, I_8)$ (`sp.diag(*list)` builds a diagonal matrix from a list); for every gamma the two diagonal blocks zero and the off-diagonal blocks equal to the record's (`G[a][:8, 8:]` is the upper right block); and $\bar{\tau}_{x_0} = \tau_{x_0} = I_8$.

```
for name, odd in STATS.items():
    data = fields[name]
    psi = data["psi"]
    V = Jet(odd, {(): m}) + data["S"].times(lam)  # m + lambda S
    others = matvec(GRAV, psi, odd)  # the gravitational term M Psi, then the sum
    for a in range(8):
        if a != X4:  # (1/f_a) gamma^(a) d_a Psi for the seven other directions
            others = [x + y for x, y in zip(others, matvec(
                G[a] / f[a], column(odd, PSI, (a,)), odd))]
    bracket = [V * psi[A] - others[A] for A in range(16)]  # the square bracket
    right = matvec(-G[X4], bracket, odd)  # R = -gamma^(x4) [ ... ]
    difference = [x - y for x, y in zip(column(odd, PSI, (X4,)), right)]  # d4 Psi - R
    left = matvec(G[X4], difference, odd)  # gamma^(x4) (d4 Psi - R)
    tag = "G" if odd else "C"
    check(all((left[A] - data["E"][A]).is_zero() for A in range(16)),
          f"{name}: the evolution form d4 Psi = R is the field equation "
          "(gamma^(x4) (d4 Psi - R) = E in all 16 components)",
          record=reproduces(WLREP, f"evolution_form_{tag}") + " (at b4 = 1)")
```

For each statistics: `others` is $M\psi + \sum_{a \neq x_4} \frac{1}{f_a} \gamma^{(a)} \partial_a \psi$, `bracket` is $V\psi -$ others, `right` is $R = -\gamma^{(x_4)}[\dots]$, `difference` is $\partial_4 \psi - R$ and `left` is $\gamma^{(x_4)}(\partial_4 \psi - R)$. The check requires `left` to equal the residual $\mathcal{E}$ in all 16 components: the evolution form is the field equation. **Out [19]:** three PASS lines with their "reproduces" lines.

In [20]: non-triviality.

```
for name, odd in STATS.items():
    data = fields[name]
```

```
    without = build(odd, no_connection)["E"]  # residual with Omega = 0
    gravity = matvec(GRAV, data["psi"], odd)  # M Psi
    ok = all((data["E"][A] - without[A] - gravity[A]).is_zero() for A in range(16))
    hidden = matvec(3 * H * G[X0], data["psi"], odd)  # M Psi at b4 = 1
    nonzero = all(len(hidden[A].terms) == 1 for A in range(16))
    number = "1_dirac16complex" if odd else "2_dirac16complex00"
    check(ok and nonzero, f"{name}: residual(Omega) - residual(Omega = 0) = M Psi "
          "with M = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4); at b4 = 1 it is "
          "3 H gamma^(x0) Psi, nonzero in all 16 components",
          record=reproduces(WLREP, f"nontriviality_{number}") + " (at b4 = 1); "
          + reproduces(PYREP_B4, "gravity_term_square_b4"))
```

For each statistics, `without` is the residual computed with $\Omega_\mu = 0$, `gravity` the column $M\psi$ and `hidden` the column $3H\gamma^{(x_0)}\psi$, which is $M\psi$ at $b_4 = 1$. The check requires residual(with Ω) minus residual(without) to equal `gravity` in all 16 components, and every component of `hidden` to be one nonzero monomial. **Out [20]:** two PASS lines with their "reproduces" lines (Wolfram checks `nontriviality_1_dirac16complex` and `nontriviality_2_dirac16complex00` at $b_4 = 1$, and the sympy check `gravity_term_square_b4` for a changing b_4).

In [21]: the exact family of solutions.

```
al, k, ch, sh = sp.symbols("alpha k ch sh", real=True)
chi0 = sp.Matrix(sp.symbols("q1:17"))  # an arbitrary constant column
M = -m * G[X4] + 3 * H * (2 * al + 1) * G[X4] * G[X0]
k_squared = 9 * H**2 * (2 * al + 1) ** 2 - m**2
check((M * M - k_squared * I16).applyfunc(sp.expand) == Z16
      and (M.T * C + C * M).applyfunc(sp.expand) == Z16,
      "M^2 = k^2 with k^2 = 9 H^2 (2 alpha + 1)^2 - m^2, and M^T C + C M = 0")
```

Symbols for α, k and the two functions $\cosh(kx_4)$, $\sinh(kx_4)$ (written `ch`, `sh`); `chi0` is a column of 16 arbitrary symbols. `M` and `k_squared` are those of Section 7.23. The check: $M^2 = k^2$ and $M^T C + CM = 0$.

```
def d4(v):  # derivative along x4 with ch' = k sh, sh' = k ch
    return v.diff(ch) * k * sh + v.diff(sh) * k * ch

def d0(v):  # derivative along x0 in the ring (s^(6 alpha) included)
    return v.diff(s) * H * c / s**5 + v.diff(c) * (-6 * H * s**6)

Psi = s ** (6 * al) * (ch * I16 + sh / k * M) * chi0  # sin^alpha z P(x4) chi0
residual = (G[X4] * Psi.applyfunc(d4) + (s**6 / c) * G[X0] * Psi.applyfunc(d0)
            + 3 * H * G[X0] * Psi - m * Psi)
```

`d4` differentiates along x_4 with $\partial_4 \mathrm{ch} = k\,\mathrm{sh}$ and $\partial_4 \mathrm{sh} = k\,\mathrm{ch}$; `d0` along x_0 in the ring (the factor $\sin^\alpha z$ is written $s^{6\alpha}$, whose derivative sympy handles). `Psi` is the family $\sin^\alpha z\,(\cosh kx_4 + \sinh(kx_4)/k\,M)\chi_0$ and `residual` the left side minus the right side of the explicit equation (the other six derivative terms vanish for a field of x_4 and x_0 only).

```
def vanishes(v):
    """Multiply by k and divide by sin^alpha z = s^(6 alpha), multiply out, use
    k^2 = 9 H^2 (2 alpha + 1)^2 - m^2: is the result zero?"""
    v = sp.expand(v * k / s ** (6 * al))
    return sp.expand(v.subs(k**2, k_squared)) == 0

without_term = residual - 3 * H * G[X0] * Psi  # the same without 3 H gamma^(x0)
check(all(vanishes(v) for v in residual)
      and not all(vanishes(v) for v in without_term),
      "Psi = sin^alpha z (cosh k x4 + sinh k x4 / k M) chi0 solves the field "
      "equation for every alpha, every a4 and constant b4 (and fails without "
      "3 H gamma^(x0))",
      record=reproduces(PYREP, "exact_solution_family_x4_x0"))
```

`vanishes(v)` multiplies a residual entry by k, divides by $s^{6\alpha}$, multiplies out, replaces k^2 by its value, and tests for zero. The check requires all 16 entries of the residual to vanish, and at least one entry of the residual without the term $3H\gamma^{(x_0)}\Psi$ not to vanish.

```
A_matrix = -sp.I * m * G[X4] + 3 * sp.I * H * G[X4] * G[X0]
check((A_matrix * A_matrix - (m**2 - 9 * H**2) * I16).applyfunc(sp.expand) == Z16,
      "the mode matrix A = -i m gamma^(x4) + 3 i H gamma^(x4) gamma^(x0) has A^2 = "
      "(m^2 - 9 H^2) I16", record=reproduces(
          SCOPE, "good_sector_x0_independent_modes_without_boundary_condition"))
```

The mode matrix of the scope record, $A = -im\gamma^{(x_4)} + 3iH\gamma^{(x_4)}\gamma^{(x_0)}$ (the matrix that $i\partial_4$ applies to the x_0-independent fields), squares to $(m^2 - 9H^2)I_{16}$. **Out [21]:** three PASS lines, the last two with their "reproduces" lines.

In [22]: two members of the family, numerically.

```
Gn = [np.array(gm.tolist(), dtype=float) for gm in G]  # the gammas as float arrays
Cn = np.array(C.tolist(), dtype=float)
chi_n = np.zeros(16)
chi_n[[0, 4]] = 1.0  # e_1 + e_5
zeta = np.pi / 4  # the point z = pi/4 of the hidden direction
xs4 = np.linspace(0.0, 2.0, 201)
```

The gammas and C as floating-point numpy arrays; `chi_n` is $e_1 + e_5$ (positions 0 and 4 set to 1); the point $z = \pi/4$ and 201 times from 0 to 2.

```
def member(alpha_value, mass=2.0, h=1.0):
    """Psi(x4) at z = pi/4 for the family member alpha (columns = times)."""
    Mn = -mass * Gn[X4] + 3 * h * (2 * alpha_value + 1) * Gn[X4] @ Gn[X0]
    ksq = 9 * h**2 * (2 * alpha_value + 1) ** 2 - mass**2
    kk = np.sqrt(complex(ksq))  # real for ksq > 0, imaginary for ksq < 0
    values = [(np.cosh(kk * t) * np.eye(16) + np.sinh(kk * t) / kk * Mn) @ chi_n
              for t in xs4]
    return np.sin(zeta) ** alpha_value * np.real(np.array(values).T)
```

`member(alpha_value)` evaluates the family at $z = \pi/4$ with $m = 2$, $H = 1$. `np.sqrt(complex(ksq))` is real for $k^2 > 0$ and imaginary for $k^2 < 0$; `np.cosh` and `np.sinh` of an imaginary argument give cos and i sin, so the formula works in both cases; `np.real` drops the zero imaginary parts. The result is a table with one column per time (`.T` transposes).

```
growing, oscillating = member(0.0), member(-0.5)
S_growing = np.einsum("it,ij,jt->t", growing, Cn, growing)  # Psi^T C Psi
S_oscillating = np.einsum("it,ij,jt->t", oscillating, Cn, oscillating)
report("S of the alpha = 0 member", f"{S_growing[0]:.6f}")
report("S of the alpha = -1/2 member", f"{S_oscillating[0]:.6f}")
check(np.allclose(S_growing, -2.0, atol=1e-9 * np.abs(growing).max() ** 2)
      and np.allclose(S_oscillating, -2.0 / np.sin(zeta), atol=1e-9),
      "S is constant along x4 for both members (-2 and -2/sin z)")
```

The growing member ($\alpha = 0$) and the oscillating member ($\alpha = -\frac{1}{2}$). `np.einsum("it,ij,jt->t", ...)` computes $\Psi^T C \Psi$ at every time t (a sum over the repeated indices i and j). The check requires the constant values -2 and $-2/\sin z$ (for the growing member the tolerance grows with the size of Ψ, because rounding errors grow with it). **Out [22]:** `RESULT S of the alpha = 0 member = -2.000000`, `RESULT S of the alpha = -1/2 member = -2.828427` and the PASS line.

In [23]: Figure 07b.5.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 3.6))
for A in range(16):
    if np.abs(growing[A]).max() > 1e-12:  # draw only the nonzero components
        axes[0].semilogy(xs4, np.abs(growing[A]), label=f"$|\\Psi_{{{A + 1}}}|$")
    if np.abs(oscillating[A]).max() > 1e-12:
        axes[1].plot(xs4, oscillating[A], label=f"$\\Psi_{{{A + 1}}}$")
axes[0].set_title("$\\alpha = 0$: growth like $e^{\\sqrt{5}x_4}$")
axes[1].set_title("$\\alpha = -1/2$: oscillation")
axes[2].plot(xs4, S_growing, label="$\\alpha = 0$")
axes[2].plot(xs4, S_oscillating, "--", label="$\\alpha = -1/2$")
axes[2].set_ylim(-3.5, 0.5)
axes[2].set_title("scalar density $S = \\Psi^T C\\Psi$")
for ax in axes:
    ax.set_xlabel("time $x_4$")
    ax.legend(fontsize=7)
axes[0].set_ylabel("value at $z = \\pi/4$")
fig.tight_layout()
save_figure(fig, "exact_solutions",
...)
```

Three panels: the size of the nonzero components of the growing member on a logarithmic axis, the nonzero components of the oscillating member, and the two scalar densities. `f"$|\\Psi_{{{A + 1}}}|$"` writes the component number as a LaTeX subscript (three braces: two give one literal brace, the third encloses the value). **What Figure 07b.5 shows.** Left: straight rising lines on the logarithmic axis, growth like $e^{\sqrt{5}x_4}$. Middle: oscillations of period π (angular frequency 2). Right: both scalar densities are flat lines, at -2 and at -2.83.

In [24]: the exact solution fails the wrong equations, Figure 07b.6.

```
Mn = -2.0 * Gn[X4] + 3.0 * Gn[X4] @ Gn[X0]  # alpha = 0, m = 2, H = 1
kk = np.sqrt(5.0)
psi_t = np.array([(np.cosh(kk * t) * np.eye(16) + np.sinh(kk * t) / kk * Mn) @ chi_n
                  for t in xs4])
dpsi_t = np.array([(kk * np.sinh(kk * t) * np.eye(16) + np.cosh(kk * t) * Mn) @ chi_n
                   for t in xs4])
full = np.array([Gn[X4] @ dp + 3.0 * Gn[X0] @ p - 2.0 * p
                 for p, dp in zip(psi_t, dpsi_t)])
no_gravity = np.array([Gn[X4] @ dp - 2.0 * p for p, dp in zip(psi_t, dpsi_t)])
wrong_mass = np.array([Gn[X4] @ dp + 3.0 * Gn[X0] @ p + 2.0 * p
                       for p, dp in zip(psi_t, dpsi_t)])
size = np.abs(psi_t).max(axis=1)  # the size of Psi at each time
relative_full = np.abs(full).max(axis=1) / size
check(relative_full.max() < 1e-12, "the full field equation holds to rounding "
      "(relative residual below 1e-12 at all 201 times)")
check(np.allclose(np.abs(no_gravity).max(axis=1), 3.0 * size),
      "without the term 3 H gamma^(x0) Psi the residual is 3 H |Psi|")
```

For the growing member, `psi_t` and `dpsi_t` are Ψ and its exact derivative $\partial_4\Psi = (k\sinh(kx_4) + \cosh(kx_4)M)\chi_0$ at the 201 times ($\partial_0\Psi = 0$ for $\alpha = 0$). `full` is the residual $\gamma^{(x_4)}\partial_4\Psi + 3H\gamma^{(x_0)}\Psi - m\Psi$, `no_gravity` the residual without the gravitational term, `wrong_mass` the residual of the equation with the mass m replaced by $-m$ (the term $-m\Psi$ becomes $+m\Psi$). `size` is the largest component of Ψ at each time. The first check: the full residual is below 10^{-12} of the size at every time; the second: without the gravitational term the residual is $3H$ times the size.

```
fig, ax = plt.subplots()
ax.semilogy(xs4, np.abs(no_gravity).max(axis=1),
            label="without $3H\\gamma^{(x_0)}\\Psi$")
ax.semilogy(xs4, np.abs(wrong_mass).max(axis=1), "--", label="mass $m \\to -m$")
ax.semilogy(xs4, size, ":", color="black", label="size of $\\Psi$")
ax.set_xlabel("time $x_4$")
ax.set_ylabel("largest component of the residual")
ax.set_title("The exact solution fails the wrong equations")
ax.legend(fontsize=8)
save_figure(fig, "residuals",
...)
```

One panel with the two wrong residuals and the size of Ψ on a logarithmic axis. **Out [24]:** two PASS lines and the figure. **What Figure 07b.6 shows.** Both wrong residuals grow as fast as the solution itself (parallel lines on the logarithmic axis); the residual without the gravitational term lies a factor 3 above the size of Ψ. The correct residual, below 10^{-12} of the size, is too small to be drawn.

In [25]: the last check.

```
names = ["scale_factors", "gamma_omega_per_direction", "lagrangian_monomials",
         "coupling_map", "exact_solutions", "residuals"]
files = [f"{FIGURE_FOLDER}/07b_{k}_{name}.png" for k, name in enumerate(names, 1)]
check(all(output_file(path).is_file() for path in files),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

The six figure files are checked and the last line printed. **Out [25]:** `PASS all 6 figure files of this notebook exist` and `ALL 47 CHECKS PASSED (notebook 07b)`.

7.28 Real fields and the Majorana-type negative control

Real fields. A **real field** is a column whose components are their own conjugates: $\Phi^* = \Phi$ for ordinary numbers, and for Grassmann components a column of real generators, $\theta^* = \theta$ (no separate conjugate generators at all). For a real column the row $\Phi^\dagger$ is just the transpose Φ^T. Real fields matter in this book for two reasons: the author's own notebook wrote its Lagrangian for a real column, and the question "what is charge conjugation?" has a surprising answer for real fields (Section 7.29).

The author's Majorana-type Lagrangian. The author's notebook used a real column Θ of 16 components and, with the canonical connection, the Lagrangian

$$L_g = \sqrt{|g|}\,[\Theta^T C\gamma^\mu D_\mu\Theta + (\text{a number})\,\Theta^T C\Theta],$$

built with the transpose Θ^T instead of the Dirac adjoint (a Lagrangian of this kind is called **Majorana-type**, after the physicist Ettore Majorana, who studied real spinor fields). If the components anticommute, as the components of dirac16complex do, this Lagrangian describes nothing:

- Its mass-type term vanishes: $\Theta^T C\Theta = 0$, because C is symmetric (Section 7.12).
- Its kinetic term is a total derivative. Three identities show it. First, for an antisymmetric matrix A (here $A = C\gamma^\mu$, which may depend on the coordinates) and an odd column, $(\partial_\mu\Theta)^T A\Theta = \Theta^T A\,\partial_\mu\Theta$: exchanging the two odd factors gives a minus sign, and the transpose of A another one. So the product rule gives $\partial_\mu(\Theta^T A\Theta) = 2\,\Theta^T A\,\partial_\mu\Theta + \Theta^T(\partial_\mu A)\Theta$, that is

$$\Theta^T C\gamma^\mu\partial_\mu\Theta = \tfrac{1}{2}\partial_\mu(\Theta^T C\gamma^\mu\Theta) - \tfrac{1}{2}\Theta^T\partial_\mu(C\gamma^\mu)\Theta.$$

Second, in $\Theta^T C\gamma^\mu\Omega_\mu\Theta$ only the antisymmetric part of the matrix $N = C\gamma^\mu\Omega_\mu$ survives (Section 7.12), and $N^T = \Omega_\mu^T(\gamma^\mu)^T C = \Omega_\mu^T(-C\gamma^\mu) = C\Omega_\mu\gamma^\mu$ (using $(\gamma^\mu)^T C = -C\gamma^\mu$ and $\Omega_\mu^T C = -C\Omega_\mu$), so $\frac{1}{2}(N - N^T) = \frac{1}{2}C[\gamma^\mu, \Omega_\mu]$ with the **commutator** $[X, Y] = XY - YX$:

$$\Theta^T C\gamma^\mu\Omega_\mu\Theta = \tfrac{1}{2}\Theta^T C[\gamma^\mu, \Omega_\mu]\Theta.$$

Third, multiply both by $\sqrt{|g|}$, use $\sqrt{|g|}\,\partial_\mu X = \partial_\mu(\sqrt{|g|}X) - (\partial_\mu\sqrt{|g|})X$ and collect:

$$\sqrt{|g|}\,\Theta^T C\gamma^\mu D_\mu\Theta = \tfrac{1}{2}\partial_\mu(\sqrt{|g|}\,\Theta^T C\gamma^\mu\Theta) - \tfrac{1}{2}\Theta^T C\Big(\partial_\mu(\sqrt{|g|}\gamma^\mu) - \sqrt{|g|}\,[\gamma^\mu, \Omega_\mu]\Big)\Theta.$$

The last bracket is zero: in the author's metric $[\gamma^\mu, \Omega_\mu] = 2\gamma^\mu\Omega_\mu$ (they anticommute) and $\partial_\mu(\sqrt{|g|}\gamma^\mu) = 2\sqrt{|g|}\gamma^\mu\Omega_\mu$ (Section 7.18); in a general metric this is the covariant constancy of the gammas (Wolfram check `gamma_covariantly_constant`). So L_g is the total derivative of

$\frac{1}{2}\sqrt{|g|}\,\Theta^T C\gamma^\mu\Theta$, and by Section 7.4 all its Euler-Lagrange expressions vanish identically: no field equation at all (PROVED; Notebook 07c computes it in the author's metric, In [5] and In [6]: L_g has 136 monomials, it equals its total-derivative form exactly, and 0 of its 16 Euler-Lagrange expressions are nonzero; the Revision checks are listed in the table at the end of this section).

This is the **negative control** of the Revision record: a test designed to show what does NOT work. It is the reason why the Revision Lagrangian of dirac16complex is written for a complex field with $\bar\Psi = \Psi^\dagger C$ (Section 7.19), and Section 7.13 showed the same mechanism with two components.

Real commuting fields. For ordinary numbers the roles are exchanged (Section 7.12): $\Phi^T C\gamma^\mu\Phi = 0$, while $\Phi^T C\Phi$ survives, and the kinetic term is not a total derivative. Varying Φ_A in $\sqrt{|g|}\,\Phi^T C\gamma^\mu D_\mu\Phi$: the derivative with respect to Φ_A is $\sqrt{|g|}\,[(C\gamma^\mu\partial_\mu\Phi)_A + (C\gamma^\mu\Omega_\mu\Phi)_A + (N^T\Phi)_A]$ (each factor Φ contributes once), the derivative with respect to $\partial_\mu\Phi_A$ is $\sqrt{|g|}\,((C\gamma^\mu)^T\Phi)_A = -\sqrt{|g|}(C\gamma^\mu\Phi)_A$, and with $N^T = C\Omega_\mu\gamma^\mu$ and $\partial_\mu(\sqrt{|g|}\gamma^\mu) = 2\sqrt{|g|}\gamma^\mu\Omega_\mu$ the Euler-Lagrange expression becomes

$$\sqrt{|g|}\,C\big[2\gamma^\mu\partial_\mu\Phi + \gamma^\mu\Omega_\mu\Phi + \Omega_\mu\gamma^\mu\Phi + 2\gamma^\mu\Omega_\mu\Phi\big] = 2\sqrt{|g|}\,C\gamma^\mu D_\mu\Phi$$

(using $\Omega_\mu\gamma^\mu = -\gamma^\mu\Omega_\mu$): a massless field equation $\gamma^\mu D_\mu\Phi = 0$ in all 16 components (PROVED; Notebook 07c, In [7]; `python-field-theory.json`, check `negative_control_majorana_commuting_contrast`, "16 of 16 components"; `wolfram-field-theory.json`, check `Majorana_Lg_commuting_control`).

The Revision Lagrangian for a real commuting field. Put $\Psi = \Phi$ real and commuting into the Lagrangian of Section 7.19. Then $\bar\Phi = \Phi^T C$, and the second half of the kinetic term equals the first: $(D_\mu\bar\Phi)\gamma^\mu\Phi = (D_\mu\Phi)^T C\gamma^\mu\Phi = \Phi^T(C\gamma^\mu)^T D_\mu\Phi = -\Phi^T C\gamma^\mu D_\mu\Phi$ (a single number equals its own transpose, and $C\gamma^\mu$ is antisymmetric). So $K = \Phi^T C\gamma^\mu D_\mu\Phi$ and

$$\mathcal{L}[\Phi] = \sqrt{|g|}\,\big[\Phi^T C\gamma^\mu D_\mu\Phi - m\,\Phi^T C\Phi - \tfrac{\lambda}{2}(\Phi^T C\Phi)^2\big]\,:$$

the author's L_g with a mass term and the interaction. Its Euler-Lagrange expressions are $2\sqrt{|g|}\,\big(C(\gamma^\mu D_\mu\Phi - (m+\lambda S)\Phi)\big)_A$ (the kinetic part as just computed; $\partial(\Phi^T C\Phi)/\partial\Phi_A = 2(C\Phi)_A$ because C is symmetric): a real commuting field obeys the same field equation as the complex one (PROVED; Notebook 07c, In [12]). Because the gammas, C and the spinor connection are real (`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, checks `representation_real` and `spinor_connection_real`), the operator $\gamma^\mu D_\mu$ is real, the complex conjugate of a solution is again a solution, and real fields are a consistent restriction of dirac16complex00.

A real field carries no charge. The phase change $\Psi \to e^{i\alpha}\Psi$ leaves the Lagrangian unchanged (every term contains as many factors of $\Psi^\dagger$ as of Ψ), and the conserved quantity that belongs to it is the **current** $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, whose time component $J^{x_4} = \Psi^\dagger B\Psi$, with $B = -iC\gamma^{(x_4)}$, is the **charge density** (Chapter 5; Chapter 21 proves its conservation). For a real commuting field $J^\mu = -i\Phi^T C\gamma^\mu\Phi = 0$ identically, because $C\gamma^\mu$ is antisymmetric (Section 7.12): a real field has no charge (PROVED; Notebook 07c, In [11]; `charge-conjugation-and-u1.json`, check `real_fields_charge_conjugation`).

Where the negative control is verified (the theory reports in the folder `Revision/theory/reports`):

statement	status	where it is verified
L_g of a real Grassmann field is a total derivative: no field equation; $\Theta^T C \Theta = 0$	PROVED; Notebook 07c, In [5] and In [6]	`python-field-theory.json`, check `negative_control_majorana_grassmann_total_derivative`; `wolfram-field-theory.json`, check `Majorana_Lg_total_derivative_grassmann`
L_g of a real commuting field gives $2\sqrt{\lvert g\rvert}\, C\gamma^\mu D_\mu \Phi$ in 16 of 16 components	PROVED; In [7]	`python-field-theory.json`, check `negative_control_majorana_commuting_contrast`; `wolfram-field-theory.json`, check `Majorana_Lg_commuting_control`

7.29 Charge conjugation is a matrix

What charge conjugation must do. A **charge conjugation** is a map that turns a field into a field of the opposite charge, the map that exchanges matter and antimatter. For a spinor field it is a MATRIX map

$$\Psi^c = \mathcal{C}\, \bar{\Psi}^T,$$

with a fixed 16×16 matrix $\mathcal{C}$, the **charge-conjugation matrix**. Since $\bar{\Psi}^T = (\Psi^\dagger C)^T = C^T \Psi^* = C\Psi^*$ (C is symmetric), it reads $\Psi^c = M\Psi^*$ with the constant matrix $M = \mathcal{C}C$. It must turn every solution of the field equation into a solution, of the same equation or of the equation with the mass reversed. The author's gammas are REAL. So for a REAL field $\Psi^* = \Psi$: the plain complex conjugate of a real field is the field itself, and plain complex conjugation cannot exchange anything. Everything therefore rests on the matrix.

The condition on M, line by line. Let Ψ solve $(\gamma^\mu D_\mu - V)\Psi = 0$ with a real V. Then

$$(\gamma^\mu D_\mu - V)\Psi^* = 0$$

(take the complex conjugate: γ^μ, Ω_μ and V are real, so only Ψ changes);

$$M(\gamma^\mu D_\mu - V)M^{-1}\,(M\Psi^*) = 0$$

(insert $M^{-1}M = 1$ in front of Ψ^* and multiply from the left by M). If $M\gamma^{(a)}M^{-1} = s\gamma^{(a)}$ for all eight a, with $s = +1$ or $s = -1$, then $M\Omega_\mu M^{-1} = \Omega_\mu$ (each S^{ab} is a product of two gammas, and $s^2 = 1$), M commutes with ∂_μ (it is constant), and $M(\gamma^\mu D_\mu - V)M^{-1} = s\gamma^\mu D_\mu - V = s(\gamma^\mu D_\mu - sV)$. So $M\Psi^*$ solves the equation with V replaced by sV: the same mass for $s = +1$, the reversed mass for $s = -1$. We must find all matrices M with

$$M\gamma^{(a)} = s\,\gamma^{(a)}M \qquad \text{for all } a.$$

All solutions, line by line. The 256 products $\gamma_I = \gamma^{(a_1)} \cdots \gamma^{(a_k)}$ with $a_1 < \cdots < a_k$ (all subsets I of the eight directions, the empty product being 1) are a **basis** of all 16×16 matrices: every matrix is exactly one combination $\sum_I c_I \gamma_I$. *Proof.* Each gamma is a signed permutation matrix with $(\gamma^{(a)})^T = (\gamma^{(a)})^{-1}$, so $\gamma_I^T = \gamma_I^{-1}$ and $\gamma_I^T \gamma_J = \pm\gamma_K$, where K is the set of directions in exactly one of I, J (the shared gammas square to ± 1). The trace of γ_K is 0 for every nonempty K: if K has an even number of elements, take a in K; by Rule 1 of Chapter 5 γ_K anticommutes with $\gamma^{(a)}$, so $\operatorname{tr}\gamma_K = \operatorname{tr}\big((\gamma^{(a)})^{-1}\gamma_K\gamma^{(a)}\big) = -\operatorname{tr}\gamma_K$ (the trace does not change when a matrix is moved from the front to the back of a product); if K has an odd number of elements fewer than 8, take a not in K, and the same argument applies. So $\operatorname{tr}(\gamma_I^T\gamma_J) = 16\,\delta_{IJ}$: the 256 matrices are **orthogonal** (for the scalar product $\operatorname{tr}(X^TY)$ of matrices), hence independent, and 256 independent matrices span the 256-dimensional space of 16×16 matrices. □ (Notebook 07c checks the orthogonality with exact integers, In [8].)

Next, each basis product either commutes or anticommutes with a given $\gamma^{(a)}$: moving $\gamma^{(a)}$ through the k factors of γ_I costs $(-1)^k$ if a is not in I and $(-1)^{k-1}$ if it is (it passes $k-1$ other factors and commutes with itself) (Rule 1 of Chapter 5). So $\gamma^{(a)}\gamma_I(\gamma^{(a)})^{-1} = \epsilon_I(a)\gamma_I$ with a sign $\epsilon_I(a)$. Write $M = \sum_I c_I\gamma_I$. The condition $\gamma^{(a)}M(\gamma^{(a)})^{-1} = sM$ (the condition above, multiplied by $(\gamma^{(a)})^{-1}$ from the right and divided by s, since $1/s = s$) becomes $\sum_I \epsilon_I(a)c_I\gamma_I = \sum_I sc_I\gamma_I$, and because the γ_I are independent, $\epsilon_I(a)c_I = sc_I$ for every I and every a. So $c_I \neq 0$ only for products that have the sign s with ALL eight gammas.

Count, for a product of k gammas, the number of gammas it commutes with. If k is even, it commutes with the $8-k$ gammas not in it and anticommutes with the k in it: $8-k$. If k is odd, it anticommutes with those not in it and commutes with those in it: k. Commuting with all eight needs $8-k=8$ ($k=0$, the identity) or $k=8$ with k odd (impossible): only the identity. Anticommuting with all eight needs $8-k=0$ ($k=8$, the product of all eight, which is $\pm\Gamma$) or $k=0$ with k odd (impossible): only Γ. Hence (PROVED; Notebook 07c, In [8] and In [9], Figure 07c.2; `charge-conjugation-and-u1.json`, checks `intertwiners_same_mass` and `intertwiners_reversed_mass`):

$$M = c\cdot 1 \quad (s=+1,\ \text{same mass}), \qquad M = c\cdot\Gamma \quad (s=-1,\ \text{mass reversed}),$$

with a constant c. With $M = \mathcal{C}C$ and $C^{-1} = C$ (because $C^2 = 1$) the two **charge-conjugation matrices** are, up to a constant factor,

$$\mathcal{C}_+ = C, \quad \Psi^c = \Psi^*; \qquad\qquad \mathcal{C}_- = \Gamma C, \quad \Psi^c = \Gamma\Psi^*.$$

Their defining properties. For $\mathcal{C}_+ = C$, line by line:

$$\mathcal{C}_+^{-1}\gamma^{(a)}\mathcal{C}_+ = (C\gamma^{(a)})\,C = -(C\gamma^{(a)})^TC = -(\gamma^{(a)})^TC^TC = -(\gamma^{(a)})^T$$

($C^{-1} = C$; $C\gamma^{(a)}$ is antisymmetric; the transpose of a product is the product of the transposes in reversed order; $C^TC = C^2 = 1$). For $\mathcal{C}_- = \Gamma C$: $\mathcal{C}_-^{-1} = C\Gamma$ (both square to 1), and $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$, so $\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = C\Gamma\gamma^{(a)}\Gamma C = -C\gamma^{(a)}C = +(\gamma^{(a)})^T$. Both matrices are real (PROVED; Notebook 07c, In [10]; checks `charge_conjugation_matrix_plus` and `charge_conjugation_matrix_minus`). A **Majorana (reality) condition** $\Psi = M\Psi^*$ is consistent only if $MM^* = 1$ (apply it twice: $\Psi^* = M^*\Psi$, so $\Psi = MM^*\Psi$); this holds for $M = 1$ and for $M = \Gamma$ (real, $\Gamma^2 = 1$), so both reality

conditions are consistent (check `majorana_conditions_consistent`). Chapter 5 derives the same matrices from the algebra alone.

What they do to a real field. For a real column Φ:

$$\Phi^c_+ = \mathcal{C}_+\bar{\Phi}^T = C\,(\Phi^T C)^T = CC\Phi = \Phi, \qquad \Phi^c_- = \mathcal{C}_-\bar{\Phi}^T = \Gamma CC\Phi = \Gamma\Phi.$$

$\mathcal{C}_+$ does nothing to a real field: a real field is its own conjugate, in agreement with $J^\mu = 0$ (Section 7.28). The only nontrivial map of real fields is the REAL matrix $\Gamma = \mathrm{diag}(-I_8, I_8)$. It keeps the scalar density and reverses every kinetic matrix:

$$\Gamma^T C\Gamma = C, \qquad \Gamma^T C\gamma^{(a)}\Gamma = -C\gamma^{(a)}$$

($\Gamma^T = \Gamma$ is diagonal; it commutes with C, a product of four gammas, and anticommutes with $\gamma^{(a)}$; and $\Gamma^2 = 1$). It also commutes with every Ω_μ (a combination of products of two gammas), so $D_\mu(\Gamma\Phi) = \Gamma D_\mu\Phi$. Therefore $K[\Gamma\Phi] = -K[\Phi]$ and $S[\Gamma\Phi] = S[\Phi]$, and

$$\mathcal{L}_{m,\lambda}[\Gamma\Phi] = \sqrt{|g|}\,\big[-K - mS - \tfrac{\lambda}{2}S^2\big] = -\sqrt{|g|}\,\big[K - (-m)S - \tfrac{(-\lambda)}{2}S^2\big] = -\mathcal{L}_{-m,-\lambda}[\Phi]\,:$$

the matrix Γ, together with $(m,\lambda) \to (-m,-\lambda)$, maps solutions to solutions; a real solution of mass m goes to a real solution of mass $-m$ (PROVED; Notebook 07c, In [11] and In [12], and numerically on an exact solution, In [13], Figure 07c.4; `charge-conjugation-and-u1.json`, check `real_fields_charge_conjugation`). This is the form that the pairing theorem T1 takes for real fields; Chapter 18 proves T1 for both fields in every gravitational field. For a COMPLEX field the same matrix map $\Psi \to \Gamma\Psi$ (without any conjugation) also reverses the current: since Γ is real, $(\Gamma\Psi)^\dagger = \Psi^\dagger\Gamma^T$, and $J^a[\Gamma\Psi] = -i\Psi^\dagger\Gamma^T C\gamma^{(a)}\Gamma\Psi = +i\Psi^\dagger C\gamma^{(a)}\Psi = -J^a[\Psi]$ by the identity just proved; for a real field both sides are zero.

The signs of S and J under the two conjugations. For a complex field and $\Psi' = M\Psi^*$ with the real $M = 1$ or $M = \Gamma$, the row is $\Psi'^\dagger = \Psi^T M^T$, and both matrices satisfy $M^T C M = C$, while $M^T C\gamma^{(a)} M = \pm C\gamma^{(a)}$ (+ for $M = 1$, − for $M = \Gamma$). So

$$S' = \Psi^T C\Psi^* = \sum_{A,B} \Psi_A C_{AB}\Psi^*_B = \sigma \sum_{A,B} \Psi^*_B C_{BA}\Psi_A = \sigma S$$

(exchange the two factors, with $\sigma = +1$ for commuting and $\sigma = -1$ for Grassmann components; then $C_{AB} = C_{BA}$), and in the same way, with the antisymmetric $C\gamma^{(a)}$, $-i\Psi^T C\gamma^{(a)}\Psi^* = -\sigma J^a$ for $M = 1$, and the opposite sign for $M = \Gamma$. In a table:

map	**commuting components**	**Grassmann components (classical)**
$\Psi \to \Psi^*$ (matrix $\mathcal{C}_+$)	$(S,J) \to (S,-J)$	$(S,J) \to (-S,+J)$
$\Psi \to \Gamma\Psi^*$ (matrix $\mathcal{C}_-$)	$(S,J) \to (S,+J)$	$(S,J) \to (-S,-J)$

(PROVED here; it reproduces `charge-conjugation-and-u1.json`, check `bilinears_under_charge_conjugation`.) For the commuting complex field dirac16complex00 the map built with $\mathcal{C}_+$

keeps the mass and reverses the charge. For the Grassmann field the classical signs differ. The record states that **normal ordering** (the subtraction of the vacuum value of an operator, its value in the state with no quanta; Section 5.34) adds no sign: it subtracts a number, so a bilinear that changes as $X \to sX + c$ has the normal-ordered form changing as $:X: \to s\ :X:$, and the quantised bilinears keep the signs of the classical Grassmann column (the record makes no Fock-space computation for this; Section 5.34 confirms it on the Fock space). The record also states that for the QUANTISED field the conjugation that preserves the canonical anticommutator $\{\Psi, \Psi^\dagger\} = B\delta$ is $\Psi \to \Gamma\Psi^{\dagger T}$, which reverses the mass (both quoted here from the same report, checks `bilinears_under_charge_conjugation` and `quantum_charge_conjugation_unitary_type`; Section 5.34 derives both; Sections 10.15 and 21.25 derive the second, and Section 21.26 confirms the first for the charge).

What this does and does not say. The two charge-conjugation matrices and the mass reversal by Γ are exact maps between the solutions of two equations (PROVED, with the checks named above). They do not say how any solution comes about: nothing in this chapter says that solutions, or universes, are created, in pairs or otherwise. Nor do they explain the observed excess of matter over antimatter: as built, the theory has no baryons, no violation of baryon number, no CP violation and no departure from equilibrium, the ingredients that such an explanation needs; Chapter 21 treats this question from zero, and Chapter 20 states exactly what the pairing theorems do and do not establish.

7.30 Example: Notebook 07c: real fields and the charge-conjugation matrices

Notebook 07c computes Sections 7.28 and 7.29 exactly. It reads the gammas, C and Γ from the Revision record and checks that they are real and that B is imaginary and Hermitian; rebuilds the spin connection of the author's metric and checks that it is real; builds a jet algebra for a real field; computes the Majorana-type Lagrangian for real Grassmann and real commuting components (no field equation in the first case, 16 equations in the second); finds all matrices that turn solutions into solutions from the 256 products of gammas; checks the two charge-conjugation matrices and the two reality conditions; shows that $\mathcal{C}_+$ is the identity on a real field and that $J = 0$; and checks the mass reversal by Γ in the author's metric and on an exact solution. Every result that the Revision record also contains is checked against it. It draws four figures and ends with the line ALL 23 CHECKS PASSED (notebook 07c).

7.31 How to run Notebook 07c

Step 1. What this notebook does and what it needs.

Notebook 07c (Real fields: the Majorana-type control and the matrix Gamma) is the file `Revision/textbook/notebooks/07c_real_fields.ipynb` of the repository Dirac_claude. It shows in the author's metric, with exact computer algebra, that the Majorana-type Lagrangian of the author's notebook is a total derivative with no field equation for a real anticommuting 16-component field but not for real commuting components; that for a real field plain complex conjugation is the identity and the conserved current vanishes; that every matrix that maps solutions to solutions in the conjugated form is a multiple of the identity (same mass) or of the chirality matrix Gamma (mass reversed), which gives the two charge-conjugation matrices C and Gamma C; and that the real matrix Gamma maps every real solution of mass m to a real solution of mass minus m; four

teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 07c_real_fields.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 07c_real_fields.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 07c_real_fields.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/07c.captions.json`
- `Revision/textbook/figures/07c_1_majorana_control.png`
- `Revision/textbook/figures/07c_2_commutation_pattern.png`
- `Revision/textbook/figures/07c_3_gamma_map_matrices.png`
- `Revision/textbook/figures/07c_4_mass_reversal.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 4 figure files of this notebook exist
ALL 23 CHECKS PASSED (notebook 07c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/07c_real_fields.ipynb` inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 07c_real_fields.ipynb
python -m nbconvert --execute --inplace 07c_real_fields.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/...": the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory Revision/algebra Revision/lead_checks
```

7.32 Notebook 07c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/07c_real_fields.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook is about REAL fields: columns of 16 components that are their own
complex conjugates. They matter for two reasons. The author's own notebook wrote its
Lagrangian for a real column; and the question "what is charge conjugation?" has a
surprising answer for real fields. The notebook

- computes, in the author's metric, the Majorana-type Lagrangian $L_g = \sqrt{|g|}\,
  \Theta^T C\gamma^\mu D_\mu\Theta$ of the author's notebook for a real column
  $\Theta$ of anticommuting (Grassmann) components and shows that it is a total
  derivative: all 16 Euler-Lagrange expressions vanish, there is no field equation;
- shows that for real COMMUTING components the same $L_g$ is not a total
  derivative: it gives a field equation in all 16 components;
- shows that the Revision Lagrangian restricted to a real commuting field gives the
  field equation $\gamma^\mu D_\mu\Phi = (m + \lambda S)\Phi$ and that its conserved
  current vanishes identically;
- finds ALL matrices $M$ that turn solutions $\Psi$ into solutions $M\Psi^*$: only
  multiples of the identity (same mass) and of the chirality matrix $\Gamma$ (mass
  reversed). Hence the two charge-conjugation matrices are $\mathcal{C}_+ = C$ and
  $\mathcal{C}_- = \Gamma C$;
- shows that for a real field plain complex conjugation, and with it
  $\mathcal{C}_+$, acts as the identity, so it cannot exchange matter and
  antimatter, while the real matrix $\Gamma$ maps every real solution of mass $m$ to
  a real solution of mass $-m$.

Every result that the Revision record also contains is checked against it
(Revision/theory/reports/ and Revision/lead_checks/reports/). Four figures are
drawn.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 07c (Real fields: the Majorana-type control and the matrix Gamma) is the file
‘Revision/textbook/notebooks/07c_real_fields.ipynb‘ of the repository Dirac_claude. It
shows in the author's metric, with exact computer algebra, that the Majorana-type
Lagrangian of the author's notebook is a total derivative with no field equation for a
real anticommuting 16-component field but not for real commuting components; that for a
real field plain complex conjugation is the identity and the conserved current vanishes;
that every matrix that maps solutions to solutions in the conjugated form is a multiple
of the identity (same mass) or of the chirality matrix Gamma (mass reversed), which gives
the two charge-conjugation matrices C and Gamma C; and that the real matrix Gamma maps
every real solution of mass m to a real solution of mass minus m; four teaching plots. It
needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
does not need Rust.
```

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home

folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 07c_real_fields.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 07c_real_fields.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 07c_real_fields.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/07c.captions.json‘
- ‘Revision/textbook/figures/07c_1_majorana_control.png‘
- ‘Revision/textbook/figures/07c_2_commutation_pattern.png‘

- ‘Revision/textbook/figures/07c_3_gamma_map_matrices.png‘
- ‘Revision/textbook/figures/07c_4_mass_reversal.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 4 figure files of this notebook exist
ALL 23 CHECKS PASSED (notebook 07c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/07c_real_fields.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 07c_real_fields.ipynb
  python -m nbconvert --execute --inplace 07c_real_fields.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event

  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "ValueError: ... is not a passing check of Revision/...": the Revision record files of your copy of the repository differ from the committed ones; restore them with the command below (run in the repository folder) and run the notebook again.

```
git restore Revision/theory Revision/algebra Revision/lead_checks
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 07c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 07c (Real fields: the Majorana-type control and the matrix Gamma) is the file
# Revision/textbook/notebooks/07c_real_fields.ipynb of the repository Dirac_claude. It
# shows in the author’s metric, with exact computer algebra, that the Majorana-type
# Lagrangian of the author’s notebook is a total derivative with no field equation for a

# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
```

```
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 07c_real_fields.ipynb
```

```
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 07c_real_fields.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 07c_real_fields.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/07c.captions.json
# - Revision/textbook/figures/07c_1_majorana_control.png
# - Revision/textbook/figures/07c_2_commutation_pattern.png
# - Revision/textbook/figures/07c_3_gamma_map_matrices.png
# - Revision/textbook/figures/07c_4_mass_reversal.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 4 figure files of this notebook exist
#     ALL 23 CHECKS PASSED (notebook 07c)
#
# and the notebook must show 4 figures below the cells that draw them.
```

```
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/07c_real_fields.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 07c_real_fields.ipynb
#     python -m nbconvert --execute --inplace 07c_real_fields.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "ValueError: ... is not a passing check of Revision/...": the Revision record files
#   of your copy of the repository differ from the committed ones; restore them with the
#   command below (run in the repository folder) and run the notebook again.
#     git restore Revision/theory Revision/algebra Revision/lead_checks
#

## 3. The words used in this notebook

- **Real field**: a column $\Phi$ whose 16 components are real ($\Phi^* = \Phi$);
  for Grassmann components, a column of real generators ($\theta^* = \theta$).
- **Complex conjugation**: replacing every number by its complex conjugate
  ($i \to -i$). On a real column it changes nothing: it is the identity.
- **Charge conjugation**: a map that turns a field into a field of the opposite
  charge. For a spinor field it is a MATRIX map $\Psi^c = \mathcal{C}\,
  \bar\Psi^T$ with a fixed $16\times16$ matrix $\mathcal{C}$, the
  **charge-conjugation matrix**; since $\bar\Psi^T = (\Psi^\dagger C)^T =
  C\Psi^*$, it is $\Psi^c = \mathcal{C}C\,\Psi^*$.
- **Chirality matrix** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$:
  the product of all eight gammas; it anticommutes with every $\gamma^{(a)}$ and
  $\Gamma^2 = 1$.
- **Majorana (reality) condition**: a condition $\Psi = M\Psi^*$ that makes a
  field real in a generalised sense; it is consistent only if $MM^* = 1$.
- **Majorana-type Lagrangian** $L_g$: the Lagrangian of the author's notebook, built
  with the transpose $\Theta^T$ of a real column instead of the Dirac adjoint
  $\bar\Psi = \Psi^\dagger C$.
- **Total derivative**: an expression $\sum_\mu \frac{d}{dx_\mu}V^\mu$; a Lagrangian
  that is a total derivative gives no field equation (its Euler-Lagrange expressions
  vanish identically).
- **Negative control**: a test designed to show that something does NOT work, here
  the Majorana-type Lagrangian; it explains why the Revision record uses the complex
  Dirac-type Lagrangian.
- **Current** $J^a = -i\bar\Psi\gamma^{(a)}\Psi$: the conserved current of the
  phase symmetry $\Psi \to e^{i\alpha}\Psi$; its time component gives the charge.
- **Commute, anticommute**: $XY = YX$ or $XY = -YX$ for two matrices.
- **Jet**, **total derivative on jets**, **coefficient ring**: as in Notebook 07b:
  the field components and their derivatives at one point are symbols, and every
  coefficient is written with $E = e^{a_4}$, $s = \sin^{1/6}z$, $c = \cos z$,
  $A_1 = a_4'$, $A_2$, $A_3$ (higher derivatives of $a_4$), $H$, $m$, $\lambda$.
```

Text cell:

```
## 4. The physical and mathematical situation

**The author's Lagrangian.** The author's notebook used a real column of 16
components and the Lagrangian $L_g = \sqrt{|g|}\,[\Theta^T C\gamma^\mu D_\mu\Theta +
(\text{number})\,\Theta^T C\Theta]$. If the components anticommute, as the
components of a fermion field must, then $\Theta^T C\Theta = 0$ because $C$ is
symmetric, and $\Theta^T C\gamma^\mu D_\mu\Theta$ is a total derivative because
$C\gamma^{(a)}$ is antisymmetric (Notebook 07a showed both rules in small form). So
```

```
$L_g$ describes nothing: this is the negative control of the Revision record, and
the reason why the Revision Lagrangian uses the complex field and $\bar\Psi =
\Psi^\dagger C$.

**Charge conjugation is a matrix.** The author's gammas are real. For a REAL
field, $\Psi^* = \Psi$, so plain complex conjugation changes nothing and cannot be
charge conjugation. Charge conjugation is the matrix map
$\Psi^c = \mathcal{C}C\,\Psi^*$, which must send every solution of $(\gamma^\mu
D_\mu - V)\Psi = 0$ ($V = m + U'(S)$, real) to a solution of the equation with $sV$,
where $s = +1$ (same mass) or $s = -1$ (mass reversed). Conjugating the equation and
multiplying by $M = \mathcal{C}C$ shows, line by line, what $M$ must do:

$$(\gamma^\mu D_\mu - V)\Psi = 0 \;\Rightarrow\; (\gamma^\mu D_\mu - V)\Psi^* = 0
\;\Rightarrow\; M(\gamma^\mu D_\mu - V)M^{-1}\,(M\Psi^*) = 0 .$$

The first step takes the complex conjugate (the gammas, $\Omega_\mu$ and $V$ are
real); the second inserts $M^{-1}M = 1$ and multiplies by $M$. The new equation is
the equation with $sV$ exactly when $M\gamma^{(a)}M^{-1} = s\gamma^{(a)}$ for every
$a$ ($\Omega_\mu$ is built from products of two gammas and then follows). Section 9
finds all such $M$: multiples of $1$ ($s = +1$) and of $\Gamma$ ($s = -1$). Hence

$$\mathcal{C}_+ = C^{-1} = C,\qquad \Psi^c = \Psi^*;\qquad\qquad
\mathcal{C}_- = \Gamma C^{-1} = \Gamma C,\qquad \Psi^c = \Gamma\Psi^* .$$

For a real field the first is the identity (a real field is its own conjugate, it
has no charge to reverse), and the second is the real matrix $\Gamma$, which maps a
solution of mass $m$ to a solution of mass $-m$. This is a map between solutions of
two equations; it says nothing about how either solution comes about.
```

Text cell:

```
## 5. The gamma matrices, $C$, $\Gamma$ and $B$ are real or imaginary

The next cell imports the packages, wraps the set-up cell's ‘check‘ so that a PASS
line and its "reproduces" line are printed by one single ‘print‘ call (Jupyter
sends printed text in pieces, and the book's tools must see the two lines
together), defines the helper ‘reproduces‘ (it makes sure that a Revision report
contains a check with the verdict PASS before a PASS line names it), and reads the
gammas, $C$ and $\Gamma$ from Revision/algebra/gammas.json. It checks that all of
them are real, that $C$ is symmetric with $C^2 = 1$, that $\Gamma = \gamma^{(x_0)}
\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ anticommutes with every gamma and $\Gamma^2 =
1$, and that the charge matrix $B = -iC\gamma^{(x_4)}$ is purely imaginary and
Hermitian with $B^2 = 1$. Finally it takes a column of 16 real symbols and checks
that complex conjugation leaves it unchanged.
```

## 6. The author's metric and its spin connection, in brief

The next cell rebuilds, exactly as Notebook 07b does step by step, the coefficient
ring, the diagonal frame $f = (c/s^6, Es, Es, Es, 1, s\sqrt{b_4}/E, s\sqrt{b_4}/E,
s\sqrt{b_4}/E)$ of the metric with $b_4$ (in the order $x_0, \dots, x_7$; the
symbol `b4` stands for $b_4(x_4)$ and `b4p`, `b4pp`, `b4ppp` for its first three
derivatives), the Christoffel symbols of
the diagonal metric, the canonical spin connection $\omega_{\mu ab}$, the spinor
connection $\Omega_\mu = \sum_{a<b}\omega_{\mu ab}S^{ab}$ and the coordinate gammas
$\gamma^\mu = \gamma^{(\mu)}/f_\mu$. It then checks two things, for arbitrary
functions $a_4$ and $b_4 > 0$. First, every entry of every $\Omega_\mu$ and
$\gamma^\mu$ is real (real gammas times the real functions $e^{\pm a_4}$,
$\sin^{1/6}z$, $\cot z$, $b_4^{1/2}$, $a_4'$, $b_4'$ and $H$; no imaginary unit $i$
anywhere): the operator $\gamma^\mu D_\mu$ is REAL, so the complex conjugate of a
solution is again a solution, and real fields are a consistent restriction. Second,
as a consistency check, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)} +
\frac34(b_4'/b_4)\gamma^{(x_4)}$, the value of the Revision record with $b_4$, which
is $3H\gamma^{(x_0)}$ at $b_4 = 1$.
```

## 7. A jet algebra for a real field

A real field has no separate conjugate components: the generators are just the
components $\theta_A$ and their derivatives, written `(A, derivatives)`. The class
`RealJet` below is the jet algebra of Notebook 07b without conjugation, with the
switch `odd` (True: anticommuting, False: commuting). The helpers `column`,
`matvec` (matrix times column), `vecmat` (row times matrix) and `dot` (row times
column) build vectors of jets.
```

In [4]:

## 8. The Majorana-type negative control

The next cell builds, for both kinds of numbers, the Majorana-type Lagrangian
```

```
$$L_g = \sqrt{|g|}\sum_\mu \Theta^T C\gamma^\mu\big(\partial_\mu\Theta +
\Omega_\mu\Theta\big)$$

and its candidate total-derivative form $\frac12\sum_\mu \frac{d}{dx_\mu}\big(
\sqrt{|g|}\,\Theta^T C\gamma^\mu\Theta\big)$, the 16 Euler-Lagrange expressions
$\mathcal{E}_A = \partial_L L_g/\partial\theta_A - \sum_\mu\frac{d}{dx_\mu}
\partial_L L_g/\partial(\partial_\mu\theta_A)$, and the mass-type term $\Theta^T
C\Theta$. Why the anticommuting case is a total derivative, in three lines
(Notebook 07a showed the two rules used):

$$\Theta^T C\gamma^\mu\partial_\mu\Theta = \tfrac12\partial_\mu\big(\Theta^T
C\gamma^\mu\Theta\big) - \tfrac12\Theta^T\partial_\mu\big(C\gamma^\mu\big)\Theta,
\qquad \Theta^T C\gamma^\mu\Omega_\mu\Theta = \tfrac12\Theta^T C[\gamma^\mu,
\Omega_\mu]\Theta,$$
$$\sqrt{|g|}\,\Theta^T C\gamma^\mu D_\mu\Theta = \tfrac12\partial_\mu\big(\sqrt{|g|}
\,\Theta^T C\gamma^\mu\Theta\big) - \tfrac12\Theta^T C\big(\partial_\mu(\sqrt{|g|}
\gamma^\mu) - \sqrt{|g|}[\gamma^\mu, \Omega_\mu]\big)\Theta .$$

The first identity: the product rule, and exchanging the two odd factors in
$(\partial_\mu\Theta)^T C\gamma^\mu\Theta$ with the antisymmetric $C\gamma^\mu$
makes it equal to $\Theta^T C\gamma^\mu\partial_\mu\Theta$. The second: only the
antisymmetric part of $C\gamma^\mu\Omega_\mu$ survives in a real Grassmann form, and
it is $\frac12 C[\gamma^\mu, \Omega_\mu]$. The third: multiply by $\sqrt{|g|}$ and
collect. The last bracket is zero by the divergence identity
$\partial_\mu(\sqrt{|g|}\gamma^\mu) = \sqrt{|g|}[\gamma^\mu, \Omega_\mu]$ (the
covariant constancy of the gammas). So $L_g$ is the total derivative of
$\frac12\sqrt{|g|}\,\Theta^T C\gamma^\mu\Theta$.
```

## 9. Which matrices turn solutions into solutions?

We look for all $16\times16$ matrices $M$ with $M\gamma^{(a)} = s\,\gamma^{(a)}M$
for all eight $a$ (for real gammas $(\gamma^{(a)})^* = \gamma^{(a)}$, so this is the
condition of section 4). The 256 products $\gamma_I = \gamma^{(a_1)}\cdots
\gamma^{(a_k)}$ with $a_1 < \dots < a_k$ (all subsets $I$ of the eight gammas,
including the empty product 1) are a basis of all $16\times16$ matrices, because
they are mutually orthogonal: $\mathrm{tr}(\gamma_I^T\gamma_J) = 16\,\delta_{IJ}$
(the next cell checks this exactly with integers), and 256 orthogonal nonzero
matrices in the 256-dimensional space of $16\times16$ matrices form a basis.

Each basis product either commutes or anticommutes with a given $\gamma^{(a)}$:
moving $\gamma^{(a)}$ through the $k$ factors costs $(-1)^k$ if $a \notin I$ and
$(-1)^{k-1}$ if $a \in I$ (it passes $k - 1$ other factors and commutes with
itself). Write $M = \sum_I c_I\gamma_I$; since $\gamma^{(a)}\gamma_I(\gamma^{(a)})^{-1}
= \pm\gamma_I$ and the $\gamma_I$ are independent, the condition holds exactly when
every $\gamma_I$ with $c_I \ne 0$ has the sign $s$ for every $a$. So the solution
space is spanned by the products that commute with ALL eight gammas ($s = +1$) or
anticommute with ALL eight ($s = -1$). The next cell counts, for each product, the
number of gammas it commutes with, and finds which products qualify.

## 10. The two charge-conjugation matrices

With $M = \mathcal{C}C$ and $C^{-1} = C$: $\mathcal{C}_+ = C$ (from $M = 1$) and
```

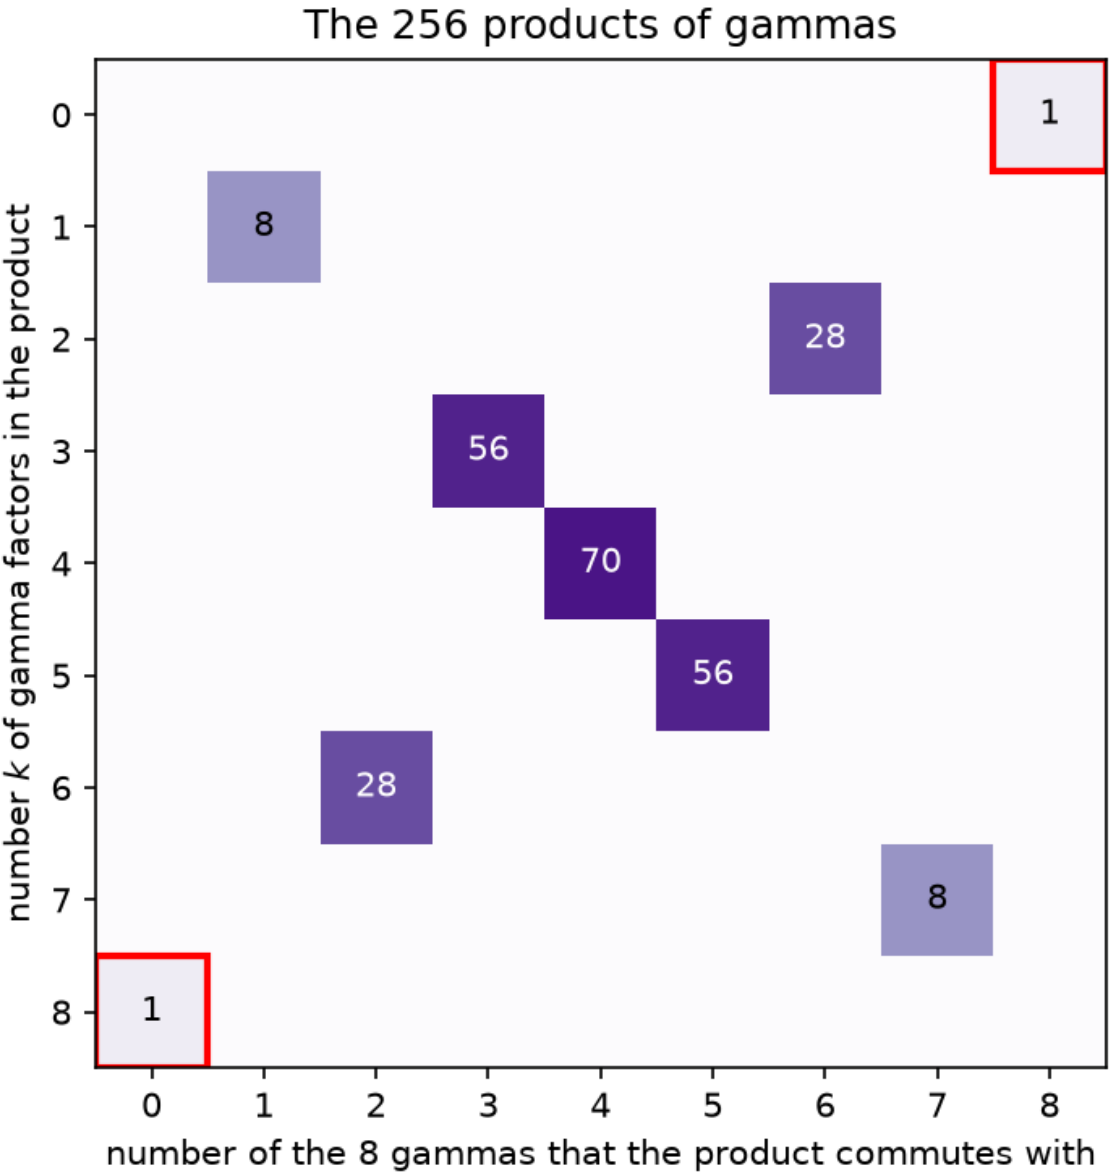

Figure 226: The 256 products γ_I of the author's gamma matrices (a basis of all 16×16 matrices), counted by the number k of factors (rows) and by the number of the eight gammas with which they commute (columns); the numbers are the binomial coefficients. Only two squares (red frames) lie in the outer columns: the identity ($k = 0$) commutes with all eight, and the chirality matrix Γ ($k = 8$) anticommutes with all eight. Hence every matrix M with $M\gamma^{(a)} = \pm\gamma^{(a)}M$ for all a is a multiple of 1 or of Γ. (Notebook 07c, figure 2.)

```
$\mathcal{C}_- = \Gamma C$ (from $M = \Gamma$). The defining properties of a
charge-conjugation matrix, $\mathcal{C}^{-1}\gamma^{(a)}\mathcal{C} =
\mp(\gamma^{(a)})^T$, follow line by line for $\mathcal{C}_+ = C$:

$$C^{-1}\gamma^{(a)}C = (C\gamma^{(a)})\,C = -(C\gamma^{(a)})^T C
= -(\gamma^{(a)})^T C^T C = -(\gamma^{(a)})^T .$$

The first step uses $C^{-1} = C$ (because $C^2 = 1$); the second that
$C\gamma^{(a)}$ is antisymmetric; the third that the transpose of a product is the
product of the transposes in reversed order; the last that $C^TC = C^2 = 1$. For
$\mathcal{C}_- = \Gamma C$: $\mathcal{C}_-^{-1} = C\Gamma$, and $\Gamma\gamma^{(a)}
\Gamma = -\gamma^{(a)}$ (anticommute, then $\Gamma^2 = 1$), so
$\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = -C\gamma^{(a)}C =
+(\gamma^{(a)})^T$. Both matrices are real, and both reality conditions $\Psi =
M\Psi^*$ are consistent because $MM^* = 1$ for $M = 1$ and for $M = \Gamma$
($\Gamma$ is real and $\Gamma^2 = 1$). The next cell checks all of this exactly.
```

Text cell:

```
## 11. Real fields: what charge conjugation does to them

For a real column $\Phi$ ($\Phi^* = \Phi$, so $\Phi^\dagger = \Phi^T$):

$$\Phi^c_+ = \mathcal{C}_+\bar\Phi^T = C\,(\Phi^T C)^T = C\,C^T\Phi = \Phi,
\qquad \Phi^c_- = \mathcal{C}_-\bar\Phi^T = \Gamma C\,C\Phi = \Gamma\Phi .$$
```

```
So $\mathcal{C}_+$ does nothing to a real field: a real field is its own
conjugate. This matches the current: $J^a = -i\Phi^T C\gamma^{(a)}\Phi = 0$
identically, because $C\gamma^{(a)}$ is antisymmetric and the components commute; a
real commuting field carries no charge. The only nontrivial real map is the matrix
$\Gamma$. It keeps the scalar density and reverses every kinetic matrix:

$$\Gamma^T C\Gamma = C,\qquad \Gamma^T C\gamma^{(a)}\Gamma = -C\gamma^{(a)} .$$

(Both from $\Gamma^T = \Gamma$, which commutes with $C$, and anticommutes with
$\gamma^{(a)}$.) Therefore, for real fields, $L_{m,\lambda}[\Gamma\Phi] =
-L_{-m,-\lambda}[\Phi]$: the matrix $\Gamma$ together with $(m, \lambda) \to (-m,
-\lambda)$ maps solutions to solutions. The next cell checks the two conjugates,
the vanishing current and the two matrix identities, and draws Figure 3.
```

## 12. The mass reversal in the author's metric

The next cell checks the statement $L_{m,\lambda}[\Gamma\Phi] =
-L_{-m,-\lambda}[\Phi]$ for a real commuting field in the author's metric, exactly,
with the jet algebra. The Lagrangian of a real field is the Revision Lagrangian with
$\Psi^\dagger = \Phi^T$: $\bar\Phi = \Phi^T C$, $D_\mu\bar\Phi = \partial_\mu
\Phi^T C - \Phi^T C\Omega_\mu$. The field $\Gamma\Phi$ has the components
$\sum_B\Gamma_{AB}\theta_B$ and the derivatives $\sum_B\Gamma_{AB}\partial_\mu
\theta_B$ ($\Gamma$ is constant). The cell also checks that the Euler-Lagrange
expressions of the real Lagrangian are $2\sqrt{|g|}\,(C(\gamma^\mu D_\mu\Phi - (m +
\lambda S)\Phi))_A$: a real commuting field obeys the same field equation as the
complex one.
```

In [12]:

```
def real_lagrangian(columns, mass, coupling):
    """sqrt|g| [K - mass S - (coupling/2) S^2] of the real field whose value and
    derivatives are columns(derivatives)."""
    field = columns(())
    bar = vecmat(field, C, False)  # Phi^T C
    K = RealJet(False)
    for mu in range(8):
        D_field = [x + y for x, y in zip(columns((mu,)), matvec(Om[mu], field, False))]
        D_bar = [x - y for x, y in zip(vecmat(columns((mu,)), C, False),
                                       vecmat(bar, Om[mu], False))]
        K = K + dot(bar, matvec(gam[mu], D_field, False), False)
        K = K - dot(vecmat(D_bar, gam[mu], False), field, False)
    S = dot(bar, field, False)
    return (K.times(sp.Rational(1, 2)) - S.times(mass)
            - (S * S).times(coupling / 2)).times(sqrt_g)

def plain(derivatives):  # the components of Phi
    return column(False, derivatives)

def mapped(derivatives):  # the components of Gamma Phi
    return matvec(GAMMA, column(False, derivatives), False)
```

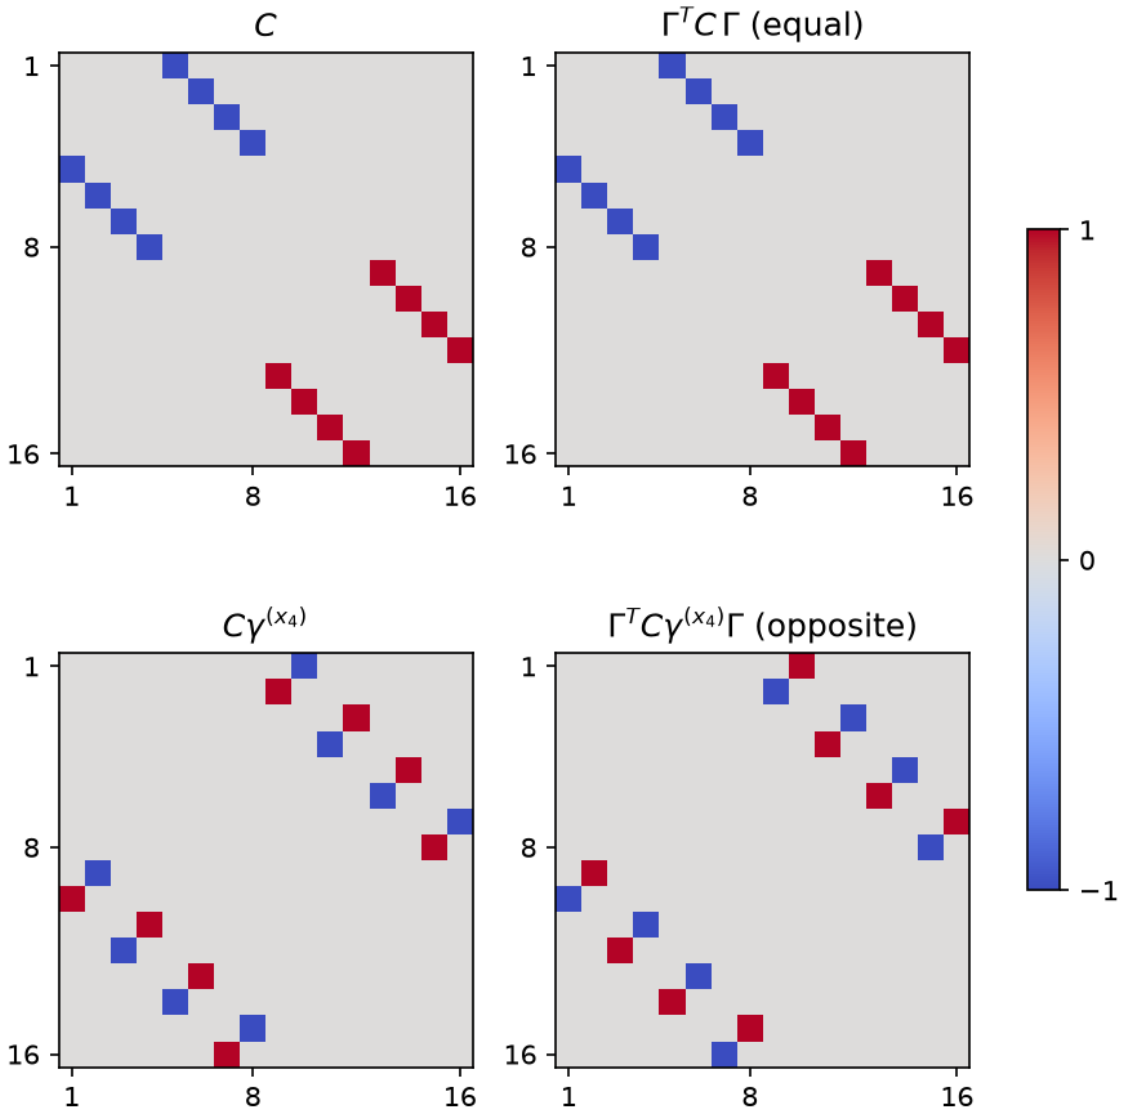

Figure 227: What the real matrix Γ does to the two kinds of terms of the Lagrangian of a real field (16×16 matrices, red $+1$, blue -1, grey 0; rows and columns 1 to 16). Top: the matrix C of the scalar density $S = \Phi^T C \Phi$ and $\Gamma^T C \Gamma$, which is the same: S is kept. Bottom: the kinetic matrix $C\gamma^{(x_4)}$ and $\Gamma^T C \gamma^{(x_4)} \Gamma$, which has every colour swapped: the kinetic term changes sign (the same holds for all eight directions). So the Lagrangian of $\Gamma\Phi$ with (m, λ) is minus the Lagrangian of Φ with $(-m, -\lambda)$. (Notebook 07c, figure 3.)

```
L_mapped = real_lagrangian(mapped, m, lam)

## 14. What this notebook showed

- The Majorana-type Lagrangian $L_g = \sqrt{|g|}\,\Theta^T C\gamma^\mu D_\mu\Theta$
  of the author's notebook is, for a real anticommuting 16-component field in the
  author's metric, exactly the total derivative of $\frac12\sqrt{|g|}\,\Theta^T
  C\gamma^\mu\Theta$: no field equation; its mass term $\Theta^T C\Theta$ vanishes.
  For real commuting components it gives a field equation in all 16 components.
  This negative control is why the Revision Lagrangian uses the complex field with
  $\bar\Psi = \Psi^\dagger C$.
- The author's gammas, $C$, $\Gamma$ and the spin connection are real; the field
  equation is real; real fields are a consistent restriction, and the real
  Lagrangian gives $\gamma^\mu D_\mu\Phi = (m + \lambda S)\Phi$.
- Charge conjugation is a MATRIX map. Every matrix $M$ with $M\gamma^{(a)} =
  s\gamma^{(a)}M$ for all $a$ is a multiple of 1 ($s = +1$) or of $\Gamma$ ($s =
  -1$), because among the 256 products of gammas only the identity commutes and
  only $\Gamma$ anticommutes with all eight. The two charge-conjugation matrices are
  $\mathcal{C}_+ = C$ (same mass, $\Psi^c = \Psi^*$) and $\mathcal{C}_- = \Gamma C$
  (mass reversed, $\Psi^c = \Gamma\Psi^*$); both reality conditions are consistent.
- For a REAL field plain complex conjugation is the identity, and so is
  $\mathcal{C}_+$: a real field is its own conjugate and its current $J^a$ vanishes.
  The nontrivial real map is the matrix $\Gamma$ with $(m, \lambda) \to (-m,
  -\lambda)$: $L_{m,\lambda}[\Gamma\Phi] = -L_{-m,-\lambda}[\Phi]$, and $\Gamma$ maps
  the real solutions of mass $m$ onto real solutions of mass $-m$.
- These are exact maps between solutions of two equations (PROVED, with the checks
  named above). They do not say that such solutions are created, in pairs or
  otherwise.
```

7.33 Line-by-line walk-through of Notebook 07c

The notebook has 15 code cells, In [1] to In [15]. This section explains every line of every one of them, with the conventions of Section 7.9; every caption is printed in full under its figure in Section 7.32.

In [1], the set-up cell. It is the set-up cell of Notebook 07d with the one line `NOTEBOOK_ID = "07c"`; its first part repeats the complete run instructions of Section 7.31 as comment lines, and its code is explained line by line in Section 7.9. **Out [1]:** `Set-up of notebook 07c complete: repository folder found, helpers defined.`

In [2]: the matrices are real or imaginary.

```
import contextlib  # redirect printed text into a buffer
import io  # an in-memory text file (the buffer)
import re  # regular expressions: read a number from a check's detail text
from itertools import combinations  # all subsets of the eight gammas

import numpy as np  # integer and floating-point arrays
import sympy as sp  # exact algebra

check_of_the_setup = check  # the helper check of the set-up cell

def check(condition, name, record=None):
    """The set-up cell's check, with its PASS line and its "reproduces" line
    printed by ONE print call, so that Jupyter delivers them together."""
    buffer = io.StringIO()
    with contextlib.redirect_stdout(buffer):  # collect what check prints
        check_of_the_setup(condition, name, record)
    print(buffer.getvalue(), end="")  # and print it in one piece
```

The modules (as in Notebook 07d, plus `combinations` from `itertools`, which lists all subsets of a given size) and the wrapper of `check` that prints a PASS line and its "reproduces" line in one piece (Section 7.9, In [2]).

```
PYREP = "Revision/theory/reports/python-field-theory.json"
WLREP = "Revision/theory/reports/wolfram-field-theory.json"
LEAD = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
PYREP_B4 = "Revision/theory/reports/python-field-theory-b4.json"  # the metric with b4

def revision_check(report, name):
    """The check called name of a Revision report: its dictionary (name, verdict,
    detail); stops if it is missing or its verdict is not PASS."""
    data = json.loads(repository_file(report).read_text(encoding="utf-8"))
    found = [item for item in data["checks"] if item["name"] == name]
    if len(found) != 1 or found[0]["verdict"].upper() != "PASS":
        raise ValueError(f"{name} is not a passing check of {report}")
    return found[0]
```

```
def reproduces(report, name):
    """The text "<report>, check <name>" after making sure the check passes."""
    revision_check(report, name)
    return f"{report}, check {name}"
```

The paths of the three Revision reports used (the sympy and Wolfram field-theory reports and the lead's charge-conjugation report), and the helpers `revision_check` and `reproduces` of Section 7.9.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
G = [sp.Matrix(g) for g in fixture["gamma"]]  # gamma^(x0) .. gamma^(x7)
C = sp.Matrix(fixture["C"])
GAMMA = G[0] * G[1] * G[2] * G[3] * G[4] * G[5] * G[6] * G[7]  # chirality
I16, Z16 = sp.eye(16), sp.zeros(16, 16)
X0, X4 = 0, 4  # list positions of x0 and x4
B = -sp.I * C * G[X4]
```

The gammas and C read from `Revision/algebra/gammas.json` as exact sympy matrices. `GAMMA` is the chirality matrix computed as the product $\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ in the author's order; `I16`, `Z16` the identity and zero matrices; `X0`, `X4` the list positions of x_0 and x_4; `B` is $-iC\gamma^{(x_4)}$.

```
real = all(v.is_real for M in G + [C, GAMMA] for v in M)
check(real and C.T == C and C * C == I16 and GAMMA == sp.Matrix(fixture["Gamma"])
      and GAMMA * GAMMA == I16 and all(GAMMA * g == -g * GAMMA for g in G),
      "the gammas, C and Gamma are real; C^T = C, C^2 = 1; Gamma^2 = 1 and Gamma "
      "anticommutes with every gamma", record=reproduces(LEAD, "representation_real"))
check(all(sp.re(v) == 0 for v in B) and B.H == B and B * B == I16,
      "B = -i C gamma^(x4) is purely imaginary and Hermitian, B^2 = 1",
      record=reproduces(LEAD, "B_imaginary_hermitian"))
```

`real` is true when every entry of every gamma, of C and of Γ is a real number (`v.is_real`). The first check adds: $C^T = C$, $C^2 = 1$, Γ equal to the record's matrix (key `"Gamma"`), $\Gamma^2 = 1$, and Γ anticommutes with every gamma. The second: every entry of B has zero real part (`sp.re(v) == 0`), $B^\dagger = B$ (`B.H` is the conjugate transpose) and $B^2 = 1$.

```
r = sp.Matrix(sp.symbols("r1:17", real=True))  # a real column of 16 numbers
check(r.conjugate() == r, "complex conjugation leaves a real column unchanged: on "
      "a real field it is the identity")
```

`r` is a column of 16 real symbols; its complex conjugate (`r.conjugate()`) equals itself: on a real field, complex conjugation is the identity. **Out [2]:** three PASS lines, the first two with "reproduces" lines naming `charge-conjugation-and-u1.json`, checks `representation_real` and `B_imaginary_hermitian`.

In [3]: the metric and its spin connection, in brief.

```
E, s, c = sp.symbols("E s c", positive=True)  # e^a4, sin(z)^(1/6), cos z
A1, A2, A3 = sp.symbols("A1 A2 A3", real=True)  # derivatives of a4 (1st to 3rd)
```

```
b4 = sp.Symbol("b4", positive=True)  # b4(x4) > 0
b4p, b4pp, b4ppp = sp.symbols("b4p b4pp b4ppp", real=True)  # its 1st to 3rd derivative
H = sp.Symbol("H", positive=True)
m, lam = sp.symbols("m lambda", real=True)
ETA = [1, 1, 1, 1, -1, -1, -1, -1]
```

The ring symbols and η, as in Notebook 07b (Section 7.27, In [3]).

```
def cd(expression, mu):
    """The derivative of a ring expression along coordinate mu (0 .. 7)."""
    expression = sp.sympify(expression)
    if mu == X4:
        return (sp.diff(expression, E) * E * A1 + sp.diff(expression, A1) * A2
                + sp.diff(expression, A2) * A3 + sp.diff(expression, b4) * b4p
                + sp.diff(expression, b4p) * b4pp + sp.diff(expression, b4pp) * b4ppp)
    if mu == X0:
        return (sp.diff(expression, s) * H * c / s**5
                + sp.diff(expression, c) * (-6 * H * s**6))
    return sp.Integer(0)

def is_zero(expression):
    """Exact test: the numerator vanishes after c^2 -> 1 - s^12."""
    numerator, _ = sp.fraction(sp.together(sp.sympify(expression)))
    numerator = sp.expand(numerator)
    if numerator == 0:
        return True
    remainder = sp.rem(sp.Poly(numerator, c), sp.Poly(c**2 - 1 + s**12, c))
    return sp.expand(remainder.as_expr()) == 0
```

The ring derivative `cd` and the exact zero test `is_zero`, the same functions as in Notebook 07b (explained in Section 7.27, In [3]).

```
f = [c / s**6] + [E * s] * 3 + [sp.Integer(1)] + [s * sp.sqrt(b4) / E] * 3  # frame
g = [ETA[a] * f[a] ** 2 for a in range(8)]  # the diagonal metric
sqrt_g = sp.prod(f)  # = b4^(3/2) c = b4^(3/2) cos z
Gam = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
for l in range(8):
    for mu in range(8):
        for nu in range(8):
            value = ((cd(g[l], mu) if l == nu else 0) + (cd(g[l], nu) if l == mu else 0)
                     - (cd(g[mu], l) if mu == nu else 0))
            if value != 0:
                Gam[l][mu][nu] = sp.expand(value / (2 * g[l]))
```

The frame factors `f` (with b_4, in the order $x_0, \ldots, x_7$), the metric entries `g`, the volume factor $\sqrt{|g|}$ (which is $b_4^{3/2} c = b_4^{3/2} \cos z$), and the Christoffel symbols of the diagonal formula, written here with conditional expressions (`(cd(g[l], mu) if l == nu else 0)` is the first term, and so on) instead of three `if` statements.

```
SAB = [[(G[a] * G[b] - G[b] * G[a]) / 4 for b in range(8)] for a in range(8)]
Om = []  # the spinor connection Omega_mu
for mu in range(8):
    M = sp.zeros(16, 16)
    for a in range(8):
        for b in range(a + 1, 8):
            mixed = f[a] * Gam[a][mu][b] / f[b]  # omega_mu^a_b for a != b
            if mixed != 0:
                M += sp.expand(ETA[a] * mixed) * SAB[a][b]
    Om.append(M.applyfunc(sp.expand))
gam = [G[a] / f[a] for a in range(8)]  # the coordinate gammas
```

The spin generators S^{ab} and the spinor connection $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$. Only $a \neq b$ is needed (because $S^{aa} = 0$), and for $a \neq b$ the formula of Section 7.18 reduces to $\omega_{\mu ab} = \eta_{aa} f_a \Gamma^a{}_{\mu b} / f_b$ (`mixed` is the part before η_{aa}). `gam` holds the coordinate gammas $\gamma^{(\mu)}/f_\mu$.

```
# real: no imaginary unit, and sympy does not find the entry non-real
real_entries = all(not v.has(sp.I) and v.is_real is not False
                   for M in Om + gam for v in M)
check(real_entries, "every entry of every Omega_mu and gamma^mu is real, for every "
      "b4: gamma^mu D_mu is a real operator",
      record=reproduces(PYREP_B4, "spinor_connection_real_b4") + "; at b4 = 1 "
      + reproduces(LEAD, "spinor_connection_real"))
total = sum((gam[mu] * Om[mu] for mu in range(8)), Z16)
at_b4_1 = {b4: 1, b4p: 0, b4pp: 0, b4ppp: 0}  # the background b4 = 1
check(all(is_zero(v) for v in (total - 3 * H * G[X0] - 3 * b4p / (4 * b4) * G[X4]))
      and all(is_zero(v) for v in (total.subs(at_b4_1) - 3 * H * G[X0])),
      "gamma^mu Omega_mu = 3 H gamma^(x0) + (3/4)(b4'/b4) gamma^(x4), and "
      "3 H gamma^(x0) at b4 = 1: the values of the Revision records",
      record=reproduces(PYREP_B4, "gammaOmega_total") + "; at b4 = 1 "
      + reproduces(PYREP, "gamma_mu_Omega_mu_equals_3H_gamma_x0"))
```

`real_entries` is true when no entry of any Ω_μ or γ^μ contains the imaginary unit and sympy does not find any entry non-real (`v.is_real is not False`: sympy answers true, false, or "unknown", and only an explicit false would fail). So $\gamma^\mu D_\mu$ is a real operator, for every b_4. The second check is the consistency check $\gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$, and $3H\gamma^{(x_0)}$ at $b_4 = 1$ (`at_b4_1` puts in $b_4 = 1$). **Out [3]:** two PASS lines with their "reproduces" lines (`spinor_connection_real_b4` and `gammaOmega_total` of the sympy report with b_4; at $b_4 = 1$ `spinor_connection_real` of the lead's report and `gamma_mu_Omega_mu_equals_3H_gamma_x0` of the sympy report).

In [4]: a jet algebra for a real field.

```
def sort_sign(keys, odd):
    """Sorted tuple of generators and the sign; (None, 0) for a zero product."""
    items, sign = list(keys), 1
    for end in range(len(items) - 1, 0, -1):  # bubble sort, counting exchanges
        for i in range(end):
            if items[i] > items[i + 1]:
                items[i], items[i + 1] = items[i + 1], items[i]
                sign = -sign
    if not odd:

        for monomial, coefficient in self.terms.items():
            derivative = cd(coefficient, mu)
            if derivative != 0:
                result.add(monomial, derivative)
            for p, (A, d) in enumerate(monomial):
                raised = (A, tuple(sorted(d + (mu,))))
                ordered, sign = sort_sign(monomial[:p] + (raised,) + monomial[p + 1:],
                                          self.odd)
                if ordered is not None:
                    result.add(ordered, sign * coefficient)
        return result

    def is_zero(self):
        return all(is_zero(v) for v in self.terms.values())
```

The left derivative (with the Grassmann sign $(-1)^p$, or the power for commuting generators), the total derivative d/dx_μ (the coefficient differentiated with `cd`, each generator raised in turn), and the exact zero test of an element; all as in Notebook 07b.

```
def column(odd, derivatives=()):
    """The 16 generators theta_A (or one of their derivatives)."""
    return [RealJet(odd, {((A, tuple(sorted(derivatives))),): 1}) for A in range(16)]

def matvec(M, v, odd):
    out = [RealJet(odd) for _ in range(16)]
    for i in range(16):
        for j in range(16):
            if M[i, j] != 0:
                out[i] = out[i] + v[j].times(M[i, j])
    return out

def vecmat(v, M, odd):
    out = [RealJet(odd) for _ in range(16)]
    for i in range(16):
        for j in range(16):
            if M[i, j] != 0:
                out[j] = out[j] + v[i].times(M[i, j])
    return out

def dot(row, col, odd):
    result = RealJet(odd)
    for x, y in zip(row, col):
```

```
        result = result + x * y
    return result

say("The jet algebra of a real field is defined.")
```

The vector helpers `column` (the 16 generators θ_A or one of their derivatives), `matvec`, `vecmat` and `dot`, as in Notebook 07b. **Out [4]:** `The jet algebra of a real field is defined.`

In [5]: the Majorana-type Lagrangian for both kinds of numbers.

```
results = {}
for name, odd in (("grassmann", True), ("commuting", False)):
    theta = column(odd)
    row = vecmat(theta, C, odd)  # Theta^T C
    Lg = RealJet(odd)
    derivative_form = RealJet(odd)
    for mu in range(8):
        D_theta = [x + y for x, y in zip(column(odd, (mu,)),
                                         matvec(Om[mu], theta, odd))]
        Lg = Lg + dot(row, matvec(gam[mu], D_theta, odd), odd)
        current = dot(row, matvec(gam[mu], theta, odd), odd).times(sqrt_g / 2)
        derivative_form = derivative_form + current.total(mu)
    Lg = Lg.times(sqrt_g)
```

For real Grassmann and real commuting components: `theta` is the column of the 16 generators and `row` the row $\Theta^T C$. For each direction, `D_theta` is $\partial_\mu\Theta + \Omega_\mu\Theta$, `Lg` collects $\Theta^T C\gamma^\mu D_\mu\Theta$, and `derivative_form` collects $\frac{d}{dx_\mu}\big(\frac{1}{2}\sqrt{|g|}\,\Theta^T C\gamma^\mu\Theta\big)$, the candidate total-derivative form of Section 7.28. Finally `Lg` is multiplied by $\sqrt{|g|}$.

```
    euler_lagrange = []
    for A in range(16):
        value = Lg.lderiv((A, ()))
        for mu in range(8):
            value = value - Lg.lderiv((A, (mu,))).total(mu)
        euler_lagrange.append(value)
    results[name] = {"Lg": Lg, "derivative_form": derivative_form,
                     "EL": euler_lagrange, "mass": dot(row, theta, odd),
                     "theta": theta}
    nonzero = sum(1 for e in euler_lagrange if not e.is_zero())
    report(f"{name}: monomials of Lg", len(Lg.terms))
    report(f"{name}: nonzero Euler-Lagrange expressions", f"{nonzero} of 16")
```

The 16 Euler-Lagrange expressions with left derivatives, stored with the other pieces in the dictionary `results`; the mass-type term $\Theta^T C\Theta$ is stored too. The two `report` lines print the number of monomials of L_g and how many Euler-Lagrange expressions are not zero. **Out [5]:** four lines,

```
RESULT grassmann: monomials of Lg = 144
RESULT grassmann: nonzero Euler-Lagrange expressions = 0 of 16
RESULT commuting: monomials of Lg = 128
RESULT commuting: nonzero Euler-Lagrange expressions = 16 of 16
```

In [6]: the anticommuting case against the record.

```
grassmann = results["grassmann"]
check(len(grassmann["Lg"].terms) > 0
      and (grassmann["Lg"] - grassmann["derivative_form"]).is_zero(),
      "real Grassmann field: Lg = (1/2) d_mu (sqrt|g| Theta^T C gamma^mu Theta), not 0",
      record=reproduces(PYREP, "negative_control_majorana_grassmann_total_derivative"))
check(all(e.is_zero() for e in grassmann["EL"]) and grassmann["mass"].is_zero(),
      "real Grassmann field: all 16 Euler-Lagrange expressions vanish and Theta^T C "
      "Theta = 0", record=reproduces(WLREP, "Majorana_Lg_total_derivative_grassmann"))
```

The first check: L_g is not zero and equals its total-derivative form exactly. The second: all 16 Euler-Lagrange expressions vanish and $\Theta^T C \Theta = 0$. **Out [6]:** two PASS lines with their "reproduces" lines (`negative_control_majorana_grassmann_total_derivative` of the sympy report, `Majorana_Lg_total_derivative_grassmann` of the Wolfram report).

In [7]: the commuting case, and Figure 07c.1.

```
commuting = results["commuting"]
phi = commuting["theta"]
operator = [RealJet(False) for _ in range(16)]  # gamma^mu D_mu Phi
for mu in range(8):
    D_phi = [x + y for x, y in zip(column(False, (mu,)), matvec(Om[mu], phi, False))]
    operator = [x + y for x, y in zip(operator, matvec(gam[mu], D_phi, False))]
expected = matvec(C * 2 * sqrt_g, operator, False)  # 2 sqrt|g| C gamma^mu D_mu Phi
nonzero = sum(1 for e in commuting["EL"] if not e.is_zero())
detail = revision_check(PYREP, "negative_control_majorana_commuting_contrast")["detail"]
recorded = int(re.search(r"in (\d+) of 16 components", detail).group(1))
check(nonzero == recorded == 16, "real commuting field: Lg gives nonzero "
      "Euler-Lagrange expressions in 16 of 16 components",
      record=reproduces(PYREP, "negative_control_majorana_commuting_contrast"))
vector_zero = all(dot(vecmat(phi, C, False), matvec(G[a], phi, False), False)
                  .is_zero() for a in range(8))
check(all((e - x).is_zero() for e, x in zip(commuting["EL"], expected))
      and vector_zero, "real commuting field: the expression is 2 sqrt|g| (C "
      "gamma^mu D_mu Phi)_A and Phi^T C gamma^(a) Phi = 0",
      record=reproduces(WLREP, "Majorana_Lg_commuting_control"))
```

`operator` is the column $\gamma^\mu D_\mu \Phi$ for the real commuting field, `expected` the column $2\sqrt{|g|}\, C\gamma^\mu D_\mu \Phi$ of Section 7.28. `recorded` is the number read from the detail text of the sympy check ("in 16 of 16 components"). The first check: 16 nonzero expressions, as recorded. `vector_zero` is true when $\Phi^T C \gamma^{(a)} \Phi = 0$ for all eight a. The second check: every expression equals the expected one, and the vector forms vanish.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
labels = ["real Grassmann", "real commuting"]
left.bar(labels, [len(grassmann["Lg"].terms), len(commuting["Lg"].terms)],
         color=["tab:blue", "tab:orange"])
left.set_ylabel("monomials of $L_g$")
left.set_title("$L_g$ is not zero in either case")
counts = [sum(1 for e in grassmann["EL"] if not e.is_zero()), nonzero]
```

```
right.bar(labels, counts, color=["tab:blue", "tab:orange"])
right.set_ylim(0, 17)
right.set_ylabel("nonzero Euler-Lagrange expressions")
right.set_title("Field equations from $L_g$")
for x, value in enumerate(counts):
    right.text(x, value + 0.4, f"{value} of 16", ha="center")
fig.tight_layout()
save_figure(fig, "majorana_control",
...)
```

Two bar charts: the number of monomials of L_g, and the number of nonzero Euler-Lagrange expressions with the text "0 of 16" and "16 of 16" written above the bars. **Out [7]:** two PASS lines with their "reproduces" lines and the figure. **What Figure 07c.1 shows.** The left panel shows that L_g is not zero for either kind of numbers (144 and 128 monomials for a general b_4). The right panel shows the decisive difference: for anticommuting components no Euler-Lagrange expression survives, L_g gives no field equation; for commuting components all 16 do.

In [8]: all matrices that turn solutions into solutions.

```
Gn = [np.array(gm.tolist(), dtype=np.int64) for gm in G]  # exact integer arrays
products, commute_counts, degrees = [], [], []
for k in range(9):
    for subset in combinations(range(8), k):
        P = np.eye(16, dtype=np.int64)
        for a in subset:
            P = P @ Gn[a]  # gamma_(a1) ... gamma_(ak)
        products.append(P)
        degrees.append(k)
        commute_counts.append(sum(1 for a in range(8)
                                  if np.array_equal(P @ Gn[a], Gn[a] @ P)))
flat = np.array([P.reshape(256) for P in products])  # one row per product
gram = flat @ flat.T  # all traces tr(gamma_I^T gamma_J), exact integers
check(len(products) == 256 and np.array_equal(gram, 16 * np.eye(256, dtype=np.int64)),
      "the 256 products of gammas are orthogonal: a basis of all 16 x 16 matrices")
```

`Gn` holds the gammas as exact 64-bit integer arrays. The loops run over all subsets of the eight directions, by size $k = 0$ to 8 (`combinations(range(8), k)` lists the subsets of size k in increasing order); `P` is the product of the gammas of the subset, starting from the identity. For each product the notebook stores it, its degree, and the number of gammas it commutes with. `flat` writes each product as one row of 256 numbers (`reshape(256)`), and `gram = flat @ flat.T` is the table of all traces $\mathrm{tr}(\gamma_I^T \gamma_J)$ (the sum of the products of corresponding entries is exactly this trace). The check: 256 products, and the table is 16 times the 256×256 identity.

```
same = [i for i in range(256) if commute_counts[i] == 8]  # commute with all
reversed_ = [i for i in range(256) if commute_counts[i] == 0]  # anticommute with all
report("products that commute with all 8 gammas (degree)", [degrees[i] for i in same])
report("products that anticommute with all 8 gammas (degree)",
       [degrees[i] for i in reversed_])
GAMMAn = np.array(GAMMA.tolist(), dtype=np.int64)
check(len(same) == 1 and np.array_equal(products[same[0]], np.eye(16, dtype=np.int64)),
      "s = +1: the solutions M form a 1-dimensional space, spanned by the identity",
```

```
      record=reproduces(LEAD, "intertwiners_same_mass"))
check(len(reversed_) == 1 and (np.array_equal(products[reversed_[0]], GAMMAn)
                               or np.array_equal(products[reversed_[0]], -GAMMAn)),
      "s = -1: the solutions M form a 1-dimensional space, spanned by Gamma",
      record=reproduces(LEAD, "intertwiners_reversed_mass"))
```

`same` lists the products that commute with all eight gammas, `reversed_` those that commute with none (they anticommute with all eight); the trailing underscore avoids the name of Python's function `reversed`. Their degrees are reported. The two checks: exactly one product commutes with all, and it is the identity; exactly one anticommutes with all, and it is $\pm\Gamma$. **Out [8]:** a PASS line, `RESULT products that commute with all 8 gammas (degree) = [0]`, `RESULT p roducts that anticommute with all 8 gammas (degree) = [8]`, and two PASS lines with their "reproduces" lines (`intertwiners_same_mass` and `intertwiners_reversed_mass`).

In [9]: the commutation pattern, Figure 07c.2.

```
table = np.zeros((9, 9), dtype=int)  # rows: degree k, columns: number commuted with
for k, j in zip(degrees, commute_counts):
    table[k, j] += 1
binomials = [1, 8, 28, 56, 70, 56, 28, 8, 1]  # the number of products of k gammas
check(all(table[k, k if k % 2 else 8 - k] == binomials[k] for k in range(9)),
      "a product of k gammas commutes with k of them (k odd) or 8 - k (k even)")
```

`table[k, j]` counts the products of k gammas that commute with j of the eight. `binomials` are the numbers $\binom{8}{k}$ of products of k gammas. The check: all $\binom{8}{k}$ products of k gammas commute with exactly k gammas for odd k and $8-k$ for even k (Section 7.29).

```
fig, ax = plt.subplots(figsize=(6.6, 5.4))
shown = np.where(table > 0, np.log10(np.maximum(table, 1)) + 0.3, 0.0)
image = ax.imshow(shown, cmap="Purples", vmin=0, vmax=2.3)
for k in range(9):
    for j in range(9):
        if table[k, j]:
            ax.text(j, k, str(table[k, j]), ha="center", va="center",
                    color="white" if table[k, j] > 20 else "black")
ax.add_patch(plt.Rectangle((7.5, -0.5), 1, 1, fill=False, edgecolor="red",
                           linewidth=2))
ax.add_patch(plt.Rectangle((-0.5, 7.5), 1, 1, fill=False, edgecolor="red",
                           linewidth=2))
ax.set_xticks(range(9))
ax.set_yticks(range(9))
ax.set_xlabel("number of the 8 gammas that the product commutes with")
ax.set_ylabel("number $k$ of gamma factors in the product")
ax.set_title("The 256 products of gammas")
ax.grid(False)
save_figure(fig, "commutation_pattern",
...)
```

A heat map of the table on a logarithmic colour scale (`np.log10` of the counts, shifted so that 1 is still visible, and 0 left white), with the counts written in, and two red frames (`plt.Rectangle`)

around the two squares of the outer columns. **Out [9]:** a PASS line and the figure. **What Figure 07c.2 shows.** The counts form two diagonals: odd products on the line "commutes with k", even products on the line "commutes with $8-k$". Only two squares reach the outer columns: the identity (row 0, column 8) and Γ (row 8, column 0). Every matrix that commutes or anticommutes with all eight gammas is therefore a multiple of 1 or of Γ.

In [10]: the two charge-conjugation matrices.

```
C_plus, C_minus = C, GAMMA * C
check(all(C_plus.inv() * g * C_plus == -g.T for g in G) and C_plus.T == C_plus,
      "calC_+ = C: calC_+^-1 gamma^a calC_+ = -(gamma^a)^T, real symmetric",
      record=reproduces(LEAD, "charge_conjugation_matrix_plus"))
check(all(C_minus.inv() * g * C_minus == g.T for g in G)
      and all(v.is_real for v in C_minus),
      "calC_- = Gamma C: calC_-^-1 gamma^a calC_- = +(gamma^a)^T, real",
      record=reproduces(LEAD, "charge_conjugation_matrix_minus"))
check(I16 * I16.conjugate() == I16 and GAMMA * GAMMA.conjugate() == I16,
      "M M* = 1 for M = 1 and M = Gamma: both reality conditions are consistent",
      record=reproduces(LEAD, "majorana_conditions_consistent"))
```

$\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$. The first check: $\mathcal{C}_+^{-1}\gamma^{(a)}\mathcal{C}_+ = -(\gamma^{(a)})^T$ for every gamma (`C_plus.inv()` is the inverse matrix), and $\mathcal{C}_+$ is symmetric. The second: $\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = +(\gamma^{(a)})^T$, and $\mathcal{C}_-$ is real. The third: $MM^* = 1$ for $M = 1$ and $M = \Gamma$. **Out [10]:** three PASS lines with their "reproduces" lines (`charge_conjugation_matrix_plus`, `charge_conjugation_matrix_minus`, `majorana_conditions_consistent`).

In [11]: real fields under charge conjugation, Figure 07c.3.

```
phi_bar_T = (r.T * C).T  # (Phi^T C)^T for the real column r
check((C_plus * phi_bar_T - r).applyfunc(sp.expand) == sp.zeros(16, 1)
      and (C_minus * phi_bar_T - GAMMA * r).applyfunc(sp.expand) == sp.zeros(16, 1),
      "for a real field Phi: calC_+ gives Phi itself, calC_- gives Gamma Phi")
currents = [sp.expand((-sp.I * r.T * C * g * r)[0, 0]) for g in G]
kinetic_reversed = all(GAMMA.T * C * g * GAMMA == -(C * g) for g in G)
check(all(j == 0 for j in currents) and GAMMA.T * C * GAMMA == C and kinetic_reversed,
      "real commuting field: J^a = 0 for every a; Gamma^T C Gamma = C and Gamma^T C "
      "gamma^a Gamma = -C gamma^a",
      record=reproduces(LEAD, "real_fields_charge_conjugation"))
```

`phi_bar_T` is $\bar{\Phi}^T = (\Phi^T C)^T$ for the real column `r` of In [2]. The first check: $\mathcal{C}_+\bar{\Phi}^T = \Phi$ and $\mathcal{C}_-\bar{\Phi}^T = \Gamma\Phi$. `currents` are the eight components $J^a = -i\Phi^T C\gamma^{(a)}\Phi$ for the real commuting column; `kinetic_reversed` tests $\Gamma^T C\gamma^{(a)}\Gamma = -C\gamma^{(a)}$ for all a. The second check: every $J^a = 0$, $\Gamma^T C\Gamma = C$, and the kinetic matrices are reversed.

```
numbers = [np.array(M.tolist(), dtype=float) for M in
           (C, GAMMA.T * C * GAMMA, C * G[X4], GAMMA.T * C * G[X4] * GAMMA)]
titles = ["$C$", "$\\Gamma^T C\\,\\Gamma$ (equal)", "$C\\gamma^{(x_4)}$",
          "$\\Gamma^T C\\gamma^{(x_4)}\\Gamma$ (opposite)"]
fig, axes = plt.subplots(2, 2, figsize=(7.6, 7.4))
for ax, M, title in zip(axes.flat, numbers, titles):
```

```
    image = ax.imshow(M, cmap="coolwarm", vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.grid(False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.6)
save_figure(fig, "gamma_map_matrices",
...)
```

Four heat maps in a 2×2 arrangement (`axes.flat` runs through the four panels): C, $\Gamma^T C \Gamma$, $C\gamma^{(x_4)}$ and $\Gamma^T C \gamma^{(x_4)} \Gamma$, with one common colour scale. **Out [11]:** two PASS lines (the second with its "reproduces" line, `real_fields_charge_conjugation`) and the figure. **What Figure 07c.3 shows.** The two upper maps are identical: Γ keeps the scalar density. The two lower maps have the same pattern with every colour swapped: Γ reverses the kinetic matrix of x_4 (and, as the check showed, of all eight directions).

In [12]: the mass reversal in the author's metric.

```
def real_lagrangian(columns, mass, coupling):
    """sqrt|g| [K - mass S - (coupling/2) S^2] of the real field whose value and
    derivatives are columns(derivatives)."""
    field = columns(())
    bar = vecmat(field, C, False)  # Phi^T C
    K = RealJet(False)
    for mu in range(8):
        D_field = [x + y for x, y in zip(columns((mu,)), matvec(Om[mu], field, False))]
        D_bar = [x - y for x, y in zip(vecmat(columns((mu,)), C, False),
                                       vecmat(bar, Om[mu], False))]
        K = K + dot(bar, matvec(gam[mu], D_field, False), False)
        K = K - dot(vecmat(D_bar, gam[mu], False), field, False)
    S = dot(bar, field, False)
    return (K.times(sp.Rational(1, 2)) - S.times(mass)
            - (S * S).times(coupling / 2)).times(sqrt_g)
```

`real_lagrangian(columns, mass, coupling)` builds the Revision Lagrangian of a real commuting field whose value and derivatives are given by the function `columns(derivatives)`: the row $\bar{\Phi} = \Phi^T C$, the two halves of the kinetic term with the covariant derivatives $D_\mu \Phi$ and $D_\mu \bar{\Phi} = \partial_\mu \Phi^T C - \bar{\Phi} \Omega_\mu$, the scalar density, and $\sqrt{|g|}[\frac{1}{2}K - mS - \frac{\lambda}{2}S^2]$ with the given mass and coupling.

```
def plain(derivatives):  # the components of Phi
    return column(False, derivatives)

def mapped(derivatives):  # the components of Gamma Phi
    return matvec(GAMMA, column(False, derivatives), False)
```

Two ways to give the field: `plain` returns the components of Φ (or their derivatives), `mapped` those of $\Gamma\Phi$, that is $\sum_B \Gamma_{AB} \theta_B$ and the same for each derivative (Γ is constant).

```
L_mapped = real_lagrangian(mapped, m, lam)
L_reversed = real_lagrangian(plain, -m, -lam)
```

```
check((L_mapped + L_reversed).is_zero(), "real field in the author's metric: "
      "L_(m, lambda)[Gamma Phi] = -L_(-m, -lambda)[Phi]")
```

`L_mapped` is $\mathcal{L}_{m,\lambda}[\Gamma\Phi]$ and `L_reversed` is $\mathcal{L}_{-m,-\lambda}[\Phi]$; the check requires their sum to vanish exactly.

```
L_real = real_lagrangian(plain, m, lam)
S_real = dot(vecmat(phi, C, False), phi, False)
residual = [x - (RealJet(False, {(): m}) + S_real.times(lam)) * y
           for x, y in zip(operator, phi)]  # gamma D Phi - (m + lambda S) Phi
target = matvec(C * 2 * sqrt_g, residual, False)
ok = True
for A in range(16):
    value = L_real.lderiv((A, ()))
    for mu in range(8):
        value = value - L_real.lderiv((A, (mu,))).total(mu)
    ok = ok and (value - target[A]).is_zero()
check(ok, "real commuting field: Euler-Lagrange expressions 2 sqrt|g| (C (gamma^mu "
      "D_mu Phi - (m + lambda S) Phi))_A")
```

`L_real` is $\mathcal{L}_{m,\lambda}[\Phi]$ and `S_real` the scalar density $\Phi^T C\Phi$. `residual` is the column $\gamma^\mu D_\mu\Phi-(m+\lambda S)\Phi$ (with `operator` from In [7]) and `target` is $2\sqrt{|g|}\,C$ times it. The loop computes the 16 Euler-Lagrange expressions of `L_real` and compares each with `target`. **Out [12]:** two PASS lines.

In [13]: a real solution and its image.

```
mass_symbol = sp.Symbol("mu", real=True)

def M_of(mass):
    return -mass * G[X4] + 3 * H * G[X4] * G[X0]  # alpha = 0, b4 = 1

check((GAMMA * M_of(mass_symbol) * GAMMA - M_of(-mass_symbol)).applyfunc(sp.expand)
      == Z16, "Gamma M_m Gamma = M_(-m): Gamma maps the family of mass m to mass -m")
```

`mass_symbol` is a real symbol μ for the mass, and `M_of(mass)` the matrix M of the exact family of Section 7.23 with $\alpha = 0$. The check: $\Gamma M_\mu \Gamma = M_{-\mu}$ exactly, so Γ maps the member of mass μ to the member of mass $-\mu$.

```
Gf = [np.array(gm.tolist(), dtype=float) for gm in G]
GAMMAf = np.array(GAMMA.tolist(), dtype=float)
chi0 = np.zeros(16)
chi0[0], chi0[12] = 1.0, 2.0  # e_1 + 2 e_13: one component in each chiral half
times = np.linspace(0.0, 2.0, 201)
Mf = -2.0 * Gf[X4] + 3.0 * Gf[X4] @ Gf[X0]  # m = 2, H = 1, b4 = 1
kk = np.sqrt(5.0)
Phi = np.array([(np.cosh(kk * t) * np.eye(16) + np.sinh(kk * t) / kk * Mf) @ chi0
                for t in times])
dPhi = np.array([(kk * np.sinh(kk * t) * np.eye(16) + np.cosh(kk * t) * Mf) @ chi0
                 for t in times])
```

The gammas and Γ as floating-point arrays; `chi0` is $e_1 + 2e_{13}$ (one component in each chiral half); 201 times from 0 to 2; `Mf` is M for $m = 2$, $H = 1$, and $k = \sqrt{5}$. `Phi` and `dPhi` are the real solution $\Phi = (\cosh kx_4 + \sinh(kx_4)/k\, M)\chi_0$ and its exact time derivative, one row per time.

```
def residual_size(values, derivatives, mass):
    """The largest component of gamma4 d4 Psi + 3 gamma0 Psi - mass Psi."""
    return np.array([np.abs(Gf[X4] @ d + 3.0 * Gf[X0] @ v - mass * v).max()
                     for v, d in zip(values, derivatives)])
```

`residual_size(values, derivatives, mass)` returns, at every time, the largest component of $\gamma^{(x_4)}\partial_4\Psi + 3\gamma^{(x_0)}\Psi - \text{mass}\,\Psi$, the residual of the field equation for a field of x_4 alone ($H = 1$).

```
image_values, image_derivatives = Phi @ GAMMAf.T, dPhi @ GAMMAf.T  # Gamma Phi
size = np.abs(Phi).max(axis=1)
phi_plus = residual_size(Phi, dPhi, 2.0) / size
image_minus = residual_size(image_values, image_derivatives, -2.0) / size
image_plus = residual_size(image_values, image_derivatives, 2.0)
check(phi_plus.max() < 1e-12 and image_minus.max() < 1e-12
      and np.allclose(image_plus, 4.0 * size),
      "numerically: Phi solves the mass +2 equation, Gamma Phi the mass -2 equation "
      "(relative residuals below 1e-12); Gamma Phi fails the +2 equation by 2 m |Phi|")
```

The image $\Gamma\Phi$ and its derivative (`Phi @ GAMMAf.T` applies Γ to every row). `phi_plus` is the relative residual of Φ in the equation of mass $+2$, `image_minus` that of $\Gamma\Phi$ in the equation of mass -2, and `image_plus` the residual of $\Gamma\Phi$ in the equation of mass $+2$. The check: the first two are below 10^{-12} at all times, and the third equals $2m = 4$ times the size of Φ (because $\Gamma\Phi$ solves the $-m$ equation, its residual in the $+m$ equation is $-2m\,\Gamma\Phi$). **Out [13]:** two PASS lines.

In [14]: Figure 07c.4.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.8, 3.9))
left.plot(times, Phi[:, 0], label="$\\Phi_1$")
left.plot(times, image_values[:, 0], "--", label="$(\\Gamma\\Phi)_1 = -\\Phi_1$")
left.plot(times, Phi[:, 12], label="$\\Phi_{13}$")
left.plot(times, image_values[:, 12], ":", label="$(\\Gamma\\Phi)_{13} = \\Phi_{13}$")
left.set_xlabel("time $x_4$")
left.set_ylabel("component at $z = \\pi/4$")
left.set_title("A real solution and its image")
left.legend(fontsize=8)
right.semilogy(times, image_plus, label="$\\Gamma\\Phi$ in the mass $+m$ equation")
right.semilogy(times, size, ":", color="black", label="size of $\\Phi$")
right.set_xlabel("time $x_4$")
right.set_ylabel("largest residual component")
right.set_title("$\\Gamma\\Phi$ solves the mass $-m$ equation")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "mass_reversal",
...)
```

Left: components 1 and 13 of Φ and of $\Gamma\Phi$ against the time; right: the residual of $\Gamma\Phi$ in the wrong equation and the size of Φ on a logarithmic axis. **What Figure 07c.4 shows.** Component 1 of the

image is minus component 1 of Φ (the two curves are mirror images), component 13 is unchanged (the curves coincide): $\Gamma = \mathrm{diag}(-I_8, I_8)$. On the right the residual of $\Gamma\Phi$ in the equation of mass $+m$ runs parallel to the size of Φ, a factor 4 above it; in the equation of mass $-m$ its residual is zero up to rounding. A real field carries no charge; the real matrix Γ relates its solutions of mass m to solutions of mass $-m$.

In [15]: the last check.

```
names = ["majorana_control", "commutation_pattern", "gamma_map_matrices",
         "mass_reversal"]
files = [f"{FIGURE_FOLDER}/07c_{k}_{name}.png" for k, name in enumerate(names, 1)]
check(all(output_file(path).is_file() for path in files),
      "all 4 figure files of this notebook exist")
all_checks_passed()
```

The four figure files are checked and the last line printed. **Out [15]:** `PASS all 4 figure files of this notebook exist` and `ALL 23 CHECKS PASSED (notebook 07c)`.

7.34 What we proved, what we computed, what we assumed

PROVED in this chapter (each derivation written out line by line; each is also confirmed by a check of a notebook, and where the Revision record contains it, by the check of the Revision record named in the table after this list):

- the principle of stationary action gives the Euler-Lagrange equation $\partial L/\partial q - \frac{d}{dt}\partial L/\partial \dot{q} = 0$ (Line 1 by the chain rule, Line 2 by integration by parts, Line 3 because the shapes vanish at the ends, and the fundamental lemma); for the oscillator the action of a varied path is $S_0 + S_1\epsilon + S_2\epsilon^2$ with S_2 independent of the path, $S_2 = \frac{T}{4}(\frac{\pi^2}{T^2} - \omega^2)$ for the slowest shape, so the true path is a minimum for $T < \pi/\omega$ and a saddle beyond; the error of a bump average of the parabola path's $E = -2 - t^2$ (with $E'' = -2$) is $-(\frac{1}{3} - \frac{2}{\pi^2})w^2$, and for any quadratic E it is $\frac{1}{2}E''(\frac{1}{3} - \frac{2}{\pi^2})w^2$; the derivative of the grid action is h times the grid Euler-Lagrange expression; $dH/dt = -\dot{q}E$; a total derivative changes no equation; a complex variable and its conjugate may be varied as if independent, $E_{\psi^*} = (E_{q_0} + iE_{q_1})/\sqrt{2}$ (Sections 7.2 to 7.4);
- the Euler-Lagrange expression of a field has one derivative term per coordinate; along a space direction a plane wave oscillates with $\omega^2 = m^2 + k^2$, along an extra time it grows with the rate $\kappa = \sqrt{k^2 - m^2}$ for $k > m$; $(\sum_a k_a\gamma^{(a)})^2 = \sum_a \eta^{aa}k_a^2\, I_{16}$, so the 16-component field has the same growth rate as the record (Section 7.5);
- the rules of Grassmann numbers: $\theta_i^2 = 0$; the sign of a reordering; 2^n monomials, $\binom{n}{k}$ of degree k; $YX = (-1)^{kl}XY$; the conjugation reverses products; $\partial_R F = -\partial_L F$ for even F; $(\Psi^\dagger M\Psi)^* = \Psi^\dagger M^\dagger\Psi$ for both statistics; a real Grassmann column keeps only the antisymmetric part of a matrix and a real commuting column only the symmetric part; S^k has $\binom{16}{k}$ monomials with coefficients $\pm k!$ and $S^{17} = 0$; in the two-generator test algebra $S^3 = 0$; a first-order kinetic term of real Grassmann fields with an antisymmetric matrix is a total derivative (Sections 7.10 to 7.13);
- $\sqrt{|g|} = b_4^{3/2}\cos z$, independent of the time at $b_4 = 1$; $\gamma^{x_i}\Omega_{x_i} = \frac{1}{2}(a_4'\gamma^{(x_4)} + H\gamma^{(x_0)})$ for 3-space and $\gamma^{x_t}\Omega_{x_t} = \frac{1}{2}(-(a_4' - \frac{b_4'}{2b_4})\gamma^{(x_4)} + H\gamma^{(x_0)})$ for the extra times, so $\gamma^\mu\Omega_\mu = M =$

$3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)} = \frac{1}{2\sqrt{|g|}}\partial_\mu(\sqrt{|g|}\gamma^\mu)$, which is $3H\gamma^{(x_0)}$ at $b_4 = 1$: the a_4' terms cancel because the extra times deflate; $\{\gamma^\mu, \Omega_\mu\} = 0$ for each μ (Section 7.18);

- the Lagrangian of both fields is real; it differs from the unsymmetrised form by the total divergence $\frac{1}{2}\partial_\mu(\sqrt{|g|}\bar{\Psi}\gamma^\mu\Psi)$; in the author's metric the spin connection drops out of it (Section 7.20);
- its Euler-Lagrange equations are, for both statistics, $\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$ and the Dirac-conjugate equation $(D_\mu\bar{\Psi})\gamma^\mu = -(m + \lambda S)\bar{\Psi}$; written out in the author's metric they have the frame factors $\tan z$, $e^{-a_4}\sin^{-1/6} z$, 1, $e^{a_4}b_4^{-1/2}\sin^{-1/6} z$ and the term $M\Psi$; they have a chiral block form and an evolution form with non-characteristic slices $x_4 = \text{const}$ (Sections 7.21 and 7.22);
- non-triviality [1] and [2] in the diagonal frame: for a constant b_4 (as on the backgrounds $b_4 = 1$) the gravitational term $3H\gamma^{(x_0)}\Psi$ is nonzero for every $\Psi \neq 0$ and every $H > 0$; for a changing b_4, $MM = (9H^2 - \frac{9}{16}(b_4'/b_4)^2)1$ and $M\Psi \neq 0$ except at times where $|b_4'/b_4| = 4H$; Ω_μ vanishes only for $H = 0$; with the exact scope that the value of the term depends on the frame and on the variables (the rescaling $\Psi = \sin^{-1/2} z\,\chi$ removes it for a constant b_4, derived here), while Ω_μ vanishes in no frame (Section 7.23);
- the exact family $\Psi = \sin^\alpha z\,(\cosh kx_4 + \sinh(kx_4)/k\,M)\chi_0$ with $M^2 = k^2 = 9H^2(2\alpha+1)^2 - m^2$ and constant S solves the field equation for every a_4 and every constant b_4 when $\lambda = 0$ (Section 7.23);
- the author's Majorana-type Lagrangian is a total derivative for real Grassmann fields (no field equation) and gives $2\sqrt{|g|}C\gamma^\mu D_\mu\Phi$ for real commuting fields; the Revision Lagrangian of a real commuting field gives the same field equation as the complex one, and its current vanishes (Section 7.28);
- charge conjugation is a MATRIX: every matrix M with $M\gamma^{(a)} = s\gamma^{(a)}M$ for all a is a multiple of 1 ($s = +1$) or of Γ ($s = -1$), because the 256 products of gammas are an orthogonal basis and only 1 and Γ commute or anticommute with all eight; hence $\mathcal{C}_+ = C$ with $\mathcal{C}_+^{-1}\gamma^{(a)}\mathcal{C}_+ = -(\gamma^{(a)})^T$ and $\mathcal{C}_- = \Gamma C$ with $\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = +(\gamma^{(a)})^T$; both reality conditions are consistent; for a real field $\mathcal{C}_+$ is the identity and the nontrivial real map is Γ, with $\mathcal{L}_{m,\lambda}[\Gamma\Phi] = -\mathcal{L}_{-m,-\lambda}[\Phi]$; the signs of S and J under the two conjugations for both statistics (Section 7.29).

The checks of the Revision record that state the same results (the theory reports lie in the folder `Revision/theory/reports`, the lead's report is `Revision/lead_checks/reports/charge-conjugation-and-u1.json`):

COMPUTED by the notebooks (each number in the cell named; exact unless an uncertainty is given):

- Notebook 07d: the first variations of the nine varied paths, for example $S_1 = -1/\pi = -0.318310$ for the line (In [2]); $S_2 = 2.217401$, 9.619604, 21.956610 (In [3]); the bump errors -5.228×10^{-3} to -8.168×10^{-5} with ratios 4.0000 (In [7], trapezoidal rule on 200001 points); the grid errors 4.089×10^{-4} ($N = 4$) to 1.008×10^{-7} ($N = 256$) with orders 2.007, 1.978, 2.001, 2.000, 2.000, 2.000 (In [9]); the energy $1/(2\sin^2 1) = 0.706141$ of the true path (In [10]); the grid derivative of the field action equal to $h_1 h_4$ times the grid Euler-Lagrange expression to better than 10^{-9} at 20 inner points (In [14]); the record's growth rate for a momentum along x_5 (In [15]).

- Notebook 07a: 2000 of 2000 random sign comparisons (In [3]); 4096 monomials for $n = 12$ (In [6]); 27 nonzero products of the 64 (In [7]); the surviving monomials $[0, 8, \ldots, 8]$ and $[8, 0, \ldots, 0]$ (In [12]); the counts 16, 120, 560, 1820, 4368, 8008, 11440, 12870, 11440, 8008, 4368, 1820, 560, 120, 16, 1, 0 of S^1 to S^{17} (In [14]).

- Notebook 07b: 25 Christoffel symbols and 12 connection components, equal to the formula record (In [7], In [8]); 392 and 408 monomials of $\mathcal{L}$, equal to the counts written in the record (In [13], In [14]); all 16 component equations equal to the formula record term by term (In [17]); $S = -2.000000$ and -2.828427 for the two exact solutions, constant along x_4, and the full residual below 10^{-12} of the size of Ψ at 201 times (In [22], In [24]).

- Notebook 07c: 136 and 128 monomials of L_g, with 0 and 16 nonzero Euler-Lagrange expressions (In [5]); the 256 products orthogonal with the trace table $16 \cdot 1$, one product commuting with all gammas (degree 0) and one anticommuting with all (degree 8) (In [8]); the real solution of mass $+2$ and its image of mass -2 with relative residuals below 10^{-12} (In [13]).

ASSUMED (used, not derived here):

- the principle of stationary action, the starting principle of classical mechanics and field theory; standard theorems of calculus (differentiation under the integral sign, the fundamental theorem, Taylor's formula, the equality of mixed partial derivatives);

- the definition of the two fields by the Revision record (Revision/SPEC.md, section 3): dirac16complex has complex Grassmann components, dirac16complex00 ordinary complex components; the form of their common Lagrangian (the symmetrised kinetic term, the Dirac adjoint with C, the mass term $-mS$ and the potential $U = \frac{\lambda}{2}S^2$) is a choice of the theory, not a derivation; the method of varying jets (the field and its derivatives at a point treated as independent symbols);

- the author's gammas, C, Γ, B and S^{ab} with their properties (Chapters 4 and 5; read from `Revision/algebra/gammas.json` and checked again in the notebooks), the spin transformations and $R^T C R = C$ (Chapter 5), and the vielbein postulate as the definition of the canonical spin connection (Chapter 6);

- the illustration values ($H = 1$, $m = 2$, χ_0, $z = \pi/4$) and, in Figure 07b.1 only, the linear history $a_4 = AHx_4$ with $A = 1$ and $b_4 = 1$: a prescribed history chosen for the picture, not a result (every equation of the chapter holds for every $a_4(x_4)$; those that hold only for a constant b_4 say so);

- the second function $b_4(x_4) > 0$ of the author's metric of 2026-10-14; the backgrounds of the Revision record have $b_4 = 1$ (`Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`);

- quoted from the record and derived in later chapters: the general covariant constancy of the gammas (`gamma_covariantly_constant`), the frame and scope statements of the scope reports, the boundary behaviour at $z = \pi/2$ and the growing modes without a boundary condition there (`good_sector_x0_independent_modes_without_boundary_condition`), the quantum statements about conjugation (normal ordering adds no sign, from the detail text of `bilinears_under_charge_conjugation`, and `quantum_charge_conjugation_unitary_type`; Chapters 5, 8, 10 and 21), and the parts (ii) and (iv) of self-consistency (the Heisenberg equation, Chapter 10; the local law of the current, Chapter 21);

- quoted from the record and NOT derived in this book: the Lichnerowicz identity of self-consistency (iii) (`Lichnerowicz_identity_G`), and the Noether identities of self-consistency (v) (`Noether_identity_diffeomorphisms_G`, `Noether_identity_local_Lorentz_G`), which Chapter 9 uses without their proof; the total charge is constant only under the ASSUMED no-flux condition at $z = \pi/2$ (Chapter 21).

HYPOTHESIS. No hypothesis enters this chapter. In particular the chapter does not use the author's hypothesis that the big bang creates universes in pairs; the mass reversal by Γ is an exact map between solutions and says nothing about creation (Chapter 20).

OPEN. The chapter leaves open what the unbounded growth of extra-time modes means for the time evolution of the fields (no well-posed initial-value problem is claimed; Chapter 8), which boundary condition belongs at $z = \pi/2$ (none is imposed here), and, for the matter-antimatter question, everything that Chapter 21 lists as needed beyond this theory.

7.35 Exercises

Exercise 1. For the oscillator with $\omega = 1$, $T = 1$, $q(0) = 0$, $q(1) = 1$, compute the action of the line $q = t$ and of the true path $q = \sin t / \sin 1$. Which is smaller, and why must it be so?

Answer. Line: $\dot q = 1$, $L = \frac12 - \frac12 t^2$, so $S = \int_0^1 (\frac12 - \frac12 t^2)\,dt = \frac12 - \frac16 = \frac13 = 0.333333$. True path: $\dot q = \cos t/\sin 1$, so $L = \frac{\cos^2 t - \sin^2 t}{2\sin^2 1} = \frac{\cos 2t}{2\sin^2 1}$ (the double-angle formula), and $S = \frac{1}{2\sin^2 1}\big[\frac12 \sin 2t\big]_0^1 = \frac{\sin 2}{4\sin^2 1} = \frac{2\sin 1\cos 1}{4\sin^2 1} = \frac12 \cot 1 = 0.321046$. The true path has the smaller action. It must: the line is the true path plus the shape $\xi = t - \sin t/\sin 1$, which vanishes at both ends, so by Section 7.2 $S[\text{line}] = S_0 + S_1 + S_2[\xi]$ with $S_1 = 0$ (the true path is stationary) and $S_2[\xi] = \int_0^1 (\frac12 \dot\xi^2 - \frac12 \xi^2)\,dt$. For the shapes $\sin(n\pi t)$ this coefficient is $(n^2\pi^2 - 1)/4 > 0$ (Section 7.2 with $T = 1$, $\omega = 1$; for $n = 1, 2, 3$ the values 2.217401, 9.619604, 21.956610 of Notebook 07d), and every smooth shape that vanishes at both ends is a combination of these sine shapes (a Fourier sine series; quoted here without proof), whose cross terms integrate to zero; so for $T = 1 < \pi$ the coefficient is positive for every nonzero such shape. Indeed $S[\text{line}] - S[\text{true}] = 0.333333 - 0.321046 = 0.012287 > 0$.

Exercise 2. Compute the first variation of the parabola $q = t^2$ for the shape $\xi_2 = \sin 2\pi t$ in two ways: from the definition $S_1 = \int_0^1 (\dot q\dot\xi - q\xi)\,dt$ and from $S_1 = \int_0^1 E\xi\,dt$ with $E = -2 - t^2$. Compare with Notebook 07d.

Answer. Second way first: $\int_0^1 \sin 2\pi t\,dt = 0$ (a whole period), and $\int_0^1 t^2 \sin 2\pi t\,dt = \big[-\frac{t^2\cos 2\pi t}{2\pi}\big]_0^1 + \frac{1}{\pi}\int_0^1 t\cos 2\pi t\,dt = -\frac{1}{2\pi} + \frac{1}{\pi}\Big(\big[\frac{t\sin 2\pi t}{2\pi}\big]_0^1 - \int_0^1 \frac{\sin 2\pi t}{2\pi}dt\Big) = -\frac{1}{2\pi} + 0$ (integration by parts twice; $\cos 2\pi = 1$, $\sin 2\pi = 0$). So $S_1 = -2\cdot 0 - (-\frac{1}{2\pi}) = \frac{1}{2\pi}$. First way: $\dot q = 2t$, $\dot\xi = 2\pi\cos 2\pi t$, so $S_1 = \int_0^1 4\pi t\cos 2\pi t\,dt - \int_0^1 t^2\sin 2\pi t\,dt = 4\pi\cdot 0 + \frac{1}{2\pi} = \frac{1}{2\pi}$, the same. Notebook 07d prints `parabola n = 2:  S1 = 1/(2*pi) = +0.159155` (In [2]).

Exercise 3. Let $F = 1 + 2\theta_0 + 3\theta_1\theta_2$ and $G = \theta_0 - \theta_1$. Compute FG and GF, and explain the difference with the rule $YX = (-1)^{kl}XY$.

Answer. $FG = \theta_0 - \theta_1 + 2\theta_0\theta_0 - 2\theta_0\theta_1 + 3\theta_1\theta_2\theta_0 - 3\theta_1\theta_2\theta_1$. Here $\theta_0\theta_0 = 0$; $\theta_1\theta_2\theta_1 = -\theta_1\theta_1\theta_2 = 0$; and $\theta_1\theta_2\theta_0 = +\theta_0\theta_1\theta_2$ (two exchanges). So $FG = \theta_0 - \theta_1 - 2\theta_0\theta_1 + 3\theta_0\theta_1\theta_2$. $GF = \theta_0 + 2\theta_0\theta_0 + 3\theta_0\theta_1\theta_2 - \theta_1 - 2\theta_1\theta_0 - 3\theta_1\theta_1\theta_2 = \theta_0 - \theta_1 + 2\theta_0\theta_1 + 3\theta_0\theta_1\theta_2$. The difference $FG - GF = -4\theta_0\theta_1$ comes only from the odd part $2\theta_0$ of F times the odd G: two odd elements anticommute ($k = l = 1$), while the even part $1 + 3\theta_1\theta_2$ commutes with everything ($k = 0$ or 2).

Exercise 4. For the odd monomial $F = \theta_0\theta_1\theta_2$ compute $\partial_L F/\partial\theta_1$ and $\partial_R F/\partial\theta_1$. Show that for every odd element the two derivatives are equal.

Answer. θ_1 stands at position $p = 1$ of a monomial of degree $n = 3$. Moving it left passes one generator: $\partial_L F/\partial\theta_1 = -\theta_0\theta_2$. Moving it right passes $n - 1 - p = 1$ generator: $\partial_R F/\partial\theta_1 = -\theta_0\theta_2$. In general the two signs differ by $(-1)^{(n-1-p)-p} = (-1)^{n-1}$; for odd n the exponent $n - 1$ is even, so the two derivatives of every odd monomial, and hence of every odd element, are equal (for even elements they are opposite, Section 7.11).

Exercise 5. A field with two complex Grassmann components has $S = \chi_0\psi_0 - \chi_1\psi_1$ (the matrix $C = \mathrm{diag}(1, -1)$). Compute S^2, S^3 and the "exponential" $1 + S + \frac12 S^2 + \frac16 S^3 + \dots$. Check the counts $\binom{2}{k}$ and the coefficients $\pm k!$ of Section 7.12.

Answer. The pairs $P_0 = \chi_0\psi_0$ and $P_1 = \chi_1\psi_1$ are even, commute and square to zero. $S^2 = P_0P_0 - P_0P_1 - P_1P_0 + P_1P_1 = -2P_0P_1 = -2\chi_0\psi_0\chi_1\psi_1$: one monomial ($\binom{2}{2} = 1$) with coefficient of size $2 = 2!$. $S^3 = S\cdot S^2 = -2(P_0 - P_1)P_0P_1 = 0$, because every term repeats a pair. So the series stops: $e^S = 1 + \chi_0\psi_0 - \chi_1\psi_1 - \chi_0\psi_0\chi_1\psi_1$, an exact finite sum. S itself has $\binom{2}{1} = 2$ monomials with coefficients $\pm 1 = \pm 1!$.

Exercise 6. For two real components and $M = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$, compute $\Theta^T M\Theta$ for a real Grassmann

column $\Theta = (\theta_0, \theta_1)^T$ and $q^T M q$ for a real column of ordinary numbers. Which part of M does each keep?

Answer. $\Theta^T M \Theta = \theta_0\theta_0 + 2\theta_0\theta_1 + 3\theta_1\theta_0 + 4\theta_1\theta_1 = 2\theta_0\theta_1 - 3\theta_0\theta_1 = -\theta_0\theta_1$. The antisymmetric part of M is $\frac{1}{2}(M - M^T) = \begin{pmatrix} 0 & -\frac{1}{2} \\ \frac{1}{2} & 0 \end{pmatrix}$, which gives $-\frac{1}{2}\theta_0\theta_1 + \frac{1}{2}\theta_1\theta_0 = -\theta_0\theta_1$, the same: only the antisymmetric part survives. For ordinary numbers $q^T M q = q_0^2 + 2q_0q_1 + 3q_1q_0 + 4q_1^2 = q_0^2 + 5q_0q_1 + 4q_1^2$, which is the form of the symmetric part $\begin{pmatrix} 1 & \frac{5}{2} \\ \frac{5}{2} & 4 \end{pmatrix}$: only the symmetric part survives.

Exercise 7. Take $b_4 = 1$ and suppose the extra times INFLATED like 3-space, with the scale factor $e^{a_4} \sin^{1/6} z$ (that is $g_{55} = -e^{2a_4} \sin^{1/3} z$). Compute $\gamma^{x_5}\Omega_{x_5}$ and $\gamma^\mu \Omega_\mu$. What does this show about the author's metric?

Answer. Now $f_5 = Es$ and $g_{55} = -E^2 s^2$, so $\partial_4 g_{55} = -2E^2 s^2 A_1$. The Christoffel symbol and the connection component are

$$\Gamma^{x_4}{}_{x_5 x_5} = -\frac{\partial_4 g_{55}}{2g_{44}} = -\frac{-2E^2 s^2 A_1}{-2} = -E^2 s^2 A_1,$$
$$\omega_{x_5 (x_4)(x_5)} = \frac{\eta_{44} f_4 \, \Gamma^{x_4}{}_{x_5 x_5}}{f_5} = \frac{E^2 s^2 A_1}{Es} = Es A_1,$$

so the a_4' part of Ω_{x_5} is $Es A_1 S^{(x_4)(x_5)} = \frac{1}{2} Es A_1 \gamma^{(x_4)}\gamma^{(x_5)}$, and the a_4' part of $\gamma^{x_5}\Omega_{x_5}$ is

$$\frac{\gamma^{(x_5)}}{Es} \cdot \tfrac{1}{2} Es A_1 \gamma^{(x_4)}\gamma^{(x_5)} = \tfrac{1}{2} A_1 \gamma^{(x_5)}\gamma^{(x_4)}\gamma^{(x_5)} = \tfrac{1}{2} A_1 \gamma^{(x_4)}$$

(as in Section 7.18, $\gamma^{(x_5)}\gamma^{(x_4)}\gamma^{(x_5)} = \gamma^{(x_4)}$). The H part is unchanged, $\frac{1}{2} H \gamma^{(x_0)}$, because the warp $\sin^{1/6} z$ is the same. So each of the six directions now contributes $+\frac{1}{2} a_4' \gamma^{(x_4)}$, and $\gamma^\mu \Omega_\mu = 3a_4' \gamma^{(x_4)} + 3H\gamma^{(x_0)}$. The cancellation of the time terms in the author's metric is due to the DEFLATION of the extra times. This is the negative control of the lead's independent check `negative_control_inflating_extra_times` in the report `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`.

Exercise 8. In flat space with $m = 2$, a plane wave of the 16-component field has the frame momenta $k_0 = 1$ along the hidden direction and $k_7 = 3$ along an extra time, all others zero. Does it oscillate or grow, and at what rate?

Answer. By the Clifford square of Section 7.5, $\omega^2 = m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2 = 4 + 1 - 9 = -4 < 0$: it grows, with the rate $\sqrt{4} = 2$. This agrees with the record's formula $\sqrt{K^2 - k_1^2 - k_2^2 - k_3^2 - k_0^2 - m^2} = \sqrt{9 - 1 - 4} = 2$ with the extra-time momentum $K = 3$ (the record writes it for x_5; the three extra times enter the formula in the same way).

Exercise 9. The reality condition with the matrix Γ is $\Psi = \Gamma \Psi^*$. What does it say about the 16 components? Is it consistent?

Answer. $\Gamma = \mathrm{diag}(-I_8, I_8)$, so the condition reads $\Psi_A = -\Psi_A^*$ for $A = 1, \ldots, 8$ and $\Psi_A = \Psi_A^*$ for $A = 9, \ldots, 16$: the upper eight components are purely imaginary and the lower eight real. It is consistent: applying it twice gives $\Psi = \Gamma(\Gamma\Psi^*)^* = \Gamma\Gamma\Psi = \Psi$, because Γ is real and $\Gamma^2 = 1$ (the condition $MM^* = 1$ of Section 7.29).

Exercise 10. Show that for $U = \frac{\lambda}{2}S^2$ the map Γ does NOT relate $\mathcal{L}_{m,\lambda}$ to $-\mathcal{L}_{-m,\lambda}$ when $\lambda \neq 0$: compute $\mathcal{L}_{m,\lambda}[\Gamma\Phi] + \mathcal{L}_{-m,\lambda}[\Phi]$ for a real commuting field.

Answer. By Section 7.29, $K[\Gamma\Phi] = -K[\Phi]$ and $S[\Gamma\Phi] = S[\Phi]$, so $\mathcal{L}_{m,\lambda}[\Gamma\Phi] = \sqrt{|g|}\,(-K - mS - \frac{\lambda}{2}S^2)$, while $\mathcal{L}_{-m,\lambda}[\Phi] = \sqrt{|g|}\,(K + mS - \frac{\lambda}{2}S^2)$. The sum is $-\lambda\sqrt{|g|}\,S^2$, which is not zero when $\lambda \neq 0$ and $S \neq 0$. The potential does not change sign under Γ, so the coupling must be reversed together with the mass: $(m, \lambda) \to (-m, -\lambda)$, as in Section 7.29.

8 Non-triviality, its exact scope, and well-posedness

When the author coupled the fields dirac16complex and dirac16complex00 to his primordial gravitational field, he asked for a test: the field equations must contain gravity through the canonical spin connection, unless spacetime is flat. This chapter answers that request exactly, and it answers a second question that every field equation must face before anyone can trust its solutions: does the equation decide the future from the present in a stable way? Both answers are more interesting than a plain yes. The gravitational term of the field equation is $3H\gamma^{(0)}\Psi$ in the natural frame on the backgrounds $b_4 = 1$ of the Revision record ($(3H\gamma^{(0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(4)})\Psi$ for the general metric with b_4), but a different, equally valid frame makes it vanish, and a change of the field variables removes it too; what no choice removes is the spin connection itself, because its curvature is the curvature of spacetime. And the field equation, with its four time-like directions, is not a well-posed evolution equation: waves along the three extra times grow, with growth rates that have no upper bound, and the deflation of the extra times pushes every such wave into growth. (This is proved exactly in flat 4+4 space and, for the author's metric, with coefficients frozen at one point; carrying it over to the author's varying coefficients needs a standard theorem that this chapter quotes without proof. Section 8.18 gives each status.) Four notebooks compute every statement anew from the definitions and reproduce the Revision record: Notebook 08c (the term in two frames), Notebook 08a (the growth rates), Notebook 08b (the onset of growth along the deflating history) and Notebook 08d (the rescaling and the two ends of the hidden direction).

8.1 What this chapter does

Why we need this chapter. The author's task, quoted in the file `Revision/README.md` of the repository, says of the two Lagrangians: "[1]- the Lagrangian for dirac16complex must be non-trivial (i.e., the Euler-Lagrange equations for dirac16complex always possess non-zero contributions from gravity (through the canonical spin-connection, unless we are in flat 4+4 spacetime), must be self consistent, must be checked and verified)", and "[2]" asks the same of dirac16complex00. Two questions hide in this request. First: what exactly is "the contribution from gravity through the canonical spin connection", and which part of it is a property of the field equation itself rather than of the way we chose to write the equation down? Second: a field equation is useful only if, given the field now, it determines the field later, and determines it stably, so that a tiny change now makes only a tiny change later. Is that true here? This chapter answers both questions exactly, and says precisely where each answer stops.

The answers in brief. Each item carries its label (the labels are explained at the end of this section).

- In the diagonal frame of the author's metric the gravitational term of the field equation is $\gamma^\mu \Omega_\mu \Psi = 3H\gamma^{(0)}\Psi$, for every history $a_4(x_4)$ and a constant b_4, as on the backgrounds $b_4 = 1$ (for a changing b_4 the term $\frac{3}{4}(b_4'/b_4)\gamma^{(4)}\Psi$ is added; Chapters 6 and 7). The time-direction pieces of the three inflating and the three deflating directions cancel; the six hidden-direction pieces add up to $3H$. The term is not zero for any field $\Psi \neq 0$ (PROVED; Sections 8.4 to 8.6; for a changing b_4 except at times where $|b_4'/b_4| = 4H$, Section 7.23).

- The spin connection vanishes only in the formal flat limit $a_4' = 0$ and $H = 0$ (at $b_4 = 1$; for every b_4 it vanishes only for $H = 0$), which is not a member of the author's family of metrics (PROVED; Section 8.6).

- The value $3H\gamma^{(0)}$ belongs to one frame and to one choice of field variables. In a frame boosted in the (x_4, x_0) plane with the rapidity $6Hx_4$ the term is identically zero (for a constant b_4), and the rescaling $\Psi = \sin^{-1/2} z\, \chi$ ($\sin^{-1/2} z\, b_4^{-3/4}\chi$ for a changing b_4) removes it in the diagonal frame (PROVED; Sections 8.9 and 8.30; Sections 6.16 and 6.18).

- What no choice removes: the spin connection itself vanishes in no frame, because its curvature is the curvature of spacetime, which is not zero for $H > 0$; and the frame factors $e^{-a_4}\sin^{-1/6} z$, $e^{a_4} b_4^{-1/2}\sin^{-1/6} z$ and $\tan z$ multiply every derivative in the field equation except the one along the time x_4 (whose factor is $1/f_4 = 1$). This is the exact, frame-independent content of the tests [1] and [2] (PROVED; Sections 8.7 and 8.10). The Revision record states this as a correction for the author: the tests hold in this qualified sense.

- The field equation can be solved for the time derivative $\partial_4\Psi$, but its initial-value problem is NOT well posed for data that depend on the extra times x_5, x_6, x_7: such waves grow, and their growth rates have no upper bound (PROVED in flat 4+4 space and, for the author's metric, with frozen coefficients, a MODEL; for the author's varying coefficients it follows from the Lax-Mizohata theorem, a standard theorem quoted without proof, so that step is ASSUMED; Sections 8.16 to 8.19).

- Along the deflating history every wave along an extra time eventually starts to grow (PROVED with frozen coefficients; followed numerically through the onset in a labelled model, COMPUTED; Sections 8.24 and 8.25).

- Even without extra-time dependence, the hidden direction has an open end at $z = \pi/2$; there the Revision record imposes no boundary condition, and fields that do not depend on x_0 grow when $m < 3H$, fed through that end. Which boundary condition is physical is OPEN (Sections 8.31 and 8.32).

What the chapter does, section by section. Section 8.2 sets the stage. Sections 8.3 to 8.11 compute the spin connection, the gravitational term, its frame dependence and the curvature, with Notebook 08c as the worked example (Sections 8.12 to 8.15). Sections 8.16 to 8.19 define well-posedness and show, with plane waves, that it fails; Notebook 08a is the example (Sections 8.20 to 8.23). Sections 8.24 and 8.25 follow waves along the deflating history; Notebook 08b is the example (Sections 8.26 to 8.29). Sections 8.30 to 8.32 change the field variables and study the two ends of the hidden direction; Notebook 08d is the example (Sections 8.33 to 8.36). Section 8.37 collects the exact scope in one table, Section 8.38 lists what we proved, computed and assumed, and Section 8.39 has the exercises.

The four notebooks.

notebook	what it computes	checks and figures	Revision records it reproduces
08c	the Christoffel symbols and the canonical spin connection of the diagonal frame and of a boosted frame, from the definitions; what cancels and what survives in $\gamma^{\mu}\Omega_{\mu}$; the connection vanishes only in flat space; the term in two frames; the curvature in both frames; the connection in the energy-momentum tensor	32 checks, 5 figures	`python-field-theory.json`, `wolfram-field-theory.json`, `python-scope.json` (all in `Revision/theory/reports/`), `Revision/kohn_sham/results/parameters.json`
08a	the mode matrix of a plane wave and its square; the growth rates of the extra-time waves; the Hadamard amplification; the Krein form	30 checks, 6 figures	`python-scope.json`, `wolfram-scope.json`, `python-field-theory.json`, `wolfram-field-theory.json`, `Revision/algebra/reports/python-algebra.json`, `Revision/pairing/reports/python-pairing.json`
08b	the scale factors along the deflating history; the frame momenta of a wave and its onset time; one wave followed through the onset with RK4 and compared with WKB formulas	25 checks, 5 figures	`parameters.json`, `python-field-theory.json`, `python-scope.json`
08d	the rescaling that removes the term; an exact family of solutions; the growing modes that do not depend on x_0; the boundary term at the patch end	23 checks, 5 figures	`python-field-theory.json`, `Revision/theory/field-theory.json`, `python-scope.json`, `parameters.json`

The chapter places the notebooks in the order in which it uses them: 08c, 08a, 08b, 08d.

How this chapter relates to Chapter 6. Chapter 6 introduces the vielbein, the canonical spin

connection, the contraction $\gamma^\mu \Omega_\mu = 3H\gamma^{(0)}$, and, with its Notebook 06b, a first look at the boosted frame, the curvature and the rescaling; it also proves local spin covariance in general. This chapter recomputes everything it needs, so that it can be read on its own, and goes further: what cancels and what survives direction by direction, the proof that the connection vanishes only in the flat limit, the boosted term derived from the uniqueness of the connection, the curvature compared in two frames, the exact family with its growing finite-norm members, the flux through the patch end, and, above all, the question of well-posedness, which Chapter 6 does not treat.

The metric with b_4. The author's metric of 2026-10-14 has a second function $b_4(x_4) > 0$ in the extra-time entries (Chapter 3; `Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`). The Revision record's scope reports and the backgrounds of its numerical work have $b_4 = 1$, and the four notebooks of this chapter compare with those reports, so their exact checks are made at $b_4 = 1$; Notebooks 06a and 06b and Chapter 7 treat a general b_4. Where a statement of this chapter changes for a changing b_4, the change is stated with it.

Labels. As everywhere in the book, every statement carries one of five labels. **PROVED** means exact: derived here line by line and confirmed by an exact check of a notebook, and, where the Revision record proves the same, the record file and its check are named. **COMPUTED** means a number obtained numerically by a notebook, with its measured accuracy. **ASSUMED** marks the inputs we choose or quote: standard theorems quoted without proof (each is named where it is used), the deflating history $a_4 = AHx_4$, which the Revision record calls a PRESCRIBED BACKGROUND, and two approximations that the notebooks label MODEL (frozen coefficients, and the local-frame model of Section 8.25). **OPEN** marks questions this record does not answer. No HYPOTHESIS enters this chapter. Nothing in this chapter concerns pairs of universes, their creation, or matter and antimatter; those questions belong to Chapters 18 to 21, which state precisely what is and what is not proved about them.

8.2 The stage: coordinates, metric, frame and the field equation

Coordinates. A point of the author's spacetime has eight coordinates, named as the author names them: x_1, x_2, x_3 are ordinary 3-space; x_4 is the time in which everything evolves; x_5, x_6, x_7 are the three **extra times**, directions that behave like time (they are time-like) and that deflate exponentially; x_0 is the **hidden** space direction. We write $z = 6Hx_0$, where $H > 0$ is a constant of the author; z runs from 0 (the **tip**) to $\pi/2$ (the **patch end**). In formulas the letter i always stands for one of the 3-space directions x_1, x_2, x_3 and the letter t for one of the extra times x_5, x_6, x_7. In Python, lists are counted from 0, like the author's coordinates: position k holds x_k, so position 0 is the hidden coordinate x_0 and position 4 the time x_4.

The metric. The author's metric is diagonal (Chapter 3). We write it with eight positive **scale factors** $f_0, \dots, f_7$:

$$g = \mathrm{diag}(f_0^2,\ f_1^2,\ f_2^2,\ f_3^2,\ -f_4^2,\ -f_5^2,\ -f_6^2,\ -f_7^2),$$

$$f_0 = \cot z, \quad f_1 = f_2 = f_3 = e^{a_4} \sin^{1/6} z, \quad f_4 = 1, \quad f_5 = f_6 = f_7 = e^{-a_4} b_4^{1/2} \sin^{1/6} z,$$

with $b_4 = 1$ on the backgrounds of the record (and in the checks of this chapter's notebooks).

A small step dx_μ along the direction x_μ has the proper length (the length measured with the metric) $f_\mu|dx_\mu|$. The function $a_4(x_4)$, the **metric function**, increases with the time: then the 3-space factor e^{a_4} grows (3-space **inflates**) and the extra-time factor e^{-a_4} shrinks (the extra times **deflate**). We write $a_4' = da_4/dx_4$ and $a_4'' = d^2a_4/dx_4^2$. With the **frame metric** $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ (in the order $x_0,\dots,x_7$) every diagonal entry is $g_{\mu\mu} = \eta_{\mu\mu}f_\mu^2$. The signs say which directions are space-like (+: x_0,x_1,x_2,x_3) and which are time-like (−: x_4,x_5,x_6,x_7); there are four of each, the signature (4,4). The product of the eight factors is the volume factor, $\sqrt{|g|} = f_0f_1\cdots f_7 = b_4^{3/2}\cos z$, which is $\cos z$ at $b_4 = 1$; it does not depend on the time there, because the inflation e^{3a_4} of 3-space and the deflation e^{-3a_4} of the extra times cancel (PROVED; `Revision/theory/reports/python-field-theory.json`, check `sqrt_det_g_equals_cos_z`; for b_4, `wolfram-field-theory-b4.json`, check `sqrt_det_g`). The value $H = 0$ is not a member of the author's family: at fixed x_0 the factor $\sin^{1/3} z$ goes to 0 and $\cot^2 z$ to infinity, so the metric degenerates (`Revision/theory/reports/wolfram-field-theory.json`, check `degenerate_at_H_0`). Every statement of this chapter assumes $H > 0$ and $0 < z < \pi/2$.

The diagonal frame. A **frame** (also called a **vielbein**) is a set of eight vectors, one for each direction $a = 0,\dots,7$, that have length 1 and are perpendicular to each other when measured with the metric. Its components ${e^a}_\mu$ (frame direction a, coordinate direction μ) obey $\sum_a \eta_{aa}{e^a}_\mu{e^a}_\nu = g_{\mu\nu}$. The **diagonal frame** is ${e^a}_\mu = f_a\delta^a_\mu$, where δ^a_μ is 1 for $a = \mu$ and 0 otherwise; its inverse is ${E_a}^\mu = \delta^\mu_a/f_a$. Indeed $\sum_a \eta_{aa}f_a\delta^a_\mu f_a\delta^a_\nu$ is zero for $\mu \neq \nu$ and $\eta_{\mu\mu}f_\mu^2 = g_{\mu\mu}$ for $\mu = \nu$.

The gamma matrices. The book uses the author's eight **real** 16×16 gamma matrices (Chapter 4), stored in the Revision file `Revision/algebra/gammas.json` in the order $x_0,\dots,x_7$; we write them $\gamma^{(0)},\dots,\gamma^{(7)}$ ($\gamma^{(4)}$ means the gamma of the direction x_4, and so on). Their entries are 0, 1 and −1. They obey the **Clifford relations**

$$\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}\,I_{16},$$

where I_{16} is the 16×16 unit matrix and $\eta^{ab} = \eta_{ab}$ (PROVED; `Revision/algebra/reports/python-algebra.json`, check `clifford_relation`). Two consequences are used in almost every line of this chapter: the square of each gamma is $\eta_{aa}I_{16}$, that is $+I_{16}$ for x_0,x_1,x_2,x_3 and $-I_{16}$ for x_4,x_5,x_6,x_7; and two different gammas **anticommute**, $\gamma^{(a)}\gamma^{(b)} = -\gamma^{(b)}\gamma^{(a)}$ for $a \neq b$. A third fact: the gammas of the space-like directions are symmetric matrices and those of the time-like directions antisymmetric, $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$ (the T means the transpose: rows become columns). The **coordinate gammas** are $\gamma^\mu = \sum_a {E_a}^\mu\gamma^{(a)}$; in the diagonal frame $\gamma^\mu = \gamma^{(\mu)}/f_\mu$. The matrix $C = \gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$ (Chapter 5) and the matrix $B = -iC\gamma^{(4)}$ (Chapters 5 and 10) appear in the notebooks; B is Hermitian, $B^2 = I_{16}$, with eight eigenvalues +1 and eight −1.

The two fields and their field equation. dirac16complex is a column Ψ of 16 complex **anticommuting** (Grassmann) components; dirac16complex00 is a column of 16 ordinary complex numbers (Chapter 7). Their Lagrangians have the same form, and so do their field equations (Chapter 7 derives them):

$$\gamma^\mu D_\mu\Psi = \big(m + U'(S)\big)\Psi, \qquad D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi.$$

Here ∂_μ is the partial derivative with respect to x_μ, the sum over $\mu = 0,\dots,7$ is understood (a repeated upper and lower index is summed), m is the mass, $S = \bar\Psi\Psi = \Psi^\dagger C\Psi$ is the scalar built

from the field and its **Dirac adjoint** $\bar\Psi = \Psi^\dagger C$ (the dagger means: transpose and take the complex conjugate of every entry), $U(S) = \frac{\lambda}{2}S^2$ is the potential, and $U'(S) = \lambda S$. The matrices Ω_μ are the **spinor connection**, built from the canonical spin connection in Section 8.4. Everything in this chapter is a statement about this matrix equation; it holds for both fields (for the Grassmann field, "$\Psi \neq 0$" means a configuration that is not identically zero). Written out in the diagonal frame at $b_4 = 1$ the equation reads (`Revision/theory/field-theory.json`, formula key `field_equation`; Section 8.5 derives the last term on the left; for a general b_4 the extra-time factor is $e^{a_4} b_4^{-1/2} \sin^{-1/6} z$ and the term $\frac{3}{4}(b_4'/b_4)\gamma^{(4)}\Psi$ is added on the left, `Revision/theory/field-theory-b4.json`, key `field_equation`):

$$
\begin{aligned}
&e^{-a_4} \sin^{-1/6} z \,\big(\gamma^{(1)}\partial_1 + \gamma^{(2)}\partial_2 + \gamma^{(3)}\partial_3\big)\Psi + \gamma^{(4)}\partial_4\Psi \\
&\quad + e^{a_4} \sin^{-1/6} z \,\big(\gamma^{(5)}\partial_5 + \gamma^{(6)}\partial_6 + \gamma^{(7)}\partial_7\big)\Psi + \tan z\, \gamma^{(0)}\partial_0\Psi + 3H\gamma^{(0)}\Psi = \big(m + U'(S)\big)\Psi .
\end{aligned}
$$

The derivative terms are $\sum_\mu \gamma^\mu \partial_\mu \Psi = \sum_\mu (\gamma^{(\mu)}/f_\mu)\partial_\mu\Psi$, with $1/f_0 = \tan z$, $1/f_i = e^{-a_4}\sin^{-1/6} z$, $1/f_4 = 1$ and $1/f_t = e^{a_4} b_4^{-1/2}\sin^{-1/6} z$ ($e^{a_4}\sin^{-1/6} z$ at $b_4 = 1$). These factors are the **frame factors**: they carry the metric into every derivative term.

Units. H, m and every momentum are measured in one unit, an inverse length, and the coordinates in its inverse; every printed number is a pure number in this unit. The examples use $H = m = 1$, the values of the Kohn-Sham record.

8.3 Frames, and why a frame is not unique

Why spinors need a frame. The gamma matrices are attached to the eight orthonormal frame directions, not to the coordinates: the Clifford relations $\{\gamma^{(a)}, \gamma^{(b)}\} = 2\eta^{ab}$ involve the fixed numbers η^{ab}, while the metric $g_{\mu\nu}$ changes from point to point. (The curly bracket $\{A, B\} = AB + BA$ is the **anticommutator**.) To write a spinor field equation in curved space one therefore needs a frame at every point, and the frame vectors turn from point to point; the canonical spin connection measures how they turn (Section 8.4).

A frame is not unique. At every point one may replace the eight frame vectors by combinations of them, $e'^a{}_\mu = \sum_b \Lambda^a{}_b e^b{}_\mu$, with a matrix Λ that keeps the frame metric: $\sum_a \eta_{aa}\Lambda^a{}_b\Lambda^a{}_c = \eta_{bc}$. The new frame describes the same metric. Line by line:

$$
\begin{aligned}
\sum_a \eta_{aa} e'^a{}_\mu e'^a{}_\nu &= \sum_a \eta_{aa}\Big(\sum_b \Lambda^a{}_b e^b{}_\mu\Big)\Big(\sum_c \Lambda^a{}_c e^c{}_\nu\Big) \\
&= \sum_{b,c}\Big(\sum_a \eta_{aa}\Lambda^a{}_b\Lambda^a{}_c\Big) e^b{}_\mu e^c{}_\nu \\
&= \sum_{b,c} \eta_{bc}\, e^b{}_\mu e^c{}_\nu = g_{\mu\nu}.
\end{aligned}
$$

The first line inserts the new frame; the second reorders the finite sums; the third uses the condition on Λ and then the frame condition of the old frame.

The boost in the (x_4, x_0) plane. The **hyperbolic functions** are $\cosh b = (e^b + e^{-b})/2$ and $\sinh b = (e^b - e^{-b})/2$. They obey

$$\cosh^2 b - \sinh^2 b = \frac{(e^b + e^{-b})^2 - (e^b - e^{-b})^2}{4} = \frac{4e^b e^{-b}}{4} = 1,$$

where the middle step expands both squares ($e^{2b} + 2 + e^{-2b}$ minus $e^{2b} - 2 + e^{-2b}$ leaves 4). The **boost** with **rapidity** b mixes the time-like frame vector of x_4 and the space-like frame vector of x_0:

$$e'^{(4)} = \cosh b\, e^{(4)} + \sinh b\, e^{(0)}, \qquad e'^{(0)} = \sinh b\, e^{(4)} + \cosh b\, e^{(0)},$$

and keeps the other six. It keeps the frame metric: the two mixed vectors enter the metric as $-e'^{(4)}e'^{(4)} + e'^{(0)}e'^{(0)}$ (products of components at the same μ and ν), and

$$\begin{aligned} -e'^{(4)}e'^{(4)} + e'^{(0)}e'^{(0)} &= -\big(\cosh^2 b\, e^{(4)}e^{(4)} + 2\cosh b \sinh b\, e^{(4)}e^{(0)} + \sinh^2 b\, e^{(0)}e^{(0)}\big) \\ &\quad + \big(\sinh^2 b\, e^{(4)}e^{(4)} + 2\sinh b \cosh b\, e^{(4)}e^{(0)} + \cosh^2 b\, e^{(0)}e^{(0)}\big) \\ &= -(\cosh^2 b - \sinh^2 b)\, e^{(4)}e^{(4)} + (\cosh^2 b - \sinh^2 b)\, e^{(0)}e^{(0)} \\ &= -e^{(4)}e^{(4)} + e^{(0)}e^{(0)}. \end{aligned}$$

The first two lines multiply out the two squares (here $e^{(4)}e^{(0)}$ stands for the symmetric combination of the two orders), the third collects the terms (the mixed terms cancel), and the fourth uses $\cosh^2 b - \sinh^2 b = 1$. The rapidity may change from point to point; we take $b = \beta x_4 + b_0$ with two constants β (the **rapidity rate**) and b_0, a different boost at every time. Every such frame describes the author's metric exactly (PROVED; `Revision/theory/reports/python-scope.json`, check `boosted_frame_reproduces_metric`, and the same check of `wolfram-scope.json`).

The principle. A change of frame changes the spin connection and the coordinate gammas, and the field changes with it, $\Psi' = S\Psi$ with an invertible 16×16 matrix $S(x)$ (Section 8.9 finds S for the boost). A statement about the field equation is a property of the equation itself only if it holds in every frame. A statement that holds in one frame only describes how we chose to write the equation.

8.4 The Christoffel symbols and the canonical spin connection of the diagonal frame

Christoffel symbols. The **Christoffel symbols** ${\Gamma^\lambda}_{\mu\nu}$ say how the coordinate directions turn from point to point (Chapter 3). In this section and the next five the metric is taken at $b_4 = 1$, as in the record's scope reports and in Notebook 08c; Sections 7.18 and 6.3 to 6.8 give the same objects for a general b_4, where the extra-time rate $-a'_4$ becomes $-a'_4 + b'_4/(2b_4)$ and the frame factor of the extra times gets the factor $b_4^{1/2}$. For a diagonal metric they are

$${\Gamma^\lambda}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}(\partial_\mu g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu}),$$

and they are symmetric in the two lower indices. The author's metric depends only on x_4 (through a_4) and on x_0 (through z), and $dz/dx_0 = 6H$. It has 25 independent nonzero symbols (PROVED; `Revision/theory/reports/python-field-theory.json`, check `christoffel_symmetric_metric_compatible`):

symbol	value	symbol	value
${\Gamma^{x_i}}_{x_i x_4}$	a_4'	${\Gamma^{x_i}}_{x_i x_0}$	$H\cot z$
${\Gamma^{x_t}}_{x_t x_4}$	$-a_4'$	${\Gamma^{x_t}}_{x_t x_0}$	$H\cot z$
${\Gamma^{x_4}}_{x_i x_i}$	$e^{2a_4}\sin^{1/3} z\, a_4'$	${\Gamma^{x_4}}_{x_t x_t}$	$e^{-2a_4}\sin^{1/3} z\, a_4'$
${\Gamma^{x_0}}_{x_i x_i}$	$-e^{2a_4}H\sin^{4/3} z/\cos z$	${\Gamma^{x_0}}_{x_t x_t}$	$e^{-2a_4}H\sin^{4/3} z/\cos z$
${\Gamma^{x_0}}_{x_0 x_0}$	$-6H/(\sin z\cos z)$		

(each of the eight entries of the first four rows stands for three symbols, one for each value of i or of t: 24 symbols, plus the last one: 25). Chapter 3 derives all of them from the metric, and Notebook 08c computes all of them again; here we repeat the three that this chapter needs most. First, ${\Gamma^{x_1}}_{x_1 x_4}$: only the term $\partial_4 g_{11}$ survives, and $g_{11} = e^{2a_4}\sin^{1/3} z$ has $\partial_4 g_{11} = 2a_4' g_{11}$ (chain rule), so ${\Gamma^{x_1}}_{x_1 x_4} = 2a_4' g_{11}/(2g_{11}) = a_4'$. Second, ${\Gamma^{x_1}}_{x_1 x_0} = \partial_0 g_{11}/(2g_{11})$, and $\partial_0 \sin^{1/3} z = \frac{1}{3}\sin^{-2/3} z\cos z \cdot 6H$, so ${\Gamma^{x_1}}_{x_1 x_0} = \frac{1}{2}\cdot\frac{1}{3}\cdot\frac{\cos z}{\sin z}\cdot 6H = H\cot z$. Third, ${\Gamma^{x_5}}_{x_5 x_4} = \partial_4 g_{55}/(2g_{55})$ with $g_{55} = -e^{-2a_4}\sin^{1/3} z$, $\partial_4 g_{55} = -2a_4' g_{55}$, so ${\Gamma^{x_5}}_{x_5 x_4} = -a_4'$: the sign is opposite to that of 3-space because the extra times deflate. A useful rule follows the same way: for a diagonal metric, ${\Gamma^{\mu}}_{\mu\nu} = \partial_\nu g_{\mu\mu}/(2g_{\mu\mu}) = \partial_\nu \ln f_\mu$ (no sum over μ), because $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$ gives $\partial_\nu g_{\mu\mu}/(2g_{\mu\mu}) = 2\eta_{\mu\mu} f_\mu \partial_\nu f_\mu/(2\eta_{\mu\mu} f_\mu^2) = \partial_\nu f_\mu/f_\mu$.

The canonical spin connection. The **canonical spin connection** of a frame is (Chapter 6)

$$\omega_\mu{}^a{}_b = \sum_\nu e^a{}_\nu \Big(\partial_\mu E_b{}^\nu + \sum_\lambda {\Gamma^\nu}_{\mu\lambda} E_b{}^\lambda\Big), \qquad \omega_{\mu ab} = \eta_{aa}\,\omega_\mu{}^a{}_b.$$

It obeys the **vielbein postulate** $\partial_\mu e^a{}_\nu - \sum_\lambda {\Gamma^\lambda}_{\mu\nu} e^a{}_\lambda + \sum_b \omega_\mu{}^a{}_b e^b{}_\nu = 0$, and $\omega_{\mu ab}$ is antisymmetric in a, b (PROVED for the diagonal frame; `python-field-theory.json`, checks `vielbein_postulate` and `spin_connection_antisymmetric`). For the diagonal frame we compute it line by line:

$$\begin{aligned}\omega_\mu{}^a{}_b &= \sum_\nu f_a \delta^a_\nu \Big(\partial_\mu \frac{\delta^\nu_b}{f_b} + \sum_\lambda {\Gamma^\nu}_{\mu\lambda}\frac{\delta^\lambda_b}{f_b}\Big)\\ &= f_a\Big(\partial_\mu \frac{\delta^a_b}{f_b} + \frac{{\Gamma^a}_{\mu b}}{f_b}\Big).\end{aligned}$$

The first line inserts $e^a{}_\nu = f_a\delta^a_\nu$ and $E_b{}^\nu = \delta^\nu_b/f_b$; the second carries out the sums (the delta keeps only $\nu = a$ and $\lambda = b$). Two cases:

- $a = b$: $\omega_\mu{}^a{}_a = f_a\partial_\mu(1/f_a) + {\Gamma^a}_{\mu a} = -\partial_\mu \ln f_a + \partial_\mu \ln f_a = 0$, by the derivative of $1/f$ ($f\,\partial(1/f) = -\partial f/f$) and the rule ${\Gamma^a}_{\mu a} = \partial_\mu \ln f_a$ above.
- $a \neq b$: $\delta^a_b = 0$, so $\omega_\mu{}^a{}_b = (f_a/f_b)\,{\Gamma^a}_{\mu b}$.

So a component with $a \neq b$ is nonzero exactly when the Christoffel symbol ${\Gamma^a}_{\mu b}$ is. The table shows that for $\mu = x_4$ and $\mu = x_0$ every symbol ${\Gamma^a}_{\mu b}$ with $a \neq b$ vanishes (the nonzero symbols with a lower index x_4 or x_0 all have $a = b$, like ${\Gamma^{x_i}}_{x_i x_4}$), so $\omega_{x_4} = \omega_{x_0} = 0$. For $\mu = x_i$ the symbols with $a \neq b$ are ${\Gamma^{x_i}}_{x_i x_4}$, ${\Gamma^{x_i}}_{x_i x_0}$, ${\Gamma^{x_4}}_{x_i x_i}$ and ${\Gamma^{x_0}}_{x_i x_i}$; for $\mu = x_t$ the same with t. We compute one member of each antisymmetric pair, with $a < b$, line by line:

- $\omega_{x_i}{}^{(i)}{}_{(4)} = (f_i/f_4)\,{\Gamma^{x_i}}_{x_i x_4} = e^{a_4}\sin^{1/6} z\cdot a_4'$, and lowering with $\eta_{ii} = +1$: $\omega_{x_i\,(i)(4)} = a_4' e^{a_4}\sin^{1/6} z$.

- $\omega_{x_i}{}^{(i)}{}_{(0)} = (f_i/f_0)\,\Gamma^{x_i}{}_{x_i x_0} = e^{a_4}\sin^{1/6} z\,\tan z \cdot H\cot z = He^{a_4}\sin^{1/6} z$ (because $\tan z\cot z = 1$), so $\omega_{x_i\,(i)(0)} = He^{a_4}\sin^{1/6} z$.
- $\omega_{x_t}{}^{(4)}{}_{(t)} = (f_4/f_t)\,\Gamma^{x_4}{}_{x_t x_t} = e^{a_4}\sin^{-1/6} z\cdot e^{-2a_4}\sin^{1/3} z\,a_4' = a_4' e^{-a_4}\sin^{1/6} z$, and lowering with $\eta_{44} = -1$: $\omega_{x_t\,(4)(t)} = -a_4' e^{-a_4}\sin^{1/6} z$.
- $\omega_{x_t}{}^{(t)}{}_{(0)} = (f_t/f_0)\,\Gamma^{x_t}{}_{x_t x_0} = e^{-a_4}\sin^{1/6} z\,\tan z\cdot H\cot z = He^{-a_4}\sin^{1/6} z$, and lowering with $\eta_{tt} = -1$: $\omega_{x_t\,(t)(0)} = -He^{-a_4}\sin^{1/6} z$.

Antisymmetry can be seen on one example: $\omega_{x_i}{}^{(4)}{}_{(i)} = (f_4/f_i)\Gamma^{x_4}{}_{x_i x_i} = e^{-a_4}\sin^{-1/6} z\cdot e^{2a_4}\sin^{1/3} z\,a_4' = a_4' e^{a_4}\sin^{1/6} z$, and lowering with $\eta_{44} = -1$ gives $\omega_{x_i\,(4)(i)} = -a_4' e^{a_4}\sin^{1/6} z = -\omega_{x_i\,(i)(4)}$. With three values of i and three of t this gives exactly 12 independent nonzero components $\omega_{\mu ab}$ with $a<b$ (PROVED; `Revision/theory/reports/wolfram-field-theory.json`, check `omega_components`).

The spinor connection. The **generators** $S^{ab} = \frac{1}{4}[\gamma^{(a)},\gamma^{(b)}]$, with the **commutator** $[A,B] = AB - BA$, are, for $a\neq b$, $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)}) = \frac{1}{4}(2\gamma^{(a)}\gamma^{(b)}) = \frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ (because the two gammas anticommute). The spinor connection is $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab} = \sum_{a<b}\omega_{\mu ab}S^{ab}$ (the pairs (a,b) and (b,a) give equal terms, because both $\omega_{\mu ab}$ and S^{ab} change sign). Inserting the components:

$$\begin{aligned}
\Omega_{x_i} &= \omega_{x_i(i)(4)}S^{i4} + \omega_{x_i(i)(0)}S^{i0} = \tfrac{1}{2}e^{a_4}\sin^{1/6} z\,\big(a_4'\gamma^{(i)}\gamma^{(4)} + H\gamma^{(i)}\gamma^{(0)}\big),\\
\Omega_{x_t} &= \omega_{x_t(4)(t)}S^{4t} + \omega_{x_t(t)(0)}S^{t0} = -\tfrac{1}{2}e^{-a_4}\sin^{1/6} z\,\big(a_4'\gamma^{(4)}\gamma^{(t)} + H\gamma^{(t)}\gamma^{(0)}\big),\\
\Omega_{x_4} &= \Omega_{x_0} = 0.
\end{aligned}$$

These are the formulas of the record (`Revision/theory/field-theory.json`, formula key `Omega_components`). Two exact properties of this connection are used below. It makes the gammas **covariantly constant**: $\partial_\mu\gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu,\gamma^\nu] = 0$ for all 64 pairs (μ,ν) (PROVED; `python-field-theory.json`, check `covariant_constancy_D_mu_gamma_nu`). And its **curvature** $F_{\mu\nu} = \partial_\mu\Omega_\nu - \partial_\nu\Omega_\mu + [\Omega_\mu,\Omega_\nu]$ equals $\frac{1}{4}\sum_{\rho,\sigma}R_{\rho\sigma\mu\nu}\gamma^\rho\gamma^\sigma$, where $R_{\rho\sigma\mu\nu}$ is the Riemann tensor of the metric with its first index lowered (PROVED; `python-field-theory.json`, check `spinor_curvature_equals_riemann`, and `wolfram-field-theory.json`, check `spin_curvature_equals_Riemann`).

8.5 What cancels and what survives: the term $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$

The gravitational term of the field equation is $\gamma^\mu D_\mu\Psi - \gamma^\mu\partial_\mu\Psi = \gamma^\mu\Omega_\mu\Psi$. We compute the matrix $\gamma^\mu\Omega_\mu$ direction by direction (no sum), then add.

A 3-space direction x_i. Line by line:

$$\begin{aligned}
\gamma^{x_i}\Omega_{x_i} &= \frac{\gamma^{(i)}}{e^{a_4}\sin^{1/6} z}\cdot\tfrac{1}{2}e^{a_4}\sin^{1/6} z\,\big(a_4'\gamma^{(i)}\gamma^{(4)} + H\gamma^{(i)}\gamma^{(0)}\big)\\
&= \tfrac{1}{2}\big(a_4'\gamma^{(i)}\gamma^{(i)}\gamma^{(4)} + H\gamma^{(i)}\gamma^{(i)}\gamma^{(0)}\big)\\
&= \tfrac{1}{2}a_4'\gamma^{(4)} + \tfrac{1}{2}H\gamma^{(0)}.
\end{aligned}$$

The first line inserts $\gamma^{x_i} = \gamma^{(i)}/f_i$ and Ω_{x_i}; the second cancels the scale factor against its inverse; the third uses $(\gamma^{(i)})^2 = +I_{16}$ (a space-like direction).

An extra time x_t. Line by line:

$$\begin{aligned}\gamma^{x_t}\Omega_{x_t} &= \frac{\gamma^{(t)}}{e^{-a_4}\sin^{1/6} z}\cdot\Big(-\tfrac{1}{2}e^{-a_4}\sin^{1/6} z\Big)\big(a_4'\gamma^{(4)}\gamma^{(t)}+H\gamma^{(t)}\gamma^{(0)}\big)\\ &= -\tfrac{1}{2}\big(a_4'\gamma^{(t)}\gamma^{(4)}\gamma^{(t)}+H\gamma^{(t)}\gamma^{(t)}\gamma^{(0)}\big)\\ &= -\tfrac{1}{2}\big(-a_4'\gamma^{(4)}\gamma^{(t)}\gamma^{(t)}+H\gamma^{(t)}\gamma^{(t)}\gamma^{(0)}\big)\\ &= -\tfrac{1}{2}\big(a_4'\gamma^{(4)}-H\gamma^{(0)}\big) = -\tfrac{1}{2}a_4'\gamma^{(4)}+\tfrac{1}{2}H\gamma^{(0)}.\end{aligned}$$

The first line inserts $\gamma^{x_t}=\gamma^{(t)}/f_t$ and Ω_{x_t}; the second cancels the scale factors; the third moves $\gamma^{(t)}$ to the right past $\gamma^{(4)}$, which changes the sign (they anticommute); the fourth uses $(\gamma^{(t)})^2=-I_{16}$ (a time-like direction) in both terms.

The time x_4 and the hidden direction x_0. $\Omega_{x_4}=\Omega_{x_0}=0$, so $\gamma^{x_4}\Omega_{x_4}=\gamma^{x_0}\Omega_{x_0}=0$.

The sum. The coefficient of $\gamma^{(4)}$ is $3\cdot\frac{1}{2}a_4'+3\cdot(-\frac{1}{2}a_4')=0$: the three inflating directions and the three deflating extra times cancel exactly. The coefficient of $\gamma^{(0)}$ is $6\cdot\frac{1}{2}H=3H$: the six directions that carry the warp $\sin^{1/6} z$ add up. Hence

$$\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$$

for every history $a_4(x_4)$, every $H>0$ and every point. This is PROVED, and the Revision record proves it twice: the sympy report `python-field-theory.json` has the checks `time_terms_cancel_hidden_term_survives` and `gamma_mu_Omega_mu_equals_3H_gamma_x0`, and the independent Wolfram report `wolfram-field-theory.json` has the checks `gammaOmega_x4_terms_cancel` and `gammaOmega_equals_3H_gamma_x0`. The cancellation happens because 3-space inflates at exactly the rate at which the extra times deflate: the same balance makes the volume factor $\cos z$ independent of the time. Exercise 2 of Section 8.39 shows what would happen if the extra times inflated too. For a changing b_4 the extra times deflate at the rate $a_4'-b_4'/(2b_4)$, and the sum is $3H\gamma^{(0)}+\frac{3}{4}(b_4'/b_4)\gamma^{(4)}$ (Section 7.18; `python-field-theory-b4.json`, check `gammaOmega_total`).

The divergence form. The same matrix has a second, shorter formula. The rule $\Gamma^\mu{}_{\mu\nu}=\partial_\nu\ln f_\mu$ of Section 8.4, summed over μ, gives $\sum_\mu\Gamma^\mu{}_{\mu\nu}=\partial_\nu\ln(f_0\cdots f_7)=\partial_\nu\ln\sqrt{|g|}$. Now sum the covariant constancy of Section 8.4 over $\mu=\nu$:

$$\begin{aligned}0 &= \sum_\mu\Big(\partial_\mu\gamma^\mu+\sum_\lambda\Gamma^\mu{}_{\mu\lambda}\gamma^\lambda+\Omega_\mu\gamma^\mu-\gamma^\mu\Omega_\mu\Big)\\ &= \sum_\mu\partial_\mu\gamma^\mu+\sum_\lambda(\partial_\lambda\ln\sqrt{|g|})\gamma^\lambda+\sum_\mu(\Omega_\mu\gamma^\mu-\gamma^\mu\Omega_\mu)\\ &= \frac{1}{\sqrt{|g|}}\sum_\mu\partial_\mu(\sqrt{|g|}\gamma^\mu)-2\sum_\mu\gamma^\mu\Omega_\mu.\end{aligned}$$

The first line is the covariant constancy with $\nu=\mu$, summed; the second uses the summed rule for the Christoffel symbols; the third combines the first two sums by the product rule ($\partial(\sqrt{|g|}\gamma)=\sqrt{|g|}\,\partial\gamma+(\partial\sqrt{|g|})\gamma$, divided by $\sqrt{|g|}$) and uses $\Omega_\mu\gamma^\mu=-\gamma^\mu\Omega_\mu$ for each μ (Section 8.8 proves this anticommutation). Therefore

$$\gamma^\mu \Omega_\mu = \frac{1}{2\sqrt{|g|}} \sum_\mu \partial_\mu (\sqrt{|g|}\gamma^\mu).$$

For the author's metric only $\mu = x_0$ contributes: $\sqrt{|g|}\gamma^{x_0} = \cos z \tan z\, \gamma^{(0)} = \sin z\, \gamma^{(0)}$, whose x_0 derivative is $6H \cos z\, \gamma^{(0)}$, and dividing by $2\cos z$ gives $3H\gamma^{(0)}$ again; the term with $\mu = x_4$ is $\partial_4(\cos z\, \gamma^{(4)}) = 0$ because $\cos z$ does not depend on the time (for a changing b_4, $\sqrt{|g|} = b_4^{3/2} \cos z$ and this term gives $\frac{3}{4}(b_4'/b_4)\gamma^{(4)}$), and the other six vanish because nothing depends on $x_1, x_2, x_3, x_5, x_6, x_7$ (PROVED; `python-field-theory.json`, check `divergence_of_sqrtg_gamma`). In words: the term is half the divergence of the coordinate gammas weighted with the volume factor, a **half-density term**.

8.6 Non-triviality: the connection vanishes only in flat space

The connection is zero only in the flat limit. Each of the 12 components of Section 8.4 is a_4' times one of the factors $\pm e^{\pm a_4} \sin^{1/6} z$ (six components), or H times one of them (the other six). These factors are never zero for $0 < z < \pi/2$: an exponential is never zero, and $\sin z > 0$ there. The 28 matrices S^{ab} with $a < b$ are **linearly independent**: no combination of them with coefficients that are not all zero gives the zero matrix (Notebook 08c checks it: written as 28 rows of $16 \times 16 = 256$ numbers they have rank 28). So, line by line:

1. $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$ is zero exactly when all its coefficients $\omega_{\mu ab}$ are zero (linear independence).
2. If $a_4' \neq 0$, the six components of the form $a_4' \times$(factor) are not zero; if $H \neq 0$, the six of the form $H \times$(factor) are not zero.
3. Therefore $\Omega_\mu = 0$ for every μ if and only if $a_4' = 0$ and $H = 0$.

The case $H = 0$ is the formal flat limit; it is not a member of the author's family (Section 8.2). For every metric of the family the canonical spin connection is therefore not zero. This is PROVED; in the Revision record it is the check `nontriviality_Omega_zero_iff_flat` of the sympy report `python-field-theory.json` and the check `Omega_vanishes_iff_a4prime_and_H_vanish` of the Wolfram report `wolfram-field-theory.json`.

The term is not zero for any field that is not zero. Suppose $3H\gamma^{(0)}\Psi = 0$ at some point. Multiply from the left by $\gamma^{(0)}/(3H)$ (allowed, since $H > 0$): $\gamma^{(0)}\gamma^{(0)}\Psi = 0$, and $(\gamma^{(0)})^2 = I_{16}$ gives $\Psi = 0$. So in the diagonal frame the gravitational term $3H\gamma^{(0)}\Psi$ is nonzero wherever the field is nonzero (PROVED; `wolfram-field-theory.json`, checks `nontriviality_1_dirac16complex` and `nontriviality_2_dirac16complex00`).

What this proves, and what it does not. Read literally, in the diagonal frame and for the field variables Ψ, the tests [1] and [2] hold: the field equations always contain the nonzero gravitational term $3H\gamma^{(0)}\Psi$, and the spin connection vanishes only in flat 4+4 space. Sections 8.7 to 8.10 and 8.30 make precise which parts of this statement survive a change of frame or of variables.

8.7 The deflation is invisible in the term, but not in the curvature

No a_4 in the term. The result $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$ contains neither a_4 nor a_4' nor a_4'': the deflation of the extra times leaves no trace in this term (PROVED; `Revision/theory/reports/python-scope.json`, check `gammaOmega_blind_to_the_deflation`). Along the deflating history the separate pieces do change: the components $\omega_{x_1\,(1)(4)}$ and $\omega_{x_1\,(1)(8)}$ of the inflating direction grow like e^{a_4}, those of a deflating extra time shrink like e^{-a_4}. Contracted with the coordinate gammas, which carry the inverse factors, each piece becomes constant, and the pieces then cancel; Notebook 08c draws this (Figure 08c.2).

The geometry of the a_4 sector is curved. The mixed Ricci tensor of the author's metric (Chapter 3) is diagonal, with

$$R^{x_i}{}_{x_i} = a_4'' - 6H^2, \quad R^{x_4}{}_{x_4} = 6(a_4')^2, \quad R^{x_t}{}_{x_t} = -a_4'' - 6H^2, \quad R^{x_0}{}_{x_0} = -6H^2,$$

and the Ricci scalar is $R = 3(a_4'' - 6H^2) + 6(a_4')^2 + 3(-a_4'' - 6H^2) - 6H^2 = 6\big((a_4')^2 - 7H^2\big)$ (adding the eight diagonal entries: the a_4'' terms cancel and $-18H^2 - 18H^2 - 6H^2 = -42H^2$). (PROVED; `wolfram-field-theory.json`, check `ricci_mixed_components`, and `python-field-theory.json`, check `curvature_nonzero_flat_only_formally`.) Since $R^{x_0}{}_{x_0} = -6H^2 < 0$ for every $H > 0$ and every a_4, the metric is never flat (`wolfram-field-theory.json`, check `never_flat_for_H_positive`). And $R^{x_4}{}_{x_4} = 6(a_4')^2$ is not zero whenever a_4 changes: the deflation is real curvature, which the term $\gamma^\mu\Omega_\mu$ does not see.

Where the deflation does enter. It enters the field equation through the frame factors of the derivative terms (Section 8.2): the 3-space derivatives carry $e^{-a_4}\sin^{-1/6} z$, which shrinks as 3-space inflates, and the extra-time derivatives carry $e^{a_4}b_4^{-1/2}\sin^{-1/6} z$ ($e^{a_4}\sin^{-1/6} z$ at $b_4 = 1$), which grows as the extra times deflate. Sections 8.24 and 8.25 show what this growth does to waves along the extra times.

8.8 The connection drops out of the Lagrangian but not out of the field equation

An anticommutation for each direction. For each μ separately (no sum), $\{\gamma^\mu, \Omega_\mu\} = 0$. For $\mu = x_i$ it suffices to check the two products in Ω_{x_i} against $\gamma^{(i)}$:

$$\gamma^{(i)}\big(\gamma^{(i)}\gamma^{(4)}\big) + \big(\gamma^{(i)}\gamma^{(4)}\big)\gamma^{(i)} = \gamma^{(4)} + \gamma^{(i)}\gamma^{(4)}\gamma^{(i)} = \gamma^{(4)} - \gamma^{(4)}\gamma^{(i)}\gamma^{(i)} = \gamma^{(4)} - \gamma^{(4)} = 0,$$

using $(\gamma^{(i)})^2 = I_{16}$, then moving $\gamma^{(i)}$ past $\gamma^{(4)}$ (one sign change), then $(\gamma^{(i)})^2 = I_{16}$ again. For the second product the same three steps read $\gamma^{(i)}\gamma^{(i)}\gamma^{(0)} + \gamma^{(i)}\gamma^{(0)}\gamma^{(i)} = \gamma^{(0)} - \gamma^{(0)}\gamma^{(i)}\gamma^{(i)} = \gamma^{(0)} - \gamma^{(0)} = 0$. For $\mu = x_t$ the products are $\gamma^{(4)}\gamma^{(t)}$ and $\gamma^{(t)}\gamma^{(0)}$: $\gamma^{(t)}\gamma^{(4)}\gamma^{(t)} + \gamma^{(4)}\gamma^{(t)}\gamma^{(t)} = -\gamma^{(4)}\gamma^{(t)}\gamma^{(t)} + \gamma^{(4)}\gamma^{(t)}\gamma^{(t)} = 0$, and $\gamma^{(t)}\gamma^{(t)}\gamma^{(0)} + \gamma^{(t)}\gamma^{(0)}\gamma^{(t)} = \gamma^{(t)}\gamma^{(t)}\gamma^{(0)} - \gamma^{(t)}\gamma^{(t)}\gamma^{(0)} = 0$. For $\mu = x_4, x_0$ the connection is zero. (PROVED; `python-scope.json`, check `connection_free_lagrangian_same_equations`, and `python-field-theory.json`, check `anticommutator_gamma_Omega_vanishes`.)

The connection drops out of the Lagrangian. The kinetic part of the Lagrangian (Chapter 7) is $\sqrt{|g|}\cdot\frac{1}{2}\big(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi\big)$ with $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$. Its connection part is, line by line,

$$\tfrac{1}{2}\big(\bar\Psi\gamma^\mu\Omega_\mu\Psi - (-\bar\Psi\Omega_\mu)\gamma^\mu\Psi\big) = \tfrac{1}{2}\bar\Psi\big(\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu\big)\Psi = \tfrac{1}{2}\bar\Psi\{\gamma^\mu, \Omega_\mu\}\Psi = 0.$$

The first step keeps only the Ω parts of the two covariant derivatives; the second collects them between $\bar\Psi$ and Ψ; the third is the anticommutation just proved, for each μ. So in this metric the Lagrangian with the canonical spin connection equals the Lagrangian with the connection left out (PROVED; `python-scope.json`, check `connection_free_lagrangian_same_equations`).

But the field equation keeps the term. Take the connection-free symmetric Lagrangian of the commuting field, $\mathcal{L}_0 = \sqrt{|g|}\big[\tfrac{1}{2}(\bar\Psi\gamma^\mu\partial_\mu\Psi - \partial_\mu\bar\Psi\gamma^\mu\Psi) - mS - U(S)\big]$, and vary it with respect to $\bar\Psi$, treating the components of $\bar\Psi$ and of Ψ as independent variables (Chapter 7 explains why this is allowed). The Euler-Lagrange expression is $\partial\mathcal{L}_0/\partial\bar\Psi - \sum_\mu \partial_\mu(\partial\mathcal{L}_0/\partial(\partial_\mu\bar\Psi))$. Line by line:

$$\begin{aligned}
\frac{\partial\mathcal{L}_0}{\partial\bar\Psi} &= \sqrt{|g|}\big[\tfrac{1}{2}\gamma^\mu\partial_\mu\Psi - m\Psi - U'(S)\Psi\big],\\
\frac{\partial\mathcal{L}_0}{\partial(\partial_\mu\bar\Psi)} &= -\tfrac{1}{2}\sqrt{|g|}\gamma^\mu\Psi,\\
\frac{\partial\mathcal{L}_0}{\partial\bar\Psi} - \sum_\mu \partial_\mu\Big(\frac{\partial\mathcal{L}_0}{\partial(\partial_\mu\bar\Psi)}\Big) &= \sqrt{|g|}\big[\tfrac{1}{2}\gamma^\mu\partial_\mu\Psi - (m+U')\Psi\big] + \tfrac{1}{2}\sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)\Psi + \tfrac{1}{2}\sqrt{|g|}\gamma^\mu\partial_\mu\Psi\\
&= \sqrt{|g|}\Big[\gamma^\mu\partial_\mu\Psi + \frac{1}{2\sqrt{|g|}}\sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)\Psi - (m+U')\Psi\Big].
\end{aligned}$$

The first line differentiates the terms that contain $\bar\Psi$ without a derivative ($\partial S/\partial\bar\Psi = \Psi$ and $\partial U/\partial\bar\Psi = U'(S)\Psi$); the second differentiates the one term that contains $\partial_\mu\bar\Psi$; the third subtracts the derivative of the second line, using the product rule $\partial_\mu(\sqrt{|g|}\gamma^\mu\Psi) = \partial_\mu(\sqrt{|g|}\gamma^\mu)\Psi + \sqrt{|g|}\gamma^\mu\partial_\mu\Psi$; the fourth collects the two halves of $\gamma^\mu\partial_\mu\Psi$. Setting it to zero and using the divergence form of Section 8.5 gives exactly $\gamma^\mu\partial_\mu\Psi + 3H\gamma^{(0)}\Psi = (m+U')\Psi$, the field equation of Section 8.2. (The record proves the same for the Grassmann field with left derivatives: `python-field-theory.json`, check `grassmann_euler_lagrange_psibar_variation`.)

So the gravitational term $3H\gamma^{(0)}\Psi$ is at the same time the term that the canonical spin connection produces and the half-density term that the volume factor produces when a Lagrangian without any spin connection is varied (PROVED; `python-scope.json`, check `connection_free_lagrangian_same_equations`, both engines). This is the first hint that the value $3H\gamma^{(0)}$ is not a deep property of gravity's coupling: the next two sections make that precise.

8.9 Another frame: the boosted frame and its term

Take the boosted frame of Section 8.3, with rapidity $b = \beta x_4 + b_0$. Its canonical spin connection (computed from the definition of Section 8.4 with the new frame) satisfies the vielbein postulate and is antisymmetric (PROVED; `python-scope.json`, check `boosted_frame_canonical_connection`). The record then finds, exactly, for every a_4, every $H > 0$ and every β (at $b_4 = 1$; for a general b_4 the term $\tfrac{3}{4}(b_4'/b_4)(\cosh b\,\gamma^{(4)} - \sinh b\,\gamma^{(0)})$ is added, Section 6.16):

$$\gamma'^\mu\Omega'_\mu = \frac{6H-\beta}{2}\big(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)}\big)$$

(PROVED; `python-scope.json`, check `boosted_frame_gammaOmega_formula`, and the same check of `wolfram-scope.json`). Notebook 08c computes it from the definitions, with sympy. Here we derive it by a shorter route that also explains it.

Step 1: the matrix that moves the gammas. Let $J = \gamma^{(4)}\gamma^{(0)}$. Its square is $J^2 = \gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\gamma^{(0)} = -\gamma^{(4)}\gamma^{(4)}\gamma^{(0)}\gamma^{(0)} = -(-I_{16})(I_{16}) = I_{16}$ (anticommute the middle pair, then use the two squares). For a matrix with $J^2 = I_{16}$ the exponential series splits into even and odd powers, and $e^{\theta J} = \cosh\theta\, I_{16} + \sinh\theta\, J$. Define

$$S = e^{-(b/2)J} = \cosh\tfrac{b}{2}\, I_{16} - \sinh\tfrac{b}{2}\, J, \qquad S^{-1} = e^{(b/2)J} = \cosh\tfrac{b}{2}\, I_{16} + \sinh\tfrac{b}{2}\, J.$$

Step 2: what S does to each gamma. J commutes with $\gamma^{(a)}$ for $a \neq 4, 8$ (moving $\gamma^{(a)}$ past the two factors of J changes the sign twice), so $S\gamma^{(a)}S^{-1} = \gamma^{(a)}$ for those six directions. J anticommutes with $\gamma^{(4)}$ and with $\gamma^{(0)}$. To see it for $\gamma^{(4)}$, move $\gamma^{(4)}$ from the left of $J = \gamma^{(4)}\gamma^{(0)}$ to its right: passing the factor $\gamma^{(4)}$ (itself) changes nothing, and passing the factor $\gamma^{(0)}$ changes the sign once, so $\gamma^{(4)}J = \gamma^{(4)}\gamma^{(4)}\gamma^{(0)} = -\gamma^{(4)}\gamma^{(0)}\gamma^{(4)} = -J\gamma^{(4)}$. For $\gamma^{(0)}$ it is the same with the roles exchanged: passing $\gamma^{(4)}$ changes the sign once and passing $\gamma^{(0)}$ changes nothing, so $\gamma^{(0)}J = \gamma^{(0)}\gamma^{(4)}\gamma^{(0)} = -\gamma^{(4)}\gamma^{(0)}\gamma^{(0)} = -J\gamma^{(0)}$. Because $\gamma^{(4)}$ anticommutes with J, it turns every power J^n into $(-J)^n$ when it is moved past it, so $\gamma^{(4)}e^{\theta J} = e^{-\theta J}\gamma^{(4)}$ for every number θ; in particular $S\gamma^{(4)} = e^{-(b/2)J}\gamma^{(4)} = \gamma^{(4)}e^{(b/2)J} = \gamma^{(4)}S^{-1}$, and line by line

$$\begin{aligned} S\gamma^{(4)}S^{-1} &= \gamma^{(4)}S^{-1}S^{-1} = \gamma^{(4)}e^{bJ} = \gamma^{(4)}\big(\cosh b\, I_{16} + \sinh b\, \gamma^{(4)}\gamma^{(0)}\big) \\ &= \cosh b\, \gamma^{(4)} + \sinh b\, (\gamma^{(4)})^2\gamma^{(0)} = \cosh b\, \gamma^{(4)} - \sinh b\, \gamma^{(0)}. \end{aligned}$$

The first line moves S to the right of $\gamma^{(4)}$ (it becomes S^{-1}), multiplies the two exponentials ($e^{(b/2)J}e^{(b/2)J} = e^{bJ}$) and writes out e^{bJ}; the second multiplies out and uses $(\gamma^{(4)})^2 = -I_{16}$. In the same way $S\gamma^{(0)}S^{-1} = \gamma^{(0)}e^{bJ} = \cosh b\, \gamma^{(0)} + \sinh b\, \gamma^{(0)}\gamma^{(4)}\gamma^{(0)} = \cosh b\, \gamma^{(0)} - \sinh b\, \gamma^{(4)}$ (here $\gamma^{(0)}\gamma^{(4)}\gamma^{(0)} = -\gamma^{(4)}(\gamma^{(0)})^2 = -\gamma^{(4)}$).

Step 3: the coordinate gammas of the boosted frame. The boosted frame is $e' = Le$, with the boost matrix L; its inverse is $E' = EL^{-1}$ (the inverse of a product is the product of the inverses in reverse order), and L^{-1} is the boost with $-b$. So $\gamma'^{\mu} = \sum_a E'_a{}^{\mu}\gamma^{(a)} = \sum_b E_b{}^{\mu}\tilde{\gamma}^{(b)}$, where $\tilde{\gamma}^{(4)} = \cosh b\, \gamma^{(4)} - \sinh b\, \gamma^{(0)}$, $\tilde{\gamma}^{(0)} = \cosh b\, \gamma^{(0)} - \sinh b\, \gamma^{(4)}$ and $\tilde{\gamma}^{(a)} = \gamma^{(a)}$ otherwise. By Step 2, $\tilde{\gamma}^{(b)} = S\gamma^{(b)}S^{-1}$ for every b, and therefore $\gamma'^{\mu} = S\gamma^{\mu}S^{-1}$.

Step 4: the connection of the boosted frame. Chapter 6 proves in general (in its section on local spin covariance) that the canonical spinor connection of the turned frame is $S\Omega_\mu S^{-1} - (\partial_\mu S)S^{-1}$. Here is a shorter argument for the same result. It rests on two facts: the canonical spin connection of every frame makes that frame's coordinate gammas covariantly constant (a consequence of the vielbein postulate), and it is a combination of the S^{ab}, so its trace (the sum of its diagonal entries) is zero. Both are established in Chapter 6; we quote them here, and the direct computation of the record and of Notebook 08c confirms their consequence. We show that $\Omega'_\mu = S\Omega_\mu S^{-1} - (\partial_\mu S)S^{-1}$ has both properties, and that only one matrix has them. First, covariant constancy, line by line (with $\partial_\mu S^{-1} = -S^{-1}(\partial_\mu S)S^{-1}$, which follows from differentiating $SS^{-1} = I_{16}$):

$$\begin{aligned} \partial_\mu\gamma'^{\nu} &= (\partial_\mu S)\gamma^{\nu}S^{-1} + S(\partial_\mu\gamma^{\nu})S^{-1} - S\gamma^{\nu}S^{-1}(\partial_\mu S)S^{-1}, \\ [\Omega'_\mu, \gamma'^{\nu}] &= S[\Omega_\mu, \gamma^{\nu}]S^{-1} - (\partial_\mu S)\gamma^{\nu}S^{-1} + S\gamma^{\nu}S^{-1}(\partial_\mu S)S^{-1}, \\ \partial_\mu\gamma'^{\nu} + \sum_\lambda \Gamma^{\nu}{}_{\mu\lambda}\gamma'^{\lambda} + [\Omega'_\mu, \gamma'^{\nu}] &= S\Big(\partial_\mu\gamma^{\nu} + \sum_\lambda \Gamma^{\nu}{}_{\mu\lambda}\gamma^{\lambda} + [\Omega_\mu, \gamma^{\nu}]\Big)S^{-1} = 0. \end{aligned}$$

The first line is the product rule for $S\gamma^{\nu}S^{-1}$; the second inserts Ω'_μ and γ'^{ν} into the commutator and

multiplies out; the third adds the two lines and the Christoffel term (Γ belongs to the metric, the same in both frames), sees the four terms with $\partial_\mu S$ cancel in pairs, and uses the covariant constancy of the diagonal frame. Second, the trace: $\mathrm{tr}(S\Omega_\mu S^{-1}) = \mathrm{tr}\,\Omega_\mu = 0$, and $(\partial_\mu S)S^{-1}$ is a multiple of J (Step 5 below), whose trace is zero (the trace of a product of two different gammas is zero: $\mathrm{tr}(\gamma^{(4)}\gamma^{(0)}) = \mathrm{tr}(\gamma^{(0)}\gamma^{(4)}) = -\mathrm{tr}(\gamma^{(4)}\gamma^{(0)})$, by the cyclic rule of the trace and then anticommutation). Third, uniqueness: if two traceless matrices Ω'_1, Ω'_2 both make the γ'^ν covariantly constant, their difference commutes with every γ'^ν; then $S^{-1}(\Omega'_1 - \Omega'_2)S$ commutes with every $\gamma^{(a)}$, so it is a multiple of I_{16} (the gammas form an irreducible representation, Chapter 5; `Revision/algebra/reports/python-algebra.json`, check `pin_commutant_dimension_1`), and a traceless multiple of I_{16} is zero. Hence the canonical connection of the boosted frame is $\Omega'_\mu = S\Omega_\mu S^{-1} - (\partial_\mu S)S^{-1}$.

Step 5: the term. Line by line:

$$
\begin{aligned}
\gamma'^\mu\Omega'_\mu &= S\gamma^\mu S^{-1}\big(S\Omega_\mu S^{-1} - (\partial_\mu S)S^{-1}\big) = S\big(\gamma^\mu\Omega_\mu - \gamma^\mu S^{-1}\partial_\mu S\big)S^{-1},\\
S^{-1}\partial_\mu S &= -\tfrac{\beta}{2}J \text{ for } \mu = x_4, \quad 0 \text{ otherwise},\\
\gamma^{x_4}S^{-1}\partial_4 S &= \gamma^{(4)}\big(-\tfrac{\beta}{2}\gamma^{(4)}\gamma^{(0)}\big) = -\tfrac{\beta}{2}(\gamma^{(4)})^2\gamma^{(0)} = \tfrac{\beta}{2}\gamma^{(0)},\\
\gamma'^\mu\Omega'_\mu &= S\big(3H\gamma^{(0)} - \tfrac{\beta}{2}\gamma^{(0)}\big)S^{-1} = \frac{6H-\beta}{2}\,S\gamma^{(0)}S^{-1} = \frac{6H-\beta}{2}\big(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)}\big).
\end{aligned}
$$

The first line inserts Steps 3 and 4 and cancels $S^{-1}S$; the second differentiates $S = e^{-(b/2)J}$ with $\partial_4 b = \beta$ (only b depends on the coordinates, and only on x_4); the third uses $\gamma^{x_4} = \gamma^{(4)}$ ($f_4 = 1$) and $(\gamma^{(4)})^2 = -I_{16}$; the fourth uses $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$ (Section 8.5) and Step 2. This is the record's formula.

The consequence. For $\beta = 6H$, that is with the rapidity $b = 6Hx_4 + b_0$, the term $\gamma'^\mu\Omega'_\mu$ is identically zero, for every $H > 0$ and every history a_4, although the metric is the author's curved metric (PROVED; `python-scope.json`, check `boosted_frame_gammaOmega_vanishes`, both engines). The connection itself is not zero in that frame: $\Omega'_\mu \neq 0$ for $\mu = x_0, \ldots, x_6$ (zero only for x_7; the same check). So the sentence "the field equation contains the gravitational term $3H\gamma^{(0)}\Psi$" is true in the diagonal frame and false in this frame: it is a statement about one frame, not about the field equation as such. In the boosted frame gravity enters the field equation through the boosted frame vectors $E'^{\,\mu}_a$ alone.

8.10 What no frame removes: the curvature of the connection

The curvature in two frames. The curvature of the spinor connection equals the Riemann tensor contracted with two coordinate gammas, $F_{\mu\nu} = \frac{1}{4}\sum_{\rho,\sigma} R_{\rho\sigma\mu\nu}\gamma^\rho\gamma^\sigma$ (Section 8.4). This identity holds in every frame (a standard theorem, quoted without proof here as in Chapter 6, so ASSUMED in general; the record proves it for this metric in the diagonal frame, and Notebook 08c checks it in the diagonal and in the boosted frame for $(\mu,\nu) = (x_1, x_0)$). Chapter 6 also derives the relation below directly from local spin covariance, without this identity. The Riemann tensor belongs to the metric and is the same in both frames, and $\gamma'^\rho = S\gamma^\rho S^{-1}$ (Section 8.9). Hence, line by line,

$$
F'_{\mu\nu} = \tfrac{1}{4}\sum_{\rho,\sigma} R_{\rho\sigma\mu\nu}\, S\gamma^\rho S^{-1}S\gamma^\sigma S^{-1} = S\Big(\tfrac{1}{4}\sum_{\rho,\sigma} R_{\rho\sigma\mu\nu}\gamma^\rho\gamma^\sigma\Big)S^{-1} = SF_{\mu\nu}S^{-1}.
$$

It is never zero. In the diagonal frame Notebook 08c finds $F_{x_1x_0} = c_{14}\,\gamma^{(1)}\gamma^{(4)} + c_{10}\,\gamma^{(1)}\gamma^{(0)}$ with

$$c_{14} = -\frac{H a_4' e^{a_4}\cos z}{2\sin^{5/6} z}, \qquad c_{10} = -\frac{H^2 e^{a_4}\cos z}{2\sin^{5/6} z}.$$

The coefficient c_{10} is never zero for $H > 0$ and $0 < z < \pi/2$, and $\gamma^{(1)}\gamma^{(4)}$ and $\gamma^{(1)}\gamma^{(0)}$ are linearly independent, so $F_{x_1x_0} \neq 0$ for every history a_4. Since S is invertible, $F'_{x_1x_0} = SF_{x_1x_0}S^{-1} \neq 0$ too. If the connection Ω'_μ vanished at all points of a region in some frame, its curvature would vanish there; it does not. So the spin connection vanishes in no frame of this kind (PROVED; `python-scope.json`, check `boosted_frame_curvature_nonzero`, both engines, which argues in general: the curvature of the connection is $\frac{1}{2}R_{ab\mu\nu}S^{ab}$ in every frame, and the metric is curved for $H > 0$).

Two frames, one curvature. The square of $F_{x_1x_0}$ is the same in both frames, $F^2 = (c_{14}^2 - c_{10}^2)I_{16} = H^2((a_4')^2 - H^2)e^{2a_4}\cos^2 z/(4\sin^{5/3} z)\cdot I_{16}$: the products $\gamma^{(1)}\gamma^{(4)}$ and $\gamma^{(1)}\gamma^{(0)}$ square to $+I_{16}$ and $-I_{16}$ and anticommute, so the cross terms cancel, and $F'^2 = SF^2S^{-1} = F^2$ because F^2 is a multiple of I_{16}. On the canonical history $a_4 = x_4$ (where $a_4' = H = 1$) this square is zero although F is not: F is then **nilpotent** (its square is the zero matrix, like the 2×2 matrix with rows $(0,1)$ and $(0,0)$), and in the boosted frame with $\beta = 6H$ it is $F' = e^{-b}F$ (Exercise 6 of Section 8.39 derives this).

The frame-independent content of non-triviality. Putting Sections 8.6 to 8.10 together: the canonical spin connection is nonzero in every frame, because its curvature is the curvature of spacetime, which is nonzero for every $H > 0$; and the frame factors $e^{\mp a_4}\sin^{-1/6} z$ and $\tan z$, none of which is identically 1, multiply every derivative term of the field equation except the one along the time x_4 (the derivatives along $x_1, x_2, x_3, x_5, x_6, x_7, x_0$; the factor of ∂_4 is $1/f_4 = 1$). These two facts do not depend on any choice. The value $3H\gamma^{(0)}$ of the term $\gamma^\mu\Omega_\mu$ does.

8.11 The connection in the energy-momentum tensor

The spin connection drops out of the Lagrangian (Section 8.8), but it does reach the energy-momentum tensor, the source of gravity (Chapter 9). For a field that depends only on the time, $\Phi = \Phi(x_4)$, the entry $K^{x_4}{}_{x_1} = \frac{1}{2}(\bar\Phi\gamma^{x_4}D_{x_1}\Phi - (D_{x_1}\bar\Phi)\gamma^{x_4}\Phi)$ has no derivative part ($\partial_1\Phi = 0$), and its connection part is $\frac{1}{2}\bar\Phi\{\gamma^{x_4}, \Omega_{x_1}\}\Phi$. Line by line, with $\gamma^{x_4} = \gamma^{(4)}$ and $\Omega_{x_1} = \frac{1}{2}f_1(a_4'\gamma^{(1)}\gamma^{(4)} + H\gamma^{(1)}\gamma^{(0)})$, $f_1 = e^{a_4}\sin^{1/6} z$:

$$\begin{aligned}
&\gamma^{(4)}\gamma^{(1)}\gamma^{(4)} + \gamma^{(1)}\gamma^{(4)}\gamma^{(4)} = -\gamma^{(1)}\gamma^{(4)}\gamma^{(4)} + \gamma^{(1)}\gamma^{(4)}\gamma^{(4)} = 0,\\
&\gamma^{(4)}\gamma^{(1)}\gamma^{(0)} + \gamma^{(1)}\gamma^{(0)}\gamma^{(4)} = \gamma^{(4)}\gamma^{(1)}\gamma^{(0)} + \gamma^{(4)}\gamma^{(1)}\gamma^{(0)} = 2\gamma^{(4)}\gamma^{(1)}\gamma^{(0)},\\
&\qquad \tfrac{1}{2}\{\gamma^{x_4}, \Omega_{x_1}\} = \tfrac{1}{2}\cdot\tfrac{1}{2}f_1\big(a_4'\cdot 0 + H\cdot 2\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\big) = \tfrac{1}{2}e^{a_4}\sin^{1/6} z\, H\,\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}.
\end{aligned}$$

The first line moves the first $\gamma^{(4)}$ past $\gamma^{(1)}$ (one sign) and finds that the a_4' part cancels; the second moves $\gamma^{(4)}$ in the second product to the front past two gammas (two signs); the third collects. The bilinear matrix $C\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}$ is not the zero matrix, so this entry is not zero in general (PROVED; `python-scope.json`, check `spin_connection_in_the_energy_momentum_tensor`, both engines). Chapter 9 uses this entry (Section 9.12).

8.12 Example: the term in two frames, computed from the definitions

Notebook 08c puts Sections 8.3 to 8.11 to work, exactly, with sympy, for a symbolic history $a_4(x_4)$ and symbolic H, β, b_0. It builds the scale factors and the metric and compares them with the record; computes all Christoffel symbols and the canonical spin connection of the diagonal frame and checks the vielbein postulate for all 512 components; shows that the connection vanishes only for $a_4' = 0$ and $H = 0$; computes $\gamma^\mu \Omega_\mu$ direction by direction and draws what cancels and what survives; computes the Ricci components and shows that the term contains no a_4; builds the boosted frame and finds $\gamma'^\mu \Omega'_\mu$; computes the spinor curvature in both frames; and checks the connection part of the energy-momentum tensor. It needs no Rust and runs in one to two minutes; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/08c_frame_dependence.PROVENANCE.md`. It ends with the line ALL 32 CHECKS PASSED (notebook 08c).

8.13 How to run Notebook 08c

Step 1. What this notebook does and what it needs.

Notebook 08c (The spin-connection term depends on the frame) is the file `Revision/textbook/notebooks/08c_frame_dependence.ipynb` of the repository Dirac_claude. From the author's metric and gamma matrices it computes exactly (sympy) the Christoffel symbols, the canonical spin connection of the diagonal frame and of a frame boosted in the (x4, x0) plane, and the term gamma^mu Omega_mu of the field equation; it shows that the connection vanishes only in the formal flat limit, which pieces cancel and which survive (3 H gamma^(x0) in the diagonal frame), that the term contains no a4 although the a4 sector is curved, that it vanishes identically in the frame boosted with rapidity 6 H x4 + b0, that the spin connection itself vanishes in no frame (its curvature is the Riemann tensor), and that it enters the energy-momentum tensor; it draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
```

```
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08c_frame_dependence.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08c_frame_dependence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 08c_frame_dependence.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/08c.captions.json`
- `Revision/textbook/figures/08c_1_cancel_and_survive.png`
- `Revision/textbook/figures/08c_2_pieces_along_history.png`
- `Revision/textbook/figures/08c_3_boost_size.png`
- `Revision/textbook/figures/08c_4_heat_maps.png`
- `Revision/textbook/figures/08c_5_curvature_maps.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08c_5_curvature_maps.png exists
ALL 32 CHECKS PASSED (notebook 08c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/08c_frame_dependence.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 08c_frame_dependence.ipynb
python -m nbconvert --execute --inplace 08c_frame_dependence.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- A cell of sections 7, 11 or 12 runs for more than a minute: these cells simplify hundreds of exact expressions with sympy; on a slow computer each can take a few minutes. Wait until the star in the brackets to the left of the cell turns into a number.

8.14 Notebook 08c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/08c_frame_dependence.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field equation of dirac16complex (and of dirac16complex00) contains the term
$\gamma^\mu\Omega_\mu\Psi$, where $\Omega_\mu$ is the canonical spin connection. In
the diagonal frame of the author's metric this term is $3H\gamma^{(0)}\Psi$. This
notebook computes everything from the definitions, exactly, with sympy, and shows
what that value means and what it does not mean. It

- builds the author's metric from the diagonal vielbein, its Christoffel symbols
  (25 independent nonzero ones) and the canonical spin connection (12 independent
  nonzero components), and checks the vielbein postulate for all 512 components;
- shows that the connection vanishes only in the formal flat limit $a_4' = 0$,
  $H = 0$ (the core of non-triviality) and that the term $3H\gamma^{(0)}\Psi$ is
  not zero for any field $\Psi \neq 0$;
- shows, direction by direction, which pieces of $\gamma^\mu\Omega_\mu$ cancel (the
  time-direction pieces of the three inflating and the three deflating
  directions) and which survive (the hidden-direction pieces, $3H\gamma^{(0)}$);
- shows that the term contains no $a_4$, although the curvature does
  ($R^{x_4}{}_{x_4} = 6(a_4')^2$): the deflation of the extra times is invisible
  in this term;
- repeats everything in a second, equally valid frame, boosted in the
  $(x_4, x_0)$ plane, finds $\gamma'^\mu\Omega'_\mu = \frac{6H - \beta}{2}
```

```
  (\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)})$, and so a frame in which the
  term is identically ZERO;
- shows that the spin connection itself is not zero in that frame (nor in any
  other): its curvature is the Riemann tensor, which is not zero;
- shows that the spin connection enters the energy-momentum tensor.

Every exact statement reproduces a check of a Revision record. Five teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 08c (The spin-connection term depends on the frame) is the file
‘Revision/textbook/notebooks/08c_frame_dependence.ipynb‘ of the repository Dirac_claude.
From the author’s metric and gamma matrices it computes exactly (sympy) the Christoffel
symbols, the canonical spin connection of the diagonal frame and of a frame boosted in
the (x4, x0) plane, and the term gamma^mu Omega_mu of the field equation; it shows that
the connection vanishes only in the formal flat limit, which pieces cancel and which
survive (3 H gamma^(x0) in the diagonal frame), that the term contains no a4 although the
a4 sector is curved, that it vanishes identically in the frame boosted with rapidity 6 H
x4 + b0, that the spin connection itself vanishes in no frame (its curvature is the
Riemann tensor), and that it enters the energy-momentum tensor; it draws five teaching
plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for
the installation, the program Git, and Python 3.12 or newer (the notebooks were built
with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:
```

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08c_frame_dependence.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,

copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08c_frame_dependence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 08c_frame_dependence.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/08c.captions.json‘
- ‘Revision/textbook/figures/08c_1_cancel_and_survive.png‘
- ‘Revision/textbook/figures/08c_2_pieces_along_history.png‘
- ‘Revision/textbook/figures/08c_3_boost_size.png‘
- ‘Revision/textbook/figures/08c_4_heat_maps.png‘
- ‘Revision/textbook/figures/08c_5_curvature_maps.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08c_5_curvature_maps.png exists
ALL 32 CHECKS PASSED (notebook 08c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/08c_frame_dependence.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 08c_frame_dependence.ipynb
      python -m nbconvert --execute --inplace 08c_frame_dependence.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- A cell of sections 7, 11 or 12 runs for more than a minute: these cells simplify hundreds of exact expressions with sympy; on a slow computer each can take a few minutes. Wait until the star in the brackets to the left of the cell turns into a number.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 08c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 08c (The spin-connection term depends on the frame) is the file
# Revision/textbook/notebooks/08c_frame_dependence.ipynb of the repository Dirac_claude.
# From the author's metric and gamma matrices it computes exactly (sympy) the Christoffel
# symbols, the canonical spin connection of the diagonal frame and of a frame boosted in
# the (x4, x0) plane, and the term gamma^mu Omega_mu of the field equation; it shows that
# the connection vanishes only in the formal flat limit, which pieces cancel and which
# survive (3 H gamma^(x0) in the diagonal frame), that the term contains no a4 although
# the a4 sector is curved, that it vanishes identically in the frame boosted with

#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
```

```
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 08c_frame_dependence.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 08c_frame_dependence.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
```

```
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 08c_frame_dependence.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/08c.captions.json
# - Revision/textbook/figures/08c_1_cancel_and_survive.png
# - Revision/textbook/figures/08c_2_pieces_along_history.png
# - Revision/textbook/figures/08c_3_boost_size.png
# - Revision/textbook/figures/08c_4_heat_maps.png
# - Revision/textbook/figures/08c_5_curvature_maps.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 08c_5_curvature_maps.png exists
#     ALL 32 CHECKS PASSED (notebook 08c)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/08c_frame_dependence.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
```

```
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 08c_frame_dependence.ipynb
#     python -m nbconvert --execute --inplace 08c_frame_dependence.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - A cell of sections 7, 11 or 12 runs for more than a minute: these cells simplify
#   hundreds of exact expressions with sympy; on a slow computer each can take a few
#   minutes. Wait until the star in the brackets to the left of the cell turns into a
#   number.
#

## 3. The words used in this notebook

- **Coordinates** (the author's names): $x_1, x_2, x_3$ ordinary space (inflating);
  $x_4$ the time; $x_5, x_6, x_7$ the three extra times (time-like, DEFLATING:
  their scale factor is $e^{-a_4}\sin^{1/6}z$); $x_0$ the hidden direction,
  $z = 6Hx_0$ between $0$ and $\pi/2$. $a_4(x_4)$ is any function of the time.
- **Metric** $g_{\mu\nu}$: the table of numbers that turns coordinate steps into
  lengths, $ds^2 = \sum g_{\mu\nu}dx_\mu dx_\nu$. The author's metric is diagonal:
  $g = \mathrm{diag}(e^{2a_4}\sin^{1/3}z\ (3\times), -1, -e^{-2a_4}\sin^{1/3}z\
```

```
  (3\times), \cot^2 z)$.
- **Frame (vielbein)** $e^a{}_\mu$: eight vectors, one per direction $a$, that are
  orthonormal for the metric: $\sum_{a} \eta_{aa}e^a{}_\mu e^a{}_\nu = g_{\mu\nu}$
  with $\eta = \mathrm{diag}(+,+,+,+,-,-,-,-)$. The *diagonal frame* has
  $e^a{}_\mu = f_a\delta^a_\mu$ with $f_a = \sqrt{|g_{aa}|}$. Its inverse is
  $E_a{}^\mu$ (written `E[mu, a]` in the code).
- **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$: the numbers that say how the
  coordinate directions turn from point to point; for a diagonal metric
  $\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}(\partial_\mu
  g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu})$.
- **Canonical spin connection** $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu
  E_b{}^\nu + \Gamma^\nu{}_{\mu\lambda}E_b{}^\lambda)$: how the frame vectors turn;
  it obeys the *vielbein postulate* $\partial_\mu e^a{}_\nu -
  \Gamma^\lambda{}_{\mu\nu}e^a{}_\lambda + \omega_\mu{}^a{}_b e^b{}_\nu = 0$, and
  $\omega_{\mu ab} = \eta_{aa}\omega_\mu{}^a{}_b$ is antisymmetric in $a, b$.
- **Spinor connection** $\Omega_\mu = \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$ with
  $S^{ab} = \frac14[\gamma^{(a)}, \gamma^{(b)}]$; $D_\mu\Psi = \partial_\mu\Psi +
  \Omega_\mu\Psi$ and $\gamma^\mu = \sum_a E_a{}^\mu\gamma^{(a)}$.
- **Boost**: a change of frame that mixes a time-like and a space-like frame vector
  with $\cosh b$ and $\sinh b$ ($b$ is the *rapidity*); because $\cosh^2 b -
  \sinh^2 b = 1$ the new vectors are again orthonormal, so the new frame describes
  the SAME metric.
- **Riemann tensor** $R^\rho{}_{\sigma\mu\nu}$ (curvature) and its traces: the Ricci
  tensor $R_{\sigma\nu} = \sum_\rho R^\rho{}_{\sigma\rho\nu}$, its mixed form
  $R^\mu{}_\nu$ (for a diagonal metric $R^a{}_a = R_{aa}/g_{aa}$) and the Ricci
  scalar $R = \sum_a R^a{}_a$. A space is flat exactly when the Riemann tensor
  vanishes.
- **Spinor curvature** $F_{\mu\nu} = \partial_\mu\Omega_\nu - \partial_\nu\Omega_\mu
  + [\Omega_\mu, \Omega_\nu]$, where $[A, B] = AB - BA$ (the *commutator*); the
  record proves $F_{\mu\nu} = \frac14\sum R_{\rho\sigma\mu\nu}\gamma^\rho
  \gamma^\sigma$.
- **Anticommutator** $\{A, B\} = AB + BA$; **trace** of a matrix: the sum of its
  diagonal.
```

Text cell:

```
## 4. The physical and mathematical situation

Coupling a spinor field to gravity needs a frame, because the gamma matrices
$\gamma^{(a)}$ belong to the orthonormal frame directions, not to the coordinates.
The frame is not unique: at every point one may turn (rotate or boost) the eight
frame vectors among themselves, and the metric stays the same. The spin connection
changes under such a turn, and so may $\gamma^\mu\Omega_\mu$. A statement is a
property of the field equation only if it holds in every frame (together with the
matching change of the field, $\Psi' = S\Psi$ with a constant-or-varying $16
\times 16$ matrix $S$).

The plan: compute $\gamma^\mu\Omega_\mu$ in the diagonal frame (result
$3H\gamma^{(0)}$, sections 7 to 10), then in the boosted frame
$e'^{(4)} = \cosh b\,e^{(4)} + \sinh b\,e^{(0)}$, $e'^{(0)} = \sinh b\,e^{(4)} +
\cosh b\,e^{(0)}$, other $e'^{(a)} = e^{(a)}$, with rapidity $b = \beta x_4 + b_0$
(section 11), and finally the curvature (section 12), which no frame can remove.
```

```
Every symbol is exact: $H > 0$, $\beta$, $b_0$ are letters, and $a_4(x_4)$ is an
unspecified function; so every check holds for EVERY history $a_4$. The second
function $b_4(x_4)$ of the author's metric is put equal to 1 here, the background
of the Revision record's scope reports with which this notebook compares; Notebook
06b (Chapter 6) repeats the frame dependence for a general $b_4$, where the
diagonal frame gives $3H\gamma^{(0)} + \frac34(b_4'/b_4)\gamma^{(4)}$. Only the plots
put numbers in: $H = 1$, $z = \pi/4$, and the canonical history $a_4 = AHx_4$ with
$A = 1$ of the Kohn-Sham record (a prescribed background).
```

Text cell:

```
## 5. The metric from the diagonal frame

The next cell first defines two helpers for the checks that reproduce a Revision
record. `record_says(report, name, ...)` opens the report (a JSON file with a list
of checks, each with a name, a verdict and a detail text) and is true when the
check `name` is there with the verdict pass and its detail text contains every
further piece of text given (for example a formula that this notebook computes).
`check_record(condition, title, report, names, ...)` is the helper `check` for such
a result (`names` is one check name or a list of names): it passes only if the
notebook's own computation (`condition`) is right AND the record says the same.
Then the cell reads the gamma matrices, defines the symbols, builds the scale
factors $f_a$ and the metric $g_{aa} = \eta_{aa}f_a^2$, and checks that this is the
author's metric entry by entry (and that the record prints the same eight entries)
and that $\sqrt{|g|} = f_0 f_1 \cdots f_7 = \cos z$. The helper `is_zero` asks sympy
to simplify an expression twice (the second time with its trigonometric simplifier
`fu`) and says whether it is exactly zero.
```

In [2]:

```
import numpy as np  # numbers and matrices (for the plots)
import sympy as sp  # exact algebra with symbols

REPORTS = {}  # report file -> {check name: (verdict, detail)}, each read once

def record_says(report_file, check_name, *pieces):
    """True when the Revision report records the check check_name with the verdict
    pass and its detail text contains every given piece of text."""
    if report_file not in REPORTS:  # read the report the first time it is needed
        data = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
        REPORTS[report_file] = {entry["name"]: (entry["verdict"].lower(),
                                                entry["detail"])
                                for entry in data["checks"]}
    verdict, detail = REPORTS[report_file][check_name]
    return verdict == "pass" and all(piece in detail for piece in pieces)

def check_record(condition, title, report_file, check_names, *pieces):
    """check() for a result that reproduces Revision checks (one name or a list of
    names): it passes only if condition is true AND the report records every one
    of them as passed, with every piece of text in the detail of the first one."""
```

```

## 7. The canonical spin connection of the diagonal frame

The function ‘frame(b)‘ below builds the frame boosted by the rapidity $b$ (for
$b = 0$ the diagonal frame), its inverse, the mixed connection
$\omega_\mu{}^a{}_c$ (stored as ‘omega[mu, a, c]‘), the spinor connections
$\Omega_\mu$ and the matrices $\gamma^\mu$. ‘postulate_failures‘ counts the
components of the vielbein postulate that are NOT zero. The next cell applies them
to the diagonal frame, checks the postulate (512 components) and the antisymmetry,
and prints the 12 independent nonzero components $\omega_{\mu ab}$ ($a < b$).
```

In [4]:

```
S_AB = [[(G[a] * G[c] - G[c] * G[a]) / 4 for c in range(8)] for a in range(8)]

## 8. The connection vanishes only in flat space: non-triviality

Every one of the 12 components printed above is $a_4'$ times, or $H$ times, one of
the four factors $\pm e^{\pm a_4}\sin^{1/6}z$, and these factors are never zero for
$0 < z < \pi/2$ (an exponential is never zero, and $\sin z > 0$ there). The 28
matrices $S^{ab}$ ($a < b$) are linearly independent: written as rows of
$16 \times 16 = 256$ numbers they have rank 28 (rank: the number of independent
rows). So $\Omega_\mu = \frac12\sum\omega_{\mu ab}S^{ab}$ is zero exactly when all
its coefficients are. The next cell finds, for each of the 12 components, which of
the two shapes it has (it writes `A1` for $a_4'$, the name the Revision record
uses), counts six of each, computes the rank of the $S^{ab}$, and so checks, line
by line:

1. each component is $a_4'\cdot(\text{factor})$ or $H\cdot(\text{factor})$, six of
   each, with a factor that is never zero;
2. if $a_4' \neq 0$, the six components of the first kind are not zero; if
   $H \neq 0$, the six of the second kind are not zero;
3. so $\Omega_\mu = 0$ for every $\mu$ if and only if $a_4' = 0$ AND $H = 0$, the
   formal flat limit. $H = 0$ is not a member of the author's family (the metric
   degenerates there), so for the author's metric the connection never vanishes.

This is the core of the non-triviality statements [1] and [2] of the Revision
record.

## 9. What cancels and what survives

For each direction $\mu$ separately (no sum) the product $\gamma^{x_\mu}
\Omega_{x_\mu}$ turns out to be a combination of $\gamma^{(4)}$ and $\gamma^{(0)}$
only. The coefficient of $\gamma^{(0)}$ in a matrix $M$ is $\mathrm{tr}(\gamma^{(0)}
M)/16$ and that of $\gamma^{(4)}$ is $-\mathrm{tr}(\gamma^{(4)}M)/16$ (because
$(\gamma^{(0)})^2 = 1$, $(\gamma^{(4)})^2 = -1$, and the trace of a product of two
different gammas is 0). The next cell computes both coefficients for every
direction, checks that nothing else is left, checks the sum
$\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$, the *divergence form*
$\frac{1}{2\sqrt{|g|}}\sum_\mu\partial_\mu(\sqrt{|g|}\gamma^\mu) = 3H\gamma^{(0)}$,
and $\{\gamma^\mu, \Omega_\mu\} = 0$ for each $\mu$ (which makes the connection
drop out of the symmetrised Lagrangian), and draws the coefficients. It prints the
three partial sums in the record's notation (`A1` for $a_4'$) and compares them
with the record's text. It also checks $(\gamma^{(0)})^2 = I_{16}$: then
$\gamma^{(0)}$ can be undone (multiply by $\gamma^{(0)}$ again), so
$3H\gamma^{(0)}\Psi = 0$ only when $\Psi = 0$; in the diagonal frame the
gravitational term is not zero for any field that is not zero (the statement [1]
of the Revision record, whose scope sections 11 and 12 below make precise).

```
## 10. The deflation is invisible in this term, but not in the curvature

The term $3H\gamma^{(0)}$ contains no $a_4$: the deflation of the extra times does
not show up in it. The geometry of the $a_4$ sector is nevertheless curved. The
next cell computes the Riemann tensor from the Christoffel symbols,
$R^\rho{}_{\sigma\mu\nu} = \partial_\mu\Gamma^\rho{}_{\nu\sigma} -
\partial_\nu\Gamma^\rho{}_{\mu\sigma} + \sum_\lambda(\Gamma^\rho{}_{\mu\lambda}
\Gamma^\lambda{}_{\nu\sigma} - \Gamma^\rho{}_{\nu\lambda}\Gamma^\lambda{}_{\mu\sigma})$,
and the diagonal Ricci components $R^{x_a}{}_{x_a}$, and checks them against the
record: $a_4'' - 6H^2$ (3-space), $6(a_4')^2$ (time), $-a_4'' - 6H^2$ (extra
times), $-6H^2$ (hidden direction), and $R = 6((a_4')^2 - 7H^2)$. Then it draws,
along the canonical history $a_4 = x_4$ at $z = \pi/4$ and $H = 1$, two pieces of
the connection (they change exponentially) and the two partial sums of the
$\gamma^{(4)}$ coefficients (they stay constant and cancel).
```

## 11. The boosted frame: the term depends on the frame

The next cell builds the frame boosted by the rapidity $b = \beta x_4 + b_0$ with
symbolic $\beta$ and $b_0$. It checks that the new frame gives the SAME metric
($\sum_a\eta_{aa}e'^a{}_\mu e'^a{}_\nu = g_{\mu\nu}$ for all 64 pairs) and that its
canonical connection obeys the vielbein postulate, and then that
$\gamma'^\mu\Omega'_\mu = \frac{6H - \beta}{2}(\cosh b\,\gamma^{(0)} -
\sinh b\,\gamma^{(4)})$ exactly. For $\beta = 6H$ this is ZERO for every $H$ and
every $a_4$, although the spinor connections $\Omega'_\mu$ themselves are not zero
(for $\mu = x_1, \dots, x_7$). The 28 matrices $S^{ab}$ ($a < b$) are linearly
independent (rank 28, checked in section 8), so $\Omega'_\mu$ is zero exactly when
all its coefficients $\omega'_{\mu ab}$ are. Every check also compares with the
```

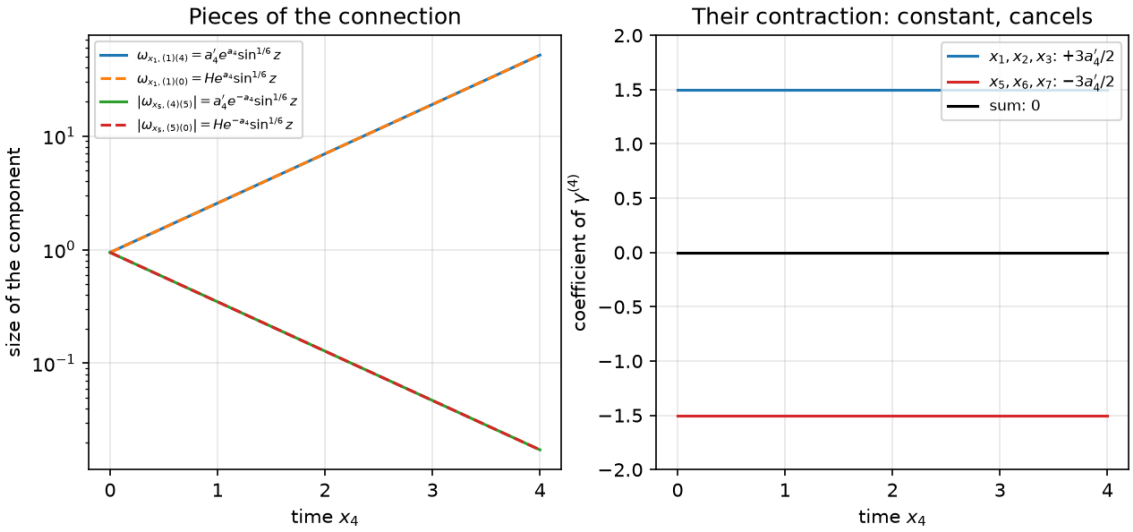

Figure 230: Along the canonical history $a_4 = x_4$ of the Kohn-Sham record ($A = H = 1$, a prescribed background) at $z = \pi/4$, against the time x_4. ## 12. The connection itself vanishes in no frame: the curvature
```

If Ω'_μ were zero in some frame, the spinor curvature $F_{\mu\nu} = \partial_\mu\Omega_\nu - \partial_\nu\Omega_\mu + [\Omega_\mu, \Omega_\nu]$ would be zero there. The next cell computes $F_{x_1x_0}$ in the diagonal frame and in the frame boosted with $\beta = 6H$ (where $\gamma'^\mu\Omega'_\mu = 0$) and checks:

1. in both frames $F_{x_1x_0} = \frac14\sum_{\rho,\sigma}R_{\rho\sigma x_1x_0} \gamma^\rho\gamma^\sigma$ with $R_{\rho\sigma\mu\nu} = g_{\rho\rho}R^\rho{}_{\sigma\mu\nu}$: the curvature of the connection is the Riemann tensor of the metric;
2. in both frames $F_{x_1x_0} = c_{14}\,\gamma^{(1)}\gamma^{(4)} + c_{10}\,\gamma^{(1)}\gamma^{(0)}$ with two numbers c_{14}, c_{10} (found as traces, like the coefficients of section 9, and printed);
3. hence $F_{x_1x_0}^2 = (c_{14}^2 - c_{10}^2)\,I_{16}$, because $(\gamma^{(1)}\gamma^{(4)})^2 = +1$, $(\gamma^{(1)}\gamma^{(0)})^2 = -1$ and the two products anticommute; and $c_{14}^2 - c_{10}^2$ is the SAME in both frames, $H^2\big((a_4')^2 - H^2\big)e^{2a_4}\cos^2 z/(4\sin^{5/3}z)$. It must be: the matrices γ^ρ and γ'^ρ of the two frames obey the same relations $\{\gamma^\rho, \gamma^\sigma\} = 2g^{\rho\sigma}$, so (because the 16-dimensional representation is irreducible; Pauli's theorem) there is an invertible 16×16 matrix S with $\gamma'^\rho = S\gamma^\rho S^{-1}$, and then $F' = SFS^{-1}$ and $F'^2 = SF^2S^{-1} = F^2$;
4. $F'_{x_1x_0}$ is not zero.

Since the Riemann tensor does not depend on the frame and is not zero, no frame can remove Ω_μ.

```
The next cell draws $F_{x_1x_0}$ in both frames as colour maps, at $H = 1$,
$z = \pi/4$, $x_4 = 0.5$, $b_0 = 0$, along the canonical history $a_4 = x_4$. On
this history $a_4' = AH = H$, so $c_{14}^2 - c_{10}^2 = 0$: the matrix $F_{x_1x_0}$
is NOT zero, but its square is zero (a *nilpotent* matrix, like the $2 \times 2$
matrix with rows $(0, 1)$ and $(0, 0)$); similar matrices have the same rank, and
the cell checks that both have rank 8. Moreover, with $a_4' = H$ the printed
boosted coefficients are $e^{-b}$ times the diagonal ones ($\cosh b - \sinh b =
e^{-b}$), so $F' = e^{-b}F$ at this point, with $b = 6Hx_4 = 3$; the cell checks
this too. The entries of the right map are therefore about $e^{-3} \approx 0.05$
times those of the left one; each map has its own colour scale.
```

In [12]:

## 13. The spin connection in the energy-momentum tensor

Although the connection drops out of the symmetrised Lagrangian (section 9), it
appears in the energy-momentum tensor. For a field that depends only on $x_4$,
the derivative part of $K^{x_4}{}_{x_1} = \frac12(\bar\Phi\gamma^{x_4}D_{x_1}\Phi -
(D_{x_1}\bar\Phi)\gamma^{x_4}\Phi)$ vanishes and the connection part is
$\frac12\bar\Phi\{\gamma^{x_4}, \Omega_{x_1}\}\Phi$. The next cell checks
```

```
$\frac12\{\gamma^{x_4}, \Omega_{x_1}\} = \frac12e^{a_4}\sin^{1/6}z\,H\,\gamma^{(4)}
\gamma^{(1)}\gamma^{(0)}$ (the $a_4'$ part cancels) and that the bilinear matrix
$C\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}$ is not zero.
```

In [13]:

```
g4_up, Omega_1 = diagonal["gamma"][4], diagonal["Omega"][1]
connection_part = (g4_up * Omega_1 + Omega_1 * g4_up) / 2
target = sp.exp(a4) * sixth * H * G[4] * G[1] * G[0] / 2
check_record(all(is_zero(v) for v in connection_part - target)

## 15. What this notebook showed

- On the background $b_4 = 1$: the canonical spin connection of the diagonal frame
  has 12 independent nonzero components, each $a_4'$ or $H$ times a factor that
  never vanishes, so
  $\Omega_\mu = 0$ for every $\mu$ only in the formal flat limit $a_4' = 0$,
  $H = 0$, which is not a member of the author's family (PROVED; Revision check
  `nontriviality_Omega_zero_iff_flat`).
- In the diagonal frame the term of the field equation is $\gamma^\mu\Omega_\mu =
  3H\gamma^{(0)}$ for EVERY history $a_4$ (PROVED, exact): the time-direction
  pieces $\pm a_4'/2$ of the three inflating and the three deflating directions
  cancel, the six hidden-direction pieces $H/2$ add up; equivalently it is the
  half-density term $\frac{1}{2\sqrt{|g|}}\partial_\mu(\sqrt{|g|}\gamma^\mu)$, and
  $\{\gamma^\mu, \Omega_\mu\} = 0$ for each $\mu$, so the connection drops out of
  the symmetrised Lagrangian. Because $(\gamma^{(0)})^2 = I_{16}$, the term
  $3H\gamma^{(0)}\Psi$ is not zero for any field $\Psi \neq 0$ (PROVED).
- The term contains no $a_4$, although $R^{x_4}{}_{x_4} = 6(a_4')^2$: the
  deflation of the extra times enters the field equation only through the frame
  factors $e^{\mp a_4}\sin^{-1/6}z$ of the derivative terms (PROVED). For a general
  $b_4$ the term is $3H\gamma^{(0)} + \frac34(b_4'/b_4)\gamma^{(4)}$ and the
  extra-time factor $e^{a_4}b_4^{-1/2}\sin^{-1/6}z$ (Chapter 6, Notebook 06a).
- The value $3H\gamma^{(0)}$ belongs to the diagonal frame: in the frame boosted in
  the $(x_4, x_0)$ plane with rapidity $\beta x_4 + b_0$ the term is
  $\frac{6H - \beta}{2}(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)})$, and for
  $\beta = 6H$ it is identically ZERO (PROVED). So "the field equation contains the
  gravitational term $3H\gamma^{(0)}$" is a statement about one frame and one
  choice of field variables, not about the field equation as such.
- What no frame removes: the spin connection itself. Its curvature equals
  $\frac14 R_{\rho\sigma\mu\nu}\gamma^\rho\gamma^\sigma$ in every frame (checked in
  two frames for $(\mu, \nu) = (x_1, x_0)$), and the Riemann tensor is not zero
  ($R^{x_0}{}_{x_0} = -6H^2$, $R = 6((a_4')^2 - 7H^2)$): the metric is curved for
  every $H > 0$ (PROVED). Together with the frame factors in every derivative
  term, this is the frame-independent content of the non-triviality statements
  [1] and [2].
- The connection also enters the energy-momentum tensor (PROVED for the component
  $K^{x_4}{}_{x_1}$ of a field that depends only on $x_4$).
```

8.15 Line-by-line walk-through of Notebook 08c

The notebook has 14 code cells, In [1] to In [14]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted exactly and then explained. A line that starts with `#` is a **comment**, which Python skips; it is there for the reader. In the quoted code a line `...` stands for the remaining lines of a long figure caption; every caption is printed in full under its figure in Section 8.14, and a paragraph "What Figure 08c.k shows" after the code says what to look for. Because Notebook 08c is the first notebook of this chapter, its set-up cell and its two record helpers are explained here in full; the walk-throughs of Notebooks 08a, 08b and 08d refer back to this explanation.

In [1], the set-up cell. The first part of the cell, down to the two lines of `-` and `=` signs, is the complete run instructions of Section 8.13 again, as comment lines, so that the notebook file carries

its own instructions. The code starts below the line that announces THE SET-UP. It computes no physics, and it is the same in every notebook of the book except for one line, the notebook's name.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of an installed package) so that the cell can use it. `json` reads and writes the text format JSON, in which the Revision record stores its results (a JSON file holds names and values: numbers, texts, lists and dictionaries); `os` gives access to the computer's environment; `textwrap` breaks long text into lines; `from pathlib import Path` takes the single name `Path` out of the module `pathlib`. A `Path` is the address of a file or a folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "08c"  # this notebook: chapter 08, example c
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell. A **variable** is a name for a value; the last line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"08c"`. The figure files are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description that Python stores but does not run. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it, and `[here, *here.parents]` is the list that starts with `here` and continues with all of them (the star unpacks one list into another). The `for` loop takes these folders one after the other; the operator `/` joins a folder and a name into a longer path; `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If no folder does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

`REPO` is the repository folder found by the function. An **environment variable** is a named text that the computer hands to every program it starts; `os.environ.get(name, default)` returns its value, or the default when it is not set. So `OUTPUT_ROOT`, the folder below which files are written, is the repository, unless the book's checking tool names a scratch folder; then a check run never changes the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path

def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`repository_file` gives the path of a repository file for reading. `output_file` gives the path at which to write a file and first creates its folder: `path.parent` is the folder of the file, and `mkdir(parents=True, exist_ok=True)` makes it together with any missing folders above it and does nothing if it exists already. `say` prints a text broken into lines of at most 89 characters; `str(text)` turns any value into a string first, and the continuation lines are indented by four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

matplotlib reads personal settings from the computer it runs on; `rcdefaults()` throws them away, so that every computer draws the same figures. `rcParams` is matplotlib's dictionary of settings (a **dictionary** is a table of pairs key: value in curly brackets); the update sets the standard figure size (7 by 4.2 inches), the font size, and a faint grid in every plot.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
```

```
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: the names in curly brackets are replaced by their values, so `CAPTION_FILE` is `Revision/textbook/figures/08c.captions.json`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes the text `{}` and a line end into the captions file, in the character encoding UTF-8 and with the line end `\n` on every operating system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
```

`setdefault(name, value)` returns the number already stored for this name, or stores and returns `value`, here one more than the number of figures so far; so the figures are numbered 1, 2, 3, ... in the order in which they are first saved, and a cell that is run twice keeps its number. The next two lines build the file name, for example `08c_1_cancel_and_survive.png`, and its path relative to the repository.

```
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`fig.savefig` writes the picture as a PNG file with the options explained in the comments. `plt.close(fig)` removes the figure from matplotlib's memory, so that Jupyter does not draw it again at the end of the cell. The caption is stored in the dictionary, and the whole dictionary is written into the captions file as JSON text (`json.dumps` turns it into a string; `indent=1` puts every entry on its own line and `sort_keys=True` sorts the entries, so that the file is always the same). `display(Image(...))` shows the saved picture below the cell; the `metadata` tells the book's tools which figure it is. The last line prints, for example, `Figure 08c.1 saved as Revision/textbook/figures/08c_1_cancel_and_survive.png`.

```
PASSED = []  # the names of the checks that passed, in order
```

```
def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (a sequence of values in square brackets). `check` is the notebook's test: if the condition is false, `raise AssertionError` stops the notebook with a message that names the check; otherwise the name is appended to `PASSED` and a line `PASS name` is printed, followed, when the argument `record` is given, by a line `reproduces ...` that names the Revision record and its check. `None` is Python's value for "nothing given".

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with `RESULT`; the expression `(f" {unit}" if u nit else "")` adds the unit only when one is given. `all_checks_passed` prints the last line of the notebook, with `len(PASSED)`, the number of checks that passed. The last statement prints the only output of the cell, `Set-up of notebook 08c complete:  repository folder found, helpers defined.`

In [2], the record helpers, the gammas, the symbols and the metric.

```
import numpy as np  # numbers and matrices (for the plots)
import sympy as sp  # exact algebra with symbols

REPORTS = {}  # report file -> {check name: (verdict, detail)}, each read once
```

numpy (short name `np`) computes with arrays of floating-point numbers; sympy (short name `sp`) computes exactly with symbols, fractions and functions. `REPORTS` is an empty dictionary that will hold each Revision report after it has been read once.

```
def record_says(report_file, check_name, *pieces):
    """True when the Revision report records the check check_name with the verdict
```

```
    pass and its detail text contains every given piece of text."""
    if report_file not in REPORTS:  # read the report the first time it is needed
        data = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
        REPORTS[report_file] = {entry["name"]: (entry["verdict"].lower(),
                                                entry["detail"])
                                for entry in data["checks"]}
    verdict, detail = REPORTS[report_file][check_name]
    return verdict == "pass" and all(piece in detail for piece in pieces)
```

A Revision report is a JSON file with a list `checks`; each entry has a `name`, a `verdict` (`PASS` or `FAIL`, written in capitals by some verifiers and in small letters by others) and a `detail` text. `*pieces` collects any number of further arguments into a tuple (a fixed list). The first time a report is needed, `json.loads` turns its text into Python values, and the **dictionary comprehension** in curly brackets builds the table name: (verdict in small letters, detail) for every entry. Then the function looks up the check and returns true only if its verdict is `pass` and every piece of text occurs in the detail (`piece in detail` asks whether one string is part of another; `all(...)` is true when every item is). A check name that the report does not contain makes the lookup fail with an error, which also stops the notebook.

```
def check_record(condition, title, report_file, check_names, *pieces):
    """check() for a result that reproduces Revision checks (one name or a list of
    names): it passes only if condition is true AND the report records every one
    of them as passed, with every piece of text in the detail of the first one."""
    names = [check_names] if isinstance(check_names, str) else list(check_names)
    on_record = record_says(report_file, names[0], *pieces) and all(
        record_says(report_file, name) for name in names[1:])
    word = "check" if len(names) == 1 else "checks"
    check(condition and on_record, title,
          record=f"{report_file}, {word} " + " and ".join(names))
```

`check_record` is `check` for a result that the Revision record also contains. `isinstance(check_names, str)` asks whether a single name (a string) was given; then it is put into a one-element list, otherwise the given names are turned into a list. The record must report the first check as passed with every piece of text in its detail, and every further check as passed. The check passes only if the notebook's own computation (`condition`) holds AND the record says so; the `record=` line then names the file and the check or checks (`" and ".join(names)` joins the names with the word `and`). So a PASS line with a `reproduces` line means two independent things agree: this notebook's computation and the Revision verifier.

```
gammas_record = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
G = [sp.Matrix(rows) for rows in gammas_record["gamma"]]  # gamma^(x0) ... (x7)
ETA = gammas_record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1]
C = sp.Matrix(gammas_record["C"])  # C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
```

The file `gammas.json` of the Revision record holds the eight gamma matrices as lists of rows of whole numbers, the frame metric `eta` and the matrix `C`. The **list comprehension** `[sp.Matrix(rows) for rows in ...]` turns each gamma into an exact sympy matrix; `G[k]` is $\gamma^{(k)}$: `G[0]` is $\gamma^{(0)}$, `G[1]` is $\gamma^{(1)}$ and `G[4]` is $\gamma^{(4)}$.

```
x = sp.symbols("x0:8", real=True)  # the coordinates; x[k] is xk
H = sp.Symbol("H", positive=True)
beta, b0 = sp.symbols("beta b0", real=True)  # the boost: rapidity beta x4 + b0
a4 = sp.Function("a4")(x[4])  # the metric function: ANY function of x4
z = 6 * H * x[0]
sixth = sp.sin(z) ** sp.Rational(1, 6)  # sin(z)^(1/6)
```

`sp.symbols("x0:8")` makes the eight symbols `x0`, ..., `x7` (the range 0 to 7; the end 8 is not included), so `x[k]` is x_k; `real=True` tells sympy they are real numbers, and `positive=True` that $H > 0$. `sp.Function("a4")(x[4])` is an unknown function $a_4(x_4)$: nothing is assumed about it, so every check below holds for every history. `z` is the expression $6Hx_0$ and `sixth` the expression $\sin^{1/6} z$ (`sp.Rational(1, 6)` is the exact fraction 1/6, not the decimal number 0.1666...).

```
f = [sp.cot(z)] + [sp.exp(a4) * sixth] * 3 + [sp.Integer(1)] \
    + [sp.exp(-a4) * sixth] * 3  # the scale factors f_0, ..., f_7 (b4 = 1)
g = [ETA[a] * f[a] ** 2 for a in range(8)]  # the diagonal entries g_aa
third = sp.sin(z) ** sp.Rational(1, 3)
authors_metric = [sp.cot(z) ** 2] + [sp.exp(2 * a4) * third] * 3 + [-1] \
    + [-sp.exp(-2 * a4) * third] * 3  # the author's metric at b4 = 1
```

`[value] * 3` is a list with three copies of the value, and `+` joins lists; so `f` is the list of the eight scale factors of Section 8.2 (the backslash at the end of a line continues the statement on the next line). `g` holds the diagonal entries $g_{aa} = \eta_{aa} f_a^2$ (`range(8)` runs through 0, 1, ..., 7). `authors_metric` is the author's metric typed directly from his formula, as a second, independent copy.

```
def is_zero(expr):
    """True when sympy shows that expr is exactly zero (two simplifications)."""
    expr = sp.sympify(expr)
    if expr == 0:
        return True
    simpler = sp.simplify(expr)
    return simpler == 0 or sp.simplify(sp.fu(simpler)) == 0
```

`is_zero` decides whether an exact expression is zero. `sp.sympify` turns plain Python numbers into sympy numbers; if the expression is already the number 0, the answer is yes. Otherwise sympy's general simplifier `sp.simplify` is tried, and if that does not reach 0, the trigonometric simplifier `sp.fu` followed by `simplify` again. (An answer "no" would only mean that sympy did not find a proof; every check of the notebook that uses `is_zero` needs the answer "yes", or that a quantity is NOT zero; for the latter the notebook also prints the expression, so that the reader can see it.)

```
# The record prints each entry as sympy writes it, e.g. "g_x0x0 = cot(6*H*x0)**2".
metric_texts = [f"g_x{a}x{a} = {sp.sstr(authors_metric[a])}" for a in range(8)]
say(metric_texts[0])
say(metric_texts[4])
check_record(all(is_zero(g[a] - authors_metric[a]) for a in range(8)),
             "eta_aa f_a^2 is the author's metric (all 8 diagonal entries)",
             "Revision/theory/reports/python-field-theory.json",
             "metric_from_vielbein_equals_SPEC", *metric_texts)
check_record(is_zero(sp.prod(f) - sp.cos(z)), "sqrt|g| = f0 f1 ... f7 = cos z (b4 = 1)",
             "Revision/theory/reports/python-field-theory.json",
             "sqrt_det_g_equals_cos_z", "cos(6 H x0)")
```

`sp.sstr` writes an expression as sympy's text (powers with `**`). The list `metric_texts` holds the eight entries in the form in which the record prints them, for example `g_x1x1 = exp(2*a4(x4))*sin(6*H*x0)**(1/3)`; two of them are printed. The first check compares the eight entries $\eta_{aa} f_a^2$ with the author's entries exactly, and it requires the record's check `metric_from_vielbein_equals_SPEC` to contain all eight texts (`*metric_texts` passes the list as eight separate arguments). The second check multiplies the eight scale factors (`sp.prod`) and compares with $\cos z$. Output: the two entries and two PASS lines, each with its `reproduces` line.

In [3], the Christoffel symbols.

```
Gam = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
for lam in range(8):
    for mu in range(8):
        for nu in range(8):
            value = 0  # the bracket of the formula; g is diagonal, so only these
            if lam == nu:  # three cases contribute
                value += sp.diff(g[lam], x[mu])
            if lam == mu:
                value += sp.diff(g[lam], x[nu])
            if mu == nu:
                value -= sp.diff(g[mu], x[lam])
            if value != 0:
                Gam[lam][mu][nu] = sp.simplify(value / (2 * g[lam]))
```

`Gam` is an $8 \times 8 \times 8$ table of exact zeros (a list of 8 lists of 8 lists of 8 zeros; `_` is a loop name that is not used). The three nested loops run over all 512 index triples. For a diagonal metric $g_{\lambda\nu}$ is nonzero only for $\lambda = \nu$, so the bracket $\partial_\mu g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu}$ of the formula of Section 8.4 has at most the three terms that the three `if` lines add (`sp.diff(expr, x[mu])` is the exact partial derivative; `+=` adds to a variable, `-=` subtracts). If the bracket is not zero, the symbol is the bracket divided by $2g_{\lambda\lambda}$, simplified.

```
independent = sum(1 for lam in range(8) for mu in range(8) for nu in range(mu, 8)
                  if Gam[lam][mu][nu] != 0)
report("independent nonzero Christoffel symbols", independent)
for lam, mu, nu in ((1, 1, 4), (5, 4, 5), (1, 0, 1), (0, 0, 0)):
    say(f"Gamma^x{lam}_x{mu} x{nu} = {Gam[lam][mu][nu]}")
check_record(independent == 25, "25 independent nonzero Christoffel symbols",
             "Revision/theory/reports/python-field-theory.json",
             "christoffel_symmetric_metric_compatible",
             f"{independent} independent nonzero symbols")
```

The **generator expression** counts 1 for every nonzero symbol with $\mu \le \nu$ (the symbols are symmetric in the two lower indices, so the pairs with $\nu < \mu$ are not new); the count is printed as a RESULT line: 25. The loop prints four symbols (index positions from 0, printed as names from 1): ${\Gamma^{x_1}}_{x_1 x_4} = a_4'$, which sympy writes `Derivative(a4(x4), x4)`; ${\Gamma^{x_5}}_{x_4 x_5} = -a_4'$; ${\Gamma^{x_1}}_{x_1 x_0} = H/\tan z = H \cot z$; and ${\Gamma^{x_0}}_{x_0 x_0} = -12H/\sin(2z)$, which is the table's $-6H/(\sin z \cos z)$ because $\sin 2z = 2 \sin z \cos z$. The check requires 25 and the record's text "25 independent nonzero symbols".

In [4], the frame, its connection and the vielbein postulate.

```
S_AB = [[(G[a] * G[c] - G[c] * G[a]) / 4 for c in range(8)] for a in range(8)]

def boost(b):
    """The boost by the rapidity b in the frame plane (x4, x0), and its inverse."""
    L, L_inverse = sp.eye(8), sp.eye(8)
    L[4, 4] = L[0, 0] = L_inverse[4, 4] = L_inverse[0, 0] = sp.cosh(b)
    L[4, 0] = L[0, 4] = sp.sinh(b)
    L_inverse[4, 0] = L_inverse[0, 4] = -sp.sinh(b)
    return L, L_inverse
```

`S_AB[a][c]` is the generator $S^{ac} = \frac{1}{4}[\gamma^{(a)}, \gamma^{(c)}]$ for all 64 pairs (the letter `c` is used for the second frame index because `b` is the rapidity). `boost(b)` starts from two 8×8 unit matrices (`sp.eye(8)`) and fills the entries of the (x_4, x_0) plane (rows and columns 4 and 0): $\cosh b$ on the diagonal and $\sinh b$ off it for the boost L of Section 8.3, and $-\sinh b$ off the diagonal for its inverse, the boost with $-b$ (multiply the two: $\cosh^2 b - \sinh^2 b = 1$ on the diagonal, $-\cosh b \sinh b + \sinh b \cosh b = 0$ off it).

```
def frame(b):
    """Vielbein e[a, mu], inverse E[mu, a], connection omega[mu, a, c] (mixed),
    Omega_mu and gamma^mu of the diagonal frame boosted by the rapidity b."""
    L, L_inverse = boost(b)
    e = L * sp.diag(*f)
    E = sp.diag(*[1 / value for value in f]) * L_inverse
```

`frame(b)` builds everything for the frame boosted by b (for $b = 0$, the diagonal frame). `sp.diag(*f)` is the diagonal matrix with the scale factors on its diagonal, the diagonal frame ${e^a}_\mu = f_a \delta^a_\mu$; multiplying by L from the left combines its rows, the frame vectors, exactly as in Section 8.3. The inverse is the product of the inverses in reverse order: the diagonal matrix of the $1/f_a$ times L^{-1}; `E[mu, a]` is ${E_a}^\mu$.

```
    omega = {}
    for mu in range(8):
        for a in range(8):
            for c in range(8):
                value = 0  # e^a_nu (d_mu E_c^nu + Gamma^nu_mu,lam E_c^lam)
                for nu in range(8):
                    if e[a, nu] == 0:
                        continue  # skip the terms that are zero anyway
                    term = sp.diff(E[nu, c], x[mu])
                    for lam in range(8):
                        if Gam[nu][mu][lam] != 0 and E[lam, c] != 0:
                            term += Gam[nu][mu][lam] * E[lam, c]
                    value += e[a, nu] * term
                omega[mu, a, c] = sp.simplify(value)
```

This is the definition of the canonical spin connection of Section 8.4, ${\omega_\mu}^a{}_c = \sum_\nu {e^a}_\nu(\partial_\mu {E_c}^\nu + \sum_\lambda {\Gamma^\nu}_{\mu\lambda} {E_c}^\lambda)$, written as four nested loops. `continue` jumps to the next ν when ${e^a}_\nu = 0$, and the inner `if` skips products with a zero factor; both only save time. The result is stored in the dictionary `omega` under the key `(mu, a, c)`; it is the connection with the first frame index up (the "mixed" form).

```
    Omega = []
    for mu in range(8):
        matrix = sp.zeros(16, 16)
        for a in range(8):
            for c in range(a + 1, 8):  # (1/2) sum over all a, c = sum over a < c
                matrix += ETA[a] * omega[mu, a, c] * S_AB[a][c]
        Omega.append(matrix)
    gamma_up = [sum((E[mu, a] * G[a] for a in range(8)), sp.zeros(16, 16))
                for mu in range(8)]
    return {"e": e, "E": E, "omega": omega, "Omega": Omega, "gamma": gamma_up}
```

For each μ the spinor connection $\Omega_\mu = \sum_{a<c} \omega_{\mu ac} S^{ac}$ is built from a 16×16 zero matrix (`sp.zeros(16, 16)`); `ETA[a] * omega[mu, a, c]` lowers the first frame index, $\omega_{\mu ac} = \eta_{aa} \omega_\mu{}^a{}_c$. The coordinate gammas are $\gamma^\mu = \sum_a E_a{}^\mu \gamma^{(a)}$ (the sum starts from the zero matrix given as the second argument of `sum`). The function returns a dictionary with the five objects.

```
def postulate_failures(fr):
    """How many of the 512 components of the vielbein postulate are not zero."""
    failures = 0
    for a in range(8):
        for mu in range(8):
            for nu in range(8):
                value = sp.diff(fr["e"][a, nu], x[mu]) \
                    - sum(Gam[lam][mu][nu] * fr["e"][a, lam] for lam in range(8)) \
                    + sum(fr["omega"][mu, a, c] * fr["e"][c, nu] for c in range(8))
                failures += 0 if is_zero(value) else 1
    return failures
```

`postulate_failures` evaluates the vielbein postulate $\partial_\mu e^a{}_\nu - \sum_\lambda \Gamma^\lambda{}_{\mu\nu} e^a{}_\lambda + \sum_c \omega_\mu{}^a{}_c e^c{}_\nu$ for all $8 \times 8 \times 8 = 512$ index triples and counts the ones that are not zero (`0 if ... else 1` is 0 when the component vanishes and 1 otherwise).

```
def antisymmetric(fr):
    """omega_mu,ac = eta_aa omega_mu^a_c is antisymmetric in a, c for every mu."""
    return all(is_zero(ETA[a] * fr["omega"][mu, a, c] + ETA[c] * fr["omega"][mu, c, a])
               for mu in range(8) for a in range(8) for c in range(8))

diagonal = frame(sp.Integer(0))
check_record(postulate_failures(diagonal) == 0 and antisymmetric(diagonal),
             "diagonal frame: vielbein postulate (512 components), omega antisymmetric",
             "Revision/theory/reports/python-field-theory.json",
             ["vielbein_postulate", "spin_connection_antisymmetric"],
             "(512 components)")
```

`antisymmetric` checks $\omega_{\mu ac} + \omega_{\mu ca} = 0$ for all 512 triples. Then the diagonal frame is built with $b = 0$ (`sp.Integer(0)` is sympy's exact zero) and the first check of the cell requires zero failures, antisymmetry, and the two record checks `vielbein_postulate` (whose detail must contain "(512 components)") and `spin_connection_antisymmetric`.

```
nonzero = [(mu, a, c) for mu in range(8) for a in range(8) for c in range(a + 1, 8)
           if not is_zero(diagonal["omega"][mu, a, c])]
omega_diagonal = diagonal["omega"]
for mu, a, c in nonzero:
    say(f"omega_x{mu},(x{a})(x{c}) = "
        f"{sp.simplify(ETA[a] * omega_diagonal[mu, a, c])}")
check_record(len(nonzero) == 12, "12 independent nonzero components omega_mu,ab (a < b)",
             "Revision/theory/reports/wolfram-field-theory.json", "omega_components",
             f"exactly {len(nonzero)} independent nonzero omega_mu,ab "
             "(a < b in the order x0..x7)")
```

`nonzero` lists every index triple (μ, a, c) with $a < c$ whose component is not zero, and the loop prints each lowered component $\omega_{\mu ac}$. The output shows exactly the 12 components of Section 8.4, in sympy's notation: for x_1, x_2, x_3 the pair `exp(a4(x4))*sin(6*H*x0)**(1/6)*Derivative(a4(x4), x4)` and `H*exp(a4(x4))*sin(6*H*x0)**(1/6)`, and for x_5, x_6, x_7 the same with e^{-a_4} and a minus sign. The check requires 12 and the Wolfram record's text with the number 12.

In [5], the connection vanishes only in flat space.

```
a4_prime = sp.diff(a4, x[4])  # a4' = d a4 / d x4
A1 = sp.Symbol("A1", real=True)  # a letter that stands for a4'
allowed = [sign * sp.exp(power * a4) * sixth for sign in (1, -1) for power in (1, -1)]
kinds = []  # for each component: "A1" (a4' times a factor) or "H" (H times a factor)
```

`a4_prime` is a_4'. `A1` is a plain symbol that the cell puts in place of a_4' (the Revision record writes `A1` for a_4'). `allowed` is the list of the four factors $\pm e^{\pm a_4} \sin^{1/6} z$ (two loops: two signs times two powers). `kinds` will record, for each of the 12 components, which shape it has.

```
for mu, a, c in nonzero:
    value = sp.simplify(ETA[a] * omega_diagonal[mu, a, c]).subs(a4_prime, A1)
    found = [str(coupling) for coupling in (A1, H) for factor in allowed
             if is_zero(value - coupling * factor)]  # which shape fits
    kinds.append(found[0] if len(found) == 1 else "no shape")
n_A1, n_H = kinds.count("A1"), kinds.count("H")
report("components of the form a4' x factor and H x factor", f"{n_A1}, {n_H}")
```

For each nonzero component, `.subs(a4_prime, A1)` replaces a_4' by the letter `A1`, and `found` lists the names of the couplings (a_4' or H) for which the component equals coupling times one allowed factor. Exactly one shape must fit; otherwise the component is marked `"no shape"`. `count` counts the two kinds. Output: `RESULT components of the form a4' x factor and H x factor = 6, 6`.

```
S_rows = np.array([[float(v) for v in S_AB[a][c]] for a in range(8)
                   for c in range(a + 1, 8)])  # 28 rows of 256 numbers
rank_S = int(np.linalg.matrix_rank(S_rows))
report("rank of the 28 matrices S^ab written as rows of 256 numbers", rank_S)
```

Each of the 28 generators S^{ac} with $a < c$ is written as one row of its 256 entries (iterating over a sympy matrix gives its entries row by row; `float` turns each into a decimal number). `np.linal`

`g.matrix_rank` computes the **rank** of the 28×256 array: the number of independent rows. Output: 28, so the 28 generators are linearly independent.

```
# a4' != 0 makes the six "A1" components nonzero, H != 0 the six "H" components;
# with independent S^ab, Omega vanishes for every mu only when a4' = 0 and H = 0.
check_record(n_A1 == 6 and n_H == 6 and rank_S == 28,
             "Omega_mu = 0 for every mu iff a4' = 0 and H = 0 (formal flat limit)",
             "Revision/theory/reports/python-field-theory.json",
             "nontriviality_Omega_zero_iff_flat",
             "the S^ab are linearly independent",
             "every Omega_mu vanishes iff a4' = 0 AND H = 0")
```

The comment repeats the three-line argument of Section 8.6, and the check combines its three ingredients (six components of each kind, rank 28) with the record's check `nontriviality_Omega_zero_iff_flat`, whose detail must contain the two quoted sentences.

In [6], what cancels and what survives.

```
per_direction = [(diagonal["gamma"][mu] * diagonal["Omega"][mu]).applyfunc(sp.simplify)
                 for mu in range(8)]
coefficient_4 = [sp.simplify(-(G[4] * M).trace() / 16) for M in per_direction]
coefficient_0 = [sp.simplify((G[0] * M).trace() / 16) for M in per_direction]
```

`per_direction[mu]` is the product $\gamma^{x_\mu}\Omega_{x_\mu}$ (no sum); `.applyfunc(sp.simplify)` simplifies each of its 256 entries. The **trace** (`.trace()`) of a matrix is the sum of its diagonal entries. If $M = c_4\gamma^{(4)} + c_0\gamma^{(0)}$, then $\mathrm{tr}(\gamma^{(0)}M) = c_4\,\mathrm{tr}(\gamma^{(0)}\gamma^{(4)}) + c_0\,\mathrm{tr}(I_{16}) = 16c_0$ and $\mathrm{tr}(\gamma^{(4)}M) = c_4\,\mathrm{tr}(-I_{16}) + c_0\,\mathrm{tr}(\gamma^{(4)}\gamma^{(0)}) = -16c_4$, because the trace of a product of two different gammas is zero (Section 8.9, Step 4). So the two lists hold the coefficients c_4 and c_0 of every direction.

```
nothing_else = all(
    all(is_zero(entry) for entry in
        per_direction[mu] - coefficient_4[mu] * G[4] - coefficient_0[mu] * G[0])
    for mu in range(8))
for mu in range(8):
    say(f"gamma^x{mu} Omega_x{mu} = ({coefficient_4[mu]}) gamma^(x4) "
        f"+ ({coefficient_0[mu]}) gamma^(x0)")
check(nothing_else, "each gamma^mu Omega_mu (no sum) is a combination of gamma^(x4) "
      "and gamma^(x0)")
```

`nothing_else` subtracts $c_4\gamma^{(4)} + c_0\gamma^{(0)}$ from each product and asks whether every entry of the remainder is zero: the trace formula is valid only if nothing else is left. The loop prints the eight products: $(a_4'/2)\gamma^{(4)} + (H/2)\gamma^{(0)}$ for x_1, x_2, x_3; zero for x_4 and x_0; $(-a_4'/2)\gamma^{(4)} + (H/2)\gamma^{(0)}$ for x_5, x_6, x_7, exactly the results of Section 8.5. The check prints its PASS line.

```
THEORY = "Revision/theory/reports/python-field-theory.json"  # the sympy record
# The record writes A1 for a4'; the partial sums in the record's notation:
inflating_sum = sp.simplify(sum(coefficient_4[1:4])).subs(a4_prime, A1)  # 3*A1/2
deflating_sum = sp.simplify(sum(coefficient_4[5:8])).subs(a4_prime, A1)  # -3*A1/2
hidden_sum = sp.simplify(sum(coefficient_0))  # 3*H
say(f"sums: inflating {inflating_sum}, deflating {deflating_sum}, hidden {hidden_sum}")
```

`THEORY` is a short name for the path of the sympy field-theory report. `coefficient_4[1:4]` is the part of the list with positions 1, 2, 3 (the directions x_1, x_2, x_3) and `coefficient_4[5:8]` the part with positions 5, 6, 7 (x_5, x_6, x_7). The three partial sums are printed in the record's notation: `sums: inflating 3*A1/2, deflating -3*A1/2, hidden 3*H`.

```
check_record([sp.simplify(c4 / a4_prime) for c4 in coefficient_4]
             == [0] + [sp.Rational(1, 2)] * 3 + [0] + [-sp.Rational(1, 2)] * 3
             and [sp.simplify(c0 / H) for c0 in coefficient_0]
             == [0] + [sp.Rational(1, 2)] * 3 + [0] + [sp.Rational(1, 2)] * 3,
             "per direction: +a4'/2 and -a4'/2 cancel, six times H/2 add up",
             THEORY, "time_terms_cancel_hidden_term_survives",
             f"inflating sum {inflating_sum}, deflating sum {deflating_sum}",
             f"the six hidden-direction terms add to {hidden_sum} gamma^(x0)")
```

The coefficients of $\gamma^{(4)}$ are divided by a_4' and must be exactly $\frac{1}{2}$ for x_1, x_2, x_3, then 0 for x_4, $-\frac{1}{2}$ for x_5, x_6, x_7 and 0 for x_0; the coefficients of $\gamma^{(0)}$ are divided by H and must be $\frac{1}{2}$ for the same six directions and 0 for x_4 and x_0. The record's check must contain the printed partial sums.

```
total = sum(per_direction, sp.zeros(16, 16))
check_record(all(is_zero(entry) for entry in total - 3 * H * G[0]),
             "gamma^mu Omega_mu = 3 H gamma^(x0) in the diagonal frame",
             THEORY, "gamma_mu_Omega_mu_equals_3H_gamma_x0",
             "gamma^mu Omega_mu = 3 H gamma^(x0) exactly")
# gamma^(x0) squares to 1, so it is invertible: 3 H gamma^(x0) Psi = 0 only for
# Psi = 0. The gravitational term is not zero for any field Psi that is not zero.
check_record(G[0] * G[0] == sp.eye(16),
             "(gamma^(x0))^2 = 1: 3 H gamma^(x0) Psi != 0 for every Psi != 0 (H > 0)",
             "Revision/theory/reports/wolfram-field-theory.json",
             "nontriviality_1_dirac16complex",
             "every Psi != 0 (gamma^(x0) is invertible)")
```

`total` adds the eight products: the matrix $\gamma^\mu \Omega_\mu$. The first check compares it entry by entry with $3H\gamma^{(0)}$. The second checks $(\gamma^{(0)})^2 = I_{16}$, the argument of Section 8.6 that $3H\gamma^{(0)}\Psi = 0$ only for $\Psi = 0$, together with the Wolfram record's non-triviality check.

```
sqrt_g = sp.cos(z)  # sqrt|g| = b4^(3/2) cos z, at b4 = 1
divergence = sum((sp.diff(sqrt_g * diagonal["gamma"][mu], x[mu]) for mu in range(8)),
                 sp.zeros(16, 16)) / (2 * sqrt_g)
check_record(all(is_zero(entry) for entry in divergence - 3 * H * G[0]),
             "(1/(2 sqrt|g|)) d_mu(sqrt|g| gamma^mu) = 3 H gamma^(x0) (divergence "
             "form)", THEORY, "divergence_of_sqrtg_gamma",
             "= 3 H gamma^(x0) = gamma^mu Omega_mu")
```

`divergence` is the half-density term $\frac{1}{2\sqrt{|g|}} \sum_\mu \partial_\mu(\sqrt{|g|}\gamma^\mu)$ of Section 8.5, computed with $\sqrt{|g|} = \cos z$ (sympy differentiates a matrix entry by entry); the check compares it with $3H\gamma^{(0)}$.

```
check_record(all(all(is_zero(entry) for entry in
                     diagonal["gamma"][mu] * diagonal["Omega"][mu]
```

```
            + diagonal["Omega"][mu] * diagonal["gamma"][mu])
        for mu in range(8)),
    "{gamma^mu, Omega_mu} = 0 for each mu: Omega drops out of the Lagrangian",
    "Revision/theory/reports/python-scope.json",
    "connection_free_lagrangian_same_equations",
    "{gamma^mu, Omega_mu} = 0 for each mu separately")
```

This check computes the anticommutator $\{\gamma^\mu, \Omega_\mu\}$ for each of the eight directions separately and requires every entry to be zero: the fact of Section 8.8 that removes the connection from the Lagrangian.

```
names = [f"$x_{mu}$" for mu in range(8)] + ["sum"]
values_4 = [float(sp.simplify(c4 / a4_prime)) for c4 in coefficient_4]
values_0 = [float(sp.simplify(c0 / H)) for c0 in coefficient_0]
values_4.append(sum(values_4))
values_0.append(sum(values_0))
colours = ["gray"] + ["tab:blue"] * 3 + ["gray"] + ["tab:red"] * 3 + ["black"]
```

For the bar chart: nine bar labels (the directions, written as LaTeX for matplotlib, and `"sum"`), the coefficients in units of a_4' and of H as decimal numbers, each list extended by its sum (`append` adds one element at the end), and nine colours (blue for 3-space, red for the extra times, gray for x_4 and x_0, black for the sum).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0), sharey=True)
left.bar(names, values_4, color=colours)
left.set_title("coefficient of $\\gamma^{(4)}$, in units of $a_4'$")
left.set_ylabel("coefficient")
right.bar(names, values_0, color=colours)
right.set_title("coefficient of $\\gamma^{(0)}$, in units of $H$")
for panel in (left, right):
    panel.axhline(0.0, color="black", linewidth=0.8)
    panel.set_xlabel("direction $\\mu$ of $\\gamma^{\\mu}\\Omega_{\\mu}$")
save_figure(fig, "cancel_and_survive",
            "The term $\\gamma^\\mu\\Omega_\\mu$ of the field equation in the "
            ...
            "history $a_4$ and every $H > 0$, on the background $b_4 = 1$.")
```

`plt.subplots(1, 2, ...)` makes a figure with one row of two panels (axes), `left` and `right`, 10 by 4 inches, with a shared vertical axis. `bar` draws one bar per label with the given heights and colours. The titles and labels are LaTeX text between dollar signs (in a Python string a backslash is written twice). `axhline(0.0, ...)` draws a horizontal line at zero in both panels. `save_figure` saves the figure as Figure 08c.1 with its caption.

What Figure 08c.1 shows. Two bar charts with the eight directions $x_0, \ldots, x_7$ and their sum on the horizontal axis; the vertical axis is a pure number. Left: the coefficient of $\gamma^{(4)}$ in units of a_4': three blue bars at $+\frac{1}{2}$ (3-space), a gray bar at 0 (x_4), three red bars at $-\frac{1}{2}$ (the extra times), a gray bar at 0 (x_0), and a black sum bar at 0. Right: the coefficient of $\gamma^{(0)}$ in units of H: six bars at $+\frac{1}{2}$ and a sum bar at 3. The student should see the cancellation of the time-direction pieces (because the extra times deflate at the rate at which 3-space inflates) and the addition of the six hidden-direction pieces. The values are exact and hold for every history.

In [7], the curvature, and the pieces along the history.

```
def riemann(rho, sigma, mu, nu):
    """R^rho_sigma,mu,nu from the Christoffel symbols (not simplified)."""
    value = sp.diff(Gam[rho][nu][sigma], x[mu]) - sp.diff(Gam[rho][mu][sigma], x[nu])
    for lam in range(8):
        value += Gam[rho][mu][lam] * Gam[lam][nu][sigma] \
            - Gam[rho][nu][lam] * Gam[lam][mu][sigma]
    return value
```

`riemann` evaluates the Riemann tensor $R^{\rho}{}_{\sigma\mu\nu} = \partial_\mu \Gamma^{\rho}{}_{\nu\sigma} - \partial_\nu \Gamma^{\rho}{}_{\mu\sigma} + \sum_\lambda (\Gamma^{\rho}{}_{\mu\lambda}\Gamma^{\lambda}{}_{\nu\sigma} - \Gamma^{\rho}{}_{\nu\lambda}\Gamma^{\lambda}{}_{\mu\sigma})$ (Chapter 3) for one index quadruple.

```
ricci = [sum(riemann(rho, a, rho, a) for rho in range(8)) / g[a] for a in range(8)]
a4_second = sp.diff(a4, x[4], 2)
expected = [-6 * H**2] + [a4_second - 6 * H**2] * 3 + [6 * a4_prime**2] \
    + [-a4_second - 6 * H**2] * 3
check_record(all(is_zero(ricci[a] - expected[a]) for a in range(8)),
             "R^x1_x1 = a4'' - 6H^2, R^x4_x4 = 6 a4'^2, R^x5_x5 = -a4'' - 6H^2, "
             "R^x0_x0 = -6H^2", "Revision/theory/reports/wolfram-field-theory.json",
             "ricci_mixed_components", "R^x0_x0 = -6 H^2",
             "R^x1_x1 = R^x2_x2 = R^x3_x3 = a4'' - 6 H^2", "R^x4_x4 = 6 a4'^2",
             "R^x5_x5 = R^x6_x6 = R^x7_x7 = -a4'' - 6 H^2")
```

The Ricci tensor is $R_{aa} = \sum_\rho R^{\rho}{}_{a\rho a}$, and for a diagonal metric its mixed form is $R^{a}{}_{a} = R_{aa}/g_{aa}$; `ricci` holds the eight diagonal entries. `sp.diff(a4, x[4], 2)` is a_4''. The check compares them with the values of Section 8.7 and with the four texts of the Wolfram record.

```
ricci_scalar = sp.factor(sp.simplify(sum(ricci)).subs(a4_prime, A1))  # A1 for a4'
say(f"Ricci scalar in the record's notation: R = {ricci_scalar}")
check_record(is_zero(sum(ricci) - 6 * (a4_prime**2 - 7 * H**2)),
             "Ricci scalar R = 6 (a4'^2 - 7 H^2): curved for every H > 0",
             THEORY, "curvature_nonzero_flat_only_formally",
             f"Ricci scalar R = {sp.sstr(ricci_scalar)}")
check_record(not total.applyfunc(sp.simplify).has(a4) and not is_zero(ricci[4]),
             "gamma^mu Omega_mu contains no a4, although R^x4_x4 = 6 a4'^2 is not zero",
             "Revision/theory/reports/python-scope.json",
             "gammaOmega_blind_to_the_deflation",
             "contains neither e^a4 nor a4' nor a4''", "R^x4_x4 = 6 a4'^2")
```

The Ricci scalar is the sum of the eight entries; `sp.factor` writes it as a product, and it is printed as `R = 6*(A1**2 - 7*H**2)`. The first check compares it with $6((a_4')^2 - 7H^2)$ and with the record's text. The second check asks whether the simplified matrix $\gamma^\mu \Omega_\mu$ contains the function a_4 at all (`.has(a4)` is true if a_4 or a derivative of it occurs anywhere in it) and requires that $R^{x_4}{}_{x_4}$ is not zero.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
A_history = parameters["physics"]["historyA"]  # the canonical history a4 = A H x4
history = sp.Lambda(x[4], A_history * x[4])  # with H = 1: a4 = x4
```

The parameters of the Revision Kohn-Sham record hold the constant A of the canonical history $a_4 = AHx_4$ (here $A = 1$), the prescribed background of the book's Kohn-Sham chapters. `sp.Lambda(x[4], A_history * x[4])` is the function $x_4 \mapsto Ax_4$, which is a_4 when $H = 1$.

```
def along_history(expr):
    """A numpy function of x4 for expr with H = 1, a4 = A x4, z = pi/4."""
    concrete = expr.replace(sp.Function("a4"), history).doit()
    concrete = concrete.subs({H: 1, x[0]: sp.pi / 24})  # z = 6 x0 = pi/4
    return sp.lambdify(x[4], concrete, "numpy")
```

`along_history` turns an exact expression into a numerical function of the time: `replace` puts the history in place of the unknown function a_4, `doit()` carries out the derivatives that then become computable ($a_4' = A$), `subs` puts in $H = 1$ and $x_0 = \pi/24$, so that $z = 6x_0 = \pi/4$, and `sp.lambdify` makes a numpy function of x_4.

```
times = np.linspace(0.0, 4.0, 201)
pieces = {"$\\omega_{x_1,(1)(4)} = a_4'e^{a_4}\\sin^{1/6}z$": diagonal["omega"][1, 1, 4],
          "$\\omega_{x_1,(1)(0)} = He^{a_4}\\sin^{1/6}z$": diagonal["omega"][1, 1, 0],
          "$|\\omega_{x_5,(4)(5)}| = a_4'e^{-a_4}\\sin^{1/6}z$":
              -ETA[4] * diagonal["omega"][5, 4, 5],
          "$|\\omega_{x_5,(5)(0)}| = He^{-a_4}\\sin^{1/6}z$":
              ETA[5] * diagonal["omega"][5, 5, 0]}
```

`np.linspace(0.0, 4.0, 201)` is an array of 201 equally spaced times from 0 to 4. The dictionary `pieces` maps four legend labels to four components of the connection: the two of the inflating direction x_1 and the two of the extra time x_5 (the factors `-ETA[3]` and `ETA[4]` turn the stored mixed components into the sizes named in the labels; the plot takes absolute values anyway).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
for (label, expr), style in zip(pieces.items(), ("-", "--", "-", "--")):
    left.plot(times, np.abs(along_history(expr)(times)) * np.ones_like(times),
              style, label=label)
left.set_yscale("log")
left.set_xlabel("time $x_4$")
left.set_ylabel("size of the component")
left.set_title("Pieces of the connection")
left.legend(fontsize=7)
```

`zip` pairs each (label, expression) with a line style: one minus sign in quotes for a solid line, two minus signs for a dashed one. Each component is evaluated along the history at the 201 times; `np.abs` takes the size, and multiplying by `np.ones_like(times)` (an array of ones) makes sure that an expression that happens to be constant is still drawn as a full curve. The vertical axis is logarithmic (`set_yscale("log")`), so an exponential is a straight line.

```
inflating = along_history(sum(coefficient_4[1:4]))(times) * np.ones_like(times)
deflating = along_history(sum(coefficient_4[5:8]))(times) * np.ones_like(times)
right.plot(times, inflating, color="tab:blue", label="$x_1, x_2, x_3$: $+3a_4'/2$")
right.plot(times, deflating, color="tab:red", label="$x_5, x_6, x_7$: $-3a_4'/2$")
```

```
right.plot(times, inflating + deflating, color="black", label="sum: $0$")
right.set_ylim(-2.0, 2.0)
right.set_xlabel("time $x_4$")
right.set_ylabel("coefficient of $\\gamma^{(4)}$")
right.set_title("Their contraction: constant, cancels")
right.legend(fontsize=8);
save_figure(fig, "pieces_along_history",
            "Along the canonical history $a_4 = x_4$ of the Kohn-Sham record ($A = "
            ...
            "sums stay constant, and they cancel exactly (black).")
```

The right panel draws the two partial sums of the $\gamma^{(4)}$ coefficients (3-space and extra times) along the history, and their sum; `set_ylim` fixes the vertical range. The semicolon after `right.legend(fontsize=8)` stops Jupyter from printing the value of that line (it would print an object with a memory address that changes from run to run). The figure is saved as Figure 08c.2. The cell prints three PASS lines, each with its `reproduces` line, and the figure line.

What Figure 08c.2 shows. Both panels have the time x_4 (units of $1/H$, with $H = 1$) on the horizontal axis, along the history $a_4 = x_4$ at $z = \pi/4$. Left, on a logarithmic vertical axis, four components of the canonical spin connection (pure numbers in units of H): the two of the inflating direction x_1 rise along a straight line (they grow like e^{a_4}), the two of the deflating extra time x_5 fall along a straight line (they shrink like e^{-a_4}); the dashed and the solid curves coincide because here $a_4' = AH = 1 = H$. Right: the coefficient of $\gamma^{(4)}$ in $\gamma^\mu \Omega_\mu$, summed over 3-space (blue, $+\frac{3}{2}$) and over the extra times (red, $-\frac{3}{2}$), and their sum (black, 0): three horizontal lines. The student should see that the pieces of the connection change exponentially while their contraction with the coordinate gammas does not change at all, and cancels: the deflation is invisible in the term.

In [8], the boosted frame.

```
rapidity = beta * x[4] + b0
boosted = frame(rapidity)
e_b = boosted["e"]
same_metric = all(
    is_zero(sum(ETA[a] * e_b[a, mu] * e_b[a, nu] for a in range(8))
            - (g[mu] if mu == nu else 0)) for mu in range(8) for nu in range(8))
SCOPE = "Revision/theory/reports/python-scope.json"  # the record of these checks
check_record(same_metric and all(is_zero(v) for v in e_b * boosted["E"] - sp.eye(8)),
             "the boosted frame gives the same metric (64 entries); e' E' = 1",
             SCOPE, "boosted_frame_reproduces_metric",
             "equals the author's metric for all 64 (mu, nu)")
```

The rapidity is the expression $b = \beta x_4 + b_0$ with symbolic β and b_0, and `frame(rapidity)` builds the boosted frame, its connection and its gammas exactly. `same_metric` checks, for all 64 pairs (μ, ν), that $\sum_a \eta_{aa} e'^a{}_\mu e'^a{}_\nu$ is $g_{\mu\mu}$ on the diagonal and 0 off it (the expression `(g[mu] if mu == nu else 0)` chooses). The check also verifies that E' is the inverse of e' ($e'E' = I_8$). `SCOPE` is a short name for the path of the scope report.

```
failures = postulate_failures(boosted)  # the number of nonzero components
check_record(failures == 0 and antisymmetric(boosted),
             "boosted frame: vielbein postulate (512 components), omega' antisymmetric",
```

```
            SCOPE, "boosted_frame_canonical_connection",
            f"holds for all 512 (a, mu, nu) ({failures} failures)")
```

The vielbein postulate and the antisymmetry for the boosted frame; the record's text must contain the same number of failures, 0.

```
total_boosted = sum((boosted["gamma"][mu] * boosted["Omega"][mu] for mu in range(8)),
                    sp.zeros(16, 16))
formula = (6 * H - beta) / 2 * (sp.cosh(rapidity) * G[0] - sp.sinh(rapidity) * G[4])
check_record(all(is_zero(entry) for entry in total_boosted - formula),
             "gamma'^mu Omega'_mu = ((6H - beta)/2) (cosh b gamma^(x0) - sinh b "
             "gamma^(x4))", SCOPE, "boosted_frame_gammaOmega_formula",
             "gamma'^mu Omega'_mu = ((6 H - beta)/2) (cosh b gamma^(x0) - sinh b "
             "gamma^(x4))")
```

`total_boosted` is $\gamma'^{\mu}\Omega'_{\mu}$ computed from the definitions; `formula` is the result of Section 8.9; the check compares all 256 entries.

```
at_6H = {beta: 6 * H}
nonzero_Omega = [mu for mu in range(8) if not all(
    is_zero(ETA[a] * boosted["omega"][mu, a, c].subs(at_6H))
    for a in range(8) for c in range(a + 1, 8))]
nonzero_text = ", ".join(f"x{mu}" for mu in nonzero_Omega)  # "x1, x2, ..."
say("beta = 6H: Omega'_mu is nonzero for mu = " + nonzero_text)
```

`at_6H` is the substitution $\beta = 6H$. `nonzero_Omega` lists the directions μ for which at least one component $\omega'_{\mu ac}$ is not zero at $\beta = 6H$; because the S^{ac} are linearly independent (In [5]), these are exactly the directions with $\Omega'_{\mu} \neq 0$. The line printed: `beta = 6H: Omega'_mu is nonzero for mu = x1, x2, x3, x4, x5, x6, x7`.

```
check_record(all(is_zero(entry.subs(at_6H)) for entry in total_boosted - formula)
             and formula.subs(at_6H) == sp.zeros(16, 16)
             and nonzero_Omega == [1, 2, 3, 4, 5, 6, 7],
             "beta = 6H: gamma'^mu Omega'_mu = 0 identically, Omega'_mu != 0 for "
             "x1..x7", SCOPE, "boosted_frame_gammaOmega_vanishes", "IDENTICALLY ZERO",
             f"nonzero for mu = {nonzero_text} (zero only for x0)")
```

The last check of the cell: at $\beta = 6H$ the computed term equals the formula, the formula is the zero matrix, and the connection is nonzero in the seven directions $x_1, \ldots, x_7$; the record must say "IDENTICALLY ZERO" and list the same directions. The cell prints four PASS lines and the line about Ω'_{μ}.

In [9], the size of the term in the boosted frames.

```
term = sp.lambdify((beta, x[4], b0), formula.subs(H, 1), "numpy")

def size(matrix):
    """sqrt(tr(M^T M)/16): the size of a 16 x 16 matrix, 1 for gamma^(x0)."""
    matrix = np.array(matrix, dtype=float)
    return np.sqrt(np.trace(matrix.T @ matrix) / 16)
```

`term` is a numerical function of (β, x_4, b_0) that returns the 16×16 matrix $\gamma'^{\mu}\Omega'_{\mu}$ at $H = 1$, from the formula that In [8] proved equal to the computed matrix. `size` measures a matrix by $\sqrt{\mathrm{tr}(M^T M)/16}$: $\mathrm{tr}(M^T M)$ is the sum of the squares of all 256 entries, so the size is the square root of that sum divided by 16 (for $\gamma^{(0)}$, a matrix with sixteen entries 1 and no others, it is 1); `@` is numpy's matrix product and `.T` the transpose.

```
beta_values = np.linspace(0.0, 12.0, 241)
sizes_beta = [size(term(bv, 0.0, 0.0)) for bv in beta_values]
check(abs(size(term(0.0, 0.0, 0.0)) - 3.0) < 1e-12 and size(term(6.0, 0.7, 0.3)) == 0,
      "size 3 in the diagonal frame (3 H gamma^(x0), H = 1), 0 for beta = 6H")
```

The sizes at 241 rapidity rates from 0 to 12, at $x_4 = 0$, $b_0 = 0$. The check: the diagonal frame ($\beta = 0$) gives size 3 to 10^{-12} (the term is $3\gamma^{(0)}$), and $\beta = 6H = 6$ gives exactly 0 at another point ($x_4 = 0.7$, $b_0 = 0.3$), because the factor $(6H - \beta)/2$ is exactly zero.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(beta_values, sizes_beta)
left.plot([0.0, 6.0], [3.0, 0.0], "o", color="black")
left.annotate("diagonal frame: $3H\\gamma^{(0)}$", (0.0, 3.0), (1.0, 3.3))
left.annotate("$\\beta = 6H$: zero", (6.0, 0.0), (6.6, 0.4))
left.set_xlabel("rapidity rate $\\beta$ (units of $H$)")
left.set_ylabel("size of $\\gamma'^\\mu\\Omega'_\\mu$ (units of $H$)")
left.set_title("At $x_4 = 0$, $b_0 = 0$")
left.set_ylim(-0.2, 4.0)
```

The left panel draws the size against β, marks the two special points with black dots (`"o"`), and writes a text next to each (`annotate(text, point, text position)`).

```
times = np.linspace(0.0, 0.5, 101)
for bv in (0.0, 3.0, 6.0, 9.0):
    right.plot(times, [size(term(bv, t, 0.0)) for t in times],
               label=f"$\\beta = {bv:g}H$")
right.set_yscale("symlog", linthresh=0.1)
right.set_xlabel("time $x_4$ (units of $1/H$)")
right.set_ylabel("size (units of $H$)")
right.set_title("Against time, $b_0 = 0$")
right.legend(fontsize=8);
save_figure(fig, "boost_size",
            "The size $\\sqrt{\\mathrm{tr}(M^TM)/16}$ of the term $M = "
            ...
            "every one of these frames.")
```

The right panel draws the size against the time from 0 to 0.5 for four rapidity rates (`{bv:g}` prints a number without unnecessary zeros, so `6.0` becomes `6`). The vertical axis is **symmetric logarithmic** (`"symlog"`): linear between -0.1 and 0.1 and logarithmic outside, so that the curve at exactly 0 can be drawn together with the growing ones. The figure is Figure 08c.3. Output: one PASS line and the figure line.

What Figure 08c.3 shows. Left: the size of $\gamma'^{\mu}\Omega'_{\mu}$ (units of H) against the rapidity rate β (units of H) at $x_4 = 0$: a V-shaped line, $|6H - \beta|/2$, from 3 at $\beta = 0$ (the diagonal frame, black dot)

down to 0 at $\beta = 6H$ (black dot) and up again. Right: the size against the time x_4 (units of $1/H$) for $\beta = 0, 3H, 6H, 9H$: constant 3 for the diagonal frame, growing for $\beta = 3H$ and $9H$ (the factor $\sqrt{\cosh 2b}$ of Exercise 5 in Section 8.39), and zero at all times for $\beta = 6H$. The student should see that the same metric and the same field equation give, in different frames, terms of every size including zero.

In [10], the term as colour maps.

```
maps = [("diagonal frame", term(0.0, 0.3, 0.0)),
        ("boosted, $\\beta = 3H$", term(3.0, 0.3, 0.0)),
        ("boosted, $\\beta = 6H$", term(6.0, 0.3, 0.0))]
fig, panels = plt.subplots(1, 3, figsize=(11.0, 3.9))
```

Three (title, matrix) pairs at $x_4 = 0.3$, $b_0 = 0$, and a figure with three panels.

```
for panel, (title, matrix) in zip(panels, maps):
    image = panel.imshow(np.array(matrix, dtype=float), cmap="RdBu_r", vmin=-3.5,
                         vmax=3.5)
    panel.set_title(title, fontsize=10)
    panel.set_xticks([0, 5, 10, 15])
    panel.set_yticks([0, 5, 10, 15])
    panel.set_xlabel("column")
    panel.grid(False)  # no grid lines over the coloured squares
panels[0].set_ylabel("row")
fig.colorbar(image, ax=list(panels), shrink=0.8, label="entry (units of $H$)")
save_figure(fig, "heat_maps",
            "The $16 \\times 16$ matrix $\\gamma^\\mu\\Omega_\\mu$ of the field "
            ...
            "matrix. Same metric, same field equation, different frames.")
```

`imshow` draws a matrix as a grid of coloured squares; the colour map `"RdBu_r"` runs from blue (negative) through white (zero) to red (positive), on the same scale -3.5 to 3.5 in all three panels (`vmin`, `vmax`). The ticks mark rows and columns 0, 5, 10, 15. One colour bar serves all three panels. The figure is Figure 08c.4; the cell prints only the figure line.

What Figure 08c.4 shows. Three 16×16 colour maps (rows and columns numbered from 0; entries in units of H). Left, the diagonal frame: $3H\gamma^{(0)}$, sixteen red squares of value 3, in rows 0 to 7 at columns 8 to 15 and in rows 8 to 15 at columns 0 to 7, along two diagonal lines ($\gamma^{(0)}$ has the entries 1 at the places (row, column) $= (k, k+8)$ and $(k+8, k)$, $k = 0, \ldots, 7$, and no others). Middle, the frame boosted with $\beta = 3H$ at $b = 0.9$: $\frac{3H}{2}(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)})$, more nonzero entries of both signs. Right, $\beta = 6H$: a white square, the zero matrix. The student should see one metric and one field equation producing three different matrices in three frames.

In [11], the spinor curvature in two frames.

```
def spinor_curvature(fr):
    """F_x1x0 = d_1 Omega_0 - d_0 Omega_1 + [Omega_1, Omega_0]."""
    O1, O0 = fr["Omega"][1], fr["Omega"][0]
    return sp.diff(O0, x[1]) - sp.diff(O1, x[0]) + O1 * O0 - O0 * O1
```

`spinor_curvature` computes the curvature component $F_{x_1x_0} = \partial_1\Omega_0 - \partial_0\Omega_1 + [\Omega_1, \Omega_0]$ of a frame.

```
def riemann_side(fr):
    """(1/4) sum R_rho,sigma,x1,x0 gamma^rho gamma^sigma in the frame fr."""
    result = sp.zeros(16, 16)
    for rho in range(8):
        for sigma in range(8):
            value = g[rho] * riemann(rho, sigma, 1, 0)  # lower the first index
            if value != 0:
                result += value * fr["gamma"][rho] * fr["gamma"][sigma] / 4
    return result
```

`riemann_side` computes the other side of the identity of Section 8.10, $\frac{1}{4}\sum_{\rho,\sigma} R_{\rho\sigma x_1 x_0}\gamma^\rho\gamma^\sigma$ with the coordinate gammas of the given frame; for a diagonal metric, lowering the first index multiplies by $g_{\rho\rho}$.

```
P14, P10 = G[1] * G[4], G[1] * G[0]  # gamma^(1) gamma^(4) and gamma^(1) gamma^(0)

def two_coefficients(F):
    """c14, c10 with F = c14 P14 + c10 P10 (P14^2 = 1, P10^2 = -1), and whether
    nothing else is left."""
    c14 = sp.simplify((P14 * F).trace() / 16)
    c10 = sp.simplify(-(P10 * F).trace() / 16)
    return c14, c10, all(is_zero(v) for v in F - c14 * P14 - c10 * P10)
```

`P14` and `P10` are the products $\gamma^{(1)}\gamma^{(4)}$ and $\gamma^{(1)}\gamma^{(0)}$. Their squares are $+I_{16}$ and $-I_{16}$ ($\gamma^{(1)}\gamma^{(4)}\gamma^{(1)}\gamma^{(4)} = -(\gamma^{(1)})^2(\gamma^{(4)})^2 = -(1)(-1) = 1$, and $\gamma^{(1)}\gamma^{(0)}\gamma^{(1)}\gamma^{(0)} = -(\gamma^{(1)})^2(\gamma^{(0)})^2 = -1$), and the trace of their product is zero, so the two coefficients are found by traces exactly as in In [6]; the third returned value says whether F is exactly $c_{14}P_{14} + c_{10}P_{10}$.

```
zero_frame = {"Omega": [M.subs(at_6H) for M in boosted["Omega"]],  # beta = 6H
              "gamma": [M.subs(at_6H) for M in boosted["gamma"]]}
F_diagonal = spinor_curvature(diagonal)
F_zero = spinor_curvature(zero_frame)
check_record(all(is_zero(v) for v in F_diagonal - riemann_side(diagonal)),
             "diagonal frame: F_x1x0 = (1/4) R_rho,sigma,x1,x0 gamma^rho gamma^sigma",
             THEORY, "spinor_curvature_equals_riemann",
             "= (1/4) R_{rho sigma mu nu} gamma^rho gamma^sigma")
check(all(is_zero(v) for v in F_zero - riemann_side(zero_frame)),
      "boosted frame (beta = 6H): F'_x1x0 = (1/4) R gamma'^rho gamma'^sigma")
```

`zero_frame` is the boosted frame at $\beta = 6H$, the frame in which $\gamma'^\mu\Omega'_\mu = 0$ (only its connection and gammas are needed). The two curvatures are computed, and the identity $F = \frac{1}{4}R\gamma\gamma$ is checked in both frames; the first check also requires the record's check `spinor_curvature_equals_riemann`.

```
c14, c10, only_two = two_coefficients(F_diagonal)
c14_b, c10_b, only_two_b = two_coefficients(F_zero)
say(f"diagonal frame: c14 = {c14}")
say(f"diagonal frame: c10 = {c10}")
say(f"boosted frame:  c14 = {c14_b}")
```

```
say(f"boosted frame:  c10 = {c10_b}")
check(only_two and only_two_b,
      "in both frames F_x1x0 = c14 gamma^(1) gamma^(4) + c10 gamma^(1) gamma^(0)")
```

The four coefficients are printed in sympy's notation. In the diagonal frame they are $c_{14} = -Ha_4' e^{a_4}\cos z/(2\sin^{5/6} z)$ and $c_{10} = -H^2 e^{a_4}\cos z/(2\sin^{5/6} z)$, the values quoted in Section 8.10; in the boosted frame they contain $\cosh(6Hx_4 + b_0)$ and $\sinh(6Hx_4 + b_0)$. The check confirms that nothing else is left in either frame.

```
kappa_F = H**2 * (a4_prime**2 - H**2) * sp.exp(2 * a4) * sp.cos(z) ** 2 \
    / (4 * sp.sin(z) ** sp.Rational(5, 3))
check(is_zero(c14**2 - c10**2 - kappa_F) and is_zero(c14_b**2 - c10_b**2 - kappa_F),
      "F^2 = F'^2 = H^2 (a4'^2 - H^2) e^(2 a4) cos^2 z / (4 sin^(5/3) z) I16 in "
      "both frames")
```

`kappa_F` is the number $H^2((a_4')^2 - H^2)e^{2a_4}\cos^2 z/(4\sin^{5/3} z)$ of Section 8.10, and the check confirms that $c_{14}^2 - c_{10}^2$ equals it in both frames: the square of the curvature is the same in both frames.

```
entries_nonzero = sum(1 for v in F_zero if not is_zero(v))
report("nonzero entries of F'_x1x0 in the frame with gamma'^mu Omega'_mu = 0",
       entries_nonzero)
check_record(entries_nonzero > 0, "beta = 6H: the spinor curvature F'_x1x0 is not "
             "zero", "Revision/theory/reports/python-scope.json",
             "boosted_frame_curvature_nonzero",
             "F'_x1x0 = d_x1 Omega'_x0 - d_x0 Omega'_x1 + [Omega'_x1, Omega'_x0] is "
             "nonzero")
```

The number of nonzero entries of $F'_{x_1x_0}$ in the frame where the term vanishes is counted and printed: 32. The last check of the cell requires at least one, together with the record's check `boosted_frame_curvature_nonzero`. The cell prints five PASS lines (two with `reproduces` lines), the four coefficients and the RESULT line.

In [12], the curvature as colour maps.

```
def at_point(matrix):
    """The numbers of a symbolic matrix at H = 1, a4 = x4, z = pi/4, x4 = 0.5."""
    concrete = matrix.replace(sp.Function("a4"), history).doit()
    concrete = concrete.subs({H: 1, x[0]: sp.pi / 24, x[4]: sp.Rational(1, 2), b0: 0})
    return np.array(concrete.evalf(), dtype=float)
```

`at_point` puts the history, $H = 1$, $z = \pi/4$, $x_4 = \frac{1}{2}$ and $b_0 = 0$ into a symbolic matrix, evaluates it as decimal numbers (`evalf`) and returns a numpy array.

```
F_numbers = [("diagonal frame: $F_{x_1x_0}$", at_point(F_diagonal)),
             ("boosted, $\\beta = 6H$: $F'_{x_1x_0}$", at_point(F_zero))]
report("largest entry of F_x1x0 at the point (diagonal, boosted)",
       ", ".join(f"{np.abs(matrix).max():.6f}" for _, matrix in F_numbers))
ranks = [int(np.linalg.matrix_rank(matrix)) for _, matrix in F_numbers]
squares = [np.abs(matrix @ matrix).max() for _, matrix in F_numbers]
report("rank of F_x1x0 at the point (diagonal, boosted)", ranks)
```

The two curvature matrices at the point. The first RESULT line prints the largest entry of each (`:.6f` prints six decimals): 0.778093 and 0.038739. `ranks` holds their ranks and `squares` the largest entry of each square F^2; the second RESULT line prints the ranks, `[8, 8]`.

```
check(ranks == [8, 8] and max(squares) < 1e-14 and
      np.allclose(F_numbers[1][1], np.exp(-3.0) * F_numbers[0][1], atol=1e-14),
      "a4 = x4: F and F' have rank 8 and square 0, and F' = e^(-3) F at x4 = 0.5")
```

On this history $a_4' = H$, so $c_{14}^2 - c_{10}^2 = 0$ and $F^2 = 0$: the check requires rank 8 for both, squares below 10^{-14} (rounding), and $F' = e^{-3}F$ entry by entry ($b = 6Hx_4 = 3$; `np.allclose` compares two arrays within the tolerance `atol`). Indeed $0.778093 \cdot e^{-3} = 0.038739$.

```
fig, panels = plt.subplots(1, 2, figsize=(10.0, 4.2))
for panel, (title, matrix) in zip(panels, F_numbers):
    largest = np.abs(matrix).max()  # each panel has its own colour scale
    image = panel.imshow(matrix, cmap="RdBu_r", vmin=-largest, vmax=largest)
    fig.colorbar(image, ax=panel, shrink=0.85, label="entry (units of $H^2$)")
    panel.set_title(title, fontsize=10)
    panel.set_xticks([0, 5, 10, 15])
    panel.set_yticks([0, 5, 10, 15])
    panel.set_xlabel("column")
    panel.grid(False)  # no grid lines over the coloured squares
panels[0].set_ylabel("row")
save_figure(fig, "curvature_maps",
            "The spinor curvature $F_{x_1x_0} = \\partial_1\\Omega_0 - "
            "\\partial_0\\Omega_1 + \\Omega_1\\Omega_0 - \\Omega_0\\Omega_1$ as a "
            ...
            "vanish. On this history both matrices have rank 8 and square zero.")
```

Two colour maps, each with its own symmetric colour scale from minus to plus its largest entry and its own colour bar. The figure is Figure 08c.5. Output: two RESULT lines, one PASS line, the figure line.

What Figure 08c.5 shows. Two 16×16 colour maps of the curvature $F_{x_1x_0}$ (entries in units of H^2) at $H = 1$, $z = \pi/4$, $x_4 = 0.5$ on the history $a_4 = x_4$. Left: the diagonal frame, entries up to 0.778. Right: the frame boosted with $\beta = 6H$, where the term of the field equation is zero; the pattern is the same and the entries are e^{-3} times smaller (up to 0.0387; the colour scales differ). The student should see that the curvature is not zero in the frame in which the term vanishes: no frame can make the spin connection vanish.

In [13], the connection in the energy-momentum tensor.

```
g4_up, Omega_1 = diagonal["gamma"][4], diagonal["Omega"][1]
connection_part = (g4_up * Omega_1 + Omega_1 * g4_up) / 2
target = sp.exp(a4) * sixth * H * G[4] * G[1] * G[0] / 2
check_record(all(is_zero(v) for v in connection_part - target)
             and C * G[4] * G[1] * G[0] != sp.zeros(16, 16),
             "(1/2){gamma^x4, Omega_x1} = (1/2) e^a4 sin^(1/6) z H gamma^(4) "
             "gamma^(1) gamma^(0), and C gamma^(4) gamma^(1) gamma^(0) != 0",
             "Revision/theory/reports/python-scope.json",
```

```
            "spin_connection_in_the_energy_momentum_tensor",
            "(1/2) e^a4 sin^(1/6) z H Phibar gamma^(x4) gamma^(x1) gamma^(x0) Phi",
            "C gamma^(x4) gamma^(x1) gamma^(x0) != 0")
```

`connection_part` is $\frac{1}{2}\{\gamma^{x_4}, \Omega_{x_1}\}$ in the diagonal frame, `target` the result of Section 8.11. The check compares them entry by entry, requires the bilinear matrix $C\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}$ to be nonzero (`!=` means "is not equal to"), and requires the record's check with its two texts. Output: one PASS line with its `reproduces` line.

In [14], the last check.

```
for name in ("08c_1_cancel_and_survive.png", "08c_2_pieces_along_history.png",
             "08c_3_boost_size.png", "08c_4_heat_maps.png", "08c_5_curvature_maps.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The loop checks that each of the five figure files exists, and the last line prints the count. The checks come from the cells as follows: two in In [2], one in In [3], two in In [4], one in In [5], six in In [6], three in In [7], four in In [8], one in In [9], five in In [11], one each in In [12] and In [13], and five here; together 32, and the last line reads `ALL 32 CHECKS PASSED (notebook 08c)`.

8.16 Well-posedness: what a good evolution equation must do

The initial-value problem. A field equation that contains the time derivative $\partial_4\Psi$ is used like this: one gives the field on the slice $x_4 = 0$ (a seven-dimensional set with the coordinates $x_1, x_2, x_3, x_5, x_6, x_7, x_0$), the **data**, and asks for the field at later times. This is the **initial-value problem**, also called the **Cauchy problem**. The French mathematician Jacques Hadamard called such a problem **well posed** if three things hold: a solution exists; it is unique; and it depends **continuously** on the data, which means: for every later time and every tolerance, data that are close enough to each other give solutions that stay within that tolerance of each other up to that time. "Close" is measured by a **norm**, a number that measures the size of a function (for example its largest value, or the square root of the integral of its square). The third condition is what makes an equation useful for prediction: data are never known exactly, and an equation in which an arbitrarily small error of the data can produce an arbitrarily large error of the solution predicts nothing.

A toy example with two time directions. Take a function $\varphi(x_4, x_5)$ of the time x_4 and of one extra time x_5, and the equation

$$\partial_4^2\varphi = -\partial_5^2\varphi.$$

Compare it with the ordinary wave equation $\partial_4^2\varphi = +\partial_1^2\varphi$ along a space direction: the only difference is the minus sign, which appears because x_5 is time-like like x_4 (we show below that the field equation of this book has exactly this sign). The function $\varphi = \epsilon\cosh(Kx_4)\cos(Kx_5)$, with any numbers $\epsilon > 0$ and $K > 0$, solves it. Line by line:

$$\partial_4^2\varphi = \epsilon K^2\cosh(Kx_4)\cos(Kx_5) = K^2\varphi,$$
$$\partial_5^2\varphi = -\epsilon K^2\cosh(Kx_4)\cos(Kx_5) = -K^2\varphi,$$
$$-\partial_5^2\varphi = K^2\varphi = \partial_4^2\varphi.$$

The first line differentiates twice with respect to x_4 ($\frac{d}{dx}\cosh(Kx) = K\sinh(Kx)$ and $\frac{d}{dx}\sinh(Kx) = K\cosh(Kx)$); the second twice with respect to x_5 ($\frac{d^2}{dx^2}\cos(Kx) = -K^2\cos(Kx)$); the third compares. Its data are $\varphi(0, x_5) = \epsilon\cos(Kx_5)$ and $\partial_4\varphi(0, x_5) = 0$ (because $\cosh 0 = 1$ and $\sinh 0 = 0$): their largest value is ϵ, as small as we like. At the time $x_4 = 1$ the largest value of the solution is $\epsilon\cosh K$. The ratio, $\cosh K$, grows without bound as K grows ($\cosh 10 = 11013.2$, $\cosh 20 = 2.43 \times 10^8$). So however small we require the data to be, some data of that size produce a solution larger than any given number after one unit of time: the solution does not depend continuously on the data, and the problem is not well posed. For the ordinary wave equation the same data give $\epsilon\cos(Kx_4)\cos(Kx_1)$, which never exceeds ϵ.

The same sign in our field equation. In flat 4+4 space (all frame factors equal to 1, no gravitational term, $U = 0$) the field equation is $\sum_a \gamma^{(a)}\partial_a\Psi = m\Psi$. Applying the operator twice, line by line:

$$\begin{aligned}\Big(\sum_a \gamma^{(a)}\partial_a\Big)\Big(\sum_b \gamma^{(b)}\partial_b\Big)\Psi &= \sum_{a,b}\gamma^{(a)}\gamma^{(b)}\partial_a\partial_b\Psi \\ &= \sum_a(\gamma^{(a)})^2\partial_a^2\Psi + \sum_{a<b}\big(\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}\big)\partial_a\partial_b\Psi \\ &= (\partial_1^2 + \partial_2^2 + \partial_3^2 + \partial_0^2 - \partial_4^2 - \partial_5^2 - \partial_6^2 - \partial_7^2)\Psi.\end{aligned}$$

The first line multiplies out (the gammas are constant matrices); the second separates the terms with $a = b$ from the pairs $a \neq b$, using $\partial_a\partial_b = \partial_b\partial_a$; the third uses $(\gamma^{(a)})^2 = \eta_{aa}I_{16}$ and the anticommutation of different gammas. On the other side, applying the operator to $m\Psi$ gives $m\sum_a \gamma^{(a)}\partial_a\Psi = m^2\Psi$. Solving for the second time derivative:

$$\partial_4^2\Psi = (\partial_1^2 + \partial_2^2 + \partial_3^2 + \partial_0^2 - \partial_5^2 - \partial_6^2 - \partial_7^2 - m^2)\Psi.$$

The three extra-time derivatives enter with the sign of the toy example. This is the root of everything that follows.

Non-characteristic slices. In the author's metric the field equation of Section 8.2 can be solved for $\partial_4\Psi$. Write it as $\gamma^{(4)}\partial_4\Psi + R = V\Psi$, where R holds all the other terms on the left and $V = m + U'(S)$. Multiplying from the left by $\gamma^{(4)}$ and using $(\gamma^{(4)})^2 = -I_{16}$ gives $-\partial_4\Psi + \gamma^{(4)}R = \gamma^{(4)}V\Psi$, so

$$\partial_4\Psi = -\gamma^{(4)}\Big[V\Psi - \sum_{a\neq 4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Psi - 3H\gamma^{(0)}\Psi\Big]$$

(PROVED; `Revision/theory/reports/wolfram-field-theory.json`, check `evolution_form_G`). A slice is called **non-characteristic** when the matrix in front of the time derivative is invertible, as here: the equation then tells how the field changes in time from its values on the slice. This is necessary for a good evolution equation, but not sufficient: the toy example can be solved for

$\partial_4^2\varphi$ too. Sections 8.17 and 8.18 show that the field equation fails the third condition of Hadamard: exactly in flat 4+4 space and with frozen coefficients, and, through a standard theorem quoted without proof, in the author's metric itself (Section 8.18 states each status).

8.17 Plane waves with frozen coefficients and the mode matrix

Frozen coefficients. In the author's metric the frame factors $1/f_a$ change from point to point and in time. Near one point and for a short time one may replace them by their values at that point; this is the method of **frozen coefficients**, a device for studying an equation near one point (labelled MODEL in the notebooks, ASSUMED in the five-label scheme). It does not say that the extra times stop deflating: in the author's metric they always deflate, and Section 8.24 follows a wave along the deflating history. In flat 4+4 space the coefficients are constant and nothing is frozen. With frozen coefficients the factors are absorbed into the **frame momenta** k_a, and the term $3H\gamma^{(0)}$ is left out; it is absent exactly in the field variables χ of Section 8.30.

Plane waves. A **plane wave** is a field $\Psi = u\, e^{i(k_1x_1+k_2x_2+k_3x_3+k_5x_5+k_6x_6+k_7x_7+k_0x_0)-iEx_4}$ with a constant column u of 16 complex numbers. The number k_a is the **momentum** (or wave number) along x_a: radians of phase per unit length; E is the **frequency**. Inserting it into $\sum_a \gamma^{(a)}\partial_a\Psi = m\Psi$, line by line:

1. $\gamma^{(4)}(-iE)u + \sum_{a\neq 4} ik_a\gamma^{(a)}u = mu$, because ∂_4 of the exponential gives the factor $-iE$ and ∂_a gives ik_a (the common exponential is divided out).
2. Multiply from the left by $\gamma^{(4)}$ and use $(\gamma^{(4)})^2 = -I_{16}$: $iEu + i\sum_{a\neq 4} k_a\gamma^{(4)}\gamma^{(a)}u = m\gamma^{(4)}u$.
3. Multiply by $-i$ (and $(-i)(i) = 1$) and solve for Eu: $Eu = h_k u$ with the **mode matrix**

$$h_k = -im\gamma^{(4)} - \gamma^{(4)}\sum_{a\neq 4} k_a\gamma^{(a)}.$$

So E is an **eigenvalue** of h_k and u an **eigenvector**: $h_k u = Eu$ with $u \neq 0$. The set of all eigenvectors of one eigenvalue (with the zero column) is its **eigenspace**, and the number of independent ones is its **dimension**.

The square of the mode matrix. Write $K = \sum_{a\neq 4} k_a\gamma^{(a)}$, so that $h_k = -\gamma^{(4)}(im + K)$. Since $\gamma^{(4)}$ anticommutes with every $\gamma^{(a)}$ in K, $K\gamma^{(4)} = -\gamma^{(4)}K$ and therefore $(im+K)\gamma^{(4)} = \gamma^{(4)}(im-K)$. Line by line:

$$\begin{aligned} h_k^2 &= \gamma^{(4)}(im+K)\gamma^{(4)}(im+K) = \gamma^{(4)}\gamma^{(4)}(im-K)(im+K) \\ &= -\big((im)^2 + imK - imK - K^2\big) = m^2 + K^2, \\ K^2 &= \sum_{a\neq 4} k_a^2(\gamma^{(a)})^2 + \sum_{a<b} k_a k_b\big(\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}\big) = \big(k_1^2+k_2^2+k_3^2+k_0^2-k_5^2-k_6^2-k_7^2\big)I_{16}. \end{aligned}$$

The first line uses $(-1)^2 = 1$ and moves $(im + K)$ past $\gamma^{(4)}$; the second uses $(\gamma^{(4)})^2 = -I_{16}$ and multiplies out (the number im commutes with K); the third line computes K^2 as in Section 8.16. Hence

$$h_k^2 = E^2\, I_{16}, \qquad E^2 = m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$$

(PROVED; `Revision/theory/reports/python-scope.json` and `wolfram-scope.json`, check `extra_time_growth_rates_unbounded`). The extra-time momenta enter with a MINUS sign, because the extra times are time-like. Every eigenvalue λ of h_k obeys $\lambda^2 = E^2$ (apply $h_k^2 = E^2$ to an eigenvector), so the eigenvalues are $+E$ and $-E$. The **trace** of h_k (the sum of its diagonal entries, which is also the sum of its eigenvalues, each counted as often as it occurs) is zero, because the trace of $\gamma^{(4)}$ and of each product of two different gammas is zero. With n_+ eigenvalues $+E$ and n_- eigenvalues $-E$, $n_+ + n_- = 16$ and $n_+E - n_-E = 0$; for $E \neq 0$ this gives $n_+ = n_- = 8$.

When is the mode matrix Hermitian? A matrix is **Hermitian** if it equals its conjugate transpose, $M^\dagger = M$, and **anti-Hermitian** if $M^\dagger = -M$. A Hermitian matrix has only real eigenvalues. The gammas are real with $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$. So $(-i\gamma^{(4)})^\dagger = i(\gamma^{(4)})^T = -i\gamma^{(4)}$: the mass term is Hermitian. For $a \neq 4$, $(\gamma^{(4)}\gamma^{(a)})^T = (\gamma^{(a)})^T(\gamma^{(4)})^T = \eta_{aa}\gamma^{(a)}(-\gamma^{(4)}) = \eta_{aa}\gamma^{(4)}\gamma^{(a)}$ (the last step anticommutes the two gammas). For a space-like direction ($\eta_{aa} = +1$) the real matrix $\gamma^{(4)}\gamma^{(a)}$ is symmetric, hence Hermitian; for an extra time ($\eta_{aa} = -1$) it is antisymmetric, hence anti-Hermitian. So the anti-Hermitian part of h_k is exactly its extra-time part, $-\gamma^{(4)}(k_5\gamma^{(5)} + k_6\gamma^{(6)} + k_7\gamma^{(7)})$, and h_k is Hermitian exactly when $k_5 = k_6 = k_7 = 0$. Fields that do not depend on the extra times are called the **good sector**. In the good sector every frequency is real, and h_k commutes with B (PROVED; `python-field-theory.json`, check `good_sector_spectrum_and_B_sectors`).

An exact example. Take $m = 1$, $k_5 = 2$ and all other momenta 0. Then $E^2 = 1 - 4 = -3$, and the eigenvalues are $E = \pm i\sqrt{3}$, eight each (PROVED; `python-field-theory.json`, check `extra_time_modes_grow`, whose detail lists the eigenvalues `-sqrt(3)*I` and `sqrt(3)*I`).

8.18 Growth without bound: the Cauchy problem is not well posed

Growth. When $E^2 < 0$, the frequencies are $E = \pm i\kappa$ with the **growth rate** $\kappa = \sqrt{-E^2} > 0$. A wave $u\, e^{-iEx_4}$ with $E = i\kappa$ behaves in time like $e^{-i(i\kappa)x_4} = e^{\kappa x_4}$: it grows exponentially (and the one with $E = -i\kappa$ decays). In the example above, $\kappa = \sqrt{3}$. With an extra-time momentum $k_5 = K$ and a space momentum k_1 (all others 0), $E^2 = m^2 + k_1^2 - K^2$, and the waves grow as soon as $K^2 > m^2 + k_1^2$, with

$$\kappa = \sqrt{K^2 - m^2 - k_1^2}.$$

No upper bound. Write $c^2 = m^2 + k_1^2$ with $c \geq 0$. For $K \geq c$ the rate satisfies $\kappa \geq K - c$: both sides are not negative, and squaring, $(K-c)^2 = K^2 - 2Kc + c^2 \leq K^2 - c^2 = \kappa^2$ is the same as $2c^2 \leq 2Kc$, which holds because $c \leq K$. So κ grows at least like K, without bound: for every rate, however large, some extra-time waves grow faster (PROVED; `python-scope.json`, check `extra_time_growth_rates_unbounded`, both engines; Notebook 08a prints $\kappa = 999.9995$ for $m = 1$, $K = 1000$).

The solution in time. The equation in time of a plane wave is $i\, du/dx_4 = h_k u$, solved by $u(x_4) = e^{-ih_k x_4}u(0)$, where the **matrix exponential** is the series $e^A = I + A + A^2/2! + A^3/3! + \ldots$. Because $h_k^2 = E^2 I_{16}$, every even power is $h_k^{2j} = E^{2j} I_{16}$ and every odd power $h_k^{2j+1} = E^{2j} h_k$. Sorting the series:

$$
\begin{aligned}
e^{-ih_k x_4} &= \sum_{j\ge 0} \frac{(-i)^{2j} E^{2j} x_4^{2j}}{(2j)!} I_{16} + \sum_{j\ge 0} \frac{(-i)^{2j+1} E^{2j} x_4^{2j+1}}{(2j+1)!} h_k \\
&= \sum_{j\ge 0} \frac{(-1)^j (Ex_4)^{2j}}{(2j)!} I_{16} - \frac{i}{E} \sum_{j\ge 0} \frac{(-1)^j (Ex_4)^{2j+1}}{(2j+1)!} h_k \\
&= \cos(Ex_4)\, I_{16} - i\, \frac{\sin(Ex_4)}{E}\, h_k .
\end{aligned}
$$

The first line separates even and odd powers; the second uses $(-i)^{2j} = (-1)^j$ and $(-i)^{2j+1} = -i(-1)^j$ and takes $1/E$ out of the odd sum; the third recognises the series of the cosine and of the sine. For $E = i\kappa$ this is $\cosh(\kappa x_4) I_{16} - i\frac{\sinh(\kappa x_4)}{\kappa} h_k$ (because $\cos(i\theta) = \cosh\theta$ and $\sin(i\theta)/i = \sinh\theta$), and for $E = 0$ it is the limit $I_{16} - i h_k x_4$.

Hadamard's third condition fails. Take as data at $x_4 = 0$ one growing wave, $\epsilon\, e^{iKx_5} u_+$, where u_+ is an eigenvector of h_k (with $k_5 = K$) for the eigenvalue $+i\kappa$, of size $u_+^\dagger u_+ = 1$. At the time x_4 the solution is $\epsilon\, e^{\kappa x_4} e^{iKx_5} u_+$. To measure the data we may even use a norm that punishes wiggly data: the **Sobolev norm of order** s counts, for one wave of momentum K and amplitude ϵ, the size $\epsilon(1+K^2)^{s/2}$ (each order of derivative brings a factor of about K). The ratio of the size of the solution at $x_4 = 1$ to the size of the data is then

$$
\frac{\epsilon\, e^{\kappa}}{\epsilon(1+K^2)^{s/2}} = e^{\kappa}(1+K^2)^{-s/2}, \qquad \ln(\text{ratio}) = \kappa - \tfrac{s}{2}\ln(1+K^2) \ge K - c - \tfrac{s}{2}\ln(1+K^2),
$$

the same for every ϵ. The right-hand side grows without bound as K grows, because the logarithm grows more slowly than any multiple of K. So for every order s data as small as we like give, after one unit of time, solutions as large as we like: the solution does not depend continuously on the data. So, in flat 4+4 space and with frozen coefficients, the initial-value problem is NOT well posed in the sense of Hadamard for data that depend on the extra times, although the slices $x_4 = \text{const}$ are non-characteristic (PROVED in this setting; `python-scope.json`, check `extra_time_growth_rates_unbounded`, both engines, whose detail names exactly this setting: "flat 4+4 space (or frozen coefficients)"). With $m = 1$ the ratio first exceeds 10^6 at $K = 13.9$ for $s = 0$, at $K = 19.9$ for $s = 2$, at $K = 27.1$ for $s = 4$ and at $K = 44.2$ for $s = 8$ (COMPUTED by Notebook 08a on a grid of step 0.1): a stronger norm only delays the rise.

From frozen coefficients to the author's metric (an ASSUMED step). In the author's metric the frame factors change from point to point, and a plane wave is not an exact solution of the field equation; so the argument above, by itself, proves nothing about the field equation in that metric. The step is made by a standard theorem of the theory of partial differential equations, the **Lax-Mizohata theorem** (P. D. Lax, 1957; S. Mizohata, 1961), which this book quotes without proof, so it is ASSUMED here. It says: if the initial-value problem of a linear system of first-order equations with smooth coefficients is well posed near a point, then at that point the frequencies of its **principal part** (the derivative terms alone, with their coefficients taken at that point) are real for every real momentum. For the field equation with $U = 0$ (then the equation is linear) the principal part at a point is the mode matrix of Section 8.17 without the mass term, with the frame momenta of that point: a wave with the coordinate momentum q_a along x_a has there the frame momentum $k_a = q_a/f_a$, with the frame factors of that point (the term $3H\gamma^{(0)}$ contains no derivative, so it does not belong to the principal part). By the formula of Section 8.17 with $m = 0$, its frequencies obey

$E^2 = k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$, which is negative for a wave along an extra time alone ($k_5 \neq 0$, all other momenta zero), at every point. So, granted the theorem, the initial-value problem of the field equation in the author's metric is not well posed for data that depend on the extra times. Status: the statements in flat 4+4 space and with frozen coefficients are PROVED, and they are what the Revision record checks; the step to the author's varying coefficients rests on the quoted theorem (ASSUMED) and is not checked by the record; for $U \neq 0$ nothing more is claimed.

8.19 The Krein form is conserved; the growing waves carry Krein form zero

Two ways to measure a column. The ordinary size of a column u is the **Hilbert norm** $u^\dagger u = |u_1|^2 + \cdots + |u_{16}|^2$. The **Krein form** is $u^\dagger B u$ with the matrix $B = -iC\gamma^{(4)}$ of the record ($B^\dagger = B$, $B^2 = I_{16}$, eight eigenvalues $+1$ and eight -1; Chapters 5 and 10). Because B has negative eigenvalues, $u^\dagger B u$ can be negative or zero for $u \neq 0$. Chapter 10 explains why the canonical quantisation of dirac16complex forces this indefinite form; here we need only one property.

The Krein form is conserved. The mode matrix satisfies $Bh_k = h_k^\dagger B$ for every momentum (PROVED; `python-field-theory.json`, check `mode_hamiltonian_B_selfadjoint_dispersion`; a matrix with this property is called **self-adjoint for the Krein form**). For a solution of $du/dx_4 = -ih_k u$, line by line:

$$\begin{aligned}\frac{d}{dx_4}(u^\dagger B u) &= \Big(\frac{du}{dx_4}\Big)^\dagger B u + u^\dagger B \frac{du}{dx_4} = (-ih_k u)^\dagger B u + u^\dagger B(-ih_k u)\\ &= i\,u^\dagger h_k^\dagger B u - i\,u^\dagger B h_k u = i\,u^\dagger(h_k^\dagger B - B h_k)u = 0.\end{aligned}$$

The first step is the product rule; the second inserts the equation; the third uses $(-ih_k u)^\dagger = u^\dagger h_k^\dagger (-i)^* = i\,u^\dagger h_k^\dagger$; the last uses $Bh_k = h_k^\dagger B$. The Hilbert norm is not conserved: the same computation gives $\frac{d}{dx_4}(u^\dagger u) = i\,u^\dagger(h_k^\dagger - h_k)u$, which is not zero when h_k is not Hermitian, that is when there is extra-time momentum.

The growing waves carry Krein form zero. Let u and v be two eigenvectors of h_k for the same growing eigenvalue $i\kappa$. Then $u(x_4) = e^{\kappa x_4}u$ and $v(x_4) = e^{\kappa x_4}v$ solve the equation, and the computation above, done with two different columns, shows that $v(x_4)^\dagger B u(x_4) = e^{2\kappa x_4}\, v^\dagger B u$ is constant in time. A constant that equals $e^{2\kappa x_4}$ times a fixed number, with $\kappa > 0$, must be zero: $v^\dagger B u = 0$. So the Krein form vanishes identically on the eigenspace of a growing frequency: the eigenspace is **Krein-neutral** (PROVED by the argument just given; the pairing record proves the same and checks it on exact samples, `Revision/pairing/reports/python-pairing.json`, check `Q.one_particle_complex_frequency_Krein_neutral`). On an eigenspace of a real frequency $E \neq 0$, by contrast, the Krein form has four positive and four negative directions: its **inertia** is (4,4) (PROVED in the pairing record for every real frequency; `python-pairing.json`, checks `Q.one_particle_Krein_inertia_proof` and, for an exact sample, `Q.one_particle_Krein_inertia`). This is how the Hilbert norm can grow while the Krein form stays constant: the positive and the negative parts of the Krein form grow together and cancel.

8.20 Example: growth rates and Hadamard ill-posedness

Notebook 08a puts Sections 8.16 to 8.19 to work. It reads the author's gammas, checks the 64 Clifford relations and $(\gamma^{(4)})^2 = -I_{16}$; builds the mode matrix with symbolic mass and momenta and proves

$h_k^2 = E^2 I_{16}$ exactly, comparing with both Revision verifiers; finds the anti-Hermitian part; checks the exact example $m = 1$, $k_5 = 2$; computes the growth rate against the extra-time momentum and maps it in the plane of k_1 and k_5; solves the equation in time in two independent ways (the closed formula and RK4); computes the Hadamard amplification for four Sobolev orders; checks the conservation of the Krein form, the Krein-neutral growing eigenspace and the inertia (4,4) of a real-frequency eigenspace; and follows the eigenvalues into the complex plane. It needs no Rust and runs in well under a minute; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/08a_growth_rates.PROVENANCE.md`. It ends with the line ALL 30 CHECKS PASSED (notebook 08a).

8.21 How to run Notebook 08a

Step 1. What this notebook does and what it needs.

Notebook 08a (Growth rates of the extra-time waves and Hadamard ill-posedness) is the file `Revision/textbook/notebooks/08a_growth_rates.ipynb` of the repository Dirac_claude. It builds the 16 x 16 mode matrix of a plane wave of the field equation with frozen coefficients from the author's gamma matrices, proves exactly that its square is E^2 times the unit matrix, computes the growth rate of the waves that move along an extra time, shows that this rate has no upper bound (so, in flat 4 + 4 space and with frozen coefficients, the initial-value problem is not well posed in the sense of Hadamard), checks that the Krein form is conserved while the ordinary norm grows, and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08a_growth_rates.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08a_growth_rates.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 08a_growth_rates.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/08a.captions.json`
- `Revision/textbook/figures/08a_1_growth_rate_vs_momentum.png`
- `Revision/textbook/figures/08a_2_growth_map.png`
- `Revision/textbook/figures/08a_3_norm_in_time.png`
- `Revision/textbook/figures/08a_4_hadamard_ratio.png`
- `Revision/textbook/figures/08a_5_krein_norm.png`
- `Revision/textbook/figures/08a_6_eigenvalue_paths.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08a_6_eigenvalue_paths.png exists
ALL 30 CHECKS PASSED (notebook 08a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/08a_growth_rates.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 08a_growth_rates.ipynb
python -m nbconvert --execute --inplace 08a_growth_rates.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- FileNotFoundError naming Revision/algebra/gammas.json: the notebook reads this Revision record of the repository. Check that the folder Revision/algebra of your copy of the repository contains the file gammas.json (clone the repository again if it does not) and that you opened the notebook from its folder Revision/textbook/notebooks.

8.22 Notebook 08a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/08a_growth_rates.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field equation of dirac16complex (and of dirac16complex00, which has the same
equation) in the author's 4 + 4 dimensional primordial universe has FOUR time-like
directions: the time $x_4$ and the three extra times $x_5, x_6, x_7$. This notebook
shows what that means for the waves of the field. It

- reads the author's sixteen-by-sixteen gamma matrices from the Revision record and
  checks the 64 Clifford relations;
- builds the *mode matrix* $h_k$ of a plane wave with frozen coefficients and proves
  exactly (with sympy) that $h_k^2 = E^2\,I_{16}$ with
  $E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$;
- shows that a wave with a large momentum $K$ along an extra time does not oscillate
  but GROWS like $e^{\kappa x_4}$ with the growth rate
  $\kappa = \sqrt{K^2 - m^2 - k_0^2 - k_1^2 - k_2^2 - k_3^2}$, and that $\kappa$ has
  no upper bound;
- solves the wave equation in time in two independent ways (an exact formula and a
  step-by-step numerical method) and compares them;
- shows that therefore a tiny change of the starting values can make an arbitrarily
  large change later: the initial-value problem is NOT well posed in the sense of
  Hadamard (for starting values that depend on the extra times; exactly in flat
  4 + 4 space, and with frozen coefficients in the author's metric);
- checks that the Krein form $u^\dagger B u$ stays constant while the ordinary size
  $u^\dagger u$ grows, and that the growing waves have Krein form zero;
- shows that without extra-time momentum (the *good sector*) every frequency is real.

Every exact statement reproduces a check of a Revision record, named in the PASS
line. The notebook draws six teaching plots.
```

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 08a (Growth rates of the extra-time waves and Hadamard ill-posedness) is the file ‘Revision/textbook/notebooks/08a_growth_rates.ipynb‘ of the repository Dirac_claude. It builds the 16 x 16 mode matrix of a plane wave of the field equation with frozen coefficients from the author’s gamma matrices, proves exactly that its square is E^2 times the unit matrix, computes the growth rate of the waves that move along an extra time, shows that this rate has no upper bound (so, in flat 4 + 4 space and with frozen coefficients, the initial-value problem is not well posed in the sense of Hadamard), checks that the Krein form is conserved while the ordinary norm grows, and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08a_growth_rates.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08a_growth_rates.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 08a_growth_rates.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/08a.captions.json‘
- ‘Revision/textbook/figures/08a_1_growth_rate_vs_momentum.png‘
- ‘Revision/textbook/figures/08a_2_growth_map.png‘
- ‘Revision/textbook/figures/08a_3_norm_in_time.png‘
- ‘Revision/textbook/figures/08a_4_hadamard_ratio.png‘
- ‘Revision/textbook/figures/08a_5_krein_norm.png‘
- ‘Revision/textbook/figures/08a_6_eigenvalue_paths.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08a_6_eigenvalue_paths.png exists
ALL 30 CHECKS PASSED (notebook 08a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/08a_growth_rates.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 08a_growth_rates.ipynb
python -m nbconvert --execute --inplace 08a_growth_rates.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- FileNotFoundError naming Revision/algebra/gammas.json: the notebook reads this Revision record of the repository. Check that the folder Revision/algebra of your copy of the repository contains the file gammas.json (clone the repository again if it does not) and that you opened the notebook from its folder Revision/textbook/notebooks.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 08a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 08a (Growth rates of the extra-time waves and Hadamard ill-posedness) is the
# file Revision/textbook/notebooks/08a_growth_rates.ipynb of the repository Dirac_claude.
# It builds the 16 x 16 mode matrix of a plane wave of the field equation with frozen
# coefficients from the author’s gamma matrices, proves exactly that its square is E^2
# times the unit matrix, computes the growth rate of the waves that move along an extra
# time, shows that this rate has no upper bound (so, in flat 4 + 4 space and with frozen
```

```
# coefficients, the initial-value problem is not well posed in the sense of Hadamard),
# checks that the Krein form is conserved while the ordinary norm grows, and draws six
# teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
# shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the

# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
```

```
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
```

```
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 08a_growth_rates.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 08a_growth_rates.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 08a_growth_rates.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/08a.captions.json
# - Revision/textbook/figures/08a_1_growth_rate_vs_momentum.png
# - Revision/textbook/figures/08a_2_growth_map.png
# - Revision/textbook/figures/08a_3_norm_in_time.png
```

```
# - Revision/textbook/figures/08a_4_hadamard_ratio.png
# - Revision/textbook/figures/08a_5_krein_norm.png
# - Revision/textbook/figures/08a_6_eigenvalue_paths.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 08a_6_eigenvalue_paths.png exists
#     ALL 30 CHECKS PASSED (notebook 08a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/08a_growth_rates.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 08a_growth_rates.ipynb
#     python -m nbconvert --execute --inplace 08a_growth_rates.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
```

```
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - FileNotFoundError naming Revision/algebra/gammas.json: the notebook reads this
#   Revision record of the repository. Check that the folder Revision/algebra of your
#   copy of the repository contains the file gammas.json (clone the repository again if
#   it does not) and that you opened the notebook from its folder
#   Revision/textbook/notebooks.

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$ (the author's names): $x_1, x_2, x_3$ ordinary
  space (it inflates); $x_4$ the time; $x_5, x_6, x_7$ the three *extra times*,
  time-like directions that DEFLATE exponentially (their lengths carry the factor
  $e^{-a_4}\sin^{1/6} z$ with $a_4$ increasing); $x_0$ the hidden space direction,
  $z = 6 H x_0$ between $0$ and $\pi/2$.
- **Gamma matrices** $\gamma^{(0)}, \dots, \gamma^{(7)}$: sixteen-by-sixteen matrices
  of the numbers $0, 1, -1$ with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}
  = 2\eta^{ab} I_{16}$ (the *Clifford relation*), $\eta = \mathrm{diag}(+1, +1, +1,
  +1, -1, -1, -1, -1)$ in the order $x_0, \dots, x_7$: a gamma squares to $+1$ for a
  space-like direction and to
  $-1$ for a time-like one. $I_{16}$ is the unit matrix.
- **Plane wave**: a field of the form $\Psi = u\, e^{i(k_0 x_0 + \dots + k_7 x_7)
  - i E x_4}$ (no $k_4$ term) with a constant column $u$ of 16 complex numbers.
  $k_a$ is the *wave number* or *momentum* along $x_a$ (radians of phase per unit
  length) and $E$ the *frequency*.
- **Frozen coefficients**: in a curved space the factors in front of the derivatives
  change from point to point and in time; near one point and for a short time one
  replaces them by their values at that point. The momenta measured with these
  factors are the *frame momenta* $k_a$. This is a device of the analysis near one
  point (labelled MODEL); it does NOT say that the extra times stop deflating: in
```

the author's metric they always deflate exponentially, and Notebook 08b follows a wave along the deflating history.
- **Mode matrix** h_k: the 16×16 complex matrix with $E u = h_k u$.
- **Eigenvalue, eigenvector**: E and $u \neq 0$ with $h_k u = E u$; the *eigenspace* of E is the set of all such u; its *dimension* is the number of independent ones.
- **Oscillation and growth**: e^{-iEx_4} oscillates (its size stays 1) when E is real; when $E = \pm i\kappa$ with $\kappa > 0$ it is $e^{\pm\kappa x_4}$, which grows or decays exponentially. κ is the **growth rate**.
- **Conjugate transpose** $M^\dagger$: transpose the matrix and replace every entry by its complex conjugate. **Hermitian**: $M^\dagger = M$; a Hermitian matrix has only real eigenvalues.
- **Hilbert norm** $u^\dagger u = |u_1|^2 + \dots + |u_{16}|^2$ (the ordinary size squared) and **Krein form** $u^\dagger B u$ with the matrix $B = -iC\gamma^{(4)}$ of the record ($B^\dagger = B$, $B^2 = 1$, eight eigenvalues $+1$ and eight -1); the Krein form can be negative or zero for $u \neq 0$.
- **Good sector**: the fields that do not depend on x_5, x_6, x_7 ($k_5 = k_6 = k_7 = 0$).
- **Initial-value (Cauchy) problem**: find the field at later times x_4 from its values at $x_4 = 0$ (the *data*). It is **well posed in the sense of Hadamard** if a solution exists, is unique, and depends *continuously* on the data: a small enough change of the data changes the solution at a later time only a little.
- **Sobolev norm of order s**: a way to measure the size of data that also counts how fast they wiggle; for one wave of momentum K and amplitude ϵ it is $\epsilon\,(1 + K^2)^{s/2}$. Larger s punishes wiggly data more.
- **RK4**: the classical fourth-order Runge-Kutta method, a step-by-step numerical method for equations $du/dt = F(t, u)$.

Text cell:

```
## 4. The physical and mathematical situation

The field equation (with $U = 0$) in the author's metric, in the diagonal frame, is

$$\tan z\,\gamma^{(0)}\partial_0\Psi + e^{-a_4}\sin^{-1/6}z\,\gamma^{(i)}\partial_i\Psi
+ \gamma^{(4)}\partial_4\Psi + e^{a_4}b_4^{-1/2}\sin^{-1/6}z\,\gamma^{(t)}\partial_t\Psi
+ M\Psi = m\Psi$$

(sums over $i = 1, 2, 3$ and $t = 5, 6, 7$; $b_4(x_4) > 0$ is the second function
of the author's metric, and the backgrounds of the record have $b_4 = 1$). $M =
3H\gamma^{(0)} + \frac34(b_4'/b_4)\gamma^{(4)}$ is the gravitational term (Chapter
6); it has no derivative, so it does not change the growth of short waves. It
disappears exactly in the variables $\chi = \sin^{1/2}z\,b_4^{3/4}\Psi$ (Revision
check 'rescaling_removes_the_connection_term', at $b_4 = 1$). With frozen
coefficients the factors $e^{-a_4}\sin^{-1/6}z$, $e^{a_4}b_4^{-1/2}\sin^{-1/6}z$ and
$\tan z$ become constants and are absorbed into the frame momenta $k_a$; in flat
4 + 4 space they are exactly 1. (Freezing them is a local MODEL: along the history
$a_4(x_4)$ the extra-time factor $e^{a_4}$ keeps growing, so the frame momentum of
a given wave along an extra time keeps growing too; Notebook 08b computes that on
the background $b_4 = 1$.) So for a plane wave the equation reads, line by
line:

1. $\gamma^{(4)}(-iE)u + \sum_{a \neq 4} i k_a \gamma^{(a)} u = m u$, because
```

```
   $\partial_4$ gives the factor $-iE$ and $\partial_a$ the factor $i k_a$.
2. Multiply from the left by $\gamma^{(4)}$ and use $(\gamma^{(4)})^2 = -1$:
   $iE u + i\sum_a k_a \gamma^{(4)}\gamma^{(a)} u = m\gamma^{(4)} u$.
3. Multiply by $-i$ and solve for $E u$:
   $E u = h_k u$ with $h_k = -i m\gamma^{(4)} - \gamma^{(4)}\sum_{a \neq 4}
   k_a\gamma^{(a)}$.

Squaring $h_k$ with the Clifford relation gives $h_k^2 = E^2 I_{16}$ with
$E^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$: the
extra-time momenta enter with a MINUS sign, because the extra times are time-like.
When $k_5^2 + k_6^2 + k_7^2 > m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2$, $E^2 < 0$, the
frequencies are $\pm i\kappa$, and half of the waves grow like $e^{\kappa x_4}$.

Units: $m$, every $k_a$ and $\kappa$ are measured in the same unit (an inverse
length) and $x_4$ in its inverse; every number below is a pure number in this unit.
```

Text cell:

```
## 5. The author's gamma matrices

The next cell first defines two helpers for the checks that reproduce a Revision
record. `record_says(report, name, ...)` opens the report (a JSON file with a list
of checks, each with a name, a verdict and a detail text) and is true when the
check `name` is there with the verdict pass and its detail text contains every
further piece of text given (for example a number that this notebook computes).
`check_record(condition, title, report, name, ...)` is the helper `check` for such
a result: it passes only if the notebook's own computation (`condition`) is right
AND the record says the same. Then the cell reads the record
`Revision/algebra/gammas.json`, turns the eight gamma matrices and the matrix $B$
into numpy arrays and checks the Clifford relation for all $8 \times 8 = 64$
ordered pairs $(a, b)$ with exact integer arithmetic. In Python lists count from 0,
like the author's coordinates: $\gamma^{(x_0)}$ is `GAMMA[0]` and $\gamma^{(x_4)}$
is `GAMMA[4]`. Last, it
checks $(\gamma^{(x_4)})^2 = -I_{16}$: multiplying the field equation by
$-\gamma^{(x_4)}$ solves it for $\partial_4\Psi$, so the field equation says how the
field changes in the time $x_4$ (the slices $x_4 = $ const are *non-characteristic*).
Section 12 shows that this does NOT make the initial-value problem well posed.
```

## 6. The mode matrix and its square, exactly
```

```
The next cell builds $h_k = -i m\gamma^{(4)} - \gamma^{(4)}\sum_{a \neq 4}
k_a\gamma^{(a)}$ with sympy, where $m$ and the seven momenta are symbols (letters
that stand for any real numbers), and checks three exact statements: $h_k^2 = E^2
I_{16}$ with the $E^2$ of section 4; the trace of $h_k$ (the sum of its diagonal) is
0, so its eigenvalues $+E$ and $-E$ occur equally often (8 times each); and
$B h_k = h_k^\dagger B$, which says that $h_k$ is *self-adjoint for the Krein form*
(section 13 uses it). sympy prints a power with two stars: `k1**2` means $k_1^2$.
The Revision record was checked by two independent programs, one in Python (sympy)
and one in the Wolfram language; the cell checks that the reports of BOTH contain
exactly the $E^2$ computed here.
```

In [3]:

```
m = sp.Symbol("m", real=True)  # the mass

Text cell:

```
## 7. When is the mode matrix Hermitian?

Split $h_k$ into its Hermitian part $(h_k + h_k^\dagger)/2$ and its anti-Hermitian
part $(h_k - h_k^\dagger)/2$. The next cell shows that the anti-Hermitian part is
exactly $-\gamma^{(4)}(k_5\gamma^{(5)} + k_6\gamma^{(6)} + k_7\gamma^{(7)})$, the
extra-time part, and that its square is $-(k_5^2 + k_6^2 + k_7^2) I_{16}$. A matrix
whose square is a negative number times $I_{16}$ is zero only when that number is
zero: $h_k$ is Hermitian exactly when there is no extra-time momentum.
```

In [4]:

```
anti = ((h - h.H) / 2).applyfunc(sp.expand)  # the anti-Hermitian part of h_k
extra_time_part = -(k[5] * g4 * G[5] + k[6] * g4 * G[6] + k[7] * g4 * G[7])
check((anti - extra_time_part).applyfunc(sp.expand) == sp.zeros(16, 16),
      "the anti-Hermitian part of h_k is the extra-time part")
anti_square = (anti * anti).applyfunc(sp.expand)
check(anti_square == (-(k[5]**2 + k[6]**2 + k[7]**2) * sp.eye(16)).applyfunc(
    sp.expand), "its square is -(k5^2 + k6^2 + k7^2) I16")
```

Out [4]:

```
PASS the anti-Hermitian part of h_k is the extra-time part
PASS its square is -(k5^2 + k6^2 + k7^2) I16
```

Text cell:

```
## 8. An exact example: $m = 1$, $k_5 = 2$

Put $m = 1$, $k_5 = 2$ and every other momentum 0. Then $E^2 = 1 - 4 = -3$, so the
eigenvalues must be $\pm i\sqrt3$. The next cell checks $h^2 = -3 I_{16}$ exactly,
computes the dimension of the eigenspace of $+i\sqrt3$ exactly (16 minus the rank of
$h - i\sqrt3\,I_{16}$), and prints the numerical eigenvalues. The waves of the
eigenvalue $+i\sqrt3$ behave like $e^{-i(i\sqrt3)x_4} = e^{\sqrt3\,x_4}$: they grow.
The Revision record lists the same two exact eigenvalues in sympy's notation,
`-sqrt(3)*I` and `sqrt(3)*I` (`I` is sympy's $i$); the check compares with that text.
```

In [5]:

```

## 9. The growth rate versus the extra-time momentum

From now on the computations are numerical (numpy). The function ‘mode_matrix‘ makes
$h_k$ from a mass and a dictionary of momenta. With only an extra-time momentum
$k_5 = K$ (and possibly a space momentum $k_1$), $E^2 = m^2 + k_1^2 - K^2$; the
growth rate is $\kappa = \sqrt{K^2 - m^2 - k_1^2}$ when this is positive and 0
otherwise. The next cell compares this formula with the largest imaginary part of
the numerically computed eigenvalues at 61 momenta (to $10^{-10}$; at the single
point $K = m$, where $h_k^2 = 0$, a computer finds the double eigenvalue 0 only to
about $10^{-8}$, so there the tolerance is $10^{-6}$), and draws $\kappa$ against
$K$: on the left for three masses, on the right for three space momenta $k_1$.
```

In [6]:

```
def mode_matrix(mass, momenta):
    """h_k = -i m gamma^(x4) - gamma^(x4) sum_a k_a gamma^(xa); momenta: {a: k_a}."""

## 11. Solving in time, in two independent ways

The equation in time is $i\,du/dx_4 = h_k u$. Because $h_k^2 = E^2 I_{16}$, the
exponential series of $e^{-ih_k x_4}$ collapses to
$u(x_4) = \big(\cos(Ex_4) I_{16} - i\,\frac{\sin(Ex_4)}{E}\,h_k\big)\,u(0)$:
the even powers of $h_k$ are powers of $E^2$ and give the cosine, the odd ones give
$h_k$ times the sine. For $E = i\kappa$ this is $\cosh(\kappa x_4) I_{16} -
i\,\frac{\sinh(\kappa x_4)}{\kappa}h_k$, and for $E = 0$ it is $I_{16} - i h_k x_4$
(the limit). The next cell implements this formula (‘evolve‘) and, independently,
the RK4 method with 3000 steps (‘rk4‘), starts both from the same random column
(fixed seed, so every run uses the same numbers) and compares them at $x_4 = 3$.
```

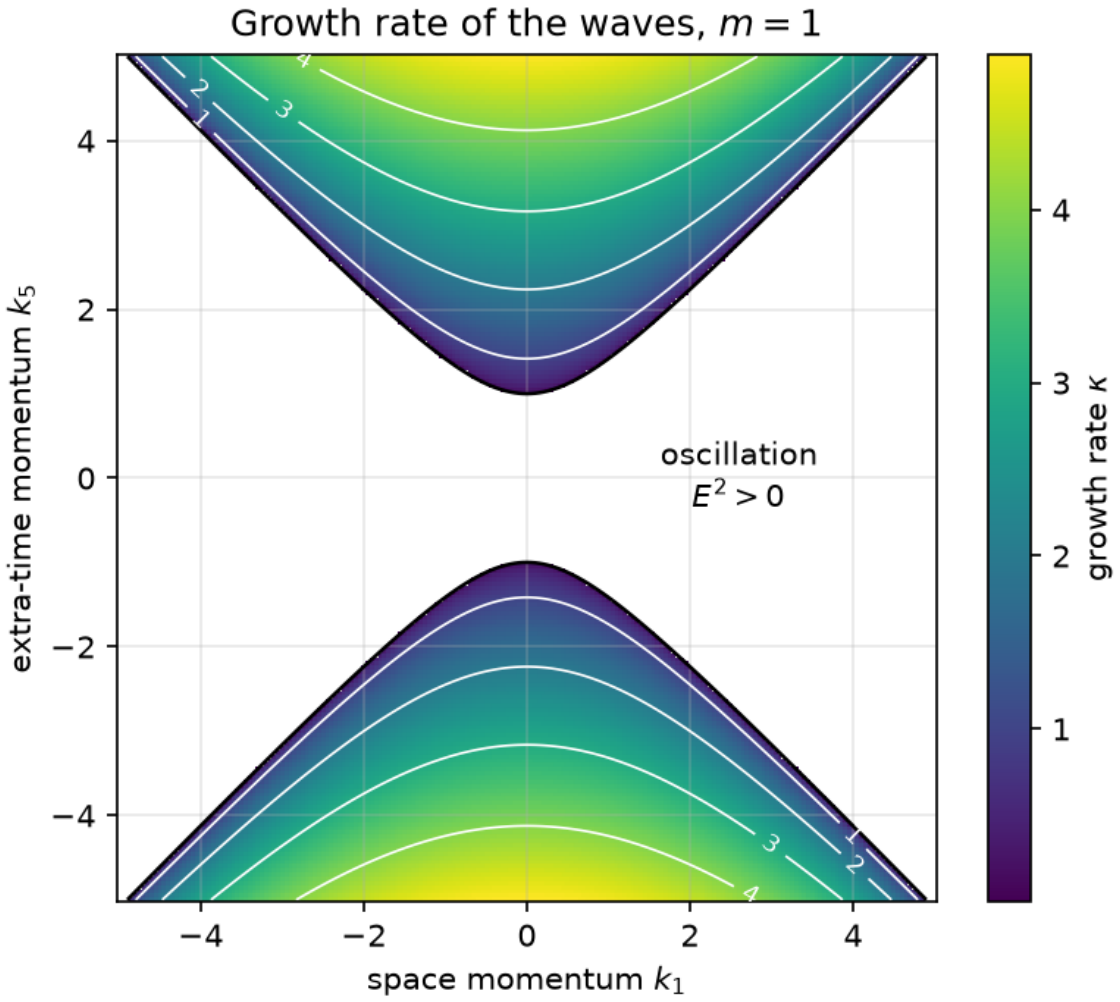

Figure 235: The growth rate κ in the plane of the space momentum k_1 (horizontal) and the extra-time momentum k_5 (vertical) for $m = 1$, both in the same unit, an inverse length; frozen coefficients. White: $E^2 = 1 + k_1^2 - k_5^2 > 0$, the waves oscillate. Coloured: the waves grow; the black curve $k_5^2 - k_1^2 = 1$ is the border, and the white contour lines mark $\kappa = 1, 2, 3, 4$. The two coloured regions reach to infinity: however large k_1 is, a large enough k_5 makes the waves grow. (Notebook 08a, figure 2.)

In [8]:

```

## 12. Hadamard: no continuous dependence on the data

Take as data at $x_4 = 0$ one growing wave, $\epsilon\,e^{iKx_5}u_+$, where $u_+$
is an eigenvector of $h_k$ for $+i\kappa$ with $u_+^\dagger u_+ = 1$. Its Sobolev
size of order $s$ is $\epsilon(1 + K^2)^{s/2}$. At $x_4 = 1$ the solution is
$\epsilon\,e^{\kappa}e^{iKx_5}u_+$, of size $\epsilon\,e^{\kappa}$. The ratio
(size of the solution at $x_4 = 1$) / (size of the data) is therefore
$e^{\kappa(K)}(1 + K^2)^{-s/2}$, the same for every $\epsilon$. Because $\kappa(K)$
grows like $K$, the exponential beats every power: for every $s$ the ratio is
unbounded. So data as small as we like (in any Sobolev norm) can give solutions as
large as we like after one unit of time: the solution does not depend continuously
on the data. The next cell finds $u_+$ numerically, confirms that it grows exactly
like $e^{\kappa x_4}$, and draws $\log_{10}$ of the ratio for $s = 0, 2, 4, 8$.
```

In [10]:

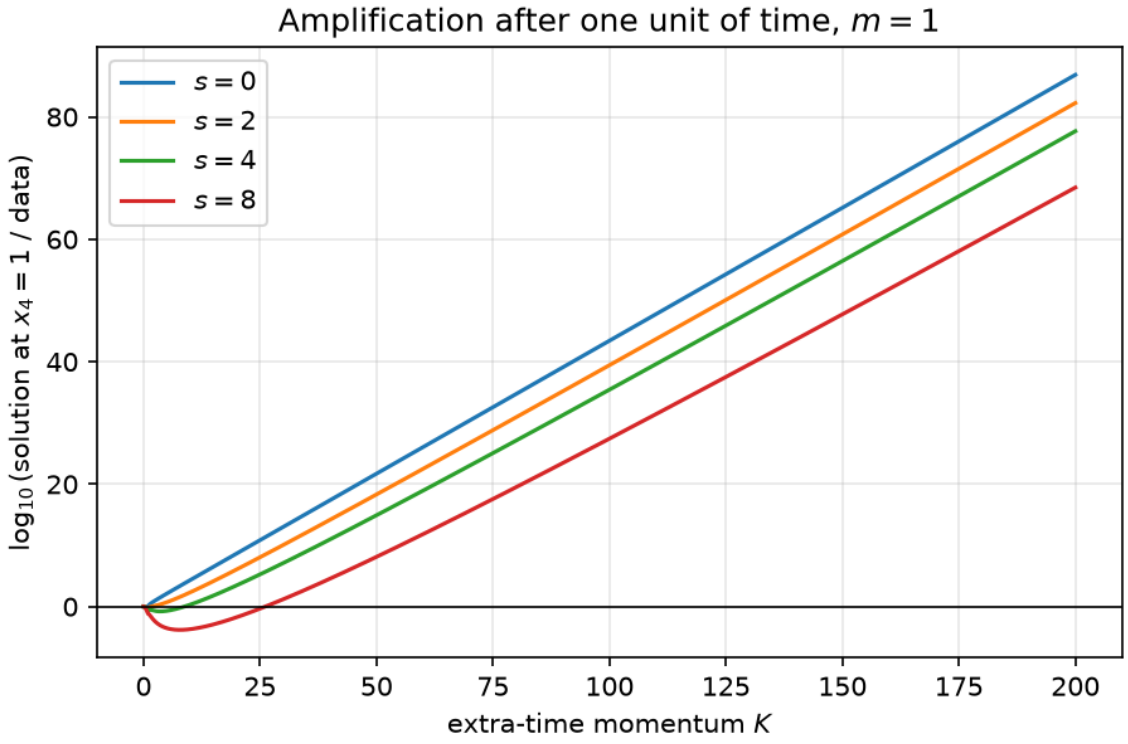

Figure 237: The base-10 logarithm of the amplification, the size of the solution at $x_4 = 1$ divided by the size of the data at $x_4 = 0$, for one growing wave of extra-time momentum K and $m = 1$, with the data measured in the Sobolev norm of order $s = 0, 2, 4, 8$; horizontal axis K in units of m. The amplification is $e^{\kappa}(1 + K^2)^{-s/2}$: a stronger norm only delays the rise, and every curve grows without bound, so arbitrarily small data give arbitrarily large solutions and the problem is not well posed in the sense of Hadamard. (Notebook 08a, figure 4.)

## 13. The Krein form is conserved; the growing waves have Krein form zero

From $B h_k = h_k^\dagger B$ (section 6): $\frac{d}{dx_4}(u^\dagger B u) = i\,u^\dagger
(h_k^\dagger B - B h_k)u = 0$, so the Krein form never changes, while
$\frac{d}{dx_4}(u^\dagger u) = i\,u^\dagger(h_k^\dagger - h_k)u$ is not zero when
$h_k$ is not Hermitian. The next cell follows a random wave with $m = 1$, $K = 2$
up to $x_4 = 4$ and compares both, then checks two exact statements of the pairing
record on its samples: the eight-dimensional eigenspace of a growing frequency
($m = 1$, $k_5 = 2$) carries the Krein form zero (every $u^\dagger B v$ vanishes on
it), while an eigenspace of a real frequency ($m = 1$, $k_1 = 2$, $k_0 = 2$, $E = 3$)
carries a Krein form with four positive and four negative directions (*inertia*
(4, 4)). Both checks compare the dimensions and the inertia found here with the
text of the pairing record (which calls the frequency $w$).
```

## 14. The good sector: every frequency is real

In the good sector ($k_5 = k_6 = k_7 = 0$) $h_k$ is Hermitian (section 7), so its
eigenvalues are real. The next cell checks this for a random good-sector momentum,
checks that $B$ commutes with $h_k$ there, and then follows the eigenvalues
$\pm\sqrt{1 + k_1^2 - K^2}$ in the complex plane along two paths: a growing space
momentum $k_1$ from 0 to 2.5 (good sector) and a growing extra-time momentum $K$
from 0 to 2.5. Along the first path the eigenvalues move outwards on the real axis;
along the second they meet at 0 when $K = 1$ and then leave the real axis.
```

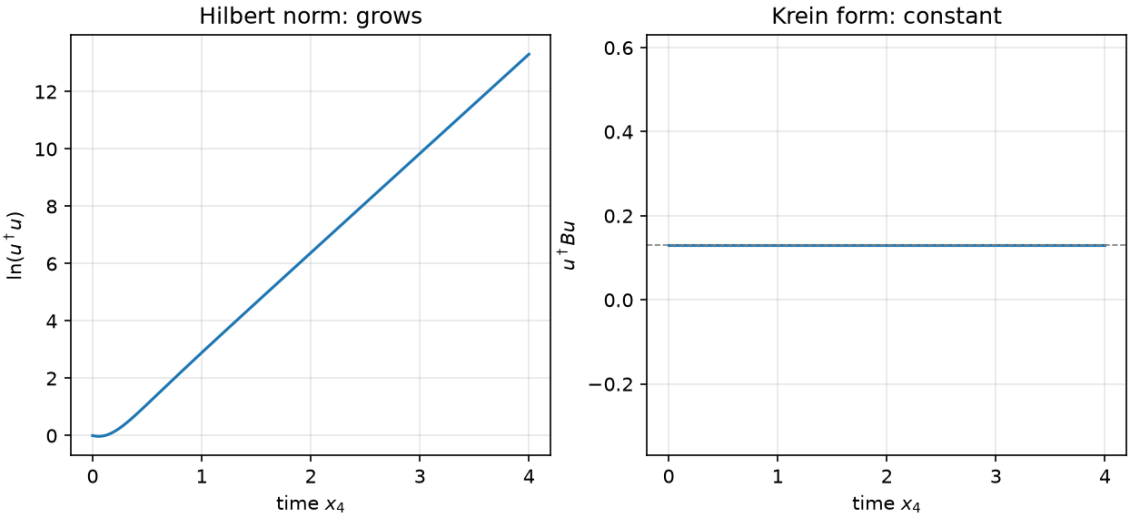

Figure 238: One wave with $m = 1$ and extra-time momentum $K = 2$ followed from $x_4 = 0$ to $x_4 = 4$ (time in units of $1/m$). Left: the natural logarithm of its Hilbert norm $u^\dagger u$, which grows like $e^{2\sqrt{3}\,x_4}$. Right: its Krein form $u^\dagger B u$, which stays exactly at its starting value (gray dashed line). The growth is possible because the growing waves have Krein form zero: the positive and the negative parts of the Krein form grow together. (Notebook 08a, figure 5.)

## 16. What this notebook showed

- With the author's gamma matrices the mode matrix of a plane wave (frozen
  coefficients) satisfies $h_k^2 = E^2 I_{16}$ exactly, with
  $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$ (PROVED, exact
  sympy; Revision check `extra_time_growth_rates_unbounded`).
- $h_k$ is Hermitian exactly when there is no extra-time momentum; in the good
  sector every frequency is real (PROVED).
- With enough extra-time momentum the frequencies are $\pm i\kappa$ and half of the
  waves grow like $e^{\kappa x_4}$; for $m = 1$, $k_5 = 2$ the rate is $\sqrt3$
  (PROVED; check `extra_time_modes_grow`).
- The growth rate $\kappa = \sqrt{K^2 - m^2 - k_1^2 - \dots}$ has no upper bound
  (PROVED). The amplification $e^{\kappa}(1 + K^2)^{-s/2}$ after one unit of time is
  unbounded in every Sobolev norm, so the initial-value problem for data that
  depend on the extra times is NOT well posed in the sense of Hadamard, although
  the slices $x_4 = $ const are non-characteristic (the equation can be solved for
  $\partial_4\Psi$).
- The Krein form $u^\dagger B u$ is conserved by every wave, also by the growing
  ones; the growing eigenspaces are Krein-neutral and the real-frequency ones have
  inertia (4, 4) (PROVED in the pairing record; reproduced here on its samples).
- Scope: these are statements with frozen coefficients (or in flat 4 + 4 space). In
  the author's metric the extra times deflate, so the frame momentum of a wave
  along an extra time grows with time; that is the subject of the next example of
  this chapter (Notebook 08b).
```

8.23 Line-by-line walk-through of Notebook 08a

The notebook has 13 code cells, In [1] to In [13]. As in Section 8.15, each line or small group of lines is quoted and explained, and a line `...` in quoted code stands for the remaining lines of a figure caption, which is printed in full under its figure in Section 8.22.

In [1], the set-up cell. It is the set-up cell explained line by line in Section 8.15, with one difference: the line `NOTEBOOK_ID = "08a" # this notebook: chapter 08, example a`. Its comment lines are the run instructions of Section 8.21. Output: `Set-up of notebook 08a complete: repository folder found, helpers defined.`

In [2], the record helpers and the author's gamma matrices.

```
import numpy as np  # arrays of numbers, matrices, linear algebra
import sympy as sp  # exact algebra with symbols

REPORTS = {}  # report file -> {check name: (verdict, detail)}, each read once
```

The two packages and the empty table of reports, as in Section 8.15.

```
def record_says(report_file, check_name, *pieces):
    ...
    verdict, detail = REPORTS[report_file][check_name]
    return verdict == "pass" and all(piece in detail for piece in pieces)

def check_record(condition, title, report_file, check_name, *pieces):
    """check() for a result that reproduces the Revision check check_name: it passes
    only if condition is true AND the report records check_name as passed, with
    every piece of text (values computed here) in its detail."""
    on_record = record_says(report_file, check_name, *pieces)
    check(condition and on_record, title,
          record=f"{report_file}, check {check_name}")
```

`record_says` is exactly the function of Notebook 08c (its body, shortened here to `...`, is quoted and explained in Section 8.15). `check_record` is the simpler form of the 08c helper: it takes one check name only. It passes only if the notebook's own condition is true AND the record reports the check as passed with every given piece of text in its detail.

```
gammas_record = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
# The record stores every matrix as a list of rows of whole numbers.
GAMMA = [np.array(rows, dtype=int) for rows in gammas_record["gamma"]]
ETA = gammas_record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1] in the order x0 ... x7
# B = -i C gamma^(x4) is stored as its real part and its imaginary part.
B = np.array(gammas_record["B"]["re"]) + 1j * np.array(gammas_record["B"]["im"])
I16 = np.eye(16, dtype=int)  # the 16 x 16 unit matrix
say(f"eta = {ETA}; each gamma is a {GAMMA[0].shape[0]} x {GAMMA[0].shape[1]} matrix")
```

The gammas are read from the record and turned into numpy arrays of whole numbers (`dtype=int`), so that the products below are exact. `ETA` is the list of the eight signs. The matrix B is complex; the record stores its real part (`"re"`) and its imaginary part (`"im"`) separately, and the line adds them, `1j` being Python's imaginary unit i. `np.eye(16, dtype=int)` is the unit matrix. The `say` line prints the signs and the shape of a gamma (`.shape` gives the number of rows and columns): `eta = [1, 1, 1, 1, -1, -1, -1, -1]; each gamma is a 16 x 16 matrix`.

```
clifford_ok = all(
    np.array_equal(GAMMA[a] @ GAMMA[b] + GAMMA[b] @ GAMMA[a],
                   2 * ETA[a] * (a == b) * I16)  # (a == b) is 1 or 0
    for a in range(8) for b in range(8))
check_record(clifford_ok, "the 64 Clifford relations {gamma^a, gamma^b} = 2 eta^ab I16",
             "Revision/algebra/reports/python-algebra.json", "clifford_relation",
             "for all 64 ordered pairs")
```

For all 64 ordered pairs (a, b) the anticommutator $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}$ (`@` is the matrix product) is compared, entry by entry and exactly (`np.array_equal`), with $2\eta_{aa} I_{16}$ when $a = b$ and the zero matrix otherwise: in arithmetic, the truth value `(a == b)` counts as 1 or 0. The check also requires the algebra record's check `clifford_relation`.

```
check(np.allclose(B, B.conj().T) and np.allclose(B @ B, np.eye(16)),
      "B is Hermitian and B^2 = 1")
# (gamma^(x4))^2 = -1: the field equation can be solved for d4 Psi (multiply it by
# -gamma^(x4)), so the slices x4 = const are non-characteristic.
check_record(np.array_equal(GAMMA[4] @ GAMMA[4], -I16),
             "(gamma^(x4))^2 = -1: the slices x4 = const are non-characteristic",
             "Revision/theory/reports/wolfram-field-theory.json", "evolution_form_G",
             "the slices x4 = const are non-characteristic")
```

`B.conj().T` is the conjugate transpose $B^\dagger$; `np.allclose` compares two arrays up to rounding. The first check confirms $B^\dagger = B$ and $B^2 = I_{16}$. The second confirms $(\gamma^{(4)})^2 = -I_{16}$, which is the reason the field equation can be solved for $\partial_4\Psi$ (Section 8.16), together with the Wolfram record's check `evolution_form_G`. Output: the line about `eta` and three PASS lines, two with `reproduces` lines.

In [3], the mode matrix and its square, exactly.

```
m = sp.Symbol("m", real=True)  # the mass
k = {a: sp.Symbol(f"k{a}", real=True) for a in (0, 1, 2, 3, 5, 6, 7)}  # momenta
G = [sp.Matrix(rows) for rows in gammas_record["gamma"]]  # the gammas, exact
B_exact = sp.I * sp.Matrix(gammas_record["B"]["im"])  # B is purely imaginary
g4 = G[4]  # gamma^(x4)
```

The mass and the seven momenta are exact symbols (a dictionary that maps each direction number a to the symbol k_a; there is no k_4). `G` holds the gammas as exact sympy matrices. The real part of B is zero (because $C\gamma^{(4)}$ is real), so `B_exact` is i times the stored imaginary part. `g4` is $\gamma^{(4)}$.

```
momentum_part = sp.zeros(16, 16)
for a, k_a in k.items():  # a runs over 0, 1, 2, 3, 5, 6, 7
    momentum_part += k_a * g4 * G[a]  # k_a gamma^(x4) gamma^(xa)
h = -sp.I * m * g4 - momentum_part  # the mode matrix h_k
E2 = m**2 + k[0]**2 + k[1]**2 + k[2]**2 + k[3]**2 - k[5]**2 - k[6]**2 - k[7]**2
say(f"E^2 = {E2}")
```

`k.items()` gives the pairs (direction, symbol); `G[a]` is the gamma of direction x_a (lists count from 0, like the coordinates). The loop adds up $\sum_{a\neq 4} k_a\gamma^{(4)}\gamma^{(a)}$, and `h` is the mode matrix $h_k = -im\gamma^{(4)} - \gamma^{(4)}\sum_a k_a\gamma^{(a)}$ of Section 8.17 (`sp.I` is the exact i). `E2` is the expected E^2; it is

printed in sympy's order: `E^2 = k1**2 + k2**2 + k3**2 - k5**2 - k6**2 - k7**2 + k8**2 + m**2`.

```
square_minus_E2 = (h * h - E2 * sp.eye(16)).applyfunc(sp.expand)
square_ok = square_minus_E2 == sp.zeros(16, 16)
# The two independent Revision verifiers print E^2 in their own notations: sympy
# writes powers with **, the Wolfram verifier with ^. Both texts must hold this E^2.
E2_sympy_text = sp.sstr(E2)  # "k0**2 + k1**2 + ... + m**2"
E2_wolfram_text = E2_sympy_text.replace("**", "^")  # "k0^2 + k1^2 + ... + m^2"
```

The matrix $h_k^2 - E^2 I_{16}$ is computed and every entry multiplied out (`sp.expand`); `square_ok` is true when all 256 entries are exactly zero. The two texts are E^2 as the sympy record writes it and as the Wolfram record writes it (`replace` swaps `**` for `^`).

```
check_record(square_ok,
             "h_k^2 = E^2 I16, E^2 = m^2 + k0^2 + k1^2 + k2^2 + k3^2 - k5^2 - k6^2 "
             "- k7^2", "Revision/theory/reports/python-scope.json",
             "extra_time_growth_rates_unbounded", f"h_k^2 = ({E2_sympy_text}) I16")
check_record(square_ok, "the same E^2 in the independent Wolfram verifier",
             "Revision/theory/reports/wolfram-scope.json",
             "extra_time_growth_rates_unbounded", f"h_k^2 = ({E2_wolfram_text}) I16")
check(sp.expand(h.trace()) == 0, "the trace of h_k is 0 (eigenvalues +E, -E, 8 each)")
```

Two checks of the same exact statement against the two independent Revision verifiers, whose details must contain exactly this E^2 in their notations; and the check that the trace of h_k is zero, which, with $h_k^2 = E^2$, gives eight eigenvalues $+E$ and eight $-E$ (Section 8.17).

```
krein = (B_exact * h - h.H * B_exact).applyfunc(sp.expand)  # .H: conjugate transpose
check_record(krein == sp.zeros(16, 16), "B h_k = h_k^dagger B (Krein self-adjoint)",
             "Revision/theory/reports/python-field-theory.json",
             "mode_hamiltonian_B_selfadjoint_dispersion", "B h = h^dagger B")
```

`h.H` is sympy's conjugate transpose $h_k^\dagger$. The check confirms $Bh_k = h_k^\dagger B$ for symbolic mass and momenta, the property that conserves the Krein form (Section 8.19). Output: the line with E^2 and four PASS lines, three with `reproduces` lines.

In [4], when is the mode matrix Hermitian?

```
anti = ((h - h.H) / 2).applyfunc(sp.expand)  # the anti-Hermitian part of h_k
extra_time_part = -(k[5] * g4 * G[5] + k[6] * g4 * G[6] + k[7] * g4 * G[7])
check((anti - extra_time_part).applyfunc(sp.expand) == sp.zeros(16, 16),
      "the anti-Hermitian part of h_k is the extra-time part")
anti_square = (anti * anti).applyfunc(sp.expand)
check(anti_square == (-(k[5]**2 + k[6]**2 + k[7]**2) * sp.eye(16)).applyfunc(
    sp.expand), "its square is -(k5^2 + k6^2 + k7^2) I16")
```

Every matrix is the sum of its Hermitian part $(h + h^\dagger)/2$ and its anti-Hermitian part $(h - h^\dagger)/2$. The first check shows that the anti-Hermitian part is exactly the extra-time part $-\gamma^{(4)}(k_5\gamma^{(5)} +$

$k_6\gamma^{(6)} + k_7\gamma^{(7)}$) (Section 8.17). The second shows that its square is $-(k_5^2 + k_6^2 + k_7^2)I_{16}$; a matrix whose square is a negative number times I_{16} is the zero matrix only when that number is zero, so h_k is Hermitian exactly when there is no extra-time momentum. Output: two PASS lines.

In [5], the exact example $m = 1$, $k_5 = 2$.

```
sample = {m: 1, k[5]: 2, k[0]: 0, k[1]: 0, k[2]: 0, k[3]: 0, k[6]: 0, k[7]: 0}
h_sample = h.subs(sample)  # an exact matrix of numbers
check(h_sample * h_sample == -3 * sp.eye(16), "m = 1, k5 = 2: h^2 = -3 I16")
dimension = 16 - (h_sample - sp.I * sp.sqrt(3) * sp.eye(16)).rank()
report("dimension of the eigenspace of +i sqrt(3)", dimension)
```

The substitution puts in $m = 1$, $k_5 = 2$ and zero for the other momenta. The check confirms $h^2 = -3I_{16}$. The dimension of the eigenspace of $+i\sqrt{3}$ is the number of independent solutions of $(h - i\sqrt{3}I)u = 0$, which is 16 minus the rank of that matrix (a standard fact of linear algebra, Chapter 1); sympy computes the rank exactly. RESULT: 8.

```
eigenvalues = np.linalg.eigvals(np.array(h_sample, dtype=complex))
# Round to 9 digits and count how often each value occurs (sorted, so the printed
# order is always the same).
rounded = sorted({complex(0.0, round(v.imag, 9)) for v in eigenvalues},
                 key=lambda v: v.imag)  # the real parts are zero (checked below)
for value in rounded:
    count = int(np.sum(np.abs(eigenvalues - value) < 1e-6))
    say(f"eigenvalue {value.imag:+.9f} i occurs {count} times")
```

numpy computes the 16 eigenvalues numerically (`np.linalg.eigvals`, on a complex array). The **set** in curly brackets keeps each rounded value once; `sorted(..., key=lambda v: v.imag)` orders them by their imaginary part (a `lambda` is a one-line function). For each distinct value the loop counts how many eigenvalues lie within 10^{-6} of it (`np.sum` of true values counts them) and prints, for example, `eigenvalue -1.732050808 i occurs 8 times` (`:+.9f` prints the sign and nine decimals).

```
# The record lists the exact eigenvalues as sympy writes them, sorted as text:
exact_text = sorted(str(sign * sp.sqrt(3) * sp.I) for sign in (1, -1))
say("exact eigenvalues as sympy writes them: " + ", ".join(exact_text))
check_record(dimension == 8 and np.max(np.abs(eigenvalues.real)) < 1e-9
             and all(abs(abs(v.imag) - 3**0.5) < 1e-9 for v in eigenvalues),
             "m = 1, k5 = 2: eigenvalues +i sqrt(3) and -i sqrt(3), 8 each",
             "Revision/theory/reports/python-field-theory.json",
             "extra_time_modes_grow", f"m = 1, k5 = 2: eigenvalues {exact_text}")
```

`exact_text` is the list of the two exact eigenvalues as sympy writes them, `-sqrt(3)*I` and `sqrt(3)*I`, sorted as texts. The check requires the eigenspace dimension 8, real parts below 10^{-9}, every imaginary part within 10^{-9} of $\pm\sqrt{3}$, and the record's text that starts with `m = 1, k5 = 2: eigenvalues` followed by this list (the f-string writes the Python list with its square brackets and quotation marks, exactly as the record does). Output: two PASS lines, one RESULT line, the two counted eigenvalues and the exact text.

In [6], the growth rate against the extra-time momentum.

```
def mode_matrix(mass, momenta):
    """h_k = -i m gamma^(x4) - gamma^(x4) sum_a k_a gamma^(xa); momenta: {a: k_a}."""
    g4n = GAMMA[4]
    result = -1j * mass * g4n.astype(complex)
    for a, k_a in momenta.items():  # a is the direction: GAMMA[a] is gamma^(xa)
        result = result - k_a * (g4n @ GAMMA[a])
    return result

def growth_rate(mass, K, k1=0.0):
    """kappa = sqrt(K^2 - m^2 - k1^2) where positive, else 0 (numpy arrays too)."""
    return np.sqrt(np.maximum(K**2 - mass**2 - k1**2, 0.0))
```

`mode_matrix` builds the numerical mode matrix for a mass and a dictionary of momenta, for example `{5: 2.0}` for $k_5 = 2$ (`.astype(complex)` makes the integer matrix complex, so that $-i$ can multiply it). `growth_rate` is the formula $\kappa = \sqrt{K^2 - m^2 - k_1^2}$ of Section 8.18 where the bracket is positive, and 0 where it is not (`np.maximum` takes the larger of the bracket and 0, entry by entry, so the function also works on whole arrays of K).

```
K_values = np.linspace(0.0, 6.0, 61)  # extra-time momenta 0, 0.1, ..., 6
numerical = np.array([np.max(np.linalg.eigvals(mode_matrix(1.0, {5: K})).imag)
                      for K in K_values])  # the largest growth rate, m = 1
deviation = np.abs(numerical - growth_rate(1.0, K_values))
at_threshold = np.abs(K_values - 1.0) < 1e-12  # K = m exactly, where h_k^2 = 0
check(np.max(deviation[~at_threshold]) < 1e-10 and np.max(deviation) < 1e-6,
      "growth rate from the eigenvalues = sqrt(K^2 - m^2) (m = 1)")
```

For 61 momenta $K = 0, 0.1, \ldots, 6$ the largest imaginary part of the 16 eigenvalues of h_k (with $m = 1$, $k_5 = K$) is the numerical growth rate. `deviation` holds the differences from the formula. `at_threshold` marks the single point $K = 1 = m$, where $h_k^2 = 0$: a matrix whose square is zero has the double eigenvalue 0, which a computer finds only to about 10^{-8}. `~` means "not", so `deviation[~at_threshold]` are the deviations at the other 60 points; the check requires them below 10^{-10}, and the one at the threshold below 10^{-6}.

```
report("growth rate at m = 1, K = 2 (sqrt 3)", f"{growth_rate(1.0, 2.0):.9f}")
report("growth rate at m = 1, K = 1000", f"{growth_rate(1.0, 1000.0):.6f}")
check_record(growth_rate(1.0, 1000.0) > 999.0 and growth_rate(1.0, 1e6) > 999999.0,
             "the growth rate has no upper bound (kappa/K tends to 1)",
             "Revision/theory/reports/python-scope.json",
             "extra_time_growth_rates_unbounded", "which has no upper bound")
```

Two RESULT lines: the rate $\sqrt{3} = 1.732050808$ at $K = 2$, and 999.999500 at $K = 1000$. The check illustrates the unbounded growth at $K = 1000$ and $K = 10^6$ (`1e6`), and requires the record's words "which has no upper bound"; the proof is the inequality $\kappa \geq K - c$ of Section 8.18.

```
K_fine = np.linspace(0.0, 6.0, 601)
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2), sharey=True)
for mass, style in ((0.5, "-"), (1.0, "--"), (2.0, ":")):
    left.plot(K_fine, growth_rate(mass, K_fine), style, label=f"$m = {mass}$")
```

```
left.plot(K_values[::3], numerical[::3], "o", markersize=4, color="black",
          label="eigenvalues, $m = 1$")
left.plot(K_fine, K_fine, color="gray", linewidth=0.8, label="$\\kappa = K$")
left.set_xlabel("extra-time momentum $K = k_5$")
left.set_ylabel("growth rate $\\kappa$")
left.set_title("$k_1 = 0$: three masses")
left.legend(loc="upper left")
```

The left panel draws the formula for three masses on a fine grid (601 points) with solid, dashed and dotted lines; the black dots are every third numerical rate of $m = 1$ (`[::3]` takes every third element); the gray line is $\kappa = K$, which every curve approaches.

```
for k1, style in ((0.0, "-"), (2.0, "--"), (4.0, ":")):
    right.plot(K_fine, growth_rate(1.0, K_fine, k1), style, label=f"$k_1 = {k1}$")
right.plot(K_fine, K_fine, color="gray", linewidth=0.8, label="$\\kappa = K$")
right.set_xlabel("extra-time momentum $K = k_5$")
right.set_title("$m = 1$: three space momenta $k_1$")
right.legend(loc="upper left")
save_figure(fig, "growth_rate_vs_momentum",
            "The growth rate $\\kappa = \\sqrt{K^2 - m^2 - k_1^2}$ of the growing "
            ...
            "$\\kappa = K$, so the rate has no upper bound.")
```

The right panel draws the formula for $m = 1$ and three space momenta, with the same gray line. The figure is Figure 08a.1. Output: one PASS line, two RESULT lines, one PASS line with its `reproduces` line, and the figure line.

What Figure 08a.1 shows. Both panels plot the growth rate κ (vertical) against the extra-time momentum $K = k_5$ (horizontal), both in the same unit, an inverse length. Left: masses $m = 0.5, 1, 2$; each curve is zero up to the threshold $K = m$, then rises steeply and bends towards the gray line $\kappa = K$; the black dots, the numerical eigenvalues for $m = 1$, lie exactly on the dashed curve. Right: $m = 1$ with $k_1 = 0, 2, 4$: a space momentum moves the threshold to $K = \sqrt{1 + k_1^2}$ but does not stop the rise. The student should see that every curve approaches $\kappa = K$, so the rate has no upper bound.

In [7], where the waves oscillate and where they grow.

```
k1_grid, k5_grid = np.meshgrid(np.linspace(-5.0, 5.0, 201), np.linspace(-5.0, 5.0, 201))
E2_grid = 1.0 + k1_grid**2 - k5_grid**2  # m = 1
kappa_grid = np.sqrt(np.maximum(-E2_grid, 0.0))
growing_fraction = float(np.mean(E2_grid < 0.0))
report("fraction of the grid where the waves grow", f"{growing_fraction:.4f}")
check(abs(kappa_grid[100, 100]) == 0.0 and abs(kappa_grid[200, 100] - 24**0.5) < 1e-12,
      "kappa = 0 at k = 0 and kappa = sqrt(24) at k1 = 0, k5 = 5")
```

`np.meshgrid` makes two 201×201 arrays: at row r and column c, `k1_grid` holds the c-th value of k_1 and `k5_grid` the r-th value of k_5, each running from -5 to 5 in steps of 0.05. `E2_grid` is $E^2 = 1 + k_1^2 - k_5^2$ at every grid point and `kappa_grid` the growth rate. `np.mean` of the true/false array `E2_grid < 0.0` is the fraction of grid points where the waves grow: RESULT 0.4439. The check tests two points: row 100, column 100 is $k_1 = k_5 = 0$, where $\kappa = 0$; row 200, column 100 is $k_5 = 5$, $k_1 = 0$, where $\kappa = \sqrt{25 - 1} = \sqrt{24}$.

```
fig, ax = plt.subplots(figsize=(6.0, 5.0))
shown = np.where(E2_grid < 0.0, kappa_grid, np.nan)  # nan: not coloured (white)
image = ax.pcolormesh(k1_grid, k5_grid, shown, cmap="viridis", shading="auto")
fig.colorbar(image, ax=ax, label="growth rate $\\kappa$")
lines = ax.contour(k1_grid, k5_grid, kappa_grid, levels=[1, 2, 3, 4], colors="white",
                   linewidths=0.8)
ax.clabel(lines, fmt="%d", fontsize=8)
ax.contour(k1_grid, k5_grid, E2_grid, levels=[0.0], colors="black", linewidths=1.2)
ax.text(2.6, 0.0, "oscillation\n$E^2 > 0$", ha="center", va="center")
ax.set_xlabel("space momentum $k_1$")
ax.set_ylabel("extra-time momentum $k_5$")
ax.set_title("Growth rate of the waves, $m = 1$")
save_figure(fig, "growth_map",
            "The growth rate $\\kappa$ in the plane of the space momentum $k_1$ "
            ...
            "makes the waves grow.")
```

`np.where(condition, a, b)` takes `a` where the condition holds and `b` elsewhere; `np.nan` ("not a number") is left uncoloured, so the oscillating region stays white. `pcolormesh` colours the grid with the colour map `"viridis"`; `contour` draws the curves of equal growth rate $\kappa = 1, 2, 3, 4$ in white, and `clabel` writes their values on them (`"%d"`: as whole numbers); a second `contour` draws the border $E^2 = 0$ in black; `text` writes a label at $(2.6, 0)$ (`\n` starts a new line). The figure is Figure 08a.2. Output: one RESULT line, one PASS line, the figure line.

What Figure 08a.2 shows. The plane of the space momentum k_1 (horizontal) and the extra-time momentum k_5 (vertical), both from -5 to 5 in units of the inverse length, for $m = 1$. The white region around the horizontal axis is where $E^2 = 1 + k_1^2 - k_5^2 > 0$: the waves oscillate. Above and below it, bounded by the black hyperbola $k_5^2 - k_1^2 = 1$, the colour shows the growth rate, with white contour lines at $\kappa = 1, 2, 3, 4$. The student should see that the two coloured regions reach to infinity: however large k_1 is, a large enough k_5 makes the waves grow.

In [8], solving in time, in two independent ways.

```
def evolve(hk, E2_value, x4, u0):
    """u(x4) = (cos(E x4) - i sin(E x4)/E h_k) u0, with E = sqrt(E^2) (complex)."""
    if E2_value == 0.0:
        return u0 - 1j * x4 * (hk @ u0)  # the limit E -> 0
    E = np.sqrt(complex(E2_value))  # E is imaginary when E^2 < 0
    return np.cos(E * x4) * u0 - 1j * np.sin(E * x4) / E * (hk @ u0)
```

`evolve` is the closed formula of Section 8.18: for $E^2 = 0$ the limit $u_0 - ix_4 h_k u_0$, otherwise $\cos(Ex_4)u_0 - i\frac{\sin(Ex_4)}{E} h_k u_0$, where `np.sqrt(complex(...))` gives the imaginary $E = i\kappa$ when $E^2 < 0$ (numpy's cosine and sine of an imaginary number are then the hyperbolic functions).

```
def rk4(hk, x4_end, u0, steps):
    """The classical RK4 method for du/dx4 = -i h_k u from 0 to x4_end."""
    step = x4_end / steps
    u = u0.astype(complex)
    for _ in range(steps):
        s1 = -1j * (hk @ u)
        s2 = -1j * (hk @ (u + step / 2 * s1))
```

```
        s3 = -1j * (hk @ (u + step / 2 * s2))
        s4 = -1j * (hk @ (u + step * s3))
        u = u + step / 6 * (s1 + 2 * s2 + 2 * s3 + s4)
    return u
```

`rk4` is the classical fourth-order Runge-Kutta method of Chapter 2 for $du/dx_4 = -ih_k u$: in each step it evaluates the right-hand side four times (at the start, twice at the middle, at the end) and advances with the weighted average $\frac{1}{6}(s_1 + 2s_2 + 2s_3 + s_4)$. It knows nothing of the closed formula, so the two are independent.

```
rng = np.random.default_rng(12345)  # fixed seed: the same numbers in every run
u_start = rng.normal(size=16) + 1j * rng.normal(size=16)
u_start = u_start / np.sqrt(np.vdot(u_start, u_start).real)  # u^dagger u = 1
```

A random-number generator with the fixed **seed** 12345 produces the same "random" numbers in every run. The starting column has 16 complex entries whose real and imaginary parts are drawn from the normal (bell-shaped) distribution; dividing by $\sqrt{u^\dagger u}$ makes its size 1 (`np.vdot(a, b)` is $a^\dagger b$).

```
worst = 0.0
for K in (0.5, 1.0, 2.0, 3.0):
    hk = mode_matrix(1.0, {5: K})
    exact = evolve(hk, 1.0 - K**2, 3.0, u_start)
    stepped = rk4(hk, 3.0, u_start, 3000)
    relative = np.linalg.norm(exact - stepped) / np.linalg.norm(exact)
    worst = max(worst, relative)
    say(f"K = {K}: u^dagger u at x4 = 3 is {np.vdot(exact, exact).real:.6e}")
check(worst < 1e-9, "the closed formula and RK4 agree at x4 = 3 (relative < 1e-9)")
```

For four extra-time momenta (with $m = 1$, so $E^2 = 1 - K^2$) the wave is followed to $x_4 = 3$ both ways, RK4 with 3000 steps. The relative difference (the length of the difference divided by the length of the exact column; `np.linalg.norm` is the length $\sqrt{u^\dagger u}$) is recorded, and the largest one must be below 10^{-9}. The printed sizes at $x_4 = 3$ (`:.6e` prints in powers of ten) are 1.347676 for $K = 0.5$ (oscillation), 20.06346 for $K = 1$ ($E = 0$, growth like a power of x_4), 1.880098×10^4 for $K = 2$ and 1.086955×10^7 for $K = 3$ (COMPUTED). Output: four lines and one PASS line.

In [9], the size of a wave in time.

```
x4_values = np.linspace(0.0, 3.0, 301)
fig, ax = plt.subplots()
for K in (0.5, 1.0, 2.0, 3.0, 5.0):
    hk = mode_matrix(1.0, {5: K})
    sizes = [np.vdot(v, v).real for v in
             (evolve(hk, 1.0 - K**2, x4, u_start) for x4 in x4_values)]
    ax.plot(x4_values, np.log(sizes), label=f"$K = {K}$")
```

For five momenta the size $u^\dagger u$ is computed with the closed formula at 301 times from 0 to 3, and its natural logarithm is drawn (`np.log`).

```
    if K > 1.0:  # the asymptotic straight line of slope 2 kappa
        kappa = growth_rate(1.0, K)
        ax.plot(x4_values, np.log(sizes[-1]) + 2 * kappa * (x4_values - 3.0), "--",
                color="gray", linewidth=0.8)
# An empty line that only adds the dashed straight lines to the legend:
ax.plot([], [], "--", color="gray", linewidth=0.8, label="slope $2\\kappa$")
ax.set_xlabel("time $x_4$")
ax.set_ylabel("$\\ln(u^\\dagger u)$")
ax.set_title("Size of a wave in time, $m = 1$")
ax.legend();
save_figure(fig, "norm_in_time",
            "The natural logarithm of the size $u^\\dagger u$ of a wave against the "
            ...
            "$2\\kappa$ (gray dashed), $2\\sqrt3$, $2\\sqrt8$ and $2\\sqrt{24}$.")
```

For the growing waves a gray dashed straight line of slope 2κ is drawn through the last point (`sizes[-1]` is the last element): $u^\dagger u$ grows like $e^{2\kappa x_4}$ (the size squared of $e^{\kappa x_4}$), so its logarithm becomes a straight line of slope 2κ. The empty plot only adds the gray line to the legend. The figure is Figure 08a.3; the cell prints only the figure line.

What Figure 08a.3 shows. The natural logarithm of $u^\dagger u$ (a pure number) against the time x_4 (units of $1/m$), for $m = 1$ and $K = 0.5, 1, 2, 3, 5$, all started from the same column of size 1 ($\ln 1 = 0$). For $K = 0.5$ the curve stays near 0 (oscillation); for $K = 1$ it rises slowly (a power of x_4); for $K = 2, 3, 5$ it soon runs along a straight line of slope $2\sqrt{3}$, $2\sqrt{8}$ and $2\sqrt{24}$ (gray dashed). The student should see exponential growth whose rate increases with the extra-time momentum.

In [10], Hadamard's amplification.

```
def growing_eigenvector(mass, K):
    """A unit eigenvector of h_k (k5 = K) for the eigenvalue +i kappa."""
    hk = mode_matrix(mass, {5: K})
    kappa = growth_rate(mass, K)
    # The null space of h_k - i kappa I: the right singular vector of the smallest
    # singular value (numpy sorts the singular values from large to small).
    _, _, vh = np.linalg.svd(hk - 1j * kappa * np.eye(16))
    u_plus = vh[-1].conj()
    return hk, kappa, u_plus / np.linalg.norm(u_plus)
```

`growing_eigenvector` finds a column u_+ with $h_k u_+ = i\kappa u_+$. The **singular value decomposition** (`np.linalg.svd`) writes a matrix A as $U\Sigma V^\dagger$ with a list of numbers Σ (the singular values, sorted from large to small) and two matrices U and V whose columns have length 1 and are perpendicular; a column of V whose singular value is zero solves $Au = 0$. numpy returns $V^\dagger$ as `vh`, so the last row of `vh`, conjugated, is the last column of V. The column is divided by its length.

```
hk, kappa, u_plus = growing_eigenvector(1.0, 4.0)
later = evolve(hk, 1.0 - 4.0**2, 1.0, u_plus)
check(np.linalg.norm(hk @ u_plus - 1j * kappa * u_plus) < 1e-12
      and abs(np.linalg.norm(later) - np.exp(kappa)) < 1e-9 * np.exp(kappa),
      "a growing eigenvector grows exactly like e^(kappa x4) (K = 4)")
```

For $m = 1$, $K = 4$ ($\kappa = \sqrt{15}$) the check confirms that u_+ is an eigenvector to 10^{-12} and that its length at $x_4 = 1$ is e^κ to a relative 10^{-9}.

```
K_axis = np.linspace(0.0, 200.0, 2001)
fig, ax = plt.subplots()
for s in (0, 2, 4, 8):
    log_ratio = (growth_rate(1.0, K_axis) - s / 2 * np.log(1 + K_axis**2)) / np.log(10)
    ax.plot(K_axis, log_ratio, label=f"$s = {s}$")
    crossing = K_axis[np.argmax(log_ratio > 6.0)]  # first K with ratio above 10^6
    report(f"s = {s}: first K (step 0.1) with ratio above 10^6", f"{crossing:.1f}")
    check(log_ratio[-1] > 50.0, f"s = {s}: the ratio exceeds 10^50 at K = 200")
```

For K from 0 to 200 in steps of 0.1 and four Sobolev orders, `log_ratio` is the base-10 logarithm of the amplification, $(\kappa - \frac{s}{2}\ln(1+K^2))/\ln 10$ (Section 8.18). `np.argmax` of a true/false array gives the position of the first true value, so `crossing` is the first K at which the ratio exceeds 10^6; it is printed (13.9, 19.9, 27.1, 44.2). Each check requires the ratio to exceed 10^{50} at $K = 200$ (`log_rati o[-1]` is the last value).

```
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("extra-time momentum $K$")
ax.set_ylabel("$\\log_{10}$(solution at $x_4 = 1$ / data)")
ax.set_title("Amplification after one unit of time, $m = 1$")
ax.legend();
save_figure(fig, "hadamard_ratio",
            "The base-10 logarithm of the amplification, the size of the solution "
            ...
            "solutions and the problem is not well posed in the sense of Hadamard.")
```

Axis labels, a black line at 0 (amplification 1), and Figure 08a.4. Output: one PASS line, four RESULT lines with four PASS lines, the figure line.

What Figure 08a.4 shows. The base-10 logarithm of the amplification after one unit of time (vertical; a pure number) against the extra-time momentum K from 0 to 200 (horizontal, units of m), for the Sobolev orders $s = 0, 2, 4, 8$. The curves of the larger orders first dip below 0 (for $s = 8$ down to about -4, back above 0 near $K = 26$, where $\sqrt{K^2-1} = 4\ln(1+K^2)$), because a strong norm punishes the wiggles of the data; then every curve rises along a nearly straight line of slope about $1/\ln 10 \approx 0.43$, without bound (at $K = 200$ the values lie between about 68 and 87). The student should see that a stronger norm only delays the rise: arbitrarily small data give arbitrarily large solutions, the failure of Hadamard's third condition.

In [11], the Krein form.

```
hk = mode_matrix(1.0, {5: 2.0})
times = np.linspace(0.0, 4.0, 401)
path = [evolve(hk, 1.0 - 4.0, x4, u_start) for x4 in times]
hilbert = np.array([np.vdot(v, v).real for v in path])  # u^dagger u
krein_values = np.array([np.vdot(v, B @ v) for v in path])  # u^dagger B u
drift = np.max(np.abs(krein_values - krein_values[0]) / np.maximum(hilbert, 1.0))
report("Krein form at x4 = 0", f"{krein_values[0].real:+.9f}")
report("u^dagger u at x4 = 4", f"{hilbert[-1]:.6e}")
imaginary = np.max(np.abs(krein_values.imag) / np.maximum(hilbert, 1.0))
check(drift < 1e-12 and imaginary < 1e-12,
      "the Krein form u^dagger B u is constant (drift / max(u^dagger u, 1) < 1e-12)")
```

The random column of In [8] is followed with $m = 1$, $K = 2$ to $x_4 = 4$ at 401 times; `hilbert` holds $u^\dagger u$ and `krein_values` holds $u^\dagger B u$. The **drift** is the largest change of the Krein form, divided by $\max(u^\dagger u, 1)$: rounding errors grow with the size of the numbers, so the change is measured relative to it. The two RESULT lines print the Krein form at the start, $+0.129919115$, and $u^\dagger u = 6.006621 \times 10^5$ at $x_4 = 4$. The check requires the drift and the imaginary part of the Krein form (a Hermitian form gives real values) below 10^{-12}.

```
def eigenspace(hk, value):
    """An orthonormal basis (columns) of the eigenspace of hk for value."""
    _, singular, vh = np.linalg.svd(hk - value * np.eye(16))
    return vh[singular < 1e-9].conj().T
```

`eigenspace` returns, as columns, all right singular vectors of $h_k - \lambda I$ whose singular value is below 10^{-9}: an **orthonormal basis** (columns of length 1, perpendicular to each other) of the eigenspace of λ. `vh[singular < 1e-9]` selects the rows of `vh` with small singular values.

```
V_grow = eigenspace(mode_matrix(1.0, {5: 2.0}), 1j * 3**0.5)
form_grow = V_grow.conj().T @ B @ V_grow  # the Krein form on that eigenspace
check_record(V_grow.shape[1] == 8 and np.max(np.abs(form_grow)) < 1e-12,
             "m = 1, k5 = 2: the 8-dim eigenspace of +i sqrt(3) is Krein-neutral",
             "Revision/pairing/reports/python-pairing.json",
             "Q.one_particle_complex_frequency_Krein_neutral",
             "(0, 0, 0, 0, 2, 0, 0): w^2 = -3, eigenspace dimensions "
             f"[{V_grow.shape[1]}, {V_grow.shape[1]}], B-form identically zero: True")
```

The eigenspace of the growing frequency $+i\sqrt{3}$ ($m = 1$, $k_5 = 2$) has 8 basis columns. The 8×8 matrix `form_grow` holds every value $v^\dagger B u$ for two basis columns; the check requires dimension 8 and all 64 values below 10^{-12} (the Krein-neutrality of Section 8.19), and the pairing record's text for the same sample (it lists the momenta in the order $k_1, k_2, k_3, k_5, k_6, k_7, k_0$ and calls the frequency w).

```
V_real = eigenspace(mode_matrix(1.0, {0: 2.0, 1: 2.0}), 3.0)
form_real = np.linalg.eigvalsh(V_real.conj().T @ B @ V_real)  # Hermitian 8 x 8
inertia = (int(np.sum(form_real > 1e-9)), int(np.sum(form_real < -1e-9)))
report("Krein inertia of the eigenspace of E = 3 (m = 1, k0 = k1 = 2)", inertia)
check_record(V_real.shape[1] == 8 and inertia == (4, 4),
             "m = 1, k0 = k1 = 2: the eigenspace of E = 3 has Krein inertia (4, 4)",
             "Revision/pairing/reports/python-pairing.json",
             "Q.one_particle_Krein_inertia",
             f"w = 3: dim {V_real.shape[1]}, Krein inertia ({inertia[0]},{inertia[1]})")
```

For the good-sector wave $m = 1$, $k_1 = k_0 = 2$ ($E^2 = 1 + 4 + 4 = 9$) the eigenspace of $E = 3$ is found; the Krein form restricted to it is a Hermitian 8×8 matrix, whose eigenvalues `np.linalg.eigvalsh` computes. Counting the positive and the negative ones gives the inertia, printed as `(4, 4)`; the check also requires the pairing record's text.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(times, np.log(hilbert))
```

```
left.set_xlabel("time $x_4$")
left.set_ylabel("$\\ln(u^\\dagger u)$")
left.set_title("Hilbert norm: grows")
right.plot(times, krein_values.real)
right.axhline(krein_values[0].real, color="gray", linestyle="--", linewidth=0.8)
right.set_ylim(krein_values[0].real - 0.5, krein_values[0].real + 0.5)
right.set_xlabel("time $x_4$")
right.set_ylabel("$u^\\dagger B u$")
right.set_title("Krein form: constant")
save_figure(fig, "krein_norm",
            "One wave with $m = 1$ and extra-time momentum $K = 2$ followed from "
            ...
            "positive and the negative parts of the Krein form grow together.")
```

Left: $\ln(u^\dagger u)$ against the time. Right: the Krein form, with a gray dashed line at its starting value and a vertical range of ± 0.5 around it. The figure is Figure 08a.5. Output: three RESULT lines, three PASS lines (two with `reproduces` lines), the figure line.

What Figure 08a.5 shows. One wave ($m = 1$, $K = 2$) from $x_4 = 0$ to 4 (units of $1/m$). Left: the logarithm of its Hilbert norm rises, after a short start, along a straight line of slope $2\sqrt{3}$, to about $\ln(6.0 \times 10^5) \approx 13.3$. Right: its Krein form (a pure number) is a flat line on the gray dashed line at 0.1299. The student should see the ordinary size growing by almost six powers of ten while the Krein form does not move, possible because the growing waves carry Krein form zero.

In [12], the good sector, and the eigenvalue paths.

```
good = mode_matrix(1.3, {0: 2.2, 1: 0.4, 2: -1.1, 3: 0.7})  # no k5, k6, k7
good_eigenvalues = np.linalg.eigvals(good)
E_good = np.sqrt(1.3**2 + 0.4**2 + 1.1**2 + 0.7**2 + 2.2**2)
check_record(np.allclose(good, good.conj().T) and np.allclose(good @ B, B @ good)
             and np.max(np.abs(np.abs(good_eigenvalues) - E_good)) < 1e-12
             and np.max(np.abs(good_eigenvalues.imag)) < 1e-12,
             "good sector: h_k Hermitian, [B, h_k] = 0, eigenvalues real +-E",
             "Revision/theory/reports/python-field-theory.json",
             "good_sector_spectrum_and_B_sectors", "h is Hermitian", "[B, h] = 0")
```

A good-sector mode matrix with $m = 1.3$ and four space momenta (no extra-time momentum). The check requires: h_k Hermitian, commuting with B, every eigenvalue of size $E = \sqrt{m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2}$ and with imaginary part below 10^{-12}, so the eigenvalues are $\pm E$, real; and the record's texts.

```
path_values = np.linspace(0.0, 2.5, 26)  # the momenta 0, 0.1, ..., 2.5
colours = np.repeat(path_values, 16)  # each matrix has 16 eigenvalues
fig, panels = plt.subplots(1, 2, figsize=(10.0, 4.6), sharey=True)
for panel, direction, name in ((panels[0], 1, "space momentum $k_1$ (good sector)"),
                               (panels[1], 5, "extra-time momentum $K = k_5$")):
    points = np.concatenate([np.linalg.eigvals(mode_matrix(1.0, {direction: p}))
                             for p in path_values])
    dots = panel.scatter(points.real, points.imag, c=colours, cmap="plasma", s=22)
```

For 26 momenta from 0 to 2.5, the 16 eigenvalues of h_k ($m = 1$) are computed with the momentum along x_1 (left panel) or along x_5 (right panel); `np.concatenate` joins the 26 lists into one. `np.repea`

`t(path_values, 16)` repeats each momentum 16 times, so that every eigenvalue gets the colour of its momentum. `scatter` draws them as dots in the complex plane (real part horizontal, imaginary part vertical).

```
    panel.set_xlim(-3.0, 3.0)
    panel.set_ylim(-3.0, 3.0)
    panel.set_aspect("equal")
    panel.set_xlabel("real part of the eigenvalue $E$")
    panel.set_title(name)
panels[0].set_ylabel("imaginary part of the eigenvalue $E$")
fig.colorbar(dots, ax=panels, label="momentum (0 to 2.5)")
save_figure(fig, "eigenvalue_paths",
            "The eigenvalues $E$ of the mode matrix for $m = 1$ in the complex "
            ...
            "leave along the imaginary axis as $\\pm i\\sqrt{K^2 - 1}$: growth.")
```

Equal ranges and equal scales on both axes (`set_aspect("equal")`), labels, one colour bar for both panels, and Figure 08a.6. Output: one PASS line with its `reproduces` line, the figure line.

What Figure 08a.6 shows. The eigenvalues E of the mode matrix for $m = 1$ in the complex plane (horizontal: real part; vertical: imaginary part; units of m), coloured from dark (momentum 0) to bright (momentum 2.5). Left, a growing space momentum: the eigenvalues $\pm\sqrt{1 + k_1^2}$ start at ± 1 and move outwards along the real axis; they stay real. Right, a growing extra-time momentum: the eigenvalues $\pm\sqrt{1 - K^2}$ move inwards along the real axis, meet at 0 for $K = 1$, and then leave along the imaginary axis as $\pm i\sqrt{K^2 - 1}$. The student should see the moment at which oscillation turns into growth.

In [13], the last check.

```
for name in ("08a_1_growth_rate_vs_momentum.png", "08a_2_growth_map.png",
             "08a_3_norm_in_time.png", "08a_4_hadamard_ratio.png",
             "08a_5_krein_norm.png", "08a_6_eigenvalue_paths.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

Six checks that the figure files exist, and the last line. The 30 checks come from the cells as follows: three in In [2], four in In [3], two each in In [4], In [5] and In [6], one each in In [7] and In [8], five in In [10], three in In [11], one in In [12] and six here (In [9] has none). The last line reads `ALL 30 C HECKS PASSED (notebook 08a)`.

8.24 The deflating history pushes every extra-time wave into growth

Sections 8.17 to 8.19 froze the coefficients. In the author's metric they are not frozen: the extra times deflate, and this changes the momentum that a wave has along them. This section follows the change exactly.

The hidden coordinate y. A second way to label the points of the hidden direction is $y = \ln(\sin z)/(6H)$. At the patch end $z = \pi/2$, $\sin z = 1$ and $y = 0$; towards the tip $z \to 0$, $\sin z \to 0$

and $y \to -\infty$. Two facts make y useful, each derived in one line. First, $\sin z = e^{6Hy}$ (undo the logarithm), so $\sin^{1/6} z = e^{Hy}$ and $\sin^{1/3} z = e^{2Hy}$. Second, $dy/dx_0 = \frac{1}{6H} \cdot \frac{\cos z}{\sin z} \cdot 6H = \cot z$ (chain rule with $dz/dx_0 = 6H$), so $\cot^2 z\, dx_0^2 = dy^2$. The author's metric therefore reads

$$ds^2 = e^{2Hy}\big(e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2 + dx_7^2)\big) - dx_4^2 + dy^2,$$

and y measures proper length along the hidden direction. The Kohn-Sham record cuts the tip at $y = -L$ with $L = 3$ (`Revision/kohn_sham/results/parameters.json`, entry `physics.L_tipCut off`).

The history. The examples use the history $a_4 = AHx_4$ with $A = 1$ and $H = m = 1$, the canonical history of the Kohn-Sham record (`parameters.json`, entries `physics.historyA`, `physics.H`, `physics.m`). It is ASSUMED: the record calls it a PRESCRIBED BACKGROUND, chosen and not solved for, because the Kohn-Sham states along it do not satisfy the source conditions of the a_4 equations (Chapter 17). Along it the 3-space scale factor $e^{a_4}e^{Hy}$ grows exponentially, the extra-time scale factor $e^{-a_4}e^{Hy}$ shrinks exponentially, and the product of the six, $e^{6Hy} = \sin z$, does not change.

Wave numbers that do not change. The coefficients of the field equation in the author's metric do not depend on $x_1, x_2, x_3, x_5, x_6, x_7$. So a field of the form $\Psi = e^{i(q_1x_1 + q_5x_5)}\psi(x_4, y)$ keeps this form for all times: every derivative ∂_1 or ∂_5 acting on it gives the factor iq_1 or iq_5, the common exponential divides out, and the equation for ψ contains neither x_1 nor x_5. The numbers q_1 and q_5 are **coordinate wave numbers**: radians of phase per unit of the coordinate. They are exact constants of the motion.

Frame momenta that do change. A frame momentum counts radians per unit of PROPER length; a coordinate length Δx_a has the proper length $f_a \Delta x_a$, so $k_{(a)} = q_a/f_a$. Line by line:

1. $k_{(1)} = q_1/f_1 = q_1 e^{-a_4} e^{-Hy}$, because $f_1 = e^{a_4} \sin^{1/6} z = e^{a_4} e^{Hy}$;
2. $k_{(5)} = q_5/f_5 = q_5 e^{a_4} e^{-Hy}$, because $f_5 = e^{-a_4} \sin^{1/6} z = e^{-a_4} e^{Hy}$;
3. with frozen coefficients at the time x_4 (Section 8.17), $E^2 = m^2 + k_{(1)}^2 - k_{(5)}^2 = m^2 + q_1^2 e^{-2Hy} e^{-2a_4} - q_5^2 e^{-2Hy} e^{2a_4}$.

As the extra times deflate (a_4 grows), a fixed number of wiggles per unit of x_5 means more and more wiggles per unit of proper length: the frame momentum $k_{(5)}$ grows like e^{a_4}, while $k_{(1)}$ shrinks like e^{-a_4} because 3-space inflates.

The onset of growth. Write $X = e^{2a_4}$ and $w = e^{-Hy}$. Then $e^{-2a_4} = 1/X$ and $E^2 = m^2 + q_1^2 w^2/X - q_5^2 w^2 X$. As a function of $X > 0$ it decreases: its derivative $-q_1^2 w^2/X^2 - q_5^2 w^2$ is negative for $q_5 \neq 0$. So along the history (where X grows with the time) E^2 crosses zero exactly once and stays negative afterwards; the moment of the crossing is the **onset**. To find it, line by line:

$$
\begin{aligned}
0 &= m^2 + \frac{q_1^2 w^2}{X} - q_5^2 w^2 X, \\
0 &= q_5^2 w^2 X^2 - m^2 X - q_1^2 w^2, \\
X^* &= \frac{m^2 + \sqrt{m^4 + 4 q_1^2 q_5^2 w^4}}{2 q_5^2 w^2}, \\
x_4^* &= \frac{\ln X^*}{2AH}.
\end{aligned}
$$

The first line sets $E^2 = 0$; the second multiplies by $-X$ (allowed, $X > 0$); the third is the quadratic formula, with the root that is positive (the other root, with the minus sign, is not positive, because the square root is at least m^2, and $X = e^{2a_4}$ must be positive); the fourth undoes $X = e^{2a_4} = e^{2AHx_4}$. For a wave without space momentum, $q_1 = 0$, the third line is $X^* = m^2/(q_5^2 w^2)$, and the onset time simplifies to

$$
x_4^* = \frac{\ln(m/q_5) - \ln w}{AH} = \frac{Hy + \ln(m/q_5)}{AH}.
$$

At $y = 0$ with $A = H = m = 1$ this is $\ln(1/q_5)$: $x_4^* = \ln 20 = 2.995732$ for $q_5 = 0.05$ and $\ln 10 = 2.302585$ for $q_5 = 0.1$ (Notebook 08b prints both). The onset time is finite for every $q_5 > 0$: a smaller wave number only delays it, logarithmically. So every wave along an extra time eventually stops oscillating and starts to grow, and after the onset its growth rate $\kappa = \sqrt{k_{(5)}^2 - m^2 - k_{(1)}^2}$ keeps increasing, since $k_{(5)}$ grows without bound (PROVED with frozen coefficients at each instant; this is the local-frame statement of the record, `Revision/theory/reports/python-field-theory.json`, check `extra_time_modes_grow`: "every extra-time mode eventually enters the growing regime"). Restricting the theory to the good sector, the fields that do not depend on the extra times, removes this growth; it is a choice, not a consequence of the equations.

8.25 Following one wave through the onset: the local-frame model and WKB

The local-frame model (labelled MODEL; ASSUMED). The field also depends on y, and the factor e^{-Hy} in the frame momenta makes the exact equation couple neighbouring values of y. The **local-frame model** holds the hidden position fixed (it freezes the coefficients in y only), works in the variables χ of Section 8.30 (in which the term $3H\gamma^{(0)}$ is absent exactly), takes no momentum along the hidden direction, and keeps the exact time dependence of the frame momenta:

$$
i\,\frac{du}{dx_4} = h(x_4)\,u, \qquad h(x_4) = -im\gamma^{(4)} - \gamma^{(4)}\big(k_{(1)}(x_4)\gamma^{(1)} + k_{(5)}(x_4)\gamma^{(5)}\big).
$$

Its solutions are not exact solutions of the field equation; they show how a wave behaves near one hidden position as the extra times deflate. The position enters only through $q_5 e^{-Hy}$, so the runs use $y = 0$. At every instant $h(x_4)^2 = E^2(x_4) I_{16}$ with the E^2 of Section 8.24 (Section 8.17 with the frame momenta of that instant).

A clean starting column. Take $q_1 = 0$. The matrix $C = \gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$ commutes with $\gamma^{(4)}$ and with $\gamma^{(5)}$ (moving either of them through the four factors of C changes the sign four times), hence with $h(x_4)$. A column u can therefore be an eigenvector of $h(0)$ for the positive frequency

$E_0 = \sqrt{m^2 - q_5^2}$ and at the same time of C for the eigenvalue $\sigma = +1$ or -1 (C is real, symmetric, and $C^2 = I_{16}$). For such a column of size $u^\dagger u = 1$ the Krein form is $u^\dagger B u = \sigma E_0/m$. Line by line:

1. $B = -iC\gamma^{(4)} = C(-i\gamma^{(4)})$, and since C is Hermitian with $Cu = \sigma u$, $u^\dagger C = \sigma u^\dagger$; so $u^\dagger B u = \sigma\, u^\dagger(-i\gamma^{(4)})u$.
2. $E_0 = E_0 u^\dagger u = u^\dagger h(0) u = m\, u^\dagger(-i\gamma^{(4)})u - q_5\, u^\dagger\gamma^{(4)}\gamma^{(5)}u$ (at $x_4 = 0$, $a_4 = 0$ and $k_{(5)} = q_5$ at $y = 0$).
3. $-i\gamma^{(4)}$ is Hermitian, so $u^\dagger(-i\gamma^{(4)})u$ is real; $\gamma^{(4)}\gamma^{(5)}$ is real and antisymmetric, so $u^\dagger\gamma^{(4)}\gamma^{(5)}u$ is purely imaginary (its complex conjugate is $u^T\gamma^{(4)}\gamma^{(5)}u^* = u^\dagger(\gamma^{(4)}\gamma^{(5)})^T u = -u^\dagger\gamma^{(4)}\gamma^{(5)}u$, a number being equal to its own transpose).
4. E_0 is real, so the imaginary term vanishes, $u^\dagger(-i\gamma^{(4)})u = E_0/m$, and by line 1, $u^\dagger B u = \sigma E_0/m$.

The notebook builds such columns with two **projectors** (matrices P with $P^2 = P$): $\Lambda_+ = \frac{1}{2}(I_{16} + h(0)/E_0)$ keeps the part of a column with eigenvalue $+E_0$, and $\frac{1}{2}(I_{16} + \sigma C)$ the part with $C = \sigma$; they commute, so their product applied to the first unit column gives a column with both properties.

The leading WKB approximation. After the onset write $Q = k_{(5)} = q_5 e^{AHx_4}$ (at $y = 0$) and $\kappa = \sqrt{Q^2 - m^2}$. When κ changes slowly, the wave follows the growing eigenvalue of $-ih$ at each instant; this is the **WKB approximation** (after Wentzel, Kramers and Brillouin). Line by line:

1. At each instant the growing eigenvalue of $-ih$ is $+\kappa$, so the size grows at the rate $\frac{d}{dx_4}\ln(u^\dagger u) \approx 2\kappa$, and $\ln(u^\dagger u) \approx 2W +$ const with $W(x_4) = \int \kappa\, dx_4$.
2. Since $dQ/dx_4 = AH\,Q$, the substitution $dx_4 = dQ/(AHQ)$ gives $W = \frac{1}{AH}\int \frac{\sqrt{Q^2-m^2}}{Q}\, dQ$.
3. This integral is $W = \frac{1}{AH}(\sqrt{Q^2 - m^2} - m \arccos\frac{m}{Q})$. To check it, differentiate the bracket with respect to Q: $\frac{d}{dQ}\sqrt{Q^2-m^2} = \frac{Q}{\kappa}$, and $\frac{d}{dQ}\arccos\frac{m}{Q} = -\frac{1}{\sqrt{1-m^2/Q^2}}\cdot(-\frac{m}{Q^2}) = \frac{m}{Q\kappa}$; so the derivative of the bracket is $\frac{Q}{\kappa} - \frac{m^2}{Q\kappa} = \frac{Q^2-m^2}{Q\kappa} = \frac{\kappa}{Q}$, the integrand.

The first-order WKB correction. The matrices $A_4 = -i\gamma^{(4)}$ and $M = -i\gamma^{(4)}\gamma^{(5)}$ are Hermitian, square to I_{16} ($(-i\gamma^{(4)})^2 = -(\gamma^{(4)})^2 = I_{16}$; $(\gamma^{(4)}\gamma^{(5)})^2 = -(\gamma^{(4)})^2(\gamma^{(5)})^2 = -I_{16}$, so $M^2 = I_{16}$) and anticommute, and with $q_1 = 0$, $h = mA_4 - iQM$. Line by line:

1. Take a column w with $A_4 w = w$; then $A_4(Mw) = -MA_4 w = -Mw$, and h maps the plane spanned by w and Mw into itself: $hw = mw - iQMw$ and $h(Mw) = -mMw - iQw$. For $u = v_1 w + v_2 Mw$ the equation $du/dx_4 = -ihu$ becomes $v' = \begin{pmatrix} -im & -Q \\ -Q & im \end{pmatrix} v$ (there are 8 such planes).
2. This symmetric 2×2 matrix has the eigenvalues $\pm\kappa$ (its determinant condition is $(-im - \lambda)(im - \lambda) - Q^2 = \lambda^2 + m^2 - Q^2 = 0$) and, for $+\kappa$, the eigenvector $r = (Q, -\kappa - im)$ (the first row gives $(-im - \kappa)Q - Q(-\kappa - im) = 0$).

3. Keep only the growing part, $v \approx c\,r$. Then $v' = c'r + cr' \approx \kappa cr$; multiplying from the left by the row r^T and writing $n = r^T r$ gives $c'n + c\,r^T r' = \kappa cn$, and $r^T r' = n'/2$ (the derivative of $r^T r$ is $2r^T r'$ for a symmetric product). So $c'/c = \kappa - n'/(2n)$.

4. $n = Q^2 + (\kappa + im)^2 = Q^2 + \kappa^2 - m^2 + 2im\kappa = 2\kappa(\kappa + im)$, using $Q^2 - m^2 = \kappa^2$; its size is $|n| = 2\kappa\sqrt{\kappa^2 + m^2} = 2\kappa Q$.

5. Integrating line 3, $\ln c = W - \frac{1}{2}\ln n +$ const, so $|c|^2 \propto e^{2W}/|n| = e^{2W}/(2\kappa Q)$. The size of the column is $|c|^2 r^\dagger r = |c|^2(Q^2 + \kappa^2 + m^2) = |c|^2 \cdot 2Q^2$, so $u^\dagger u \propto e^{2W} Q/\kappa$, and

$$\ln(u^\dagger u) \approx 2W + \ln\frac{Q}{\kappa} + \text{const}, \qquad \frac{d}{dx_4}\ln(u^\dagger u) \approx 2\kappa - \frac{AH\,m^2}{\kappa^2},$$

because $\frac{d}{dx_4}\ln Q = AH$ and $\frac{d}{dx_4}\ln\kappa = \frac{Q}{\kappa^2}\frac{dQ}{dx_4} = AH\frac{Q^2}{\kappa^2}$, whose difference is $AH\frac{\kappa^2 - Q^2}{\kappa^2} = -\frac{AHm^2}{\kappa^2}$.

What the computation shows (COMPUTED). Both approximations fail at the onset itself, where $\kappa \to 0$, so Notebook 08b compares increases over a window from 1.5 to 3 time units after the onset (the unknown constants drop out of increases). For $q_5 = 0.05$ the RK4 solution of the model increases $\ln(u^\dagger u)$ by 31.0009 over the window; the leading WKB formula gives 31.0328 (relative difference 1.03×10^{-3}) and the first-order formula 31.0085 (relative difference 2.48×10^{-4}); for $q_5 = 0.1$ the numbers are 30.9993, 31.0312 and 31.0069. Late in the run the growth rate computed from the solution is 40.09851 and the first-order prediction 40.09868 (agreement to 10^{-5}). The RK4 solution itself is accurate to 10^{-8} (relative), and halving the step divides its error by 15.89, close to the value 16 of a fourth-order method. Before the onset the size does not stay exactly 1: with extra-time momentum the mode matrix is not Hermitian, so the Hilbert norm is not conserved (Section 8.19), and the size $u^\dagger u$, which starts at 1, has grown to 1.52 ($q_5 = 0.05$) and 1.54 ($q_5 = 0.1$) when the onset is reached. Three time units after the onset $\ln(u^\dagger u) = 37.071$ for $q_5 = 0.05$, that is $u^\dagger u \approx 1.26 \times 10^{16}$, while the Krein form stays constant to rounding (its change divided by $\max(u^\dagger u, 1)$ stays below 10^{-9}). Because the rate $2\kappa \approx 2q_5 e^{AHx_4}$ itself grows exponentially, the growth is faster than any exponential.

8.26 Example: the onset of growth along the deflating history

Notebook 08b puts Sections 8.24 and 8.25 to work along the prescribed history of the Kohn-Sham record. It reads A, H, m and L from the record; checks exactly that $dy/dx_0 = \cot z$, $e^{Hy} = \sin^{1/6} z$ and that the product of the scale factors is $\cos z$ for every a_4; draws the scale factors along the history; computes the frame momenta and the exact onset time and compares it with a numerical root search; shows that the onset time is finite for every $q_5 > 0$; builds the model's mode matrix, checks $h(x_4)^2 = E^2(x_4) I_{16}$ against the record's formula, chooses clean starting columns, follows two waves through the onset with RK4 (with a convergence test), and compares with both WKB formulas; and checks the Krein form. It needs no Rust and runs in well under a minute; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/08b_deflation_onset.PROVENANCE.md`. It ends with the line ALL 25 CHECKS PASSED (notebook 08b).

8.27 How to run Notebook 08b

Step 1. What this notebook does and what it needs.

Notebook 08b (The deflating extra times drive every extra-time wave into growth) is the file `Revision/textbook/notebooks/08b_deflation_onset.ipynb` of the repository Dirac_claude. Along the deflating history a4 = A H x4 of the Kohn-Sham record (A = 1, H = m = 1, a prescribed background) it computes the scale factors and the frame momenta of a wave with fixed wave numbers along x1 and x5, the exact time at which such a wave turns from oscillation to growth, and shows that every wave along an extra time reaches this onset; it then follows one wave through the onset with the local-frame model (RK4, convergence of order 4) and compares the growth with the WKB formulas, checks the Krein form, and draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08b_deflation_onset.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08b_deflation_onset.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 08b_deflation_onset.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/08b.captions.json`
- `Revision/textbook/figures/08b_1_scale_factors.png`
- `Revision/textbook/figures/08b_2_frame_momenta.png`
- `Revision/textbook/figures/08b_3_onset_times.png`
- `Revision/textbook/figures/08b_4_growth_along_history.png`
- `Revision/textbook/figures/08b_5_rate_and_krein.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08b_5_rate_and_krein.png exists
ALL 25 CHECKS PASSED (notebook 08b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/08b_deflation_onset.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 08b_deflation_onset.ipynb
python -m nbconvert --execute --inplace 08b_deflation_onset.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- FileNotFoundError naming Revision/kohn_sham/results/parameters.json: the notebook reads this Revision record of the repository. Check that your copy of the repository contains the folder Revision/kohn_sham/results with the file parameters.json (clone the repository again if it does not) and that you opened the notebook from its folder Revision/textbook/notebooks.

8.28 Notebook 08b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/08b_deflation_onset.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

In the author's metric the three extra times $x_5, x_6, x_7$ DEFLATE: their lengths
carry the factor $e^{-a_4}b_4^{1/2}\sin^{1/6}z$, and $a_4$ increases with the time
$x_4$ ($b_4(x_4) > 0$ is the second function of the metric; this notebook works on
the background $b_4 = 1$ of the record, where the factor is $e^{-a_4}\sin^{1/6}z$).
A wave that wiggles a fixed number of times per unit of the coordinate $x_5$
therefore wiggles more and more often per unit of PROPER length (length measured
with the metric): its frame momentum grows like $e^{a_4}$. This notebook uses the
deflating history of the Kohn-Sham record, $a_4 = A H x_4$ with $A = 1$ and
$H = m = 1$ (a PRESCRIBED background, not a solution of the $a_4$ equations), and

- draws the scale factors of 3-space (inflating) and of the extra times (deflating)
  and checks exactly that the volume factor $\sqrt{|g|} = b_4^{3/2}\cos z$ is
  $\cos z$ at $b_4 = 1$ and does not change in time;
- computes the frame momenta of a wave with fixed wave numbers $q_1$ along $x_1$
  and $q_5$ along $x_5$, and the exact time $x_4^\ast$ at which $E^2 = m^2 +
  k_{(1)}^2 - k_{(5)}^2$ turns negative (the *onset*), checked against a numerical
  root search;
- shows that every wave with $q_5 \neq 0$ reaches the onset at a finite time: every
  wave along an extra time eventually grows (the Revision statement
  'extra_time_modes_grow');
- follows one wave through the onset with the local-frame model (explained in
  section 4), solved with RK4 (fourth-order convergence checked), and compares its
  growth with the WKB formulas; the growth is faster than any exponential;
- checks that the Krein form stays constant while the ordinary size grows by a
  factor of about $10^{16}$.

It draws five teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 08b (The deflating extra times drive every extra-time wave into growth) is the
file 'Revision/textbook/notebooks/08b_deflation_onset.ipynb' of the repository
Dirac_claude. Along the deflating history a4 = A H x4 of the Kohn-Sham record (A = 1, H =
m = 1, a prescribed background) it computes the scale factors and the frame momenta of a
wave with fixed wave numbers along x1 and x5, the exact time at which such a wave turns
```

from oscillation to growth, and shows that every wave along an extra time reaches this onset; it then follows one wave through the onset with the local-frame model (RK4, convergence of order 4) and compares the growth with the WKB formulas, checks the Krein form, and draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 08b_deflation_onset.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 08b_deflation_onset.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp]

Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 08b_deflation_onset.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/08b.captions.json‘
- ‘Revision/textbook/figures/08b_1_scale_factors.png‘
- ‘Revision/textbook/figures/08b_2_frame_momenta.png‘
- ‘Revision/textbook/figures/08b_3_onset_times.png‘
- ‘Revision/textbook/figures/08b_4_growth_along_history.png‘
- ‘Revision/textbook/figures/08b_5_rate_and_krein.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08b_5_rate_and_krein.png exists
ALL 25 CHECKS PASSED (notebook 08b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/08b_deflation_onset.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt

  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 08b_deflation_onset.ipynb
      python -m nbconvert --execute --inplace 08b_deflation_onset.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- FileNotFoundError naming Revision/kohn_sham/results/parameters.json: the notebook reads
  this Revision record of the repository. Check that your copy of the repository contains
  the folder Revision/kohn_sham/results with the file parameters.json (clone the
  repository again if it does not) and that you opened the notebook from its folder
  Revision/textbook/notebooks.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 08b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 08b (The deflating extra times drive every extra-time wave into growth) is the
# file Revision/textbook/notebooks/08b_deflation_onset.ipynb of the repository
# Dirac_claude. Along the deflating history a4 = A H x4 of the Kohn-Sham record (A = 1, H
# = m = 1, a prescribed background) it computes the scale factors and the frame momenta
# of a wave with fixed wave numbers along x1 and x5, the exact time at which such a wave
# turns from oscillation to growth, and shows that every wave along an extra time reaches
# this onset; it then follows one wave through the onset with the local-frame model (RK4,
# convergence of order 4) and compares the growth with the WKB formulas, checks the Krein
# form, and draws five teaching plots. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
```

```
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
```

```
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
```

```
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 08b_deflation_onset.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 08b_deflation_onset.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 08b_deflation_onset.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/08b.captions.json
# - Revision/textbook/figures/08b_1_scale_factors.png
# - Revision/textbook/figures/08b_2_frame_momenta.png
# - Revision/textbook/figures/08b_3_onset_times.png
# - Revision/textbook/figures/08b_4_growth_along_history.png
# - Revision/textbook/figures/08b_5_rate_and_krein.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
```

```
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 08b_5_rate_and_krein.png exists
#     ALL 25 CHECKS PASSED (notebook 08b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/08b_deflation_onset.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 08b_deflation_onset.ipynb
#     python -m nbconvert --execute --inplace 08b_deflation_onset.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - FileNotFoundError naming Revision/kohn_sham/results/parameters.json: the notebook
#   reads this Revision record of the repository. Check that your copy of the repository
#   contains the folder Revision/kohn_sham/results with the file parameters.json (clone
#   the repository again if it does not) and that you opened the notebook from its folder
#   Revision/textbook/notebooks.
```

```

## 3. The words used in this notebook

- **Coordinates** (the author's names): $x_1, x_2, x_3$ ordinary space; $x_4$ the
  time; $x_5, x_6, x_7$ the three extra times (time-like, deflating); $x_0$ the
  hidden direction, $z = 6Hx_0$ between $0$ and $\pi/2$.
- **Hidden coordinate** $y = \ln(\sin z)/(6H)$: a second way to label the points of
  the hidden direction. $y = 0$ at $z = \pi/2$ (the *patch end*, where the author's
  coordinate patch ends) and $y \to -\infty$ at the *tip* $z \to 0$; the Kohn-Sham
  record cuts the tip at $y = -L$ with $L = 3$. In this coordinate
  $\sin^{1/6}z = e^{Hy}$.
- **Scale factor**: the factor by which a coordinate length must be multiplied to
  give the proper length; $e^{a_4}\sin^{1/6}z$ for $x_1, x_2, x_3$ and
  $e^{-a_4}b_4^{1/2}\sin^{1/6}z$ for $x_5, x_6, x_7$ ($e^{-a_4}\sin^{1/6}z$ at
  $b_4 = 1$). **Inflating** means growing,
  **deflating** shrinking.
- **History** $a_4(x_4)$: how $a_4$ changes with time. Here $a_4 = A H x_4$ with
  $A = 1$ (the canonical history of the Kohn-Sham record). It is PRESCRIBED: chosen,
  not solved for (the record shows that the Kohn-Sham states do not satisfy the
  source conditions of the $a_4$ equations).
- **Coordinate wave number** $q_a$ and **frame momentum** $k_{(a)} = q_a/f_a$, where
  $f_a$ is the scale factor: the wave $e^{iq_a x_a}$ has $q_a$ radians of phase per
  unit of coordinate length and $k_{(a)}$ radians per unit of proper length.
- **Mode matrix** $h = -im\gamma^{(4)} - \gamma^{(4)}\sum_a k_{(a)}\gamma^{(a)}$:
  with frozen coefficients a wave $u\,e^{-iEx_4}$ needs $hu = Eu$, and $h^2 = E^2$
  with $E^2 = m^2 + k_{(1)}^2 - k_{(5)}^2$ when only $k_{(1)}$ and $k_{(5)}$ are
  nonzero. **Onset**: the time at which $E^2$ turns negative.
- **Local-frame model**: the equation $i\,du/dx_4 = h(x_4)u$ in which the frame
  momenta change with $x_4$ as the history prescribes, while the hidden position is
  held fixed (section 4).
- **WKB approximation** (after Wentzel, Kramers and Brillouin): when the growth rate
  $\kappa$ changes slowly, the size grows like $e^{2W}$ with $W = \int\kappa\,dx_4$.
- **Krein form** $u^\dagger B u$ with the matrix $B = -iC\gamma^{(4)}$ of the record
```

  ($B^\dagger = B$, $B^2 = 1$); **Hilbert norm** $u^\dagger u$.
- **RK4**: the classical fourth-order Runge-Kutta method; *fourth order* means that
  halving the step divides the error by about $2^4 = 16$.

Text cell:

```
## 4. The physical and mathematical situation

In the hidden coordinate $y$ the author's metric reads
$ds^2 = e^{2Hy}\big(e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2
+ dx_7^2)\big) - dx_4^2 + dy^2$, because $\sin^{1/3}z = e^{2Hy}$ and $dy = \cot z\,
dx_0$. Its coefficients do not depend on $x_1, x_2, x_3, x_5, x_6, x_7$, so a wave
$e^{i(q_1x_1 + q_5x_5)}$ keeps its coordinate wave numbers $q_1, q_5$ exactly for
all times. Its frame momenta are, line by line:

1. $k_{(1)} = q_1/f_1 = q_1\,e^{-a_4}e^{-Hy}$ (the factor of $x_1$ is
   $f_1 = e^{a_4}e^{Hy}$);
2. $k_{(5)} = q_5/f_5 = q_5\,e^{a_4}e^{-Hy}$ (the factor of $x_5$ is
   $f_5 = e^{-a_4}e^{Hy}$);
3. with frozen coefficients $E^2 = m^2 + k_{(1)}^2 - k_{(5)}^2
   = m^2 + q_1^2e^{-2Hy}e^{-2a_4} - q_5^2e^{-2Hy}e^{2a_4}$.

As $a_4$ grows, the last term grows like $e^{2a_4}$ and the middle one decays like
$e^{-2a_4}$: $E^2$ must turn negative. With $X = e^{2a_4}$ and $w = e^{-Hy}$ the
onset $E^2 = 0$ is the quadratic equation $q_5^2w^2X^2 - m^2X - q_1^2w^2 = 0$, whose
positive root is $X^\ast = \big(m^2 + \sqrt{m^4 + 4q_1^2q_5^2w^4}\big)/(2q_5^2w^2)$;
the onset time is $x_4^\ast = \ln(X^\ast)/(2AH)$. For $q_1 = 0$ this is
$x_4^\ast = \big(Hy + \ln(m/q_5)\big)/(AH)$.

THE MODEL (labelled). The field also depends on $y$, and the factor $e^{-Hy}$ in
the frame momenta makes the exact equation couple neighbouring values of $y$. The
*local-frame model* holds the hidden position fixed (it freezes the coefficients
in $y$, the WKB statement of the Revision record), works in the variables
$\chi = \sin^{1/2}z\,\Psi$ (in which the term $3H\gamma^{(0)}$ of the diagonal
frame is absent exactly), takes no momentum along the hidden direction, and keeps
the exact time dependence of the frame momenta: $i\,du/dx_4 = h(x_4)u$ with
$h(x_4) = -im\gamma^{(4)} - \gamma^{(4)}\big(k_{(1)}(x_4)\gamma^{(1)} +
k_{(5)}(x_4)\gamma^{(5)}\big)$. Its solutions are not exact solutions of the field
equation; they show how a wave behaves near one hidden position. The position
enters only through $q_5e^{-Hy}$, so the runs below use $y = 0$.

Units: $H = m = 1$, as in the Kohn-Sham record; times in units of $1/m$, momenta
in units of $m$.
```

Text cell:

```
## 5. The deflating history of the Kohn-Sham record

The next cell first defines two helpers for the checks that reproduce a Revision
record. `record_says(report, name, ...)` opens the report (a JSON file with a list
of checks, each with a name, a verdict and a detail text) and is true when the
check `name` is there with the verdict pass and its detail text contains every
```

further piece of text given. ‘check_record(condition, title, report, name, ...)‘ is the helper ‘check‘ for such a result: it passes only if the notebook’s own computation (‘condition‘) is right AND the record says the same. Then the cell reads the parameters of the Kohn-Sham record, takes from it H, m, the history constant A and the tip cutoff L, prints how the record describes the history and its status, and checks the values $A = H = m = 1$, $L = 3$.

In [2]:

```
import numpy as np  # arrays of numbers, matrices, linear algebra
import sympy as sp  # exact algebra with symbols

REPORTS = {}  # report file -> {check name: (verdict, detail)}, each read once

def record_says(report_file, check_name, *pieces):

## 6. The scale factors and the constant volume

The next cell first checks three exact statements with sympy: $dy/dx_0 = \cot z$
for $y = \ln(\sin z)/(6H)$; $e^{Hy} = \sin^{1/6}z$; and the product of the eight
scale factors, $\cot z \cdot (e^{a_4}\sin^{1/6}z)^3 \cdot 1 \cdot
(e^{-a_4}b_4^{1/2}\sin^{1/6}z)^3$, equals $b_4^{3/2}\cos z$ for every $a_4$, and
$\cos z$ at $b_4 = 1$: the inflation of 3-space and the deflation of the extra
times compensate exactly. Then it draws the scale factors along the
history at two hidden positions.
```

In [3]:

## 8. Every wave along an extra time reaches the onset

The onset time $x_4^\ast$ is finite for EVERY $q_5 > 0$: the formula of section 4
has $q_5$ only in a denominator inside a logarithm, so a smaller $q_5$ only delays
the onset logarithmically, and a deeper position (more negative $y$) or a nonzero
$q_1$ changes it by a bounded amount. The next cell evaluates the onset time on a
grid of $q_5$ from $10^{-4}$ to $1$, checks that it is finite and decreasing in
$q_5$, and draws it for three hidden positions and for $q_1 = 1$.
```

In [6]:

```

## 9. Following one wave through the onset: the local-frame model

The next cell reads the gamma matrices and builds the time-dependent mode matrix
$h(x_4)$ of the local-frame model. It checks at five instants, for a wave with
$q_1 = 0.3$ and $q_5 = 0.1$, that $h(x_4)^2 = E^2(x_4)\,I_{16}$, where $E^2$ is the
formula of the Revision record for frozen coefficients, $E^2 = m^2 + k_1^2 + k_2^2 +
k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$, taken at the frame momenta of that instant
(and checks that the record holds exactly this formula). Then it chooses the
starting column for $q_1 = 0$.
With $q_1 = 0$ the matrix $C = \gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$
commutes with $h$ ($\gamma^{(4)}$ and $\gamma^{(5)}$ each anticommute with all four
factors of $C$), so there are columns that are eigenvectors of $h(0)$ for the
positive frequency $E_0 = \sqrt{m^2 - q_5^2}$ AND of $C$ for $+1$ or $-1$. The
projectors $\Lambda_+ = (1 + h(0)/E_0)/2$ and $(1 \pm C)/2$ produce them from the
first unit column. For such a column the Krein form is $u^\dagger B u = \pm E_0/m$:
$B = -iC\gamma^{(4)} = C(-i\gamma^{(4)})$ gives $u^\dagger B u = \pm u^\dagger
```

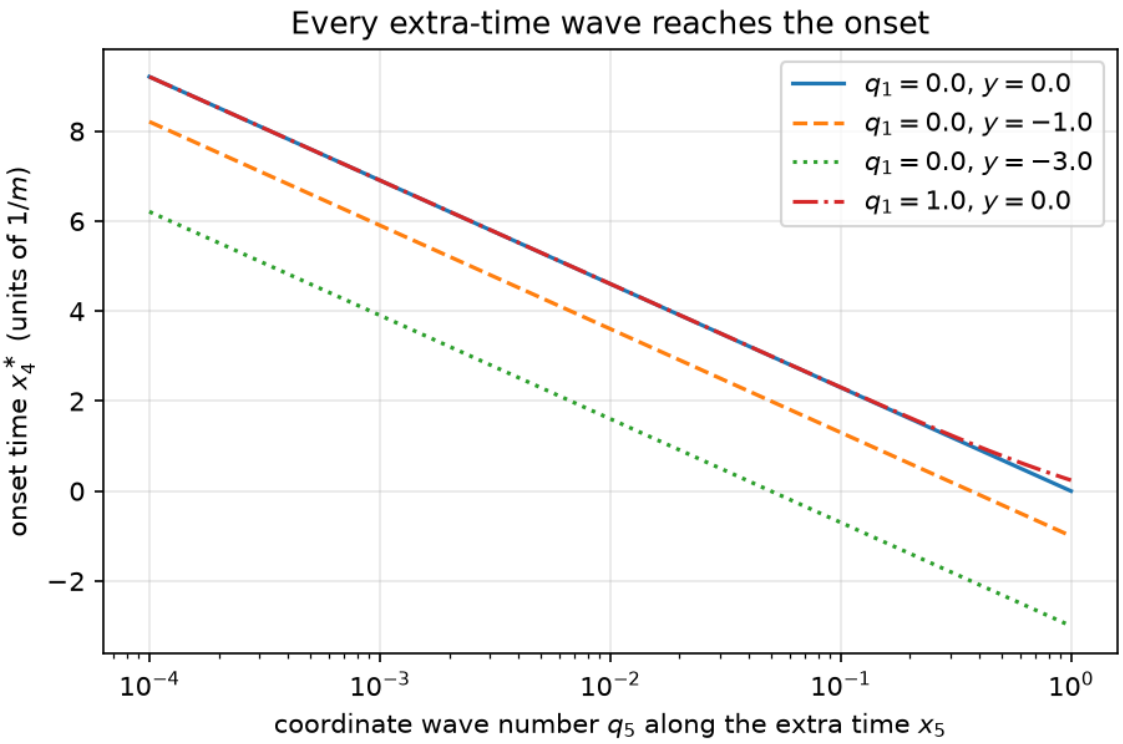

Figure 242: The onset time x_4^* at which a wave with coordinate wave number q_5 along the extra time x_5 stops oscillating and starts to grow, against q_5 from 10^{-4} to 1 on a logarithmic axis, along the history $a_4 = x_4$ with $m = H = 1$, at the hidden positions $y = 0$ (the patch end), $y = -1$ and $y = -3$ (the tip cutoff of the Kohn-Sham record), and for a wave that also has $q_1 = 1$. Every curve is finite and rises only like $\ln(1/q_5)$: however small q_5 is, the deflation of the extra times eventually drives the wave into growth; a negative onset time means that the wave grows already at $x_4 = 0$. (Notebook 08b, figure 3.)

```
(-i\gamma^{(4)})u$, and $E_0 = u^\dagger h u = m\,u^\dagger(-i\gamma^{(4)})u -
q_5\,u^\dagger\gamma^{(4)}\gamma^{(5)}u$, where the first term is real and the
second imaginary ($\gamma^{(4)}\gamma^{(5)}$ is real and antisymmetric), so the
second term vanishes. The cell checks all of this.
```

The next cell solves $du/dx_4 = -i\,h(x_4)u$ with RK4 from $x_4 = 0$ to three
time units after the onset, for $q_5 = 0.05$ and $q_5 = 0.1$, with 12000 steps,
and records $u^\dagger u$ and $u^\dagger B u$ after every step. It prints the size
$u^\dagger u$ at the onset (at the first step after it) and $\ln(u^\dagger u)$ at
the end. Before the onset the size does not stay exactly 1: with extra-time
momentum the mode matrix is not Hermitian, so the Hilbert norm is not conserved.
For $q_5 = 0.05$ it repeats the run with 6000 and 24000 steps: the differences of
the end values must shrink by a factor close to 16 (fourth order).

## 10. The WKB formulas and the comparison

After the onset, write $Q = k_{(5)} = q_5e^{AHx_4}$ and
$\kappa = \sqrt{Q^2 - m^2}$. Line by line:

1. Leading order: at each instant the growing eigenvalue of $-ih$ is $+\kappa$, so
   $\frac{d}{dx_4}\ln(u^\dagger u) \approx 2\kappa$ and $\ln(u^\dagger u) \approx
```

```
   2W + $ const with $W(x_4) = \int\kappa\,dx_4$.
2. Because $dQ/dx_4 = AH\,Q$, the substitution $dx_4 = dQ/(AHQ)$ gives
   $W = \frac{1}{AH}\int\frac{\sqrt{Q^2 - m^2}}{Q}dQ = \frac{1}{AH}\Big(\sqrt{Q^2 -
   m^2} - m\arccos\frac{m}{Q}\Big)$ (differentiate the bracket: $\frac{Q}{\kappa} -
   \frac{m^2}{Q\kappa} = \frac{\kappa}{Q}$).
3. First order: the matrices $A_4 = -i\gamma^{(4)}$ and $M = -i\gamma^{(4)}
   \gamma^{(5)}$ are Hermitian, square to 1 and anticommute, and $h = mA_4 - iQM$.
   In each of 8 planes spanned by a column $w$ with $A_4w = w$ and by $Mw$ the
   equation is $v' = \begin{pmatrix}-im & -Q\\ -Q & im\end{pmatrix}v$.
4. This symmetric matrix has the eigenvector $r = (Q, -\kappa - im)$ for $+\kappa$.
   Multiplying the equation by $r^T$ and keeping only the growing part $v \approx
   c\,r$ gives $c'/c = \kappa - n'/(2n)$ with $n = r^Tr = 2\kappa(\kappa + im)$.
5. Hence $|c|^2 \propto e^{2W}/|n| = e^{2W}/(2\kappa Q)$, and $u^\dagger u \approx
   |c|^2\,r^\dagger r = |c|^2\,2Q^2 \propto e^{2W}Q/\kappa$: $\ln(u^\dagger u)
   \approx 2W + \ln(Q/\kappa) + $ const, and the rate is $2\kappa + \frac{d}{dx_4}
   \ln\frac{Q}{\kappa} = 2\kappa - AH\,m^2/\kappa^2$.

Both approximations fail at the onset itself ($\kappa \to 0$), so the comparison
uses increases over a window from 1.5 to 3 time units after the onset (the
unknown constants drop out of increases). The next cell computes them.

Out [11]:

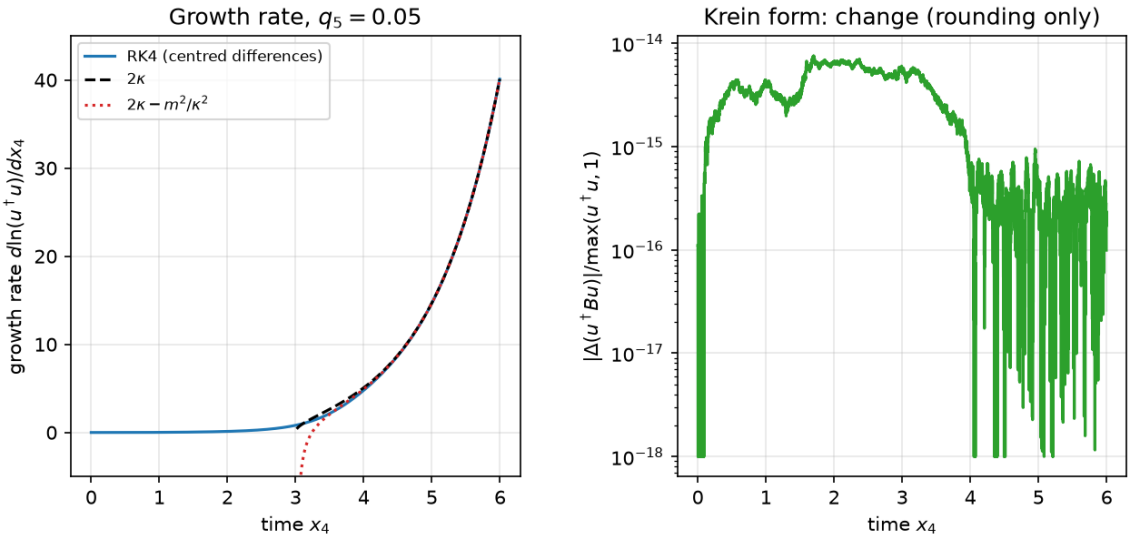

Figure 244: Left: the growth rate $d\ln(u^\dagger u)/dx_4$ of the wave with $q_5 = 0.05$ against the time x_4 (units of $1/m$ and m), computed from the RK4 solution (blue), with the leading WKB rate 2κ (black dashed) and the first-order rate $2\kappa - m^2/\kappa^2$ (red dotted); before the onset the rate stays below 1, after it the rate itself grows exponentially, so the growth is faster than any exponential, and far from the onset the first-order rate is accurate. Right: the change of the Krein form $u^\dagger Bu$ divided by $\max(u^\dagger u, 1)$, on a logarithmic axis (exact zeros are drawn at 10^{-18}); it stays at the level of rounding errors, far below 10^{-9}. (Notebook 08b, figure 5.)

```
## 12. What this notebook showed

- Along the prescribed deflating history $a_4 = AHx_4$ of the Kohn-Sham record
  ($A = H = m = 1$) 3-space inflates like $e^{a_4}$ and the extra times deflate like
  $e^{-a_4}$, while the volume factor $\sqrt{|g|} = \cos z$ (at $b_4 = 1$; $b_4^{3/2}
  \cos z$ in general) stays constant (PROVED,
  exact sympy; Revision check ‘sqrt_det_g_equals_cos_z‘).
- A wave $e^{i(q_1x_1 + q_5x_5)}$ keeps its coordinate wave numbers; its frame
  momentum along the extra time grows like $q_5e^{a_4}e^{-Hy}$ and along 3-space it
  shrinks like $q_1e^{-a_4}e^{-Hy}$ (PROVED).
- With frozen coefficients its $E^2$ turns negative at the onset time
  $x_4^\ast = \ln(X^\ast)/(2AH)$, finite for every $q_5 > 0$: every wave along an
  extra time eventually enters the growing regime (PROVED for the frozen
  coefficients; the Revision statement ‘extra_time_modes_grow‘ is this local-frame
  statement).
- In the local-frame model (MODEL: hidden position frozen; not an exact solution of
  the field equation) a wave started with positive frequency oscillates until the
  onset, while its size grows only slowly (to about 1.5 at the onset, because with
  extra-time momentum the mode matrix is not Hermitian), and then grows faster than
  any exponential, by about $10^{16}$ in three time units; the growth follows the
  WKB formulas (COMPUTED: leading order to about $10^{-3}$, first order to about
  $2.5 \times 10^{-4}$ over the window, late rate to $10^{-5}$), and the Krein form
  is conserved to rounding.
- Consequence (with Notebook 08a): in flat 4 + 4 space and with frozen
  coefficients the initial-value problem is not well posed for data that depend on
  the extra times, and the deflation makes every such wave reach the growing
  regime. Only the good sector (no dependence on $x_5, x_6, x_7$) is free of this
  growth; restricting to it is a choice, not a result.
```

8.29 Line-by-line walk-through of Notebook 08b

The notebook has 12 code cells, In [1] to In [12]. The conventions are those of Section 8.15; captions shortened to ... are printed in full in Section 8.28.

In [1], the set-up cell. It is the set-up cell explained in Section 8.15, with the line `NOTEBOOK_ID = "08b" # this notebook: chapter 08, example b`; its comment lines are the run instructions of Section 8.27. Output: `Set-up of notebook 08b complete: repository folder found, helpers defined.`

In [2], the record helpers and the history of the Kohn-Sham record. The cell starts with the imports of numpy and sympy, the empty table `REPORTS` and the two helpers `record_says` and `check_record`, word for word those of Notebook 08a (Section 8.23; `check_record` takes one check name). Then:

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
H = parameters["physics"]["H"]  # the author's constant H
mass = parameters["physics"]["m"]  # the mass m
A = parameters["physics"]["historyA"]  # the history a4 = A H x4
L_tip = parameters["physics"]["L_tipCutoff"]  # the record cuts the tip at y = -L
```

The parameters of the Kohn-Sham record are read; the four numbers are taken from its part `physics` (a dictionary inside the dictionary; two square brackets reach into it).

```
say("history: " + parameters["theoryInputs"]["adiabaticityHistory"])
say("status: " + parameters["conventions"]["history"].split(". ")[0] + ".")
check(H == 1.0 and mass == 1.0 and A == 1.0 and L_tip == 3.0,
      "the canonical history: A = 1, H = 1, m = 1, tip cutoff L = 3",
      record="Revision/kohn_sham/results/parameters.json, physics.historyA, "
             "physics.H, physics.m, physics.L_tipCutoff")
```

The first line prints the record's description of the history: `a4 = A H x4 (A = 1 canonical), a4' = A H; slices a4,0 = a4(x4); PRESCRIBED BACKGROUND (see historyStatus)`. The second prints the first sentence of the record's statement of its status (`split(".  ")` cuts the text at every full stop followed by a blank, `[0]` takes the first piece, and the full stop is added back): `PRESCRIBED BACKGROUND: the history a4 = A H x4 is prescribed, not solved for.` The check confirms the four values and names the record entries it reproduces.

```
def a4_of(x4):
    """The prescribed deflating history a4 = A H x4."""
    return A * H * x4
```

`a4_of` returns $a_4 = AHx_4$; it works for a single time and for a whole numpy array of times. Output of the cell: the two lines and one PASS line with its `reproduces` line.

In [3], the scale factors and the constant volume.

```
x0, H_symbol = sp.symbols("x0 H", positive=True)
a4_symbol = sp.Symbol("a4", real=True)
z = 6 * H_symbol * x0
y_of_x0 = sp.log(sp.sin(z)) / (6 * H_symbol)  # the hidden coordinate y
check(sp.simplify(sp.diff(y_of_x0, x0) - sp.cot(z)) == 0, "dy/dx0 = cot z")
check(sp.simplify(sp.exp(H_symbol * y_of_x0) - sp.sin(z) ** sp.Rational(1, 6)) == 0,
      "e^(H y) = sin(z)^(1/6)")
```

Exact symbols for x_0, H and a_4 (here a plain number-like symbol, because only its value enters). `y_of_x0` is $y = \ln(\sin z)/(6H)$. The two checks are the two facts of Section 8.24: $dy/dx_0 = \cot z$ and $e^{Hy} = \sin^{1/6} z$.

```
space_factor = sp.exp(a4_symbol) * sp.sin(z) ** sp.Rational(1, 6)  # x1, x2, x3
b4_symbol = sp.Symbol("b4", positive=True)  # the second function of the metric
extra_factor = (sp.exp(-a4_symbol) * sp.sqrt(b4_symbol)
```

```
                * sp.sin(z) ** sp.Rational(1, 6))  # x5, x6, x7
volume = sp.cot(z) * space_factor**3 * 1 * extra_factor**3  # x4 has the factor 1
check_record(sp.simplify(volume - b4_symbol ** sp.Rational(3, 2) * sp.cos(z)) == 0
             and sp.simplify(volume.subs(b4_symbol, 1) - sp.cos(z)) == 0,
             "sqrt|g| = product of the scale factors = b4^(3/2) cos z, for every a4; "
             "cos z at b4 = 1",
             "Revision/theory/reports/python-field-theory.json",
             "sqrt_det_g_equals_cos_z", "cos(6 H x0)")
```

The product of the eight scale factors is compared with $b_4^{3/2}\cos z$ for a symbolic a_4 and a symbol `b4_symbol` for b_4, and at $b_4 = 1$ with $\cos z$, together with the record's check, whose detail contains `cos(6 H x0)`.

```
times = np.linspace(0.0, 6.0, 601)
fig, ax = plt.subplots()
for y, style in ((0.0, "-"), (-1.0, "--")):
    warp = np.exp(H * y)  # sin^(1/6) z = e^(H y)
    ax.plot(times, np.exp(a4_of(times)) * warp, style, color="tab:blue",
            label=f"3-space $e^{{a_4}}e^{{Hy}}$, $y = {y}$")
    ax.plot(times, np.exp(-a4_of(times)) * warp, style, color="tab:red",
            label=f"extra times $e^{{-a_4}}e^{{Hy}}$, $y = {y}$")
    ax.plot(times, np.full_like(times, warp**6), style, color="black",
            linewidth=0.8, label=f"product of the six, $e^{{6Hy}}$, $y = {y}$")
```

601 times from 0 to 6. For the two hidden positions $y = 0$ (solid lines) and $y = -1$ (dashed), the cell draws the 3-space factor $e^{a_4}e^{Hy}$ (blue), the extra-time factor $e^{-a_4}e^{Hy}$ (red) and the product of the six, e^{6Hy} (black; `np.full_like(times, value)` is an array of the same length filled with the value). In an f-string a curly bracket that must appear in the text is written twice, so `e^{{a_4}}` prints as `e^{a_4}`.

```
ax.set_yscale("log")
ax.set_xlabel("time $x_4$ (units of $1/m$)")
ax.set_ylabel("scale factor")
ax.set_title("Scale factors along the history $a_4 = x_4$")
ax.legend(fontsize=7, loc="upper left");
save_figure(fig, "scale_factors",
            "The scale factors of the author's metric along the prescribed "
            ...
            "change in time.")
```

A logarithmic vertical axis, labels, a small legend, and Figure 08b.1. Output: three PASS lines (one with its `reproduces` line) and the figure line.

What Figure 08b.1 shows. The scale factors (pure numbers, logarithmic vertical axis) against the time x_4 from 0 to 6 (units of $1/m$), along $a_4 = x_4$, at $y = 0$ (solid) and $y = -1$ (dashed). Blue: 3-space, a rising straight line from e^{Hy} to $e^6 e^{Hy}$. Red: the extra times, a falling straight line from e^{Hy} to $e^{-6}e^{Hy}$. Black: the product of the six, a horizontal line at e^{6Hy} (1 at $y = 0$, e^{-6} at $y = -1$). The student should see exponential inflation of 3-space, exponential deflation of the extra times, and a product that does not change in time.

In [4], frame momenta and the onset.

```
def frame_momenta(x4, q1, q5, y):
    """(k_(1), k_(5)) of the wave exp(i (q1 x1 + q5 x5)) at time x4 and position y."""
    w = np.exp(-H * y)  # e^(-H y) = sin^(-1/6) z
    return q1 * np.exp(-a4_of(x4)) * w, q5 * np.exp(a4_of(x4)) * w

def local_E2(x4, q1, q5, y):
    """E^2 = m^2 + k_(1)^2 - k_(5)^2 with frozen coefficients."""
    k1, k5 = frame_momenta(x4, q1, q5, y)
    return mass**2 + k1**2 - k5**2
```

`frame_momenta` returns the pair $(k_{(1)}, k_{(5)})$ of Section 8.24, lines 1 and 2; `local_E2` returns E^2 of line 3 (a function may return two values, which the caller unpacks into two names).

```
def onset_time(q1, q5, y):
    """The exact time at which E^2 = 0 (positive root of the quadratic in X)."""
    w = np.exp(-H * y)
    X = (mass**2 + np.sqrt(mass**4 + 4 * q1**2 * q5**2 * w**4)) / (2 * q5**2 * w**2)
    return np.log(X) / (2 * A * H)
```

`onset_time` is the formula $x_4^* = \ln(X^*)/(2AH)$ with the positive root X^* of Section 8.24.

```
def bisection(q1, q5, y, low=-30.0, high=30.0):
    """The time at which E^2 changes sign, by halving [low, high] 200 times."""
    for _ in range(200):
        middle = (low + high) / 2
        if local_E2(middle, q1, q5, y) > 0:  # still oscillating: onset is later
            low = middle
        else:
            high = middle
    return (low + high) / 2
```

`bisection` finds the same time independently, by the **bisection method**: start with an interval $[-30, 30]$ in which E^2 changes sign; look at the middle; if E^2 is still positive there, the onset is later and the middle becomes the new left end, otherwise the new right end; after 200 halvings the interval is far smaller than the rounding of the numbers, and its middle is returned. (`low=-30.0` gives a default value used when the caller does not pass one.)

```
worst = max(abs(onset_time(q1, q5, y) - bisection(q1, q5, y))
            for q1 in (0.0, 0.5, 1.0, 3.0) for q5 in (0.01, 0.05, 0.1, 0.4)
            for y in (0.0, -1.0, -3.0))
check(worst < 1e-12, "the exact onset time equals the bisection result (48 waves)")
check(abs(onset_time(0.0, 0.05, 0.0) - np.log(1 / 0.05)) < 1e-14,
      "q1 = 0, y = 0: onset time = ln(m/q5)")
for q5 in (0.05, 0.1):
    report(f"onset time for q1 = 0, q5 = {q5}, y = 0", f"{onset_time(0.0, q5, 0.0):.6f}")
```

The two methods are compared for $4 \times 4 \times 3 = 48$ waves (four values of q_1, four of q_5, three positions); the largest difference must be below 10^{-12}. The second check is the simple form $x_4^* = \ln(m/q_5)$ for

$q_1 = 0$, $y = 0$ (with $m = 1$). The RESULT lines print 2.995732 ($\ln 20$) and 2.302585 ($\ln 10$). Output: two PASS lines and two RESULT lines.

In [5], the frame momenta and the local E^2 along the history.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
k1_path, k5_path = frame_momenta(times, 0.1, 0.1, 0.0)
left.plot(times, k5_path, color="tab:red", label="extra time: $k_{(5)} = q_5e^{a_4}$")
left.plot(times, k1_path, color="tab:blue", label="3-space: $k_{(1)} = q_1e^{-a_4}$")
left.axhline(mass, color="black", linewidth=0.8, linestyle=":", label="$m$")
left.set_yscale("log")
left.set_xlabel("time $x_4$")
left.set_ylabel("frame momentum (units of $m$)")
left.set_title("$q_1 = q_5 = 0.1$, $y = 0$")
left.legend(fontsize=8)
```

The left panel draws the two frame momenta of the wave with $q_1 = q_5 = 0.1$ at $y = 0$ along the 601 times, on a logarithmic axis, with a dotted line at the mass.

```
for q1, q5, style in ((0.0, 0.02, "-"), (0.0, 0.05, "-"), (0.0, 0.1, "-"),
                      (0.0, 0.2, "-"), (1.0, 0.05, "--")):
    right.plot(times, local_E2(times, q1, q5, 0.0), style,
               label=f"$q_1 = {q1}$, $q_5 = {q5}$")
    t_star = onset_time(q1, q5, 0.0)
    right.plot([t_star], [0.0], "o", color="black", markersize=4)
right.axhline(0.0, color="black", linewidth=0.8)
right.set_ylim(-4.0, 2.5)
right.set_xlabel("time $x_4$")
right.set_ylabel("$E^2 = m^2 + k_{(1)}^2 - k_{(5)}^2$")
right.set_title("Local $E^2$ along the history, $y = 0$")
right.legend(fontsize=8, loc="lower left");
save_figure(fig, "frame_momenta",
            "Left: the frame momenta of one wave with coordinate wave numbers "
            ...
            "onset is almost that of the same wave with $q_1 = 0$.")
```

The right panel draws the local E^2 of five waves (four with $q_1 = 0$, one dashed with $q_1 = 1$) and marks each onset time with a black dot on the zero line. The figure is Figure 08b.2; the cell prints only the figure line.

What Figure 08b.2 shows. Left: the frame momenta (units of m, logarithmic axis) against the time x_4 for $q_1 = q_5 = 0.1$ at $y = 0$: the red line $k_{(5)} = 0.1e^{x_4}$ rises and crosses the dotted mass line at $x_4 = \ln 10 \approx 2.3$; the blue line $k_{(1)} = 0.1e^{-x_4}$ falls. Right: the local E^2 (units of m^2) of five waves: each starts near 1, decreases, crosses zero once at its onset (black dot) and stays negative; smaller q_5 cross later. The dashed wave with $q_1 = 1$ starts at $E^2 = 1 + 1 - 0.0025 \approx 2$, but its space term dies away like e^{-2a_4}, and its onset (2.997) is almost that of the wave with $q_1 = 0$, $q_5 = 0.05$ (2.996). The student should see that the deflation drives every wave from oscillation into growth.

In [6], every wave along an extra time reaches the onset.

```
q5_grid = np.logspace(-4.0, 0.0, 200)  # 10^-4 ... 1, equally spaced on a log axis
fig, ax = plt.subplots()
```

```
all_finite_and_decreasing = True
for q1, y, style in ((0.0, 0.0, "-"), (0.0, -1.0, "--"), (0.0, -L_tip, ":"),
                     (1.0, 0.0, "-.")):
    onsets = onset_time(q1, q5_grid, y)
    all_finite_and_decreasing &= bool(np.all(np.isfinite(onsets))
                                      and np.all(np.diff(onsets) < 0))
    ax.plot(q5_grid, onsets, style, label=f"$q_1 = {q1}$, $y = {y}$")
```

`np.logspace(-4.0, 0.0, 200)` gives 200 values of q_5 from 10^{-4} to 1, equally spaced on a logarithmic axis. For four cases (three hidden positions, including the tip cutoff $y = -3$, and one wave with $q_1 = 1$) the onset times are computed for the whole grid at once. `np.isfinite` is true for an ordinary number (not infinite, not "not a number"); `np.diff` gives the differences of neighbours, which must all be negative (the onset time decreases as q_5 grows). `&=` keeps the variable true only while every case passes.

```
ax.set_xscale("log")
ax.set_xlabel("coordinate wave number $q_5$ along the extra time $x_5$")
ax.set_ylabel("onset time $x_4^\\ast$ (units of $1/m$)")
ax.set_title("Every extra-time wave reaches the onset")
ax.legend();
save_figure(fig, "onset_times",
            "The onset time $x_4^\\ast$ at which a wave with coordinate wave number "
            ...
            "$x_4 = 0$.")
check_record(all_finite_and_decreasing,
             "the onset time is finite for every q5 > 0 on the grid and decreases "
             "with q5", "Revision/theory/reports/python-field-theory.json",
             "extra_time_modes_grow",
             "every extra-time mode eventually enters the growing regime")
```

A logarithmic horizontal axis, labels, Figure 08b.3, and the check, which requires the record's sentence "every extra-time mode eventually enters the growing regime". Output: the figure line and one PASS line with its `reproduces` line.

What Figure 08b.3 shows. The onset time x_4^* (vertical, units of $1/m$) against the coordinate wave number q_5 from 10^{-4} to 1 (horizontal, logarithmic). Each curve is a falling, nearly straight line: on a logarithmic q_5 axis, $x_4^* = (Hy + \ln(m/q_5))/(AH)$ is a straight line of slope -1 per factor e. At $q_5 = 10^{-4}$ and $y = 0$ the onset is at $\ln 10^4 \approx 9.2$; the curve for $y = -1$ lies one unit lower and that for $y = -3$ three units lower (for large q_5 these are negative: such waves grow already at $x_4 = 0$); the curve with $q_1 = 1$ lies on top of the $y = 0$ curve except at the largest q_5. The student should see that no curve goes to infinity: however small q_5 is, the onset comes.

In [7], the model's mode matrix and the starting columns.

```
gammas_record = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
GAMMA = [np.array(rows, dtype=int) for rows in gammas_record["gamma"]]
C = np.array(gammas_record["C"], dtype=int)  # C = g^(x0) g^(x1) g^(x2) g^(x3)
B = np.array(gammas_record["B"]["re"]) + 1j * np.array(gammas_record["B"]["im"])
g4 = GAMMA[4].astype(complex)  # gamma^(x4)
g4g1 = (GAMMA[4] @ GAMMA[1]).astype(complex)  # gamma^(x4) gamma^(x1)
```

```
g4g5 = (GAMMA[4] @ GAMMA[5]).astype(complex)  # gamma^(x4) gamma^(x5)
check(np.array_equal(C @ GAMMA[4], GAMMA[4] @ C) and
      np.array_equal(C @ GAMMA[5], GAMMA[5] @ C),
      "C commutes with gamma^(x4) and gamma^(x5)")
```

The gammas, C and B are read as in Notebook 08a; the three matrices of the model, $\gamma^{(4)}$, $\gamma^{(4)}\gamma^{(1)}$ and $\gamma^{(4)}\gamma^{(5)}$, are prepared as complex arrays. The check confirms that C commutes with $\gamma^{(4)}$ and $\gamma^{(5)}$ (Section 8.25).

```
def h_local(x4, q1, q5, y):
    """The mode matrix of the local-frame model at time x4."""
    k1, k5 = frame_momenta(x4, q1, q5, y)
    return -1j * mass * g4 - k1 * g4g1 - k5 * g4g5
```

`h_local` is the model's mode matrix $h(x_4) = -im\gamma^{(4)} - k_{(1)}(x_4)\gamma^{(4)}\gamma^{(1)} - k_{(5)}(x_4)\gamma^{(4)}\gamma^{(5)}$.

```
# At every instant h(x4)^2 = E^2(x4) I16, where E^2 is the frozen-coefficient E^2 of
# the record with k1 = k_(1)(x4), k5 = k_(5)(x4) and all other momenta 0.
m_s = sp.Symbol("m", real=True)
k_s = {a: sp.Symbol(f"k{a}", real=True) for a in (0, 1, 2, 3, 5, 6, 7)}
E2_record = m_s**2 + sum(k_s[a] ** 2 for a in (0, 1, 2, 3)) \
    - sum(k_s[a] ** 2 for a in (5, 6, 7))
```

`E2_record` is the record's general formula $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$, built with exact symbols.

```
squares_ok = True
for x4 in (0.0, 1.0, 2.0, 3.0, 4.0):
    k1_now, k5_now = frame_momenta(x4, 0.3, 0.1, 0.0)  # q1 = 0.3, q5 = 0.1, y = 0
    values = {symbol: 0 for symbol in k_s.values()}  # every momentum 0 ...
    values.update({m_s: mass, k_s[1]: k1_now, k_s[5]: k5_now})  # ... but these
    E2_now = float(E2_record.subs(values))
    h_now = h_local(x4, 0.3, 0.1, 0.0)
    squares_ok &= bool(np.allclose(h_now @ h_now, E2_now * np.eye(16), atol=1e-12)
                       and abs(E2_now - local_E2(x4, 0.3, 0.1, 0.0)) < 1e-12)
check_record(squares_ok, "x4 = 0, 1, 2, 3, 4: h(x4)^2 = E^2(x4) I16 (q1 = 0.3, "
             "q5 = 0.1)", "Revision/theory/reports/python-scope.json",
             "extra_time_growth_rates_unbounded", f"h_k^2 = ({sp.sstr(E2_record)}) I16")
```

At five instants, for the wave $q_1 = 0.3$, $q_5 = 0.1$, the record's formula is evaluated with the frame momenta of that instant (a dictionary sets every momentum to 0, and `update` then sets the mass, k_1 and k_5), and the square of the model's matrix is compared with $E^2 I_{16}$ to 10^{-12}; the value must also agree with `local_E2`. The check requires the record's text with the general E^2.

```
def starting_column(q5, sign):
    """A unit column with h(0) u = E0 u and C u = sign u (q1 = 0, y = 0)."""
    h0 = h_local(0.0, 0.0, q5, 0.0)
    E0 = np.sqrt(mass**2 - q5**2)
```

```
    first = np.zeros(16, dtype=complex)
    first[0] = 1.0  # the first unit column
    u = (np.eye(16) + h0 / E0) @ ((np.eye(16) + sign * C) @ first) / 4
    return u / np.linalg.norm(u), h0, E0
```

`starting_column` applies the two projectors of Section 8.25, $\frac{1}{2}(I+\sigma C)$ and $\frac{1}{2}(I+h(0)/E_0)$ (together the factor $\frac{1}{4}$), to the first unit column (a column of zeros with a 1 in position 0) and divides by the length.

```
starts = {}
for q5, sign in ((0.05, +1), (0.1, -1)):
    u0, h0, E0 = starting_column(q5, sign)
    starts[q5] = u0
    krein0 = np.vdot(u0, B @ u0)  # u^dagger B u
    report(f"q5 = {q5}: E0, Krein form of the start",
           f"{E0:.9f}, {krein0.real:+.9f}")
    sign_text = "+" if sign > 0 else "-"  # the sign as a character
    check(np.linalg.norm(h0 @ u0 - E0 * u0) < 1e-14 and
          np.linalg.norm(C @ u0 - sign * u0) < 1e-14 and
          abs(krein0 - sign * E0 / mass) < 1e-14,
          f"q5 = {q5}: h(0) u = E0 u, C u = {sign_text}u, "
          f"Krein form = {sign_text}E0/m")
```

Two starting columns are made, for $q_5 = 0.05$ with $\sigma = +1$ and for $q_5 = 0.1$ with $\sigma = -1$, and stored in the dictionary `starts`. For each, the RESULT line prints E_0 and the Krein form (0.998749218 and +0.998749218; 0.994987437 and −0.994987437), and the check confirms to 10^{-14} the three properties: eigenvector of $h(0)$ for E_0, eigenvector of C for σ, Krein form $\sigma E_0/m$. Output: three PASS lines (one with its `reproduces` line) and two RESULT lines.

In [8], RK4 through the onset.

```
def rk4_history(u0, q5, x4_end, steps):
    """RK4 for du/dx4 = -i h(x4) u (q1 = 0, y = 0); returns the times, u^dagger u,
    u^dagger B u after every step, and the final column."""
    step = x4_end / steps
    u = u0.copy()
    times_out = [0.0]
    hilbert = [np.vdot(u, u).real]
    krein = [np.vdot(u, B @ u)]

    def rate(x4, v):  # the right-hand side -i h(x4) v
        return -1j * (h_local(x4, 0.0, q5, 0.0) @ v)
```

`rk4_history` solves the model with RK4 and records, after every step, the time, the Hilbert norm and the Krein form (`u0.copy()` makes a copy, so that the starting column itself is not changed). The inner function `rate` is the right-hand side $-ih(x_4)v$; unlike In [8] of Notebook 08a the matrix now depends on the time.

```
    for n in range(steps):
        x4 = n * step
```

```
        s1 = rate(x4, u)
        s2 = rate(x4 + step / 2, u + step / 2 * s1)
        s3 = rate(x4 + step / 2, u + step / 2 * s2)
        s4 = rate(x4 + step, u + step * s3)
        u = u + step / 6 * (s1 + 2 * s2 + 2 * s3 + s4)
        times_out.append((n + 1) * step)
        hilbert.append(np.vdot(u, u).real)
        krein.append(np.vdot(u, B @ u))
    return np.array(times_out), np.array(hilbert), np.array(krein), u
```

The classical RK4 step for an equation whose right-hand side depends on the time: the four slopes are taken at the start, twice at the middle and at the end of the step. The function returns three arrays and the final column.

```
runs = {}
for q5 in (0.05, 0.1):
    x4_end = onset_time(0.0, q5, 0.0) + 3.0
    runs[q5] = rk4_history(starts[q5], q5, x4_end, 12000)
    at_onset = np.searchsorted(runs[q5][0], onset_time(0.0, q5, 0.0))  # its index
    report(f"q5 = {q5}: u^dagger u at the onset", f"{runs[q5][1][at_onset]:.2f}")
    final_size = runs[q5][1][-1]  # u^dagger u at the end of the run
    report(f"q5 = {q5}: ln(u^dagger u) at the onset + 3", f"{np.log(final_size):.6f}")
```

Each wave is followed from $x_4 = 0$ to three time units after its onset with 12000 steps; the results are stored in `runs` (for each wave the four results of `rk4_history`: `runs[q5][0]` is the array of the times, `runs[q5][1]` the array of the sizes $u^\dagger u$). `np.searchsorted(runs[q5][0], onset_time(0.0, q5, 0.0))` is the position of the first recorded time that is not earlier than the onset time, that is the first step at or after the onset; the first RESULT line of each wave prints the size $u^\dagger u$ there, with two decimals: 1.52 for $q_5 = 0.05$ and 1.54 for $q_5 = 0.1$. The size started at 1, so before the onset it grows only slowly, by about half (the mode matrix is not Hermitian, so the size is not conserved; Section 8.19). The second RESULT line of each wave prints $\ln(u^\dagger u)$ at the end of the run: 37.071245 and 37.113916.

```
x4_end = onset_time(0.0, 0.05, 0.0) + 3.0
end_6000 = rk4_history(starts[0.05], 0.05, x4_end, 6000)[3]
end_24000 = rk4_history(starts[0.05], 0.05, x4_end, 24000)[3]
end_12000 = runs[0.05][3]
ratio = np.linalg.norm(end_6000 - end_12000) / np.linalg.norm(end_12000 - end_24000)
relative_error = np.linalg.norm(end_12000 - end_24000) / np.linalg.norm(end_24000)
report("RK4 error ratio (6000 vs 12000) / (12000 vs 24000) steps", f"{ratio:.2f}")
check(14.0 < ratio < 18.0, "RK4 converges with order 4 (error ratio near 16)")
check(relative_error < 1e-8, "the 12000-step run is accurate to 1e-8 (relative)")
```

The convergence test: the run with $q_5 = 0.05$ is repeated with 6000 and 24000 steps (`[3]` takes the final column). For a fourth-order method the difference between 6000 and 12000 steps is about $2^4 = 16$ times the difference between 12000 and 24000 steps; the ratio printed is 15.89, and the check requires it between 14 and 18. The difference between 12000 and 24000 steps, relative to the length of the column, estimates the error of the 12000-step run; it must be below 10^{-8}. Output of the whole cell: five RESULT lines and two PASS lines.

In [9], the WKB formulas and the comparison.

```
def Q_of(x4, q5):
    return q5 * np.exp(a4_of(x4))  # the frame momentum k_(5) at y = 0

def kappa_of(x4, q5):
    return np.sqrt(Q_of(x4, q5) ** 2 - mass**2)

def W_of(x4, q5):
    Q = Q_of(x4, q5)
    return (np.sqrt(Q**2 - mass**2) - mass * np.arccos(mass / Q)) / (A * H)
```

The three functions of Section 8.25: $Q = q_5 e^{a_4}$, $\kappa = \sqrt{Q^2 - m^2}$ and $W = \frac{1}{AH}(\sqrt{Q^2 - m^2} - m \arccos(m/Q))$ (`np.arccos` is the inverse cosine).

```
comparison = {}
for q5 in (0.05, 0.1):
    x4s, hilbert, krein, _ = runs[q5]
    start = np.searchsorted(x4s, onset_time(0.0, q5, 0.0) + 1.5)  # window start
    xa, xb = x4s[start], x4s[-1]
    increase = np.log(hilbert[-1]) - np.log(hilbert[start])
    leading = 2 * (W_of(xb, q5) - W_of(xa, q5))
    first = leading + np.log(Q_of(xb, q5) / kappa_of(xb, q5)) \
        - np.log(Q_of(xa, q5) / kappa_of(xa, q5))
    comparison[q5] = (xa, increase, leading, first)
```

For each run the window starts at the first recorded time 1.5 units after the onset (`np.searchsorted` finds the position at which a value would be inserted into a sorted array) and ends at the last time. `increase` is the increase of $\ln(u^\dagger u)$ over the window in the RK4 solution; `leading` is the leading WKB increase $2(W(x_b) - W(x_a))$; `first` adds the first-order correction $\ln(Q/\kappa)$ at the two ends. The four numbers are stored for the plot.

```
    say(f"q5 = {q5}: window {xa:.4f} to {xb:.4f}; increase of ln(u^dagger u) "
        f"{increase:.4f}, leading WKB {leading:.4f} (relative difference "
        f"{abs(increase - leading) / increase:.2e}), first order {first:.4f} "
        f"(relative difference {abs(increase - first) / increase:.2e})")
    check(abs(increase - leading) / increase < 2e-3,
          f"q5 = {q5}: leading WKB agrees to 2e-3 over the window")
    check(abs(increase - first) < abs(increase - leading) and
          abs(increase - first) / increase < 5e-4,
          f"q5 = {q5}: first-order WKB is better and agrees to 5e-4")
```

The comparison is printed (the numbers quoted in Section 8.25), and two checks per wave require the leading formula to agree to 2×10^{-3} and the first-order formula to be better and to agree to 5×10^{-4}.

```
x4s, hilbert, _, _ = runs[0.05]
step = x4s[1] - x4s[0]
late_rate = (np.log(hilbert[-1]) - np.log(hilbert[-3])) / (2 * step)  # centred
kappa_late = kappa_of(x4s[-2], 0.05)  # kappa at the middle of the centred difference
```

```
predicted = 2 * kappa_late - A * H * mass**2 / kappa_late**2
report("q5 = 0.05: computed late rate, predicted 2 kappa - m^2/kappa^2",
       f"{late_rate:.5f}, {predicted:.5f}")
check(abs(late_rate - predicted) / predicted < 1e-5,
      "the late growth rate equals 2 kappa - A H m^2/kappa^2 to 1e-5")
```

The growth rate at the end of the run is computed by a **centred difference**, the change of $\ln(u^\dagger u)$ over the last two steps divided by their length, which approximates the derivative at the middle point; the first-order prediction is evaluated at that middle point. RESULT: 40.09851 and 40.09868; the check requires a relative agreement better than 10^{-5}. Output: two comparison texts, five PASS lines and one RESULT line.

In [10], the growth of the size along the history.

```
fig, ax = plt.subplots()
for q5, colour in ((0.05, "tab:blue"), (0.1, "tab:orange")):
    x4s, hilbert, _, _ = runs[q5]
    xa, _, _, _ = comparison[q5]
    ax.plot(x4s, np.log(hilbert), color=colour, label=f"RK4, $q_5 = {q5}$")
    after = x4s >= onset_time(0.0, q5, 0.0) + 0.05
    shift = np.log(hilbert[np.searchsorted(x4s, xa)]) - 2 * W_of(xa, q5)
    ax.plot(x4s[after], 2 * W_of(x4s[after], q5) + shift, "--", color="black",
            linewidth=0.9)
    ax.axvline(onset_time(0.0, q5, 0.0), color=colour, linestyle=":", linewidth=0.9)
```

For both runs: $\ln(u^\dagger u)$ of the RK4 solution; the leading WKB curve $2W$, drawn from 0.05 units after the onset (`after` is a true/false array that selects those times) and shifted by a constant so that it agrees with the solution at the window start; and a dotted vertical line at the onset (`axvline`).

```
ax.plot([], [], "--", color="black", linewidth=0.9, label="WKB $2W$ + const")
ax.set_xlabel("time $x_4$ (units of $1/m$)")
ax.set_ylabel("$\\ln(u^\\dagger u)$")
ax.set_title("A wave along an extra time, $a_4 = x_4$, $y = 0$")
ax.legend();
save_figure(fig, "growth_along_history",
            "The natural logarithm of the size $u^\\dagger u$ of a wave with "
            ...
            "the WKB curve $2W$ (black dashed, matched 1.5 units after the onset).")
```

An empty dashed line for the legend, labels, and Figure 08b.4; the cell prints only the figure line.

What Figure 08b.4 shows. The natural logarithm of $u^\dagger u$ (vertical, pure number) against the time x_4 (units of $1/m$) for the two waves $q_5 = 0.05$ (blue) and $q_5 = 0.1$ (orange). Before its onset (dotted vertical line at $\ln 10 \approx 2.30$ or $\ln 20 \approx 3.00$) each curve rises only slowly, from 0 to about 0.4 ($\ln 1.52 = 0.42$, $\ln 1.54 = 0.43$): the wave oscillates and its size grows only by about half, because with extra-time momentum the mode matrix is not Hermitian and the size is not conserved. After the onset the curve bends upwards ever more steeply and reaches about 37 three units later (a factor of about 10^{16}), following the black dashed WKB curve. The student should see the switch from oscillation to growth at the predicted time, and growth that accelerates.

In [11], the growth rate and the Krein form.

```
x4s, hilbert, krein, _ = runs[0.05]
step = x4s[1] - x4s[0]
computed_rate = (np.log(hilbert[2:]) - np.log(hilbert[:-2])) / (2 * step)
middle = x4s[1:-1]
after = middle > onset_time(0.0, 0.05, 0.0) + 0.02
drift = np.abs(krein - krein[0]) / np.maximum(hilbert, 1.0)
check(drift.max() < 1e-9, "the Krein form is conserved (drift below 1e-9)")
check(hilbert[-1] > 1e15, "the Hilbert norm grows by more than 10^15")
```

For the run with $q_5 = 0.05$: the growth rate at every inner time by centred differences (`hilbert[2:]` drops the first two values, `hilbert[:-2]` the last two, so the two arrays are shifted by two steps; `middle` are the middle times); `after` selects the times just after the onset; `drift` is the change of the Krein form divided by $\max(u^\dagger u, 1)$. The checks require the drift below 10^{-9} and a final size above 10^{15}.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
fig.subplots_adjust(wspace=0.35)  # room for the label of the right panel
left.plot(middle, computed_rate, color="tab:blue", label="RK4 (centred differences)")
left.plot(middle[after], 2 * kappa_of(middle[after], 0.05), "--", color="black",
          label="$2\\kappa$")
left.plot(middle[after], 2 * kappa_of(middle[after], 0.05)
          - mass**2 / kappa_of(middle[after], 0.05) ** 2, ":", color="tab:red",
          label="$2\\kappa - m^2/\\kappa^2$")
left.set_ylim(-5.0, 45.0)
left.set_xlabel("time $x_4$")
left.set_ylabel("growth rate $d\\ln(u^\\dagger u)/dx_4$")
left.set_title("Growth rate, $q_5 = 0.05$")
left.legend(fontsize=8)
```

The left panel draws the computed growth rate with the two WKB rates (`subplots_adjust(wspace=0.35)` widens the gap between the panels).

```
right.semilogy(x4s[1:], np.maximum(drift[1:], 1e-18), color="tab:green")
right.set_xlabel("time $x_4$")
right.set_ylabel("$|\\Delta(u^\\dagger Bu)| / \\max(u^\\dagger u, 1)$")
right.set_title("Krein form: change (rounding only)")
save_figure(fig, "rate_and_krein",
            "Left: the growth rate $d\\ln(u^\\dagger u)/dx_4$ of the wave with "
            ...
            "$10^{-9}$.")
```

The right panel draws the drift on a logarithmic axis (`semilogy`); a logarithm cannot show an exact zero, so zeros are raised to 10^{-18} (`np.maximum`). The figure is Figure 08b.5. Output: two PASS lines and the figure line.

What Figure 08b.5 shows. Left: the growth rate $d\ln(u^\dagger u)/dx_4$ (units of m) against the time x_4 (units of $1/m$): small before the onset at $x_4 \approx 3$ (it starts at 0 and stays below 1; on the vertical scale up to 45 this looks almost flat), then rising ever more steeply to about 40; the black dashed curve 2κ and the red dotted curve $2\kappa - m^2/\kappa^2$ start at the onset, where both fail ($\kappa \to 0$), and the computed rate approaches the red curve as κ grows. Right: the change of the Krein form relative to

$\max(u^\dagger u, 1)$, on a logarithmic axis: it stays below about 10^{-14} (the drops to 10^{-18} are exact zeros), the level of rounding errors. The student should see that the rate itself grows exponentially (growth faster than any exponential) while the Krein form is conserved.

In [12], the last check.

```
for name in ("08b_1_scale_factors.png", "08b_2_frame_momenta.png",
             "08b_3_onset_times.png", "08b_4_growth_along_history.png",
             "08b_5_rate_and_krein.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

Five checks that the figure files exist, and the last line. The 25 checks come from the cells as follows: one in In [2], three in In [3], two in In [4], one in In [6], four in In [7], two in In [8], five in In [9], two in In [11] and five here (In [5] and In [10] have none). The last line reads `ALL 25 CHECKS PASSED (notebook 08b)`.

8.30 Changing the field variables: the rescaling $\Psi = \sin^{-1/2} z\,\chi$

Section 8.9 changed the frame. This section keeps the diagonal frame and changes the field variables instead: we write the field as a known function times a new field, $\Psi = w\,\chi$ with $w = \sin^{-1/2} z$, and ask which equation χ obeys.

The derivative of the factor. w depends only on x_0. Line by line:

$$\partial_0 w = -\tfrac{1}{2}\sin^{-3/2} z \cdot \cos z \cdot 6H = -3H \sin^{-3/2} z \cos z,$$
$$\tan z\,\partial_0 w = \frac{\sin z}{\cos z} \cdot \big(-3H \sin^{-3/2} z \cos z\big) = -3H \sin^{-1/2} z = -3H\,w.$$

The first line is the chain rule (the power rule for $\sin^{-1/2}$, the derivative $\cos z$ of $\sin z$, and $dz/dx_0 = 6H$); the second multiplies by $\tan z = \sin z/\cos z$ and combines the powers of $\sin z$ ($\sin z \cdot \sin^{-3/2} z = \sin^{-1/2} z$).

The term disappears. For $\mu \neq 8$, $\partial_\mu(w\chi) = w\,\partial_\mu\chi$, because w does not depend on x_μ. For $\mu = 8$ the product rule gives $\partial_0(w\chi) = (\partial_0 w)\chi + w\,\partial_0\chi$. So, line by line,

$$\begin{aligned}\gamma^\mu D_\mu(w\chi) &= \sum_\mu \gamma^\mu \partial_\mu(w\chi) + 3H\gamma^{(0)} w\chi \\ &= w\sum_\mu \gamma^\mu \partial_\mu\chi + \tan z\,\gamma^{(0)}(\partial_0 w)\chi + 3H\gamma^{(0)} w\chi \\ &= w\sum_\mu \gamma^\mu \partial_\mu\chi + \big(-3Hw + 3Hw\big)\gamma^{(0)}\chi = w\sum_\mu \gamma^\mu \partial_\mu\chi.\end{aligned}$$

The first line uses $\gamma^\mu D_\mu = \gamma^\mu\partial_\mu + \gamma^\mu\Omega_\mu$ and $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$ (Section 8.5); the second applies the two derivative rules, with $\gamma^{x_0} = \tan z\,\gamma^{(0)}$; the third inserts $\tan z\,\partial_0 w = -3Hw$. For every column χ of 16 functions the spin-connection term is gone: in the variables χ the derivative part of the field equation is $w\,\gamma^\mu\partial_\mu\chi$, with no term $3H\gamma^{(0)}$ (PROVED; `Revision/theory/reports/python-s`

`cope.json`, check `rescaling_removes_the_connection_term`, both engines). The frame factors $e^{\mp a_4}\sin^{-1/6} z$ and $\tan z$ stay: they are part of γ^μ.

The potential. S is quadratic in the field and w is real, so $S[w\chi] = (w\chi)^\dagger C(w\chi) = w^2\,\chi^\dagger C\chi = S[\chi]/\sin z$ (because $w^2 = \sin^{-1} z$). With $U = \frac{\lambda}{2}S^2$, $U'(S[\Psi]) = \lambda S[\Psi] = \lambda S[\chi]/\sin z$. The field equation $\gamma^\mu D_\mu\Psi = (m+\lambda S[\Psi])\Psi$ becomes $w\,\gamma^\mu\partial_\mu\chi = (m+\lambda S[\chi]/\sin z)\,w\chi$, and dividing by $w > 0$:

$$\gamma^\mu\partial_\mu\chi = \Big(m + \frac{\lambda S[\chi]}{\sin z}\Big)\chi.$$

For $U = 0$ the term $3H\gamma^{(0)}$ is removed completely; for $U \neq 0$ it reappears in a new form, as the x_0-dependent coupling $\lambda S[\chi]/\sin z$ (PROVED; `python-scope.json`, check `rescaled_equation_quadratic_potential`, both engines).

The weight moves into the measure. The norm of a field along the hidden direction is $\int \cos z\,\Psi^\dagger\Psi\,dx_0$ ($\cos z = \sqrt{|g|}$ is the volume factor). In the new variables $\cos z\,\Psi^\dagger\Psi\,dx_0 = \cos z\,w^2\,\chi^\dagger\chi\,dx_0 = \cot z\,\chi^\dagger\chi\,dx_0 = \chi^\dagger\chi\,dy$, by $dy = \cot z\,dx_0$ (Section 8.24). So the norm of Ψ is the plain y-integral of $\chi^\dagger\chi$.

The scope of "the field equation contains $3H\gamma^{(0)}$". Together with Section 8.9: the value $3H\gamma^{(0)}$ belongs to one frame (the diagonal one) AND to one choice of field variables (Ψ). A boosted frame removes it, and so does the rescaling (for a changing b_4 the rescaling $\Psi = \sin^{-1/2} z\,b_4^{-3/4}\chi$ removes the whole term $3H\gamma^{(0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(4)}$, Section 6.18). Interpretation (labelled as such, not a theorem): in the variables Ψ with the measure $\cos z\,dx_0$ the term makes the hidden-direction operator $\tan z\,\partial_0 + 3H$ antisymmetric up to a boundary term (Section 8.32); in the variables χ with the measure dy the plain ∂_y has the same property without any H term. The role of $3H$ therefore depends on the variables and the measure.

8.31 The two ends of the hidden direction and an exact family of solutions

The two ends. Proper length along the hidden direction is $\sqrt{g_{00}}\,dx_0 = \cot z\,dx_0 = dy$. The **tip** $z \to 0$ is $y \to -\infty$: infinitely far from every point. The **patch end** $z = \pi/2$ is $y = 0$: at the finite proper distance $|y|$ from the point y. At the patch end $g_{00} = \cot^2 z = 0$ and $\sqrt{|g|} = \cos z = 0$: the surface is degenerate, and the Revision record claims nothing about it and imposes no boundary condition there. (The Kohn-Sham record ASSUMES a Z_2 **brane** at $z = \pi/2$. A **brane** is a boundary surface of spacetime, here the surface $z = \pi/2$ where the author's coordinate patch ends; "Z_2" says that the patch is glued there to a mirror copy of itself, and the mirror fixes a boundary condition for the field at that surface. Chapter 14 works it out. This chapter does not use it.)

An exact family. For $U = 0$ and a field that depends only on x_4 and x_0, the field equation of Section 8.2 is $\gamma^{(4)}\partial_4\Psi + \tan z\,\gamma^{(0)}\partial_0\Psi + 3H\gamma^{(0)}\Psi = m\Psi$. The record gives a family of exact solutions (`Revision/theory/reports/python-field-theory.json`, check `exact_solution_family_x4_x0`):

$$\Psi = \sin^\alpha z\; e^{Mx_4}\chi_0, \qquad M = -m\gamma^{(4)} + c\,\gamma^{(4)}\gamma^{(0)}, \qquad c = 3H(2\alpha+1),$$

with any real exponent α and any constant column χ_0. We derive it line by line. First, M^2:

$$
\begin{aligned}
M^2 &= m^2(\gamma^{(4)})^2 - mc\big((\gamma^{(4)})^2\gamma^{(0)} + \gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\big) + c^2\gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\gamma^{(0)} \\
&= -m^2 - mc\big(-\gamma^{(0)} + \gamma^{(0)}\big) - c^2(\gamma^{(4)})^2(\gamma^{(0)})^2 \\
&= (c^2 - m^2)\, I_{16} = k^2 I_{16}, \qquad k^2 = 9H^2(2\alpha+1)^2 - m^2.
\end{aligned}
$$

The first line multiplies out; the second uses $(\gamma^{(4)})^2 = -I_{16}$, $\gamma^{(4)}\gamma^{(0)}\gamma^{(4)} = -(\gamma^{(4)})^2\gamma^{(0)} = \gamma^{(0)}$ and, in the last term, one anticommutation and the two squares. As in Section 8.18, $M^2 = k^2 I_{16}$ makes the exponential series collapse: $e^{Mx_4} = \cosh(kx_4)I_{16} + \frac{\sinh(kx_4)}{k}M$. Second, the equation. With $s = \sin z$: $\partial_0 s^\alpha = \alpha s^{\alpha-1}\cos z \cdot 6H$, so $\tan z\, \partial_0 s^\alpha = 6H\alpha\, s^\alpha$; and $\partial_4 e^{Mx_4} = Me^{Mx_4}$. Inserting, and dividing by the common factor s^α:

$$
\begin{aligned}
&\gamma^{(4)}Me^{Mx_4}\chi_0 + 6H\alpha\,\gamma^{(0)}e^{Mx_4}\chi_0 + 3H\gamma^{(0)}e^{Mx_4}\chi_0 = \big(\gamma^{(4)}M + c\,\gamma^{(0)}\big)e^{Mx_4}\chi_0, \\
&\gamma^{(4)}M = -m(\gamma^{(4)})^2 + c(\gamma^{(4)})^2\gamma^{(0)} = m - c\,\gamma^{(0)}, \\
&\big(\gamma^{(4)}M + c\,\gamma^{(0)}\big)e^{Mx_4}\chi_0 = m\,e^{Mx_4}\chi_0.
\end{aligned}
$$

The first line collects the two $\gamma^{(0)}$ terms ($6H\alpha + 3H = 3H(2\alpha+1) = c$); the second multiplies out $\gamma^{(4)}M$; the third inserts it: the left side equals $m\Psi$ after the factor s^α is put back. So every member solves the field equation, for every history a_4 (nothing in the solution depends on a_4, because the term $3H\gamma^{(0)}$ does not; PROVED).

Which members grow. A member grows like e^{kx_4} when $k^2 > 0$, that is when $3H|2\alpha+1| > m$, and oscillates when $k^2 < 0$. The member $\alpha = -\frac{1}{2}$ has $c = 0$, $M = -m\gamma^{(4)}$ without any H, and $k^2 = -m^2$: it oscillates with the frequency m. It is the rescaled field of Section 8.30, $\Psi = \sin^{-1/2} z\,\chi$ with χ independent of x_0 (PROVED; `python-scope.json`, check `rescaled_equation_quadratic_potential`, whose detail states this member). The member $\alpha = 0$, the fields that do not depend on x_0, has $k^2 = 9H^2 - m^2$ and grows exactly when $m < 3H$.

Which members have a finite norm. The norm of a member along the hidden direction is a function of x_4 times the integral of $\cos z\,\sin^{2\alpha} z$ over x_0 from the tip to the patch end (where $z = 6Hx_0 = \pi/2$, that is $x_0 = \pi/(12H)$). We substitute $s = \sin z$, so that $ds = 6H\cos z\, dx_0$. Line by line:

$$
\int_0^{\pi/(12H)} \cos z\,\sin^{2\alpha} z\, dx_0 = \frac{1}{6H}\int_0^1 s^{2\alpha}\, ds = \frac{1}{6H}\Big[\frac{s^{2\alpha+1}}{2\alpha+1}\Big]_0^1 = \frac{1}{6H(2\alpha+1)} \quad (2\alpha+1 > 0).
$$

The first step changes the variable (s runs from 0 to 1 as x_0 runs over the patch); the second takes the antiderivative of a power; the third evaluates it, and $s^{2\alpha+1} \to 0$ at $s = 0$ exactly when $2\alpha+1 > 0$. For $2\alpha + 1 \le 0$ the integral diverges at the tip; at $\alpha = -\frac{1}{2}$ it is $\int ds/s$, which grows like $\ln(1/\epsilon)$ as the lower limit ϵ goes to 0. So the member without H has an infinite norm, and the growing members with a finite norm are those with $2\alpha + 1 > m/(3H)$ and $\alpha > -\frac{1}{2}$.

For every mass some member grows and has a finite norm. Take $\alpha = m/(3H)$, which is $> -\frac{1}{2}$. Then $2\alpha + 1 = (2m + 3H)/(3H)$, $c = 2m + 3H$, and $k^2 = (2m + 3H)^2 - m^2 = (2m + 3H - m)(2m + 3H + m) = (m + 3H)(3m + 3H) = 3(m + H)(m + 3H) > 0$ (a difference of two squares). The record states the case $\alpha = 0$, $m < 3H$; the statement for every mass is this book's own exact consequence of the record's family, proved here and checked by Notebook 08d (PROVED).

8.32 The boundary term at the patch end and the growing modes of the good sector

The fields that do not depend on x_0. Such a field of the good sector depends only on x_4, and the field equation, multiplied by $\gamma^{(4)}$ as in Section 8.16, becomes $i\,\partial_4\Psi = A\Psi$ with the constant matrix $A = -im\gamma^{(4)} + 3iH\gamma^{(4)}\gamma^{(0)}$, which is i times the matrix M of the family at $\alpha = 0$. Its square is $A^2 = -M^2 = (m^2 - 9H^2)I_{16}$, so for $m < 3H$ its eigenvalues are $\pm i\sqrt{9H^2 - m^2}$, eight each, and half of the modes grow; at $m = H = 1$ the eigenvalues are $\pm 2\sqrt{2}\,i$. A is not Hermitian (its second term is anti-Hermitian, see below). These modes have the finite norm factor $\int_0^{\pi/(12H)} \cos(6Hx_0)\,dx_0 = \frac{1}{6H}$ (the case $\alpha = 0$ above). (PROVED; `python-scope.json`, check `good_sector_x0_independent_modes_without_boundary_condition`, both engines.) So even the good sector, without any extra-time dependence, contains growing modes of finite norm, as long as nothing is imposed at the patch end.

The mode operator. For fields of x_4 and x_0 (and $U = 0$), multiplying the field equation $\gamma^{(4)}\partial_4\Psi + \gamma^{(0)}(\tan z\,\partial_0 + 3H)\Psi = m\Psi$ from the left by $\gamma^{(4)}$ gives $-\partial_4\Psi + \gamma^{(4)}\gamma^{(0)}(\tan z\,\partial_0 + 3H)\Psi = m\gamma^{(4)}\Psi$, and multiplying by $-i$ and rearranging: $i\,\partial_4\Psi = h\Psi$ with the **mode operator**

$$h = -im\gamma^{(4)} + i\gamma^{(4)}\gamma^{(0)}\big(\tan z\,\partial_0 + 3H\big) = A + P\,\partial_0, \qquad P = i\tan z\,\gamma^{(4)}\gamma^{(0)}.$$

Three matrix facts. Let $M_0 = i\gamma^{(4)}\gamma^{(0)}$. The real matrix $\gamma^{(4)}\gamma^{(0)}$ is symmetric: $(\gamma^{(4)}\gamma^{(0)})^T = (\gamma^{(0)})^T(\gamma^{(4)})^T = \gamma^{(0)}(-\gamma^{(4)}) = \gamma^{(4)}\gamma^{(0)}$. Hence:

1. $P^\dagger = -i\tan z\,(\gamma^{(4)}\gamma^{(0)})^T = -P$: the coefficient of ∂_0 is anti-Hermitian.
2. $\cos z\,P = i\sin z\,\gamma^{(4)}\gamma^{(0)} = \sin z\,M_0$.
3. $(-im\gamma^{(4)})^\dagger = im(\gamma^{(4)})^T = -im\gamma^{(4)}$ (Hermitian) and $(3iH\gamma^{(4)}\gamma^{(0)})^\dagger = -3iH\gamma^{(4)}\gamma^{(0)}$ (anti-Hermitian), so $A - A^\dagger = 6iH\gamma^{(4)}\gamma^{(0)} = 6H\,M_0$, and $\cos z\,(A - A^\dagger) = 6H\cos z\,M_0 = (\partial_0 \sin z)\,M_0$.

The boundary identity. For any two columns $u(x_0)$, $v(x_0)$, line by line (a prime is ∂_0 here):

$$\begin{aligned}\cos z\big[u^\dagger(hv) - (hu)^\dagger v\big] &= \cos z\,u^\dagger(A - A^\dagger)v + \cos z\big[u^\dagger Pv' - u'^\dagger P^\dagger v\big]\\ &= \cos z\,u^\dagger(A - A^\dagger)v + \cos z\big[u^\dagger Pv' + u'^\dagger Pv\big]\\ &= (\partial_0\sin z)\,u^\dagger M_0 v + \sin z\big[u^\dagger M_0 v' + u'^\dagger M_0 v\big] = \partial_0\big(\sin z\,u^\dagger M_0 v\big).\end{aligned}$$

The first line inserts $h = A + P\partial_0$ and uses $(hu)^\dagger = u^\dagger A^\dagger + u'^\dagger P^\dagger$; the second uses fact 1; the third uses facts 3 and 2 and then recognises the product rule for the three factors $\sin z$, $u^\dagger$ and v (M_0 is constant). (PROVED; `python-scope.json`, check `good_sector_hermiticity_up_to_the_brane_flux`, both engines.) Integrated over the hidden direction, the left side is the failure of h to be symmetric for the norm $\int \cos z\,u^\dagger v\,dx_0$, and the right side gives the **boundary term** (or **flux**) $[\sin z\,u^\dagger M_0 v]$, taken between the tip and the patch end. At the tip $\sin z \to 0$; at the patch end $\sin z = 1$, and the flux need not vanish: for a column with $\gamma^{(4)}\gamma^{(0)}u = u$ (such columns exist, because $(\gamma^{(4)}\gamma^{(0)})^2 = -(\gamma^{(4)})^2(\gamma^{(0)})^2 = I_{16}$ and the matrix is not $\pm I_{16}$), $u^\dagger M_0 u = i\,u^\dagger u \neq 0$; the record's example has $u^\dagger u = 2$ and $u^\dagger M_0 u = 2i$.

The norm changes only through the patch end. For a solution of $i\,\partial_4\Psi = h\Psi$ let $N(x_4) = \int_0^{\pi/(12H)} \cos z\,\Psi^\dagger\Psi\,dx_0$. Line by line:

$$\begin{aligned}\frac{dN}{dx_4} &= \int \cos z\big[(\partial_4\Psi)^\dagger\Psi + \Psi^\dagger\partial_4\Psi\big]dx_0 = \int \cos z\big[(-ih\Psi)^\dagger\Psi + \Psi^\dagger(-ih\Psi)\big]dx_0 \\ &= -i\int \cos z\big[\Psi^\dagger(h\Psi) - (h\Psi)^\dagger\Psi\big]dx_0 = -i\big[\sin z\,\Psi^\dagger M_0\Psi\big]_{\text{tip}}^{\text{end}} \\ &= -i\,\Psi^\dagger M_0\Psi\big|_{z=\pi/2} = \Psi^\dagger\gamma^{(4)}\gamma^{(0)}\Psi\big|_{z=\pi/2}.\end{aligned}$$

The first line differentiates under the integral and inserts the equation; the second collects the factors $\mp i$ and uses the boundary identity with $u = v = \Psi$ (the integral of a derivative is the difference of its end values); the third uses $\sin z = 0$ at the tip and 1 at the end, and $-i \cdot i = 1$. The norm of a solution changes ONLY by the flux through the patch end. For a field that does not depend on x_0, $N = \Psi^\dagger\Psi/(6H)$. Notebook 08d follows such a growing mode at $m = H = 1$: its norm first dips (the flux is briefly negative) and then grows by a factor $N(1.5)/N(0) = 2094.786$ in 1.5 time units, and dN/dx_4 equals the flux at every time to rounding (COMPUTED).

What this means (labelled). Interpretation: the growth of the good-sector modes is fed through the patch end. A boundary condition at $z = \pi/2$ that stops the flux would make h symmetric and would change the spectrum; which condition is physical is OPEN. Without one, the initial-value problem of the good sector has growing solutions: this is the second way, besides the extra-time waves of Sections 8.17 to 8.25, in which the field equation as recorded fails to define a stable evolution.

8.33 Example: the rescaling and the modes of the hidden direction

Notebook 08d puts Sections 8.30 to 8.32 to work, exactly, with sympy. It takes the spin connection of the diagonal frame from the record's formula and verifies it (the gammas are covariantly constant); proves the rescaling for sixteen arbitrary component functions; draws the rescaling factor and the hidden coordinate y with the tip cutoff of the Kohn-Sham record; verifies the exact family for symbolic α, m, H and every a_4, and maps which members grow and which have a finite norm; checks the matrix A of the modes that do not depend on x_0; proves the boundary identity on explicit columns; and follows a growing mode whose norm changes exactly by the flux through the patch end. It needs no Rust and runs in one to two minutes; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/08d_rescaling_modes.PROVENANCE.md`. It ends with the line ALL 23 CHECKS PASSED (notebook 08d).

8.34 How to run Notebook 08d

Step 1. What this notebook does and what it needs.

Notebook 08d (The rescaling that removes the term, and the growing modes at the patch end) is the file `Revision/textbook/notebooks/08d_rescaling_modes.ipynb` of the repository Dirac_claude. It takes the spin connection of the diagonal frame from the Revision record and verifies it, proves exactly that the rescaling Psi = sin(z)^(-1/2) chi removes the term 3 H gamma^(x0) from the field equation (for 16 arbitrary component functions) and turns the quadratic potential into the

coupling lambda S/sin z, verifies the exact family of solutions sin(z)^alpha exp(M x4) chi0, finds which of them grow and which have a finite norm, verifies the growing x0-independent modes of the good sector, proves that the norm of the hidden direction changes only through a boundary term at the patch end z = pi/2, and draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
```

```
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08d_rescaling_modes.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08d_rescaling_modes.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 08d_rescaling_modes.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/08d.captions.json`
- `Revision/textbook/figures/08d_1_rescaling_factors.png`
- `Revision/textbook/figures/08d_2_family_k_squared.png`
- `Revision/textbook/figures/08d_3_growing_finite_norm.png`
- `Revision/textbook/figures/08d_4_patch_end_modes.png`
- `Revision/textbook/figures/08d_5_norm_and_flux.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08d_5_norm_and_flux.png exists
ALL 23 CHECKS PASSED (notebook 08d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/08d_rescaling_modes.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 08d_rescaling_modes.ipynb
python -m nbconvert --execute --inplace 08d_rescaling_modes.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- A cell of section 6 or 7 runs for more than a minute: sympy simplifies the field equation for sixteen arbitrary functions there; on a slow computer this can take a few minutes. Wait until the star in the brackets to the left of the cell turns into a number.

8.35 Notebook 08d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/08d_rescaling_modes.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

In the diagonal frame the field equation of dirac16complex (and of dirac16complex00)
in the author's metric contains the term $3H\gamma^{(0)}\Psi$ (on the background
$b_4 = 1$ of the Revision record's scope reports, with which this notebook compares;
for a general $b_4(x_4)$ the term is $(3H\gamma^{(0)} + \frac34(b_4'/b_4)
\gamma^{(4)})\Psi$ and the rescaling $\sin^{-1/2}z\,b_4^{-3/4}$ removes it, Notebook
06b). This notebook shows,
exactly, that a change of the field VARIABLES removes it, and then studies the
hidden direction $x_0$ near its two ends: the tip $z \to 0$ and the patch end
$z = \pi/2$. It

- takes the spin connection of the diagonal frame from the Revision record and
  verifies it (the gammas are covariantly constant), and recomputes
  $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$;
- proves that for $\Psi = \sin^{-1/2}z\,\chi$ the field equation becomes
  $\gamma^\mu\partial_\mu\chi = (m + U')\chi$ with no spin-connection term, for
  sixteen arbitrary component functions, and that the quadratic potential turns
  into the coupling $\lambda S[\chi]/\sin z$;
- verifies the exact family of solutions $\Psi = \sin^\alpha z\,e^{Mx_4}\chi_0$ with
  $k^2 = 9H^2(2\alpha + 1)^2 - m^2$, and finds which members grow ($k^2 > 0$) and
  which have a finite norm at the tip ($\alpha > -\frac12$);
- verifies the growing $x_0$-independent modes of the good sector ($m < 3H$) and
  their finite norm;
- proves that the norm in the hidden direction changes only through a boundary
  term at the patch end $z = \pi/2$, and shows a growing mode whose norm grows
  exactly as fast as this boundary term feeds it.

Every exact statement reproduces a check of a Revision record or is labelled as
this notebook's own exact computation. Five teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 08d (The rescaling that removes the term, and the growing modes at the patch
end) is the file 'Revision/textbook/notebooks/08d_rescaling_modes.ipynb' of the
repository Dirac_claude. It takes the spin connection of the diagonal frame from the
Revision record and verifies it, proves exactly that the rescaling Psi = sin(z)^(-1/2)
chi removes the term 3 H gamma^(x0) from the field equation (for 16 arbitrary component
functions) and turns the quadratic potential into the coupling lambda S/sin z, verifies
the exact family of solutions sin(z)^alpha exp(M x4) chi0, finds which of them grow and
which have a finite norm, verifies the growing x0-independent modes of the good sector,
proves that the norm of the hidden direction changes only through a boundary term at the
patch end z = pi/2, and draws five teaching plots. It needs a computer with Windows 11,
macOS or Linux, an internet connection for the installation, the program Git, and Python
3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
Jupyter, the program that shows and runs notebooks. It does not need Rust.
```

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home

folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 08d_rescaling_modes.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 08d_rescaling_modes.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 08d_rescaling_modes.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/08d.captions.json‘
- ‘Revision/textbook/figures/08d_1_rescaling_factors.png‘

- ‘Revision/textbook/figures/08d_2_family_k_squared.png‘
- ‘Revision/textbook/figures/08d_3_growing_finite_norm.png‘
- ‘Revision/textbook/figures/08d_4_patch_end_modes.png‘
- ‘Revision/textbook/figures/08d_5_norm_and_flux.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 08d_5_norm_and_flux.png exists
ALL 23 CHECKS PASSED (notebook 08d)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/08d_rescaling_modes.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 08d_rescaling_modes.ipynb
  python -m nbconvert --execute --inplace 08d_rescaling_modes.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- A cell of section 6 or 7 runs for more than a minute: sympy simplifies the field equation for sixteen arbitrary functions there; on a slow computer this can take a few minutes. Wait until the star in the brackets to the left of the cell turns into a number.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 08d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 08d (The rescaling that removes the term, and the growing modes at the patch
# end) is the file Revision/textbook/notebooks/08d_rescaling_modes.ipynb of the
# repository Dirac_claude. It takes the spin connection of the diagonal frame from the
# Revision record and verifies it, proves exactly that the rescaling Psi = sin(z)^(-1/2)
# chi removes the term 3 H gamma^(x0) from the field equation (for 16 arbitrary component
# functions) and turns the quadratic potential into the coupling lambda S/sin z, verifies
# the exact family of solutions sin(z)^alpha exp(M x4) chi0, finds which of them grow and
# which have a finite norm, verifies the growing x0-independent modes of the good sector,
# proves that the norm of the hidden direction changes only through a boundary term at
# the patch end z = pi/2, and draws five teaching plots. It needs a computer with Windows
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the

#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
```

```
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 08d_rescaling_modes.ipynb
```

```
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 08d_rescaling_modes.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 08d_rescaling_modes.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/08d.captions.json
# - Revision/textbook/figures/08d_1_rescaling_factors.png
# - Revision/textbook/figures/08d_2_family_k_squared.png
# - Revision/textbook/figures/08d_3_growing_finite_norm.png
# - Revision/textbook/figures/08d_4_patch_end_modes.png
# - Revision/textbook/figures/08d_5_norm_and_flux.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 08d_5_norm_and_flux.png exists
#     ALL 23 CHECKS PASSED (notebook 08d)
#
```

```
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/08d_rescaling_modes.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 08d_rescaling_modes.ipynb
#     python -m nbconvert --execute --inplace 08d_rescaling_modes.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - A cell of section 6 or 7 runs for more than a minute: sympy simplifies the field
#   equation for sixteen arbitrary functions there; on a slow computer this can take a
#   few minutes. Wait until the star in the brackets to the left of the cell turns into a
#   number.

## 3. The words used in this notebook

- **Coordinates** (the author's names): $x_1, x_2, x_3$ ordinary space (inflating);
  $x_4$ the time; $x_5, x_6, x_7$ the three extra times (time-like, DEFLATING);
  $x_0$ the hidden direction, $z = 6Hx_0$ between $0$ (the *tip*) and $\pi/2$ (the
  *patch end*, at $x_0 = \pi/(12H)$).
- **Diagonal frame**, scale factors $f_a$: $f_{1,2,3} = e^{a_4}\sin^{1/6}z$,
  $f_4 = 1$, $f_{5,6,7} = e^{-a_4}\sin^{1/6}z$, $f_0 = \cot z$; $\gamma^\mu =
  \gamma^{(\mu)}/f_\mu$.
- **Spin connection** $\Omega_\mu$ and **covariant derivative** $D_\mu\Psi =
  \partial_\mu\Psi + \Omega_\mu\Psi$; the gammas are *covariantly constant*:
  $\partial_\mu\gamma^\nu + \sum_\lambda\Gamma^\nu{}_{\mu\lambda}\gamma^\lambda +
  \Omega_\mu\gamma^\nu - \gamma^\nu\Omega_\mu = 0$ ($\Gamma$: Christoffel symbols).
  This property fixes $\Omega_\mu$ and is used to verify it.
- **Rescaling** (a change of field variables): $\Psi = w\,\chi$ with the function
  $w = \sin^{-1/2}z$.
- **Bilinear** $S = \bar\Psi\Psi = \Psi^\dagger C\Psi$ and the quadratic potential
  $U = \frac{\lambda}{2}S^2$, $U' = \lambda S$.
- **Norm** of a field in the hidden direction: $\int \cos z\,\Psi^\dagger\Psi\,dx_0$
  ($\cos z = \sqrt{|g|}$ is the volume factor). It is *finite* when the integral
  does not diverge at the ends.
- **Hidden coordinate** $y = \ln(\sin z)/(6H)$, $dy = \cot z\,dx_0$; $y = 0$ at the
  patch end and $y \to -\infty$ at the tip.
- **Good sector**: fields that do not depend on the extra times $x_5, x_6, x_7$.
- **Mode operator** $h$: the field equation written as $i\,\partial_4\Psi = h\Psi$;
  for fields that depend only on $x_4$ and $x_0$ (and $U = 0$),
  $h = -im\gamma^{(4)} + i\gamma^{(4)}\gamma^{(0)}(\tan z\,\partial_0 + 3H)$.
- **Hermitian, anti-Hermitian**: $M^\dagger = M$ or $M^\dagger = -M$
  ($M^\dagger$: the conjugate transpose).
- **Boundary term (flux)**: a total derivative $\partial_0(\dots)$ whose integral is
  the difference of its values at the two ends.
- **$Z_2$ brane**: a boundary surface of spacetime, here the patch end
  $z = \pi/2$, at which the patch is glued to a mirror copy of itself; the mirror
  fixes a boundary condition for the field there. The Kohn-Sham record ASSUMES
  one; this notebook does not use it.
```

Text cell:

```
## 4. The physical and mathematical situation

For a field that depends only on $x_4$ and $x_0$ the field equation (with $U = 0$)
is $\gamma^{(4)}\partial_4\Psi + \tan z\,\gamma^{(0)}\partial_0\Psi +
```

```
3H\gamma^{(0)}\Psi = m\Psi$. The rescaling works because, line by line,

1. $\partial_0\sin^{-1/2}z = -\frac12\sin^{-3/2}z\cos z \cdot 6H$ (chain rule, with
   $dz/dx_0 = 6H$);
2. so $\tan z\,\partial_0\sin^{-1/2}z = -3H\,\sin^{-1/2}z$ (because $\tan z\cos z =
   \sin z$);
3. so $\tan z\,\gamma^{(0)}\partial_0(w\chi) + 3H\gamma^{(0)}w\chi =
   w\tan z\,\gamma^{(0)}\partial_0\chi$: the product rule produces exactly
   $-3H\gamma^{(0)}w\chi$, which cancels the spin-connection term.

The weight moves into the measure: $\cos z\,\Psi^\dagger\Psi\,dx_0 = \cos z\,
\sin^{-1}z\,\chi^\dagger\chi\,dx_0 = \chi^\dagger\chi\,dy$.

Proper lengths along the hidden direction are $\sqrt{g_{00}}\,dx_0 = \cot z\,dx_0 =
dy$. So the *patch end* $z = \pi/2$ ($y = 0$) lies at the finite proper distance
$|y|$ from every point, while the tip $z \to 0$ ($y \to -\infty$) is infinitely far
away. The Revision
record imposes no boundary condition at $z = \pi/2$ (the Kohn-Sham record ASSUMES a
$Z_2$ brane there). Without one, the mode operator is symmetric only up to a
boundary term at $z = \pi/2$, and the good sector contains growing modes: this is
the second way (besides the extra-time waves) in which the initial-value problem
fails to be well posed.

Every symbol is exact ($H > 0$, $m$, $\alpha$, $\lambda$ letters; $a_4(x_4)$ any
function). The plots use $H = 1$.
```

Text cell:

```
## 5. The spin connection from the record, verified

The next cell first defines two helpers for the checks that reproduce a Revision
record. ‘record_says(report, name, ...)‘ opens the report (a JSON file with a list
of checks, each with a name, a verdict and a detail text) and is true when the
check ‘name‘ is there with the verdict pass and its detail text contains every
further piece of text given (for example a value that this notebook computes).
‘check_record(condition, title, report, name, ...)‘ is the helper ‘check‘ for such
a result: it passes only if the notebook’s own computation (‘condition‘) is right
AND the record says the same. Then the cell reads the gammas and the formula
record ‘Omega_components‘ of
‘Revision/theory/field-theory.json‘ (written in the Wolfram language: ‘g[xi]‘ is
$\gamma^{(x_i)}$, ‘a4’[x4]‘ is $a_4’$), enters the same formula in sympy, computes
the Christoffel symbols of the author’s metric, and checks that the gammas are
covariantly constant for all 64 pairs $(\mu, \nu)$ and that $\gamma^\mu\Omega_\mu =
3H\gamma^{(0)}$. The helper ‘is_zero‘ asks sympy to simplify twice (the second time
with its trigonometric simplifier ‘fu‘).
```

In [2]:

```
import numpy as np  # numbers and matrices (for the plots)
import sympy as sp  # exact algebra with symbols

REPORTS = {}  # report file -> {check name: (verdict, detail)}, each read once
```

```

## 6. The rescaling removes the term
```

```
The next cell checks the one-line identity $\tan z\,\partial_0\sin^{-1/2}z =
-3H\sin^{-1/2}z$, and then the full statement on sixteen ARBITRARY component
functions $\chi_A(x_0, \dots, x_7)$ (sympy ‘Function‘ objects, about which nothing
is assumed): $\gamma^\mu D_\mu(w\chi) - w\,\gamma^\mu\partial_\mu\chi = 0$ for all 16
components. Then it checks the potential: $S[w\chi] = w^2S[\chi] = S[\chi]/\sin z$
($w$ is real), so $\lambda S[\Psi]\Psi = w\,\frac{\lambda S[\chi]}{\sin z}\chi$, and
the measure: $\cos z\,w^2 = \cot z = dy/dx_0$.
```

In [3]:

```

```
The next cell draws the rescaling factor $w = \sin^{-1/2}z$, the new coupling factor
$1/\sin z$ of the potential, and the hidden coordinate $y = \ln(\sin z)/(6H)$, for
$H = 1$. It reads $H$ and the tip cutoff $L$ of the Kohn-Sham record (that record
cuts the hidden direction at $y = -L$) and computes where the cutoff lies in $z$:
$y = -L$ means $\ln(\sin z) = -6HL$, so $\sin z = e^{-6HL}$ and
$z_{\rm cut} = \arcsin(e^{-6HL})$. This number is tiny, so the right panel uses a
logarithmic $z$ axis: on it $y$ is almost a straight line, because $\sin z \approx
z$ for small $z$ and then $y \approx \ln(z)/(6H)$.
```

## 7. An exact family of solutions

For $U = 0$ and a field that depends only on $x_4$ and $x_0$ the record gives the
family $\Psi = \sin^\alpha z\,\big(\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M\big)\chi_0$
```

```
with a constant column $\chi_0$, $M = -m\gamma^{(4)} + c\,\gamma^{(4)}\gamma^{(0)}$,
$c = 3H(2\alpha + 1)$ and $k^2 = c^2 - m^2$. The bracket is $e^{Mx_4}$, because
$M^2 = k^2 I_{16}$. The next cell checks $M^2 = (c^2 - m^2)I_{16}$ and
$M^TC + CM = 0$ (so $S$ does not change in time), and then that $\Psi$ solves the
full field equation $\gamma^\mu D_\mu\Psi = m\Psi$ (all eight directions, with the
spin connection of section 5) for symbolic $\alpha$, $m$, $H$ and every $a_4$.
For $\alpha = -\frac12$: $c = 0$, $M = -m\gamma^{(4)}$ contains no $H$, and
$k^2 = -m^2$ (oscillation with frequency $m$): this is the rescaling of section 6
at work.
```

## 8. Which members grow, and which have a finite norm

A member GROWS when $k^2 > 0$, that is when $3H|2\alpha + 1| > m$. Its norm in the
hidden direction is $\int_0^{\pi/(12H)}\cos z\,\sin^{2\alpha}z\,dx_0$ times a
function of $x_4$; with $s = \sin z$, $ds = 6H\cos z\,dx_0$, this is
$\frac{1}{6H}\int_0^1 s^{2\alpha}ds$, which is $\frac{1}{6H(2\alpha + 1)}$ for
$\alpha > -\frac12$ and infinite for $\alpha \le -\frac12$ (at $\alpha = -\frac12$
the integral of $1/s$ diverges like $\ln$ at the tip). So the H-free member
$\alpha = -\frac12$ has an infinite norm, and the growing members with a finite norm
are those with $2\alpha + 1 > m/(3H)$. For EVERY mass $m > 0$ there are such
members: $\alpha = m/(3H)$ gives $k^2 = (2m + 3H)^2 - m^2 = 3(m + H)(m + 3H) > 0$.
The Revision record states the $x_0$-independent case $\alpha = 0$, which grows when
$m < 3H$; the statement for every mass is this notebook's own exact consequence of
the record's family. The next cell checks the integrals and this example, and draws
$k^2$ against $\alpha$ for three masses.

```
## 10. The boundary term at the patch end
```

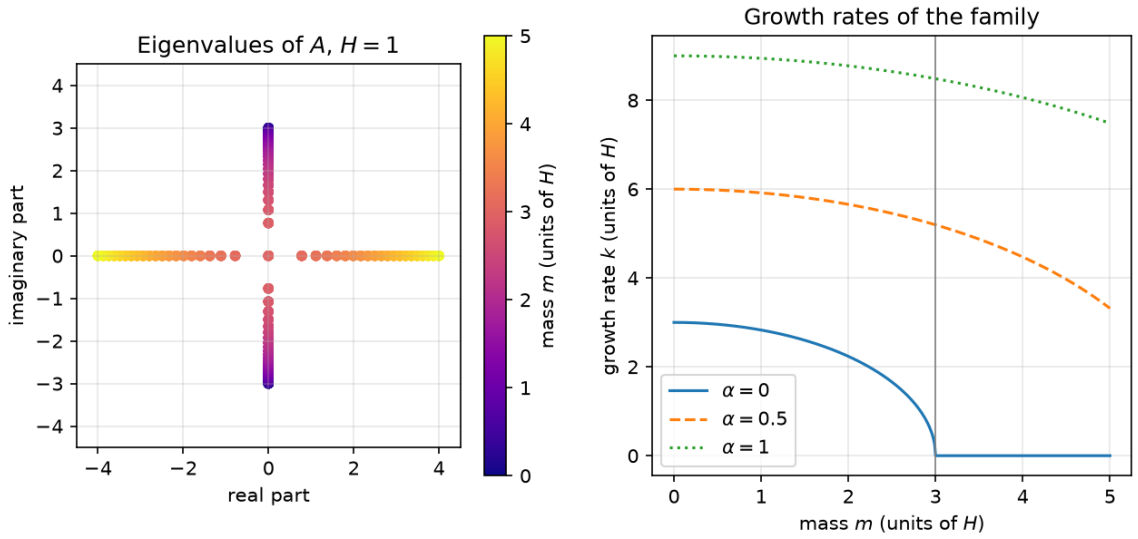

Figure 248: Left: the eigenvalues $\pm\sqrt{m^2 - 9H^2}$ of the matrix $A = -im\gamma^{(4)} + 3iH\gamma^{(4)}\gamma^{(0)}$, which acts on the x_0-independent fields of the good sector, in the complex plane, coloured by the mass m from 0 to $5H$ ($H = 1$). For $m < 3H$ they lie on the imaginary axis (the mode e^{-iEx_4} grows, at most like e^{3Hx_4} at $m = 0$); at $m = 3H$ they meet at 0; for $m > 3H$ they are real. Right: the growth rate $k = \sqrt{9H^2(2\alpha + 1)^2 - m^2}$ of the members $\alpha = 0, 0.5, 1$ of the exact family against m; members with larger α still grow when $m > 3H$ (gray line). (Notebook 08d, figure 4.)

```
For fields of $x_4$ and $x_0$ the mode operator is $h = -im\gamma^{(4)} +
i\gamma^{(4)}\gamma^{(0)}(\tan z\,\partial_0 + 3H)$. With $M_0 = i\gamma^{(4)}
\gamma^{(0)}$ the record proves, for all columns $u(x_0)$, $v(x_0)$,
$$\cos z\,\big[u^\dagger(hv) - (hu)^\dagger v\big] = \partial_0\big(\sin z\,
u^\dagger M_0 v\big).$$
It follows from three matrix facts: $\cos z\cdot(i\tan z\,\gamma^{(4)}\gamma^{(0)})
= \sin z\,M_0$ (the coefficient of $\partial_0$); $\cos z\,(A - A^\dagger) =
(\partial_0\sin z)\,M_0$ for the algebraic part $A$; and the coefficient of
$\partial_0$ is anti-Hermitian. The next cell checks the three facts, the identity
itself for two explicit columns of polynomials with complex coefficients, and the
value at the patch end: for $u$ with $\gamma^{(4)}\gamma^{(0)}u = u$,
$u^\dagger M_0u = i\,u^\dagger u \neq 0$. So $h$ is symmetric for the norm
$\int\cos z\,u^\dagger v\,dx_0$ only up to $[\sin z\,u^\dagger M_0v]$, which
vanishes at the tip ($\sin z \to 0$) but not at $z = \pi/2$ ($\sin z = 1$).
```

## 11. A growing mode is fed through the patch end

Integrate the identity of section 10 over the hidden direction. For a solution of
$i\,\partial_4\Psi = h\Psi$ the norm $N(x_4) = \int_0^{\pi/(12H)}\cos z\,
\Psi^\dagger\Psi\,dx_0$ changes, line by line, as
$\frac{dN}{dx_4} = \int\cos z\,\big[(-ih\Psi)^\dagger\Psi + \Psi^\dagger(-ih\Psi)
\big]dx_0 = -i\int\cos z\,\big[\Psi^\dagger h\Psi - (h\Psi)^\dagger\Psi\big]dx_0
= -i\big[\sin z\,\Psi^\dagger M_0\Psi\big]_{\rm tip}^{\rm end} =
\Psi^\dagger\gamma^{(4)}\gamma^{(0)}\Psi\big|_{z = \pi/2}$:
the norm changes ONLY through the patch end. The next cell follows the
$x_0$-independent mode $\Psi = e^{-iAx_4}\chi_0$ with $m = H = 1$ (so
$N = \Psi^\dagger\Psi/(6H)$) from a fixed random column $\chi_0$, computes
$dN/dx_4 = 2\,\mathrm{Re}\big(\Psi^\dagger(-iA\Psi)\big)/(6H)$ and the flux
$\Psi^\dagger\gamma^{(4)}\gamma^{(0)}\Psi$, checks that they agree, and draws them.
Interpretation (labelled): the growth is fed through the patch end; a boundary
condition at $z = \pi/2$ that stops this flux would change the spectrum, and which
condition is physical is a question this notebook does not decide.
```

## 13. What this notebook showed

- The spin connection of the record makes the gammas covariantly constant, and
  $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$ in the diagonal frame (PROVED).
- The rescaling $\Psi = \sin^{-1/2}z\,\chi$ removes this term exactly: $\gamma^\mu
  D_\mu\Psi = \sin^{-1/2}z\,\gamma^\mu\partial_\mu\chi$ for every $\chi$, so for
  $U = 0$ the equation for $\chi$ has no spin-connection term, and for $U =
  \frac{\lambda}{2}S^2$ the term reappears as the $x_0$-dependent coupling
  $\lambda S[\chi]/\sin z$ (PROVED). The weight moves into the measure: the norm of
  $\Psi$ is $\int\chi^\dagger\chi\,dy$. Together with the frame dependence of
  the term, this is the exact scope of the statement "the field equation contains
  $3H\gamma^{(0)}$": it belongs to one frame AND one choice of field variables.
- The exact family $\sin^\alpha z\,e^{Mx_4}\chi_0$ solves the field equation for
  every $a_4$ (PROVED); its member $\alpha = -\frac12$ contains no $H$. Members with
  $3H|2\alpha + 1| > m$ grow; members with $\alpha > -\frac12$ have a finite norm at
  the tip; for every mass some member does both (PROVED here; the record states the
  case $\alpha = 0$, $m < 3H$).
- The $x_0$-independent modes of the good sector grow for $m < 3H$ (at $m = H = 1$
  with rate $2\sqrt2$) and have a finite norm (PROVED; Revision check
  `good_sector_x0_independent_modes_without_boundary_condition`).
- The mode operator is symmetric only up to the boundary term $[\sin z\,u^\dagger
  M_0v]$, which does not vanish at the patch end $z = \pi/2$ (PROVED), and the norm
  of the growing mode changes exactly by the flux through the patch end (COMPUTED,
  to rounding). Without a boundary condition at $z = \pi/2$ the initial-value
  problem of the good sector therefore has growing solutions; which boundary
  condition is physical is OPEN here (the Kohn-Sham record ASSUMES a $Z_2$ brane).
```

8.36 Line-by-line walk-through of Notebook 08d

The notebook has 12 code cells, In [1] to In [12]. The conventions are those of Section 8.15; captions shortened to `...` are printed in full in Section 8.35.

In [1], the set-up cell. It is the set-up cell explained in Section 8.15, with the line `NOTEBOOK_ID = "08d" # this notebook: chapter 08, example d`; its comment lines are the run instructions of Section 8.34. Output: `Set-up of notebook 08d complete: repository folder found, helpers defined.`

In [2], the spin connection from the record, verified. The cell starts with the imports of numpy and sympy, the empty table `REPORTS` and the helpers `record_says` and `check_record`, word for word those of Notebook 08a (Section 8.23; `check_record` takes one check name). Then:

```
THEORY = "Revision/theory/reports/python-field-theory.json"  # the sympy records
SCOPE = "Revision/theory/reports/python-scope.json"
gammas_record = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
G = [sp.Matrix(rows) for rows in gammas_record["gamma"]]  # gamma^(x0) ... (x7)
ETA = gammas_record["eta"]  # [1, 1, 1, 1, -1, -1, -1, -1]
C = sp.Matrix(gammas_record["C"])  # C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
B = sp.Matrix(gammas_record["B"]["re"]) + sp.I * sp.Matrix(gammas_record["B"]["im"])
```

Short names for the paths of the two sympy reports, and the gammas, the signs, C and B as exact sympy matrices.

```
theory = json.loads(
    repository_file("Revision/theory/field-theory.json").read_text(encoding="utf-8"))
formulas = {entry["key"]: entry for entry in theory["formulas"]}
say("record Omega_components: " + formulas["Omega_components"]["wl"])
```

The formula file of the field-theory record holds a list `formulas`, each with a `key` and the formula as text; the dictionary comprehension makes a table key: entry. The `say` line prints the record's formula of the spinor connection in the Wolfram language (`g[xi]` is $\gamma^{(x_i)}$, `a4'[x4]` is a_4', `E^a4[x4]` is e^{a_4}), which the next lines enter in sympy.

```
x = sp.symbols("x0:8", real=True)  # the coordinates; x[k] is xk
H = sp.Symbol("H", positive=True)
m = sp.Symbol("m", real=True)
a4 = sp.Function("a4")(x[4])  # any function of the time x4
a4_prime = sp.diff(a4, x[4])
z = 6 * H * x[0]
sixth = sp.sin(z) ** sp.Rational(1, 6)
f = [sp.cot(z)] + [sp.exp(a4) * sixth] * 3 + [sp.Integer(1)] \
    + [sp.exp(-a4) * sixth] * 3  # the frame factors at b4 = 1
g = [ETA[a] * f[a] ** 2 for a in range(8)]  # the diagonal metric
gamma_up = [G[mu] / f[mu] for mu in range(8)]  # gamma^mu = gamma^(mu) / f_mu
```

The symbols, the unknown history $a_4(x_4)$ and its derivative, z, $\sin^{1/6} z$, the scale factors, the diagonal metric and the coordinate gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ of the diagonal frame, as in Notebook 08c.

```
Omega = [sp.zeros(16, 16) for _ in range(8)]
for i in (1, 2, 3):  # x1, x2, x3 (inflating)
    Omega[i] = sp.exp(a4) * sixth * (a4_prime * G[i] * G[4] + H * G[i] * G[0]) / 2
for t in (5, 6, 7):  # x5, x6, x7 (deflating extra times)
    Omega[t] = -sp.exp(-a4) * sixth * (a4_prime * G[4] * G[t] + H * G[t] * G[0]) / 2
```

The record's formula entered in sympy: $\Omega_{x_i} = \frac{1}{2} e^{a_4} \sin^{1/6} z (a_4' \gamma^{(i)} \gamma^{(4)} + H \gamma^{(i)} \gamma^{(0)})$, $\Omega_{x_t} = -\frac{1}{2} e^{-a_4} \sin^{1/6} z (a_4' \gamma^{(4)} \gamma^{(t)} + H \gamma^{(t)} \gamma^{(0)})$, and zero for x_4 and x_0 (the starting zero matrices are kept). These are the formulas derived in Section 8.4.

```
def is_zero(expr):
    ...
Gam = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
for lam in range(8):  # Christoffel symbols of the diagonal metric
    ...
                Gam[lam][mu][nu] = sp.simplify(value / (2 * g[lam]))
```

`is_zero` and the Christoffel symbols are computed exactly as in Notebook 08c (In [2] and In [3]; the lines shortened to `...` here are the same lines, explained in Section 8.15).

```
constant = all(
    all(is_zero(v) for v in sp.diff(gamma_up[nu], x[mu])
        + sum((Gam[nu][mu][lam] * gamma_up[lam] for lam in range(8)), sp.zeros(16, 16))
        + Omega[mu] * gamma_up[nu] - gamma_up[nu] * Omega[mu])
    for mu in range(8) for nu in range(8))
check_record(constant, "the record's Omega_mu makes every gamma^nu covariantly "
             "constant (64 pairs)", THEORY, "covariant_constancy_D_mu_gamma_nu",
             "= 0 for all 64 (mu, nu)")
```

For all 64 pairs (μ, ν) the covariant derivative of the coordinate gamma, $\partial_\mu \gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + \Omega_\mu \gamma^\nu - \gamma^\nu \Omega_\mu$, is computed and every entry must vanish. This verifies the record's connection independently of the definition used in Notebook 08c: covariant constancy fixes the connection (Section 8.9, Step 4).

```
gamma_Omega = sum((gamma_up[mu] * Omega[mu] for mu in range(8)), sp.zeros(16, 16))
check_record(all(is_zero(v) for v in gamma_Omega - 3 * H * G[0]),
             "gamma^mu Omega_mu = 3 H gamma^(x0) (diagonal frame)",
             THEORY, "gamma_mu_Omega_mu_equals_3H_gamma_x0",
             "gamma^mu Omega_mu = 3 H gamma^(x0) exactly")
```

The sum $\gamma^\mu \Omega_\mu$, compared with $3H\gamma^{(0)}$. Output: the formula line and two PASS lines with their `reproduces` lines.

In [3], the rescaling removes the term.

```
w = sp.sin(z) ** sp.Rational(-1, 2)  # the rescaling factor sin(z)^(-1/2)
check_record(is_zero(sp.tan(z) * sp.diff(w, x[0]) + 3 * H * w),
             "tan z d0 sin(z)^(-1/2) = -3 H sin(z)^(-1/2)", SCOPE,
             "rescaling_removes_the_connection_term",
             "(tan z (-3 H sin^(-1/2) z) + 3 H sin^(-1/2) z) gamma^(x0) chi = 0")
```

The one-line identity $\tan z \, \partial_0 w = -3Hw$ of Section 8.30, with the record's text of the same identity.

```
chi = sp.Matrix([sp.Function(f"chi{A}")(*x) for A in range(1, 17)])  # arbitrary
Psi = w * chi
D_Psi = sum((gamma_up[mu] * (sp.diff(Psi, x[mu]) + Omega[mu] * Psi)
             for mu in range(8)), sp.zeros(16, 1))  # gamma^mu D_mu Psi
D_chi = sum((gamma_up[mu] * sp.diff(chi, x[mu]) for mu in range(8)),
            sp.zeros(16, 1))  # gamma^mu d_mu chi (no connection)
```

```
check_record(all(is_zero(v) for v in D_Psi - w * D_chi),
             "gamma^mu D_mu (w chi) = w gamma^mu d_mu chi for 16 arbitrary functions",
             SCOPE, "rescaling_removes_the_connection_term",
             "the field equation has no spin-connection term: gamma^mu d_mu chi = "
             "(m + U'(S)) chi")
```

`chi` is a column of sixteen unknown functions $\chi_1, \ldots, \chi_{16}$ of all eight coordinates (`*x` passes the eight symbols as arguments); nothing is assumed about them. `Psi` is $w\chi$; `D_Psi` is $\gamma^\mu D_\mu \Psi$ with the connection, `D_chi` is $\gamma^\mu \partial_\mu \chi$ without it (both start from a 16×1 zero column). The check requires $\gamma^\mu D_\mu(w\chi) - w\gamma^\mu \partial_\mu \chi = 0$ in all 16 components, the statement of Section 8.30 for every field.

```
lam, S_chi = sp.symbols("lambda S_chi", real=True)  # S_chi stands for S[chi]
S_Psi = w**2 * S_chi  # S[w chi] = (w chi)^dagger C (w chi) = w^2 S[chi]
check_record(is_zero(lam * S_Psi - lam * S_chi / sp.sin(z)),
             "U = (lambda/2) S^2: lambda S[Psi] = lambda S[chi]/sin z (the new "
             "coupling)", SCOPE, "rescaled_equation_quadratic_potential",
             "gamma^mu d_mu chi = (m + lambda S[chi]/sin z) chi")
y_of_x0 = sp.log(sp.sin(z)) / (6 * H)
check(is_zero(sp.cos(z) * w**2 - sp.cot(z)) and
      is_zero(sp.diff(y_of_x0, x[0]) - sp.cot(z)),
      "cos z w^2 = cot z = dy/dx0: the norm of Psi is the y-norm of chi")
```

The potential: with a symbol `S_chi` for $S[\chi]$, $\lambda S[\Psi] = \lambda w^2 S[\chi]$ is compared with $\lambda S[\chi]/\sin z$. The measure: $\cos z\, w^2 = \cot z = dy/dx_0$. Output: four PASS lines, three with `reproduces` lines.

In [4], the rescaling factors and the hidden coordinate.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
H_record = parameters["physics"]["H"]  # the author's constant H of the record
L_tip = parameters["physics"]["L_tipCutoff"]  # the record cuts the tip at y = -L
z_cut = np.arcsin(np.exp(-6 * H_record * L_tip))  # the z at which y = -L
report("H and the tip cutoff L of the Kohn-Sham record", f"{H_record}, {L_tip}")
report("z at the tip cutoff, arcsin(e^(-6 H L))", f"{z_cut:.6e}")
check(H_record == 1.0 and abs(np.log(np.sin(z_cut)) / (6 * H_record) + L_tip) < 1e-12,
      "the record has H = 1, and y(z_cut) = -L",
      record="Revision/kohn_sham/results/parameters.json, physics.H, "
             "physics.L_tipCutoff")
```

H and the tip cutoff L are read from the Kohn-Sham record. The cutoff $y = -L$ means $\ln(\sin z) = -6HL$, so $\sin z = e^{-6HL}$ and $z_{\mathrm{cut}} = \arcsin(e^{-6HL})$ (`np.arcsin` is the inverse sine). The RESULT lines print `1.0, 3.0` and $z_{\mathrm{cut}} = 1.522998 \times 10^{-8}$; the check confirms $H = 1$ and that $y(z_{\mathrm{cut}}) = -L$ to 10^{-12}.

```
zs = np.linspace(0.01, np.pi / 2, 400)
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(zs, np.sin(zs) ** -0.5, label="rescaling factor $\\sin^{-1/2}z$")
left.plot(zs, 1 / np.sin(zs), "--", label="coupling factor $1/\\sin z$")
left.set_yscale("log")
left.set_xlabel("$z = 6Hx_0$ (tip at 0, patch end at $\\pi/2$)")
```

```
left.set_ylabel("factor")
left.set_title("The rescaling $\\Psi = \\sin^{-1/2}z\\,\\chi$")
left.legend()
```

The left panel draws the two factors $\sin^{-1/2} z$ and $1/\sin z$ for 400 values of z from 0.01 to $\pi/2$ on a logarithmic axis.

```
mantissa, exponent = f"{z_cut:.1e}".split("e")  # "1.5e-08" -> "1.5" and "-08"
exponent = int(exponent)  # -8, for the caption
z_log = np.logspace(-10.0, np.log10(np.pi / 2), 400)  # 10^-10 ... pi/2, log spaced
right.semilogx(z_log, np.log(np.sin(z_log)) / (6 * H_record), color="tab:green")
right.axhline(-L_tip, color="gray", linestyle=":", linewidth=0.9)
right.plot([z_cut], [-L_tip], "o", color="black")  # where y reaches the cutoff
right.text(2e-8, -L_tip + 0.15, "tip cutoff $y = -L$ of the Kohn-Sham record",
           fontsize=8)
```

The cutoff value is written with one decimal in powers of ten and split at the letter `e` into the two parts that the caption prints (`1.5` and `-8`). The right panel draws $y = \ln(\sin z)/(6H)$ for 400 values of z from 10^{-10} to $\pi/2$, equally spaced on a logarithmic axis (`semilogx`; `np.log10` is the base-10 logarithm), a dotted line at $y = -L$, a black dot where y reaches it, and a label.

```
right.set_xlabel("$z = 6Hx_0$ (logarithmic axis)")
right.set_ylabel("$y = \\ln(\\sin z)/(6H)$")
right.set_title("The hidden coordinate $y$, $H = 1$")
save_figure(fig, "rescaling_factors",
            "Left, on a logarithmic axis, against $z = 6Hx_0$ from the tip (near 0) "
            ...
            "lies in a tiny neighbourhood of the tip.")
```

Labels, a title, and Figure 08d.1; the caption is an f-string, so the values read from the record ($y = -3$, $\arcsin(e^{-18}) \approx 1.5 \times 10^{-8}$) are put in when the cell runs. Output: two RESULT lines, one PASS line with its `reproduces` line, the figure line.

What Figure 08d.1 shows. Left: the two factors (pure numbers, logarithmic vertical axis) against z from 0.01 to $\pi/2$: the rescaling factor $\sin^{-1/2} z$ falls from 10 to 1, the coupling factor $1/\sin z$ from 100 to 1; both equal 1 at the patch end and grow without bound towards the tip. Right: the hidden coordinate y (vertical, units of $1/H$) against z on a logarithmic axis from 10^{-10} to $\pi/2$: an almost straight line from about -3.84 up to 0 (because $\sin z \approx z$ for small z, $y \approx \ln(z)/6$ is a straight line on this axis), with the cutoff $y = -3$ reached at $z \approx 1.5 \times 10^{-8}$. The student should see that almost the whole range of y used by the Kohn-Sham record lies in a tiny neighbourhood of the tip.

In [5], the exact family.

```
alpha = sp.Symbol("alpha", real=True)
c = 3 * H * (2 * alpha + 1)
k = sp.sqrt(c**2 - m**2)  # k^2 = 9 H^2 (2 alpha + 1)^2 - m^2
M = -m * G[4] + c * G[4] * G[0]
check_record((M * M - (c**2 - m**2) * sp.eye(16)).applyfunc(sp.expand)
             == sp.zeros(16, 16)
```

```
            and (M.T * C + C * M).applyfunc(sp.expand) == sp.zeros(16, 16),
            "M^2 = (9 H^2 (2 alpha + 1)^2 - m^2) I16 and M^T C + C M = 0",
            THEORY, "exact_solution_family_x4_x0",
            "M = -m gamma^(x4) + 3 H (2 alpha + 1) gamma^(x4) gamma^(x0)",
            "k^2 = 9 H^2 (2 alpha + 1)^2 - m^2", "(M^2 = k^2 I16, M^T C + C M = 0")
```

The exponent α, the number $c = 3H(2\alpha+1)$, k and the matrix M of Section 8.31. The check confirms $M^2 = (c^2 - m^2)I_{16}$ (derived in Section 8.31) and $M^T C + CM = 0$; the second property means that the scalar $S = \Psi^\dagger C \Psi$ of a member does not change in time, because $\frac{d}{dx_4}(e^{M^T x_4} C e^{M x_4}) = e^{M^T x_4}(M^T C + CM)e^{M x_4} = 0$ (M is real). The record's detail must contain the three texts.

```
chi0 = sp.Matrix(sp.symbols("q1:17"))  # 16 arbitrary constants
family = sp.sin(z) ** alpha * (sp.cosh(k * x[4]) * chi0
                               + sp.sinh(k * x[4]) / k * (M * chi0))
residual = sum((gamma_up[mu] * (sp.diff(family, x[mu]) + Omega[mu] * family)
                for mu in range(8)), sp.zeros(16, 1)) - m * family
check_record(all(is_zero(v) for v in residual),
            "Psi = sin(z)^alpha (cosh(k x4) + sinh(k x4)/k M) chi0 solves the field "
            "equation", THEORY, "exact_solution_family_x4_x0",
            "solves gamma^mu D_mu Psi = m Psi exactly for every a4(x4) and every "
            "alpha")
```

χ_0 is a column of sixteen symbols `q1`, ..., `q16` (arbitrary constants). `family` is the member $\sin^\alpha z(\cosh(kx_4)\chi_0 + \frac{\sinh(kx_4)}{k} M\chi_0)$, and `residual` is $\gamma^\mu D_\mu \Psi - m\Psi$ with the full connection, summed over all eight directions; every entry must vanish, for symbolic α, m, H and every a_4.

```
M_half = M.subs(alpha, -sp.Rational(1, 2))
check_record(not M_half.has(H)
            and sp.expand(k.subs(alpha, -sp.Rational(1, 2)) ** 2) == -m**2,
            "alpha = -1/2: M = -m gamma^(x4) has no H and k^2 = -m^2 (oscillation)",
            SCOPE, "rescaled_equation_quadratic_potential",
            "= -m gamma^(x4) and k^2 = -m^2 (no H)")
```

At $\alpha = -\frac{1}{2}$, M contains no H and $k^2 = -m^2$: the rescaled field of Section 8.30. Output: three PASS lines with their `reproduces` lines.

In [6], which members grow and which have a finite norm.

```
s, p, eps = sp.symbols("s p epsilon", positive=True)
check(sp.integrate(s ** (p - 1), (s, 0, 1)) == 1 / p and
      sp.limit(sp.integrate(1 / s, (s, eps, 1)), eps, 0, "+") == sp.oo,
      "int_0^1 s^(2 alpha) ds = 1/(2 alpha + 1) for 2 alpha + 1 > 0; diverges at -1/2")
```

With $p = 2\alpha + 1 > 0$, sympy integrates $s^{p-1} = s^{2\alpha}$ from 0 to 1 and finds $1/p$; and the integral of $1/s$ from ϵ to 1 goes to infinity (`sp.oo`) as $\epsilon \to 0$ from above (`"+"`): the two integrals of Section 8.31.

```
k2_every_mass = sp.factor(sp.expand((c**2 - m**2).subs(alpha, m / (3 * H))))
say(f"k^2 at alpha = m/(3H): {k2_every_mass}")
check(sp.expand(k2_every_mass - 3 * (m + H) * (m + 3 * H)) == 0,
      "alpha = m/(3H) > -1/2 gives k^2 = 3 (m + H)(m + 3H) > 0 for every m > 0")
```

At $\alpha = m/(3H)$ sympy factors k^2 and prints `3*(H + m)*(3*H + m)`; the check compares with $3(m+H)(m+3H)$.

```
alphas = np.linspace(-2.0, 1.0, 601)
fig, ax = plt.subplots()
for mass, style in ((1.0, "-"), (2.0, "--"), (4.0, ":")):
    ax.plot(alphas, 9 * (2 * alphas + 1) ** 2 - mass**2, style, label=f"$m = {mass:g}H$")
    ax.plot([-0.5, 0.0], [-mass**2, 9 - mass**2], "o", color="black", markersize=4)
ax.axhline(0.0, color="black", linewidth=0.8)
ax.axvspan(-2.0, -0.5, color="gray", alpha=0.15)
ax.text(-1.4, 66, "infinite norm\nat the tip", fontsize=8)
ax.text(0.05, 66, "grows where\n$k^2 > 0$", fontsize=8)
```

For three masses ($H = 1$) the parabola $k^2 = 9(2\alpha+1)^2 - m^2$ is drawn against α from -2 to 1, with black dots at $\alpha = -\frac{1}{2}$ ($k^2 = -m^2$) and $\alpha = 0$ ($k^2 = 9 - m^2$); `axvspan` shades the band $\alpha \le -\frac{1}{2}$ light gray (here `alpha=0.15` is matplotlib's transparency, not the exponent).

```
ax.set_ylim(-20.0, 80.0)
ax.set_xlabel("exponent $\\alpha$ of $\\sin^{\\alpha}z$")
ax.set_ylabel("$k^2 = 9H^2(2\\alpha + 1)^2 - m^2$ (units of $H^2$)")
ax.set_title("The exact family $\\sin^\\alpha z\\,e^{Mx_4}\\chi_0$, $H = 1$")
ax.legend(loc="upper center");
save_figure(fig, "family_k_squared",
            "The number $k^2 = 9H^2(2\\alpha + 1)^2 - m^2$ of the exact family of "
            ...
            "finite norm grows.")
```

The vertical range, labels, and Figure 08d.2. Output: two PASS lines, the factored k^2, the figure line.

What Figure 08d.2 shows. The number k^2 (vertical, units of H^2) against the exponent α (horizontal) for $m = H, 2H, 4H$: three upward parabolas with their lowest point $-m^2$ at $\alpha = -\frac{1}{2}$ (black dots at -1, -4, -16); at $\alpha = 0$ the dots are at 8, 5 and -7. The shaded band $\alpha \le -\frac{1}{2}$ is where the norm diverges at the tip. The student should see that to the right of the band every parabola eventually becomes positive: for every mass, some members with a finite norm grow; and that the x_0-independent member $\alpha = 0$ grows for $m = H$ and $2H$ but not for $4H$.

In [7], the plane of mass and exponent.

```
masses = np.linspace(0.0, 6.0, 301)
A_grid, M_grid = np.meshgrid(np.linspace(-1.0, 1.5, 251), masses)
grows = 9 * (2 * A_grid + 1) ** 2 - M_grid**2 > 0
finite = A_grid > -0.5
region = np.where(grows & finite, 2, np.where(grows, 1, 0))  # 2, 1 or 0
```

A grid of 301 masses (0 to $6H$) and 251 exponents (-1 to 1.5). `grows` and `finite` are true/false arrays; `&` is "and" for such arrays. `region` is 2 where a member grows with a finite norm, 1 where it grows with an infinite norm, and 0 where it oscillates.

```
fig, ax = plt.subplots(figsize=(6.4, 4.6))
ax.contourf(M_grid, A_grid, region, levels=[-0.5, 0.5, 1.5, 2.5],
            colors=["white", "#d9d9d9", "#9ecae1"])
ax.plot(masses, (masses / 3 - 1) / 2, color="black", linewidth=1.0)
ax.axhline(-0.5, color="gray", linestyle="--", linewidth=0.9)
ax.axhline(0.0, color="tab:red", linewidth=1.2)
ax.plot([3.0], [0.0], "o", color="tab:red")
ax.text(0.2, 1.2, "grows, finite norm", fontsize=9)
ax.text(4.2, -0.2, "oscillates", fontsize=9)
ax.text(0.2, -0.9, "grows, infinite norm", fontsize=9)
ax.text(3.1, 0.05, "$\\alpha = 0$: grows for $m < 3H$", fontsize=8, color="tab:red")
ax.set_xlabel("mass $m$ (units of $H$)")
ax.set_ylabel("exponent $\\alpha$")
ax.set_title("Members of the family that grow and have a finite norm")
```

`contourf` fills the three regions with white, light gray and light blue (colours given as hexadecimal codes, `"#9ecae1"`). The black line is $2\alpha + 1 = m/(3H)$, that is $\alpha = (m/3 - 1)/2$ for $H = 1$; the gray dashed line is $\alpha = -\frac{1}{2}$; the red line is $\alpha = 0$, with a red dot at $m = 3H$; four labels.

```
fraction = float(np.mean(grows & finite))
report("fraction of the drawn (m, alpha) rectangle that grows with finite norm",
       f"{fraction:.4f}")
check(all(np.any(grows[i] & finite[i]) for i in range(len(masses))),
      "for every drawn mass some alpha gives a growing finite-norm member")
save_figure(fig, "growing_finite_norm",
            "The plane of the mass $m$ (horizontal, units of $H$) and the exponent "
            ...
            "every mass has growing finite-norm members.")
```

The fraction of the drawn rectangle where members grow with a finite norm is printed (0.5996). The check requires, for each of the 301 masses (each row `i` of the grid), at least one exponent with a growing finite-norm member (`np.any` is true when at least one entry is). Figure 08d.3. Output: one RESULT line, one PASS line, the figure line.

What Figure 08d.3 shows. The plane of the mass m (horizontal, 0 to $6H$) and the exponent α (vertical, -1 to 1.5). Light blue, above the rising black line $2\alpha + 1 = m/(3H)$: growing members with a finite norm. Light gray, a wedge below the dashed line $\alpha = -\frac{1}{2}$ at small masses: growing members whose norm diverges at the tip. White: oscillating members. The red line $\alpha = 0$ lies in the blue region exactly for $m < 3H$ (red dot). The student should see that every vertical line (every mass) meets the blue region.

In [8], the modes that do not depend on x_0.

```
A = -sp.I * m * G[4] + 3 * sp.I * H * G[4] * G[0]
A_squared = (A * A).applyfunc(sp.expand)
A_one = A.subs({m: 1, H: 1})
dimension = 16 - (A_one - 2 * sp.sqrt(2) * sp.I * sp.eye(16)).rank()
norm_factor = sp.integrate(sp.cos(6 * H * x[0]), (x[0], 0, sp.pi / (12 * H)))
report("dimension of the eigenspace of +2 sqrt(2) i at m = H = 1", dimension)
report("int_0^(pi/(12H)) cos(6 H x0) dx0", norm_factor)
```

The matrix $A = -im\gamma^{(4)} + 3iH\gamma^{(4)}\gamma^{(0)}$ of Section 8.32, its square, its value at $m = H = 1$, the dimension of the eigenspace of $+2\sqrt{2}\,i$ (16 minus a rank, as in Notebook 08a), and the norm factor $\int_0^{\pi/(12H)} \cos(6Hx_0)\,dx_0$ integrated exactly. RESULT lines: 8 and `1/(6*H)`.

```
all_true = ((A - sp.I * M.subs(alpha, 0)).applyfunc(sp.expand) == sp.zeros(16, 16)
            and A != A.H
            and A_squared == ((m**2 - 9 * H**2) * sp.eye(16)).applyfunc(sp.expand)
            and A_one * A_one == -8 * sp.eye(16) and A_one.trace() == 0
            and dimension == 8 and sp.simplify(norm_factor - 1 / (6 * H)) == 0)
# The record states the same matrix, square, eigenvalues and norm in its text:
check_record(all_true,
             "A = -i m g4 + 3 i H g4 g0: not Hermitian, A^2 = (m^2 - 9H^2) I16, "
             "eigenvalues +-2 sqrt(2) i at m = H = 1, finite norm 1/(6H)",
             SCOPE, "good_sector_x0_independent_modes_without_boundary_condition",
             f"cos(6 H x0) dx0 = {sp.sstr(norm_factor)})",
             "A = -i m gamma^(x4) + 3 i H gamma^(x4) gamma^(x0)",
             "A^2 = (m^2 - 9 H^2) I16 exactly",
             f"the eigenvalues are +-2 sqrt(2) i ({dimension} each)")
```

Seven facts in one condition: $A = iM$ at $\alpha = 0$; A is not Hermitian ($A \neq A^\dagger$); $A^2 = (m^2 - 9H^2)I_{16}$; at $m = H = 1$, $A^2 = -8I_{16}$ and the trace is 0 (so the eigenvalues are $\pm 2\sqrt{2}\,i$, eight each, as in Section 8.17); the eigenspace dimension is 8; and the norm factor is $1/(6H)$. The record's detail must contain the four texts. Output: two RESULT lines and one PASS line with its `reproduces` line.

In [9], the eigenvalues of A against the mass.

```
A_number = sp.lambdify((m, H), A, "numpy")
mass_path = np.linspace(0.0, 5.0, 51)
points = np.concatenate([np.linalg.eigvals(np.array(A_number(mv, 1.0), dtype=complex))
                         for mv in mass_path])
largest_growth = max(abs(points.imag))
report("largest |imaginary part| on the path (reached at m = 0)",
       f"{largest_growth:.9f}")
check(abs(largest_growth - 3.0) < 1e-9, "at m = 0 the growth rate is 3H")
```

`A_number` is a numerical function of m and H. For 51 masses from 0 to 5 (with $H = 1$) the 16 eigenvalues are computed and joined; the largest imaginary part, reached at $m = 0$ where the eigenvalues are $\pm 3i$, is printed as 3.000000000, and the check requires $3H$ to 10^{-9}.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
dots = left.scatter(points.real, points.imag, c=np.repeat(mass_path, 16),
                    cmap="plasma", s=20)
fig.colorbar(dots, ax=left, label="mass $m$ (units of $H$)")
left.set_aspect("equal")
left.set_xlim(-4.5, 4.5)
left.set_ylim(-4.5, 4.5)
left.set_xlabel("real part")
left.set_ylabel("imaginary part")
left.set_title("Eigenvalues of $A$, $H = 1$")
```

The left panel draws the eigenvalues in the complex plane, coloured by the mass, with equal scales on both axes.

```
mass_fine = np.linspace(0.0, 5.0, 501)  # a finer grid for the smooth curves
for a_value, style in ((0.0, "-"), (0.5, "--"), (1.0, ":")):
    rate = np.sqrt(np.maximum(9 * (2 * a_value + 1) ** 2 - mass_fine**2, 0.0))
    right.plot(mass_fine, rate, style, label=f"$\\alpha = {a_value:g}$")
right.axvline(3.0, color="gray", linewidth=0.8)
right.set_xlabel("mass $m$ (units of $H$)")
right.set_ylabel("growth rate $k$ (units of $H$)")
right.set_title("Growth rates of the family")
right.legend();
save_figure(fig, "patch_end_modes",
            "Left: the eigenvalues $\\pm\\sqrt{m^2 - 9H^2}$ of the matrix $A = "
            ...
            "line).")
```

The right panel draws the growth rate $k = \sqrt{9(2\alpha+1)^2 - m^2}$ (0 where the bracket is negative) of the members $\alpha = 0, 0.5, 1$ against the mass, with a gray vertical line at $m = 3H$. Figure 08d.4. Output: one RESULT line, one PASS line, the figure line.

What Figure 08d.4 shows. Left: the eigenvalues of A (units of H) in the complex plane, coloured by the mass from 0 to $5H$: for small masses they sit on the imaginary axis at $\pm 3i$ (dark), move towards 0 as m grows, meet at 0 for $m = 3H$, and then move out along the real axis to ± 4 at $m = 5H$ ($\sqrt{25-9} = 4$). Right: the growth rates (units of H) against the mass: the member $\alpha = 0$ falls from 3 to 0 at $m = 3H$ (gray line) and stays 0; the members $\alpha = 0.5$ and $\alpha = 1$ start at 6 and 9 and still grow at $m = 5H$ (about 3.3 and 7.5). The student should see that the x_0-independent modes stop growing above $m = 3H$, but members that vary along x_0 do not.

In [10], the boundary term at the patch end.

```
M0 = sp.I * G[4] * G[0]
d0_coefficient = sp.I * sp.tan(z) * G[4] * G[0]  # the matrix in front of d0 in h
fact_1 = all(is_zero(v) for v in sp.cos(z) * d0_coefficient - sp.sin(z) * M0)
fact_2 = all(is_zero(v) for v in sp.cos(z) * (A - A.H) - sp.diff(sp.sin(z), x[0]) * M0)
fact_3 = (d0_coefficient + d0_coefficient.H).applyfunc(sp.simplify) == sp.zeros(16, 16)
```

$M_0 = i\gamma^{(4)}\gamma^{(0)}$ and the coefficient P of ∂_0 in h. The three facts of Section 8.32, in the order of the notebook: $\cos z\, P = \sin z\, M_0$; $\cos z\,(A - A^\dagger) = (\partial_0 \sin z) M_0$; and $P + P^\dagger = 0$.

```
X0 = x[0]
u_col = sp.Matrix([(A_ + 1) + sp.I * (2 * A_ - 3) * X0 + (A_ - 5) * X0**2 / 3
                   for A_ in range(16)])  # a column of polynomials in x0
v_col = sp.Matrix([(3 - A_) * X0 + sp.I * (A_ + 2) + sp.I * A_ * X0**3 / 7
                   for A_ in range(16)])

def h_of(column):
    """The mode operator h applied to a column of functions of x0 (U = 0)."""
    return -sp.I * m * G[4] * column + sp.I * G[4] * G[0] * (
        sp.tan(z) * sp.diff(column, X0) + 3 * H * column)
```

Two explicit columns of polynomials in x_0 with complex coefficients that differ from entry to entry (the loop variable `A_` runs from 0 to 15; its name has an underscore so that it does not overwrite the matrix `A`), and the mode operator h applied to a column.

```
left_side = sp.cos(z) * ((u_col.H * h_of(v_col))[0] - (h_of(u_col).H * v_col)[0])
right_side = sp.diff(sp.sin(z) * (u_col.H * M0 * v_col)[0], X0)
u0 = (G[4] * G[0] - sp.eye(16)).nullspace()[0]  # gamma^(4) gamma^(0) u0 = u0
flux = sp.simplify((u0.H * M0 * u0)[0])
size_u0 = (u0.H * u0)[0]
report("u0^dagger M0 u0 and u0^dagger u0", f"{flux}, {size_u0}")
```

The two sides of the boundary identity for these columns (a row times a column is a 1×1 matrix, and `[0]` takes its entry). `nullspace()` returns a list of independent columns u with $(\gamma^{(4)}\gamma^{(0)} - I)u = 0$; the first one is `u0`. RESULT: $u_0^\dagger M_0 u_0 = 2i$ (sympy writes `2*I`) and $u_0^\dagger u_0 = 2$.

```
# The record states the same identity and the same flux (sympy writes i as I):
check_record(fact_1 and fact_2 and fact_3 and is_zero(left_side - right_side)
             and flux == 2 * sp.I and size_u0 == 2,
             "cos z (u^dagger h v - (h u)^dagger v) = d0(sin z u^dagger M0 v); at "
             "z = pi/2 the flux u0^dagger M0 u0 = 2 i is not zero",
             SCOPE, "good_sector_hermiticity_up_to_the_brane_flux",
             "cos z [u^dagger (h v) - (h u)^dagger v] = d_x0(sin z u^dagger M0 v)",
             f"u^dagger M0 u = {sp.sstr(flux)} (|u|^2 = {sp.sstr(size_u0)})")
```

The check combines the three facts, the identity for the two columns, and the flux; the record's detail must contain the identity and the same flux. (The record proves the identity for all columns; here it is confirmed on one explicit pair, and the three facts are what make it general, Section 8.32.) Output: one RESULT line and one PASS line with its `reproduces` line.

In [11], a growing mode is fed through the patch end.

```
A_num = np.array(A_number(1.0, 1.0), dtype=complex)  # m = H = 1
g4g0 = np.array(G[4] * G[0], dtype=float)  # real symmetric
rng = np.random.default_rng(12345)  # fixed seed: the same column in every run
chi_start = rng.normal(size=16) + 1j * rng.normal(size=16)
chi_start = chi_start / np.linalg.norm(chi_start)
omega = np.sqrt(complex(1.0 - 9.0))  # A^2 = (m^2 - 9 H^2) = -8: omega = 2 sqrt(2) i
times = np.linspace(0.0, 1.5, 151)
```

The matrix A at $m = H = 1$, the real symmetric matrix $\gamma^{(4)}\gamma^{(0)}$, a random starting column of size 1 (fixed seed, as in Notebook 08a), the frequency $\omega = \sqrt{m^2 - 9H^2} = \sqrt{-8} = 2\sqrt{2}\,i$ (here the name `omega` is a frequency, not the spin connection), and 151 times from 0 to 1.5.

```
norms, slopes, fluxes = [], [], []
for x4 in times:
    state = np.cos(omega * x4) * chi_start \
        - 1j * np.sin(omega * x4) / omega * (A_num @ chi_start)  # e^(-i A x4) chi
    norms.append(np.vdot(state, state).real / 6.0)  # N = Psi^dagger Psi / (6 H)
    slopes.append(2 * np.vdot(state, -1j * (A_num @ state)).real / 6.0)  # dN/dx4
    fluxes.append(np.vdot(state, g4g0 @ state).real)  # flux at z = pi/2
norms, slopes, fluxes = map(np.array, (norms, slopes, fluxes))
```

At each time the mode $\Psi = e^{-iAx_4}\chi_0$ is computed with the closed formula of Section 8.18 (valid because $A^2 = \omega^2 I_{16}$). Three numbers are recorded: the norm $N = \Psi^\dagger\Psi/(6H)$; its rate of change $dN/dx_4 = 2\,\mathrm{Re}(\Psi^\dagger(-iA\Psi))/(6H)$ (the derivative of $\Psi^\dagger\Psi$ is twice the real part of $\Psi^\dagger\partial_4\Psi$, and $\partial_4\Psi = -iA\Psi$); and the flux $\Psi^\dagger\gamma^{(4)}\gamma^{(0)}\Psi$ at the patch end (a field that does not depend on x_0 has the same value there). `map(np.array, ...)` turns the three lists into arrays.

```
agreement = np.max(np.abs(slopes - fluxes) / np.maximum(np.abs(fluxes), 1.0))
check(agreement < 1e-12, "dN/dx4 equals the flux through the patch end at every x4")
report("N(1.5) / N(0)", f"{norms[-1] / norms[0]:.6e}")
check(norms[-1] / norms[0] > 100.0, "the norm grows by more than a factor 100")
```

The check requires dN/dx_4 to equal the flux at all 151 times, to 10^{-12} relative to $\max(|\text{flux}|, 1)$: the result of Section 8.32. The RESULT line prints $N(1.5)/N(0) = 2.094786 \times 10^3$, and the second check requires growth by more than 100.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.semilogy(times, norms)
left.set_xlabel("time $x_4$ (units of $1/H$)")
left.set_ylabel("norm $N(x_4)$")
left.set_title("The $x_0$-independent mode, $m = H = 1$")
right.plot(times, slopes, label="$dN/dx_4$")
right.plot(times[::10], fluxes[::10], "o", color="black", markersize=4,
           label="flux at $z = \\pi/2$")
right.axhline(0.0, color="black", linewidth=0.8)
right.set_yscale("symlog", linthresh=1.0)  # linear between -1 and 1, log outside
right.set_ylim(-1.5, 3.0e3)
right.set_xlabel("time $x_4$ (units of $1/H$)")
right.set_ylabel("rate (units of $H$)")
right.set_title("Rate of change of the norm = flux")
right.legend();
save_figure(fig, "norm_and_flux",
            "An $x_0$-independent mode of the good sector, $\\Psi = e^{-iAx_4}"
            ...
            "condition.")
```

Left: the norm on a logarithmic axis. Right: dN/dx_4 as a line and every tenth flux value as a black dot, on a symmetric logarithmic axis that is linear between -1 and 1, so that the short negative phase is visible. Figure 08d.5. Output: two PASS lines, one RESULT line, the figure line.

What Figure 08d.5 shows. Left: the norm N (logarithmic vertical axis) against the time x_4 from 0 to 1.5 (units of $1/H$): it starts at $1/6$, dips a little during the first tenth of a unit, and then rises along a straight line (growth like $e^{4\sqrt{2}\,x_4}$, twice the rate $2\sqrt{2}$ of the column) to about 350. Right: the rate of change dN/dx_4 (line) and the flux through the patch end (dots), in units of H: slightly negative at the start, zero near $x_4 \approx 0.05$, then rising to about 2000. The student should see the dots lie exactly on the line: the norm changes only through the patch end, where the Revision record imposes no boundary condition.

In [12], the last check.

```
for name in ("08d_1_rescaling_factors.png", "08d_2_family_k_squared.png",
             "08d_3_growing_finite_norm.png", "08d_4_patch_end_modes.png",
```

```
            "08d_5_norm_and_flux.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

Five checks that the figure files exist, and the last line. The 23 checks come from the cells as follows: two in In [2], four in In [3], one in In [4], three in In [5], two in In [6], one each in In [7], In [8], In [9] and In [10], two in In [11] and five here. The last line reads `ALL 23 CHECKS PASSED (notebook 08d)`.

8.37 The exact scope of non-triviality and of the evolution, in one table

Every statement of the chapter in one place. The last column names the Revision check, the short name of its report file in brackets, and the notebook that reproduces it. The report files are these:

```
Revision/theory/reports/python-field-theory.json     (python-field-theory)
Revision/theory/reports/wolfram-field-theory.json    (wolfram-field-theory)
Revision/theory/reports/python-scope.json            (python-scope)
Revision/theory/reports/wolfram-scope.json           (wolfram-scope)
Revision/pairing/reports/python-pairing.json         (python-pairing)
Revision/theory/reports/python-field-theory-b4.json  (python-field-theory-b4)
```

The rows that concern the metric are statements at $b_4 = 1$, as in the scope reports (Section 8.1, "The metric with b_4"); the last two rows give the general-b_4 forms.

which boundary condition at $z = \pi/2$ is physical; a well-posed formulation of the full field equation	OPEN	none imposed in the record

8.38 What we proved, what we computed, what we assumed

PROVED in this chapter, line by line (and in the Revision record, with the file and check named in the section):

- The canonical spin connection of the diagonal frame: the rule $\omega_\mu{}^a{}_b = (f_a/f_b)\Gamma^a{}_{\mu b}$ for $a \neq b$, its 12 independent nonzero components, and the spinor connections Ω_{x_i}, Ω_{x_t}, $\Omega_{x_4} = \Omega_{x_0} = 0$ (Section 8.4).
- $\gamma^\mu \Omega_\mu = 3H\gamma^{(0)}$, direction by direction: the time-direction pieces of the three inflating and the three deflating directions cancel, the six hidden-direction pieces add; and the divergence form $\gamma^\mu \Omega_\mu = \frac{1}{2\sqrt{|g|}} \partial_\mu (\sqrt{|g|}\gamma^\mu)$ (Section 8.5).
- $\Omega_\mu = 0$ for every μ if and only if $a_4' = 0$ and $H = 0$; $3H\gamma^{(0)}\Psi \neq 0$ for every $\Psi \neq 0$ (Section 8.6). The term contains no a_4, while $R^{x_4}{}_{x_4} = 6(a_4')^2$ and $R = 6((a_4')^2 - 7H^2)$ (Section 8.7).
- $\{\gamma^\mu, \Omega_\mu\} = 0$ for each μ; the connection drops out of the Lagrangian, and the Euler-Lagrange

equation of the connection-free symmetric Lagrangian contains the same term as its half-density term (Section 8.8).

- The boost keeps the metric; the spin transformation $S = e^{-(b/2)\gamma^{(4)}\gamma^{(0)}}$ moves the gammas of the boosted frame; the connection of the boosted frame and the formula $\gamma'^{\mu}\Omega'_{\mu} = \frac{6H-\beta}{2}(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)})$, zero for $\beta = 6H$ (Sections 8.3 and 8.9).

- $F' = SFS^{-1}$; $F_{x_1 x_0} \neq 0$ in every frame of this kind; the square of the curvature is the same in both frames (Section 8.10). The connection part $\frac{1}{2}e^{a_4}\sin^{1/6} z\, H\, \gamma^{(4)}\gamma^{(1)}\gamma^{(0)}$ of $K^{x_4}{}_{x_1}$ (Section 8.11).

- The Hadamard toy example; the second-order form with the extra-time derivatives of the "wrong" sign; the evolution form (Section 8.16). The mode matrix, $h_k^2 = E^2 I_{16}$, its eigenvalues $\pm E$ eight each, its anti-Hermitian part (Section 8.17). Unbounded growth rates ($\kappa \geq K - c$), the closed solution in time, and the failure of continuous dependence in every Sobolev norm, in flat 4+4 space and with frozen coefficients (Section 8.18); the frequencies of the principal part, which are not real for a wave along an extra time at any point of the author's metric (Section 8.18). Conservation of the Krein form and the Krein-neutrality of the growing eigenspaces (Section 8.19).

- Conserved coordinate wave numbers, growing frame momenta, the exact onset time and its finiteness for every $q_5 > 0$ (Section 8.24). The Krein form $\sigma E_0/m$ of the starting columns and the leading and first-order WKB formulas (Section 8.25).

- The rescaling removes the term for every field, and turns the quadratic potential into $\lambda S[\chi]/\sin z$; the norm becomes $\int \chi^{\dagger}\chi\, dy$ (Section 8.30). The exact family, its growth condition, its finite-norm condition, and a growing finite-norm member for every mass (Section 8.31). The matrix A and its growing modes; the boundary identity; the change of the norm only through the flux at the patch end (Section 8.32).

PROVED in the Revision record and used here without its proof: the Clifford relations and the reality and symmetry of the author's gammas (Chapter 4); the irreducibility of the 16-dimensional representation (commutant dimension 1; Chapter 5); the 25 Christoffel symbols and the Ricci components (Chapter 3); the vielbein postulate and the covariant constancy of the gammas in the diagonal frame; the curvature identity $F = \frac{1}{4}R\gamma\gamma$ in the diagonal frame; $Bh_k = h_k^{\dagger}B$; the Krein inertia (4,4) of every real-frequency eigenspace; the Euler-Lagrange equations of the Grassmann field; and the direct computation of the boosted frame's connection.

COMPUTED by the notebooks (every exact statement is also checked there, and every number reproduces the record where they overlap): Notebook 08c, 32 checks, computes everything of Sections 8.4 to 8.11 exactly with sympy, including the curvature in both frames, and at one point of the history $a_4 = x_4$ the largest curvature entries 0.778093 and 0.038739 ($= e^{-3} \cdot 0.778093$) and ranks 8. Notebook 08a, 30 checks, confirms $h_k^2 = E^2$ exactly, the growth rates against the eigenvalues to 10^{-10}, the closed formula against RK4 to 10^{-9}, the Hadamard ratio (first above 10^6 at $K = 13.9, 19.9, 27.1, 44.2$ for $s = 0, 2, 4, 8$), the Krein drift below 10^{-12}. Notebook 08b, 25 checks, confirms the onset times against bisection to 10^{-12}, RK4 with the error ratio 15.89 and accuracy 10^{-8}, the WKB agreement (1.03×10^{-3}, 2.48×10^{-4}, late rate 10^{-5}), the slow growth of the size before the onset (to $u^{\dagger}u = 1.52$ and 1.54 at the onset), and growth to $u^{\dagger}u \approx 1.26 \times 10^{16}$ with the Krein drift below 10^{-9}. Notebook 08d, 23 checks, proves the rescaling for arbitrary functions, the

family for symbolic α, the boundary identity on explicit columns, and finds $N(1.5)/N(0) = 2094.786$ with dN/dx_4 equal to the flux to 10^{-12}. Run times: 08a and 08b run in well under a minute, 08c and 08d in one to two minutes; the provenance file of each notebook (in the folder `Revision/textbook/notebooks`, named after the notebook, for example `08c_frame_dependence.PROVENANCE.md`) records the times measured on the build computer in its build and check runs, which depend on how busy that computer is.

ASSUMED, chosen, or an interpretation. The history $a_4 = AHx_4$ with $A = H = m = 1$ is a PRESCRIBED BACKGROUND (the Kohn-Sham record's own label); every exact identity of the chapter holds for every history. The second function of the metric is put equal to $b_4 = 1$ in every exact check of this chapter, as in the Revision record's scope reports; the general-b_4 forms of the gravitational term and of the non-triviality statement are quoted from Chapters 6 and 7 (Sections 8.1 and 8.37). Frozen coefficients (Sections 8.17 to 8.19) and the local-frame model (Section 8.25) are labelled MODEL: they describe a wave near one point, not exact solutions of the field equation in the author's metric. Facts taken from Chapter 6 (where local spin covariance is proved): the canonical spin connection of every frame makes its gammas covariantly constant and is a combination of the S^{ab}. Standard theorems quoted without proof: the Lax-Mizohata theorem, which carries the failure of well-posedness from frozen coefficients to the author's varying coefficients (Section 8.18; so that conclusion is ASSUMED, not PROVED, and the record does not check it); the general curvature identity $F = \frac{1}{4}R\gamma\gamma$ in every frame (proved for this metric by the record); the trace of a matrix is the sum of its eigenvalues; the dimension of an eigenspace is 16 minus the rank of $h - \lambda I$. Treating $\bar{\Psi}$ and Ψ as independent variables in the Euler-Lagrange equations is the method of Chapter 7. Two statements are interpretations, labelled as such: that the role of the term $3H$ depends on the variables and the measure (Section 8.30), and that the growth of the good-sector modes is "fed through the patch end" (Section 8.32).

OPEN. Which boundary condition at the patch end $z = \pi/2$ is physical (the Kohn-Sham record ASSUMES a Z_2 brane there; this record imposes none). Whether and how the full field equation can be given a well-posed evolution: restricting to the good sector removes the extra-time growth but is a choice, not a consequence, and even the good sector needs a boundary condition. A positive-norm quantum theory of the full field with the growing modes present, and a stable vacuum, are not constructed (Chapter 10 states what is). Whether the frame-dependent term $3H\gamma^{(0)}$ has any observable effect is not claimed.

8.39 Exercises

Exercise 1. At $b_4 = 1$, compute $\gamma^{x_6}\Omega_{x_6}$ directly from $\Omega_{x_6} = -\frac{1}{2}e^{-a_4}\sin^{1/6} z\,(a_4'\gamma^{(4)}\gamma^{(6)} + H\gamma^{(6)}\gamma^{(0)})$, line by line.

Answer. $\gamma^{x_6} = \gamma^{(6)}/f_6$ with $f_6 = e^{-a_4}\sin^{1/6} z$. Then $\gamma^{x_6}\Omega_{x_6} = -\frac{1}{2}(a_4'\gamma^{(6)}\gamma^{(4)}\gamma^{(6)} + H\gamma^{(6)}\gamma^{(6)}\gamma^{(0)})$ (the scale factors cancel). Anticommuting $\gamma^{(6)}$ past $\gamma^{(4)}$: $\gamma^{(6)}\gamma^{(4)}\gamma^{(6)} = -\gamma^{(4)}(\gamma^{(6)})^2 = -\gamma^{(4)}(-I_{16}) = \gamma^{(4)}$; and $(\gamma^{(6)})^2 = -I_{16}$. So $\gamma^{x_6}\Omega_{x_6} = -\frac{1}{2}(a_4'\gamma^{(4)} - H\gamma^{(0)}) = -\frac{1}{2}a_4'\gamma^{(4)} + \frac{1}{2}H\gamma^{(0)}$, the value of every extra time in Section 8.5.

Exercise 2. Suppose the extra times inflated like 3-space, $f_5 = f_6 = f_7 = e^{+a_4}\sin^{1/6} z$ (this is NOT the author's metric). Compute $\gamma^{x_t}\Omega_{x_t}$ and $\gamma^{\mu}\Omega_{\mu}$, and confirm the result with the divergence form.

Answer. Now $g_{tt} = -e^{2a_4}\sin^{1/3} z$, so $\Gamma^{x_t}{}_{x_t x_4} = \partial_4 \ln f_t = +a_4'$ and $\Gamma^{x_4}{}_{x_t x_t} = -\partial_4 g_{tt}/(2g_{44}) = -(2a_4' g_{tt})/(-2) = a_4' g_{tt} = -a_4' f_t^2$. By the rule of Section 8.4, $\omega_{x_t}{}^{(4)}{}_{(t)} = (f_4/f_t)\Gamma^{x_4}{}_{x_t x_t} = -a_4' f_t$,

and lowering with $\eta_{44} = -1$, $\omega_{x_t\,(4)(t)} = +a_4' f_t$ (the opposite sign of the author's metric). The H component is unchanged, $\omega_{x_t\,(t)(0)} = -H f_t$. So $\Omega_{x_t} = \frac{1}{2} f_t (a_4' \gamma^{(4)}\gamma^{(t)} - H\gamma^{(t)}\gamma^{(0)})$, and $\gamma^{x_t}\Omega_{x_t} = \frac{1}{2}(a_4'\gamma^{(t)}\gamma^{(4)}\gamma^{(t)} - H(\gamma^{(t)})^2\gamma^{(0)}) = \frac{1}{2}(a_4'\gamma^{(4)} + H\gamma^{(0)})$, the same as a 3-space direction. The six directions then give $\gamma^\mu\Omega_\mu = 3a_4'\gamma^{(4)} + 3H\gamma^{(0)}$: nothing cancels. Divergence form: $\sqrt{|g|} = e^{6a_4}\cos z$, so $\frac{1}{2\sqrt{|g|}}\partial_4(\sqrt{|g|}\gamma^{(4)}) = \frac{6a_4' e^{6a_4}\cos z}{2e^{6a_4}\cos z}\gamma^{(4)} = 3a_4'\gamma^{(4)}$, and $\frac{1}{2\sqrt{|g|}}\partial_0(e^{6a_4}\sin z\,\gamma^{(0)}) = 3H\gamma^{(0)}$. The cancellation of Section 8.5 happens because in the author's metric the volume factor does not depend on the time.

Exercise 3. (a) Show that $\varphi = \epsilon\cosh(Kx_4)\cos(Kx_5)$ solves $\partial_4^2\varphi = -\partial_5^2\varphi$. (b) For data of largest value ϵ, compute the ratio of the largest value of the solution at $x_4 = 1$ to ϵ for $K = 10$ and $K = 20$. (c) Show that $\varphi = \epsilon\cos(Kx_4)\cos(Kx_1)$ solves the ordinary wave equation $\partial_4^2\varphi = \partial_1^2\varphi$, and compare.

Answer. (a) Section 8.16: both sides equal $\epsilon K^2\cosh(Kx_4)\cos(Kx_5)$. (b) The ratio is $\cosh K$: $\cosh 10 = 11013.2$ and $\cosh 20 = 2.4258\times 10^8$. Doubling K multiplies the amplification by about $e^{10} \approx 22000$; data of the same size give ever larger solutions. (c) $\partial_4^2\varphi = -\epsilon K^2\cos(Kx_4)\cos(Kx_1) = \partial_1^2\varphi$; the largest value stays ϵ at every time, for every K: the ordinary wave equation depends continuously on its data.

Exercise 4. With frozen coefficients and $m = 1$, decide whether the waves oscillate or grow, and give the frequency or the growth rate: (a) $k_1 = 2$, $k_5 = 3$; (b) $k_5 = 2$, $k_0 = 1$; (c) $k_6 = k_7 = 0.5$. (d) With $k_1 = 4$, how large must k_5 be for growth? Compare with Figure 08a.1.

Answer. $E^2 = m^2 + k_1^2 + k_2^2 + k_3^2 + k_0^2 - k_5^2 - k_6^2 - k_7^2$. (a) $E^2 = 1 + 4 - 9 = -4$: growth with $\kappa = 2$. (b) $E^2 = 1 + 1 - 4 = -2$: growth with $\kappa = \sqrt{2} = 1.414214$. (c) $E^2 = 1 - 0.25 - 0.25 = 0.5$: oscillation with $E = \pm 0.707107$. (d) Growth needs $k_5^2 > 1 + 16 = 17$, that is $k_5 > \sqrt{17} = 4.123106$; in the right panel of Figure 08a.1 the dotted curve ($k_1 = 4$) leaves zero there.

Exercise 5. Show that the size $\sqrt{\mathrm{tr}(M^T M)/16}$ of $M = c\,(\cosh b\,\gamma^{(0)} - \sinh b\,\gamma^{(4)})$ is $|c|\sqrt{\cosh 2b}$. Evaluate it for the boosted frame with $\beta = 3H$, $H = 1$, $b_0 = 0$ at $x_4 = 0$, 0.3 and 0.5, and for $\beta = 9H$ at $x_4 = 0.5$, and compare with Figure 08c.3.

Answer. $(\gamma^{(0)})^T = \gamma^{(0)}$ and $(\gamma^{(4)})^T = -\gamma^{(4)}$, so $M^T = c(\cosh b\,\gamma^{(0)} + \sinh b\,\gamma^{(4)})$ and $M^T M = c^2(\cosh^2 b\,(\gamma^{(0)})^2 - \sinh^2 b\,(\gamma^{(4)})^2 + \cosh b\sinh b\,(\gamma^{(4)}\gamma^{(0)} - \gamma^{(0)}\gamma^{(4)})) = c^2((\cosh^2 b + \sinh^2 b)I_{16} + 2\cosh b\sinh b\,\gamma^{(4)}\gamma^{(0)})$. The trace of $\gamma^{(4)}\gamma^{(0)}$ is zero, so $\mathrm{tr}(M^T M)/16 = c^2(\cosh^2 b + \sinh^2 b) = c^2\cosh 2b$ (because $\cosh^2 b + \sinh^2 b = \frac{(e^b+e^{-b})^2+(e^b-e^{-b})^2}{4} = \frac{e^{2b}+e^{-2b}}{2}$). For $\beta = 3H$, $c = (6-3)/2 = 1.5$ and $b = 3x_4$: at $x_4 = 0$ the size is 1.5; at $x_4 = 0.3$ ($b = 0.9$) it is $1.5\sqrt{\cosh 1.8} = 2.644204$; at $x_4 = 0.5$ ($b = 1.5$) it is $1.5\sqrt{\cosh 3} = 4.759437$. For $\beta = 9H$, $|c| = 1.5$, $b = 4.5$: $1.5\sqrt{\cosh 9} = 95.477587$. The orange and red curves of the right panel of Figure 08c.3 end near 4.8 and 95.

Exercise 6. On the history $a_4 = x_4$ ($a_4' = H = 1$), use the coefficients c_{14}, c_{10} printed by Notebook 08c in both frames to show that $F' = e^{-b}F$ and $F^2 = 0$; check the largest entries 0.778093 and 0.038739 at $x_4 = 0.5$.

Answer. Write $Q = e^{a_4}\cos z/(2\sin^{5/6} z)$. Diagonal frame: $c_{14} = -Ha_4'Q = -H^2Q$ and $c_{10} = -H^2Q$, equal. Boosted frame ($b = 6Hx_4 + b_0$): $c_{14}' = H(H\sinh b - a_4'\cosh b)Q = H^2(\sinh b - \cosh b)Q = -H^2e^{-b}Q$ and $c_{10}' = -H(H\cosh b - a_4'\sinh b)Q = -H^2(\cosh b - \sinh b)Q = -H^2e^{-b}Q$, using $\cosh b - \sinh b = e^{-b}$. Both coefficients are e^{-b} times the diagonal ones, and both frames use the same matrices $\gamma^{(1)}\gamma^{(4)}$, $\gamma^{(1)}\gamma^{(0)}$, so $F' = e^{-b}F$. Since $c_{14} = c_{10}$, $F^2 = (c_{14}^2 - c_{10}^2)I_{16} = 0$. At $x_4 = 0.5$, $b_0 = 0$: $b = 3$ and $0.778093\cdot e^{-3} = 0.778093\times 0.049787 = 0.038739$, the printed value.

Exercise 7. Along $a_4 = x_4$ with $m = H = 1$, compute the onset times of the waves (a) $q_1 = 0$, $q_5 = 0.01$, $y = 0$; (b) the same at $y = -3$; (c) $q_1 = 0$, $q_5 = 10^{-4}$, $y = 0$; (d) $q_1 = 1$, $q_5 = 0.05$, $y = 0$.

Answer. For $q_1 = 0$, $x_4^* = (Hy + \ln(m/q_5))/(AH) = y + \ln(1/q_5)$. (a) $\ln 100 = 4.605170$. (b) $-3 + 4.605170 = 1.605170$. (c) $\ln 10^4 = 9.210340$, the left end of the top curve in Figure 08b.3. (d) $w = 1$, $X^* = (1 + \sqrt{1 + 4 \cdot 1 \cdot 0.0025})/(2 \cdot 0.0025) = (1 + \sqrt{1.01})/0.005 = 400.997512$, and $x_4^* = \frac{1}{2} \ln X^* = 2.996978$, slightly later than the 2.995732 of the same wave without space momentum: the space term dies away like e^{-2a_4} and hardly matters.

Exercise 8. For the rescaling $\Psi = \sin^p z\, \chi$ with any real power p, find the term that replaces $3H\gamma^{(0)}$ in the equation for χ, and the power that removes it. What does the norm become for that power?

Answer. $\tan z\, \partial_0 \sin^p z = \tan z \cdot p \sin^{p-1} z \cos z \cdot 6H = 6Hp \sin^p z$. As in Section 8.30, $\gamma^\mu D_\mu(\sin^p z\, \chi) = \sin^p z (\gamma^\mu \partial_\mu \chi + (6Hp + 3H)\gamma^{(0)}\chi)$, so the term becomes $3H(2p+1)\gamma^{(0)}$. It vanishes exactly for $p = -\frac{1}{2}$. For $p = 0$ it is the original $3H\gamma^{(0)}$. For $p = -\frac{1}{2}$ the norm is $\int \cos z\, \sin^{-1} z\, \chi^\dagger \chi\, dx_0 = \int \chi^\dagger \chi\, dy$. (The exact family of Section 8.31 is this computation with $\chi = e^{Mx_4}\chi_0$: its $c = 3H(2\alpha + 1)$ is the same factor.)

Exercise 9. For $m = H = 1$ take the member $\alpha = m/(3H) = \frac{1}{3}$ of the exact family. Compute k^2 in two ways, the growth factor of e^{Mx_4} over one unit of time for large kx_4, and the norm factor $\int_0^{\pi/(12H)} \cos z \sin^{2\alpha} z\, dx_0$.

Answer. $k^2 = 9H^2(2\alpha + 1)^2 - m^2 = 9 \cdot (5/3)^2 - 1 = 25 - 1 = 24$, and also $3(m + H)(m + 3H) = 3 \cdot 2 \cdot 4 = 24$. So $k = 2\sqrt{6} = 4.898979$, and the member grows by the factor $e^k = 134.15$ per unit of time once cosh and sinh are both close to $\frac{1}{2}e^{kx_4}$. The norm factor is $\frac{1}{6H(2\alpha+1)} = \frac{1}{6 \cdot 5/3} = 0.1$: finite. This member varies along x_0 like $\sin^{1/3} z$. Unlike the x_0-independent member, whose growth needs $m < 3H$, the members $\alpha = m/(3H)$ grow for every mass.

Exercise 10. Prove the Krein-neutrality of a growing eigenvector algebraically: if $h_k u = i\kappa u$ with $\kappa > 0$ and $Bh_k = h_k^\dagger B$, then $u^\dagger B u = 0$.

Answer. Compute $u^\dagger B h_k u$ in two ways. First, $h_k u = i\kappa u$ gives $u^\dagger B h_k u = i\kappa\, u^\dagger B u$. Second, $Bh_k = h_k^\dagger B$ gives $u^\dagger B h_k u = u^\dagger h_k^\dagger B u = (h_k u)^\dagger B u = (i\kappa u)^\dagger B u = -i\kappa\, u^\dagger B u$ (the dagger conjugates the number $i\kappa$). Equating: $i\kappa\, u^\dagger B u = -i\kappa\, u^\dagger B u$, so $2i\kappa\, u^\dagger B u = 0$, and since $\kappa \neq 0$, $u^\dagger B u = 0$. The same computation with two eigenvectors u, v of $i\kappa$ gives $v^\dagger B u = 0$: the Krein form vanishes on the whole eigenspace. For a real eigenvalue E the two sides are $E\, u^\dagger B u$ and $E\, u^\dagger B u$, and nothing follows; that is why the real-frequency eigenspaces can carry the inertia (4,4).

9 The energy-momentum tensor, pressures, equations of state, conservation identities

Gravity has to be told where the energy is. In Einstein's theory, and in the Einstein-Lovelock theory that Chapter 12 uses for the author's metric, the right-hand side of the field equations is a table of numbers called the energy-momentum tensor. It says, at every point, how much energy there is in a unit of volume, how hard the matter pushes in each direction (the pressures), and how energy and momentum flow. This chapter builds that table for the field dirac16complex00 in the author's primordial metric, splits it into a kinetic part and a potential part, defines the energy density, the pressures of 3-space, of the extra times and of the hidden direction, and the equations of state, and derives the two exact conservation identities that the table obeys: one along the time x_4, which

describes how energy flows between the inflating 3-space and the deflating extra times, and one along the hidden direction x_0. Three notebooks compute every statement anew from the Revision record: Notebook 09a builds the tensor at one point and derives the two identities, Notebook 09b studies the condensates (fields that depend on the time only) and their equations of state, and Notebook 09c computes the complete tensor of a condensate, including the entries off the diagonal that the spin connection creates.

9.1 What this chapter does

Why we need this chapter. Cosmologists describe the matter of the universe, at each moment, by two numbers: the **energy density** ρ (energy per unit volume) and the **pressure** p (the push per unit area, which is also energy per unit volume). Their ratio $w = p/\rho$ is called the **equation of state**. Three values are famous: dust (matter at rest whose particles do not push on each other) has $w = 0$, radiation (light) has $w = 1/3$, and a cosmological constant (the simplest model of dark energy) has $w = -1$. **Dark energy** is the name for the unknown cause of the observed speeding-up of the expansion of the universe, and **dark matter** for the unseen matter that is detected only through its gravity. The author's two hypotheses, called Hypothesis (for dirac16complex) and Hypothesis00 (for dirac16complex00), say that these fields might provide a time-varying equation of state for dark energy or dark matter (they are HYPOTHESES; the Revision record investigates them and establishes neither, Chapter 22; this chapter does not test them). Before anyone can test such a statement, one must know exactly what ρ and p are for these fields in the author's eight-dimensional metric. That is what this chapter derives.

What it does. In eight dimensions there is one energy density and seven pressures, one for each direction other than the time x_4. They come in three families: the pressure p_3 of the three directions of ordinary space, the pressure p_t of the three extra times, and the pressure p_0 of the hidden direction. The chapter

- defines the energy-momentum tensor by the response of the action to a change of the metric, and derives from this definition, line by line, its diagonal entries $T^{\mu}{}_{\mu} = L_0 - K_\mu$ (Section 9.5);
- states the tensor that a variation of the vielbein gives and its symmetric part, the complete tensor used in this book, says when the two agree, and proves that the complete tensor is real and that its lowered form is symmetric (Section 9.6);
- splits the energy density and the pressures into kinetic and potential parts and defines the equations of state (Section 9.7);
- derives the trace identity and the values that the field equation imposes (Section 9.8);
- derives the covariant divergence of a diagonal tensor in the author's metric and from it the two conservation identities (Sections 9.9 to 9.11);
- shows where the spin connection, which drops out of the Lagrangian, does enter the tensor (Section 9.12);
- builds the exact condensates, computes their equation of state $w = x/(2 + x)$ with $x = \lambda S/m$, and shows that the energy of the commuting field has no lower bound (Sections 9.18 to 9.21);

- computes the complete tensor of a condensate, with 42 entries off the diagonal, and the exact condensates whose tensor is diagonal (Section 9.26).

What it does not do. The equation of state that an observer living in 3-space would infer (after integrating over the hidden direction and the extra times), its change in time and any comparison with supernova data (the measured brightness of distant exploding stars, from which astronomers infer the equation of state of dark energy) are not computed in this chapter (Section 9.19 quotes the record's result for a condensate). The Revision record computes them in `Revision/dark_sector/` (written up in `Revision/docs/DARK_SECTOR_HYPOTHESES.md`; COMPUTED, and taught in Chapter 22) under an ASSUMED normalisation of the observer's energy density over the extra times (three definitions, called A, B and C), compares them with the supernova fit values of a document of the author (the record calls them the Unite values), and establishes neither hypothesis. Which normalisation, if any, describes a physical observer, and a fit to the supernova data themselves, are OPEN. The anticommuting field dirac16complex obeys the same formulas in its Grassmann algebra; for the quantised field the record defines the tensor as a normal-ordered operator, on a positive space of states constructed only for single good-sector momenta with frozen coefficients, and for $\lambda \neq 0$ it verifies the operator form of the on-shell identity only in a finite model under Wick ordering (Section 9.13 explains these words and states these limits exactly); this chapter computes numbers only for the commuting field dirac16complex00.

Labels. As everywhere in the book, every statement carries one of five labels: PROVED (exact; the Revision report file and the name of its check are given), COMPUTED (a number of a notebook, with its accuracy), ASSUMED, HYPOTHESIS, OPEN.

9.2 The stage: coordinates, metric and the field dirac16complex00

Coordinates. The eight coordinates are named as the author names them: x_1, x_2, x_3 are ordinary 3-space; x_4 is the time in which everything evolves; x_5, x_6, x_7 are the three **extra times**, which behave like time and deflate exponentially; x_0 is the **hidden** space direction. We write $z = 6Hx_0$, where $H > 0$ is the author's constant; z lies between 0 and $\pi/2$. In formulas the letter i always stands for one of the 3-space directions x_1, x_2, x_3, and the letter t for one of the extra times x_5, x_6, x_7.

The metric. The author's metric is diagonal (Chapter 3). We write it with eight positive **vielbein factors** $f_0, \ldots, f_7$:

$$g = \mathrm{diag}(f_0^2,\, f_1^2,\, f_2^2,\, f_3^2,\, -f_4^2,\, -f_5^2,\, -f_6^2,\, -f_7^2),$$

$$f_0 = \cot z, \quad f_1 = f_2 = f_3 = e^{a_4} \sin^{1/6} z, \quad f_4 = 1, \quad f_5 = f_6 = f_7 = e^{-a_4} \sin^{1/6} z.$$

These are the factors on the backgrounds $b_4 = 1$ of the Revision record. The author's metric of 2026-10-14 has a second function $b_4(x_4) > 0$, and then $f_5 = f_6 = f_7 = e^{-a_4} b_4^{1/2} \sin^{1/6} z$ and $\sqrt{|g|} = b_4^{3/2} \cos z$ (Chapters 3, 6 and 7). This chapter works at $b_4 = 1$, as the record's energy-momentum checks do (`Revision/theory/reports/wolfram-field-theory.json`); where the record has the tensor or its identities for a general b_4, the section says so (Sections 9.10 and 9.11). So $g_{x_1x_1} = e^{2a_4} \sin^{1/3} z$, $g_{x_4x_4} = -1$, $g_{x_5x_5} = -e^{-2a_4} \sin^{1/3} z$ and $g_{x_0x_0} = \cot^2 z$, exactly the author's entries. A small step dx_μ along the direction x_μ has the proper length $f_\mu\, |dx_\mu|$; that is

the meaning of f_μ. With the frame metric $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order $x_0,\dots,x_7$ every entry is $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$. The function $a_4(x_4)$ grows with the time: then the 3-space factor e^{a_4} grows (3-space inflates) and the extra-time factor e^{-a_4} shrinks (the extra times deflate). We write $a_4' = da_4/dx_4$. The examples of this chapter take $a_4 = AHx_4$ with $A = 1$ (the deflating history that the Kohn-Sham part of the book uses as a prescribed background) and, in Notebook 09c, the curved history $a_4 = 0.3x_4 + 0.05x_4^2$; every identity of the chapter holds for every function a_4. Which a_4 the field equations of gravity allow, and with which source, is the subject of Chapter 12.

The volume factor. The product of the eight factors is the volume factor $\sqrt{|g|}$ (the square root of the absolute value of the determinant of the diagonal matrix g, which is the product of its diagonal entries):

$$\begin{aligned}\sqrt{|g|} &= f_1 f_2 f_3\, f_4\, f_5 f_6 f_7\, f_0 \\ &= \left(e^{a_4}\sin^{1/6} z\right)^3 \cdot 1 \cdot \left(e^{-a_4}\sin^{1/6} z\right)^3 \cdot \cot z \\ &= e^{3a_4}\sin^{1/2} z \cdot e^{-3a_4}\sin^{1/2} z \cdot \frac{\cos z}{\sin z} \\ &= \cos z.\end{aligned}$$

The first line is the definition; the second inserts the factors; the third multiplies the powers $((e^{a_4})^3 = e^{3a_4}$, $(\sin^{1/6} z)^3 = \sin^{1/2} z)$ and writes $\cot z = \cos z/\sin z$; the fourth uses $e^{3a_4}e^{-3a_4} = 1$ and $\sin^{1/2} z \sin^{1/2} z = \sin z$. The volume factor does not depend on the time x_4: the growth of 3-space and the shrinking of the extra times cancel exactly (PROVED; `Revision/theory/reports/python-field-theory.json`, check `sqrt_det_g_equals_cos_z`).

The gamma matrices. The book uses the author's eight **real** 16×16 gamma matrices (Chapter 4), stored in the Revision fixture `Revision/algebra/gammas.json` in the order $x_0,\dots,x_7$. We write them $\gamma^{(0)},\dots,\gamma^{(7)}$ ($\gamma^{(4)}$ means $\gamma^{(x_4)}$, and so on). They obey the Clifford relations $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}\cdot 1$. Two consequences are used again and again in this chapter: the square of each gamma is η_{aa} times the unit matrix ($+1$ for x_0, x_1, x_2, x_3 and -1 for $x_4,\dots,x_7$), and two different gammas anticommute, $\gamma^{(a)}\gamma^{(b)} = -\gamma^{(b)}\gamma^{(a)}$ for $a \neq b$. The matrix $C = \gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$ (Chapter 5) is real and symmetric, $C^2 = 1$, and every product $C\gamma^{(a)}$ is antisymmetric: $(C\gamma^{(a)})^T = -C\gamma^{(a)}$ (PROVED; `Revision/algebra/reports/python-algebra.json`, checks `clifford_relation`, `C_real_symmetric_involution` and `C_gamma_antisymmetric`). The **coordinate gammas** are $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (no sum), and with a lower index $\gamma_\mu = g_{\mu\mu}\gamma^\mu = \eta_{\mu\mu} f_\mu \gamma^{(\mu)}$.

The field. dirac16complex00 is a column Φ of 16 ordinary (commuting) complex numbers at every point (Chapter 7). Its **Dirac adjoint** is the row $\bar\Phi = \Phi^\dagger C$ (the dagger means: transpose and take the complex conjugate of every entry), and the **scalar** is the number $S = \bar\Phi\Phi = \Phi^\dagger C\Phi$. A number of the form $\bar\Phi M\Phi$, with a fixed 16×16 matrix M, is called a **bilinear** of the field (it contains the field twice: once in the row $\bar\Phi$ and once in the column Φ); S is the simplest bilinear, with $M = 1$. The potential is $U(S) = \frac{\lambda}{2}S^2$, so $U'(S) = \lambda S$; m is the mass.

The spin connection and the covariant derivative (Chapter 6). For the diagonal vielbein of this metric the spin connection is

$$\begin{aligned}\Omega_{x_i} &= \tfrac{1}{2} f_i \left(a_4'\,\gamma^{(i)}\gamma^{(4)} + H\,\gamma^{(i)}\gamma^{(0)}\right), \qquad i = 1,2,3, \\ \Omega_{x_t} &= -\tfrac{1}{2} f_t \left(a_4'\,\gamma^{(4)}\gamma^{(t)} + H\,\gamma^{(t)}\gamma^{(0)}\right), \qquad t = 5,6,7, \\ \Omega_{x_4} &= \Omega_{x_0} = 0,\end{aligned}$$

with $f_i = e^{a_4}\sin^{1/6} z$ and $f_t = e^{-a_4}\sin^{1/6} z$ (Revision record `Revision/theory/field-theory.json`, formula `Omega_components`). The covariant derivatives are $D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$ and $D_\mu\bar\Phi = \partial_\mu\bar\Phi - \bar\Phi\,\Omega_\mu$, where ∂_μ is the partial derivative with respect to x_μ.

The Lagrangian. The Lagrangian density is $\mathcal{L} = \sqrt{|g|}\,L_0$ with

$$L_0 = \tfrac{1}{2}\sum_\mu \left(\bar\Phi\gamma^\mu D_\mu\Phi - (D_\mu\bar\Phi)\gamma^\mu\Phi\right) - mS - U(S),$$

and its Euler-Lagrange equation is the **field equation** $\gamma^\mu D_\mu\Phi = V\Phi$ with the **effective mass** $V = m + U'(S) = m + \lambda S$ (Chapter 7). Written out in the author's metric (record formula `field_equation`) it reads

$$\sum_{a=1}^{8}\frac{1}{f_a}\,\gamma^{(a)}\partial_a\Phi + 3H\gamma^{(0)}\Phi = V\Phi,$$

and because $(\gamma^{(4)})^2 = -1$ and $f_4 = 1$ it can be solved for the time derivative (the **evolution form**; multiply by $-\gamma^{(4)}$):

$$\partial_4\Phi = -\gamma^{(4)}\Big[V\Phi - \sum_{a\neq 4}\frac{1}{f_a}\,\gamma^{(a)}\partial_a\Phi - 3H\gamma^{(0)}\Phi\Big].$$

A configuration that satisfies the field equation is said to be **on shell**; one that need not satisfy it is **off shell**. Some identities of this chapter hold off shell (for every configuration), others only on shell; each statement says which.

9.3 Two exact facts about the spin connection of this metric

Two facts about Ω_μ decide where the spin connection appears in the energy-momentum tensor. Both are proved here line by line.

Fact 1: for every direction separately, $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu = 0$ (no sum). For x_4 and x_0 this is clear, because $\Omega_{x_4} = \Omega_{x_0} = 0$. Take a 3-space direction x_i:

$$\begin{aligned}\gamma^{x_i}\Omega_{x_i} &= \frac{1}{f_i}\gamma^{(i)}\cdot\tfrac{1}{2}f_i(a_4'\gamma^{(i)}\gamma^{(4)} + H\gamma^{(i)}\gamma^{(0)})\\ &= \tfrac{1}{2}(a_4'\,\gamma^{(i)}\gamma^{(i)}\gamma^{(4)} + H\,\gamma^{(i)}\gamma^{(i)}\gamma^{(0)})\\ &= \tfrac{1}{2}(a_4'\gamma^{(4)} + H\gamma^{(0)}).\end{aligned}$$

The first line inserts $\gamma^{x_i} = \gamma^{(i)}/f_i$ and the formula for Ω_{x_i}; the second cancels $1/f_i$ against f_i and multiplies out the bracket; the third uses $\gamma^{(i)}\gamma^{(i)} = \eta_{ii} = +1$. In the other order:

$$\begin{aligned}\Omega_{x_i}\gamma^{x_i} &= \tfrac{1}{2}(a_4'\,\gamma^{(i)}\gamma^{(4)}\gamma^{(i)} + H\,\gamma^{(i)}\gamma^{(0)}\gamma^{(i)})\\ &= \tfrac{1}{2}(-a_4'\,\gamma^{(i)}\gamma^{(i)}\gamma^{(4)} - H\,\gamma^{(i)}\gamma^{(i)}\gamma^{(0)})\\ &= -\tfrac{1}{2}(a_4'\gamma^{(4)} + H\gamma^{(0)}).\end{aligned}$$

The first line is the same insertion; the second exchanges the last two gammas of each product, which costs a minus sign because different gammas anticommute ($\gamma^{(4)}\gamma^{(i)} = -\gamma^{(i)}\gamma^{(4)}$, $\gamma^{(0)}\gamma^{(i)} = -\gamma^{(i)}\gamma^{(0)}$); the third uses $\gamma^{(i)}\gamma^{(i)} = 1$ again. Adding the two results gives zero. Now an extra time x_t, with $\Omega_{x_t} = -\frac{1}{2} f_t (a_4' \gamma^{(4)}\gamma^{(t)} + H\gamma^{(t)}\gamma^{(0)})$:

$$\begin{aligned}\gamma^{x_t}\Omega_{x_t} &= -\tfrac{1}{2}\big(a_4'\,\gamma^{(t)}\gamma^{(4)}\gamma^{(t)} + H\,\gamma^{(t)}\gamma^{(t)}\gamma^{(0)}\big)\\ &= -\tfrac{1}{2}\big(-a_4'\,\gamma^{(t)}\gamma^{(t)}\gamma^{(4)} + H\,\gamma^{(t)}\gamma^{(t)}\gamma^{(0)}\big)\\ &= -\tfrac{1}{2}\big(a_4'\gamma^{(4)} - H\gamma^{(0)}\big) = -\tfrac{a_4'}{2}\gamma^{(4)} + \tfrac{H}{2}\gamma^{(0)}.\end{aligned}$$

The first line inserts $\gamma^{x_t} = \gamma^{(t)}/f_t$ and cancels f_t; the second exchanges $\gamma^{(4)}$ and $\gamma^{(t)}$ in the first product (a minus sign); the third uses $\gamma^{(t)}\gamma^{(t)} = \eta_{tt} = -1$ in both products and multiplies out. In the same way

$$\Omega_{x_t}\gamma^{x_t} = -\tfrac{1}{2}\big(a_4'\,\gamma^{(4)}\gamma^{(t)}\gamma^{(t)} + H\,\gamma^{(t)}\gamma^{(0)}\gamma^{(t)}\big) = -\tfrac{1}{2}\big(-a_4'\gamma^{(4)} + H\gamma^{(0)}\big) = \tfrac{a_4'}{2}\gamma^{(4)} - \tfrac{H}{2}\gamma^{(0)},$$

where the middle step uses $\gamma^{(t)}\gamma^{(t)} = -1$ in the first product and, in the second, $\gamma^{(0)}\gamma^{(t)} = -\gamma^{(t)}\gamma^{(0)}$ followed by $\gamma^{(t)}\gamma^{(t)} = -1$ (two minus signs). The sum is again zero. Fact 1 is PROVED (Revision record `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `gamma_mu_anticommutes_with_Omega_mu_no_sum`).

Fact 2: summed over the directions, $\gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$. Add the results above over the three 3-space directions and the three extra times (the directions x_4 and x_0 give zero):

$$\sum_\mu \gamma^\mu\Omega_\mu = 3\cdot\tfrac{1}{2}\big(a_4'\gamma^{(4)} + H\gamma^{(0)}\big) + 3\cdot\big(-\tfrac{a_4'}{2}\gamma^{(4)} + \tfrac{H}{2}\gamma^{(0)}\big) = \big(\tfrac{3a_4'}{2} - \tfrac{3a_4'}{2}\big)\gamma^{(4)} + \big(\tfrac{3H}{2} + \tfrac{3H}{2}\big)\gamma^{(0)} = 3H\gamma^{(0)}.$$

The terms with a_4' cancel: the three inflating directions and the three deflating directions contribute equal and opposite amounts. The cancellation is due to the deflation. The lead's independent check computes the same sum for a metric in which the extra times inflate like 3-space and finds that a term $3a_4'\gamma^{(4)}$ survives. Both statements are PROVED in the Revision record:

statement	**Revision report**	**check**
$\sum_\mu \gamma^\mu\Omega_\mu = 3H\gamma^{(0)}$	`Revision/theory/reports/python-field-theory.json`	`gamma_mu_Omega_mu_equals_3H_gamma_x0`
the same, computed independently by the lead	`Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`	`gamma_Omega_equals_3H_gamma0`
with inflating extra times a term $3a_4'\gamma^{(4)}$ survives	`Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`	`negative_control_inflating_extra_times`

What Fact 1 does to the Lagrangian. Insert $D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$ and $D_\mu\bar\Phi = \partial_\mu\bar\Phi - \bar\Phi\Omega_\mu$ into one term of L_0:

$$\tfrac{1}{2}(\bar\Phi\gamma^\mu D_\mu\Phi - (D_\mu\bar\Phi)\gamma^\mu\Phi) = \tfrac{1}{2}(\bar\Phi\gamma^\mu\partial_\mu\Phi - \partial_\mu\bar\Phi\,\gamma^\mu\Phi) + \tfrac{1}{2}\,\bar\Phi(\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu)\Phi$$
$$= \frac{1}{2f_\mu}(\bar\Phi\gamma^{(\mu)}\partial_\mu\Phi - \partial_\mu\bar\Phi\,\gamma^{(\mu)}\Phi) = K_\mu.$$

The first line collects the terms with Ω_μ (the term $+\bar\Phi\Omega_\mu\gamma^\mu\Phi$ comes from $-(-\bar\Phi\Omega_\mu)\gamma^\mu\Phi$); the second drops them by Fact 1 and writes $\gamma^\mu = \gamma^{(\mu)}/f_\mu$. The number K_μ (no sum) is called the **kinetic term of the direction** x_μ: the part of the Lagrangian that holds the derivative along x_μ. So

$$L_0 = \sum_\mu K_\mu - mS - U(S), \qquad K_\mu = \frac{1}{2f_\mu}(\bar\Phi\gamma^{(\mu)}\partial_\mu\Phi - \partial_\mu\bar\Phi\,\gamma^{(\mu)}\Phi).$$

The spin connection has disappeared from the Lagrangian; it reaches the field equation only through Fact 2 (the term $3H\gamma^{(0)}\Phi$), and the energy-momentum tensor only off its diagonal (Section 9.12).

9.4 What an energy-momentum tensor is

A table of 8×8 numbers. The energy-momentum tensor $T^\nu{}_\mu$ is, at every point, a table of 64 numbers, one for each ordered pair of directions (ν,μ). We write the upper index ν as the row and the lower index μ as the column. The entries on the diagonal ($\nu=\mu$) are the energy density and the pressures; the entries off the diagonal ($\nu\neq\mu$) describe flows: the entries with one index x_4 hold the density of momentum and the flow of energy along the other direction, and the entries with two indices other than x_4 hold shearing stresses. Lowering the upper index with the metric gives $T_{\nu\mu} = g_{\nu\nu}T^\nu{}_\mu$ (the metric is diagonal, so no sum is needed).

A familiar example. In ordinary four-dimensional flat space with the coordinates (x_1,x_2,x_3,x_4), x_4 the time and the metric $\mathrm{diag}(1,1,1,-1)$, a gas at rest with energy density ρ and pressure p has $T^\nu{}_\mu = \mathrm{diag}(p,p,p,-\rho)$. The minus sign in front of ρ comes from $g_{x_4x_4}=-1$: lowering the index gives $T_{x_4x_4} = g_{x_4x_4}T^{x_4}{}_{x_4} = \rho$, the energy density, as in every book on relativity.

The conventions of the book (Revision record, `Revision/SPEC.md` section 4; record formula `equation_of_state_definitions`): the energy density and the pressures are

$$\rho = -T^{x_4}{}_{x_4}, \qquad p_\mu = T^\mu{}_\mu \ \text{(no sum, } \mu\neq x_4), \qquad p_3 = T^{x_1}{}_{x_1}, \quad p_t = T^{x_5}{}_{x_5}, \quad p_0 = T^{x_0}{}_{x_0},$$

and the **equations of state** are the ratios

$$w_3 = \frac{p_3}{\rho}, \qquad w_t = \frac{p_t}{\rho}, \qquad w_0 = \frac{p_0}{\rho}.$$

For a configuration that looks the same in the three directions of 3-space (such a configuration is called **isotropic** in 3-space), $T^{x_1}{}_{x_1} = T^{x_2}{}_{x_2} = T^{x_3}{}_{x_3} = p_3$, and likewise p_t for a configuration isotropic in the extra times. Along an extra time, which is time-like, the entry $T^{x_t}{}_{x_t}$ is called a pressure by definition; it has no everyday meaning.

The definition. The **action** is the integral of the Lagrangian density over the eight coordinates, $S_{\mathrm{act}} = \int \mathcal{L}\, d^8x$. The energy-momentum tensor is defined by how the action responds when the metric is changed a little, everywhere inside a bounded region:

$$\delta S_{\text{act}} = \tfrac{1}{2} \int \sqrt{|g|}\, T^{\mu\nu}\, \delta g_{\mu\nu}\, d^8x$$

for every small change $\delta g_{\mu\nu}$ (record normalisation; `Revision/docs/DIRAC16COMPLEX00_FIELD_THEORY.md` section 8). Here δ means "the first-order change": if a quantity changes from Q to $Q + \varepsilon Q_1 + \varepsilon^2 Q_2 + \dots$ when a small number ε is switched on, then $\delta Q = \varepsilon Q_1$, and the terms with ε^2 and higher powers are dropped. For a spinor field the metric is changed through the vielbein factors, with the 16 components of Φ held fixed (the record's definition is $T^{\nu}{}_{\mu} = e^{b}{}_{\mu}\, \frac{1}{\sqrt{|g|}}\, \delta S_{\text{act}}/\delta e^{b}{}_{\nu}$; check `T_vielbein_variation_closed_form_C` of `Revision/theory/reports/wolfram-field-theory.json` computes it for all 64 entries).

What the definition fixes, and what it does not. The metric is symmetric, $g_{\mu\nu} = g_{\nu\mu}$, so every change $\delta g_{\mu\nu}$ is symmetric too. Split any table $T^{\mu\nu}$ into its symmetric part $\frac{1}{2}(T^{\mu\nu} + T^{\nu\mu})$ and its antisymmetric part $A^{\mu\nu} = \frac{1}{2}(T^{\mu\nu} - T^{\nu\mu})$. In the double sum $\sum_{\mu,\nu} A^{\mu\nu}\, \delta g_{\mu\nu}$ the term (μ, ν) and the term (ν, μ) cancel, because $A^{\nu\mu} = -A^{\mu\nu}$ while $\delta g_{\nu\mu} = \delta g_{\mu\nu}$; so the antisymmetric part never enters the formula above, and the formula fixes only the **symmetric part** of $T^{\mu\nu}$. The vielbein carries more information than the metric (it also fixes the orientation of the frame), and the tensor obtained by varying the vielbein can have an antisymmetric part as well. Section 9.6 states what that part is and which tensor this book uses.

9.5 The diagonal entries, derived from the definition

We now derive the diagonal entries from the definition, using only the product rule and the first terms of a power series.

The change. Choose one direction x_b and a small function $\varepsilon(x)$ that vanishes outside a bounded region. Change the vielbein factor of that direction, $f_b \to f_b\,(1 + \varepsilon)$, keep the other seven factors and keep Φ fixed. The metric is still diagonal. Its entry g_{bb} changes by

$$\delta g_{bb} = \eta_{bb}(f_b^2(1+\varepsilon)^2 - f_b^2) = \eta_{bb} f_b^2\,(2\varepsilon + \varepsilon^2) \;\to\; 2\, g_{bb}\, \varepsilon.$$

The first step writes the new entry minus the old one; the second multiplies out $(1+\varepsilon)^2 = 1 + 2\varepsilon + \varepsilon^2$; the arrow keeps the first order and uses $\eta_{bb} f_b^2 = g_{bb}$. Every other entry is unchanged.

What the definition says. Insert this change into the definition. Only the term $\mu = \nu = b$ of the double sum survives:

$$\delta S_{\text{act}} = \tfrac{1}{2} \int \sqrt{|g|}\, T^{bb} \cdot 2 g_{bb}\, \varepsilon\, d^8x = \int \sqrt{|g|}\, T^{b}{}_{b}\, \varepsilon\, d^8x \qquad \text{(no sum over } b\text{)},$$

because lowering the second index with the diagonal metric gives $T^{bb} g_{bb} = T^{b}{}_{b}$.

What the Lagrangian says. For every diagonal vielbein, not only the author's, the spin connection drops out of the Lagrangian (the Revision record proves this for an arbitrary diagonal vielbein; `Revision/theory/reports/python-field-theory.json`, check `commuting_emt_equals_vielbein_variation_diagonal`). So, with the same kinetic terms as in Section 9.3,

$$\mathcal{L} = (f_0 f_1 \cdots f_7)\Big[\sum_a \frac{1}{2f_a} X_a - mS - U(S)\Big], \qquad X_a = \bar{\Phi}\gamma^{(a)}\partial_a\Phi - \partial_a\bar{\Phi}\,\gamma^{(a)}\Phi.$$

The numbers X_a, S and $U(S)$ contain no vielbein factor (Φ is held fixed and the frame gammas $\gamma^{(a)}$ are constant matrices), so only two places change: the product $f_0\cdots f_7$ becomes $(1+\varepsilon)f_0\cdots f_7$, and the coefficient $1/(2f_b)$ becomes $1/(2f_b(1+\varepsilon))$. To first order $1/(1+\varepsilon) = 1-\varepsilon$ (the series $1/(1+\varepsilon) = 1-\varepsilon+\varepsilon^2-\ldots$, cut after the first order). Therefore, with $K_a = X_a/(2f_a)$,

$$\begin{aligned}\mathcal{L} \;&\to (1+\varepsilon)\sqrt{|g|}\,\Big[\sum_{a\neq b} K_a + (1-\varepsilon)K_b - mS - U\Big] \\ &= (1+\varepsilon)\sqrt{|g|}\,[L_0 - \varepsilon K_b] \\ &= \sqrt{|g|}\,[L_0 + \varepsilon L_0 - \varepsilon K_b] + (\text{terms with } \varepsilon^2),\end{aligned}$$

where the second line uses $\sum_a K_a - mS - U = L_0$, and the third multiplies out. The first-order change is $\delta\mathcal{L} = \sqrt{|g|}\,(L_0 - K_b)\,\varepsilon$, hence

$$\delta S_{\text{act}} = \int \sqrt{|g|}\;(L_0 - K_b)\,\varepsilon\; d^8x.$$

Comparison. The two expressions for δS_{act} agree for every small function ε. If $\int A\,\varepsilon\,d^8x = \int B\,\varepsilon\,d^8x$ for every such ε, then $A = B$ at every point (choose ε concentrated near any point you like; this is the fundamental lemma of the calculus of variations). So

$$T^b{}_b = L_0 - K_b \qquad (\text{no sum},\ b = x_0,\ldots,x_7).$$

This is the record's formula (PROVED; `Revision/theory/reports/wolfram-field-theory.json`, check `T_diagonal_components_C`, and `Revision/theory/field-theory.json`, formula `EMT_diagonal`). It holds off shell: the derivation never used the field equation.

9.6 The whole tensor: its formula, its reality and its symmetry

The tensor from the vielbein variation. The off-diagonal entries need a change of the vielbein that is not diagonal, and with it the change of the spin connection; this calculation is long, and the Revision record carries it out exactly for all 64 entries (PROVED; `Revision/theory/reports/wolfram-field-theory.json`, check `T_vielbein_variation_closed_form_C`; record formula `T_variation` of `Revision/theory/field-theory.json`). Its result, which we call the **variation tensor** T_{var}, is

$$T_{\text{var}}{}^{\nu}{}_{\mu} = \delta^{\nu}_{\mu}\,L_0 - \tfrac{1}{2}\Big(\bar{\Phi}\gamma^{\nu}D_{\mu}\Phi - D_{\mu}\bar{\Phi}\,\gamma^{\nu}\Phi\Big) - \tfrac{1}{4}\sum_{\rho,\lambda} g_{\mu\rho}\,\nabla_{\lambda}\Big(\bar{\Phi}\{\gamma^{\lambda},\Sigma^{\nu\rho}\}\Phi\Big), \qquad \Sigma^{\nu\rho} = \tfrac{1}{4}(\gamma^{\nu}\gamma^{\rho} - \gamma^{\rho}\gamma^{\nu}),$$

where δ^{ν}_{μ} is 1 for $\nu = \mu$ and 0 otherwise, $\{A,B\} = AB + BA$ is the anticommutator and ∇_{λ} is the covariant derivative (the derivative corrected by Christoffel symbols, Section 9.9). The last

term comes from the change of the spin connection; the record calls the bilinear in it the totally antisymmetric **spin density** (it changes sign when two of its three indices are exchanged). We take this formula from the record and do not derive it. Because of its last term, the variation tensor is in general not symmetric: its lowered form $g_{\nu\nu}T_{\mathrm{var}}{}^{\nu}{}_{\mu}$ has an antisymmetric part.

Its symmetric part: the Belinfante tensor. The record proves that the symmetric part of the variation tensor (with both indices raised, $\frac{1}{2}(T^{\nu\rho}_{\mathrm{var}} + T^{\rho\nu}_{\mathrm{var}})$) is, for all 36 pairs $\nu \le \rho$ and for every configuration, solution or not, the **symmetric (Belinfante) energy-momentum tensor** (named after the physicist F. J. Belinfante, who showed how to make the energy-momentum tensor of a spinor field symmetric) (PROVED; same report, check `T_symmetric_part_Belinfante_C`; record formula `T_symmetric`):

$$T^{\nu}{}_{\mu} = \delta^{\nu}_{\mu}\, L_0 - \tfrac{1}{4}\Big(\bar{\Phi}\gamma^{\nu} D_{\mu}\Phi - D_{\mu}\bar{\Phi}\,\gamma^{\nu}\Phi + \bar{\Phi}\gamma_{\mu} D^{\nu}\Phi - D^{\nu}\bar{\Phi}\,\gamma_{\mu}\Phi\Big),$$

where $\gamma_{\mu} = g_{\mu\mu}\gamma^{\mu}$ and $D^{\nu} = g^{\nu\nu}D_{\nu}$ with $g^{\nu\nu} = 1/g_{\nu\nu}$.

When the two tensors agree. On the diagonal they always agree: the diagonal of an antisymmetric table is zero, so $T_{\mathrm{var}}{}^{\mu}{}_{\mu} = T^{\mu}{}_{\mu}$ for every configuration (the 8 entries of Section 9.5). Off the diagonal they differ by the antisymmetric part of T_{var}, and the record proves that this difference is proportional to the field equation: on every solution of the field equation the variation tensor is symmetric and equals $T^{\nu}{}_{\mu}$ in all 64 entries, while for a configuration that is not a solution, in general, only the 8 diagonal entries agree (PROVED; `Revision/theory/reports/python-field-theory.json`, check `commuting_emt_equals_general_vielbein_variation_on_shell`, which compares all 64 entries of a general first-order vielbein variation around the author's metric). The reason is the invariance of the action under a rotation of the frame at fixed metric (local Lorentz invariance, in the record's words).

Which tensor the book uses. This book, like the record's formulas for the energy density and the pressures, uses the symmetric tensor $T^{\nu}{}_{\mu}$ above as "the" energy-momentum tensor: on a solution it is the variation tensor, and for a configuration that is not a solution it is the symmetric part of the variation tensor. Notebook 09a evaluates it for random values of Φ and its derivatives, which do not solve the field equation; that is why its table $T_{\nu\mu}$ comes out symmetric, while the variation tensor of values that do not solve the field equation is in general not symmetric. Notebooks 09b and 09c evaluate it on exact solutions, where the two tensors are the same. We check two consequences of the formula here.

Its diagonal agrees with Section 9.5. Set $\nu = \mu$. Then $\gamma_{\mu}D^{\mu} = g_{\mu\mu}\gamma^{\mu}g^{\mu\mu}D_{\mu} = \gamma^{\mu}D_{\mu}$, so the last two terms in the bracket equal the first two, and

$$\begin{aligned} T^{\mu}{}_{\mu} &= L_0 - \tfrac{1}{4}\cdot 2(\bar{\Phi}\gamma^{\mu}D_{\mu}\Phi - D_{\mu}\bar{\Phi}\,\gamma^{\mu}\Phi) \\ &= L_0 - \tfrac{1}{2}(\bar{\Phi}\gamma^{\mu}\partial_{\mu}\Phi - \partial_{\mu}\bar{\Phi}\,\gamma^{\mu}\Phi) - \tfrac{1}{2}\,\bar{\Phi}\{\gamma^{\mu}, \Omega_{\mu}\}\Phi \\ &= L_0 - K_{\mu}. \end{aligned}$$

The first line uses $\delta^{\mu}_{\mu} = 1$ and the equality of the two pairs; the second inserts the covariant derivatives as in Section 9.3 ($\{A, B\} = AB + BA$ is the anticommutator); the third uses Fact 1 and the definition of K_{μ}. This is the result of Section 9.5, as it must be.

Symmetry. Multiply by $g_{\nu\nu}$. Because $g_{\nu\nu}\gamma^{\nu} = \gamma_{\nu}$ and $g_{\nu\nu}D^{\nu} = D_{\nu}$,

$$T_{\nu\mu} = g_{\nu\nu}T^{\nu}{}_{\mu} = g_{\nu\mu}L_0 - \tfrac{1}{4}\Big(\bar{\Phi}\gamma_\nu D_\mu\Phi - D_\mu\bar{\Phi}\,\gamma_\nu\Phi + \bar{\Phi}\gamma_\mu D_\nu\Phi - D_\nu\bar{\Phi}\,\gamma_\mu\Phi\Big),$$

and this expression is unchanged when ν and μ are exchanged (the first pair of terms becomes the second pair and the reverse; $g_{\nu\mu}$ is symmetric). So the lowered tensor is symmetric, $T_{\nu\mu} = T_{\mu\nu}$, while the mixed table $T^{\nu}{}_{\mu}$ is in general not symmetric as printed (PROVED; `Revision/theory/reports/python-field-theory.json`, check `commuting_emt_symmetric`).

Reality. Every entry is a real number. The proof needs three facts. (a) $D_\nu\bar{\Phi} = (D_\nu\Phi)^\dagger C$: indeed $(D_\nu\Phi)^\dagger C = \partial_\nu\Phi^\dagger C + \Phi^\dagger\Omega_\nu^T C$ (Ω_ν is real, so its dagger is its transpose), and $\Omega_\nu^T C = -C\Omega_\nu$, because Ω_ν is a sum of products $\gamma^{(a)}\gamma^{(b)}$ with $a \neq b$ and real coefficients, and $(\gamma^{(a)}\gamma^{(b)})^T C = \gamma^{(b)T}\gamma^{(a)T}C = -\gamma^{(b)T}C\gamma^{(a)} = C\gamma^{(b)}\gamma^{(a)} = -C\gamma^{(a)}\gamma^{(b)}$ (each step uses $\gamma^{(a)T}C = -C\gamma^{(a)}$, the transpose of the antisymmetry of $C\gamma^{(a)}$, and the last step the anticommutation of different gammas); so $(D_\nu\Phi)^\dagger C = \partial_\nu\bar{\Phi} - \bar{\Phi}\Omega_\nu = D_\nu\bar{\Phi}$. (b) Call $Y = \bar{\Phi}\gamma_\mu D_\nu\Phi = \Phi^\dagger(C\gamma_\mu)D_\nu\Phi$, a single number. Its complex conjugate is $Y^* = \Phi^T(C\gamma_\mu)(D_\nu\Phi)^*$ (the matrix $C\gamma_\mu$ is real); a single number equals its own transpose, so $Y^* = (D_\nu\Phi)^\dagger(C\gamma_\mu)^T\Phi = -(D_\nu\Phi)^\dagger C\gamma_\mu\Phi = -D_\nu\bar{\Phi}\,\gamma_\mu\Phi$, by the antisymmetry of $C\gamma_\mu$ and by (a). (c) Hence each pair in the bracket has the form $Y + Y^*$, which is twice the real part of Y, a real number. The same argument with ∂ in place of D shows that each K_μ is real, and $S^* = \Phi^T C\Phi^* = \Phi^\dagger C^T\Phi = S$ shows that S is real. So L_0 and all 64 entries are real (PROVED; `Revision/theory/reports/wolfram-field-theory.json`, check `L_real_C`; Notebook 09a confirms it numerically).

9.7 Energy density, pressures, kinetic and potential parts, equations of state

The energy density. With $\mu = x_4$ in $T^{\mu}{}_{\mu} = L_0 - K_\mu$:

$$\begin{aligned}\rho &= -T^{x_4}{}_{x_4} = -(L_0 - K_4)\\ &= -\Big(\sum_\mu K_\mu - mS - U - K_4\Big)\\ &= -\sum_{\mu\neq x_4} K_\mu + mS + U(S).\end{aligned}$$

The first line is the definition and Section 9.5; the second inserts $L_0 = \sum_\mu K_\mu - mS - U$; the third removes K_4 from the sum, where it cancels, and distributes the minus sign.

The pressures. For every direction $\mu \neq x_4$, in the same way,

$$p_\mu = T^{\mu}{}_{\mu} = L_0 - K_\mu = \sum_{\nu\neq\mu} K_\nu - mS - U(S).$$

Kinetic and potential parts. The terms with derivatives (the K's) form the **kinetic part**; the terms without derivatives, $mS + U(S)$, form the **potential part**. The record's split (formula `EMT_kinetic_potential`) gives:

quantity	kinetic part	potential part	total
energy density $\rho = -T^{x_4}{}_{x_4}$	$-\sum_{\mu\neq x_4} K_\mu$	$mS+U$	$-\sum_{\mu\neq x_4} K_\mu + mS + U$
3-space pressure $p_3 = T^{x_1}{}_{x_1}$	$\sum_{\mu\neq x_1} K_\mu$	$-(mS+U)$	$\sum_{\mu\neq x_1} K_\mu - mS - U$
extra-time pressure $p_t = T^{x_5}{}_{x_5}$	$\sum_{\mu\neq x_5} K_\mu$	$-(mS+U)$	$\sum_{\mu\neq x_5} K_\mu - mS - U$
hidden pressure $p_0 = T^{x_0}{}_{x_0}$	$\sum_{\mu\neq x_0} K_\mu$	$-(mS+U)$	$\sum_{\mu\neq x_0} K_\mu - mS - U$

Four remarks.

- The time derivative $\partial_4\Phi$ does not occur in ρ: the kinetic term K_4 cancels. As for Dirac's electron field, the field equation is of first order in time, and its energy is fixed by the derivatives along the other seven directions and by the potential.
- Each kinetic term carries the weight $1/f_\mu$: $e^{-a_4}\sin^{-1/6} z$ along 3-space (it shrinks as 3-space inflates), 1 along the time, $e^{a_4}\sin^{-1/6} z$ along the extra times (it grows as they deflate) and $\tan z$ along the hidden direction. Figure 09a.1 of Notebook 09a draws these weights.
- The potential part is the same, $-(mS+U)$, in all seven pressures, and $+(mS+U)$ in the energy density.
- Neither the K_μ nor S has a fixed sign, so ρ can be negative (Section 9.21).

All of this is PROVED in the record (`Revision/theory/reports/wolfram-field-theory.json`, check `T_diagonal_components_C`; `Revision/theory/field-theory.json`, formulas `EMT_diagonal` and `EMT_kinetic_potential`) and holds off shell.

9.8 The trace, and what the field equation adds

The trace off shell. The **trace** is the sum of the diagonal entries. Summing $T^\mu{}_\mu = L_0 - K_\mu$ over the eight directions:

$$\begin{aligned}\sum_\mu T^\mu{}_\mu &= 8L_0 - \sum_\mu K_\mu \\ &= 8\Big(\sum_\mu K_\mu - mS - U\Big) - \sum_\mu K_\mu \\ &= 7\sum_\mu K_\mu - 8(mS+U).\end{aligned}$$

The first line adds eight copies of L_0 and subtracts every K_μ once; the second inserts L_0; the third collects the kinetic terms (PROVED; check `EMT_trace_C` of `Revision/theory/reports/wolfram-field-theory.json`).

The kinetic sum. Define the **field-equation expression** $E = \gamma^\mu D_\mu\Phi - V\Phi$ and its adjoint $\bar{E} = (D_\mu\bar{\Phi})\gamma^\mu + V\bar{\Phi}$ (sums over μ); a configuration is on shell exactly when $E = 0$, and then $\bar{E} = 0$ too. Multiply E by $\bar{\Phi}$ from the left and $\bar{E}$ by Φ from the right:

$$\bar{\Phi}E = \sum_\mu \bar{\Phi}\gamma^\mu D_\mu \Phi - VS, \qquad \bar{E}\Phi = \sum_\mu D_\mu \bar{\Phi}\,\gamma^\mu \Phi + VS.$$

Subtract the second from the first and use Section 9.3 (the sum of the differences $\bar{\Phi}\gamma^\mu D_\mu\Phi - D_\mu\bar{\Phi}\gamma^\mu\Phi$ is $2\sum_\mu K_\mu$):

$$\bar{\Phi}E - \bar{E}\Phi = 2\sum_\mu K_\mu - 2VS, \qquad \text{so} \qquad \sum_\mu K_\mu = VS + \tfrac{1}{2}(\bar{\Phi}E - \bar{E}\Phi).$$

This **kinetic-sum identity** holds off shell (PROVED; check `kinetic_sum_on_shell_C`).

On shell. With $E = 0$ and $\bar{E} = 0$, line by line:

$$\begin{aligned}
\sum_\mu K_\mu &= VS = (m + U'(S))S, \\
L_0 &= \sum_\mu K_\mu - mS - U = mS + SU' - mS - U = SU'(S) - U(S), \\
\sum_\mu T^\mu{}_\mu &= 7(m + U')S - 8(mS + U) = -mS + 7SU'(S) - 8U(S).
\end{aligned}$$

The first line is the kinetic sum with $E = \bar{E} = 0$; the second inserts it into L_0 and cancels mS; the third inserts it into the trace. For $U = \frac{\lambda}{2}S^2$, $SU' = \lambda S^2$ and $8U = 4\lambda S^2$, so the trace on shell is $-mS + 7\lambda S^2 - 4\lambda S^2 = -mS + 3\lambda S^2$ (PROVED; `Revision/theory/reports/python-field-theory.json`, check `commuting_trace_on_shell`).

9.9 The covariant divergence of a diagonal tensor

Why a divergence. In flat space, energy that is not created or destroyed obeys a **conservation law**: the change in time of the energy density equals minus the outflow through the walls. In curved space the derivatives must be corrected by the **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$, which say how the coordinate directions turn and stretch from point to point (Chapter 3). The corrected derivative summed over the upper index is the **covariant divergence**

$$\nabla_\mu T^\mu{}_\nu = \sum_\mu \partial_\mu T^\mu{}_\nu + \sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda}\, T^\lambda{}_\nu - \sum_{\mu,\lambda} \Gamma^\lambda{}_{\mu\nu}\, T^\mu{}_\lambda,$$

one number for each of the eight values of ν. **Conservation** means $\nabla_\mu T^\mu{}_\nu = 0$ for all eight. On every solution of the field equation the tensor is conserved: this is a theorem, proved in the record from the invariance of the action under a change of coordinates (the **Noether identity**; PROVED, see the table below). We do not repeat that proof. We ask instead: what does conservation say about a tensor of the simplest kind?

statement	Revision report	check

a wrong tensor is not conserved (negative control)	`Revision/theory/reports/python-field-theory.json`	`commuting_emt_conservation_negative_control`

The Christoffel symbols of the author's metric. For a metric the symbols are $\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2}\sum_\rho g^{\lambda\rho}(\partial_\mu g_{\rho\nu} + \partial_\nu g_{\rho\mu} - \partial_\rho g_{\mu\nu})$. For a diagonal metric only $\rho = \lambda$ survives and

$$\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}(\partial_\mu g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu}) \qquad \text{(no sum over } \lambda\text{)}.$$

The symbol is symmetric in μ and ν. Six of them, computed line by line (the entries depend only on x_4, through a_4, and on x_0, through $z = 6Hx_0$, whose derivative is $dz/dx_0 = 6H$):

- $\Gamma^{x_1}{}_{x_1x_4} = \frac{1}{2g_{11}}\partial_4 g_{11} = \frac{1}{2}\,\partial_4 \ln g_{11} = \frac{1}{2}\,\partial_4(2a_4 + \frac{1}{3}\ln\sin z) = a_4'$; the first step keeps the only nonzero derivative, the second uses $\partial(\ln Q) = \partial Q/Q$, the third writes $\ln g_{11} = 2a_4 + \frac{1}{3}\ln\sin z$, and the last differentiates ($\sin z$ does not depend on x_4).
- $\Gamma^{x_4}{}_{x_1x_1} = \frac{1}{2g_{44}}(-\partial_4 g_{11}) = \frac{1}{-2}(-2a_4' e^{2a_4}\sin^{1/3} z) = a_4'\, e^{2a_4}\sin^{1/3} z$; only the third term of the bracket survives ($g_{41} = 0$), $g_{44} = -1$, and the chain rule gives $\partial_4 e^{2a_4} = 2a_4' e^{2a_4}$.
- $\Gamma^{x_0}{}_{x_1x_1} = \frac{1}{2g_{00}}(-\partial_0 g_{11}) = -\frac{\tan^2 z}{2}\, e^{2a_4}\cdot\frac{1}{3}\sin^{-2/3} z\cos z\cdot 6H = -He^{2a_4}\,\frac{\sin^{4/3} z}{\cos z}$; here $1/g_{00} = \tan^2 z$, the chain rule gives $\partial_0 \sin^{1/3} z = \frac{1}{3}\sin^{-2/3} z\cos z\cdot 6H$, and $\tan^2 z\,\sin^{-2/3} z\cos z = \sin^{4/3} z/\cos z$.
- $\Gamma^{x_0}{}_{x_0x_0} = \frac{1}{2}\,\partial_0 \ln\cot^2 z = \partial_0 \ln\cot z = 6H\cdot\frac{-1/\sin^2 z}{\cot z} = -\frac{6H}{\sin z\cos z} = -\frac{12H}{\sin(12Hx_0)}$, using $\frac{d}{dz}\cot z = -1/\sin^2 z$ and $2\sin z\cos z = \sin 2z$.
- $\Gamma^{x_4}{}_{x_5x_5} = \frac{1}{2g_{44}}(-\partial_4 g_{55}) = \frac{1}{-2}(-2a_4' e^{-2a_4}\sin^{1/3} z) = a_4'\, e^{-2a_4}\sin^{1/3} z$; only the third term of the bracket survives ($g_{45} = 0$), $g_{44} = -1$, and the chain rule gives $\partial_4 g_{55} = \partial_4(-e^{-2a_4}\sin^{1/3} z) = -(-2a_4')e^{-2a_4}\sin^{1/3} z = 2a_4' e^{-2a_4}\sin^{1/3} z$ (two minus signs: the one of the entry and the one of the exponent $-2a_4$).
- $\Gamma^{x_0}{}_{x_5x_5} = \frac{1}{2g_{00}}(-\partial_0 g_{55}) = \frac{\tan^2 z}{2}\, e^{-2a_4}\cdot\frac{1}{3}\sin^{-2/3} z\cos z\cdot 6H = He^{-2a_4}\,\frac{\sin^{4/3} z}{\cos z}$; here $-\partial_0 g_{55} = +\partial_0(e^{-2a_4}\sin^{1/3} z)$ because the entry g_{55} carries a minus sign, and the rest is the computation of $\Gamma^{x_0}{}_{x_1x_1}$; the sign is opposite to that of $\Gamma^{x_0}{}_{x_1x_1}$ because g_{55} and g_{11} have opposite signs.

The three remaining kinds, $\Gamma^{x_i}{}_{x_ix_0}$, $\Gamma^{x_t}{}_{x_4x_t}$ and $\Gamma^{x_t}{}_{x_tx_0}$, have the form of the first bullet, a logarithmic derivative of one diagonal entry; the lemma below gives each of them in one line, and Exercise 1

works two of them out in full. The directions x_2, x_3 give the same values as x_1, and x_6, x_7 the same values as x_5, because their entries of the metric are equal. The complete list of the nonzero symbols with $\mu \le \nu$ is (25 symbols: four for each of the six directions x_i and x_t, and one more; why there are exactly 25 is shown after the lemma below):

symbol	value	symbol	value
$\Gamma^{x_i}{}_{x_i x_4}$	a_4'	$\Gamma^{x_t}{}_{x_4 x_t}$	$-a_4'$
$\Gamma^{x_i}{}_{x_i x_0}$	$H\cot z$	$\Gamma^{x_t}{}_{x_t x_0}$	$H\cot z$
$\Gamma^{x_4}{}_{x_i x_i}$	$a_4' e^{2a_4}\sin^{1/3} z$	$\Gamma^{x_4}{}_{x_t x_t}$	$a_4' e^{-2a_4}\sin^{1/3} z$
$\Gamma^{x_0}{}_{x_i x_i}$	$-He^{2a_4}\sin^{4/3} z/\cos z$	$\Gamma^{x_0}{}_{x_t x_t}$	$He^{-2a_4}\sin^{4/3} z/\cos z$
$\Gamma^{x_0}{}_{x_0 x_0}$	$-6H/(\sin z\cos z)$	(none)	(none)

(PROVED; `Revision/theory/field-theory.json`, formula `christoffel_nonzero`, and `Revision/theory/reports/wolfram-field-theory.json`, check `christoffel_count`. Notebook 09a computes the 25 symbols with sympy and compares them with the record one by one.)

A lemma for diagonal metrics. Set $\lambda = \mu$ in the formula above (no sum):

$$\Gamma^{\mu}{}_{\mu\nu} = \frac{1}{2g_{\mu\mu}}\left(\partial_\mu g_{\mu\nu} + \partial_\nu g_{\mu\mu} - \partial_\mu g_{\mu\nu}\right) = \frac{\partial_\nu g_{\mu\mu}}{2g_{\mu\mu}} = \frac{2\eta_{\mu\mu} f_\mu\, \partial_\nu f_\mu}{2\eta_{\mu\mu} f_\mu^2} = \partial_\nu \ln f_\mu .$$

The first and the third term of the bracket cancel; then $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$ and the chain rule $\partial_\nu f_\mu^2 = 2 f_\mu \partial_\nu f_\mu$; finally $\partial_\nu f_\mu / f_\mu = \partial_\nu \ln f_\mu$. Summed over μ this gives $\sum_\mu \Gamma^{\mu}{}_{\mu\nu} = \partial_\nu \ln(f_0 \cdots f_7) = \partial_\nu \ln\sqrt{|g|}$. For example, $\Gamma^{x_1}{}_{x_1 x_0} = \partial_0 \ln f_1 = \partial_0 (a_4 + \frac{1}{6}\ln\sin z) = \frac{1}{6}\cdot\frac{\cos z}{\sin z}\cdot 6H = H\cot z$, by the chain rule with $dz/dx_0 = 6H$.

Why there are exactly 25 symbols. Sort the symbols by how many of the three indices λ, μ, ν are equal, and use the diagonal formula. Remember that the entries of the metric depend only on x_4 and x_0, that $g_{44} = -1$ is a constant, and that $g_{00} = \cot^2 z$ does not depend on x_4.

- Three different indices: every entry in the bracket, $g_{\lambda\nu}$, $g_{\lambda\mu}$ and $g_{\mu\nu}$, lies off the diagonal and is zero, so the symbol is zero.
- $\mu = \nu \neq \lambda$: the first two terms of the bracket contain $g_{\lambda\mu} = 0$, so $\Gamma^{\lambda}{}_{\mu\mu} = -\partial_\lambda g_{\mu\mu}/(2g_{\lambda\lambda})$. It is nonzero only when $g_{\mu\mu}$ depends on x_λ: λ is x_4 or x_0, and μ is one of the six directions x_i, x_t, whose entries depend on both ($\mu = x_4$ is excluded because g_{44} is constant, and $\mu = x_0$ with $\lambda = x_4$ because g_{00} does not depend on x_4). That makes $2 \cdot 6 = 12$ symbols.
- λ equal to exactly one of μ, ν (stored as $\Gamma^{\lambda}{}_{\lambda\nu}$ or $\Gamma^{\lambda}{}_{\nu\lambda}$, whichever has the smaller index first): by the lemma it is $\partial_\nu \ln f_\lambda$, nonzero only when f_λ depends on x_ν, that is for λ one of the six directions x_i, x_t and $\nu = x_4$ or x_0 ($f_4 = 1$ is constant, and $f_0 = \cot z$ does not depend on x_4). That makes another $6 \cdot 2 = 12$ symbols.
- All three equal: $\Gamma^{\lambda}{}_{\lambda\lambda} = \partial_\lambda \ln f_\lambda$ by the lemma, nonzero only for $\lambda = x_0$, since $f_0 = \cot z$ is the only factor that depends on its own coordinate. One symbol.

The total is $12 + 12 + 1 = 25$, the count of the table and of the record.

The divergence of a diagonal tensor. Now let $T^{\mu}{}_{\nu}$ be diagonal: $T^{\mu}{}_{\nu} = 0$ for $\mu \neq \nu$. In each of the three sums of the divergence only the terms with a diagonal entry survive:

- first sum: only $\mu=\nu$, giving $\partial_\nu T^\nu{}_\nu$;
- second sum: only $\lambda=\nu$, giving $\sum_\mu \Gamma^\mu{}_{\mu\nu} T^\nu{}_\nu = \sum_\mu (\partial_\nu \ln f_\mu)\, T^\nu{}_\nu$;
- third sum: only $\lambda=\mu$, giving $\sum_\mu \Gamma^\mu{}_{\mu\nu} T^\mu{}_\mu = \sum_\mu (\partial_\nu \ln f_\mu)\, T^\mu{}_\mu$.

Both corrections use only the lemma. Subtracting the third from the second:

$$\nabla_\mu T^\mu{}_\nu = \partial_\nu T^\nu{}_\nu + \sum_\mu (\partial_\nu \ln f_\mu)(T^\nu{}_\nu - T^\mu{}_\mu) \qquad (\text{diagonal } T,\ \text{no sum over } \nu).$$

This formula holds for every diagonal metric and every diagonal tensor. We apply it to the author's metric and to

$$T^\mu{}_\nu = \operatorname{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0),$$

whose four entries are any functions of x_4 and x_0. The logarithmic derivatives we need are, from $\ln f_i = a_4 + \frac{1}{6}\ln\sin z$, $\ln f_t = -a_4 + \frac{1}{6}\ln\sin z$, $\ln f_4 = 0$ and $\ln f_0 = \ln\cot z$:

$$\begin{aligned} &\partial_4 \ln f_i = a_4', \qquad \partial_4 \ln f_t = -a_4', \qquad \partial_4 \ln f_4 = \partial_4 \ln f_0 = 0, \\ &\partial_0 \ln f_i = \partial_0 \ln f_t = \tfrac{1}{6}\cdot\frac{\cos z}{\sin z}\cdot 6H = H\cot z, \qquad \partial_0 \ln f_4 = 0. \end{aligned}$$

The component $\nu = x_4$. Here $T^{x_4}{}_{x_4} = -\rho$:

$$\begin{aligned} \nabla_\mu T^\mu{}_{x_4} &= \partial_4(-\rho) + 3a_4'(-\rho - p_3) + 3(-a_4')(-\rho - p_t) \\ &= -\partial_4\rho - 3a_4'\rho - 3a_4'p_3 + 3a_4'\rho + 3a_4'p_t \\ &= -\partial_4\rho - 3a_4'(p_3 - p_t). \end{aligned}$$

The first line takes the three 3-space directions (weight a_4', entry p_3) and the three extra times (weight $-a_4'$, entry p_t); the directions x_4 and x_0 have weight 0. The second multiplies out; the third cancels $\mp 3a_4'\rho$ and factors.

The component $\nu = x_0$. Here $T^{x_0}{}_{x_0} = p_0$. The direction $\mu = x_0$ gives $(p_0 - p_0) = 0$ whatever its weight, and $\mu = x_4$ has weight 0:

$$\nabla_\mu T^\mu{}_{x_0} = \partial_0 p_0 + 3H\cot z\,(p_0 - p_3) + 3H\cot z\,(p_0 - p_t) = \partial_0 p_0 + 3H\cot z\,(2p_0 - p_3 - p_t).$$

The other six components. For $\nu = x_1$ (and likewise x_2, x_3, x_5, x_6, x_7) every term contains a derivative ∂_1 of something that depends only on x_4 and x_0; all vanish: $\nabla_\mu T^\mu{}_{x_1} = 0$ identically.

These are exactly the record's statements (PROVED; the table lists the record files and checks). Notebook 09a derives them again with sympy, from the 25 Christoffel symbols and the general divergence formula, without using the lemma.

9.10 The x4 identity: energy exchange between 3-space and the extra times

Conservation of a diagonal tensor along x_4 is therefore

$$\frac{\partial \rho}{\partial x_4} = -3a_4' \, (p_3 - p_t).$$

What it says. On a deflating history ($a_4' > 0$) the energy density falls when the 3-space pressure exceeds the extra-time pressure, rises when it is smaller, and stays constant only when $p_3 = p_t$. Energy flows between 3-space and the extra times. Reversing the history ($a_4' \to -a_4'$: the extra times inflate and 3-space deflates) reverses the flow. Note what is absent: in ordinary cosmology the energy density of a gas always falls as space expands, $d\rho/dt = -3\,(\dot{a}/a)\,(\rho + p)$ with the scale factor a, because the volume grows. Here the volume factor $\sqrt{|g|} = \cos z$ does not change with x_4, so no term with ρ itself appears; only the difference of the two pressures drives the energy.

With a changing b_4. For the metric with $b_4(x_4)$ the volume factor is $b_4^{3/2} \cos z$, and the extra times shrink at the rate $a_4' - b_4'/(2b_4)$. The Revision record computes the divergence of a diagonal tensor for this metric (`Revision/theory/field-theory-b4.json`, formula `energy_exchange`; `wolfram-field-theory-b4.json`, check `energy_exchange_equation_b4`): the x_4 component becomes

$$\nabla_\mu T^\mu{}_{x_4} = -\frac{\partial \rho}{\partial x_4} - 3a_4' \, (p_3 - p_t) - \frac{3}{2}\,\frac{b_4'}{b_4}\,(p_t + \rho),$$

so a changing b_4 adds a term of the ordinary cosmological kind, with $\rho + p_t$, for the three extra times; the x_0 component is unchanged. The derivation of this section and Notebook 09a are for $b_4 = 1$.

A first-law reading (an interpretation, not an extra result). At fixed x_0 take a small box of coordinate size 1 along each of the seven directions other than x_4. Its 3-space volume is $V_3 = f_1 f_2 f_3 = e^{3a_4} \sin^{1/2} z$, its extra-time volume $V_t = f_5 f_6 f_7 = e^{-3a_4} \sin^{1/2} z$, and its 7-volume $V_7 = V_3 V_t f_8 = \cos z$ does not change with x_4. The first law of thermodynamics says that the energy

of a box changes by minus the pressure times the change of its volume. Applied separately to the two families of directions, with each change of volume taken relative to the volume of its family,

$$\frac{d}{dx_4}(\rho V_7) = -p_3\,\frac{V_7}{V_3}\frac{dV_3}{dx_4} - p_t\,\frac{V_7}{V_t}\frac{dV_t}{dx_4}.$$

Divide by the constant V_7 and insert $\frac{1}{V_3}\frac{dV_3}{dx_4} = 3a_4'$ and $\frac{1}{V_t}\frac{dV_t}{dx_4} = -3a_4'$ (the logarithmic derivatives of $e^{\pm 3a_4}$): the result is $d\rho/dx_4 = -3a_4'p_3 + 3a_4'p_t$, the conservation identity. While 3-space inflates ($dV_3 > 0$), a positive p_3 takes energy out of the box; while the extra times deflate ($dV_t < 0$), a positive p_t puts energy in. Notebook 09a checks with sympy that this reading is exactly the identity, and Figure 09a.4 draws the three volumes.

Toy fluids (an ILLUSTRATION, not solutions of the field equations of this book). Suppose a source had pressures proportional to its energy density, $p_3 = w_3\rho$ and $p_t = w_t\rho$ with constants w_3, w_t, on the history $a_4 = AHx_4$ ($a_4' = AH$). The identity becomes $d\rho/dx_4 = -3AH(w_3 - w_t)\,\rho$: the rate of change of ρ is a constant times ρ. The function $\rho_0 e^{cx_4}$ has the derivative $c\,\rho_0 e^{cx_4}$, so the solution with $\rho(0) = \rho_0$ is

$$\rho(x_4) = \rho_0\, e^{-3AH(w_3 - w_t)x_4}.$$

With $A = 1$, $H = 0.25$ and $w_3 - w_t = 1/3$, at $x_4 = 8$ the exponent is $-3 \cdot 0.25 \cdot \frac{1}{3} \cdot 8 = -2$ and $\rho(8)/\rho(0) = e^{-2} = 0.135335$, the number that Notebook 09b computes with the Runge-Kutta method. The condensates of Section 9.18 have $p_3 = p_t$ and exchange no energy at all.

9.11 The x0 identity: the balance along the hidden direction

Conservation along x_0 is

$$\frac{\partial p_0}{\partial x_0} = -3H\cot z\,(2p_0 - p_3 - p_t).$$

It is a balance of pressures, like the balance of pressure and weight in a column of air: a change of the hidden pressure along x_0 must be paid for by the difference between p_0 and the mean of the other two pressures.

Entries that do not depend on x_0. Then the left side is zero, and because $\cot z > 0$ for $0 < z < \pi/2$ the bracket must vanish:

$$p_0 = \tfrac{1}{2}(p_3 + p_t).$$

The field equations of gravity force the same condition, $p_3 + p_t = 2p_0$, for every source with which the author's metric solves them (Chapter 12 derives these equations). Add the record's 3-space equation (right-hand side κp_3) and its extra-time equation (right-hand side κp_t): every term with a_4'' appears in the two left-hand sides with opposite signs and cancels, and what remains is exactly twice the left-hand side of the hidden equation (right-hand side κp_0). Hence $\kappa(p_3 + p_t) = 2\kappa p_0$, and for a coupling $\kappa \neq 0$, $p_3 + p_t = 2p_0$ (PROVED; the table names the record's entries and checks). The conservation identity and the field equations of gravity are therefore consistent.

statement	Revision record	entry or check
the 3-space, extra-time and hidden equations	`Revision/field_equations_a4/a4-equations.json`	entry `generalSource`: `space_x1_eq_x2_eq_x3`, `extraTime_x5_eq_x6_eq_x7`, `hidden_x0`
the condition $p_3 + p_t = 2p_0$	`Revision/field_equations_a4/a4-equations.json`	`generalSource.algebraic_condition`
the identity of the Lovelock tensors behind it	`Revision/field_equations_a4/reports/wolfram-a4-report.json`	`algebraic_identity_x1_plus_x5_minus_2x0`
the same, verified independently with sympy	`Revision/field_equations_a4/reports/python-a4-report.json`	`algebraic_identity`

All solutions when $p_3 + p_t = P$ is a constant. Write $q = p_0 - P/2$. Then $2p_0 - P = 2q$, and with $dz = 6H\,dx_0$ the identity becomes

$$6H\frac{dq}{dz} = -3H\cot z \cdot 2q, \qquad \text{that is} \qquad \frac{dq}{dz} + \cot z\; q = 0.$$

Multiply by $\sin z$: $\sin z\,\frac{dq}{dz} + \cos z\; q = \frac{d}{dz}(q\sin z) = 0$ (the product rule read backwards). So $q\sin z$ is a constant c, and every solution is

$$p_0 = \frac{P}{2} + \frac{c}{\sin z}.$$

Only $c = 0$ gives a profile independent of x_0; every other profile grows in size like $1/\sin z$ towards the tip $z = 0$ (Figure 09a.5).

In the Kohn-Sham coordinate. The Kohn-Sham solver of Chapter 15 uses the hidden coordinate $y = \ln(\sin z)/(6H)$, for which $dy/dx_0 = \frac{1}{6H}\cdot\frac{\cos z}{\sin z}\cdot 6H = \cot z$. By the chain rule $\partial_0 p_0 = \cot z\, dp_0/dy$, so the x_0 component of the divergence is $\cot z\,[dp_0/dy + 6Hp_0 - 3H(p_3 + p_t)]$, the form that solver checks (PROVED; `Revision/lead_checks/reports/emt-divergence-and-spin-connection.json`, checks `ks_coordinate_jacobian` and `ks_coordinate_form`).

9.12 Where the spin connection does enter the tensor

The spin connection drops out of the Lagrangian and of the diagonal entries (Fact 1). It does enter entries off the diagonal. Take a **homogeneous** configuration: one that depends on the time x_4 only, so that $\partial_\mu\Phi = 0$ for every $\mu \neq x_4$. Consider the piece

$$K^{x_4}{}_{x_1} = \tfrac{1}{2}\big(\bar\Phi\gamma^{x_4}D_{x_1}\Phi - D_{x_1}\bar\Phi\,\gamma^{x_4}\Phi\big)$$

of the entry $T^{x_4}{}_{x_1}$. Line by line:

$$K^{x_4}{}_{x_1} = \tfrac{1}{2}\big(\bar\Phi\gamma^{(4)}\Omega_{x_1}\Phi + \bar\Phi\,\Omega_{x_1}\gamma^{(4)}\Phi\big) = \tfrac{1}{2}\,\bar\Phi\{\gamma^{(4)},\Omega_{x_1}\}\Phi,$$
$$\{\gamma^{(4)},\gamma^{(1)}\gamma^{(4)}\} = \gamma^{(4)}\gamma^{(1)}\gamma^{(4)} + \gamma^{(1)}\gamma^{(4)}\gamma^{(4)} = -\gamma^{(1)}\gamma^{(4)}\gamma^{(4)} + \gamma^{(1)}\gamma^{(4)}\gamma^{(4)} = 0,$$
$$\{\gamma^{(4)},\gamma^{(1)}\gamma^{(0)}\} = \gamma^{(4)}\gamma^{(1)}\gamma^{(0)} + \gamma^{(1)}\gamma^{(0)}\gamma^{(4)} = 2\gamma^{(4)}\gamma^{(1)}\gamma^{(0)},$$
$$K^{x_4}{}_{x_1} = \tfrac{1}{2}\cdot\tfrac{1}{2}f_1\big(a_4'\cdot 0 + H\cdot 2\,\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi\big) = \tfrac{1}{2}\,e^{a_4}\sin^{1/6} z\; H\;\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi.$$

The first line uses $\partial_1\Phi = 0$, so $D_{x_1}\Phi = \Omega_{x_1}\Phi$ and $D_{x_1}\bar\Phi = -\bar\Phi\Omega_{x_1}$, and $\gamma^{x_4} = \gamma^{(4)}$ ($f_4 = 1$). The second moves $\gamma^{(4)}$ past $\gamma^{(1)}$ (a minus sign). The third moves $\gamma^{(4)}$ in the second product to the front past $\gamma^{(0)}$ and then past $\gamma^{(1)}$ (two minus signs, so no sign change). The fourth inserts $\Omega_{x_1} = \frac{1}{2}f_1(a_4'\gamma^{(1)}\gamma^{(4)} + H\gamma^{(1)}\gamma^{(0)})$ and the two anticommutators. The a_4' part cancels, the H part survives, and the three-gamma bilinear $\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi$ is not zero in general: the canonical spin connection contributes to the energy-momentum tensor even though it drops out of the Lagrangian (PROVED; `Revision/theory/reports/python-scope.json` and `wolfram-scope.json`, check `spin_connection_in_the_energy_momentum_tensor`). Section 9.26 and Notebook 09c compute all such entries of a condensate.

9.13 The same tensor for dirac16complex

Everything in Sections 9.3 to 9.12 is algebra with the bilinears $\bar\Phi M\Phi$ and $\bar\Phi M\partial\Phi$, in which the row $\bar\Phi$ always stands to the left of the column. For the anticommuting field dirac16complex (Chapter 7) the same formulas hold, with every bilinear an even element of the Grassmann algebra (a sum of products of two anticommuting numbers; such a product commutes with every element of the algebra, as an ordinary number does); the Revision record verifies them (PROVED; for example the checks `T_diagonal_components_G`, `EMT_trace_G` and `kinetic_sum_on_shell_G` of `Revision/theory/reports/wolfram-field-theory.json` and the check `grassmann_homogeneous_on_shell_rho_p` of `Revision/theory/reports/python-field-theory.json`). After canonical quantisation (Chapter 10; the field becomes an **operator**, a rule that acts on the quantum states) the record defines the tensor as an operator too: every bilinear is replaced by the **normal-ordered** product of the quantised field (the product rearranged so that the operators that remove a particle stand to the right of those that create one, which gives the empty state the energy zero; Chapter 10 defines it exactly), $\hat T^{\nu}{}_{\mu} = :T^{\nu}{}_{\mu}[\hat\Psi,\hat{\bar\Psi}]:$, normal ordered with respect to the waves of the **good sector** (the waves that do not depend on the extra times x_5, x_6, x_7), and the numbers are **expectation values** (the average value that measurements of the operator give in a given quantum state) (record `Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`, section 12). Three limits of the record must be stated.

1. The space of quantum states with positive norms on which this normal ordering rests (the positive **Fock space** of Chapter 10, built from states with definite numbers of particles) is constructed and checked only for single good-sector momenta with frozen coefficients, that is, for plane waves of a flat frame at one point, in which the deflation of the extra times does not enter (PROVED for these examples; the table below names the checks). In the author's curved metric the record imposes no boundary condition at the patch end $z = \pi/2$, and without one the good sector has complex frequencies (waves that grow or decay in time instead of oscillating), for $U = 0$ whenever $m^2 < 9H^2$ (PROVED). A space of states with positive norms for the full field is not established (OPEN).

2. For $\lambda \neq 0$ the operator form of the on-shell identity $\sum_\mu \langle :K_\mu: \rangle = \langle :(m + U')S: \rangle$ is verified only in a finite model: the Fock space of one good-sector plane-wave mode set with frozen coefficients (flat frame, volume 1, 16 modes, 2^{16} states). There it holds as an exact operator identity, for the solution of the interacting operator field equation, if and only if the potential and the tensor are both **Wick ordered** (the whole product of field operators is normal ordered at once: the potential as $\frac{\lambda}{2}:SS:$, not as $\frac{\lambda}{2}:S::S:$, and the tensor as a Wick product, not by subtracting its value in the empty state); with every other ordering tested it fails, already in expectation values (PROVED in that model; its report, named in the table below, passes 21 of 21 checks). For the field on a whole slice (many momenta), for the curved x_0 dependence and for the extra-time sector the operator identity is OPEN (the field-equations record of Chapter 12 ASSUMES it), and symmetry and conservation of the quartic operator are not verified.

3. Numerical expectation values of the tensor for many-fermion states are computed only in the Kohn-Sham approximation of Part IV. The finite model of limit 2 gives exact values on the **occupation states** of its one mode set at rest (momentum $k = 0$). An occupation state has each of the 16 modes either empty or holding one **quantum** (one excitation of the quantised field); Chapter 10 splits the 16 modes into 8 particle modes and 8 **antiparticle** modes (an antiparticle has the opposite charge of a particle, and both have positive energy). On an occupation state with n quanta, particles and antiparticles counted together, $\rho = mn + \frac{\lambda}{2}n(n-1)$ and $p = \frac{\lambda}{2}n(n-1)$, so that $\langle :U(S): \rangle = \frac{\lambda}{2}n(n-1)$ differs from $U(\langle :S: \rangle) = \frac{\lambda}{2}n^2$ for $n \geq 1$ and $\lambda \neq 0$ (PROVED in that model; the table below names the check). For example, one particle and one antiparticle at rest ($n = 2$) give $\rho = 2m + \lambda$ and $p = \lambda$, and two particles and one antiparticle ($n = 3$) give $\rho = 3m + 3\lambda$ and $p = 3\lambda$. The model gives no numerical expectation value for a physical many-fermion state.

The records of the three limits:

statement	**Revision report**	**check**
positive Fock space for single good-sector momenta with frozen coefficients	`Revision/theory/reports/wolfram-field-theory.json`	`mode_hamiltonian_good_sector`, `Fock_space_good_sector_example`
the same with sympy, for another momentum	`Revision/theory/reports/python-field-theory.json`	`good_sector_positive_fock_realisation`
complex frequencies of the curved good sector without a boundary condition at $z = \pi/2$	`Revision/theory/reports/wolfram-scope.json` and `python-scope.json`	`good_sector_hermiticity_up_to_the_brane_flux`, `good_sector_x0_independent_modes_without_boundary_condition`
finite model, $\lambda \neq 0$: the identity holds when both are Wick ordered	`Revision/theory/fock_quartic/reports/fock-quartic.json`	`trace_identity_operator_identity_wick`
finite model: it fails for every other ordering tested	the same report	`trace_identity_fails_for_every_other_combination`

statement	Revision report	check
finite model, occupation states with n quanta at rest: $\rho = mn + \frac{\lambda}{2}n(n-1)$, $p = \frac{\lambda}{2}n(n-1)$	the same report	`homogeneous_expectation_values_are_not_U_of_expectation`

This chapter therefore computes numbers only for the commuting field dirac16complex00.

9.14 Example: the tensor at one point and the two identities

The first worked example puts Sections 9.3 to 9.12 on the computer. At one point of the deflating history ($H = 0.25$, $a_4 = AHx_4$ with $A = 1$, so $a_4 = 0.5$ and $a_4' = 0.25$ at $x_4 = 2$, and $z = \pi/4$) it builds the coordinate gammas and the spin connection from the Revision fixture and formula, draws a configuration of dirac16complex00 at random, computes its 64 entries $T^{\nu}{}_{\mu}$ literally from the formula of Section 9.6, and checks every identity of Sections 9.5 to 9.8, first off shell and then after putting the configuration on shell with the evolution form. It checks the connection term of Section 9.12. Then it switches to exact symbols: it computes the 25 Christoffel symbols with sympy, compares them with the record, derives the eight components of the divergence of a diagonal tensor and compares them with the record's formula `energy_exchange` and with the lead's checks, checks the first-law reading and the profiles of the x_0 balance, and draws five figures.

9.15 How to run Notebook 09a

Step 1. What this notebook does and what it needs.

Notebook 09a (The energy-momentum tensor and its conservation identities) is the file `Revision/textbook/notebooks/09a_emt_and_identities.ipynb` of the repository Dirac_claude. It builds the energy-momentum tensor of the commuting field dirac16complex00 at one point of the author's metric from the Revision gamma matrices and spin connection, checks that the tensor is real and symmetric, that its diagonal entries are the energy density and the pressures with their kinetic and potential parts, and the trace and on-shell identities; it then derives with sympy the Christoffel symbols of the metric and the two conservation identities of a diagonal tensor (the energy exchange between 3-space and the extra times along x4, and the balance along the hidden direction x0), reads the first one as a first law of thermodynamics, and draws five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at

the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09a_emt_and_identities.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09a_emt_and_identities.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 09a_emt_and_identities.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/09a.captions.json`

- `Revision/textbook/figures/09a_1_kinetic_weights.png`
- `Revision/textbook/figures/09a_2_tensor_heat_map.png`
- `Revision/textbook/figures/09a_3_diagonal_parts.png`
- `Revision/textbook/figures/09a_4_volumes_first_law.png`
- `Revision/textbook/figures/09a_5_hidden_balance.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the five figures of this notebook are saved and captioned
ALL 27 CHECKS PASSED (notebook 09a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/09a_emt_and_identities.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 09a_emt_and_identities.ipynb
python -m nbconvert --execute --inplace 09a_emt_and_identities.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not contain that check: your copy is older or newer than the notebook. Run `git pull` in the repository folder, then run the notebook again.
- The cell of the Christoffel symbols runs for more than a minute: sympy simplifies 288 expressions there; on a slow computer this takes longer; wait until the cell has finished (its number appears in the margin) before you run the next cell.

9.16 Notebook 09a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/09a_emt_and_identities.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook is the first worked example of the chapter on the energy-momentum
tensor. It works with the commuting field dirac16complex00 (16 complex numbers at
every point) in the author's primordial metric, and it

- builds, at one chosen point of the deflating history, the coordinate gamma
  matrices, the spin connection and the energy-momentum tensor $T^\nu{}_\mu$ (an
```

```
  $8 \times 8$ table of numbers) of a field configuration chosen at random;
- checks that the tensor is real and symmetric, that its diagonal entries are
  $T^\mu{}_\mu = L_0 - K_\mu$, and computes from them the energy density $\rho$,
  the pressures $p_3$ (3-space), $p_t$ (extra times) and $p_0$ (hidden direction)
  with their kinetic and potential parts;
- checks the trace identity and the kinetic-sum identity, and what they become
  when the configuration satisfies the field equation (on shell);
- shows where the spin connection does enter the tensor (an off-diagonal entry);
- derives exactly, with sympy, the 25 Christoffel symbols of the metric and the
  covariant divergence of a diagonal tensor: the two conservation identities
  $\partial_4\rho = -3a_4'(p_3 - p_t)$ and
  $\partial_0 p_0 = -3H\cot z (2p_0 - p_3 - p_t)$;
- reads the first identity as a first law of thermodynamics for the 7-volume and
  the second one as a balance of pressures along the hidden direction;
- compares every result that the Revision record also contains with that record
  and draws five teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 09a (The energy-momentum tensor and its conservation identities) is the file
‘Revision/textbook/notebooks/09a_emt_and_identities.ipynb‘ of the repository
Dirac_claude. It builds the energy-momentum tensor of the commuting field
dirac16complex00 at one point of the author’s metric from the Revision gamma matrices and
spin connection, checks that the tensor is real and symmetric, that its diagonal entries
are the energy density and the pressures with their kinetic and potential parts, and the
trace and on-shell identities; it then derives with sympy the Christoffel symbols of the
metric and the two conservation identities of a diagonal tensor (the energy exchange
between 3-space and the extra times along x4, and the balance along the hidden direction
x0), reads the first one as a first law of thermodynamics, and draws five teaching plots.
It needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and
matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It
does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".
```

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
```

```
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09a_emt_and_identities.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09a_emt_and_identities.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 09a_emt_and_identities.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/09a.captions.json‘
- ‘Revision/textbook/figures/09a_1_kinetic_weights.png‘
- ‘Revision/textbook/figures/09a_2_tensor_heat_map.png‘
- ‘Revision/textbook/figures/09a_3_diagonal_parts.png‘
- ‘Revision/textbook/figures/09a_4_volumes_first_law.png‘
- ‘Revision/textbook/figures/09a_5_hidden_balance.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS the five figures of this notebook are saved and captioned
    ALL 27 CHECKS PASSED (notebook 09a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/09a_emt_and_identities.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 09a_emt_and_identities.ipynb
      python -m nbconvert --execute --inplace 09a_emt_and_identities.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not

  contain that check: your copy is older or newer than the notebook. Run ‘git pull‘ in
  the repository folder, then run the notebook again.
- The cell of the Christoffel symbols runs for more than a minute: sympy simplifies 288
  expressions there; on a slow computer this takes longer; wait until the cell has
  finished (its number appears in the margin) before you run the next cell.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 09a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 09a (The energy-momentum tensor and its conservation identities) is the file
# Revision/textbook/notebooks/09a_emt_and_identities.ipynb of the repository
# Dirac_claude. It builds the energy-momentum tensor of the commuting field
# dirac16complex00 at one point of the author's metric from the Revision gamma matrices
# and spin connection, checks that the tensor is real and symmetric, that its diagonal
# entries are the energy density and the pressures with their kinetic and potential
# parts, and the trace and on-shell identities; it then derives with sympy the
# Christoffel symbols of the metric and the two conservation identities of a diagonal
# tensor (the energy exchange between 3-space and the extra times along x4, and the
# balance along the hidden direction x0), reads the first one as a first law of
# thermodynamics, and draws five teaching plots. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
```

```
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
```

```
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 09a_emt_and_identities.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
```

```
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 09a_emt_and_identities.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 09a_emt_and_identities.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/09a.captions.json
# - Revision/textbook/figures/09a_1_kinetic_weights.png
# - Revision/textbook/figures/09a_2_tensor_heat_map.png
# - Revision/textbook/figures/09a_3_diagonal_parts.png
# - Revision/textbook/figures/09a_4_volumes_first_law.png
# - Revision/textbook/figures/09a_5_hidden_balance.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the five figures of this notebook are saved and captioned
#     ALL 27 CHECKS PASSED (notebook 09a)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
```

```
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/09a_emt_and_identities.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 09a_emt_and_identities.ipynb
#     python -m nbconvert --execute --inplace 09a_emt_and_identities.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "KeyError" with the words "has no check": the notebook asks a Revision report for the
#   verdict of one of its checks, and the report in your copy of the repository does not
#   contain that check: your copy is older or newer than the notebook. Run git pull in
#   the repository folder, then run the notebook again.
# - The cell of the Christoffel symbols runs for more than a minute: sympy simplifies 288
#   expressions there; on a slow computer this takes longer; wait until the cell has
#   finished (its number appears in the margin) before you run the next cell.
#

```
## 3. The words used in this notebook

- **Coordinates**: $x_1, x_2, x_3$ are ordinary 3-space; $x_4$ is the time;
  $x_5, x_6, x_7$ are the three extra times; $x_0$ is the hidden space direction.
  In the code, index 0 means $x_1$, index 3 means $x_4$ and index 7 means $x_0$.
- **Tensor** $T^\nu{}_\mu$: a table of $8 \times 8$ numbers at every point, one
  for each pair of directions $(\nu, \mu)$. The upper index $\nu$ is the row, the
  lower index $\mu$ the column. Lowering the upper index with the metric gives
  $T_{\nu\mu} = g_{\nu\nu} T^\nu{}_\mu$ (the metric here is diagonal).
- **Energy-momentum tensor**: the tensor that says how much energy and momentum
  the field has and how they flow. Its diagonal entries are the energy density
  and the pressures; its off-diagonal entries are flows of energy and momentum.
- **Energy density** $\rho = -T^{x_4}{}_{x_4}$: energy per unit (proper) volume.
  **Pressure** in direction $\mu$: $p_\mu = T^\mu{}_\mu$ (no sum).
  **Equation of state**: the ratio $w = p/\rho$.
- **Kinetic term** $K_\mu$: the part of the Lagrangian that holds the derivative
  along the direction $\mu$; **potential energy**: $mS + U(S)$, the part without
  derivatives.
- **Trace**: the sum of the diagonal entries, $T^\mu{}_\mu$ summed over $\mu$.
- **Jet at a point**: the values of the field and of its eight first derivatives
  at one point. The energy-momentum tensor needs nothing else.
- **On shell / off shell**: a configuration is on shell when it satisfies the
  field equation, off shell when it need not.
- **Spin connection** $\Omega_\mu$: the $16 \times 16$ matrix that turns the
  ordinary derivative of the spinor into the covariant one,
  $D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$.
- **Christoffel symbols** $\Gamma^\lambda{}_{\mu\nu}$: the numbers that turn
  ordinary derivatives of tensors into covariant ones.
- **Covariant divergence** $\nabla_\mu T^\mu{}_\nu$: the derivative of the
  tensor summed over its upper index, corrected by the Christoffel symbols.
  **Conservation** means $\nabla_\mu T^\mu{}_\nu = 0$.
- **Heat map**: a picture of a table of numbers in which each entry is a coloured
  square; the colour scale says which number each colour means.

## 4. The physical and mathematical situation

**The metric.** The author's primordial metric is diagonal,
$g = \mathrm{diag}(f_1^2, f_2^2, f_3^2, -f_4^2, -f_5^2, -f_6^2, -f_7^2, f_0^2)$,
with the vielbein factors
$f_1 = f_2 = f_3 = e^{a_4}\sin^{1/6}z$ (3-space, inflating as $a_4$ grows),
$f_4 = 1$ (the time), $f_5 = f_6 = f_7 = e^{-a_4}\sin^{1/6}z$ (the extra times,
deflating exponentially), $f_0 = \cot z$, where $z = 6Hx_0$ lies between $0$ and
$\pi/2$, $H > 0$ is the author's constant and $a_4$ depends on $x_4$. The volume
factor is $\sqrt{|g|} = f_0 f_1 \cdots f_7 = \cos z$: it does not depend on $x_4$.
The Kohn-Sham part of the book uses the deflating history $a_4 = AHx_4$ with
$A > 0$ as a prescribed background; this notebook takes its point on that
```

history.

The field and its Lagrangian. dirac16complex00 is a column Φ of 16
complex numbers at every point. With $\bar\Phi = \Phi^\dagger C$, $S = \bar\Phi\Phi$
and $U(S) = \frac{\lambda}{2}S^2$, the Lagrangian per unit volume is
$L_0 = \frac12\sum_\mu(\bar\Phi\gamma^\mu D_\mu\Phi
- (D_\mu\bar\Phi)\gamma^\mu\Phi) - mS - U(S)$, with the coordinate gammas
$\gamma^\mu = \gamma^{(\mu)}/f_\mu$,
$D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$ and
$D_\mu\bar\Phi = \partial_\mu\bar\Phi - \bar\Phi\Omega_\mu$.

The energy-momentum tensor (Revision record, ‘Revision/theory/field-theory.json‘,
formula ‘T_symmetric‘):
$T^\nu{}_\mu = \delta^\nu_\mu L_0 - \frac14(\bar\Phi\gamma^\nu D_\mu\Phi
- D_\mu\bar\Phi \gamma^\nu\Phi + \bar\Phi\gamma_\mu D^\nu\Phi
- D^\nu\bar\Phi \gamma_\mu\Phi)$, with $\gamma_\mu = g_{\mu\mu}\gamma^\mu$ and
$D^\nu = g^{\nu\nu}D_\nu$. The sign convention is $\rho = -T^{x_4}{}_{x_4}$ and
$p_\mu = T^\mu{}_\mu$ (no sum) for $\mu \neq x_4$. This symmetric (Belinfante)
tensor is the symmetric part of the tensor that a variation of the vielbein
gives (record formula ‘T_variation‘, which has an extra spin-density term); the
two are equal on every solution of the field equation, and for other
configurations they agree in general only on the diagonal (record check
‘commuting_emt_equals_general_vielbein_variation_on_shell‘). This notebook uses
the symmetric tensor ‘T_symmetric‘; so the lowered table $T_{\nu\mu}$ computed
below for random values, which do not solve the field equation, is symmetric by
construction.

The diagonal entries. With the kinetic term of direction μ,
$K_\mu = \frac{1}{2f_\mu}(\bar\Phi\gamma^{(\mu)}\partial_\mu\Phi
- \partial_\mu\bar\Phi \gamma^{(\mu)}\Phi)$, the record states
$L_0 = \sum_\mu K_\mu - mS - U$ and $T^\mu{}_\mu = L_0 - K_\mu$, so
$\rho = -\sum_{\mu \neq x_4}K_\mu + mS + U$ and
$p_\mu = \sum_{\nu \neq \mu}K_\nu - mS - U$.

Conservation. On shell $\nabla_\mu T^\mu{}_\nu = 0$ (a theorem of the record,
proved from the invariance of the action under changes of coordinates). For a
diagonal tensor $\mathrm{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0)$ whose
entries depend on x_4 and x_0, this notebook derives the two conditions it
becomes.

Both fields. The same formulas hold for the anticommuting field
dirac16complex, whose bilinears are even elements of a Grassmann algebra (the
record verifies them, for example in the checks ‘T_diagonal_components_G‘,
‘EMT_trace_G‘ and ‘kinetic_sum_on_shell_G‘ of
‘Revision/theory/reports/wolfram-field-theory.json‘). After quantisation the record
defines the tensor as a normal-ordered operator; the positive space of quantum
states this needs is constructed only for single good-sector momenta (waves that
do not depend on the extra times) with frozen coefficients, and for
$\lambda \neq 0$ the operator form of the on-shell identity
$\sum_\mu\langle{:}K_\mu{:}\rangle = \langle{:}(m + U')S{:}\rangle$ is verified
only in a finite model of one such mode set, and there only when the potential
and the tensor are Wick (normal) ordered as whole products
(‘Revision/theory/fock_quartic/reports/fock-quartic.json‘, 21 of 21 checks); for
the field on a whole slice it is OPEN. This notebook computes with ordinary

```
complex numbers, that is, for dirac16complex00.
```

Text cell:

```
## 5. The gamma matrices and the matrix C

The next cell reads the Revision fixture ‘Revision/algebra/gammas.json‘, which
holds the author’s real $16 \times 16$ gamma matrices in the order
$x_0, \dots, x_7$, the frame metric $\eta$ and the matrix
$C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$. It also defines the
helper ‘recorded(path, name)‘, which opens a Revision report and returns the
verdict of one of its checks; every check of this notebook that reproduces a
Revision check asks the report for that verdict too.
```

In [2]:

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
# gamma[a] is the frame matrix gamma^(xa): gamma[0] = x0, ..., gamma[7] = x7.
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]
eta = np.array(fixture["eta"], dtype=float)  # (+1, +1, +1, +1, -1, -1, -1, -1)
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
I16 = np.eye(16)  # the 16 x 16 unit matrix
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # the author’s coordinates

def recorded(path, name):

## 6. The author's metric at one point and the weights of the kinetic terms

The next cell fixes the point at which the tensor is built. The author's
constant is $H = 0.25$ (all quantities are pure numbers: lengths in a unit of
our choice, $H$, $m$ and $\lambda$ in the matching powers of it). The history is
the deflating member $a_4 = AHx_4$ with $A = 1$, so $a_4' = AH = 0.25$; the point
is $x_4 = 2$ (hence $a_4 = 0.5$) and $z = \pi/4$. The function `frame_factors`
returns the eight factors $f_a$; the cell checks that $\eta_{aa}f_a^2$ is the
author's metric and that $f_0 f_1 \cdots f_7 = \cos z$.

In the energy-momentum tensor every derivative along $x_\mu$ carries the weight
$1/f_\mu$: $e^{-a_4}\sin^{-1/6}z$ along 3-space, $1$ along the time,
$e^{a_4}\sin^{-1/6}z$ along the extra times and $\tan z$ along the hidden
direction. The figure shows these weights against $a_4$ and against $z$.
```

In [3]:

```
H = 0.25  # the author's constant H
A = 1.0  # the history a4 = A H x4; A > 0: the extra times deflate

## 7. The spin connection at the point

The record gives the spin connection of the diagonal vielbein in closed form
(‘Revision/theory/field-theory.json‘, formula ‘Omega_components‘):
$\Omega_{x_i} = \frac12 e^{a_4}\sin^{1/6}z (a_4'\gamma^{(i)}\gamma^{(4)}
+ H\gamma^{(i)}\gamma^{(0)})$ for $i = 1, 2, 3$,
$\Omega_{x_t} = -\frac12 e^{-a_4}\sin^{1/6}z (a_4'\gamma^{(4)}\gamma^{(t)}
+ H\gamma^{(t)}\gamma^{(0)})$ for $t = 5, 6, 7$, and
$\Omega_{x_4} = \Omega_{x_0} = 0$. The next cell builds these eight matrices and
the coordinate gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$, and confirms two exact
facts of the record at this point: for each direction separately
$\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu = 0$ (no sum), which is why no spin
connection survives in the diagonal entries of the tensor; and summed over the
directions $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$, the term of the field
equation.
```

In [5]:

```

## 8. A field configuration at the point and its energy-momentum tensor

The tensor at a point needs only the jet there: the 16 complex values of $\Phi$
and the $8 \times 16$ complex values of its first derivatives
$\partial_\mu\Phi$. The next cell defines two functions. ‘bar‘ returns the Dirac
adjoint $\bar\Phi = \Phi^\dagger C$ as a row of 16 numbers. ‘energy_momentum‘
follows the formula of section 4 literally: from the jet it builds
$D_\mu\Phi$ and $D_\mu\bar\Phi$, the Lagrangian $L_0$ and the 64 entries
$T^\nu{}_\mu$ (row $\nu$, column $\mu$), and also the eight kinetic terms
$K_\mu$ from their own formula (without the spin connection), so that the two
can be compared later. The cell only defines the functions; it prints nothing.
```

In [6]:

```
def bar(vector):
    """The Dirac adjoint: the row vector vector^dagger C."""
    return vector.conj() @ C

def energy_momentum(phi, dphi, f_values, gup, gdown, omega):
    """S, U, L0, the kinetic terms K_mu and the tensor T (T[nu, mu] = T^nu_mu)."""
    g_values = eta * f_values ** 2  # g_mumu
    S = (bar(phi) @ phi).real  # S = Phibar Phi (a real number)
    U = lam / 2 * S ** 2  # U(S) = (lambda/2) S^2
    D = [dphi[mu] + omega[mu] @ phi for mu in range(8)]  # D_mu Phi
    Dbar = [bar(dphi[mu]) - bar(phi) @ omega[mu] for mu in range(8)]  # D_mu Phibar
    L0 = 0.5 * sum(bar(phi) @ gup[mu] @ D[mu] - Dbar[mu] @ gup[mu] @ phi
                   for mu in range(8)) - m * S - U
    T = np.zeros((8, 8), dtype=complex)
    for nu in range(8):
        for mu in range(8):
            bracket = (bar(phi) @ gup[nu] @ D[mu] - Dbar[mu] @ gup[nu] @ phi
                       # gamma_mu D^nu = gamma_mu D_nu / g_nunu
                       + (bar(phi) @ gdown[mu] @ D[nu]
                          - Dbar[nu] @ gdown[mu] @ phi) / g_values[nu])
            T[nu, mu] = (nu == mu) * L0 - bracket / 4
    # K_mu = (1/(2 f_mu)) (Phibar gamma^(mu) d_mu Phi - d_mu Phibar gamma^(mu) Phi)
    K = np.array([(bar(phi) @ gamma[mu] @ dphi[mu] - bar(dphi[mu]) @ gamma[mu] @ phi)
                  / (2 * f_values[mu]) for mu in range(8)])
    return S, U, L0, K, T
```

Text cell:

```
The next cell draws the jet at random, with a fixed seed so that every run draws
the same numbers. The jet need not satisfy the field equation: the identities of
sections 8 to 10 hold off shell. The cell computes the tensor and checks that
every entry is real (its imaginary part is rounding noise) and that
$T_{\nu\mu} = g_{\nu\nu}T^\nu{}_\mu$ is symmetric.
```

## 9. The diagonal entries: energy density, pressures, kinetic and potential parts

The next cell checks the record's statement $T^\mu{}_\mu = L_0 - K_\mu$ for all
eight directions and $L_0 = \sum_\mu K_\mu - mS - U$. It then computes the energy
density and the pressures and splits each into its kinetic part (made of the
$K_\nu$) and its potential part ($mS + U$):
$\rho = \rho_{\rm kin} + \rho_{\rm pot}$ with
$\rho_{\rm kin} = -\sum_{\mu \neq x_4}K_\mu$, $\rho_{\rm pot} = mS + U$, and
$p_\mu = \sum_{\nu \neq \mu}K_\nu - (mS + U)$. A random configuration is not
isotropic, so the three 3-space pressures differ, and so do the three extra-time
pressures. Its energy density may come out negative: the energy of
dirac16complex00 has no lower bound (Revision record
‘Revision/theory/reports/python-scope.json‘, check
‘commuting_field_energy_unbounded_below‘), because both $S$ and the kinetic
terms can have either sign.
```

## 10. The trace, the kinetic sum, and the configuration put on shell

Summing $T^\mu{}_\mu = L_0 - K_\mu$ over the eight directions gives
```

```
$8L_0 - \sum_\mu K_\mu = 7\sum_\mu K_\mu - 8(mS + U)$ (the record's trace
identity). The record also states, for every configuration, the kinetic-sum
identity $\sum_\mu K_\mu = VS + \frac12(\bar\Phi E - \bar E\Phi)$ with
$V = m + U'(S) = m + \lambda S$, the field-equation expression
$E = \gamma^\mu D_\mu\Phi - V\Phi$ and its adjoint
$\bar E = (D_\mu\bar\Phi)\gamma^\mu + V\bar\Phi$. The next cell checks both.

Then it puts the configuration on shell at the point: the field equation can be
solved for the time derivative (its evolution form),
$\partial_4\Phi = -\gamma^{(4)}\big[V\Phi - \sum_{a \neq 4}\frac{1}{f_a}\gamma^{(a)}
\partial_a\Phi - 3H\gamma^{(0)}\Phi\big]$; the cell replaces the random
$\partial_4\Phi$ by this one, checks that $E = 0$, and checks the on-shell values
$\sum_\mu K_\mu = VS$, $L_0 = SU' - U$ and
$T^\mu{}_\mu = -mS + 7SU' - 8U = -mS + 3\lambda S^2$.
```

## 11. Where the spin connection does enter the tensor

The spin connection drops out of the Lagrangian and of the diagonal entries.
It does enter off-diagonal entries. Take a homogeneous configuration (it depends
on $x_4$ only, so $\partial_\mu\Phi = 0$ for $\mu \neq x_4$). In the piece
$K^{x_4}{}_{x_1} = \frac12(\bar\Phi\gamma^{x_4}D_{x_1}\Phi
- D_{x_1}\bar\Phi \gamma^{x_4}\Phi)$ of $T^{x_4}{}_{x_1}$ the derivative part
vanishes and only the connection part
$\frac12\bar\Phi\{\gamma^{x_4}, \Omega_{x_1}\}\Phi$ is left; the record states
that it equals $\frac12 e^{a_4}\sin^{1/6}z H \bar\Phi\gamma^{(4)}\gamma^{(1)}
\gamma^{(0)}\Phi$ (the $a_4'$ part cancels). The next cell checks this at the
point.
```

In [12]:

```

## 12. The Christoffel symbols of the author's metric (exact, with sympy)

From here on the notebook computes exactly with symbols. For a diagonal metric
the Christoffel symbols are
$\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}(\partial_\mu
g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu})$
(no sum over $\lambda$). The next cell writes the author's metric with symbols
(a general function $a_4(x_4)$, the symbol $H$) and computes all the symbols with
$\mu \le \nu$ (the symbol is symmetric in $\mu$ and $\nu$), keeping the nonzero
ones in a dictionary. It prints how many it found.
```

In [13]:

```
import sympy as sp  # exact algebra and calculus with symbols

x = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7 (x[0] ... x[7])
Hs = sp.symbols("H", positive=True)  # the author's constant, as a symbol
a4_function = sp.Function("a4")(x[4])  # a general function a4(x4)
zs = 6 * Hs * x[0]  # z = 6 H x0
space_entry = sp.exp(2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
extra_entry = -sp.exp(-2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
g = sp.diag(*([sp.cot(zs) ** 2] + [space_entry] * 3 + [-1] + [extra_entry] * 3))
christoffel = {}  # (lambda, mu, nu) -> Gamma^lambda_mu nu, only the nonzero ones
for l in range(8):
    for i in range(8):
        for j in range(i, 8):  # mu <= nu
            value = sp.simplify((sp.diff(g[l, j], x[i]) + sp.diff(g[l, i], x[j])
                                 - sp.diff(g[i, j], x[l])) / (2 * g[l, l]))
            if value != 0:
                christoffel[(l, i, j)] = value
say(f"{len(christoffel)} nonzero Christoffel symbols with mu <= nu")
```

Out [13]:

## 13. The covariant divergence of a diagonal tensor: the two identities

For a tensor $T^\mu{}_\nu$ the covariant divergence is
$\nabla_\mu T^\mu{}_\nu = \partial_\mu T^\mu{}_\nu + \Gamma^\mu{}_{\mu\lambda}
T^\lambda{}_\nu - \Gamma^\lambda{}_{\mu\nu}T^\mu{}_\lambda$ (sums over $\mu$ and
$\lambda$). The next cell takes the diagonal tensor
$\mathrm{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0)$ whose four entries are
arbitrary functions of $x_4$ and $x_0$ and computes the eight components with the
Christoffel symbols of the previous section. It prints which components are not
identically zero.
```

In [15]:

```
rho_f, p3_f, pt_f, p0_f = [sp.Function(n)(x[4], x[0]) for n in ("rho", "p3", "pt",
                                                                "p0")]

## 14. The x4 identity read as a first law

Conservation, $\nabla_\mu T^\mu{}_{x_4} = 0$, says
$\partial_4\rho = -3a_4'(p_3 - p_t)$. Here is why. At fixed $x_0$ take a small
box of coordinate size 1 in each of the seven directions other than $x_4$. Its
3-space volume is $V_3 = f_1 f_2 f_3 = e^{3a_4}\sin^{1/2}z$, its extra-time
volume $V_t = f_5 f_6 f_7 = e^{-3a_4}\sin^{1/2}z$, and its 7-volume
$V_7 = V_3 V_t f_0 = \cos z$ does not change with $x_4$. The first law of
thermodynamics (energy changes by minus pressure times change of volume), applied
to each family of directions, would say that the energy $\rho V_7$ in the box
changes as
$\frac{d}{dx_4}(\rho V_7) = -p_3\frac{V_7}{V_3}\frac{dV_3}{dx_4}
- p_t\frac{V_7}{V_t}\frac{dV_t}{dx_4}$. The next cell checks with sympy that this
is exactly the conservation identity. This is a reading of the identity (an
interpretation, not an extra result): dividing by the constant $V_7$,
$d\rho = -p_3\,dV_3/V_3 - p_t\,dV_t/V_t$. While 3-space inflates ($dV_3 > 0$) a
positive $p_3$ takes energy out of the box; while the extra times deflate
($dV_t < 0$) a positive $p_t$ puts energy in. The energy density stays constant
only if $p_3 = p_t$.
```

In [17]:

```
f_space = sp.exp(a4_function) * sp.sin(zs) ** sp.Rational(1, 6)  # f1 = f2 = f3
f_extra = sp.exp(-a4_function) * sp.sin(zs) ** sp.Rational(1, 6)  # f5 = f6 = f7
```

```
V3 = f_space ** 3  # e^(3 a4) sin^(1/2) z
Vt = f_extra ** 3  # e^(-3 a4) sin^(1/2) z
V7 = V3 * Vt * sp.cot(zs)  # times f0 = cot z (and f4 = 1)
check(sp.simplify(V7 - sp.cos(zs)) == 0, "V3 Vt f0 = cos z, independent of x4")
first_law = (sp.diff(rho_f * V7, x[4]) + p3_f * V7 / V3 * sp.diff(V3, x[4])
             + pt_f * V7 / Vt * sp.diff(Vt, x[4]))
# The first law says first_law = 0; it must be -V7 times the x4 divergence.
check(sp.simplify(first_law + V7 * divergence[4]) == 0,

## 15. The x0 identity: the balance along the hidden direction

Conservation along $x_0$ says
$\partial_0 p_0 = -3H\cot z (2p_0 - p_3 - p_t)$, a balance of pressures like
the balance of pressure and weight in a column of air. If the entries do not
depend on $x_0$, it forces $p_0 = (p_3 + p_t)/2$. If $p_3 + p_t = P$ is a
constant, every solution is $p_0 = P/2 + c/\sin z$ with a constant $c$; only
$c = 0$ is independent of $x_0$. The next cell checks this with sympy, then the
same identity in the hidden coordinate $y = \ln(\sin z)/(6H)$ used by the
Kohn-Sham solver of the book: $dy/dx_0 = \cot z$, and the $x_0$ component is
$\cot z [p_0'(y) + 6Hp_0 - 3H(p_3 + p_t)]$ (the lead's checks).
```

In [19]:

```
P, c = sp.symbols("P c", real=True)  # P = p3 + p_t (a constant) and the constant c

## 17. What this notebook showed

- At a point of the deflating history the energy-momentum tensor of
  dirac16complex00 is a real $8 \times 8$ table whose lowered form is symmetric;
  its diagonal entries are $T^\mu{}_\mu = L_0 - K_\mu$, so the energy density is
  $\rho = -\sum_{\mu \neq x_4}K_\mu + mS + U$ and each pressure is the sum of the
  other seven kinetic terms minus $mS + U$ (exact statements of the record,
  confirmed here numerically).
- The trace is $7\sum_\mu K_\mu - 8(mS + U)$ for every configuration; on shell
  $\sum_\mu K_\mu = (m + U')S$, $L_0 = SU' - U$ and the trace is
  $-mS + 3\lambda S^2$.
- The spin connection drops out of the diagonal entries, because
  $\{\gamma^\mu, \Omega_\mu\} = 0$ for each direction, but it enters off-diagonal
  entries such as $T^{x_4}{}_{x_1}$; summed, $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$.
- The author's metric has 25 nonzero Christoffel symbols, the record's list
  exactly, and conservation of a diagonal tensor is exactly two conditions:
  $\partial_4\rho = -3a_4'(p_3 - p_t)$ (energy exchange between 3-space and the
  extra times, a first law for the constant 7-volume) and
  $\partial_0 p_0 = -3H\cot z (2p_0 - p_3 - p_t)$ (a balance along the hidden
  direction, which forces $p_0 = (p_3 + p_t)/2$ for $x_0$-independent entries).
- Status: the identities are PROVED in the record (exact, Wolfram and sympy);
  this notebook re-derives the two conservation identities exactly and confirms
  the tensor identities numerically at one point. The parameter values are
  choices of this notebook, not results.
```

9.17 Line-by-line walk-through of Notebook 09a

The notebook has 21 code cells, In [1] to In [21]. This section explains every line of every one of them, in order. Code that is printed again here is quoted exactly, except that a long figure caption is shortened to a line "...)" (it is printed in full in Section 9.16, under its figure) and that the texts in triple quotes that document a function (its docstring, explained under In [1]) and the comment lines inside the function `save_figure` are left out.

In [1], the set-up cell. Every line that starts with `#` is a **comment**, which Python skips. The first part of the cell, down to the lines of `-` and `=` signs, is the complete run instructions of Section 9.15 again, as comments, so that the notebook file carries its own instructions. The code starts after the heading THE SET-UP; it computes no physics and is the same in every notebook of the book, except for the name of the notebook.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "09a"  # this notebook: chapter 09, example a
```

`import` loads a **module** (a part of Python or of an installed package) so that the cell can use it; `from pathlib import Path` takes only the name `Path`, the address of a file or folder, written the same way on every operating system. `plt` is the usual short name of matplotlib's drawing functions, and `Image` and `display` show a saved picture below a cell. The last line gives the **variable** `NOTEBOOK_ID` the **string** (a text in quotes) `"09a"`; the figure files are named after it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called (the notebook's version also has a **docstring**, the text in triple quotes under the `def` line, which only documents it; it is left out here). Jupyter runs a notebook in the folder that holds it, `Path.cwd()`, and `.resolve()` writes it as a complete address. The `for` loop walks up from that folder through its parents; the operator `/` joins folder and file names, and `.is_file()` asks whether the file exists. The first folder that contains `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none qualifies, `raise` stops the notebook with an error message that says what to do.

```
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
```

```
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))

def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path

def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`REPO` is the repository folder; it is never printed, because it differs from computer to computer. `OUTPUT_ROOT` is where files are written: the repository, unless the **environment variable** `TEXTBOOK_OUTPUT_ROOT` (a named text that the computer hands to a program) names another folder; the book's checking tool sets it, so that a check never changes the repository. `repository_file` gives the path of a repository file for reading; `output_file` gives the path at which to write a file and first creates its folder (`mkdir`, where `exist_ok=True` does nothing if the folder exists). `say` prints a text in lines of at most 89 characters (the width of a page of the book), indenting the continuation lines by four blanks. (The comment lines above `REPO` and `OUTPUT_ROOT` and the docstrings of the three functions are left out here; they say the same in words.)

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})

FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

The first two lines make every figure look the same on every computer: the built-in settings, a figure size of 7.0 by 4.2 inches, 10-point letters and a faint grid. The braces `{...}` make a **dictionary** (pairs `key: value`). A string that starts with `f` is an **f-string**: each name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/09a.captions.json"`. The last line starts that file as an empty dictionary `{}`; `newline="\n"` writes the same line end on every operating system.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
```

```
    relative = f"{FIGURE_FOLDER}/{file_name}"
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` (shown without its docstring and its comment lines) numbers the figures 1, 2, 3, ... in the order of their first appearance (`setdefault` returns the number stored for a name, or stores and returns the next one), saves the picture as a PNG file at 150 dots per inch with the empty margin cut away and without a program name inside the file (so that two runs write the same bytes), closes it, stores the caption in the captions file (`json.dumps` turns the dictionary into text with the keys sorted), shows the saved picture below the cell and prints one line saying where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")

def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`PASSED` is an empty **list** (an ordered collection, in square brackets). `check` is the function behind every check: `condition` is either `True` or `False`; if it is false, the notebook stops with an `AssertionError` that names the check; if it is true, the name is appended to `PASSED` and the line `PASS name` is printed, followed, when the check reproduces a Revision record, by a line `reproduces <file>, check <name>`. (An `if` statement is used instead of Python's `assert`, which Python started with the option `-O` would skip.) `report` prints a key number as a line that starts with `RESULT`. `all_checks_passed` prints the last line of the notebook with the number of checks that passed. The cell prints one line: `Set-up of notebook 09a complete:  repository folder found, helpers defined.`

In [2], the gamma matrices and the matrix C.

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
# gamma[a] is the frame matrix gamma^(xa): gamma[0] = x0, ..., gamma[7] = x7.
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]
eta = np.array(fixture["eta"], dtype=float)  # (+1, +1, +1, +1, -1, -1, -1, -1)
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
I16 = np.eye(16)  # the 16 x 16 unit matrix
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # the author's coordinates
```

numpy is the package for arrays of numbers. `read_text` reads the fixture file as text, and `json.loads` turns the text into Python objects: here a dictionary whose entry `"gamma"` is a list of eight matrices, each a list of 16 rows of 16 numbers. The line `gamma = [... for rows in fixture["gamma"]]` is a **list comprehension**: it builds a list by evaluating the expression before `for` for each item; `np.array(rows, dtype=float)` turns one matrix into a numpy array of real (floating-point) numbers. Python counts from 0, like the author's coordinates, so `gamma[k]` is $\gamma^{(k)}$: `gamma[0]` is $\gamma^{(0)}$, `gamma[4]` is $\gamma^{(4)}$ and `gamma[7]` is $\gamma^{(7)}$. The eight matrices are real; their entries are the whole numbers 0, 1 and -1. `eta` holds the eight diagonal entries of η, `C` the matrix C, `I16` the 16×16 unit matrix, and `NAMES` the names of the coordinates for printing.

```
def recorded(path, name):
    """The verdict (PASS or FAIL) of the check name in the Revision report path."""
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for item in report_data["checks"]:
        if item["name"] == name:
            return item["verdict"].upper()  # some reports write "pass"
    raise KeyError(f"{path} has no check {name}")
```

A Revision report is a JSON file with a list `"checks"`; each check has a `"name"` and a `"verdict"`. `recorded` opens the report, looks for the check of the given name and returns its verdict in capital letters (`.upper()`, because some reports write `pass`). If the name is missing it stops with a `KeyError`. Every check of the notebook that reproduces a record also asks the record for its own verdict, so a notebook check passes only when the record agrees.

```
ALGEBRA = "Revision/algebra/reports/python-algebra.json"
# {gamma^a, gamma^b} = gamma^a gamma^b + gamma^b gamma^a must be 2 eta^ab times 1.
clifford = all(np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                              2 * eta[a] * (a == b) * I16)
               for a in range(8) for b in range(8))
check(clifford and recorded(ALGEBRA, "clifford_relation") == "PASS",
      "the 64 Clifford relations {gamma^a, gamma^b} = 2 eta^ab",
      record=f"{ALGEBRA}, check clifford_relation")
```

The operator `@` is the matrix product. `(a == b)` is `True` (counted as 1) when $a = b$ and `False` (counted as 0) otherwise, so `2 * eta[a] * (a == b) * I16` is $2\eta^{ab} \cdot 1$ (for this diagonal η, $\eta^{aa} = \eta_{aa}$). `np.array_equal` asks whether two arrays are equal entry by entry, exactly: the gammas hold whole

numbers, so no rounding occurs. `all(... for a in range(8) for b in range(8))` is true only when the comparison holds for all 64 pairs; `range(8)` is 0, 1, ..., 7. The check passes when all 64 Clifford relations hold and the record's check `clifford_relation` passed.

```
# C is symmetric, C times C is 1, and every C gamma^a is antisymmetric.
c_ok = np.array_equal(C, C.T) and np.array_equal(C @ C, I16) and all(
    np.array_equal((C @ g).T, -(C @ g)) for g in gamma)
check(c_ok and recorded(ALGEBRA, "C_real_symmetric_involution") == "PASS"
      and recorded(ALGEBRA, "C_gamma_antisymmetric") == "PASS",
      "C is real symmetric, C^2 = 1, every C gamma^a is antisymmetric",
      record=f"{ALGEBRA}, checks C_real_symmetric_involution and "
             "C_gamma_antisymmetric")
```

`.T` is the transpose. The three conditions are $C^T = C$, $C^2 = 1$ and $(C\gamma^{(a)})^T = -C\gamma^{(a)}$ for each of the eight gammas (`for g in gamma` takes them in turn): the facts used in Sections 9.6 and 9.18. The cell prints the two PASS lines with their record lines.

In [3], the author's metric at one point.

```
H = 0.25  # the author's constant H
A = 1.0  # the history a4 = A H x4; A > 0: the extra times deflate
m = 1.0  # the mass m of the field
lam = 0.5  # the strength lambda of the potential U(S) = (lambda/2) S^2
X4 = 2.0  # the time x4 of the point
a4 = A * H * X4  # a4 at the point: 0.5
a4p = A * H  # its derivative da4/dx4 (written a4p, "a4 prime"): 0.25
z = np.pi / 4  # z = 6 H x0 at the point
```

These lines choose the numbers of the example: $H = 0.25$, the deflating history $a_4 = AHx_4$ with $A = 1$, the mass $m = 1$, the strength $\lambda = 0.5$ (written `lam`, because `lambda` is a reserved word of Python), the time $x_4 = 2$, hence $a_4 = 0.5$ and $a_4' = AH = 0.25$, and $z = \pi/4$ (`np.pi` is π). They are choices, not results.

```
def frame_factors(a4_value, z_value):
    """The eight factors f_a of the diagonal vielbein, in the order x0, ..., x7."""
    space = np.exp(a4_value) * np.sin(z_value) ** (1 / 6)  # e^a4 sin^(1/6) z
    extra = np.exp(-a4_value) * np.sin(z_value) ** (1 / 6)  # e^(-a4) sin^(1/6) z
    return np.array([1 / np.tan(z_value)] + [space] * 3 + [1.0] + [extra] * 3)

f = frame_factors(a4, z)
g_diag = eta * f ** 2  # the diagonal entries g_mumu = eta_mumu f_mu^2
```

`frame_factors` returns the eight factors f_a of Section 9.2. `**` means "to the power", so `np.sin(z_value) ** (1 / 6)` is $\sin^{1/6} z$. `[space] * 3` is a list of three copies of `space`, and `+` joins lists, so the returned array is $(f_1, f_1, f_1, 1, f_5, f_5, f_5, \cot z)$ with $\cot z = 1/\tan z$. Then `f` holds the factors at the point, and `g_diag` the eight diagonal entries $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$; arithmetic on arrays acts entry by entry.

```
# The author's metric written out: e^(2 a4) sin^(1/3) z, -1, -e^(-2 a4) sin^(1/3) z,
# cot^2 z.
authors = np.array([1 / np.tan(z) ** 2] + [np.exp(2 * a4) * np.sin(z) ** (1 / 3)] * 3
                   + [-1.0] + [-np.exp(-2 * a4) * np.sin(z) ** (1 / 3)] * 3)
THEORY_PY = "Revision/theory/reports/python-field-theory.json"
check(np.allclose(g_diag, authors, rtol=1e-14, atol=0)
      and recorded(THEORY_PY, "metric_from_vielbein_equals_SPEC") == "PASS",
      "eta_aa f_a^2 is the author's metric at the point",
      record=f"{THEORY_PY}, check metric_from_vielbein_equals_SPEC")
check(abs(np.prod(f) - np.cos(z)) < 1e-14
      and recorded(THEORY_PY, "sqrt_det_g_equals_cos_z") == "PASS",
      "the volume factor f0 f1 ... f7 equals cos z",
      record=f"{THEORY_PY}, check sqrt_det_g_equals_cos_z")
for name, value in zip(NAMES, f):
    report(f"f_{name}", f"{value:.6f}")
```

The two comment lines say what the next line builds: `authors` writes the author's eight metric entries directly, copied from the author's matrix and not from the factors f_a, so that the comparison is a real test. `np.allclose(x, y, rtol=1e-14, atol=0)` is true when every entry of `x` differs from the entry of `y` by less than 10^{-14} times its size (a relative tolerance; floating-point numbers carry about 16 significant digits). The second check compares the product of the eight factors (`np.prod`) with $\cos z$, the computation of Section 9.2. `zip(NAMES, f)` pairs each name with its factor, and `report` prints each with six decimals (the format `:.6f`): $f_{x_1} = e^{0.5}\sin^{1/6}(\pi/4) = 1.6487213 \cdot 0.9438743 = 1.556186$, $f_{x_4} = 1$, $f_{x_5} = e^{-0.5}\sin^{1/6}(\pi/4) = 0.6065307 \cdot 0.9438743 = 0.572489$ and $f_{x_0} = \cot(\pi/4) = 1$ (each factor written with seven decimals and each product rounded to six, the precision that the notebook prints; with factors rounded to four decimals the sixth decimal of a product would come out wrong).

In [4], the weights of the kinetic terms (Figure 09a.1).

```
from matplotlib.ticker import NullFormatter  # a tick label that prints nothing

a4_axis = np.linspace(-2.0, 2.0, 401)  # values of a4 for the left panel
z_axis = np.linspace(0.02, 1.50, 400)  # values of z for the right panel
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9))
weights_a4 = np.array([1 / frame_factors(value, z) for value in a4_axis])
weights_z = np.array([1 / frame_factors(a4, value) for value in z_axis])
```

`np.linspace(a, b, n)` makes `n` equally spaced numbers from `a` to `b`. `plt.subplots(1, 2, ...)` makes a figure with one row of two panels, named `left` and `right`, 9.6 by 3.9 inches. `weights_a4` is a table with one row per value of a_4 and eight columns, the weights $1/f_\mu$ at $z = \pi/4$; `weights_z` is the same against z at $a_4 = 0.5$.

```
for panel, axis, weights in ((left, a4_axis, weights_a4), (right, z_axis, weights_z)):
    panel.plot(axis, weights[:, 1], label="3-space $x_1, x_2, x_3$")
    panel.plot(axis, weights[:, 4], "--", label="time $x_4$")
    panel.plot(axis, weights[:, 5], label="extra times $x_5, x_6, x_7$")
    panel.plot(axis, weights[:, 0], ":", label="hidden direction $x_0$")
    panel.set_yscale("log")  # equal factors are equal distances on this axis
    panel.yaxis.set_minor_formatter(NullFormatter())  # no labels on minor ticks
    panel.set_ylabel("weight $1/f_\\mu$")
```

The loop runs twice, once per panel. `weights[:, 1]` is column 1 of the table (all rows), the weight of x_1; columns 4, 5 and 0 are x_4, x_5 and x_0. The style string of two hyphens draws a dashed line and `":"` a dotted one; `label` is the name in the legend; text between dollar signs is typeset as mathematics, and a backslash inside a Python string is written twice. On a **logarithmic axis** equal ratios are equal distances, so a function $e^{\pm a_4}$ appears as a straight line. The minor ticks get no labels.

```
ticks = [0.03, 0.1, 0.2, 0.5, 1, 2, 5, 10]  # plain numbers on the vertical axes
left.set_yticks(ticks[2:7], [str(t) for t in ticks[2:7]])
right.set_yticks(ticks, [str(t) for t in ticks])
left.set_xlabel("$a_4$ (at $z = \\pi/4$)")
right.set_xlabel("$z = 6 H x_0$ (at $a_4 = 0.5$)")
left.set_title("Weights against $a_4$")
right.set_title("Weights against $z$")
left.legend(fontsize=8)
save_figure(fig, "kinetic_weights",
            "The weights $1/f_\\mu$ with which a derivative along each direction "
            ...)
```

These lines put plain numbers on the vertical axes (`ticks[2:7]` is the part of the list from position 2 up to, not including, position 7), label the axes, set the titles, draw the legend in the left panel and save the figure as `09a_1_kinetic_weights.png` with its caption. **What Figure 09a.1 shows.** Both panels plot the weight $1/f_\mu$ (a pure number) on a logarithmic vertical axis. Left, against a_4: the 3-space weight $e^{-a_4}\sin^{-1/6} z$ falls and the extra-time weight $e^{a_4}\sin^{-1/6} z$ rises, two straight lines of opposite slope; the time weight 1 and the hidden weight $\tan(\pi/4) = 1$ lie on top of each other. The student should see that as the extra times deflate, derivatives along them count more and more in ρ and in the pressures. Right, against z: the hidden weight $\tan z$ grows without bound near $z = \pi/2$.

In [5], the spin connection at the point.

```
def spin_connection(a4_value, a4p_value, z_value):
    """The eight 16 x 16 matrices Omega_mu of the record's formula Omega_components."""
    s = np.sin(z_value) ** (1 / 6)  # sin^(1/6) z
    omega = [np.zeros((16, 16)) for _ in range(8)]  # Omega_x4 = Omega_x0 = 0
    for i in range(1, 4):  # the three 3-space directions x1, x2, x3
        omega[i] = 0.5 * np.exp(a4_value) * s * (
            a4p_value * gamma[i] @ gamma[4] + H * gamma[i] @ gamma[0])
    for t in range(5, 8):  # the three extra times x5, x6, x7
        omega[t] = -0.5 * np.exp(-a4_value) * s * (
            a4p_value * gamma[4] @ gamma[t] + H * gamma[t] @ gamma[0])
    return omega
```

The function writes the formula of Section 9.2 literally. It starts with eight zero matrices (`np.zeros ((16, 16))`; the name `_` is used for a loop counter that is not needed), which stay zero for x_4 and x_0, then fills the 3-space entries $\Omega_{x_i} = \frac{1}{2}e^{a_4}\sin^{1/6} z\,(a_4'\gamma^{(i)}\gamma^{(4)} + H\gamma^{(i)}\gamma^{(0)})$ at the indices 1, 2, 3 (`range(1, 4)`) and the extra-time entries $\Omega_{x_t} = -\frac{1}{2}e^{-a_4}\sin^{1/6} z\,(a_4'\gamma^{(4)}\gamma^{(t)} + H\gamma^{(t)}\gamma^{(0)})$ at the indices 5, 6, 7 (`range(5, 8)` is 5, 6, 7): the index is the direction.

```
Omega = spin_connection(a4, a4p, z)
gamma_up = [gamma[mu] / f[mu] for mu in range(8)]  # coordinate gammas gamma^mu
```

```
gamma_down = [g_diag[mu] * gamma_up[mu] for mu in range(8)]  # gamma_mu
# {gamma^mu, Omega_mu} for each mu separately: the largest entry of all eight.
anti = max(np.abs(gamma_up[mu] @ Omega[mu] + Omega[mu] @ gamma_up[mu]).max()
           for mu in range(8))
A4_REPORT = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
check(anti < 1e-14
      and recorded(A4_REPORT, "gamma_mu_anticommutes_with_Omega_mu_no_sum") == "PASS",
      "{gamma^mu, Omega_mu} = 0 for each direction mu (no sum)",
      record=f"{A4_REPORT}, check gamma_mu_anticommutes_with_Omega_mu_no_sum")
```

`Omega` holds the eight matrices at the point; `gamma_up` the coordinate gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and `gamma_down` the lowered ones $\gamma_\mu = g_{\mu\mu}\gamma^\mu$. For each direction the cell computes the anticommutator $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu$ and takes the largest absolute value of its 256 entries (`np.abs(...).max()`); `anti` is the largest of these eight numbers. Fact 1 of Section 9.3 says it is zero; the check allows rounding errors below 10^{-14}.

```
total = sum(gamma_up[mu] @ Omega[mu] for mu in range(8))  # gamma^mu Omega_mu, summed
LEAD = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
check(np.abs(total - 3 * H * gamma[0]).max() < 1e-14
      and recorded(THEORY_PY, "gamma_mu_Omega_mu_equals_3H_gamma_x0") == "PASS"
      and recorded(LEAD, "gamma_Omega_equals_3H_gamma0") == "PASS",
      "gamma^mu Omega_mu = 3 H gamma^(x0) at the point",
      record=f"{THEORY_PY}, check gamma_mu_Omega_mu_equals_3H_gamma_x0; {LEAD}, "
             "check gamma_Omega_equals_3H_gamma0")
```

`sum(...)` adds the eight products $\gamma^\mu\Omega_\mu$, and the check compares the result with $3H\gamma^{(0)} = 0.75\,\gamma^{(0)}$: Fact 2, which the theory record and the lead's independent check both state.

In [6], the Dirac adjoint and the energy-momentum tensor.

```
def bar(vector):
    """The Dirac adjoint: the row vector vector^dagger C."""
    return vector.conj() @ C
```

`.conj()` takes the complex conjugate of every entry. For a one-dimensional numpy array, `@` with a matrix on its right treats the array as a row, so `vector.conj() @ C` is the row $\Phi^\dagger C = \bar{\Phi}$.

```
def energy_momentum(phi, dphi, f_values, gup, gdown, omega):
    """S, U, L0, the kinetic terms K_mu and the tensor T (T[nu, mu] = T^nu_mu)."""
    g_values = eta * f_values ** 2  # g_mumu
    S = (bar(phi) @ phi).real  # S = Phibar Phi (a real number)
    U = lam / 2 * S ** 2  # U(S) = (lambda/2) S^2
    D = [dphi[mu] + omega[mu] @ phi for mu in range(8)]  # D_mu Phi
    Dbar = [bar(dphi[mu]) - bar(phi) @ omega[mu] for mu in range(8)]  # D_mu Phibar
    L0 = 0.5 * sum(bar(phi) @ gup[mu] @ D[mu] - Dbar[mu] @ gup[mu] @ phi
                   for mu in range(8)) - m * S - U
```

The arguments are the 16 values `phi` of Φ at the point, the 8×16 table `dphi` whose row `mu` holds $\partial_\mu\Phi$, the factors, the coordinate gammas with upper and lower index, and the spin connection. `S`

is $\bar\Phi\Phi$; it is real (Section 9.6), and `.real` keeps the real part, dropping a rounding remainder. `D` and `Dbar` are the lists of the eight covariant derivatives $D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$ and $D_\mu\bar\Phi = \partial_\mu\bar\Phi - \bar\Phi\Omega_\mu$ (`bar(dphi[mu])` is $\partial_\mu\bar\Phi$, because C is the same at every point). `L0` is the formula of Section 9.2, with the spin connection included: the cell computes it the long way, and a later check compares it with $\sum_\mu K_\mu - mS - U$.

```
T = np.zeros((8, 8), dtype=complex)
for nu in range(8):
    for mu in range(8):
        bracket = (bar(phi) @ gup[nu] @ D[mu] - Dbar[mu] @ gup[nu] @ phi
                   # gamma_mu D^nu = gamma_mu D_nu / g_nunu
                   + (bar(phi) @ gdown[mu] @ D[nu]
                      - Dbar[nu] @ gdown[mu] @ phi) / g_values[nu])
        T[nu, mu] = (nu == mu) * L0 - bracket / 4
```

The two loops fill the 8×8 table `T`, row `nu` and column `mu`, with the formula of Section 9.6: `bracket` is $\bar\Phi\gamma^\nu D_\mu\Phi - D_\mu\bar\Phi\gamma^\nu\Phi + \bar\Phi\gamma_\mu D^\nu\Phi - D^\nu\bar\Phi\gamma_\mu\Phi$, where $D^\nu = D_\nu / g_{\nu\nu}$ is the division by `g_values[nu]`, and `(nu == mu) * L0` is $\delta^\nu_\mu L_0$. The table is complex at first (`dtype=complex`), because the field is complex; it must come out real.

```
# K_mu = (1/(2 f_mu)) (Phibar gamma^(mu) d_mu Phi - d_mu Phibar gamma^(mu) Phi)
K = np.array([(bar(phi) @ gamma[mu] @ dphi[mu] - bar(dphi[mu]) @ gamma[mu] @ phi)
              / (2 * f_values[mu]) for mu in range(8)])
return S, U, L0, K, T
```

`K` holds the eight kinetic terms computed from their own formula, with ordinary derivatives and frame gammas and without any spin connection, so that the record's statements $T^\mu{}_\mu = L_0 - K_\mu$ and $L_0 = \sum_\mu K_\mu - mS - U$ can be tested independently. The function returns five results; the cell prints nothing.

In [7], a random configuration and its tensor.

```
rng = np.random.default_rng(12345)  # a fixed seed: the same numbers in every run
Phi = rng.normal(size=16) + 1j * rng.normal(size=16)  # the 16 values of Phi
dPhi = rng.normal(size=(8, 16)) + 1j * rng.normal(size=(8, 16))  # d_mu Phi
# np.roll moves the last row to the front: the eight rows are the derivatives along
# x0, x1, ..., x7, and the numbers are those of the earlier edition of this notebook.
dPhi = np.roll(dPhi, 1, axis=0)
S, U, L0, K, T = energy_momentum(Phi, dPhi, f, gamma_up, gamma_down, Omega)
```

`np.random.default_rng(12345)` makes a generator of random numbers; the fixed **seed** 12345 makes it produce the same numbers in every run, so the notebook's output never changes. `rng.normal(size=16)` draws 16 numbers from the bell-shaped normal distribution; `1j` is Python's imaginary unit i, so `Phi` is a random complex column, and `dPhi` a random 8×16 table of first derivatives, row k for the direction x_k. `np.roll(dPhi, 1, axis=0)` moves the last row of the drawn table to the front; it changes no number, only which direction each row belongs to, so that the configuration is the same as in the first edition of this notebook (which listed the directions in another order) and every printed number below is unchanged. The **jet** at the point, the values of the field and of its eight first derivatives, is all the tensor needs; it need not satisfy the field equation. The last line computes everything and names the five results.

```
largest_imaginary = max(np.abs(T.imag).max(), np.abs(K.imag).max(), abs(L0.imag))
check(largest_imaginary < 1e-12, "every entry of T, every K_mu and L0 are real")
T, K, L0 = T.real, K.real, L0.real  # keep the real parts
T_low = g_diag[:, None] * T  # T_numu = g_nunu T^nu_mu
check(np.abs(T_low - T_low.T).max() < 1e-12
      and recorded(THEORY_PY, "commuting_emt_symmetric") == "PASS",
      "T_numu is symmetric (64 entries, 28 pairs compared)",
      record=f"{THEORY_PY}, check commuting_emt_symmetric")
report("S = Phibar Phi", f"{S:.6f}")
report("L0", f"{L0:.6f}")
```

`.imag` is the imaginary part. The first check confirms the reality of Section 9.6: the largest imaginary part is rounding noise, below 10^{-12}. Then only the real parts are kept. `g_diag[:, None] * T` multiplies row ν of the table by $g_{\nu\nu}$ (`[:, None]` turns the eight numbers into a column, which numpy repeats across the eight columns of `T`), giving $T_{\nu\mu}$; the second check compares it with its transpose, the symmetry of Section 9.6 (the 56 entries off the diagonal form 28 pairs). The random values do not solve the field equation, and the table is symmetric because the notebook computes the symmetric (Belinfante) tensor; the tensor of the vielbein variation is in general not symmetric for values that do not solve the field equation (Section 9.6). The cell prints $S = -6.527875$ (negative: S has no fixed sign) and $L_0 = 13.616346$.

In [8], the heat map of the tensor (Figure 09a.2).

```
fig, ax = plt.subplots(figsize=(6.6, 5.6))
largest = np.abs(T).max()  # the colour scale runs from -largest to +largest
picture = ax.imshow(T, cmap="RdBu_r", vmin=-largest, vmax=largest)
for nu in range(8):
    for mu in range(8):
        # white digits on dark squares, black digits on light ones
        colour = "white" if abs(T[nu, mu]) > 0.6 * largest else "black"
        ax.text(mu, nu, f"{T[nu, mu]:.1f}", ha="center", va="center", fontsize=7,
                color=colour)
```

`ax.imshow` draws the table as a **heat map**, a grid of coloured squares: row ν from top to bottom, column μ from left to right. The colour map `"RdBu_r"` runs from blue (negative) through white (zero) to red (positive), with a scale symmetric about zero. The loops write each value with one decimal in its square (`ha` and `va` centre the text), white on dark squares and black on light ones (`x if condition else y` chooses one of two values).

```
ax.set_xticks(range(8), [f"${n[0]}_{n[1]}$" for n in NAMES])
ax.set_yticks(range(8), [f"${n[0]}_{n[1]}$" for n in NAMES])
ax.set_xlabel("lower index $\\mu$ (column)")
ax.set_ylabel("upper index $\\nu$ (row)")
ax.set_title("$T^\\nu{}_\\mu$ of one random configuration at one point")
ax.grid(False)  # no grid lines across the squares
fig.colorbar(picture, ax=ax, label="value of $T^\\nu{}_\\mu$ (energy per volume)")
save_figure(fig, "tensor_heat_map",
            "Heat map of the energy-momentum tensor $T^\\nu{}_\\mu$ of a random "
            ...)
```

The tick labels turn a name such as `"x1"` into x_1 (`n[0]` is its letter, `n[1]` its digit). The colour bar beside the map says which value each colour means. **What Figure 09a.2 shows.** The 64 entries of the tensor of one random configuration, in units of energy per unit volume. The diagonal holds $-\rho$ at (x_4, x_4) and the seven pressures; every square off the diagonal is coloured, because a random configuration has flows of energy and momentum in every direction. The student should notice that the printed table is not symmetric: the upper index is raised with the metric, and only $g_{\nu\nu}T^{\nu}{}_{\mu}$ is symmetric.

In [9], the diagonal entries.

```
THEORY_WL = "Revision/theory/reports/wolfram-field-theory.json"
check(np.abs(np.diag(T) - (L0 - K)).max() < 1e-12
      and abs(L0 - (K.sum() - m * S - U)) < 1e-12
      and recorded(THEORY_WL, "T_diagonal_components_C") == "PASS",
      "T^mu_mu = L0 - K_mu for all eight mu, and L0 = sum K - m S - U",
      record=f"{THEORY_WL}, check T_diagonal_components_C")
```

`np.diag(T)` is the list of the eight diagonal entries, and `L0 - K` the list of the numbers $L_0 - K_\mu$. The check confirms Section 9.5 for all eight directions, and that the L_0 computed with the spin connection equals $\sum_\mu K_\mu - mS - U$ computed without it (Section 9.3).

```
potential = m * S + U  # the potential energy density m S + U(S)
# kinetic part of T^mu_mu: the sum of the K_nu with nu different from mu
kinetic_parts = np.array([K.sum() - K[mu] for mu in range(8)])
rho = -T[4, 4]  # the energy density
rho_kin = -(K.sum() - K[4])  # minus the sum of the K_mu with mu different from x4
check(abs(rho - (rho_kin + potential)) < 1e-12
      and np.abs(np.diag(T) - (kinetic_parts - potential)).max() < 1e-12,
      "rho = rho_kin + rho_pot and p_mu = (sum of the other K) - (m S + U)")
```

These lines build the split of Section 9.7: `potential` is $mS + U$; `kinetic_parts[mu]` is $\sum_{\nu\neq\mu} K_\nu$; `rho` is $-T^{x_4}{}_{x_4}$ (row and column 3 are x_4); `rho_kin` is $-\sum_{\mu\neq x_4} K_\mu$. The check confirms $\rho = \rho_{\text{kin}} + \rho_{\text{pot}}$ and, for every direction, that the diagonal entry is its kinetic part minus $mS + U$.

```
report("rho = -T^x4_x4", f"{rho:.6f}")
report("rho_kin", f"{rho_kin:.6f}")
report("rho_pot = m S + U", f"{potential:.6f}")
for mu in (0, 1, 2, 3, 5, 6, 7):
    report(f"pressure T^{NAMES[mu]}_{NAMES[mu]}", f"{T[mu, mu]:.6f}")
```

The cell prints $\rho = -7.531406$, made of $\rho_{\text{kin}} = -11.656818$ and $\rho_{\text{pot}} = 4.125412$ (indeed $-11.656818 + 4.125412 = -7.531406$), and the seven pressures, from $T^{x_7}{}_{x_7} = -1.976597$ to $T^{x_2}{}_{x_2} = 21.578866$. The energy density of this random configuration is negative, and the three 3-space pressures differ from each other (as do the three extra-time pressures): a random configuration is not isotropic.

In [10], the diagonal entries and their two parts (Figure 09a.3).

```
positions = np.arange(8)  # one group of bars per direction
fig, ax = plt.subplots(figsize=(8.0, 4.2))
```

```
ax.bar(positions - 0.27, kinetic_parts, width=0.27, label="kinetic part")
ax.bar(positions, [-potential] * 8, width=0.27, label="potential part $-(mS + U)$")
ax.bar(positions + 0.27, np.diag(T), width=0.27, label="total $T^\\mu{}_\\mu$")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(positions, [f"${n[0]}_{n[1]}$" for n in NAMES])
ax.set_xlabel("direction $\\mu$")
ax.set_ylabel("value (energy per unit volume)")
ax.set_title("Diagonal entries $T^\\mu{}_\\mu$ and their two parts")
ax.legend(fontsize=8)
save_figure(fig, "diagonal_parts",
            "The eight diagonal entries $T^\\mu{}_\\mu$ (right bar of each group) "
            ...)
```

`np.arange(8)` is 0, 1, ..., 7. `ax.bar(x, heights, width=...)` draws bars; the three calls place three bars side by side for each direction, shifted by -0.27, 0 and $+0.27$. `ax.axhline(0.0, ...)` draws a horizontal line at zero. **What Figure 09a.3 shows.** For each of the eight directions: the kinetic part $\sum_{\nu\neq\mu} K_\nu$ (left bar), the potential part $-(mS+U)$ (middle bar, the same in every group) and their sum $T^\mu{}_\mu$ (right bar), in units of energy per unit volume. The group at x_4 shows $-\rho$. The student should see that only the kinetic parts make the directions differ.

In [11], the trace, the kinetic sum, and the configuration put on shell.

```
V = m + lam * S  # V = m + U'(S), with U'(S) = lambda S
E = sum(gamma_up[mu] @ (dPhi[mu] + Omega[mu] @ Phi) for mu in range(8)) - V * Phi
E_bar = sum((bar(dPhi[mu]) - bar(Phi) @ Omega[mu]) @ gamma_up[mu]
            for mu in range(8)) + V * bar(Phi)
```

These lines compute the effective mass $V = m + \lambda S$, the field-equation expression $E = \gamma^\mu D_\mu \Phi - V\Phi$ (a column of 16 numbers) and its adjoint $\bar{E} = (D_\mu \bar{\Phi})\gamma^\mu + V\bar{\Phi}$ (a row), exactly as defined in Section 9.8.

```
check(abs(np.trace(T) - (7 * K.sum() - 8 * (m * S + U))) < 1e-11
      and recorded(THEORY_WL, "EMT_trace_C") == "PASS",
      "trace: sum of T^mu_mu = 7 sum K - 8 (m S + U), off shell",
      record=f"{THEORY_WL}, check EMT_trace_C")
kinetic_sum = V * S + 0.5 * (bar(Phi) @ E - E_bar @ Phi)
check(abs(K.sum() - kinetic_sum) < 1e-11
      and recorded(THEORY_WL, "kinetic_sum_on_shell_C") == "PASS",
      "sum K = V S + (1/2)(Phibar E - Ebar Phi), off shell",
      record=f"{THEORY_WL}, check kinetic_sum_on_shell_C")
report("|E| of the random configuration (it is off shell)",
       f"{np.linalg.norm(E):.6f}")
```

`np.trace(T)` is the sum of the diagonal. The two checks confirm, for the random (off-shell) configuration, the trace identity and the kinetic-sum identity of Section 9.8. `np.linalg.norm(E)` is the length of the column E, the square root of the sum of the squared sizes of its 16 entries; it is 19.335808, far from zero: the random configuration does not satisfy the field equation.

```
# The evolution form of the field equation gives d4 Phi from the other derivatives.
rest = sum(gamma[a] @ dPhi[a] / f[a] for a in range(8) if a != 4)
```

```
dPhi_on = dPhi.copy()
dPhi_on[4] = -gamma[4] @ (V * Phi - rest - 3 * H * gamma[0] @ Phi)
E_on = sum(gamma_up[mu] @ (dPhi_on[mu] + Omega[mu] @ Phi) for mu in range(8)) - V * Phi
S_on, U_on, L0_on, K_on, T_on = energy_momentum(Phi, dPhi_on, f, gamma_up, gamma_down,
                                                Omega)
check(np.abs(E_on).max() < 1e-12, "with d4 Phi from the evolution form, E = 0")
```

Now the configuration is put on shell at the point. `rest` is $\sum_{a\neq 4} \frac{1}{f_a}\gamma^{(a)}\partial_a\Phi$ (the `if a != 3` in the comprehension skips x_4). `dPhi.copy()` makes a separate copy of the table, so that the random one is kept, and its row 3 is replaced by the evolution form of Section 9.2, $\partial_4\Phi = -\gamma^{(4)}[V\Phi - \text{rest} - 3H\gamma^{(0)}\Phi]$. The value of Φ and the other seven derivatives are unchanged, so S and V are unchanged. The field-equation expression is computed again, and the tensor of the new jet; the check confirms that now $E = 0$ up to rounding.

```
check(abs(K_on.real.sum() - V * S) < 1e-11
      and abs(L0_on.real - (S * lam * S - U)) < 1e-11
      and abs(np.trace(T_on.real) - (-m * S + 3 * lam * S ** 2)) < 1e-10
      and recorded(THEORY_PY, "commuting_trace_on_shell") == "PASS",
      "on shell: sum K = V S, L0 = S U' - U, trace = -m S + 3 lambda S^2",
      record=f"{THEORY_PY}, check commuting_trace_on_shell")
report("trace on shell, -m S + 3 lambda S^2", f"{np.trace(T_on.real):.6f}")
```

The check confirms the three on-shell values of Section 9.8: $\sum_\mu K_\mu = VS$, $L_0 = SU' - U$ (here `S * lam * S` is $SU'(S)$) and the trace $-mS + 3\lambda S^2$, which is printed: 70.447596. By hand, with the value of S that the notebook holds before rounding, $S = -6.5278747$: $-1\cdot(-6.5278747) + 3\cdot 0.5\cdot 6.5278747^2 = 6.527875 + 63.919721 = 70.447596$. (With the printed, rounded value $S = -6.527875$ the second term would come out as 63.919728 and the sum as 70.447603; the difference of $7\cdot 10^{-6}$ is the effect of rounding S in its seventh digit, multiplied by the slope $|-1+3S| \approx 20.6$ of the trace as a function of S.)

In [12], the spin connection in the entry $T^{x_4}{}_{x_1}$.

```
dPhi_hom = np.zeros((8, 16), dtype=complex)  # homogeneous: only d4 Phi is nonzero
dPhi_hom[4] = rng.normal(size=16) + 1j * rng.normal(size=16)
D_x1 = dPhi_hom[1] + Omega[1] @ Phi  # D_x1 Phi = Omega_x1 Phi here
Dbar_x1 = bar(dPhi_hom[1]) - bar(Phi) @ Omega[1]  # D_x1 Phibar = -Phibar Omega_x1
K_41 = 0.5 * (bar(Phi) @ gamma_up[4] @ D_x1 - Dbar_x1 @ gamma_up[4] @ Phi)
expected = 0.5 * np.exp(a4) * np.sin(z) ** (1 / 6) * H * (
    bar(Phi) @ gamma[4] @ gamma[1] @ gamma[0] @ Phi)
```

A homogeneous jet has only the time derivative: the table `dPhi_hom` is zero except row 3, which is drawn at random. Then $D_{x_1}\Phi = \Omega_{x_1}\Phi$ and $D_{x_1}\bar\Phi = -\bar\Phi\Omega_{x_1}$ (the derivative parts are zero), `K_41` is $K^{x_4}{}_{x_1} = \frac{1}{2}(\bar\Phi\gamma^{x_4}D_{x_1}\Phi - D_{x_1}\bar\Phi\gamma^{x_4}\Phi)$, and `expected` is the result of Section 9.12, $\frac{1}{2}e^{a_4}\sin^{1/6} z\, H\, \bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi$.

```
SCOPE_PY = "Revision/theory/reports/python-scope.json"
SCOPE_WL = "Revision/theory/reports/wolfram-scope.json"
check(abs(K_41 - expected) < 1e-12 and abs(K_41) > 0.01
      and recorded(SCOPE_PY, "spin_connection_in_the_energy_momentum_tensor") == "PASS"
```

```
      and recorded(SCOPE_WL, "spin_connection_in_the_energy_momentum_tensor") == "PASS",
      "K^x4_x1 of a homogeneous configuration is the nonzero connection term",
      record=f"{SCOPE_PY} and {SCOPE_WL}, check "
             "spin_connection_in_the_energy_momentum_tensor")
report("K^x4_x1 (homogeneous configuration)", f"{K_41.real:.6f}")
```

The check requires the two numbers to agree and, so that the test is not empty, the result to be clearly nonzero (larger than 0.01 in size). It prints $K^{x_4}{}_{x_1} = -0.203311$.

In [13], the Christoffel symbols with sympy.

```
import sympy as sp  # exact algebra and calculus with symbols

x = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7 (x[0] ... x[7])
Hs = sp.symbols("H", positive=True)  # the author's constant, as a symbol
a4_function = sp.Function("a4")(x[4])  # a general function a4(x4)
zs = 6 * Hs * x[0]  # z = 6 H x0
space_entry = sp.exp(2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
extra_entry = -sp.exp(-2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
g = sp.diag(*([sp.cot(zs) ** 2] + [space_entry] * 3 + [-1] + [extra_entry] * 3))
```

From here on the notebook computes exactly, with symbols instead of numbers. `sp.symbols("x0:8", real=True)` makes the eight real symbols $x_0, \ldots, x_7$, stored as `x[0]` to `x[7]`; `Hs` is the symbol H, declared positive. `sp.Function("a4")(x[4])` is an unknown function $a_4(x_4)$: the results hold for every history. `sp.Rational(1, 3)` is the exact fraction $1/3$ (the Python number `1 / 3` would be rounded). `sp.diag(*list)` builds the diagonal matrix with the list on its diagonal (the star hands the items of the list over as separate arguments): the author's metric, symbol by symbol.

```
christoffel = {}  # (lambda, mu, nu) -> Gamma^lambda_mu nu, only the nonzero ones
for l in range(8):
    for i in range(8):
        for j in range(i, 8):  # mu <= nu
            value = sp.simplify((sp.diff(g[l, j], x[i]) + sp.diff(g[l, i], x[j])
                                 - sp.diff(g[i, j], x[l])) / (2 * g[l, l]))
            if value != 0:
                christoffel[(l, i, j)] = value
say(f"{len(christoffel)} nonzero Christoffel symbols with mu <= nu")
```

The three loops take every λ (`l`) and every pair $\mu \le \nu$ (`i`, `j`; `range(i, 8)` starts at `i`) and compute the diagonal-metric formula of Section 9.9, $\frac{1}{2g_{\lambda\lambda}}(\partial_\mu g_{\lambda\nu} + \partial_\nu g_{\lambda\mu} - \partial_\lambda g_{\mu\nu})$; `sp.diff(expr, x[i])` is the partial derivative and `sp.simplify` brings the result to a simplest form. The nonzero symbols are stored in the dictionary `christoffel` under the key `(l, i, j)`. There are $8 \cdot 36 = 288$ expressions to simplify, which takes a few seconds. The cell prints `25 nonzero Christoffel symbols with mu <= nu`, the count of Section 9.9.

In [14], comparison with the record's list.

```
a4s, a4ps = sp.symbols("a4 a4p", real=True)  # plain symbols for a4 and da4/dx4
```

```
def plain(expression):
    """Replace da4/dx4 by the symbol a4p and a4(x4) by the symbol a4."""
    return expression.subs(sp.Derivative(a4_function, x[4]), a4ps).subs(
        a4_function, a4s)
```

The record writes a_4 and a_4' as plain names. `plain` makes our symbols comparable: `.subs(old, new)` replaces every occurrence of `old` by `new`; the derivative is replaced first (replacing $a_4(x_4)$ first would destroy it).

```
WOLFRAM_TO_SYMPY = [  # (Wolfram text, sympy text), applied in this order
    ("Derivative[1][a4][x4]", "a4p"), ("Derivative[1, 0][rho][x4, x0]", "rho_4"),
    ("Derivative[0, 1][p0][x4, x0]", "p0_0"), ("[x4, x0]", ""), ("a4[x4]", "a4"),
    ("Sin[", "sin("), ("Cos[", "cos("), ("Cot[", "cot("), ("Sec[", "sec("),
    ("Csc[", "csc("), ("E^", "E**"), ("^", "**"), ("[", "("), ("]", ")"),
    ("{", "["), ("}", "]")]

def from_wolfram(text):
    """Translate a formula of the record from the Wolfram Language into sympy."""
    for old, new in WOLFRAM_TO_SYMPY:
        text = text.replace(old, new)
    return text
```

The record's formulas are written in the Wolfram Language, which uses square brackets for the arguments of functions (`Sin[z]`), `^` for powers and braces for lists. `from_wolfram` translates such a text into sympy's notation by plain text replacements, in the order of the list: the long derivative names first, then the function names, then the single brackets and braces.

```
FORMULAS = {item["key"]: item["wl"] for item in json.loads(repository_file(
    "Revision/theory/field-theory.json").read_text(encoding="utf-8"))["formulas"]}
NAMES_SYMPY = {"a4": a4s, "a4p": a4ps, "H": Hs, "x0": x[0], "E": sp.E}
record_list = sp.sympify(from_wolfram(FORMULAS["christoffel_nonzero"]),
                         locals=NAMES_SYMPY)
# The record counts the coordinates 1 ... 8; Python counts 0 ... 7.
record_symbols = {(int(e[0]) - 1, int(e[1]) - 1, int(e[2]) - 1): e[3]
                  for e in record_list}
```

`FORMULAS` is a **dictionary comprehension**: it maps the key of every formula of the record file to its Wolfram text. `sp.sympify(text, locals=...)` reads a translated text as a sympy expression, with the names `a4`, `a4p`, `H`, `x0` and `E` (Euler's number e) bound to our symbols. The record's list consists of entries $\{\lambda, \mu, \nu, \Gamma^{\lambda}{}_{\mu\nu}\}$ with the coordinates counted from 1; `record_symbols` stores them under keys counted from 0.

```
same = sorted(record_symbols) == sorted(christoffel) and all(
    sp.simplify(plain(christoffel[key]) - record_symbols[key]) == 0
    for key in christoffel)
check(len(christoffel) == 25 and same
      and recorded(THEORY_WL, "christoffel_count") == "PASS",
      "25 nonzero Christoffel symbols, equal to the record's list one by one",
```

```
      record=f"{THEORY_WL}, check christoffel_count (formula christoffel_nonzero)")
for (l, i, j), value in sorted(christoffel.items()):
    print(f"Gamma^{NAMES[l]}_({NAMES[i]} {NAMES[j]}) = {plain(value)}")
```

`same` is true when both dictionaries have the same 25 keys (`sorted` lists the keys in order) and, for each key, the difference of the two symbols simplifies to exactly 0. The loop prints the 25 symbols in order; sympy writes cot as `1/tan` and sec z as `1/cos`. The printed list is the table of Section 9.9; for example `Gamma^x0_(x0 x0) = -12*H/sin(12*H*x0)`.

In [15], the covariant divergence of a diagonal tensor.

```
rho_f, p3_f, pt_f, p0_f = [sp.Function(n)(x[4], x[0]) for n in ("rho", "p3", "pt",
                                                                "p0")]
T_diag = sp.diag(p0_f, p3_f, p3_f, p3_f, -rho_f, pt_f, pt_f, pt_f)  # T^mu_nu

def gamma_symbol(l, i, j):
    """Gamma^l_ij for any order of i and j (zero when it is not in the list)."""
    return christoffel.get((l, min(i, j), max(i, j)), 0)
```

`rho_f`, `p3_f`, `pt_f` and `p0_f` are four unknown functions of x_4 and x_0, and `T_diag` is the diagonal tensor $\mathrm{diag}(p_3, p_3, p_3, -\rho, p_t, p_t, p_t, p_0)$ of Section 9.9. `gamma_symbol(l, i, j)` returns $\Gamma^{l}{}_{ij}$ for either order of `i` and `j` (the symbol is symmetric, and the dictionary stores only $i \le j$); `.get(key, 0)` returns 0 for a symbol that is not stored.

```
divergence = []
for nu in range(8):
    value = sum(sp.diff(T_diag[mu, nu], x[mu]) for mu in range(8))
    value += sum(gamma_symbol(mu, mu, l) * T_diag[l, nu]
                 for mu in range(8) for l in range(8))
    value -= sum(gamma_symbol(l, mu, nu) * T_diag[mu, l]
                 for mu in range(8) for l in range(8))
    divergence.append(sp.simplify(value))
nonzero = [NAMES[nu] for nu in range(8) if divergence[nu] != 0]
say("components of the divergence that are not identically zero: nu = "
    + ", ".join(nonzero))
```

For each ν the loop builds the three sums of the general formula of Section 9.9 literally (without the lemma): $\sum_\mu \partial_\mu T^\mu{}_\nu$, plus $\sum_{\mu,\lambda} \Gamma^\mu{}_{\mu\lambda} T^\lambda{}_\nu$, minus $\sum_{\mu,\lambda} \Gamma^\lambda{}_{\mu\nu} T^\mu{}_\lambda$ (`+=` adds to `value`, `-=` subtracts from it), simplifies the result and appends it to the list. `", ".join(...)` writes the names of the nonzero components separated by commas. The cell prints `nu = x4, x0`: the other six components vanish identically.

In [16], comparison with the record's identities.

```
rho_4, p0_0, p3s, pts, p0s = sp.symbols("rho_4 p0_0 p3 pt p0", real=True)

def plain_t(expression):
    """Write the derivatives and functions as the plain symbols of the record."""
```

```
    expression = expression.subs({sp.Derivative(rho_f, x[4]): rho_4,
                                  sp.Derivative(p0_f, x[0]): p0_0})
    expression = expression.subs({p3_f: p3s, pt_f: pts, p0_f: p0s,
                                  rho_f: sp.Symbol("rho", real=True)})
    return plain(expression)
```

`plain_t` writes our results with the record's plain names: $\partial_4\rho$ as `rho_4`, $\partial_0 p_0$ as `p0_0`, and the four functions as plain symbols; `.subs` also accepts a dictionary of replacements.

```
NAMES_T = dict(NAMES_SYMPY, rho_4=rho_4, p0_0=p0_0, p3=p3s, pt=pts, p0=p0s)
record_divergence = sp.sympify(from_wolfram(FORMULAS["energy_exchange"][0]),
                               locals=NAMES_T)
agree = all(sp.simplify(plain_t(divergence[n]) - record_divergence[n]) == 0
            for n in range(8))
x4_line = -rho_4 - 3 * a4ps * (p3s - pts)
x0_line = p0_0 + 3 * Hs * sp.cot(zs) * (2 * p0s - p3s - pts)
```

`NAMES_T` extends the dictionary of names. The record's formula `energy_exchange` is a list of three texts; the first one (`[0]`) is the list of all eight components of the divergence, which `record_divergence` reads. `agree` is true when each of our eight components equals the record's, exactly. `x4_line` and `x0_line` are the two results of Section 9.9, typed by hand.

```
check(agree and recorded(THEORY_WL, "energy_exchange_equation") == "PASS"
      and recorded(THEORY_PY, "energy_exchange_equation") == "PASS",
      "the eight components agree with the record formula energy_exchange",
      record=f"{THEORY_WL} and {THEORY_PY}, check energy_exchange_equation")
check(sp.simplify(plain_t(divergence[4]) - x4_line) == 0
      and recorded(LEAD, "divergence_x4_component") == "PASS",
      "nabla_mu T^mu_x4 = -d4 rho - 3 a4p (p3 - p_t)",
      record=f"{LEAD}, check divergence_x4_component")
check(sp.simplify(plain_t(divergence[0]) - x0_line) == 0
      and recorded(LEAD, "divergence_x0_component") == "PASS",
      "nabla_mu T^mu_x0 = d0 p0 + 3 H cot z (2 p0 - p3 - p_t)",
      record=f"{LEAD}, check divergence_x0_component")
check(all(divergence[n] == 0 for n in (1, 2, 3, 5, 6, 7))
      and recorded(LEAD, "divergence_other_components_zero") == "PASS",
      "the components x1, x2, x3, x5, x6, x7 vanish identically",
      record=f"{LEAD}, check divergence_other_components_zero")
print("nabla_mu T^mu_x4 =", x4_line)  # rho_4 = d rho/d x4
print("nabla_mu T^mu_x0 =", x0_line)  # p0_0 = d p0/d x0
```

Four checks: all eight components agree with the record's formula (whose check passed in both engines); the x_4 component and the x_0 component equal the hand-derived lines (and the lead's independent checks passed); and the other six components are zero. The last two lines print the two identities in sympy's spelling, `-3*a4p*(p3 - pt) - rho_4` and `3*H*(-p3 + 2*p0 - pt)*cot(6*H*x0) + p0_8`.

In [17], the first-law reading.

```
f_space = sp.exp(a4_function) * sp.sin(zs) ** sp.Rational(1, 6)  # f1 = f2 = f3
f_extra = sp.exp(-a4_function) * sp.sin(zs) ** sp.Rational(1, 6)  # f5 = f6 = f7
```

```
V3 = f_space ** 3  # e^(3 a4) sin^(1/2) z
Vt = f_extra ** 3  # e^(-3 a4) sin^(1/2) z
V7 = V3 * Vt * sp.cot(zs)  # times f0 = cot z (and f4 = 1)
check(sp.simplify(V7 - sp.cos(zs)) == 0, "V3 Vt f0 = cos z, independent of x4")
```

These lines build the three volumes of Section 9.10 with symbols and check $V_7 = \cos z$ exactly.

```
first_law = (sp.diff(rho_f * V7, x[4]) + p3_f * V7 / V3 * sp.diff(V3, x[4])
             + pt_f * V7 / Vt * sp.diff(Vt, x[4]))
# The first law says first_law = 0; it must be -V7 times the x4 divergence.
check(sp.simplify(first_law + V7 * divergence[4]) == 0,
      "d(rho V7)/dx4 + p3 (V7/V3) dV3/dx4 + p_t (V7/Vt) dVt/dx4 = -V7 nabla_mu T^mu_x4")
```

`first_law` is the first law of Section 9.10 with everything on one side, $\frac{d}{dx_4}(\rho V_7) + p_3 \frac{V_7}{V_3}\frac{dV_3}{dx_4} + p_t \frac{V_7}{V_t}\frac{dV_t}{dx_4}$. The check shows that it equals $-V_7$ times the x_4 component of the divergence: setting one to zero is the same as setting the other to zero. The reading is an interpretation of an exact identity, not an extra result.

In [18], the volumes along the history (Figure 09a.4).

```
x4_axis = np.linspace(0.0, 8.0, 401)  # the time x4
growth = np.exp(3 * A * H * x4_axis)  # V3(x4)/V3(0) = e^(3 A H x4)
fig, ax = plt.subplots()
ax.plot(x4_axis, growth, label="3-space volume $V_3$ (inflates)")
ax.plot(x4_axis, 1 / growth, "--", label="extra-time volume $V_t$ (deflates)")
ax.plot(x4_axis, growth / growth, ":", color="black",
        label="7-volume $V_7 = V_3 V_t \\cot z$ (constant)")
ax.set_yscale("log")
ax.set_xlabel("time $x_4$")
ax.set_ylabel("volume divided by its value at $x_4 = 0$")
ax.set_title("Volumes along the history $a_4 = A H x_4$ ($A = 1$, $H = 0.25$)")
ax.legend()
save_figure(fig, "volumes_first_law",
            "The 3-space volume $V_3 = e^{3a_4}\\sin^{1/2}z$ (solid), the "
            ...)
```

On the history $a_4 = AHx_4$ the ratio $V_3(x_4)/V_3(0)$ is e^{3AHx_4}, the ratio for V_t is its inverse, and the ratio for V_7 is 1 (`growth / growth`). **What Figure 09a.4 shows.** The three volume ratios (pure numbers) against the time x_4 from 0 to 8 on a logarithmic axis: V_3 rises along a straight line to $e^6 \approx 403$, V_t falls along the mirror line to e^{-6}, and V_7 stays at 1. The student should see that the extra times deflate, exponentially, and that their shrinking exactly compensates the growth of 3-space; this is why the energy density changes only through the difference $p_3 - p_t$.

In [19], the x0 identity with sympy.

```
P, c = sp.symbols("P c", real=True)  # P = p3 + p_t (a constant) and the constant c
profile = P / 2 + c / sp.sin(zs)  # p0 as a function of x0 (through z)
balance = sp.diff(profile, x[0]) + 3 * Hs * sp.cot(zs) * (2 * profile - P)
check(sp.simplify(balance) == 0,
      "p0 = P/2 + c/sin z solves the x0 identity for every c")
```

`balance` is the x_0 component of the divergence for $p_0 = P/2 + c/\sin z$ and $p_3 + p_t = P$; the check confirms that it is zero for every c, the solution found in Section 9.11.

```
y = sp.symbols("y", real=True)
dy_dx0 = sp.diff(sp.log(sp.sin(zs)) / (6 * Hs), x[0])  # y = ln(sin z)/(6 H)
check(sp.simplify(dy_dx0 - sp.cot(zs)) == 0
      and recorded(LEAD, "ks_coordinate_jacobian") == "PASS",
      "y = ln(sin z)/(6 H) has dy/dx0 = cot z",
      record=f"{LEAD}, check ks_coordinate_jacobian")
```

This check differentiates $y = \ln(\sin z)/(6H)$ with respect to x_0 and confirms $dy/dx_0 = \cot z$.

```
z_of_y = sp.asin(sp.exp(6 * Hs * y))  # sin z = e^(6 H y), z between 0 and pi/2
P0, P3, PT = [sp.Function(n)(y) for n in ("P0", "P3", "PT")]
in_x0 = sp.cot(z_of_y) * sp.diff(P0, y) + 3 * Hs * sp.cot(z_of_y) * (2 * P0 - P3 - PT)
in_y = sp.cot(z_of_y) * (sp.diff(P0, y) + 6 * Hs * P0 - 3 * Hs * (P3 + PT))
check(sp.simplify(in_x0 - in_y) == 0
      and recorded(LEAD, "ks_coordinate_form") == "PASS",
      "x0 component = cot z [p0'(y) + 6 H p0 - 3 H (p3 + p_t)]",
      record=f"{LEAD}, check ks_coordinate_form")
```

Solving $\sin z = e^{6Hy}$ for z gives $z = \arcsin(e^{6Hy})$ (`sp.asin`). `P0`, `P3` and `PT` are the three pressures as functions of y. `in_x0` is the x_0 component with $\partial_0 p_0 = \cot z \, dp_0/dy$, and `in_y` the form of Section 9.11; the check confirms that they are the same expression.

In [20], the pressure profiles of the x0 balance (Figure 09a.5).

```
z_grid = np.linspace(0.1, np.pi / 2 - 0.01, 2001)  # z from 0.1 to just below pi/2
x0_grid = z_grid / (6 * H)  # the matching x0 = z/(6 H)
fig, ax = plt.subplots()
worst = 0.0  # the largest relative residual of the balance on the grid
for c_value in (-0.2, -0.1, 0.0, 0.1, 0.2):
    p0_values = 0.5 + c_value / np.sin(z_grid)  # P = 1
    slope = np.gradient(p0_values, x0_grid)  # d p0/d x0, by finite differences
    rhs = -3 * H / np.tan(z_grid) * (2 * p0_values - 1.0)
```

The grid has 2001 values of z between 0.1 and $\pi/2 - 0.01$, and the matching $x_0 = z/(6H)$. For each of five constants c the loop computes the profile $p_0 = 1/2 + c/\sin z$ (so $P = 1$), its slope dp_0/dx_0 by **finite differences** (`np.gradient` approximates a derivative by the difference of neighbouring values divided by their distance), and the right-hand side $-3H \cot z \, (2p_0 - 1)$ of the balance.

```
    # The size of the terms; 1 (the size of P) is added, so that for the flat
    # profile c = 0, whose terms are zero, rounding noise is not divided by zero.
    scale = 1.0 + np.abs(slope).max() + np.abs(rhs).max()
    # [5:-5] leaves out five points at each end, where np.gradient is less exact.
    worst = max(worst, np.abs(slope - rhs)[5:-5].max() / scale)
    style = "-" if c_value == 0.0 else "--"
    ax.plot(z_grid, p0_values, style, label=f"$c = {c_value:g}$")  # g: short form
check(worst < 1e-4, "the drawn profiles satisfy the x0 balance on the grid")
```

The residual, slope minus right-hand side, is divided by the size of the terms; `[5:-5]` drops five points at each end of the grid, and `worst` keeps the largest relative residual of the five profiles. The profile with $c = 0$ is drawn solid, the others dashed; the format `:g` writes a number in its shortest form. The check requires the residual to be below 10^{-4}: it measures the error of the finite differences, not a failure of the identity.

```
ax.set_ylim(-2.0, 3.0)
ax.set_xlabel("$z = 6 H x_0$")
ax.set_ylabel("$p_0$ (with $p_3 + p_t = 1$)")
ax.set_title("Pressure profiles allowed by the balance along $x_0$")
ax.legend()
save_figure(fig, "hidden_balance",
            "The hidden-direction pressure profiles $p_0 = P/2 + c/\\sin z$ that "
            "satisfy the conservation identity along $x_0$, "
            "$\\partial_0 p_0 = -3H\\cot z\\,(2p_0 - p_3 - p_t)$, when "
            ...)
report("largest relative residual of the balance on the grid", f"{worst:.1e}")
```

These lines fix the vertical range, label the axes, save the figure and print the residual, $2.3 \cdot 10^{-5}$ (the format `.1e` writes one decimal and a power of ten). **What Figure 09a.5 shows.** The hidden pressure p_0 (energy per unit volume) against z from 0.1 to just below $\pi/2$ for five values of c. Only the solid line $c = 0$ is flat, at $p_0 = P/2 = 0.5$; every other profile grows in size like $1/\sin z$ towards the tip $z = 0$, upwards for $c > 0$ and downwards for $c < 0$. The student should see that an x_0-independent tensor must have $p_0 = (p_3 + p_t)/2$.

In [21], the last check.

```
captions = json.loads(output_file(CAPTION_FILE).read_text(encoding="utf-8"))
expected_files = ["09a_1_kinetic_weights.png", "09a_2_tensor_heat_map.png",
                  "09a_3_diagonal_parts.png", "09a_4_volumes_first_law.png",
                  "09a_5_hidden_balance.png"]
check(sorted(captions) == expected_files and all(
    output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected_files),
    "the five figures of this notebook are saved and captioned")
all_checks_passed()
```

The cell reads the captions file back, checks that it holds exactly the five figure names (sorted) and that the five files exist, and prints the last line, `ALL 27 CHECKS PASSED (notebook 09a)`: two checks each in In [2], In [3], In [5], In [7] and In [9], four in In [11], one each in In [12] and In [14], four in In [16], two in In [17], three in In [19], and one each in In [20] and In [21].

9.18 Condensates: exact solutions that depend on the time only

A **condensate** (also called a **homogeneous configuration**) is a field that is the same at every place: it depends on the time x_4 only, not on $x_1, x_2, x_3, x_5, x_6, x_7, x_0$. Condensates are the simplest candidates for a smooth cosmological fluid, and the field equation can be solved for them exactly.

The field equation of a condensate. In the explicit field equation of Section 9.2 every derivative term with $a \neq 4$ vanishes, and $f_4 = 1$:

$$\gamma^{(4)}\partial_4\Phi + 3H\gamma^{(0)}\Phi = V\Phi, \qquad V = m + \lambda S.$$

Multiply from the left by $-\gamma^{(4)}$. Because $(\gamma^{(4)})^2 = -1$, the first term becomes $-\gamma^{(4)}\gamma^{(4)}\partial_4\Phi = \partial_4\Phi$, the second $-3H\gamma^{(4)}\gamma^{(0)}\Phi$, and the right side $-V\gamma^{(4)}\Phi$. Moving the second term to the right:

$$\partial_4\Phi = M\Phi, \qquad M = -V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}.$$

Neither a_4 nor x_0 appears: the same condensate solves the field equation on every history $a_4(x_4)$, the deflating one included. (This is the effect of Section 9.3: the connection enters only as $3H\gamma^{(0)}$, which contains no a_4.)

The scalar S is constant. The equation is nonlinear, because V contains $S = \Phi^\dagger C\Phi$. But S does not change. By the product rule,

$$\frac{dS}{dx_4} = (\partial_4\Phi)^\dagger C\Phi + \Phi^\dagger C\,\partial_4\Phi = (M\Phi)^\dagger C\Phi + \Phi^\dagger CM\Phi = \Phi^\dagger\big(M^TC + CM\big)\Phi,$$

where the last step uses $(M\Phi)^\dagger = \Phi^\dagger M^\dagger$ and $M^\dagger = M^T$ (M is real). Now compute M^TC. From the antisymmetry of $C\gamma^{(a)}$ and the symmetry of C: $\gamma^{(a)T}C = (C\gamma^{(a)})^T = -C\gamma^{(a)}$. Hence

$$\begin{aligned}
\gamma^{(4)T}C &= -C\gamma^{(4)},\\
\big(\gamma^{(4)}\gamma^{(0)}\big)^TC &= \gamma^{(0)T}\gamma^{(4)T}C = -\gamma^{(0)T}C\gamma^{(4)} = C\gamma^{(0)}\gamma^{(4)} = -C\gamma^{(4)}\gamma^{(0)},\\
M^TC &= -V\gamma^{(4)T}C + 3H\big(\gamma^{(4)}\gamma^{(0)}\big)^TC = VC\gamma^{(4)} - 3HC\gamma^{(4)}\gamma^{(0)} = -CM.
\end{aligned}$$

The first line is the rule just stated; the second applies it twice (the transpose of a product is the product of the transposes in reverse order) and then uses $\gamma^{(0)}\gamma^{(4)} = -\gamma^{(4)}\gamma^{(0)}$; the third inserts both. So $M^TC + CM = 0$ and $dS/dx_4 = 0$: S keeps its initial value $S_0 = \chi^\dagger C\chi$, where $\chi = \Phi(0)$. Then $V = m + \lambda S_0$ is a constant, and M is a constant matrix.

The square of M. Multiply out $M^2 = (-V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)})(-V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)})$:

$$\begin{aligned}
M^2 &= V^2\gamma^{(4)}\gamma^{(4)} - 3HV\big(\gamma^{(4)}\gamma^{(4)}\gamma^{(0)} + \gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\big) + 9H^2\gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\gamma^{(0)}\\
&= -V^2 - 3HV\big(-\gamma^{(0)} + \gamma^{(0)}\big) + 9H^2\cdot 1\\
&= \big(9H^2 - V^2\big)\cdot 1 = k^2\cdot 1, \qquad k^2 = 9H^2 - V^2.
\end{aligned}$$

The first line multiplies out the four products; the second uses $\gamma^{(4)}\gamma^{(4)} = -1$, then $\gamma^{(4)}\gamma^{(0)}\gamma^{(4)} = -\gamma^{(4)}\gamma^{(4)}\gamma^{(0)} = \gamma^{(0)}$, and $\gamma^{(4)}\gamma^{(0)}\gamma^{(4)}\gamma^{(0)} = -\gamma^{(4)}\gamma^{(4)}\gamma^{(0)}\gamma^{(0)} = -(-1)(+1) = 1$; the third collects.

The solution. For a number k the exponential series $e^{kx} = \sum_n (kx)^n/n!$ splits into its even and odd terms, $\cosh(kx) = \sum_j (kx)^{2j}/(2j)!$ and $\sinh(kx) = \sum_j (kx)^{2j+1}/(2j+1)!$. The same series with the matrix Mx_4 in place of kx defines the **matrix exponential** e^{Mx_4}, and $e^{Mx_4}\chi$ solves $\partial_4\Phi = M\Phi$ with $\Phi(0) = \chi$. Because $M^2 = k^2$, every even power is $M^{2j} = k^{2j}$ and every odd power is $M^{2j+1} = k^{2j}M$, so the even terms sum to $\cosh(kx_4)$ and the odd terms to $\frac{\sinh(kx_4)}{k}M$:

$$\Phi(x_4) = \Big(\cosh(kx_4) + \frac{\sinh(kx_4)}{k}\,M\Big)\chi.$$

A direct check, without series: at $x_4 = 0$ this is χ; its derivative is $\big(k\sinh(kx_4) + \cosh(kx_4)M\big)\chi$; and $M\Phi = \big(\cosh(kx_4)M + \frac{\sinh(kx_4)}{k}M^2\big)\chi = \big(\cosh(kx_4)M + k\sinh(kx_4)\big)\chi$ (using $M^2 = k^2$), the same. Three cases:

- $k^2 < 0$, that is $|V| > 3H$: $k = i\omega$ with $\omega = \sqrt{V^2 - 9H^2}$; since $\cosh(i\omega x) = \cos(\omega x)$ and $\sinh(i\omega x)/(i\omega) = \sin(\omega x)/\omega$, the condensate **oscillates** with the angular frequency ω;
- $k^2 > 0$, that is $|V| < 3H$: the solution contains e^{kx_4} and **grows**;
- $k^2 = 0$: the limit $\Phi = \chi + x_4 M\chi$.

These are the record's exact nonlinear homogeneous solutions (PROVED; record formula `exact_solutions` of `Revision/theory/field-theory.json`, and the checks in the table).

statement	**Revision report**	**check**
$M^2 = k^2 \cdot 1$ and $M^T C + CM = 0$	`Revision/theory/reports/wolfram-field-theory.json`	`solution_matrix_square`
the condensate solves the field equation, $S = S_0$, and its ρ, p	`Revision/theory/reports/wolfram-field-theory.json`	`exact_solution_nonlinear_homogeneous_C`
the same, verified independently with sympy	`Revision/theory/reports/python-field-theory.json`	`exact_nonlinear_homogeneous_solution`

9.19 The energy density, pressure and equation of state of a condensate

The kinetic terms. For a condensate $\partial_\mu\Phi = 0$ for $\mu \neq x_4$, so every kinetic term except K_4 is zero. On shell the kinetic sum of Section 9.8 gives $\sum_\mu K_\mu = VS$, hence $K_4 = VS$.

Energy density and pressures. Insert into Section 9.7:

$$\rho = -\sum_{\mu \neq x_4} K_\mu + mS + U = 0 + mS + U(S),$$
$$p_\mu = \sum_{\nu \neq \mu} K_\nu - mS - U = K_4 - mS - U = (m + U')S - mS - U = S\,U'(S) - U(S) \qquad (\mu \neq x_4).$$

In the first line all seven kinetic terms vanish; in the second the only kinetic term left in the sum is K_4 (because $\mu \neq x_4$), which is $VS = (m + U')S$. The pressure is the same in all seven directions, $p_3 = p_t = p_0 = p$. The kinetic part of the energy density is zero, the kinetic part of every pressure is VS, the potential parts are $\pm(mS + U)$. For $U = \frac{\lambda}{2}S^2$, with $SU' = \lambda S^2$:

$$\rho = mS + \tfrac{\lambda}{2}S^2, \qquad p = \lambda S^2 - \tfrac{\lambda}{2}S^2 = \tfrac{\lambda}{2}S^2.$$

(PROVED; `Revision/theory/reports/python-field-theory.json`, check `commuting_homogeneous_on_shell_rho_p`; record formula `EMT_homogeneous_on_shell`.) The trace is $-\rho + 7p =$

$-mS - \frac{\lambda}{2}S^2 + \frac{7\lambda}{2}S^2 = -mS + 3\lambda S^2$, as Section 9.8 requires. Because S is constant, ρ and p are constant in time; this agrees with the energy exchange of Section 9.10, since $p_3 = p_t$ gives $d\rho/dx_4 = 0$.

No x_4-x_0 flow. The record gives the entry (formula `EMT_offdiagonal_x4_x0`)

$$T^{x_4}{}_{x_0} = -\tfrac{1}{4}(B_{40} - \cot z\, B_{04}), \qquad B_{40} = \bar\Phi\gamma^{(4)}\partial_0\Phi - \partial_0\bar\Phi\,\gamma^{(4)}\Phi, \qquad B_{04} = \bar\Phi\gamma^{(0)}\partial_4\Phi - \partial_4\bar\Phi\,\gamma^{(0)}\Phi.$$

For a condensate $B_{40} = 0$ (no x_0 derivative). For B_{04}: $\partial_4\Phi = M\Phi$ and $\partial_4\bar\Phi = (M\Phi)^\dagger C = \Phi^\dagger M^T C = -\Phi^\dagger C M = -\bar\Phi M$, so

$$B_{04} = \bar\Phi\gamma^{(0)}M\Phi + \bar\Phi M\gamma^{(0)}\Phi = \bar\Phi\{\gamma^{(0)}, M\}\Phi = \bar\Phi(-V\{\gamma^{(0)}, \gamma^{(4)}\} + 3H\{\gamma^{(0)}, \gamma^{(4)}\gamma^{(0)}\})\Phi = 0,$$

because $\{\gamma^{(0)}, \gamma^{(4)}\} = 2\eta^{84} = 0$ and $\{\gamma^{(0)}, \gamma^{(4)}\gamma^{(0)}\} = \gamma^{(0)}\gamma^{(4)}\gamma^{(0)} + \gamma^{(4)}\gamma^{(0)}\gamma^{(0)} = -\gamma^{(4)} + \gamma^{(4)} = 0$. So $T^{x_4}{}_{x_0} = 0$, and $T^{x_0}{}_{x_4} = -\tan^2 z\, T^{x_4}{}_{x_0} = 0$ (PROVED; check `commuting_T_x4x0_homogeneous`). The other entries off the diagonal are not zero in general (Section 9.26).

The equation of state. For $S \neq 0$, divide the numerator and the denominator of p/ρ by $mS/2$:

$$w = \frac{p}{\rho} = \frac{\frac{\lambda}{2}S^2}{mS + \frac{\lambda}{2}S^2} = \frac{\lambda S/m}{2 + \lambda S/m} = \frac{x}{2+x}, \qquad x = \frac{\lambda S}{m}.$$

(The record writes it $w = \lambda S/(2m + \lambda S)$.) It depends on m, λ and S only through x, and the effective mass is $V = m + \lambda S = m(1 + x)$. Its special values, each by elementary algebra:

$x = \lambda S/m$	w	**why**
$x = 0$ ($\lambda = 0$)	$w = 0$ (like dust)	$p = 0$
$x = 1$	$w = 1/3$ (like radiation)	$1/(2+1)$
$x = -1$	$w = -1$ (like a cosmological constant)	$-1/(2-1)$; here $V = m(1+x) = 0$
$-2 < x < -1$	$w < -1$ (called **phantom**)	$2 + x > 0$, and $x < -(2+x)$ means $x < -1$
$x = -2$	not defined	$\rho = mS(1 + x/2) = 0$
$x < -2$ (with $m > 0$, $S > 0$)	$w > 1$	$\rho < 0$ and $p < 0$; $x/(2+x) > 1$ means $x < 2 + x$ after multiplying by the negative $2 + x$
$x \to \pm\infty$	$w \to 1$	$x/(2+x) = 1/(1 + 2/x)$

What these numbers are, and what they are not. They are the ratios p/ρ of the eight-dimensional tensor of exact solutions, constant in time (COMPUTED in Notebook 09b on twelve exact solutions; the formula is PROVED in the record). They are not the equation of state that an observer in 3-space would infer: that observer sees neither the extra times nor the hidden direction as space, and to relate the two one must integrate over x_5, x_6, x_7, x_0 and follow the deflation. This chapter makes no such computation. The Revision dark-sector record makes it under an ASSUMED

normalisation of the observer's energy density (the definitions A, B and C of Chapter 22): for a homogeneous condensate of either field, the equation of state w_{eff} that the observer infers from the dilution of that density is 0 (dust-like) under A and B and -1 under C, constant in time and independent of x wherever $\rho \neq 0$, because $p_3 = p_t$ (PROVED in that record; `Revision/docs/DARK_SECTOR_HYPOTHESES.md`, sections 3.2 and 13.1). Which definition, if any, describes a physical observer, and a fit to supernova data, are OPEN. In particular, the phantom range $w < -1$ of this table is not a claim about dark energy: the commuting field has negative energies (Section 9.21), and any use of them for a phantom equation of state is a HYPOTHESIS, not a result (the record's dark-sector study obtains a crossing of $w = -1$ only in a model with a component of negative classical energy whose share was chosen; Chapter 22).

9.20 Where condensates oscillate and where they grow

With $V = m(1 + x)$ the number $k^2 = 9H^2 - V^2 = 9H^2 - m^2(1 + x)^2$ is positive exactly when $|1 + x| < 3H/|m|$. In the plane of the two pure numbers x and $3H/|m|$ the growing condensates fill the wedge between the lines $3H/|m| = |1 + x|$; outside it they oscillate. The equation of state depends on x alone, so every line of constant w is vertical in this plane. At $x = -1$ ($w = -1$) the effective mass vanishes, $k^2 = 9H^2 > 0$, and the condensate grows like e^{3Hx_4}: every condensate with $w = -1$ grows (for $H > 0$).

The two condensates of Notebook 09b have $m = 1$, $H = 0.25$ (so $3H = 0.75$) and $S_0 = 1$:

- $\lambda = 0.5$: $V = 1.5 > 0.75$, $k^2 = 0.5625 - 2.25 = -1.6875$; it oscillates with $\omega = \sqrt{1.6875} = 1.299$, that is with the period $2\pi/\omega = 4.84$;
- $\lambda = -0.5$: $V = 0.5 < 0.75$, $k^2 = 0.5625 - 0.25 = 0.3125$, $k = 0.559$; it grows: for large x_4 its size $\Phi^\dagger\Phi$ grows like e^{2kx_4}, and the exponential factor alone reaches $e^{2 \cdot 0.559 \cdot 12} \approx 7 \cdot 10^5$ at $x_4 = 12$ (Figure 09b.2 shows a growth by more than a factor 100000).

In both cases S stays exactly at 1. A growing Φ with a constant $S = \Phi^\dagger C \Phi$ is possible because C has eight eigenvalues $+1$ and eight -1: the growth happens along directions in which the indefinite form $\Phi^\dagger C \Phi$ does not grow. Whether growing condensates are acceptable physically is the question of well-posedness and boundary conditions discussed in Chapter 8; this chapter only computes their tensor.

9.21 The energy of the commuting field has no lower bound

S has no sign. C is real and symmetric with $C^2 = 1$, so its eigenvalues are $+1$ or -1; the record writes $C = \text{diag}(-\sigma, \sigma)$ (the block $-\sigma$ in the upper left corner, σ in the lower right, zeros elsewhere) with a real symmetric 8×8 matrix σ that obeys $\sigma^2 = 1$ and has trace 0. The eigenvalues of σ are therefore $+1$ or -1 (if $\sigma v = \mu v$ then $v = \sigma^2 v = \mu^2 v$, so $\mu^2 = 1$), and because the trace of a symmetric matrix is the sum of its eigenvalues, trace 0 means four eigenvalues $+1$ and four -1. The block $-\sigma$ has the same eigenvalues with the signs exchanged, again four of each. So C has eight eigenvalues $+1$ and eight -1 (PROVED; see the table at the end of this section). For an eigenvector χ with eigenvalue -1, $S_0 = \chi^\dagger C \chi = -\chi^\dagger \chi < 0$. A condensate with $\lambda = 0$ has $\rho = mS_0$: for $m > 0$ its energy density is negative whenever $S_0 < 0$.

Plane waves of positive frequency with negative energy. Take flat 4+4 space (all $f_a = 1$, no spin connection), $U = 0$, and a **plane wave** $\Phi = u\, e^{i(k_1x_1+k_2x_2+k_3x_3+k_0x_0-Ex_4)}$ with a constant column u, no dependence on the extra times, and a positive frequency E. Then $\partial_a\Phi = ik_a\Phi$ for $a = 1, 2, 3, 8$, $\partial_4\Phi = -iE\Phi$, and $\partial_a\bar\Phi = -ik_a\bar\Phi$ (complex conjugation turns i into $-i$). Line by line:

$$
\begin{aligned}
K_a &= \tfrac{1}{2}\big(\bar\Phi\gamma^{(a)}(ik_a\Phi) - (-ik_a\bar\Phi)\gamma^{(a)}\Phi\big) = ik_a\,\bar\Phi\gamma^{(a)}\Phi \qquad (a = 1, 2, 3, 8),\\
\rho &= -\sum_{a\neq x_4} K_a + mS = \bar\Phi\Big(m - i\sum_a k_a\gamma^{(a)}\Big)\Phi,\\
mu &= -iE\gamma^{(4)}u + i\sum_a k_a\gamma^{(a)}u \quad\Longrightarrow\quad \Big(m - i\sum_a k_a\gamma^{(a)}\Big)\Phi = -iE\gamma^{(4)}\Phi,\\
\rho &= \bar\Phi\big(-iE\gamma^{(4)}\big)\Phi = E\,\Phi^\dagger\big(-iC\gamma^{(4)}\big)\Phi = E\,\Phi^\dagger B\Phi = E\,u^\dagger Bu.
\end{aligned}
$$

The first line inserts the derivatives into K_a (the two terms are equal); the second inserts K_a into ρ (Section 9.7, with $U = 0$; the extra-time terms are zero); the third is the flat field equation $\sum_a \gamma^{(a)}\partial_a\Phi = m\Phi$ for the plane wave, rearranged; the fourth inserts it, writes $\bar\Phi = \Phi^\dagger C$, uses the matrix $B = -iC\gamma^{(4)}$ of Chapter 5, and the fact that the exponential factor has size 1. B is Hermitian with $B^2 = 1$, with eight eigenvalues $+1$ and eight -1. The field equation multiplied by $-i\gamma^{(4)}$ reads $Eu = hu$ with the matrix $h = m\beta + \sum_a k_a\alpha^a$, $\beta = -i\gamma^{(4)}$, $\alpha^a = -\gamma^{(4)}\gamma^{(a)}$; for $m = 2$ and $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, $h^2 = (4+16+1+4+0)\cdot 1 = 25$, so $E = \pm 5$. The record proves that h commutes with B and that on the 8-dimensional space of solutions with $E = 5$ the form $u^\dagger Bu$ has four positive and four negative directions (**Krein inertia** (4,4)): there are unit columns u with $Bu = -u$, whose waves have $\rho = -5$, and with $Bu = +u$, whose waves have $\rho = +5$ (PROVED; the table lists the checks). Multiplying such a wave by a large constant makes ρ as negative as we like: the classical energy of dirac16complex00 has no lower bound, already for $U = 0$.

statement	**Revision report**	**check**
h commutes with B; waves with $\rho = -5$ and $\rho = +5$ at $E = 5$	`Revision/theory/reports/python-scope.json` and `wolfram-scope.json`	`commuting_field_energy_unbounded_below`
every space of solutions of one real frequency has Krein inertia (4,4)	`Revision/pairing/reports/python-pairing.json`	`Q.one_particle_Krein_inertia_proof`
C has eight eigenvalues $+1$ and eight -1	`Revision/algebra/reports/python-algebra.json` and `wolfram-algebra.json`	`C_equals_notebook_sigma16`, `sigma8_involution`

This is the classical form of the **spin-statistics** problem of a commuting field with a first-order Lagrangian. The **spin-statistics rule** of ordinary four-dimensional quantum field theory says that particles of half-integer **spin** (the spin is the intrinsic angular momentum of a particle, measured in units of Planck's constant divided by 2π; the electron has spin $\frac{1}{2}$), which are the fermions of Chapter 7, must be described by anticommuting fields; described by commuting fields, as dirac16complex00 is, the energy of a spinor field has no lower bound, and this is exactly what the plane waves above show. (The rule is a theorem of ordinary four-dimensional physics; this book does not prove it, and for 4+4 dimensions it claims only the statements of this section.) It must be remembered in every reading of the author's Hypothesis00 (for example a phantom equation of state), and it is why the anticommuting, quantised field dirac16complex is treated separately (Chapter 10).

In Part V the chirality map Γ sends every solution with parameters (m, λ) to a solution with $(-m, -\lambda)$ and reverses the sign of the energy-momentum tensor (theorem T1; PROVED, `Revision/pairing/reports/python-pairing.json`, checks `T1.metric.commuting.euler_lagrange_map` and `T1.metric.commuting.emt`; Chapter 18 gives the proof). That theorem is an exact map between sets of solutions: it does not prove that any universe is created, in pairs or otherwise, and it gives no creation process, rate or amplitude.

9.22 Example: condensates

The second worked example builds the exact condensates of Section 9.18 and measures their energy-momentum tensor. It first shows with 20000 random columns that $S_0 = \chi^\dagger C \chi$ takes both signs; checks $M^2 = k^2$ and $M^T C + CM = 0$ for 18 pairs (V, H); builds one oscillating ($\lambda = 0.5$) and one growing ($\lambda = -0.5$) condensate with $m = 1$, $H = 0.25$ and $S_0 = 1$ and checks the field equation and the constancy of S at 401 times; computes from the solutions K_4, ρ, p and B_{04} and checks the values of Section 9.19; measures $w = p/\rho$ on twelve exact solutions and compares it with $x/(2 + x)$; draws the map of Section 9.20; confirms that a condensate keeps its energy density along the deflating history and, as an ILLUSTRATION only, solves the energy exchange of toy fluids with the Runge-Kutta method; and reproduces the negative energies of Section 9.21. It draws seven figures.

9.23 How to run Notebook 09b

Step 1. What this notebook does and what it needs.

Notebook 09b (Homogeneous condensates: energy, pressure, equation of state and energy exchange) is the file `Revision/textbook/notebooks/09b_condensates.ipynb` of the repository Dirac_claude. It builds the exact homogeneous solutions (condensates) of the commuting field dirac16complex00 with the potential U = (lambda/2) S^2 in the author's metric from the Revision gamma matrices, checks that S stays constant and that the energy density and pressure are rho = m S + U and p = S U' - U in every direction, measures the equation of state w = p/rho of actual solutions against lambda S/m, maps where condensates oscillate or grow, shows with assumed toy fluids how energy is exchanged between 3-space and the extra times when the two pressures differ (and that a condensate exchanges none), and shows that the energy of the commuting field has no lower bound, in seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its

first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook,

skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09b_condensates.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09b_condensates.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 09b_condensates.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/09b.captions.json`
- `Revision/textbook/figures/09b_1_sign_of_s.png`
- `Revision/textbook/figures/09b_2_condensate_solutions.png`
- `Revision/textbook/figures/09b_3_energy_and_pressure.png`

- `Revision/textbook/figures/09b_4_equation_of_state.png`
- `Revision/textbook/figures/09b_5_regime_map.png`
- `Revision/textbook/figures/09b_6_energy_exchange.png`
- `Revision/textbook/figures/09b_7_energy_sign.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the seven figures of this notebook are saved and captioned
ALL 33 CHECKS PASSED (notebook 09b)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/09b_condensates.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 09b_condensates.ipynb
python -m nbconvert --execute --inplace 09b_condensates.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not contain that check: your copy is older or newer than the notebook. Run `git pull` in the repository folder, then run the notebook again.

9.24 Notebook 09b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/09b_condensates.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A *condensate* is a configuration of the field that is the same at every place:
it depends on the time $x_4$ only. This notebook builds the exact condensates of
the commuting field dirac16complex00 with the potential
$U(S) = \frac{\lambda}{2}S^2$ in the author's metric and studies their
energy-momentum tensor. It

- shows that the number $S = \bar\Phi\Phi$ can have either sign (a histogram);
- builds the exact solution
  $\Phi(x_4) = (\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M)\chi$ of the Revision
  record, checks the field equation and that $S$ stays constant, for one
```

```
  condensate that oscillates and one that grows;
- computes from the solution the energy density $\rho$ and the pressure $p$ and
  checks the record's values $\rho = mS + U$ and $p = SU' - U$, the same in all
  seven directions, and the vanishing of the $x_4$-$x_0$ component;
- measures the equation of state $w = p/\rho$ of actual solutions and compares it
  with $w = \lambda S/(2m + \lambda S)$; finds where $w = -1$;
- maps where condensates oscillate and where they grow;
- shows with toy fluids (an ILLUSTRATION, not solutions of the field equations)
  how energy flows between 3-space and the extra times when $p_3 \neq p_t$, and
  that a condensate, with $p_3 = p_t$, exchanges none;
- shows that the energy of the commuting field has no lower bound;
- draws seven teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 09b (Homogeneous condensates: energy, pressure, equation of state and energy
exchange) is the file ‘Revision/textbook/notebooks/09b_condensates.ipynb‘ of the
repository Dirac_claude. It builds the exact homogeneous solutions (condensates) of the
commuting field dirac16complex00 with the potential U = (lambda/2) S^2 in the author's
metric from the Revision gamma matrices, checks that S stays constant and that the energy
density and pressure are rho = m S + U and p = S U' - U in every direction, measures the
equation of state w = p/rho of actual solutions against lambda S/m, maps where
condensates oscillate or grow, shows with assumed toy fluids how energy is exchanged
between 3-space and the extra times when the two pressures differ (and that a condensate
exchanges none), and shows that the energy of the commuting field has no lower bound, in
seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):
```

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09b_condensates.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09b_condensates.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 09b_condensates.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/09b.captions.json‘
- ‘Revision/textbook/figures/09b_1_sign_of_s.png‘
- ‘Revision/textbook/figures/09b_2_condensate_solutions.png‘
- ‘Revision/textbook/figures/09b_3_energy_and_pressure.png‘
- ‘Revision/textbook/figures/09b_4_equation_of_state.png‘
- ‘Revision/textbook/figures/09b_5_regime_map.png‘
- ‘Revision/textbook/figures/09b_6_energy_exchange.png‘
- ‘Revision/textbook/figures/09b_7_energy_sign.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the seven figures of this notebook are saved and captioned
ALL 33 CHECKS PASSED (notebook 09b)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/09b_condensates.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

  ```
  python -m jupyterlab 09b_condensates.ipynb
  python -m nbconvert --execute --inplace 09b_condensates.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not contain that check: your copy is older or newer than the notebook. Run `git pull` in the repository folder, then run the notebook again.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 09b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 09b (Homogeneous condensates: energy, pressure, equation of state and energy
# exchange) is the file Revision/textbook/notebooks/09b_condensates.ipynb of the
# repository Dirac_claude. It builds the exact homogeneous solutions (condensates) of the
# commuting field dirac16complex00 with the potential U = (lambda/2) S^2 in the author's
# metric from the Revision gamma matrices, checks that S stays constant and that the
# energy density and pressure are rho = m S + U and p = S U' - U in every direction,
# measures the equation of state w = p/rho of actual solutions against lambda S/m, maps
# where condensates oscillate or grow, shows with assumed toy fluids how energy is
# exchanged between 3-space and the extra times when the two pressures differ (and that a
# condensate exchanges none), and shows that the energy of the commuting field has no
# lower bound, in seven teaching plots. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
```

```
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
```

```
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 09b_condensates.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
```

```
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 09b_condensates.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 09b_condensates.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/09b.captions.json

#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the seven figures of this notebook are saved and captioned
#     ALL 33 CHECKS PASSED (notebook 09b)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
```

```
#   Revision/textbook/notebooks/09b_condensates.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 09b_condensates.ipynb
#     python -m nbconvert --execute --inplace 09b_condensates.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "KeyError" with the words "has no check": the notebook asks a Revision report for the
#   verdict of one of its checks, and the report in your copy of the repository does not
#   contain that check: your copy is older or newer than the notebook. Run git pull in
#   the repository folder, then run the notebook again.
#

```
## 3. The words used in this notebook
```

- **Condensate (homogeneous configuration)**: a field that depends only on the time x_4, not on $x_1, x_2, x_3, x_5, x_6, x_7, x_0$.
- **Effective mass** $V = m + U'(S) = m + \lambda S$: the number that multiplies Φ on the right side of the field equation.
- **Matrix exponential**: for a square matrix M the matrix $e^{Mx_4} = 1 + Mx_4 + \frac{1}{2}M^2x_4^2 + \dots$; the column $e^{Mx_4}\chi$ solves $\frac{d}{dx_4}\Phi = M\Phi$ with $\Phi(0) = \chi$. When $M^2 = k^2$ times the unit matrix, the series sums to $\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M$.
- **Oscillating / growing**: when $k^2 < 0$ the number k is imaginary, $\cosh(kx_4)$ becomes a cosine and the solution oscillates; when $k^2 > 0$ it contains e^{kx_4} and grows.
- **Energy density** ρ, **pressure** p, **equation of state** $w = p/\rho$. Dust has $w = 0$, radiation $w = 1/3$, a cosmological constant $w = -1$; a value $w < -1$ is called *phantom*.
- **Energy exchange**: the change of the energy density in time caused by work done by the inflating 3-space and the deflating extra times.
- **Toy fluid (ILLUSTRATION)**: a source with assumed pressures $p_3 = w_3\rho$ and $p_t = w_t\rho$, used only to show what the conservation identity does; it is not a solution of the field equations of this book.
- **Runge-Kutta method (RK4)**: a step-by-step method that solves a differential equation numerically with four slope evaluations per step.
- **Histogram**: a bar chart that counts how many numbers fall into each of a row of equal intervals.
- **Krein (indefinite) form**: the form $\Phi^\dagger B\Phi$ built with the matrix B, which has eight eigenvalues $+1$ and eight eigenvalues -1; it can be positive or negative.

Text cell:

```
## 4. The physical and mathematical situation

**The field equation of a condensate.** In the author's metric the field
equation of dirac16complex00 is
$\sum_a\frac{1}{f_a}\gamma^{(a)}\partial_a\Phi + 3H\gamma^{(0)}\Phi = V\Phi$ with
$V = m + \lambda S$. For a condensate every derivative except $\partial_4$ is
zero, and $f_4 = 1$, so the equation is
$\gamma^{(4)}\partial_4\Phi + 3H\gamma^{(0)}\Phi = V\Phi$. Multiplying by
$-\gamma^{(4)}$ and using $(\gamma^{(4)})^2 = -1$ gives
$\partial_4\Phi = M\Phi$ with $M = -V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}$.
Neither $a_4$ nor $x_0$ appears: the same condensate solves the equation on
every history $a_4(x_4)$, the deflating one included.

**The exact solution** (Revision record, `Revision/theory/field-theory.json`,
formula `exact_solutions`): $M^2 = k^2$ with $k^2 = 9H^2 - V^2$, and
$M^TC + CM = 0$, so $S = \Phi^\dagger C\Phi$ does not change with $x_4$; then $V$
is a constant and $\Phi = (\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M)\chi$
with $S = S_0 = \chi^\dagger C\chi$.

**Its energy-momentum tensor** (formula `EMT_homogeneous_on_shell`): only $K_4$
is nonzero, $K_4 = VS$ on shell, so $\rho = mS + U$ and
$p_3 = p_t = p_0 = SU' - U$; for $U = \frac{\lambda}{2}S^2$:
$\rho = mS + \frac{\lambda}{2}S^2$, $p = \frac{\lambda}{2}S^2$ and
```

```
$w = \lambda S/(2m + \lambda S)$.

**Energy exchange** (formula `energy_exchange`): conservation gives
$d\rho/dx_4 = -3a_4'(p_3 - p_t)$. A condensate has $p_3 = p_t$, so its energy
density is constant along every history.

**What is not computed here.** The equation of state that an observer living in
3-space would infer (after integrating over the hidden direction and the extra
times), its time dependence and its comparison with supernova fit values are not
computed in this notebook. The Revision record computes them in
`Revision/dark_sector/` under an ASSUMED normalisation of the observer's energy
density (definitions A, B and C; `Revision/docs/DARK_SECTOR_HYPOTHESES.md`,
taught in Chapter 22); which normalisation, if any, describes a physical
observer, and a fit to supernova data, are OPEN. The $w$ of this notebook is the
ratio $p/\rho$ of the 8-dimensional tensor. The condensate's off-diagonal entries,
which are not zero in general, are not used here.
```

Text cell:

```
## 5. The matrices C and B, and the sign of S

The next cell reads the Revision fixture (the gammas $\gamma^{(x_0)}, \dots,
\gamma^{(x_7)}$, the matrix $C$ and the matrix $B = -iC\gamma^{(4)}$) and defines
the helper `recorded(path, name)`, which returns the verdict of a check in a
Revision report. The record says that $C = \mathrm{diag}(-\sigma, \sigma)$ with
an $8 \times 8$ matrix $\sigma$ that squares to 1 and has trace 0; so $C$ has
eight eigenvalues $+1$ and eight $-1$, and $S_0 = \chi^\dagger C\chi$ can be
positive or negative. The cell computes the eigenvalues of $C$ and the values of
$S_0$ for 20000 random columns $\chi$ of length 1.
```

In [2]:

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]  # x0, ..., x7
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
B = (np.array(fixture["B"]["re"], dtype=float)  # B = -i C gamma^(x4), stored as its
     + 1j * np.array(fixture["B"]["im"], dtype=float))  # real and imaginary parts
I16 = np.eye(16)  # the 16 x 16 unit matrix
g4, g0 = gamma[4], gamma[0]  # gamma^(x4) and gamma^(x0)

    solution_matrix_square
```

Text cell:

```
## 7. Two exact condensates: one oscillates, one grows

The next cell fixes $m = 1$ and $H = 0.25$ and a column $\chi$ with
$S_0 = \chi^\dagger C\chi = 1$ (it draws random columns with a fixed seed until
$S_0 > 0$ and divides by $\sqrt{S_0}$). With $\lambda = 0.5$ the effective mass is
$V = 1.5 > 3H = 0.75$, so $k^2 = 9H^2 - V^2 < 0$: the condensate oscillates.
```

```
With $\lambda = -0.5$ it is $V = 0.5 < 0.75$, so $k^2 > 0$: the condensate grows.
The cell also defines the function ‘condensate(x4, chi, M, k2)‘, which returns
$\Phi(x_4)$ and its derivative
$\Phi'(x_4) = k\sinh(kx_4)\chi + \cosh(kx_4)M\chi$; numpy computes $\cosh$ and
$\sinh$ of the imaginary $k$ correctly when $k$ is stored as a complex number.
It prints the value of $S_0$ after the division, which must be 1.
```

In [5]:

```
m, H = 1.0, 0.25  # the mass and the author's constant
rng = np.random.default_rng(7)
while True:  # draw until S0 > 0 (the first draw usually succeeds)
    chi = rng.normal(size=16) + 1j * rng.normal(size=16)
    S0 = (chi.conj() @ C @ chi).real
    if S0 > 0:
        break
chi = chi / np.sqrt(S0)  # now chi^dagger C chi = 1

def condensate(x4, chi_value, M, k2):

## 8. Energy density, pressures, kinetic and potential parts of the condensates

For a condensate every kinetic term except $K_4$ vanishes, because every other
derivative is zero. The next cell computes, at every tested time,
$K_4 = \frac12(\bar\Phi\gamma^{(4)}\Phi' - \bar\Phi'\gamma^{(4)}\Phi)$ from the
solution, the Lagrangian $L_0 = K_4 - mS - U$, the energy density
$\rho = -T^{x_4}{}_{x_4} = K_4 - L_0$ and the pressures
$p_\mu = T^\mu{}_\mu = L_0 - K_\mu = L_0$ for $\mu \neq x_4$, which are equal in
all seven directions. It checks $K_4 = VS$, $\rho = mS + \frac{\lambda}{2}S^2$ and
$p = \frac{\lambda}{2}S^2$, hence the kinetic and potential parts
($\rho_{\rm kin} = 0$, $p_{\rm kin} = K_4 = VS$, $p_{\rm pot} = -(mS + U)$), the trace
$-\rho + 7p = -mS + 3\lambda S^2$, and that the $x_4$-$x_0$ component vanishes:
$T^{x_4}{}_{x_0} = -\frac14(B_{40} - \cot z B_{04})$ with
$B_{40} = 0$ (no $x_0$ derivative) and
$B_{04} = \bar\Phi\gamma^{(0)}\Phi' - \bar\Phi'\gamma^{(0)}\Phi$, which must be 0.
```

## 10. The equation of state of actual solutions

The ratio $w = p/\rho$ depends on $m$, $\lambda$ and $S$ only through
$x = \lambda S/m$: $w = \frac{\lambda S^2/2}{mS + \lambda S^2/2} = \frac{x}{2 + x}$.
The next cell does not use this formula to compute $w$. For twelve values of $x$
it builds the exact condensate with $m = 1$, $S_0 = 1$ and $\lambda = x$, takes
$\Phi$ and $\Phi'$ at the time $x_4 = 1.3$, computes $\rho$ and $p$ from them as
in section 8, and only then compares $p/\rho$ with $x/(2 + x)$. It also finds the
special values: $w = 0$ at $x = 0$ (dust-like), $w = -1$ at $x = -1$, where the
effective mass $V = m + \lambda S$ is zero, $w < -1$ (phantom) for
$-2 < x < -1$, and $w \to 1$ as $x$ grows. At $x = -2$ the energy density is zero
and $w$ is not defined. For $x < -2$ (with $m > 0$ and $S > 0$) the energy
density and the pressure are both negative, and $w > 1$.
```

In [10]:

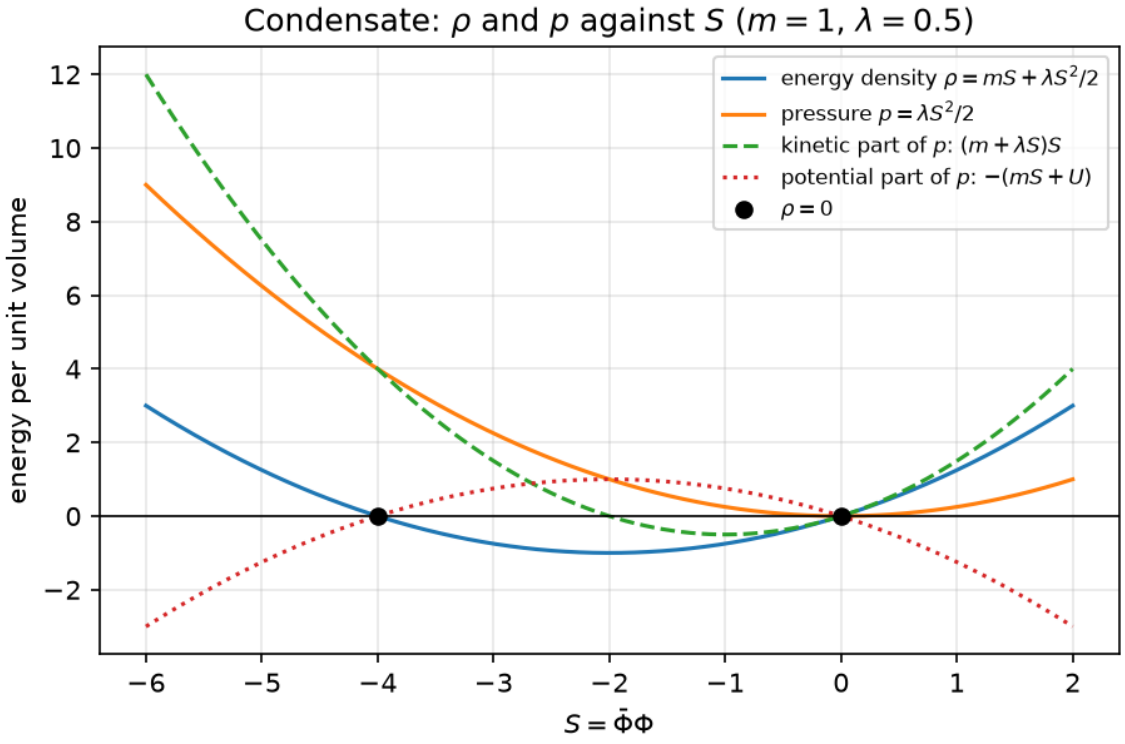

Figure 257: Energy density $\rho = mS + \lambda S^2/2$ (solid), pressure $p = \lambda S^2/2$ (solid) and the two parts of the pressure, the kinetic part $(m + \lambda S)S$ (dashed) and the potential part $-(mS + U)$ (dotted), of a condensate of dirac16complex00 with $m = 1$, $\lambda = 0.5$, against S from -6 to 2; vertical axis in units of energy per unit volume. The energy density vanishes at $S = 0$ and $S = -2m/\lambda = -4$ (black dots) and is negative between them; the pressure is the same in all seven directions. (Notebook 09b, figure 3.)

## 11. Where condensates oscillate and where they grow

A condensate oscillates when $k^2 = 9H^2 - V^2 < 0$, that is when
$|1 + x| > 3H/|m|$ with $x = \lambda S/m$, and grows when $|1 + x| < 3H/|m|$
(because $V = m(1 + x)$). The equation of state depends on $x$ alone, so on the
map of the plane $(x, 3H/|m|)$ every line of constant $w$ is vertical. The next
cell draws the map, the lines $w = -1$, $0$, $1/3$ and the two condensates of
section 7, and checks that each of them lies in the region the map gives.
```

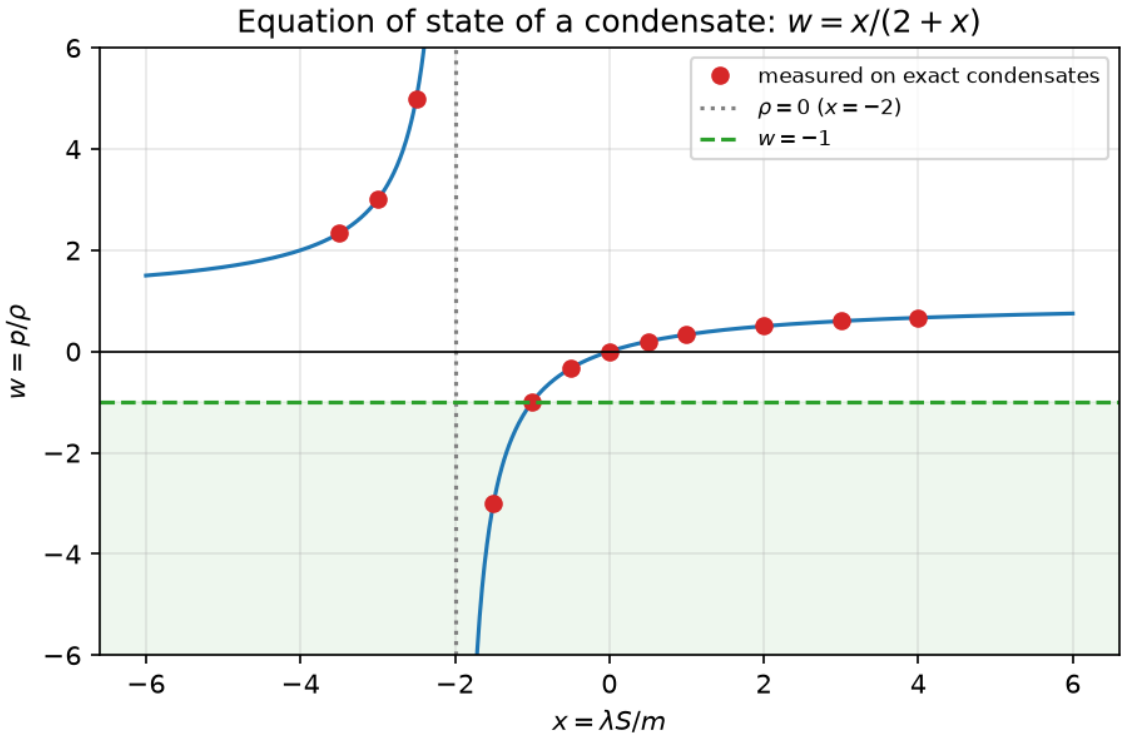

Figure 258: Equation of state $w = p/\rho$ of a condensate of dirac16complex00 against $x = \lambda S/m$ (pure numbers): the curve is $w = x/(2+x)$, the red points are p/ρ computed from twelve exact solutions ($m = 1$, $H = 0.25$, $S_0 = 1$, $\lambda = x$) and lie on it. $w = 0$ at $x = 0$, $w = -1$ (dashed) at $x = -1$, where the effective mass $m + \lambda S$ vanishes, $w < -1$ (shaded) for $-2 < x < -1$, w is undefined at $x = -2$ (dotted) where $\rho = 0$, $w > 1$ for $x < -2$, where ρ and p are both negative, and w approaches 1 for large x. This is the 8-dimensional ratio, not the equation of state a 3-space observer would infer. (Notebook 09b, figure 4.)

## 12. Energy exchange between 3-space and the extra times

Conservation says $d\rho/dx_4 = -3a_4'(p_3 - p_t)$. A condensate has $p_3 = p_t$,
so along every history its energy density stays constant; the next cell confirms
this on the oscillating condensate along the deflating history $a_4 = AHx_4$
($A = 1$): the solution does not depend on $a_4$, and $\rho$ is the same at all
401 times.
```

In [13]:

```
A = 1.0  # the deflating history a4 = A H x4
M, k2 = condensate_matrix(m + 0.5 * 1.0, H)  # the oscillating condensate, S0 = 1
# rho at every time; homogeneous_tensor returns (S, U, K4, rho, p, B04): index 3.
# The condensate does not contain a4, so these are its values on this history too.
rho_at_times = np.array([homogeneous_tensor(*condensate(x4, chi, M, k2), 0.5)[3]
                         for x4 in times])
check(np.abs(rho_at_times - rho_at_times[0]).max() < 1e-9,
      "the condensate has p3 = p_t, so its rho is constant along the history")
```

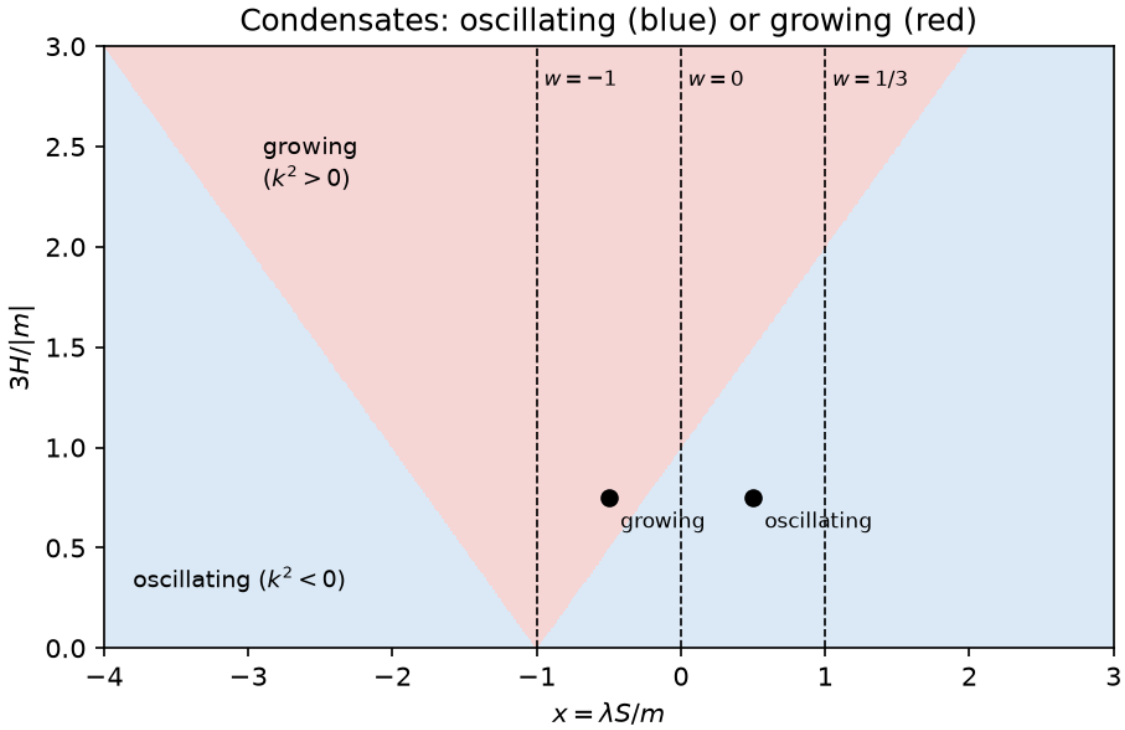

Figure 259: Map of the condensates of dirac16complex00 in the plane of $x = \lambda S/m$ (horizontal) and $3H/|m|$ (vertical), pure numbers. In the red wedge $|1+x| < 3H/|m|$ the number $k^2 = 9H^2-(m+\lambda S)^2$ is positive and the condensate grows; in the blue region it oscillates. The dashed vertical lines are the equations of state $w = -1$ ($x = -1$), $w = 0$ and $w = 1/3$ ($x = 1$); w depends on x only. The black dots are the two condensates of the second figure ($H = 0.25$, $m = 1$). Every condensate with $w = -1$ lies in the growing wedge. (Notebook 09b, figure 5.)

Out [13]:

```
PASS the condensate has p3 = p_t, so its rho is constant along the history
```

Text cell:

```
Then, as an ILLUSTRATION only, the next cell takes toy fluids with assumed
pressures $p_3 = w_3\rho$ and $p_t = w_t\rho$ (constant $w_3$, $w_t$; these are
not solutions of the field equations of this book). The identity becomes
$d\rho/dx_4 = -3AH(w_3 - w_t)\rho$, whose solution is
$\rho = \rho_0 e^{-3AH(w_3 - w_t)x_4}$. The cell solves it numerically with the
Runge-Kutta method (RK4, step $0.05$) for five values of $\Delta w = w_3 - w_t$,
compares with the exact solution (and checks that halving the step divides the
error by about $2^4 = 16$, as it must for a fourth-order method), and checks that
reversing the history ($A \to -A$: the extra times inflate, 3-space deflates)
reverses the flow.

## 13. The energy of the commuting field has no lower bound

The record proves that the classical energy of dirac16complex00 is unbounded
below already for $U = 0$, with an exact example: in flat 4+4 space (all
$f_a = 1$, no spin connection) with $m = 2$ and the momentum
$(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$, the plane waves
$\Phi = u e^{i(k_1x_1 + k_2x_2 + k_0x_0 - Ex_4)}$ with $E = 5$ solve the field
equation when $u$ lies in the 8-dimensional eigenspace of the matrix
$h = m\beta + \sum_a k_a\alpha^a$ ($\beta = -i\gamma^{(4)}$,
$\alpha^a = -\gamma^{(4)}\gamma^{(a)}$) with eigenvalue 5, and the energy density
is $\rho = E u^\dagger Bu$. On that eigenspace the form $u^\dagger Bu$ has four
positive and four negative directions (Krein inertia (4,4)). The next cell
builds $h$, checks that it is Hermitian, that $h^2 = 25$ and that it commutes
with $B$, finds its eigenvalues and the eigenspace with eigenvalue 5, and the
inertia of the form $u^\dagger Bu$ on that eigenspace (the eigenvalues of the
$8 \times 8$ matrix of the form).
```

PASS the seven figures of this notebook are saved and captioned
ALL 33 CHECKS PASSED (notebook 09b)
```

Text cell:

```
## 15. What this notebook showed

- The exact condensates of dirac16complex00,
  $\Phi = (\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M)\chi$ with
  $k^2 = 9H^2 - (m + \lambda S_0)^2$, solve the field equation on every history
  $a_4$; $S$ stays equal to $S_0$, whether the condensate oscillates
  ($k^2 < 0$) or grows ($k^2 > 0$).
- Their energy density and pressure are $\rho = mS + \frac{\lambda}{2}S^2$ and
  $p = \frac{\lambda}{2}S^2$, the same in all seven directions; the kinetic
  energy density is zero, the kinetic pressure is $(m + \lambda S)S$; the
  $x_4$-$x_0$ component vanishes (record values, computed here anew from the
  solutions).
- The equation of state is $w = x/(2 + x)$ with $x = \lambda S/m$, measured on
  twelve exact solutions; $w = -1$ exactly where the effective mass vanishes, and
  such condensates always grow. These $w$ are constant in time and are
  8-dimensional ratios; what a 3-space observer would infer rests on an ASSUMED
  normalisation of its energy density (Chapter 22).
- Because $p_3 = p_t$, a condensate exchanges no energy between 3-space and the
  extra times; toy fluids with $p_3 \neq p_t$ (an illustration) show the exchange
  $d\rho/dx_4 = -3a_4'(p_3 - p_t)$ and its reversal under $A \to -A$.
- $S$ and the energy density of the commuting field have no sign: half of all
  random condensates with $\lambda = 0$ have $\rho < 0$, and positive-frequency
  plane waves have $\rho$ anywhere between $-E$ and $E$ (record:
  `commuting_field_energy_unbounded_below`).
- Status: the exact condensates, their $\rho$ and $p$, the vanishing $x_4$-$x_0$
  component, the energy-exchange identity and the unbounded energy are PROVED in
  the Revision record (exact, Wolfram and sympy); this notebook re-computes them
  numerically (COMPUTED). The toy fluids are an ILLUSTRATION, not solutions. The
  equation of state of a 3-space observer is not computed here; the Revision
  record computes it under the ASSUMED definitions A, B and C (Chapter 22), and
  which definition describes a physical observer is OPEN. The parameter values
  are choices of this notebook.
```

9.25 Line-by-line walk-through of Notebook 09b

The notebook has 20 code cells, In [1] to In [20]. As in Section 9.17, long figure captions are shortened to a line "...)" and docstrings are left out here; the captions are printed in full in Section 9.24.

In [1], the set-up cell. It is word for word the set-up cell of Notebook 09a, explained line by line in Section 9.17, with two differences: its comment lines are the run instructions of Notebook 09b (Section 9.23), and its line `NOTEBOOK_ID = "09b"` names this notebook, so the figures are saved as `09b_<k>_<name>.png` and their captions in `09b.captions.json`. It prints `Set-up of notebook 09b complete:  repository folder found, helpers defined.`

In [2], the matrices C and B, and the sign of S.

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]  # x0, ..., x7
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
B = (np.array(fixture["B"]["re"], dtype=float)  # B = -i C gamma^(x4), stored as its
     + 1j * np.array(fixture["B"]["im"], dtype=float))  # real and imaginary parts
I16 = np.eye(16)  # the 16 x 16 unit matrix
g4, g0 = gamma[4], gamma[0]  # gamma^(x4) and gamma^(x0)
```

As in Notebook 09a, the fixture gives the eight real gammas (`gamma[0]` is $\gamma^{(0)}$, ..., `gamma[7]` is $\gamma^{(7)}$) and C. The matrix $B = -iC\gamma^{(4)}$ is complex; JSON has no complex numbers, so the fixture stores its real part and its imaginary part separately, and the cell adds them as `re + 1j * im`. The last line gives $\gamma^{(4)}$ and $\gamma^{(0)}$ the short names `g4` and `g8` (two names assigned at once from two values).

```
def recorded(path, name):
    """The verdict (PASS or FAIL) of the check name in the Revision report path."""
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for item in report_data["checks"]:
        if item["name"] == name:
            return item["verdict"].upper()  # some reports write "pass"
    raise KeyError(f"{path} has no check {name}")
```

The same helper as in Notebook 09a: the verdict of one check of a Revision report.

```
ALGEBRA_PY = "Revision/algebra/reports/python-algebra.json"
ALGEBRA_WL = "Revision/algebra/reports/wolfram-algebra.json"
eigenvalues_C = np.linalg.eigvalsh(C)  # C is symmetric: eigvalsh, sorted ascending
check(np.allclose(eigenvalues_C, [-1.0] * 8 + [1.0] * 8, atol=1e-12)
      and recorded(ALGEBRA_PY, "C_equals_notebook_sigma16") == "PASS"
      and recorded(ALGEBRA_WL, "sigma8_involution") == "PASS",
      "C has eight eigenvalues -1 and eight eigenvalues +1",
      record=f"{ALGEBRA_PY}, check C_equals_notebook_sigma16; {ALGEBRA_WL}, check "
             "sigma8_involution")
```

An **eigenvalue** of a matrix M is a number μ for which $Mv = \mu v$ has a solution column $v \neq 0$ (an **eigenvector**). `np.linalg.eigvalsh` computes the eigenvalues of a symmetric (or Hermitian) matrix and returns them sorted from the smallest to the largest. The check compares them with eight -1 followed by eight $+1$ (the list `[-1.0] * 8 + [1.0] * 8`), with an absolute tolerance of 10^{-12}: the fact of Section 9.21.

```
rng = np.random.default_rng(2026)  # a fixed seed: the same numbers in every run
chis = rng.normal(size=(20000, 16)) + 1j * rng.normal(size=(20000, 16))
chis /= np.linalg.norm(chis, axis=1)[:, None]  # every row now has length 1
# S0 = chi^dagger C chi for every row at once (einsum sums over the indices i, j).
S0_values = np.einsum("ni,ij,nj->n", chis.conj(), C, chis).real
negative_share = float(np.mean(S0_values < 0))  # the fraction of negative S0
check(S0_values.min() < 0 < S0_values.max() and np.abs(S0_values).max() <= 1 + 1e-12,
      "S0 = chi^dagger C chi takes both signs and lies between -1 and 1")
report("fraction of the 20000 random chi with S0 < 0", f"{negative_share:.4f}")
```

`chis` is a table of 20000 random complex columns χ, one per row. `np.linalg.norm(chis, axis=1)` computes the length of each row, and `/=` divides each row by its length (the `[:, None]` makes the 20000 lengths a column so that each row is divided by its own length): every χ now has length 1. `np.einsum("ni,ij,nj->n", ...)` is Einstein's summation written as a recipe: for every row n it computes $\sum_{i,j} \chi^*_{ni} C_{ij} \chi_{nj} = \chi_n^\dagger C \chi_n$, all 20000 values of S_0 at once. `S0_values < 0` is an array of `True` and `False`, and its mean (`np.mean`, with `True` counted as 1) is the fraction of negative values. The check requires values of both signs (`a < 0 < b` means $a < 0$ and $0 < b$) and all values between -1 and 1, as they must be for a unit column and eigenvalues ± 1. It prints the fraction 0.4983: about half.

In [3], the histogram of S_0 (Figure 09b.1).

```
fig, ax = plt.subplots()
ax.hist(S0_values, bins=60, range=(-1.0, 1.0), color="tab:blue", edgecolor="white")
ax.axvline(0.0, color="black", linewidth=1.0)
ax.set_xlabel("$S_0 = \\chi^\\dagger C \\chi$ for a random $\\chi$ of length 1")
ax.set_ylabel("number of the 20000 random $\\chi$")
ax.set_title("The scalar $S = \\bar\\Phi\\Phi$ has no sign")
save_figure(fig, "sign_of_s",
            "Histogram of $S_0 = \\chi^\\dagger C\\chi$ for 20000 random complex "
            ...)
```

A **histogram** is a bar chart that counts how many numbers fall into each of a row of equal intervals: `ax.hist` uses 60 intervals between -1 and 1. `ax.axvline(0.0, ...)` draws a vertical line at zero. **What Figure 09b.1 shows.** The number of random unit columns (vertical axis) whose S_0 falls into each interval (horizontal axis, a pure number between -1 and 1). The histogram is symmetric about zero, roughly a hill: about half of the values are negative. The student should see that S has no sign; for a condensate with $\lambda = 0$, $\rho = mS_0$ has the sign of S_0.

In [4], the matrix M and its square.

```
def condensate_matrix(V, H):
    """M = -V gamma^(x4) + 3 H gamma^(x4) gamma^(x0) and k^2 = 9 H^2 - V^2."""
    return -V * g4 + 3 * H * g4 @ g0, 9 * H ** 2 - V ** 2
```

The function returns two results, the matrix M of Section 9.18 and the number $k^2 = 9H^2 - V^2$.

```
THEORY_WL = "Revision/theory/reports/wolfram-field-theory.json"
THEORY_PY = "Revision/theory/reports/python-field-theory.json"
worst_square, worst_c = 0.0, 0.0  # the largest deviations found
for V_test in (-2.0, -0.5, 0.0, 0.75, 1.5, 3.0):
    for H_test in (0.1, 0.25, 1.0):
        M_test, k2_test = condensate_matrix(V_test, H_test)
        worst_square = max(worst_square, np.abs(M_test @ M_test - k2_test * I16).max())
        worst_c = max(worst_c, np.abs(M_test.T @ C + C @ M_test).max())
check(worst_square < 1e-12 and worst_c < 1e-12
      and recorded(THEORY_WL, "solution_matrix_square") == "PASS",
      "M^2 = (9 H^2 - V^2) times 1 and M^T C + C M = 0 for 18 pairs (V, H)",
      record=f"{THEORY_WL}, check solution_matrix_square")
```

For six values of V and three of H (18 pairs) the loops compute the largest entry of $M^2 - k^2 \cdot 1$ and of $M^T C + CM$, and keep the largest over all pairs. The check confirms the two facts derived in Section 9.18 up to rounding.

In [5], one column χ with $S_0 = 1$, and the solution formula.

```
m, H = 1.0, 0.25  # the mass and the author's constant
rng = np.random.default_rng(7)
while True:  # draw until S0 > 0 (the first draw usually succeeds)
    chi = rng.normal(size=16) + 1j * rng.normal(size=16)
    S0 = (chi.conj() @ C @ chi).real
    if S0 > 0:
        break
chi = chi / np.sqrt(S0)  # now chi^dagger C chi = 1
```

The cell fixes $m = 1$ and $H = 0.25$, starts a new random generator with the seed 7, and repeats (`while True:` loops until `break`) drawing a random column until its S_0 is positive. Dividing χ by $\sqrt{S_0}$ divides $S_0 = \chi^\dagger C \chi$ by S_0, so afterwards $S_0 = 1$.

```
def condensate(x4, chi_value, M, k2):
    """Phi(x4) and dPhi/dx4 of the exact condensate with Phi(0) = chi_value."""
    if k2 == 0.0:  # cosh(k x4) -> 1 and sinh(k x4)/k -> x4 when k -> 0
        return chi_value + x4 * M @ chi_value, M @ chi_value
    k = np.sqrt(complex(k2))  # k is imaginary when k2 < 0
    phi = np.cosh(k * x4) * chi_value + np.sinh(k * x4) / k * (M @ chi_value)
    dphi = k * np.sinh(k * x4) * chi_value + np.cosh(k * x4) * (M @ chi_value)
    return phi, dphi
```

`condensate` returns $\Phi(x_4) = (\cosh(kx_4) + \frac{\sinh(kx_4)}{k} M)\chi$ and its derivative $\Phi'(x_4) = k \sinh(kx_4)\chi + \cosh(kx_4) M\chi$ (Section 9.18). The special case $k^2 = 0$ uses the limit $\Phi = \chi + x_4 M\chi$. `complex(k2)` turns k^2 into a complex number, so that `np.sqrt` returns an imaginary k when $k^2 < 0$ (for a real negative number it would fail); numpy computes cosh and sinh of complex arguments correctly.

```
S0_now = (chi.conj() @ C @ chi).real  # 1 up to rounding
report("S0 = chi^dagger C chi after the division", f"{S0_now:.6f}")
```

The cell prints `1.000000`.

In [6], two exact condensates and the field equation at 401 times.

```
times = np.linspace(0.0, 12.0, 401)  # the times x4 at which the solution is tested
EXAMPLES = {"oscillating": 0.5, "growing": -0.5}  # name -> lambda
solutions = {}  # name -> (Phi at every time, S at every time)
for name, lam in EXAMPLES.items():
    V = m + lam * 1.0  # S0 = 1
    M, k2 = condensate_matrix(V, H)
    phis, S_values, worst_residual = [], [], 0.0
```

The two examples are stored in a dictionary from their names to their λ; `.items()` gives the pairs. For each, $V = m + \lambda S_0$ with $S_0 = 1$, and M, k^2 follow. Three empty containers collect the values of Φ, the values of S and the largest residual.

```
    for x4 in times:
        phi, dphi = condensate(x4, chi, M, k2)
        S_now = (phi.conj() @ C @ phi).real
        residual = g4 @ dphi + 3 * H * g0 @ phi - (m + lam * S_now) * phi
        # The residual relative to the size of the solution at this time.  Rounding
        # errors grow with the solution (S is a difference of large numbers when
        # Phi grows), so the tolerance below is 1e-9, not 1e-15.
        worst_residual = max(worst_residual,
                             np.abs(residual).max() / max(1.0, np.abs(phi).max()))
        phis.append(phi)
        S_values.append(S_now)
    solutions[name] = (np.array(phis), np.array(S_values))
```

At each of the 401 times the inner loop evaluates the solution, its S, and the **residual** of the field equation $\gamma^{(4)}\Phi' + 3H\gamma^{(0)}\Phi - (m + \lambda S)\Phi$, which must vanish; note that it uses S computed at that time, so the test also covers the nonlinearity. The residual is divided by the size of the solution (at least 1), because rounding errors grow with a growing solution. The values are appended (`.append`) to the lists and finally stored in `solutions`.

```
    report(f"{name}: lambda = {lam}, V = m + lambda S0", f"{V:.4f}")
    report(f"{name}: k^2 = 9 H^2 - V^2", f"{k2:.4f}")
    check(worst_residual < 1e-9,
          f"{name}: the field equation holds at 401 times")
    check(np.abs(np.array(S_values) - 1.0).max() < 1e-9,
          f"{name}: S stays equal to S0 = 1 at 401 times")
check(recorded(THEORY_WL, "exact_solution_nonlinear_homogeneous_C") == "PASS"
      and recorded(THEORY_PY, "exact_nonlinear_homogeneous_solution") == "PASS",
      "both condensates are the record's exact nonlinear homogeneous solution",
      record=f"{THEORY_WL}, check exact_solution_nonlinear_homogeneous_C; "
             f"{THEORY_PY}, check exact_nonlinear_homogeneous_solution")
```

For each example the cell prints V and k^2 (oscillating: $V = 1.5$, $k^2 = -1.6875$; growing: $V = 0.5$, $k^2 = 0.3125$, the numbers of Section 9.20) and checks the field equation and the constancy of S at

all 401 times; after the loop, one more check confirms that the record proved these solutions exactly. Five PASS lines in all.

In [7], the two condensates (Figure 09b.2).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9))
phis, S_values = solutions["oscillating"]
for component in (0, 5, 10):  # three of the 16 components (rows 1, 6 and 11)
    left.plot(times, phis[:, component].real,
              label=f"Re $\\Phi_{{{component + 1}}}$")
left.plot(times, S_values, "k--", label="$S = \\bar\\Phi\\Phi$")
left.set_xlabel("time $x_4$")
left.set_ylabel("value")
left.set_ylim(-0.8, 1.35)  # room for the legend above the curves
left.set_title("Oscillating: $\\lambda = 0.5$, $V = 1.5$")
left.legend(fontsize=7, loc="upper center", ncol=4)
```

The left panel draws the real parts (`.real`) of the components 1, 6 and 11 of the oscillating condensate against the time, and S as a black dashed line (the style string is the letter `k`, which means black, followed by two hyphens). In the f-string, a doubled brace prints a single brace, so the label of component 1 reads Re Φ_1. The legend is placed at the top in four columns.

```
phis, S_values = solutions["growing"]
right.plot(times, np.einsum("ti,ti->t", phis.conj(), phis).real,
           label="$\\Phi^\\dagger\\Phi$")
right.plot(times, S_values, "k--", label="$S = \\bar\\Phi\\Phi$")
right.set_yscale("log")
right.set_xlabel("time $x_4$")
right.set_title("Growing: $\\lambda = -0.5$, $V = 0.5$")
right.legend(fontsize=8)
save_figure(fig, "condensate_solutions",
            "Two exact condensates of dirac16complex00 with $m = 1$, $H = 0.25$ and "
            ...)
```

The right panel draws, for the growing condensate, the size $\Phi^\dagger\Phi = \sum_i |\Phi_i|^2$ at every time (the recipe `"ti,ti->t"` sums over the components `i` for each time `t`) and S, on a logarithmic axis. **What Figure 09b.2 shows.** Left: three components oscillate with the period $2\pi/\omega = 4.84$ while S stays at 1. Right: $\Phi^\dagger\Phi$ rises, soon along a straight line on the logarithmic axis, like e^{2kx_4} with $k = 0.559$, by more than a factor 100000, while S stays exactly 1. The student should see that a constant S does not mean a constant field: the indefinite form $\Phi^\dagger C\Phi$ can stay fixed while the field grows.

In [8], the energy density and pressure of the condensates.

```
def homogeneous_tensor(phi, dphi, lam):
    """K4, rho, p and B04 of a condensate at one time."""
    S = (phi.conj() @ C @ phi).real
    U = lam / 2 * S ** 2
    K4 = 0.5 * (phi.conj() @ C @ g4 @ dphi - dphi.conj() @ C @ g4 @ phi)
    L0 = K4.real - m * S - U  # the other seven kinetic terms are zero
    B04 = phi.conj() @ C @ g0 @ dphi - dphi.conj() @ C @ g0 @ phi
    return S, U, K4, K4.real - L0, L0, B04  # rho = K4 - L0, p = L0
```

The function computes from Φ and Φ' at one time: S, U, the kinetic term $K_4 = \frac{1}{2}(\bar{\Phi}\gamma^{(4)}\Phi' - \bar{\Phi}'\gamma^{(4)}\Phi)$ (with $f_4 = 1$; `phi.conj() @ C` is $\bar{\Phi}$), $L_0 = K_4 - mS - U$ (the other seven kinetic terms vanish), and $B_{04} = \bar{\Phi}\gamma^{(0)}\Phi' - \bar{\Phi}'\gamma^{(0)}\Phi$. It returns six values; the fourth is $\rho = -T^{x_4}{}_{x_4} = -(L_0 - K_4) = K_4 - L_0$ and the fifth is $p = T^{\mu}{}_{\mu} = L_0 - K_\mu = L_0$ for every $\mu \neq x_4$.

```
values = {}  # name -> (rho, p) of the condensate
for name, lam in EXAMPLES.items():
    V = m + lam * 1.0
    M, k2 = condensate_matrix(V, H)
    rhos, ps, worst = [], [], 0.0
    for x4 in times:
        phi, dphi = condensate(x4, chi, M, k2)
        S, U, K4, rho, p, B04 = homogeneous_tensor(phi, dphi, lam)
        size = max(1.0, (phi.conj() @ phi).real)  # for relative tolerances
        worst = max(worst, abs(K4.imag) / size, abs(K4.real - V * S) / size,
                    abs(B04) / size)
        rhos.append(rho)
        ps.append(p)
    rhos, ps = np.array(rhos), np.array(ps)
    values[name] = (rhos.mean(), ps.mean())
```

For both condensates and all 401 times the loop evaluates the tensor and keeps the largest of three numbers that must vanish: the imaginary part of K_4, the difference $K_4 - VS$, and B_{04}, each relative to the size $\Phi^\dagger\Phi$ (at least 1). The energy densities and pressures are collected, and their means are stored.

```
    check(worst < 1e-12, f"{name}: K4 is real, K4 = V S, and B04 = 0 (T^x4_x0 = 0)")
    check(np.abs(rhos - (m + lam / 2)).max() < 1e-9
          and np.abs(ps - lam / 2).max() < 1e-9,
          f"{name}: rho = m S + lambda S^2/2 and p = lambda S^2/2 at 401 times")
    check(abs(-values[name][0] + 7 * values[name][1] - (-m + 3 * lam)) < 1e-9,
          f"{name}: trace -rho + 7 p = -m S + 3 lambda S^2")
    report(f"{name}: rho", f"{values[name][0]:.6f}")
    report(f"{name}: p (all seven directions)", f"{values[name][1]:.6f}")
    report(f"{name}: w = p/rho", f"{values[name][1] / values[name][0]:.6f}")
```

Three checks per condensate: K_4 is real and equals VS and $B_{04} = 0$ (so $T^{x_4}{}_{x_0} = 0$, Section 9.19); $\rho = m + \lambda/2$ and $p = \lambda/2$ at all 401 times (the values $mS + \frac{\lambda}{2}S^2$ and $\frac{\lambda}{2}S^2$ with $S = 1$); and the trace $-\rho + 7p = -mS + 3\lambda S^2$. The printed values are: oscillating, $\rho = 1.25$, $p = 0.25$, $w = 0.2$; growing, $\rho = 0.75$, $p = -0.25$, $w = -0.333333$. (By hand: $1 + 0.5/2 = 1.25$, $0.5/2 = 0.25$, $0.25/1.25 = 0.2$; $1 - 0.25 = 0.75$, $-0.25/0.75 = -1/3$.)

```
check(recorded(THEORY_PY, "commuting_homogeneous_on_shell_rho_p") == "PASS"
      and recorded(THEORY_PY, "commuting_T_x4x0_homogeneous") == "PASS"
      and recorded(THEORY_PY, "commuting_trace_on_shell") == "PASS",
      "these are the record's homogeneous values and its vanishing x4-x0 component",
      record=f"{THEORY_PY}, checks commuting_homogeneous_on_shell_rho_p, "
             "commuting_T_x4x0_homogeneous and commuting_trace_on_shell")
```

The last check confirms that the record proved these statements exactly. Seven PASS lines in all.

In [9], energy density and pressure against S (Figure 09b.3).

```
lam = 0.5
S_axis = np.linspace(-6.0, 2.0, 401)
rho_axis = m * S_axis + lam / 2 * S_axis ** 2  # rho = m S + U
p_axis = lam / 2 * S_axis ** 2  # p = S U' - U
p_kin = (m + lam * S_axis) * S_axis  # V S
p_pot = -(m * S_axis + lam / 2 * S_axis ** 2)  # -(m S + U)
check(np.abs(p_kin + p_pot - p_axis).max() < 1e-12,
      "p = p_kin + p_pot = V S - (m S + U) at every drawn S")
```

With $m = 1$ and $\lambda = 0.5$ these lines tabulate, for 401 values of S from -6 to 2, the energy density, the pressure and its two parts, and check that the parts add up to the pressure.

```
fig, ax = plt.subplots()
ax.plot(S_axis, rho_axis, label="energy density $\\rho = mS + \\lambda S^2/2$")
ax.plot(S_axis, p_axis, label="pressure $p = \\lambda S^2/2$")
ax.plot(S_axis, p_kin, "--", label="kinetic part of $p$: $(m + \\lambda S)S$")
ax.plot(S_axis, p_pot, ":", label="potential part of $p$: $-(mS + U)$")
ax.plot([0.0, -2 * m / lam], [0.0, 0.0], "ko", label="$\\rho = 0$")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("$S = \\bar\\Phi\\Phi$")
ax.set_ylabel("energy per unit volume")
ax.set_title("Condensate: $\\rho$ and $p$ against $S$ ($m = 1$, $\\lambda = 0.5$)")
ax.legend(fontsize=8)
save_figure(fig, "energy_and_pressure",
            "Energy density $\\rho = mS + \\lambda S^2/2$ (solid), pressure "
            ...)
```

Four curves and two black dots (`"ko"`: black circles) at the zeros $S = 0$ and $S = -2m/\lambda = -4$ of ρ. **What Figure 09b.3 shows.** Against S (horizontal, a pure number) in units of energy per unit volume: the energy density, a parabola through 0 and -4 with its lowest point -1 at $S = -2$; the pressure, a parabola that touches zero at $S = 0$; the kinetic part of the pressure (dashed) and its potential part (dotted). The student should see that the energy density is negative for $-4 < S < 0$ and that the pressure is the sum of a kinetic and a potential part that partly cancel.

In [10], the equation of state of twelve exact condensates.

```
x_measured = np.array([-3.5, -3.0, -2.5, -1.5, -1.0, -0.5, 0.0, 0.5, 1.0, 2.0, 3.0,
                       4.0])  # values of x = lambda S/m (here lambda = x)
rho_measured, p_measured = [], []  # rho and p of each of the twelve condensates
for x_value in x_measured:
    V = m + x_value * 1.0  # lambda = x_value, S0 = 1
    M, k2 = condensate_matrix(V, H)
    phi, dphi = condensate(1.3, chi, M, k2)
    S, U, K4, rho, p, B04 = homogeneous_tensor(phi, dphi, x_value)
    rho_measured.append(rho)
    p_measured.append(p)
rho_measured, p_measured = np.array(rho_measured), np.array(p_measured)
w_measured = p_measured / rho_measured  # the equation of state of each condensate
w_formula = x_measured / (2 + x_measured)
```

With $m = 1$ and $S_0 = 1$ the number $x = \lambda S/m$ equals λ, so the cell builds, for twelve values of x, the exact condensate with $\lambda = x$, takes Φ and Φ' at the time $x_4 = 1.3$, and computes ρ and p from them as in In [8]; the formula $w = x/(2 + x)$ is used only afterwards, for the comparison. The value $x = -2$ is left out, because there $\rho = 0$.

```
check(np.abs(w_measured - w_formula).max() < 1e-9,
      "w = p/rho of 12 exact condensates equals x/(2 + x), x = lambda S/m")
at_minus_one = w_measured[list(x_measured).index(-1.0)]
check(abs(at_minus_one + 1.0) < 1e-12,
      "w = -1 exactly where the effective mass m + lambda S vanishes (x = -1)")
below = x_measured < -2  # the three condensates with x < -2
check(np.all(rho_measured[below] < 0) and np.all(p_measured[below] < 0)
      and np.all(w_measured[below] > 1),
      "for x < -2: rho < 0, p < 0 and w > 1")
for x_value, w_value in zip(x_measured, w_measured):
    say(f"x = lambda S/m = {x_value:5.1f}:  w = p/rho = {w_value: .6f}")
```

Three checks: the twelve measured values agree with $x/(2 + x)$; the value at $x = -1$ (`list(... ).index(-1.0)` finds its position) is -1; and the three condensates with $x < -2$ (`below` is an array of `True`/`False` that selects them) have negative ρ, negative p and $w > 1$ (`np.all` is true when every selected value satisfies the condition). The loop prints the table: for example $x = -1.5$ gives $w = -3$, $x = 1$ gives $w = 1/3$, $x = -2.5$ gives $w = 5$. The format `{x_value:5.1f}` prints with one decimal in five places and `{w_value:  .6f}` leaves a blank in place of a plus sign, so the columns line up.

In [11], the equation of state against x (Figure 09b.4).

```
fig, ax = plt.subplots()
for piece in (np.linspace(-6.0, -2.05, 300), np.linspace(-1.95, 6.0, 500)):
    ax.plot(piece, piece / (2 + piece), color="tab:blue")  # two branches
ax.plot(x_measured, w_measured, "o", color="tab:red",
        label="measured on exact condensates")
ax.axvline(-2.0, color="gray", linestyle=":", label="$\\rho = 0$ ($x = -2$)")
ax.axhline(-1.0, color="tab:green", linestyle="--", label="$w = -1$")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.axhspan(-6.0, -1.0, xmin=0.0, xmax=1.0, color="tab:green", alpha=0.08)
ax.set_ylim(-6.0, 6.0)
ax.set_xlabel("$x = \\lambda S / m$")
ax.set_ylabel("$w = p/\\rho$")
ax.set_title("Equation of state of a condensate: $w = x/(2 + x)$")
ax.legend(fontsize=8, loc="upper right")
save_figure(fig, "equation_of_state",
            "Equation of state $w = p/\\rho$ of a condensate of dirac16complex00 "
            ...)
```

The curve $w = x/(2 + x)$ is drawn in two pieces that stop short of $x = -2$, where it jumps from $+\infty$ to $-\infty$. The twelve measured values are red dots; a dotted vertical line marks $x = -2$, a dashed horizontal line $w = -1$, and `ax.axhspan` shades the band $w < -1$ faintly (`alpha=0.08` is 8 per cent opaque). **What Figure 09b.4 shows.** The equation of state (vertical) against x (horizontal), both pure numbers. The red dots lie on the curve. The student should read off: $w = 0$ at $x = 0$; $w = -1$

at $x = -1$; the phantom band $w < -1$ for $-2 < x < -1$; $w > 1$ for $x < -2$, where ρ and p are both negative; and $w \to 1$ for large x. This is the eight-dimensional ratio, not the equation of state an observer in 3-space would infer (that one rests on an ASSUMED definition of the observer's energy density; Section 9.19).

In [12], where condensates oscillate and where they grow (Figure 09b.5).

```
x_grid = np.linspace(-4.0, 3.0, 701)  # x = lambda S/m
h_grid = np.linspace(0.0, 3.0, 301)  # h = 3 H/|m|
X, Hgrid = np.meshgrid(x_grid, h_grid)  # every pair (x, h) of the two grids
growing_region = (np.abs(1 + X) < Hgrid).astype(float)  # 1 where k^2 > 0
fig, ax = plt.subplots()
ax.contourf(X, Hgrid, growing_region, levels=[-0.5, 0.5, 1.5],
            colors=["#dbe9f6", "#f6d5d5"])
```

`np.meshgrid` makes two tables that together list every pair (x, h) of the two grids, with $h = 3H/|m|$. The condition $|1 + x| < h$ of Section 9.20 is evaluated at every pair and turned into 1 (growing) or 0 (oscillating) by `.astype(float)`. `ax.contourf` colours the plane by these values: the levels -0.5, 0.5, 1.5 separate 0 from 1, and the two colours are a light blue and a light red, given as hexadecimal colour codes.

```
for label, x_line in (("$w = -1$", -1.0), ("$w = 0$", 0.0), ("$w = 1/3$", 1.0)):
    ax.axvline(x_line, color="black", linestyle="--", linewidth=0.8)
    ax.text(x_line + 0.05, 2.8, label, fontsize=8)
for name, lam_value in EXAMPLES.items():
    ax.plot([lam_value * 1.0 / m], [3 * H / abs(m)], "ko")
    ax.text(lam_value / m + 0.08, 3 * H / abs(m) - 0.15, name, fontsize=8)
ax.text(-3.8, 0.3, "oscillating ($k^2 < 0$)", fontsize=9)
ax.text(-2.9, 2.3, "growing\n($k^2 > 0$)", fontsize=9)
ax.set_xlabel("$x = \\lambda S / m$")
ax.set_ylabel("$3H/|m|$")
ax.set_title("Condensates: oscillating (blue) or growing (red)")
ax.grid(False)
save_figure(fig, "regime_map",
            "Map of the condensates of dirac16complex00 in the plane of "
            ...)
```

The first loop draws the vertical lines of constant w at $x = -1$, 0 and 1 with their labels; the second marks the two condensates of In [6] as black dots at $(x, 3H/|m|) = (0.5, 0.75)$ and $(-0.5, 0.75)$ with their names; two more labels name the regions (`\n` starts a new line). **What Figure 09b.5 shows.** The plane of x (horizontal) and $3H/|m|$ (vertical), both pure numbers: a red wedge with its tip at $x = -1$ on the horizontal axis, opening upwards, where condensates grow, and the blue rest, where they oscillate. The student should see that the line $w = -1$ runs through the middle of the wedge: every condensate with $w = -1$ grows.

```
for name, lam_value in EXAMPLES.items():
    grows = abs(1 + lam_value / m) < 3 * H / abs(m)
    check(grows == (name == "growing"),
          f"the {name} condensate lies in the {name} region of the map")
```

The two checks confirm that the map puts each condensate of In [6] into the region of its name.

In [13], a condensate keeps its energy along the deflating history.

```
A = 1.0  # the deflating history a4 = A H x4
M, k2 = condensate_matrix(m + 0.5 * 1.0, H)  # the oscillating condensate, S0 = 1
# rho at every time; homogeneous_tensor returns (S, U, K4, rho, p, B04): index 3.
# The condensate does not contain a4, so these are its values on this history too.
rho_at_times = np.array([homogeneous_tensor(*condensate(x4, chi, M, k2), 0.5)[3]
                         for x4 in times])
check(np.abs(rho_at_times - rho_at_times[0]).max() < 1e-9,
      "the condensate has p3 = p_t, so its rho is constant along the history")
```

`A = 1` names the deflating history $a_4 = AHx_4$. The oscillating condensate does not contain a_4 (Section 9.18), so it is a solution on this history too. `condensate(...)` returns the pair (Φ, Φ'), and the star in `homogeneous_tensor(*condensate(...), 0.5)` hands the two over as the first two arguments; `[3]` picks the fourth result, ρ. The check confirms that ρ is the same at all 401 times, as $p_3 = p_t$ and the identity of Section 9.10 require.

In [14], toy fluids solved with the Runge-Kutta method (an ILLUSTRATION).

```
def rk4(rate, y0, step, count):
    """Solve dy/dx = rate(y) from y(0) = y0 with count Runge-Kutta steps."""
    y, path = y0, [y0]
    for _ in range(count):
        s1 = rate(y)
        s2 = rate(y + step / 2 * s1)
        s3 = rate(y + step / 2 * s2)
        s4 = rate(y + step * s3)
        y = y + step / 6 * (s1 + 2 * s2 + 2 * s3 + s4)
        path.append(y)
    return np.array(path)
```

The **Runge-Kutta method** of fourth order (RK4, Chapter 2) solves an equation $dy/dx = \text{rate}(y)$ step by step: from the value y it evaluates four slopes (at the start, twice at the middle of the step, and at the end) and moves on by the step times their weighted mean $(s_1 + 2s_2 + 2s_3 + s_4)/6$. The function returns the whole path, the starting value included.

```
STEP, COUNT = 0.05, 160  # x4 from 0 to 8
toy_times = STEP * np.arange(COUNT + 1)
DELTAS = (-2 / 3, -1 / 3, 0.0, 1 / 3, 2 / 3)  # Delta w = w3 - w_t
toy = {}  # Delta w -> rho(x4)/rho0 along A = +1
errors = {STEP: 0.0, STEP / 2: 0.0}  # the largest relative error for two steps
```

160 steps of 0.05 cover x_4 from 0 to 8; `toy_times` holds the 161 times. Five toy fluids are labelled by $\Delta w = w_3 - w_t$. `toy` will hold their paths, and `errors` the largest relative error for the step 0.05 and for half of it.

```
for delta in DELTAS:
    for step in errors:
```

```
        count = round(8.0 / step)  # the number of steps from x4 = 0 to 8
        path = rk4(lambda r, d=delta: -3 * A * H * d * r, 1.0, step, count)
        exact = np.exp(-3 * A * H * delta * step * np.arange(count + 1))
        errors[step] = max(errors[step], np.abs(path / exact - 1).max())
        if step == STEP:
            toy[delta] = path
```

For each toy fluid and each of the two steps, the cell solves $d\rho/dx_4 = -3AH\,\Delta w\,\rho$ from $\rho(0) = 1$ (Section 9.10). `lambda r, d=delta: ...` is a short nameless function of `r`; the extra argument `d=delta` freezes the current value of `delta` inside it. `exact` is the exact solution $e^{-3AH\Delta w\,x_4}$ at the same times, and the largest relative error of the path is kept. The paths with the step 0.05 are stored for the figure.

```
check(errors[STEP] < 1e-7,
      "RK4 (step 0.05) reproduces rho0 exp(-3 A H Delta w x4) for 5 toy fluids")
ratio = errors[STEP] / errors[STEP / 2]  # RK4: half the step, 1/16 of the error
check(14 < ratio < 18, "halving the RK4 step divides the error by about 2^4 = 16")
report("largest relative RK4 error, step 0.05", f"{errors[STEP]:.2e}")
report("error ratio of the steps 0.05 and 0.025", f"{ratio:.2f}")
```

The first check requires the error with the step 0.05 to be below 10^{-7} (it is $1.33 \cdot 10^{-8}$). The error of a fourth-order method is proportional to the fourth power of the step, so halving the step must divide it by about $2^4 = 16$; the measured ratio is 16.17, and the second check accepts 14 to 18.

```
reversed_path = rk4(lambda r: -3 * (-A) * H * (1 / 3) * r, 1.0, STEP, COUNT)
check(np.abs(reversed_path * toy[1 / 3] - 1).max() < 1e-8,
      "A -> -A reverses the energy flow (the product of the two paths is 1)")
report("toy fluid Delta w = 1/3: rho(8)/rho(0) along A = 1", f"{toy[1 / 3][-1]:.6f}")
```

The reversed history ($A \to -A$: the extra times inflate and 3-space deflates) gives the path $e^{+3AH\Delta w\,x_4}$, the inverse of the original: the check requires their product to be 1 at every time. The cell prints $\rho(8)/\rho(0) = 0.135335 = e^{-2}$ for $\Delta w = 1/3$, the number computed by hand in Section 9.10. (`toy[1 / 3][-1]` is the last value of the path; the index -1 counts from the end.)

In [15], the energy exchange (Figure 09b.6).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9))
fig.subplots_adjust(wspace=0.35)  # more room between the two panels
for delta in DELTAS:
    left.plot(toy_times, toy[delta], label=f"toy, $\\Delta w = {delta:+.2f}$")
left.plot(times[times <= 8.0], rho_at_times[times <= 8.0] / rho_at_times[0], "k:",
          linewidth=2.0, label="condensate ($p_3 = p_t$)")
left.set_yscale("log")
left.set_xlabel("time $x_4$")
left.set_ylabel("$\\rho(x_4) / \\rho(0)$")
left.set_title("Energy density along $a_4 = AHx_4$ ($A = 1$)")
left.legend(fontsize=7)
```

The left panel draws the five toy paths (the format `+.2f` prints the sign and two decimals) and, as a thick black dotted line, the condensate's $\rho(x_4)/\rho(0)$ for the times up to 8 (`times <= 8.0` selects them), on a logarithmic axis.

```
rho_toy = toy[-1 / 3]  # Delta w = -1/3: w3 = 1/3, w_t = 2/3
work_space = -3 * A * H * (1 / 3) * rho_toy  # -3 a4' p3 with p3 = rho/3
work_extra = 3 * A * H * (2 / 3) * rho_toy  # +3 a4' p_t with p_t = 2 rho/3
right.plot(toy_times, work_space, label="3-space: $-3a_4' p_3$")
right.plot(toy_times, work_extra, "--", label="extra times: $+3a_4' p_t$")
right.plot(toy_times, np.gradient(rho_toy, toy_times), ":", color="black",
           label="$d\\rho/dx_4$ (finite differences)")
right.axhline(0.0, color="black", linewidth=0.8)
right.set_xlabel("time $x_4$")
right.set_ylabel("rate of change of $\\rho$")
right.set_title("Toy fluid $(w_3, w_t) = (1/3, 2/3)$")
right.legend(fontsize=7)
save_figure(fig, "energy_exchange",
            "Energy exchange along the deflating history $a_4 = AHx_4$, $A = 1$, "
            ...)
```

For the toy fluid with $w_3 = 1/3$ and $w_t = 2/3$ the right panel draws the two terms of $d\rho/dx_4 = -3a_4'p_3 + 3a_4'p_t$ separately, and the slope of the path by finite differences. **What Figure 09b.6 shows.** Left, the energy density divided by its starting value (a pure number, logarithmic axis) against x_4 from 0 to 8: the toy fluids with $p_3 > p_t$ ($\Delta w > 0$) lose energy, those with $p_3 < p_t$ gain energy, $\Delta w = 0$ and the exact condensate stay constant. Right, rates in units of energy per unit volume per unit time: the 3-space term is negative (inflating 3-space takes energy out), the extra-time term is positive and twice as large (the deflating extra times put energy in), and the dotted slope is their sum. The student should see the energy exchange of Section 9.10 at work, remembering that the toy fluids are an illustration, not solutions.

```
# [2:-2] leaves out two points at each end, where np.gradient is less exact.
check(np.abs(np.gradient(rho_toy, toy_times) - (work_space + work_extra))[2:-2].max()
      < 1e-3, "d rho/dx4 equals the sum of the two work terms on the drawn path")
```

The check confirms that the finite-difference slope equals the sum of the two terms within 10^{-3}.

In [16], negative energies: the plane waves of flat space.

```
m_flat, E_flat = 2.0, 5.0
momentum = {0: 4.0, 1: 1.0, 2: 2.0, 3: 0.0}  # k0, k1, k2, k3 (x5, x6, x7: zero)
beta = -1j * g4
h = m_flat * beta + sum(k_a * (-g4 @ gamma[a]) for a, k_a in momentum.items())
check(np.abs(h - h.conj().T).max() < 1e-12 and np.abs(h @ h - 25 * I16).max() < 1e-12
      and np.abs(B @ h - h @ B).max() < 1e-12,
      "h is Hermitian, h^2 = 25, and h commutes with B")
```

The cell sets up the example of Section 9.21: $m = 2$, the momenta $(k_0, k_1, k_2, k_3) = (4, 1, 2, 0)$ stored in a dictionary from the index of the direction to its momentum, $\beta = -i\gamma^{(4)}$ and $h = m\beta + \sum_a k_a \alpha^a$ with $\alpha^a = -\gamma^{(4)}\gamma^{(a)}$. The check confirms that h is **Hermitian** (equal to its own dagger, `h.conj().T`), that $h^2 = 25$ and that $hB = Bh$.

```
energies, vectors = np.linalg.eigh(h)  # eigenvalues in ascending order
U5 = vectors[:, energies > 0]  # the eight columns with eigenvalue +5
form = U5.conj().T @ B @ U5  # u^dagger B u on the eigenspace, as an 8 x 8 matrix
inertia, directions = np.linalg.eigh(form)
```

`np.linalg.eigh` returns the eigenvalues of a Hermitian matrix in ascending order and, as the columns of a second matrix, unit eigenvectors that are perpendicular to each other. `energies > 0` selects the eight columns with $E = +5$: `U5` is a 16×8 matrix whose columns span the space of solutions with $E = 5$. Every unit column of that space is $u = U_5 c$ with a unit column c of eight numbers, and then $u^\dagger B u = c^\dagger (U_5^\dagger B U_5) c$: the 8×8 matrix `form` describes the form $u^\dagger B u$ on the space. Its eigenvalues `inertia` and unit eigenvectors `directions` give its positive and negative directions.

```
PAIRING = "Revision/pairing/reports/python-pairing.json"
check(np.allclose(energies, [-5.0] * 8 + [5.0] * 8, atol=1e-12)
      and np.allclose(inertia, [-1.0] * 4 + [1.0] * 4, atol=1e-12)
      and recorded(PAIRING, "Q.one_particle_Krein_inertia_proof") == "PASS",
      "E = +-5 (eight each); u^dagger B u has inertia (4,4) on the E = 5 space",
      record=f"{PAIRING}, check Q.one_particle_Krein_inertia_proof (every real "
             "frequency)")
```

The check confirms the frequencies ± 5, eight each, and that the form has four eigenvalues -1 and four $+1$: Krein inertia (4,4), which the pairing record proves for every real frequency.

In [17], the energy density of two plane waves.

```
def flat_energy_density(u):
    """rho = -sum over a != x4 of K_a + m S for the plane wave u e^(i(k.x - E x4))."""
    S = (u.conj() @ C @ u).real
    kinetic = 0.0
    for a, k_a in momentum.items():  # d_a Phi = i k_a Phi
        d_u = 1j * k_a * u
        kinetic += 0.5 * (u.conj() @ C @ gamma[a] @ d_u - d_u.conj() @ C @ gamma[a] @ u)
    return (-kinetic + m_flat * S).real
```

The function computes $\rho = -\sum_{a \neq x_4} K_a + mS$ from its definition (Section 9.7, flat space, $U = 0$), with $\partial_a \Phi = i k_a \Phi$; the common exponential factor has size 1 and drops out of every bilinear, so the column u can stand for Φ.

```
rho_pair = []
# column 0 of directions has the eigenvalue -1 of the form, column 7 the value +1
for column, b_value in ((0, -1.0), (7, 1.0)):
    u = U5 @ directions[:, column]  # a unit vector of the eigenspace, B u = b_value u
    d4_u = -1j * E_flat * u  # d4 Phi = -i E Phi
    field = (g4 @ d4_u + sum(gamma[a] @ (1j * k_a * u) for a, k_a in momentum.items())
             - m_flat * u)  # sum_a gamma^(a) d_a Phi - m Phi
    check(np.abs(field).max() < 1e-12 and np.abs(B @ u - b_value * u).max() < 1e-12,
          f"the plane wave with B u = {b_value:+.0f} u solves the field equation")
    rho_pair.append(flat_energy_density(u))
```

For the two extreme directions of the form (the first eigenvector, eigenvalue -1, and the last, eigenvalue $+1$) the loop builds the unit column u of the solution space, checks that the plane wave solves the flat field equation $\sum_a \gamma^{(a)} \partial_a \Phi = m \Phi$ and that $B u = \mp u$, and computes its energy density.

```
SCOPE_PY = "Revision/theory/reports/python-scope.json"
SCOPE_WL = "Revision/theory/reports/wolfram-scope.json"
check(abs(rho_pair[0] + 5.0) < 1e-12 and abs(rho_pair[1] - 5.0) < 1e-12
      and recorded(SCOPE_PY, "commuting_field_energy_unbounded_below") == "PASS"
      and recorded(SCOPE_WL, "commuting_field_energy_unbounded_below") == "PASS",
      "rho = -5 for B u = -u and rho = +5 for B u = +u (|u| = 1)",
      record=f"{SCOPE_PY} and {SCOPE_WL}, check commuting_field_energy_unbounded_below")
```

The check confirms the record's values: the wave with $Bu = -u$ has $\rho = -5$, the wave with $Bu = +u$ has $\rho = +5$, both at the positive frequency $E = 5$, in agreement with $\rho = E\,u^\dagger Bu$ of Section 9.21.

In [18], 5000 random waves of positive frequency.

```
samples = rng.normal(size=(5000, 8)) + 1j * rng.normal(size=(5000, 8))
samples /= np.linalg.norm(samples, axis=1)[:, None]
us = samples @ U5.T  # 5000 random unit vectors of the eigenspace
charges = np.einsum("ni,ij,nj->n", us.conj(), B, us).real  # u^dagger B u
rho_samples = np.array([flat_energy_density(u) for u in us])
check(np.abs(rho_samples - E_flat * charges).max() < 1e-12
      and rho_samples.min() < 0 < rho_samples.max(),
      "rho = E u^dagger B u for all 5000 random u of the eigenspace; both signs")
report("smallest and largest rho of the 5000 samples",
       f"{rho_samples.min():.4f} and {rho_samples.max():.4f}")
```

5000 random unit columns c of eight numbers give 5000 random unit columns $u = U_5 c$ of the solution space (`samples @ U5.T` computes all of them at once, one per row). For each, `charges` holds $u^\dagger Bu$ and `rho_samples` the energy density computed from the kinetic terms. The check confirms $\rho = E\,u^\dagger Bu$ every time and that both signs occur. The smallest and largest values are -4.3821 and 4.4892.

In [19], the histogram of the 5000 energy densities (Figure 09b.7).

```
fig, ax = plt.subplots()
ax.hist(rho_samples, bins=50, range=(-5.0, 5.0), color="tab:purple", edgecolor="white")
ax.axvline(0.0, color="black", linewidth=1.0)
ax.set_xlabel("energy density $\\rho = E\\,u^\\dagger B u$ of the plane wave")
ax.set_ylabel("number of the 5000 random $u$")
ax.set_title("Waves of positive frequency $E = 5$: $\\rho$ has both signs")
save_figure(fig, "energy_sign",
            "Histogram of the energy density $\\rho = -\\sum_{a \\neq x_4} K_a + mS$ "
            ...)
```

What Figure 09b.7 shows. The number of waves (vertical) whose energy density, in units of energy per unit volume, falls into each of 50 intervals between -5 and 5 (horizontal). The values are spread symmetrically about zero, and about half are negative. The possible values fill the whole interval from -5 (reached for $Bu = -u$) to 5 (for $Bu = u$), but random columns seldom come near the two ends. The student should see that for this commuting field a positive frequency does not mean a positive energy.

In [20], the last check.

```
captions = json.loads(output_file(CAPTION_FILE).read_text(encoding="utf-8"))
expected_files = ["09b_1_sign_of_s.png", "09b_2_condensate_solutions.png",
                  "09b_3_energy_and_pressure.png", "09b_4_equation_of_state.png",

    output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in expected_files),
    "the seven figures of this notebook are saved and captioned")
all_checks_passed()
```

As in Notebook 09a: the seven figures exist and are captioned, and the last line is `ALL 33 CHECKS PASSED (notebook 09b)`: two checks in In [2], one in In [4], five in In [6], seven in In [8], one in In [9], three in In [10], two in In [12], one in In [13], three in In [14], one in In [15], two in In [16], three in In [17], one in In [18] and one in In [20].

9.26 The full tensor of a condensate

A condensate has the same pressure in all seven directions. That does not yet make it a **perfect fluid at rest**, which has a diagonal energy-momentum tensor: Section 9.12 showed that the spin connection puts entries off the diagonal. For a condensate $\partial_\mu \Phi = 0$ for $\mu \neq x_4$, but $D_\mu \Phi = \Omega_\mu \Phi$ is not zero along 3-space and the extra times, because Ω_{x_i} and Ω_{x_t} are not zero.

The structure, from the record. Off the diagonal the tensor of Section 9.6 is $T^\nu{}_\mu = -K^{(\nu}{}_{\mu)}$ with

$$K^\nu{}_\mu = \tfrac{1}{2}\big(\bar{\Phi}\gamma^\nu D_\mu \Phi - D_\mu \bar{\Phi}\,\gamma^\nu \Phi\big), \qquad K^{(\nu}{}_{\mu)} = \tfrac{1}{2}\big(K^\nu{}_\mu + g^{\nu\nu} g_{\mu\mu} K^\mu{}_\nu\big),$$

because the first pair of terms in the bracket of Section 9.6 is $2K^\nu{}_\mu$ and the second pair is $g_{\mu\mu} g^{\nu\nu} \cdot 2K^\mu{}_\nu$ (move the metric factors of γ_μ and D^ν in front). The Revision record proves three facts for every exact condensate (PROVED; the table names the record files and checks; the coefficients themselves are stored in the record file `Revision/field_equations_a4/a4-equations.json` under the entry `offDiagonalKinetic`):

statement	Revision report	check
the diagonal of the tensor of a condensate	`Revision/field_equations_a4/reports/wolfram-a4-report.json`	`condensate_kinetic_tensor_diagonal`
the same, with the author's gammas	`Revision/field_equations_a4/reports/python-a4-report.json`	`authorT16_condensate_kinetic_diagonal`
the entries off the diagonal are multiples of three-gamma bilinears	`Revision/field_equations_a4/reports/wolfram-a4-report.json`	`condensate_offdiagonal_are_three_gamma_bilinears`

statement	Revision report	check
the same, with the author's gammas	`Revision/field_equations_a4/reports/python-a4-report.json`	`authorT16_condensate_offdiagonal_three_gamma`
the stored coefficients are the computed ones	`Revision/field_equations_a4/reports/python-a4-report.json`	`json_offdiagonal_coefficients`

The three facts are:

- the diagonal is $T^{x_4}{}_{x_4} = -VS + L_0$ and $T^{\mu}{}_{\mu} = L_0$ otherwise (Section 9.19), and $T^{x_4}{}_{x_0} = T^{x_0}{}_{x_4} = 0$;
- exactly 42 of the 56 entries off the diagonal are nonzero in general: the 12 flows $T^{x_4}{}_{x_j}$ and $T^{x_j}{}_{x_4}$ (x_j any of the six directions $x_1, x_2, x_3, x_5, x_6, x_7$), whose coefficients contain H and not a_4'; the 18 entries $T^{x_i}{}_{x_t}$ and $T^{x_t}{}_{x_i}$ between 3-space and the extra times; and the 12 entries $T^{x_j}{}_{x_0}$ and $T^{x_0}{}_{x_j}$; the last 30 are proportional to a_4' (the 14 entries inside 3-space, inside the extra times, and x_4-x_0 vanish);
- each nonzero entry is a fixed number (depending on a_4, a_4', z and H, not on V) times one of 15 **three-gamma bilinears** $B_{abc} = \bar{\Phi}\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$, with $\{a,b,c\} = \{j,4,8\}$ (six of them) or $\{i,4,t\}$ with i in 3-space and t an extra time (nine of them).

One entry, line by line. Take $T^{x_1}{}_{x_5}$. Both $K^{x_1}{}_{x_5}$ and $K^{x_5}{}_{x_1}$ contain no derivative of Φ (there is none along x_1 or x_5), so, exactly as in Section 9.12, each is $\frac{1}{2}\bar{\Phi}\{\gamma^{\nu}, \Omega_{\mu}\}\Phi$. With $\gamma^{x_1} = \gamma^{(1)}/f_1$, $\gamma^{x_5} = \gamma^{(5)}/f_5$ and the anticommutators of a gamma with a product of two other gammas, $\{\gamma^{(a)}, \gamma^{(b)}\gamma^{(c)}\} = 2\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}$ (move $\gamma^{(a)}$ from the right end to the front past two gammas: two minus signs):

$$
\begin{aligned}
K^{x_1}{}_{x_5} &= \tfrac{1}{2}\cdot\frac{1}{f_1}\cdot\Big(-\frac{f_5}{2}\Big)\,\bar{\Phi}\big(a_4'\{\gamma^{(1)},\gamma^{(4)}\gamma^{(5)}\} + H\{\gamma^{(1)},\gamma^{(5)}\gamma^{(0)}\}\big)\Phi \\
&= -\frac{f_5}{2f_1}\big(a_4' B_{145} + H B_{158}\big), \\
K^{x_5}{}_{x_1} &= \tfrac{1}{2}\cdot\frac{1}{f_5}\cdot\frac{f_1}{2}\,\bar{\Phi}\big(a_4'\{\gamma^{(5)},\gamma^{(1)}\gamma^{(4)}\} + H\{\gamma^{(5)},\gamma^{(1)}\gamma^{(0)}\}\big)\Phi \\
&= \frac{f_1}{2f_5}\big(a_4' B_{145} - H B_{158}\big), \\
g^{11}g_{55}K^{x_5}{}_{x_1} &= \frac{1}{f_1^2}\big(-f_5^2\big)\frac{f_1}{2f_5}\big(a_4' B_{145} - H B_{158}\big) = -\frac{f_5}{2f_1}\big(a_4' B_{145} - H B_{158}\big), \\
T^{x_1}{}_{x_5} &= -\tfrac{1}{2}\Big(K^{x_1}{}_{x_5} + g^{11}g_{55}K^{x_5}{}_{x_1}\Big) = \tfrac{1}{2}\cdot\frac{f_5}{2f_1}\cdot 2a_4' B_{145} = \tfrac{1}{2}\,e^{-2a_4}\,a_4'\,\bar{\Phi}\gamma^{(1)}\gamma^{(4)}\gamma^{(5)}\Phi.
\end{aligned}
$$

The first line inserts $\gamma^{x_1} = \gamma^{(1)}/f_1$ and Ω_{x_5}; the second replaces each anticommutator by twice the product of its three gammas, which are already in the order $1,4,5$ and $1,5,8$, and cancels

the factors 2 and $\frac{1}{2}$. The third line inserts $\gamma^{x_5} = \gamma^{(5)}/f_5$ and Ω_{x_1}; the fourth does the same and reorders the three gammas into the order $1,4,5$ and $1,5,8$ ($\gamma^{(5)}\gamma^{(1)}\gamma^{(4)} = \gamma^{(1)}\gamma^{(4)}\gamma^{(5)}$ after two exchanges; $\gamma^{(5)}\gamma^{(1)}\gamma^{(0)} = -\gamma^{(1)}\gamma^{(5)}\gamma^{(0)}$ after one). The fifth multiplies by $g^{11}g_{55} = (1/f_1^2)(-f_5^2)$; the sixth adds, so that the H terms cancel and the a_4' terms double, and uses $f_5/f_1 = e^{-2a_4}$. The entry is proportional to the deflation rate a_4': it exists only because the extra times deflate (or, for $a_4' < 0$, inflate). The coefficient $\frac{1}{2}e^{-2a_4}a_4'$ is exactly the record's (its table lists $K^{x_i}{}_{x_t}$ with the coefficient $-\frac{1}{2}e^{-2a_4}a_4'$, and $T = -K$); at $a_4 = 0.5$, $a_4' = 0.25$ it is $0.5 \cdot e^{-1} \cdot 0.25 = 0.045985$, the number Notebook 09c prints for $T^{x_1}{}_{x_5}$.

A second entry: the momentum flow $T^{x_4}{}_{x_1}$. Section 9.12 computed the piece $K^{x_4}{}_{x_1} = \frac{1}{2}f_1 H\,\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi$, with the coefficient $\frac{1}{2}$. The record's coefficient of the whole entry is $\frac{7}{4}$. The difference is the second piece of the symmetrised tensor, $g^{44}g_{11}K^{x_1}{}_{x_4}$, which contains the time derivative of the condensate. Line by line, with $\partial_4\Phi = M\Phi$ and $\partial_4\bar\Phi = -\bar\Phi M$ (Section 9.19) and $\Omega_{x_4} = 0$, so that $D_{x_4} = \partial_4$:

$$
\begin{aligned}
K^{x_4}{}_{x_1} &= \tfrac{1}{2}f_1 H\,\bar\Phi\gamma^{(4)}\gamma^{(1)}\gamma^{(0)}\Phi = -\tfrac{1}{2}f_1 H\,B_{148},\\
K^{x_1}{}_{x_4} &= \tfrac{1}{2}\big(\bar\Phi\gamma^{x_1}M\Phi + \bar\Phi M\gamma^{x_1}\Phi\big) = \frac{1}{2f_1}\,\bar\Phi\{\gamma^{(1)}, M\}\Phi,\\
\{\gamma^{(1)}, M\} &= -V\{\gamma^{(1)},\gamma^{(4)}\} + 3H\{\gamma^{(1)},\gamma^{(4)}\gamma^{(0)}\} = 0 + 6H\,\gamma^{(1)}\gamma^{(4)}\gamma^{(0)},\\
K^{x_1}{}_{x_4} &= \frac{3H}{f_1}\,B_{148}, \qquad g^{44}g_{11}K^{x_1}{}_{x_4} = (-1)\,f_1^2\cdot\frac{3H}{f_1}\,B_{148} = -3f_1 H\,B_{148},\\
T^{x_4}{}_{x_1} &= -\tfrac{1}{2}\Big(K^{x_4}{}_{x_1} + g^{44}g_{11}K^{x_1}{}_{x_4}\Big) = -\tfrac{1}{2}\Big(-\tfrac{1}{2}-3\Big)f_1 H\,B_{148} = \tfrac{7}{4}\,e^{a_4}\sin^{1/6}z\;H\,B_{148}.
\end{aligned}
$$

The first line is the result of Section 9.12, with $\gamma^{(4)}\gamma^{(1)}\gamma^{(0)} = -\gamma^{(1)}\gamma^{(4)}\gamma^{(0)}$ (one exchange). The second inserts the derivatives of the condensate into the definition of $K^{x_1}{}_{x_4}$ and $\gamma^{x_1} = \gamma^{(1)}/f_1$. The third inserts $M = -V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}$: two different gammas anticommute, so $\{\gamma^{(1)},\gamma^{(4)}\} = 0$, and the anticommutator with a product of two other gammas is twice the product of the three. The fourth collects, and multiplies by $g^{44}g_{11} = (1/g_{44})\,g_{11} = (-1)f_1^2$. The fifth adds the two pieces, with $-\frac{1}{2}(-\frac{1}{2}-3) = \frac{7}{4}$, and writes $f_1 = e^{a_4}\sin^{1/6}z$. Three things follow. The effective mass V has dropped out. The coefficient contains H and not a_4', so the 12 momentum flows remain when $a_4' = 0$. And the larger part, 3 of the $\frac{7}{2}$ inside the bracket, comes from the term $3H\gamma^{(4)}\gamma^{(0)}$ of M, that is from the gravitational term $3H\gamma^{(0)}$ of the field equation (Fact 2 of Section 9.3). At $a_4 = 0.5$, $z = \pi/4$, $H = 1$ the coefficient is $\frac{7}{4}\cdot 1.6487213\cdot 0.9438743 = 2.723325$ (rounded to six decimals); the record writes the symmetrised K with the coefficient -2.723325, and Notebook 09c prints `T^x4_x1 = -(-2.723325) x its bilinear`.

Condensates with a diagonal tensor. The record also constructs exact condensates for which all 15 bilinears vanish, so that their tensor is diagonal at every point of every history: a perfect fluid at rest, with $T^{x_4}{}_{x_4} = -VS + L_0$ and pressure L_0. The construction uses the three matrices $P_1 = \gamma^{(1)}\gamma^{(5)}$, $P_2 = \gamma^{(2)}\gamma^{(6)}$, $P_3 = \gamma^{(3)}\gamma^{(7)}$, which pair each 3-space direction with an extra time. Each squares to 1 ($\gamma^{(1)}\gamma^{(5)}\gamma^{(1)}\gamma^{(5)} = -\gamma^{(1)}\gamma^{(1)}\gamma^{(5)}\gamma^{(5)} = -(1)(-1) = 1$), they commute with each other and with M (moving a product of two gammas past another gamma with a different index costs two minus signs), and each anticommutes with C ($C = \gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$ contains $\gamma^{(k)}$ but not $\gamma^{(k+4)}$, so moving P_k through C costs three minus signs for $\gamma^{(k)}$ and four for $\gamma^{(k+4)}$). When $V^2 > 9H^2$, let $\omega = \sqrt{V^2 - 9H^2}$; then $M^2 = -\omega^2$ (Section 9.18, with $k^2 = 9H^2 - V^2 = -\omega^2$). Four steps build the condensate.

- **Step 1: two spaces of dimension 8.** For any column u put $u_- = \frac{1}{2}(u + \frac{i}{\omega}Mu)$ and $u_+ = \frac{1}{2}(u - \frac{i}{\omega}Mu)$. Then $u_- + u_+ = u$, and $Mu_- = \frac{1}{2}(Mu + \frac{i}{\omega}M^2u) = \frac{1}{2}(Mu - i\omega u) = -i\omega\, u_-$ (insert $M^2 = -\omega^2$, then take out the factor $-i\omega$, using $-i\omega \cdot \frac{i}{\omega} = 1$); in the same way $Mu_+ = +i\omega\, u_+$. So every column is the sum of a column of the space E_- of the eigenvalue $-i\omega$ and a column of the space E_+ of the eigenvalue $+i\omega$; a nonzero column cannot lie in both (it cannot have two different eigenvalues), so the dimensions of E_- and E_+ add up to 16. M is real, so for $Mu = -i\omega u$ the complex conjugate column $\bar{u}$ obeys $M\bar{u} = \overline{Mu} = \overline{-i\omega u} = +i\omega\,\bar{u}$: complex conjugation carries E_- into E_+ and E_+ into E_-, and it keeps independent columns independent, so the two spaces have the same dimension, $16/2 = 8$.

- **Step 2: eight sectors.** P_1, P_2, P_3 commute with M, so they map E_- into itself (if $Mu = -i\omega u$ then $M(P_k u) = P_k Mu = -i\omega\, P_k u$). Because $P_k^2 = 1$, the matrix $\frac{1}{2}(1 + \varepsilon P_k)$, for a sign $\varepsilon = \pm 1$, keeps the columns with $P_k u = \varepsilon u$ and sends those with $P_k u = -\varepsilon u$ to zero (it is a **projector**), and $\frac{1}{2}(1 + \frac{i}{\omega}M)$, which turns u into u_-, keeps E_- and sends E_+ to zero. For three signs $\varepsilon_1, \varepsilon_2, \varepsilon_3$ the product $\Pi = \frac{1}{2}(1 + \frac{i}{\omega}M) \cdot \frac{1}{2}(1 + \varepsilon_1 P_1) \cdot \frac{1}{2}(1 + \varepsilon_2 P_2) \cdot \frac{1}{2}(1 + \varepsilon_3 P_3)$ of these four commuting projectors keeps exactly the columns of E_- with $P_1 = \varepsilon_1$, $P_2 = \varepsilon_2$, $P_3 = \varepsilon_3$ (a **sector** of E_-; there are $2^3 = 8$ of them) and sends every other column to zero; it obeys $\Pi^2 = \Pi$.

- **Step 3: every sector has dimension 1.** For a matrix with $\Pi^2 = \Pi$ every column splits as $u = \Pi u + (u - \Pi u)$, a part that Π keeps ($\Pi\Pi u = \Pi u$) and a part that it sends to zero ($\Pi(u - \Pi u) = 0$). In a basis made of kept and of removed columns Π is diagonal with entries 1 and 0, so its **trace** (the sum of its diagonal entries, which is the same in every basis because $\mathrm{tr}(AB) = \mathrm{tr}(BA)$) is the dimension of the kept space. Multiply out Π: it is $\frac{1}{16}$ times the unit matrix plus terms that are each a number times a product of 1 to 8 different frame gammas (the indices of P_k are k and $k+4$, those of $M = -V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}$ are 4 and 8: all different). A product X of n different frame gammas has trace 0: choose a gamma $\gamma^{(b)}$ among its factors if n is even, and one that is not among them if n is odd (then $n \le 7$, so one is left); moving $\gamma^{(b)}$ through X costs $n - 1$ minus signs in the first case and n in the second, an odd number either way, so $X\gamma^{(b)} = -\gamma^{(b)}X$; then $\mathrm{tr}X = \mathrm{tr}\big(X\gamma^{(b)}(\gamma^{(b)})^{-1}\big) = \mathrm{tr}\big((\gamma^{(b)})^{-1}X\gamma^{(b)}\big) = -\mathrm{tr}\big((\gamma^{(b)})^{-1}\gamma^{(b)}X\big) = -\mathrm{tr}X$ (the inverse exists because $(\gamma^{(b)})^2 = \pm 1$; the second step is $\mathrm{tr}(AB) = \mathrm{tr}(BA)$), and a number equal to minus itself is 0. Only the unit matrix contributes, $\mathrm{tr}\,\Pi = 16/16 = 1$, and every one of the eight sectors of E_- has dimension 1.

- **Step 4: the condensate.** Take a unit column v_1 (a column of length 1) in the sector $P_1 = P_2 = P_3 = -1$ and a unit column v_2 in the sector $P_1 = P_2 = P_3 = +1$. By Step 3 each is unique up to a factor $e^{i\theta}$ of size 1. Put $c = \overline{v_1^\dagger C v_2}$ (the bar over a number means its complex conjugate) and $\Phi_0 = v_1 + cv_2$, a column of E_-. Other choices of the factors change nothing that matters: replacing v_1 by $e^{i\alpha}v_1$ and v_2 by $e^{i\beta}v_2$ replaces c by $e^{i(\alpha-\beta)}c$ and Φ_0 by $e^{i\alpha}\Phi_0$, which leaves every bilinear unchanged. Since $M\Phi_0 = -i\omega\Phi_0$, the column $\Phi = e^{-i\omega x_4}\Phi_0$ solves $\partial_4\Phi = M\Phi$: an exact condensate that oscillates with the angular frequency ω.

A **witness** is an explicit example that proves that something exists. For three choices of (V, H) the record builds this condensate with exact arithmetic and proves that all 15 of its bilinears vanish (and with them every off-diagonal entry, for every a_4 and a_4'); each of the three is a witness: it proves that condensates with a diagonal tensor exist. Notebook 09c builds the same three and confirms numerically the dimensions 8 and 1 of Steps 1 and 3. The record's three witnesses

have $(V, H) = (5, 1)$, $(5, 4/3)$ and $(-5, 1)$, so $\omega = \sqrt{25-9} = 4$, $\sqrt{25-16} = 3$ and 4 (PROVED; check `condensate_diagonal_witness_exact`; the record writes the effective mass V as M and the frequency as w). Their S is never negative: C anticommutes with P_1, which is real and symmetric, so for $P_1 v_1 = -v_1$

$$v_1^\dagger C v_1 = -v_1^\dagger C P_1 v_1 = v_1^\dagger P_1 C v_1 = (P_1 v_1)^\dagger C v_1 = -v_1^\dagger C v_1,$$

hence $v_1^\dagger C v_1 = 0$ (a number equal to minus itself is zero), and likewise $v_2^\dagger C v_2 = 0$; with $s = v_1^\dagger C v_2$ one has $v_2^\dagger C v_1 = \bar{s}$ (C is real and symmetric) and $c = \bar{s}$, so $S = \Phi_0^\dagger C \Phi_0 = 0 + c\,s + \bar{c}\,\bar{s} + 0 = 2|s|^2 \geq 0$. (The first step replaces v_1 by $-P_1 v_1$, the second uses $CP_1 = -P_1 C$, the third $P_1^\dagger = P_1$, the fourth $P_1 v_1 = -v_1$.)

What this means for the field equations of gravity. The field equations of a_4 (Chapter 12) have one equation for each of the 64 entries. For every entry off the diagonal the gravitational side (the left-hand side) vanishes identically, so the equation reads $0 = \kappa T^\nu{}_\mu$, and for a coupling $\kappa \neq 0$ every off-diagonal entry of the source must vanish (PROVED; the table below names the record's entries and checks). For a condensate the record turns this into conditions on the 15 bilinears: the six B_{j48} must vanish, and on a deflating history ($a_4' \neq 0$) the nine B_{i4t} as well. So on a deflating history a condensate meets the off-diagonal conditions only if all 15 bilinears vanish, as for the witnesses.

the linear history: A enters only through even powers	`Revision/field_equations_a4/a4-equations.json`	`linearMember`

The theorem of the linear history (PROVED; record entry `theoremLinear`, see the table). Its hypotheses are four: (1) Φ is a homogeneous condensate of the commuting field that solves its field equation; (2) it meets the off-diagonal conditions above; (3) a_4 is twice continuously differentiable (a_4' and a_4'' exist and are continuous functions of x_4); (4) the three Lovelock couplings $\alpha_1, \alpha_2, \alpha_3$ of Chapter 12 are not all zero. Its conclusion: if the author's metric with this a_4 solves the field equations of gravity with the condensate as the source, then $a_4 = AHx_4 + a_0$ with real constants A and a_0. The argument uses, besides (3) and (4), the equality $p_3 = p_t$ of a condensate and one equation of the record:

- the evolution equation, the 3-space equation minus the extra-time equation, is $a_4'' F(a_4') = \kappa(p_3 - p_t)$ with $F = 2\alpha_1 - 48(a_4')^2\alpha_2 + 720(a_4')^4\alpha_3 - 80\alpha_2H^2 + 864(a_4')^2\alpha_3H^2 + 720\alpha_3H^4$ (see the table);
- a condensate has $p_3 = p_t$ (Section 9.19: all seven pressures equal $SU' - U$), so $a_4'' F(a_4') = 0$ at every time;
- F is a polynomial in a_4' that is not the zero polynomial: its coefficient of $(a_4')^4$ is $720\alpha_3$; if $\alpha_3 = 0$, its coefficient of $(a_4')^2$ is $-48\alpha_2$; if $\alpha_2 = \alpha_3 = 0$, its constant term is $2\alpha_1$; by (4) one of these is not zero, so F has at most four roots (see the table);
- suppose $a_4'' \neq 0$ at some time; since a_4'' is continuous it stays different from zero on a small interval around that time, where a_4' is then strictly increasing or strictly decreasing and takes infinitely many different values; but $a_4'' F(a_4') = 0$ forces $F(a_4') = 0$ on that interval, so F would have infinitely many roots, which is impossible; hence $a_4'' = 0$ at every time;
- so a_4' is a constant, which we write AH, and integrating once more gives $a_4 = AHx_4 + a_0$.

Deflation is a choice of sign. The equations of the linear history contain A only through A^2, A^4 and A^6 (record entry `linearMember`), so they do not change when A is replaced by $-A$: extra times that deflate ($A > 0$, the author's history), extra times that inflate ($A < 0$) and the static case ($A = 0$) are allowed on exactly the same footing. That the author's extra times deflate is a choice of sign, an initial condition; the equations do not select it (record entry `theoremLinear`; Chapter 12).

What is and is not known about a condensate as the source. The Revision record contains no check that combines a witness with the remaining equations of gravity for definite values of κ, Λ, m, λ and A. Chapter 12 makes that combination for Einstein gravity: Notebook 12d constructs, with exact arithmetic, condensates whose 15 bilinears vanish and chooses m, λ and Λ so that all the Einstein equations hold on the deflating history $a_4 = Hx_4$; that is a computation of the book under stated ASSUMED inputs, not a Revision record, and Chapter 12 gives its status. For Einstein-Lovelock gravity with α_2 or α_3 different from zero no such solution is constructed, in the record or in this book (OPEN).

Conservation of the full tensor. The Noether identity proves $\nabla_\mu T^\mu{}_\nu = 0$ for every solution, the 42 off-diagonal entries included (Section 9.9). Notebook 09c tests it numerically on a condensate along the curved history $a_4 = 0.3x_4 + 0.05x_4^2$, with a **negative control**: a configuration built so that the test must fail, which shows that the test can detect an error. The control is the condensate of an equation without the gravitational term $3H\gamma^{(0)}$ ($M = -V\gamma^{(4)}$). Its S is constant and its $K_4 = \frac{1}{2}\bar{\Phi}\{\gamma^{(4)}, M\}\Phi = \frac{1}{2}(-V)(-2)S = VS$ is the same as for the true condensate, so its energy density and pressures, and with them the energy balance (x_4) and the hidden balance (x_0), are unchanged; but it does not solve the field equation of the author's metric, and its six momentum balances along 3-space and the extra times fail.

9.27 Example: the full tensor of a condensate

The third worked example computes all 64 entries of the tensor of exact condensates. It shows the tensor of a generic condensate (effective mass $V = 5$, $H = 1$, at the point $a_4 = 0.5$, $a_4' = 0.25$, $z = \pi/4$) as a heat map and counts its nonzero off-diagonal entries (42, and 12 when $a_4' = 0$); shows how three entries depend on a_4'; checks that each of the 42 entries is a fixed multiple of one of 15 bilinears and that the multiple is exactly minus the record's coefficient; builds the record's three witnesses, checks the dimensions 8 and 1 of their construction, checks that their tensor is diagonal at 36 points and that their $S = 2|v_1^\dagger C v_2|^2$, and reproduces the record's frequencies and values of S; and tests the conservation of the full tensor with finite differences along a curved history, with the negative control. In this notebook the matrix of the condensate equation is called $A = -\gamma^{(4)}(V - 3H\gamma^{(0)})$; it is the matrix M of Section 9.18 (multiply out: $-V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}$), and it has nothing to do with the constant A of the history $a_4 = AHx_4$. The angular frequency of the witnesses is called ω (in the code `freq`), to keep it apart from the equation of state w. The notebook draws five figures.

9.28 How to run Notebook 09c

Step 1. What this notebook does and what it needs.

Notebook 09c (The full energy-momentum tensor of a condensate) is the file `Revision/textbook/notebooks/09c_condensate_tensor.ipynb` of the repository Dirac_claude. It computes all 64 entries of the energy-momentum tensor of exact condensates of the commuting field dirac16complex00 in the author's metric, including the off-diagonal entries that the spin connection produces, finds the 42 nonzero off-diagonal entries of a generic condensate and checks that each is a multiple of one of 15 three-gamma bilinears with exactly the coefficient that the record lists for it, builds the exact condensates whose tensor is diagonal and reproduces their frequencies omega and their S from the record (S up to one common factor), and tests the conservation of the full tensor along a curved history with finite differences of shrinking step, with a negative control that leaves out the gravitational term of the field equation; five teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09c_condensate_tensor.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09c_condensate_tensor.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 09c_condensate_tensor.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/09c.captions.json`
- `Revision/textbook/figures/09c_1_generic_condensate.png`
- `Revision/textbook/figures/09c_2_offdiagonal_entries.png`
- `Revision/textbook/figures/09c_3_witness_condensate.png`
- `Revision/textbook/figures/09c_4_conservation_convergence.png`
- `Revision/textbook/figures/09c_5_divergence_components.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the five figures of this notebook are saved and captioned
ALL 25 CHECKS PASSED (notebook 09c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/09c_condensate_tensor.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 09c_condensate_tensor.ipynb
python -m nbconvert --execute --inplace 09c_condensate_tensor.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not contain that check: your copy is older or newer than the notebook. Run `git pull` in the repository folder, then run the notebook again.

9.29 Notebook 09c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/09c_condensate_tensor.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A condensate (a field that depends on the time $x_4$ only) has the same energy
density and pressure in every direction. That does not yet make it a *perfect
fluid*: a perfect fluid at rest has a diagonal energy-momentum tensor, and the
spin connection of the author's metric puts entries off the diagonal. This
notebook computes all 64 entries of the tensor of exact condensates of
dirac16complex00 and
```

```
- shows the tensor of a generic condensate as a heat map and counts its nonzero
  off-diagonal entries: 42 on the deflating history, 12 when $a_4' = 0$;
- shows how these entries depend on the deflation rate $a_4'$;
- checks that each of the 42 entries is a multiple of one of 15 *three-gamma
  bilinears* $\bar\Phi\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$, with exactly the
  coefficient that the Revision record lists for it;
- builds the exact condensates of the Revision record for which all 15
  bilinears vanish, and checks that their tensor is diagonal at 36 points with
  different $a_4$, $a_4'$ and $z$ (the record states it for all of them);
- shows why $S$ of these condensates is never negative, and reproduces the
  record's numbers for them: their frequencies $\omega = 4, 3, 4$ exactly, and
  its three values of $S$ up to one common factor (the record's columns are not
  of length 1);
- tests the conservation $\nabla_\mu T^\mu{}_\nu = 0$ of the full tensor of a
  condensate along a curved (non-linear) history with finite differences whose
  step shrinks, and contrasts it with a configuration that leaves out the
  gravitational term $3H\gamma^{(0)}$ of the field equation (a negative control);
- draws five teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 09c (The full energy-momentum tensor of a condensate) is the file
‘Revision/textbook/notebooks/09c_condensate_tensor.ipynb‘ of the repository Dirac_claude.
It computes all 64 entries of the energy-momentum tensor of exact condensates of the
commuting field dirac16complex00 in the author's metric, including the off-diagonal
entries that the spin connection produces, finds the 42 nonzero off-diagonal entries of a
generic condensate and checks that each is a multiple of one of 15 three-gamma bilinears
with exactly the coefficient that the record lists for it, builds the exact condensates
whose tensor is diagonal and reproduces their frequencies omega and their S from the
record (S up to one common factor), and tests the conservation of the full tensor along a
curved history with finite differences of shrinking step, with a negative control that
leaves out the gravitational term of the field equation; five teaching plots. It needs a
computer with Windows 11, macOS or Linux, an internet connection for the installation,
the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
```

"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in
this one window only; it changes nothing permanently.

macOS (zsh):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 09c_condensate_tensor.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 09c_condensate_tensor.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 09c_condensate_tensor.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/09c.captions.json‘
- ‘Revision/textbook/figures/09c_1_generic_condensate.png‘
- ‘Revision/textbook/figures/09c_2_offdiagonal_entries.png‘
- ‘Revision/textbook/figures/09c_3_witness_condensate.png‘
- ‘Revision/textbook/figures/09c_4_conservation_convergence.png‘
- ‘Revision/textbook/figures/09c_5_divergence_components.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the five figures of this notebook are saved and captioned
ALL 25 CHECKS PASSED (notebook 09c)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/09c_condensate_tensor.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

  ```
  python -m jupyterlab 09c_condensate_tensor.ipynb
  python -m nbconvert --execute --inplace 09c_condensate_tensor.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

- "KeyError" with the words "has no check": the notebook asks a Revision report for the verdict of one of its checks, and the report in your copy of the repository does not contain that check: your copy is older or newer than the notebook. Run ‘git pull‘ in the repository folder, then run the notebook again.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 09c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 09c (The full energy-momentum tensor of a condensate) is the file
# Revision/textbook/notebooks/09c_condensate_tensor.ipynb of the repository Dirac_claude.
# It computes all 64 entries of the energy-momentum tensor of exact condensates of the
# commuting field dirac16complex00 in the author's metric, including the off-diagonal
# entries that the spin connection produces, finds the 42 nonzero off-diagonal entries of
# a generic condensate and checks that each is a multiple of one of 15 three-gamma
# bilinears with exactly the coefficient that the record lists for it, builds the exact
# condensates whose tensor is diagonal and reproduces their frequencies omega and their S
# from the record (S up to one common factor), and tests the conservation of the full
# tensor along a curved history with finite differences of shrinking step, with a
# negative control that leaves out the gravitational term of the field equation; five
# teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
# shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
```

```
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
```

```
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 09c_condensate_tensor.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
```

```
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 09c_condensate_tensor.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 09c_condensate_tensor.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/09c.captions.json
# - Revision/textbook/figures/09c_1_generic_condensate.png
# - Revision/textbook/figures/09c_2_offdiagonal_entries.png
# - Revision/textbook/figures/09c_3_witness_condensate.png
# - Revision/textbook/figures/09c_4_conservation_convergence.png
# - Revision/textbook/figures/09c_5_divergence_components.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the five figures of this notebook are saved and captioned
#     ALL 25 CHECKS PASSED (notebook 09c)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
```

```
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/09c_condensate_tensor.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 09c_condensate_tensor.ipynb
#     python -m nbconvert --execute --inplace 09c_condensate_tensor.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "KeyError" with the words "has no check": the notebook asks a Revision report for the
#   verdict of one of its checks, and the report in your copy of the repository does not
#   contain that check: your copy is older or newer than the notebook. Run git pull in
#   the repository folder, then run the notebook again.
#

```
## 3. The words used in this notebook

- **Condensate**: a configuration that depends only on the time $x_4$.
- **Diagonal / off-diagonal entry**: the entry $T^\nu{}_\mu$ with $\nu = \mu$ /
  with $\nu \neq \mu$. Off-diagonal entries describe flows of energy and momentum
  (for example $T^{x_4}{}_{x_1}$ is a flow of momentum along $x_1$) and stresses
  that shear.
- **Perfect fluid (at rest)**: matter whose energy-momentum tensor is diagonal,
  with the energy density and the pressures on the diagonal.
- **Three-gamma bilinear**: the number $\bar\Phi\gamma^{(a)}\gamma^{(b)}
  \gamma^{(c)}\Phi$ for three different directions $a$, $b$, $c$.
- **Eigenvector, joint eigenvector**: a column $v$ with $Mv = \mu v$ for a
  number $\mu$ (the eigenvalue); a joint eigenvector of several matrices is an
  eigenvector of each of them.
- **Witness**: an explicit example that proves that something exists.
- **Trace** of a square matrix: the sum of its diagonal entries.
- **Rank** of a matrix: the number of its independent columns.
- **Projector**: a matrix $\Pi$ with $\Pi^2 = \Pi$; it keeps some columns
  unchanged and sends others to zero, and its trace is the dimension of the
  space it keeps.
- **Sector**: the columns $v$ of one eigenvalue space of $A$ with fixed signs
  $P_1v = \pm v$, $P_2v = \pm v$, $P_3v = \pm v$ (the matrices $P_k$ are defined
  in section 8).
- **Frequency** $\omega$ (the Greek letter omega): the number in the factor
  $e^{-i\omega x_4} = \cos(\omega x_4) - i\sin(\omega x_4)$; a field with this
  factor repeats itself after the time $2\pi/\omega$. It has nothing to do with
  the equation of state $w = p/\rho$ of the other examples of this chapter.
- **Finite difference**: the derivative approximated by
  $\frac{F(x + h) - F(x - h)}{2h}$; its error falls like $h^2$ when the step $h$
  shrinks, until rounding errors take over.
- **Covariant divergence**: $\nabla_\mu T^\mu{}_\nu = \partial_\mu T^\mu{}_\nu
  + \Gamma^\mu{}_{\mu\lambda}T^\lambda{}_\nu - \Gamma^\lambda{}_{\mu\nu}
  T^\mu{}_\lambda$, with the Christoffel symbols $\Gamma$.
- **Negative control**: a test case built so that the check must FAIL; it shows
  that the check can detect an error.
```

Text cell:

```
## 4. The physical and mathematical situation

**The condensates.** For a field that depends on $x_4$ only, the field equation
of dirac16complex00 in the author's metric reduces to $\partial_4\Phi = A\Phi$
with $A = -\gamma^{(4)}(V - 3H\gamma^{(0)})$ and the effective mass
$V = m + \lambda S$; $S$ is constant, and the exact solution is
$\Phi = e^{Ax_4}\chi$. It does not contain $a_4$: it solves the equation on every
history $a_4(x_4)$.

**The tensor.** $T^\nu{}_\mu = \delta^\nu_\mu L_0 - \frac14(\bar\Phi\gamma^\nu
D_\mu\Phi - D_\mu\bar\Phi \gamma^\nu\Phi + \bar\Phi\gamma_\mu D^\nu\Phi
- D^\nu\bar\Phi \gamma_\mu\Phi)$ with $D_\mu\Phi = \partial_\mu\Phi
```

```
+ \Omega_\mu\Phi$. For a condensate $\partial_\mu\Phi = 0$ for $\mu \neq x_4$,
but $D_\mu\Phi = \Omega_\mu\Phi$ is not zero along 3-space and the extra times,
because the spin connection $\Omega_{x_i}$, $\Omega_{x_t}$ is not zero. This is
what fills the off-diagonal entries.

**The record** (‘Revision/field_equations_a4/reports/wolfram-a4-report.json‘ and
the independent ‘python-a4-report.json‘): for a condensate the diagonal is
$T^{x_4}{}_{x_4} = -VS + L_0$ and $T^\mu{}_\mu = L_0$ otherwise, and
$T^{x_4}{}_{x_0} = T^{x_0}{}_{x_4} = 0$; 42 ordered pairs $(\nu, \mu)$ carry
nonzero off-diagonal entries, each a multiple of one of the 15 bilinears with
$\{a, b, c\} = \{i, x_4, x_0\}$ ($i$ any of $x_1, x_2, x_3, x_5, x_6, x_7$) or
$\{i, j, x_4\}$ ($i$ in 3-space, $j$ an extra time); and exact witnesses exist
for which all 15 vanish. The field equations for $a_4$ require, among other
conditions, that every off-diagonal entry of the source vanishes (for a
coupling $\kappa \neq 0$; record
‘Revision/field_equations_a4/a4-equations.json‘, entries
‘generalSource.offDiagonal_other‘ and
‘fields.dirac16complex00.offDiagonalConditions‘); on the deflating history a
condensate meets this one condition only if all 15 bilinears vanish, as for the
witnesses.

**Conservation.** The record proves $\nabla_\mu T^\mu{}_\nu = 0$ for every
solution (the Noether identity of coordinate invariance) and checks it exactly
on the condensate (‘exact_solution_nonlinear_homogeneous_C‘). This notebook
tests it numerically, for all eight components and with the off-diagonal entries
included, along the non-linear history $a_4 = 0.3x_4 + 0.05x_4^2$.
```

```
## 5. The gammas, the geometry and the tensor at a point

The next cell reads the Revision gammas and $C$ from the fixture
‘Revision/algebra/gammas.json‘ and defines two helpers for the Revision
reports: ‘record_entry(path, name)‘ returns the whole entry of one check (its
name, its verdict and its detail text), and ‘recorded(path, name)‘ returns only
its verdict (PASS or FAIL).
```

In [2]:

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]  # x0, ..., x7
eta = np.array(fixture["eta"], dtype=float)  # (+1, +1, +1, +1, -1, -1, -1, -1)
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
I16 = np.eye(16)  # the 16 x 16 unit matrix
g4, g0 = gamma[4], gamma[0]  # gamma^(x4) and gamma^(x0)
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # the author's coordinates

def record_entry(path, name):
```

```
    """The entry (name, verdict, detail) of the check name in the report path."""
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for item in report_data["checks"]:
        if item["name"] == name:
            return item
    raise KeyError(f"{path} has no check {name}")

```

Text cell:

```
The next cell defines the geometry at one point, the same functions as in the
first example of this chapter: ‘frame_factors(a4, z)‘ returns the eight vielbein
factors $f_a$ in the order $x_0, \dots, x_7$ ($\cot z$, $e^{a_4}\sin^{1/6}z$ three
times, $1$, $e^{-a_4}\sin^{1/6}z$ three times; the background $b_4 = 1$), and
‘spin_connection(a4, a4p, z, H)‘ returns the eight
$16 \times 16$ matrices $\Omega_\mu$ of the record’s formula ‘Omega_components‘:
$\Omega_{x_i} = \frac12 e^{a_4}\sin^{1/6}z (a_4’\gamma^{(i)}\gamma^{(4)}
+ H\gamma^{(i)}\gamma^{(0)})$, $\Omega_{x_t} = -\frac12 e^{-a_4}\sin^{1/6}z
(a_4’\gamma^{(4)}\gamma^{(t)} + H\gamma^{(t)}\gamma^{(0)})$ and
$\Omega_{x_4} = \Omega_{x_0} = 0$.
```

In [3]:

```
def frame_factors(a4, z):
    """The eight factors f_a of the diagonal vielbein, in the order x0, ..., x7."""
    space = np.exp(a4) * np.sin(z) ** (1 / 6)  # 3-space: e^a4 sin^(1/6) z

## 6. The tensor of a generic condensate

The next cell takes the effective mass $V = 5$ ($m = 5$, $\lambda = 0$), the
constant $H = 1$, a random column $\chi$ of length 1 (fixed seed), and the point
$a_4 = 0.5$, $a_4' = 0.25$, $z = \pi/4$ of a deflating history. The condensate's
jet at the point is $\Phi = \chi$ and $\partial_4\Phi = A\chi$ (the solution at
$x_4 = 0$; any other time gives another column $\chi$ with the same $S$). The
cell computes the 64 entries, checks the record's diagonal ($T^{x_4}{}_{x_4} =
-VS$ and the other diagonal entries $0$, because $\lambda = 0$ makes $L_0 = 0$ on
shell) and $T^{x_4}{}_{x_0} = T^{x_0}{}_{x_4} = 0$, counts the nonzero
off-diagonal entries (42), and counts them again with $a_4' = 0$ (12: only the
flows $T^{x_4}{}_{x_j}$ and $T^{x_j}{}_{x_4}$ remain, where $x_j$ is one of the
six directions $x_1, x_2, x_3, x_5, x_6, x_7$).
```

## 7. How the off-diagonal entries depend on the deflation rate

The next cell computes three off-diagonal entries of the same condensate at the
same point for 41 values of $a_4'$ from $-1$ to $1$: the momentum flow
$T^{x_4}{}_{x_1}$, the 3-space/extra-time entry $T^{x_1}{}_{x_5}$ and the
3-space/hidden entry $T^{x_1}{}_{x_0}$. The first does not depend on $a_4'$ (it
comes from the $H$ part of the spin connection); the other two are proportional
to $a_4'$, so they appear only because the extra times deflate (or, for
$a_4' < 0$, inflate). The cell checks both statements.
```

## 8. The 15 three-gamma bilinears and the condensates with a diagonal tensor

**Each entry is one bilinear.** The record says that each of the 42 nonzero
off-diagonal entries is a multiple of one bilinear
$\bar\Phi\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$: for the pair $(\nu, \mu)$
the three directions are $\nu$, $\mu$ and the missing one of $x_4$, $x_0$ (or
$x_4$ when neither occurs). The next cell checks this by computing the ratio of
each entry to its bilinear for three different random columns: the ratio must
be the same number for all three (it depends on the point and on $V$, $H$, not on
the column). It also checks that exactly 15 bilinears occur.
```

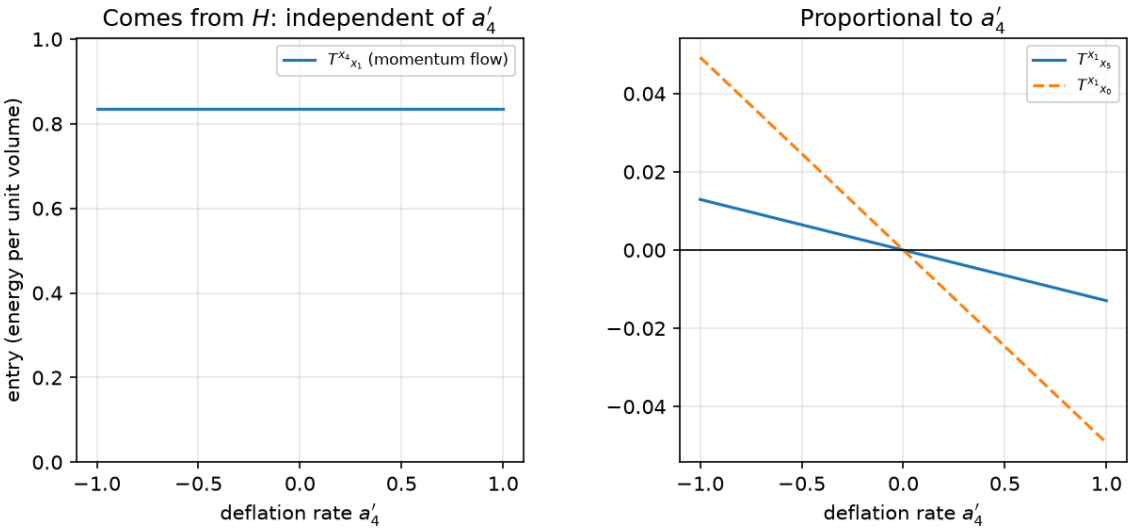

Figure 263: Three off-diagonal entries of the generic condensate of the previous figure ($V = 5$, $H = 1$, $a_4 = 0.5$, $z = \pi/4$) against the deflation rate a_4' from -1 to 1, in units of energy per unit volume. Left: the momentum flow $T^{x_4}{}_{x_1}$ comes from the H part of the spin connection and does not depend on a_4'. Right: $T^{x_1}{}_{x_5}$ (solid) and $T^{x_1}{}_{x_0}$ (dashed) are proportional to a_4'; at $a_4' = 0$ they vanish, and only the 12 flows $T^{x_4}{}_{x_j}$ and $T^{x_j}{}_{x_4}$ remain (x_j one of $x_1, x_2, x_3, x_5, x_6, x_7$). (Notebook 09c, figure 2.)

```
**The witnesses.** The record builds condensates for which all 15 bilinears
vanish. The three matrices $P_1 = \gamma^{(1)}\gamma^{(5)}$,
$P_2 = \gamma^{(2)}\gamma^{(6)}$, $P_3 = \gamma^{(3)}\gamma^{(7)}$ square to 1 and
commute with each other and with $A$. Let $\omega = \sqrt{V^2 - 9H^2}$ (a real
number when $V^2 > 9H^2$); then $A^2 = (9H^2 - V^2) \cdot 1 = -\omega^2 \cdot 1$,
and $A$ has the eigenvalue $-i\omega$ on an 8-dimensional space: every column
$u$ is the sum of $\frac12(u + \frac{i}{\omega}Au)$, with eigenvalue $-i\omega$,
and $\frac12(u - \frac{i}{\omega}Au)$, with eigenvalue $+i\omega$, and because
$A$ is real, complex conjugation carries the one space onto the other, so both
have dimension $16/2 = 8$. The three $P_k$ split that space into eight sectors
(one for each choice of the signs of $P_1$, $P_2$, $P_3$). The matrix that keeps
one sector, $\frac12(1 + \frac{i}{\omega}A) \cdot \frac12(1 \pm P_1) \cdot
\frac12(1 \pm P_2) \cdot \frac12(1 \pm P_3)$, has trace 1, because every
product of different gammas has trace 0; so every sector has dimension 1. In
the sector $P_1 = P_2 = P_3 = -1$ take a unit vector $v_1$ and in the sector
$P_1 = P_2 = P_3 = +1$ a unit vector $v_2$ (each unique up to a factor of size
1, which does not change the bilinears), put $c = \overline{v_1^\dagger Cv_2}$
(the bar means the complex conjugate number) and $\Phi_0 = v_1 + cv_2$. The
condensate is $\Phi = e^{-i\omega x_4}\Phi_0$: it oscillates with the frequency
$\omega$. The record gives three such witnesses, $(V, H) = (5, 1)$, $(5, 4/3)$,
$(-5, 1)$, with $\omega = 4$, $3$, $4$ (the record writes the effective mass $V$
as $M$ and the frequency $\omega$ as w).

**The coefficients of the record.** The record
‘Revision/field_equations_a4/a4-equations.json‘ lists, for each of the 42
entries, its bilinear and its coefficient as a formula in the Wolfram Language,
in the names ‘cc‘ $= \cot z$, ‘a4v‘ $= a_4$, ‘ad1‘ $= a_4’$ and ‘H‘, for the
symmetrised kinetic tensor $K^{(\nu}{}_{\mu)}$, the average of
$K^\nu{}_\mu = \frac12(\bar\Phi\gamma^\nu D_\mu\Phi - D_\mu\bar\Phi\gamma^\nu\Phi)$
and of $g^{\nu\nu}g_{\mu\mu}K^\mu{}_\nu$ (the same with the two indices
exchanged, then moved back to their places with the metric). Off the diagonal the
tensor is $T^\nu{}_\mu = -K^{(\nu}{}_{\mu)}$, so every entry must equal minus
the coefficient times the bilinear. The next cell translates each formula into
sympy (‘E^x‘ becomes ‘E**x‘, ‘^‘ becomes ‘**‘), evaluates it at the point
$a_4 = 0.5$, $a_4’ = 0.25$, $z = \pi/4$, $H = 1$, and compares, for the generic
condensate and for the three random columns, all 42 entries. The coefficients
contain $V$ nowhere: they are the same for every effective mass. The cell prints
one entry of each of the ten groups of equal coefficients.

```
The next cell defines the function ‘witness(V_w, H_w)‘. It finds the
8-dimensional space of $A$ for the eigenvalue $-i\omega$ (as the null space of
$A + i\omega$, from a singular value decomposition), then inside it the joint
eigenvectors $v_1$, $v_2$ (with the projector
$\frac18(1 \pm P_1)(1 \pm P_2)(1 \pm P_3)$, which keeps exactly the vectors with
$P_1 = P_2 = P_3 = \pm1$), each of length 1, and returns $\omega$, $A$, $v_1$,
$v_2$ and $\Phi_0 = v_1 + cv_2$ (in the code the frequency $\omega$ is called
‘freq‘). The cell builds the three witnesses and prints their frequencies
$\omega = \sqrt{V^2 - 9H^2}$. It then checks the two dimensions of the
construction with numbers: each of the $2^8 - 1 = 255$ products of 1 to 8
different gammas has trace 0; for each witness the space of $A$ for $-i\omega$
has dimension 8 (the rank of $A + i\omega$ is $16 - 8$); and the matrix that keeps
one sector has trace 1 for all eight choices of the three signs.
```

**Why $S$ of a witness is never negative.** $C$ anticommutes with each $P_k$ (it
contains $\gamma^{(x_k)}$ but not $\gamma^{(x_{k+4})}$), and each $P_k$ is real
```

```
and symmetric, so $P_k^\dagger = P_k$. Take $P_1v_1 = -v_1$. Then, line by line:
$v_1^\dagger Cv_1 = -v_1^\dagger CP_1v_1$ (replace $v_1$ by $-P_1v_1$)
$= v_1^\dagger P_1Cv_1$ ($CP_1 = -P_1C$) $= (P_1v_1)^\dagger Cv_1$
($P_1^\dagger = P_1$) $= -v_1^\dagger Cv_1$ ($P_1v_1 = -v_1$). A number equal to
minus itself is zero: $v_1^\dagger Cv_1 = 0$, and in the same way
$v_2^\dagger Cv_2 = 0$. Write $s = v_1^\dagger Cv_2$; then
$v_2^\dagger Cv_1 = \bar s$ ($C$ is real and symmetric) and $c = \bar s$, so
$S = \Phi_0^\dagger C\Phi_0 = v_1^\dagger Cv_1 + c\,s + \bar c\,\bar s
+ |c|^2 v_2^\dagger Cv_2 = 0 + |s|^2 + |s|^2 + 0 = 2|s|^2 \geq 0$. The next cell
checks each step numerically for the three witnesses. It also checks an
observation (COMPUTED for these three witnesses, not proved here): with $v_1$,
$v_2$ of length 1, $|s| = |\omega/V|$, so $S = 2\omega^2/V^2$; this gives
$2 \cdot 16/25 = 1.28$ and $2 \cdot 9/25 = 0.72$.

```
**The numbers of the record.** The Wolfram report of the record lists, in the
detail text of its check ‘condensate_diagonal_witness_exact‘, the frequencies
$\omega$ (written w there) and the values of $S$ of the three witnesses. The
record’s verifier builds the witnesses with exact columns $v_1$, $v_2$ that are
not of length 1; since $S = 2|v_1^\dagger Cv_2|^2$ grows with the lengths of
$v_1$ and $v_2$, its $S$ cannot equal ours, while $\omega = \sqrt{V^2 - 9H^2}$
must agree exactly. The next cell reads the numbers out of the detail text (with
a regular expression, a pattern that finds text), prints them, checks $\omega$,
and divides each $S$ of the record by our $S$: the three quotients must be one
and the same number, so that the record’s three values are reproduced up to one
common factor, which the cell prints. That factor is the product of the squared
lengths of the record’s columns, a choice of its verifier, not a physical
number.
```

The next cell draws the tensor of the witness $(V, H) = (5, 1)$ at the same point
and with the same colour scale as the generic condensate: only one square is
coloured. (The value of $S$, and hence of $-VS$, depends on the lengths of $v_1$
and $v_2$; here both have length 1, so $S = 1.28$ and $-VS = -6.4$.)
```

In [14]:

```
T_witness = condensate_tensor(witness_columns[(5.0, 1.0)], **POINT)
fig, ax = plt.subplots(figsize=(6.6, 5.6))
picture = heat_map(ax, T_witness, "Witness condensate: $T^\\nu{}_\\mu$", SCALE)
fig.colorbar(picture, ax=ax, label="value (energy per unit volume)", extend="both")
save_figure(fig, "witness_condensate",
            "Heat map of the 64 entries $T^\\nu{}_\\mu$ of the exact witness "
```

```
            "condensate $\\Phi = e^{-4ix_4}\\Phi_0$ of the Revision record with "
            "$V = 5$, $H = 1$, $\\lambda = 0$, at the same point "
            "($a_4 = 0.5$, $a_4' = 0.25$, $z = \\pi/4$) and with the same colour "
            "scale as the generic condensate, in units of energy per unit volume. "
            "All 15 three-gamma bilinears of $\\Phi_0$ vanish, so every off-diagonal "
            "entry is zero (by the record, at every point of every history): this "
            "condensate is a perfect fluid at rest, with $T^{x_4}{}_{x_4} = -VS$ "
            "and zero pressure.")
check(len(off_diagonal_pairs(T_witness)) == 0 and abs(T_witness[4, 4]) > 0.1,
      "the drawn witness tensor is diagonal with T^x4_x4 = -V S != 0")
```

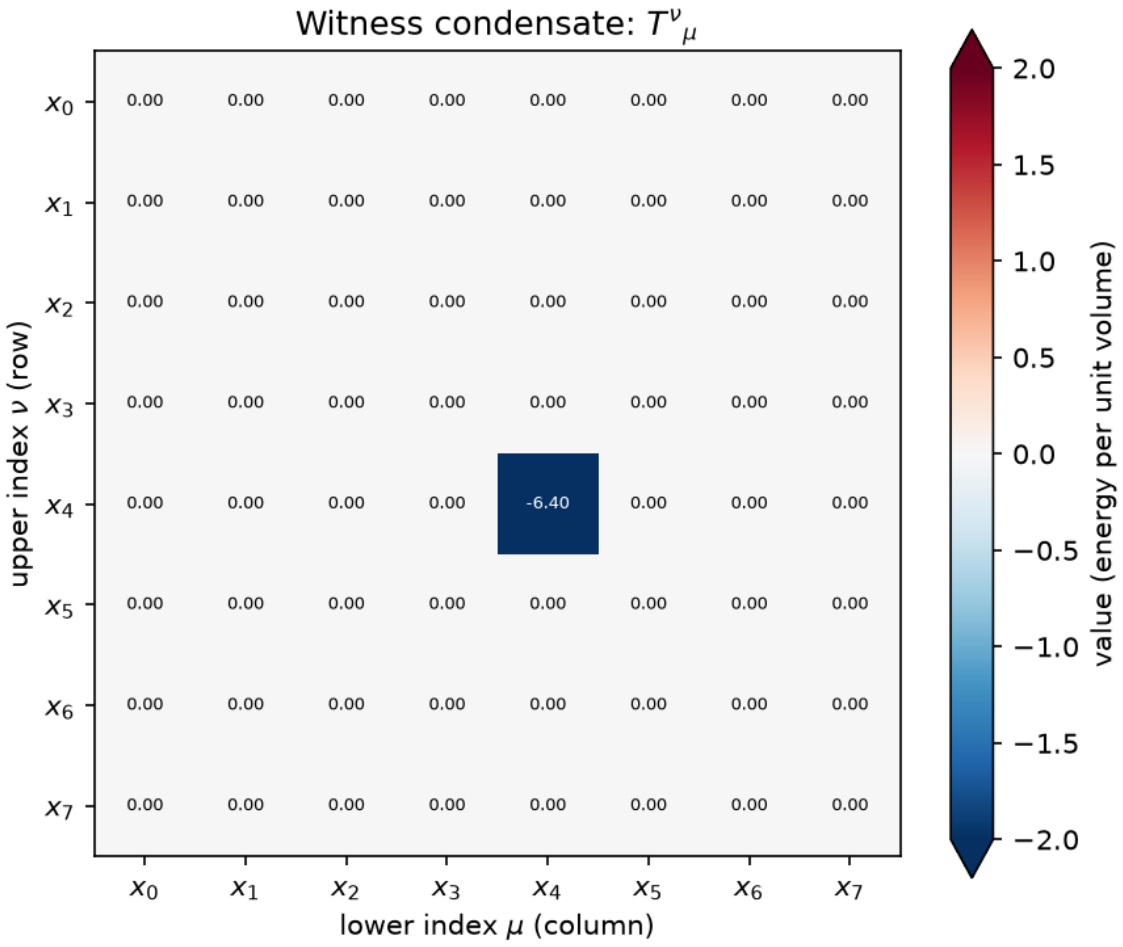

Figure 264: Heat map of the 64 entries $T^{\nu}{}_{\mu}$ of the exact witness condensate $\Phi = e^{-4ix_4}\Phi_0$ of the Revision record with $V = 5$, $H = 1$, $\lambda = 0$, at the same point ($a_4 = 0.5$, $a_4' = 0.25$, $z = \pi/4$) and with the same colour scale as the generic condensate, in units of energy per unit volume. All 15 three-gamma bilinears of Φ_0 vanish, so every off-diagonal entry is zero (by the record, at every point of every history): this condensate is a perfect fluid at rest, with $T^{x_4}{}_{x_4} = -VS$ and zero pressure. (Notebook 09c, figure 3.)

## 9. Conservation of the full tensor, tested with finite differences

The full tensor of a condensate, off-diagonal entries included, must satisfy
$\nabla_\mu T^\mu{}_\nu = 0$. Because the condensate solves the field equation on
every history, the test uses a non-linear one, $a_4 = 0.3x_4 + 0.05x_4^2$
($a_4' = 0.3 + 0.1x_4$), with $m = 1$, $\lambda = 0.5$, $H = 0.25$ and a random
unit column $\chi$. The tensor depends on $x_4$ (through $\Phi$, $a_4$ and $a_4'$)
and on $x_0$ (through $z$); the derivatives $\partial_4 T$ and $\partial_0 T$ are
taken by central finite differences with step $h$.

The next cell computes the 25 Christoffel symbols of the metric with sympy
(the formula $\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2g_{\lambda\lambda}}
(\partial_\mu g_{\lambda\nu} + \partial_\nu g_{\lambda\mu}
- \partial_\lambda g_{\mu\nu})$ of a diagonal metric), puts the history into
them and turns each into a fast numpy function of $(x_4, x_0, H)$ with
`sp.lambdify`.
```

In [15]:

```
x = sp.symbols("x0:8", real=True)  # sympy was imported in section 8
Hs = sp.symbols("H", positive=True)
a4_function = sp.Function("a4")(x[4])
zs = 6 * Hs * x[0]

extra_entry = -sp.exp(-2 * a4_function) * sp.sin(zs) ** sp.Rational(1, 3)
g = sp.diag(*([sp.cot(zs) ** 2] + [space_entry] * 3 + [-1] + [extra_entry] * 3))
history = sp.Rational(3, 10) * x[4] + sp.Rational(1, 20) * x[4] ** 2  # a4(x4)
christoffel = {}  # (l, i, j) with i <= j -> a numpy function of (x4, x0, H)
for l in range(8):
    for i in range(8):
        for j in range(i, 8):
            value = sp.simplify((sp.diff(g[l, j], x[i]) + sp.diff(g[l, i], x[j])
                                 - sp.diff(g[i, j], x[l])) / (2 * g[l, l]))
            if value != 0:  # put the history in, then make a numpy function
                christoffel[(l, i, j)] = sp.lambdify(
                    (x[4], x[0], Hs), value.subs(a4_function, history).doit(), "numpy")
check(len(christoffel) == 25, "25 nonzero Christoffel symbols (i <= j)")
```

Out [15]:

```
PASS 25 nonzero Christoffel symbols (i <= j)
```

Text cell:

```
The next cell builds the two condensates of the test and the divergence. The
true condensate uses $M = -V\gamma^{(4)} + 3H\gamma^{(4)}\gamma^{(0)}$; the
```

negative control uses $M = -V\gamma^{(4)}$, the condensate of an equation without the gravitational term $3H\gamma^{(0)}$. Its S is also constant, but it does not solve the field equation of the author's metric, so its tensor must not be conserved. The function `field(M, k2, x4)` returns $\Phi(x_4)$ and $\partial_4\Phi = M\Phi$, `tensor_at(M, k2, x4, x0)` the 64 entries of the tensor at a point of the history, and `divergence(M, k2, x4, x0, h)` the eight components of $\nabla_\mu T^\mu{}_\nu$, with the derivatives $\partial_4 T$ and $\partial_0 T$ replaced by central finite differences of step h (the tensor of a condensate depends on x_4 and x_0 only). The cell only defines; it prints the effective mass V of the test.

```

Text cell:

```
## 11. What this notebook showed

- A generic exact condensate of dirac16complex00 has the diagonal of a perfect
  fluid ($-VS$ at $x_4$, the same pressure elsewhere, zero for $\lambda = 0$) but
  42 nonzero off-diagonal entries, all produced by the spin connection: the 12
  flows $T^{x_4}{}_{x_j}$ and $T^{x_j}{}_{x_4}$ ($x_j$ one of the six directions
  of 3-space and of the extra times), which come from $H$, and 30 more that are
  proportional to the deflation rate $a_4'$. Its $x_4$-$x_0$ entries vanish.
- Each off-diagonal entry is a fixed multiple of one of 15 three-gamma bilinears
  (the record's statement, confirmed with three random columns), and the
  multiple is exactly minus the coefficient that the record lists for the
  entry (all 42 entries, ten groups of equal coefficients, four columns).
- The record's witnesses, built from joint eigenvectors of
  $\gamma^{(1)}\gamma^{(5)}$, $\gamma^{(2)}\gamma^{(6)}$, $\gamma^{(3)}\gamma^{(7)}$,
  make all 15 bilinears vanish: their tensor is diagonal (the record shows it for
  every $a_4$ and $a_4'$; this notebook checked 36 points). The space of the
  eigenvalue $-i\omega$ has dimension 8 and each of its eight sectors dimension
  1, so $v_1$ and $v_2$ are unique up to a factor of size 1. Their
  $S = 2|v_1^\dagger Cv_2|^2$ is never negative; the record's frequencies
  $\omega = 4, 3, 4$ are reproduced exactly and its three values of $S$ up to one
  common factor (the factor printed above; the record's columns are not of
  length 1).
  On the deflating history only condensates whose 15 bilinears all vanish, such
  as these, meet the condition of the $a_4$ field equations that the
```

```
  off-diagonal entries of the source vanish (one condition among several).
- The full tensor of a condensate is conserved, $\nabla_\mu T^\mu{}_\nu = 0$,
  along a curved history: the finite-difference divergence falls like $h^2$. A
  configuration that leaves out the gravitational term $3H\gamma^{(0)}$ keeps the
  energy balance but breaks the six momentum balances along 3-space and the
  extra times: the term is needed for the conservation of the tensor.
- Status: the statements are PROVED in the Revision record (exact, Wolfram and
  sympy); this notebook confirms them numerically (COMPUTED). The formula
  $S = 2\omega^2/V^2$ for unit $v_1$, $v_2$ is an observation for the three
  witnesses (COMPUTED, not proved). The parameter values are choices of this
  notebook.
```

9.30 Line-by-line walk-through of Notebook 09c

The notebook has 20 code cells, In [1] to In [20]. As in Section 9.17, long figure captions are shortened to a line "...)" and docstrings are left out here; the captions are printed in full in Section 9.29.

In [1], the set-up cell. It is word for word the set-up cell of Notebook 09a, explained line by line in Section 9.17, except that its comment lines are the run instructions of Notebook 09c (Section 9.28) and its line `NOTEBOOK_ID = "09c"` names this notebook. It prints `Set-up of notebook 09c complete:  repository folder found, helpers defined.`

In [2], the gammas and two report helpers.

```
import numpy as np  # arrays of numbers, matrices, linear algebra

fixture = json.loads(
    repository_file("Revision/algebra/gammas.json").read_text(encoding="utf-8"))
gamma = [np.array(rows, dtype=float) for rows in fixture["gamma"]]  # x0, ..., x7
eta = np.array(fixture["eta"], dtype=float)  # (+1, +1, +1, +1, -1, -1, -1, -1)
C = np.array(fixture["C"], dtype=float)  # gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
I16 = np.eye(16)  # the 16 x 16 unit matrix
g4, g0 = gamma[4], gamma[0]  # gamma^(x4) and gamma^(x0)
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # the author's coordinates
```

These lines read the eight real gammas, η and C from the fixture, as in In [2] of Notebooks 09a and 09b, and name $\gamma^{(4)}$, $\gamma^{(0)}$, the unit matrix and the coordinates.

```
def record_entry(path, name):
    """The entry (name, verdict, detail) of the check name in the report path."""
    report_data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for item in report_data["checks"]:
        if item["name"] == name:
            return item
    raise KeyError(f"{path} has no check {name}")

def recorded(path, name):
    """The verdict (PASS or FAIL) of the check name in the Revision report path."""
    return record_entry(path, name)["verdict"].upper()  # some reports write "pass"
```

```
say("The gammas, C and the two report helpers are ready.")
```

`record_entry` returns the whole entry of one check of a report (its name, its verdict and its **detail**, a text in which the record writes what it computed); In [13] reads numbers out of a detail text. `recorded` returns only the verdict, as in the other notebooks. The cell prints one line.

In [3], the geometry at a point.

```
def frame_factors(a4, z):
    """The eight factors f_a of the diagonal vielbein, in the order x0, ..., x7."""
    space = np.exp(a4) * np.sin(z) ** (1 / 6)  # 3-space: e^a4 sin^(1/6) z
    extra = np.exp(-a4) * np.sin(z) ** (1 / 6)  # extra times: e^(-a4) sin^(1/6) z
    return np.array([1 / np.tan(z)] + [space] * 3 + [1.0] + [extra] * 3)

def spin_connection(a4, a4p, z, H):
    """The eight matrices Omega_mu (record formula Omega_components)."""
    s = np.sin(z) ** (1 / 6)  # sin^(1/6) z
    omega = [np.zeros((16, 16)) for _ in range(8)]  # Omega_x4 = Omega_x0 = 0
    for i in range(1, 4):  # the three 3-space directions x1, x2, x3
        omega[i] = 0.5 * np.exp(a4) * s * (a4p * gamma[i] @ g4 + H * gamma[i] @ g0)
    for t in range(5, 8):  # the three extra times x5, x6, x7
        omega[t] = -0.5 * np.exp(-a4) * s * (a4p * g4 @ gamma[t] + H * gamma[t] @ g0)
    return omega

say("frame_factors and spin_connection are defined.")
```

The same two functions as in In [3] and In [5] of Notebook 09a (explained in Section 9.17), with one change: H is now an argument of `spin_connection`, because this notebook uses several values of H.

In [4], the Dirac adjoint and the tensor at a point.

```
def bar(vector):
    """The Dirac adjoint vector^dagger C."""
    return vector.conj() @ C

def energy_momentum(phi, dphi, m, lam, a4, a4p, z, H):
    """The 64 entries T[nu, mu] = T^nu_mu at one point (real parts)."""
    f = frame_factors(a4, z)
    g_values = eta * f ** 2  # g_mumu
    omega = spin_connection(a4, a4p, z, H)
    gup = [gamma[mu] / f[mu] for mu in range(8)]  # gamma^mu
    S = (bar(phi) @ phi).real
    D = [dphi[mu] + omega[mu] @ phi for mu in range(8)]  # D_mu Phi
    Dbar = [bar(dphi[mu]) - bar(phi) @ omega[mu] for mu in range(8)]  # D_mu Phibar
    L0 = 0.5 * sum(bar(phi) @ gup[mu] @ D[mu] - Dbar[mu] @ gup[mu] @ phi
                   for mu in range(8)) - m * S - lam / 2 * S ** 2
```

`bar` is the Dirac adjoint, as before. This `energy_momentum` takes the jet and the parameters m, λ, a_4, a_4', z and H, and builds everything at the point itself: the factors, the metric entries, the spin connection, the coordinate gammas, S, the covariant derivatives and L_0, each line as in In [6] of Notebook 09a.

```
    T = np.zeros((8, 8), dtype=complex)
    for nu in range(8):
        for mu in range(8):
            bracket = (bar(phi) @ gup[nu] @ D[mu] - Dbar[mu] @ gup[nu] @ phi
                       + g_values[mu] / g_values[nu]  # gamma_mu D^nu
                       * (bar(phi) @ gup[mu] @ D[nu] - Dbar[nu] @ gup[mu] @ phi))
            T[nu, mu] = (nu == mu) * L0 - bracket / 4
    if np.abs(T.imag).max() > 1e-9 * max(1.0, np.abs(T).max()):
        raise ValueError("the tensor is not real")  # it must be real
    return T.real

say("bar and energy_momentum are defined.")
```

The 64 entries are the formula of Section 9.6, with $\gamma_\mu D^\nu$ written as $(g_{\mu\mu}/g_{\nu\nu})\gamma^\mu D_\nu$. The function stops with a `ValueError` if the imaginary parts exceed rounding noise (the tensor must be real, Section 9.6), and otherwise returns the real parts.

In [5], the tensor of a generic condensate.

```
V, H = 5.0, 1.0  # effective mass (m = 5, lambda = 0) and the author's constant
POINT = {"a4": 0.5, "a4p": 0.25, "z": np.pi / 4}  # a point of a deflating history
rng = np.random.default_rng(11)  # a fixed seed
chi = rng.normal(size=16) + 1j * rng.normal(size=16)
chi /= np.linalg.norm(chi)  # length 1
```

The example has $V = 5$ (with $m = 5$ and $\lambda = 0$) and $H = 1$, so $V^2 > 9H^2$ and the condensate oscillates. `POINT` is a dictionary with the point $a_4 = 0.5$, $a_4' = 0.25$, $z = \pi/4$. The column χ is random (seed 11) and divided by its length.

```
def condensate_tensor(column, a4, a4p, z, V_value=V, H_value=H):
    """T of the condensate (lambda = 0, m = V_value) whose jet at the point is
    Phi = column and d4 Phi = A column, A = -gamma^(x4) (V - 3 H gamma^(x0))."""
    A_value = -g4 @ (V_value * I16 - 3 * H_value * g0)
    dphi = np.zeros((8, 16), dtype=complex)
    dphi[4] = A_value @ column  # the only nonzero derivative
    return energy_momentum(column, dphi, V_value, 0.0, a4, a4p, z, H_value)
```

The jet of a condensate at a point is $\Phi = \chi$ and $\partial_4\Phi = A\chi$ (the solution at $x_4 = 0$; at any other time the solution is another column with the same S, so nothing is lost), all other derivatives zero. `V_value=V` gives an argument a **default value**, used when the call leaves it out. With $\lambda = 0$ the mass m equals V.

```
def off_diagonal_pairs(T):
    """The ordered pairs (nu, mu), nu != mu, whose entry is not zero."""
```

```
    tolerance = 1e-10 * max(1.0, np.abs(T).max())
    return [(nu, mu) for nu in range(8) for mu in range(8)
            if nu != mu and abs(T[nu, mu]) > tolerance]
```

This function lists the pairs (ν, μ) off the diagonal whose entry is larger than rounding noise (10^{-10} times the largest entry, or 10^{-10}).

```
T_generic = condensate_tensor(chi, **POINT)
S_chi = (bar(chi) @ chi).real
expected_diagonal = np.zeros(8)
expected_diagonal[4] = -V * S_chi
A4_WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
A4_PY = "Revision/field_equations_a4/reports/python-a4-report.json"
check(np.abs(np.diag(T_generic) - expected_diagonal).max() < 1e-12
      and abs(T_generic[4, 0]) < 1e-12 and abs(T_generic[0, 4]) < 1e-12
      and recorded(A4_WL, "condensate_kinetic_tensor_diagonal") == "PASS"
      and recorded(A4_PY, "authorT16_condensate_kinetic_diagonal") == "PASS",
      "diagonal (0, 0, 0, 0, -V S, 0, 0, 0) and T^x4_x0 = T^x0_x4 = 0",
      record=f"{A4_WL}, check condensate_kinetic_tensor_diagonal; {A4_PY}, check "
             "authorT16_condensate_kinetic_diagonal")
```

`**POINT` hands the three entries of the dictionary over as the named arguments `a4`, `a4p` and `z`. With $\lambda = 0$, $L_0 = SU' - U = 0$ on shell, so the diagonal of Section 9.26 is $(0, 0, 0, -VS, 0, 0, 0, 0)$; the check confirms it, and $T^{x_4}{}_{x_0} = T^{x_0}{}_{x_4} = 0$.

```
pairs = off_diagonal_pairs(T_generic)
# the same condensate and point with a4p = 0 (a4 not changing at this moment)
pairs_constant_a4 = off_diagonal_pairs(
    condensate_tensor(chi, POINT["a4"], 0.0, POINT["z"]))
check(len(pairs) == 42, "a generic condensate has 42 nonzero off-diagonal entries")
momentum_flows = sorted([(4, i) for i in (1, 2, 3, 5, 6, 7)]
                        + [(i, 4) for i in (1, 2, 3, 5, 6, 7)])
check(sorted(pairs_constant_a4) == momentum_flows,
      "with a4p = 0 only the 12 flows T^x4_xj, T^xj_x4 (j = 1, 2, 3, 5, 6, 7) remain")
report("S of the random column", f"{S_chi:.6f}")
report("T^x4_x4 = -V S", f"{T_generic[4, 4]:.6f}")
```

The cell counts the nonzero entries off the diagonal (42) and repeats the count with $a_4' = 0$: then exactly the 12 pairs (x_4, x_j) and (x_j, x_4) with x_j one of the six directions of 3-space and the extra times remain (`momentum_flows`). It prints $S = 0.293667$ and $T^{x_4}{}_{x_4} = -VS = -1.468334$.

In [6], the heat map of the generic condensate (Figure 09c.1).

```
def heat_map(ax, T, title, largest):
    """Draw T as coloured squares with the value printed in each."""
    picture = ax.imshow(T, cmap="RdBu_r", vmin=-largest, vmax=largest)
    for nu in range(8):
        for mu in range(8):
            text = f"{T[nu, mu]:.2f}"
            if text == "-0.00":  # a tiny negative number: print it as 0.00
```

```
                text = "0.00"
            # white digits on dark squares, black digits on light ones
            colour = "white" if abs(T[nu, mu]) > 0.6 * largest else "black"
            ax.text(mu, nu, text, ha="center", va="center", fontsize=6,
                    color=colour)
    ticks = [f"${n[0]}_{n[1]}$" for n in NAMES]
    ax.set_xticks(range(8), ticks)
    ax.set_yticks(range(8), ticks)
    ax.set_xlabel("lower index $\\mu$ (column)")
    ax.set_ylabel("upper index $\\nu$ (row)")
    ax.set_title(title)
    ax.grid(False)
    return picture
```

`heat_map` draws a table as in In [8] of Notebook 09a, with two decimals in each square; a rounding remainder such as -0.0000001 would print as `-0.00`, which the `if` replaces by `0.00`. The function returns the picture, for the colour bar.

```
SCALE = 2.0  # the colour scale runs from -2 to 2 in both heat maps of this notebook
fig, ax = plt.subplots(figsize=(6.6, 5.6))
picture = heat_map(ax, T_generic, "Generic condensate: $T^\\nu{}_\\mu$", SCALE)
fig.colorbar(picture, ax=ax, label="value (energy per unit volume)", extend="both")
save_figure(fig, "generic_condensate",
            "Heat map of the 64 entries $T^\\nu{}_\\mu$ (row $\\nu$, column $\\mu$, "
            ...)
```

Both heat maps of the notebook use the fixed colour scale from -2 to 2, so they can be compared; `extend="both"` adds arrows to the colour bar for values beyond the scale. **What Figure 09c.1 shows.** The 64 entries of the generic condensate's tensor, in units of energy per unit volume. The only diagonal entry that is not zero is $-VS = -1.47$ at (x_4, x_4); 42 squares off the diagonal are coloured, all of them produced by the spin connection; the squares (x_4, x_0) and (x_0, x_4) are zero, and so are the squares inside 3-space and inside the extra times. The student should see that equal pressures do not make a condensate a perfect fluid.

In [7], the dependence on the deflation rate (Figure 09c.2).

```
rates = np.linspace(-1.0, 1.0, 41)  # values of a4p
entries = np.array([[T[4, 1], T[1, 5], T[1, 0]] for T in (
    condensate_tensor(chi, POINT["a4"], rate, POINT["z"]) for rate in rates)])
check(np.abs(entries[:, 0] - entries[20, 0]).max() < 1e-12 and abs(entries[20, 0]) > 0.1,
      "T^x4_x1 does not depend on a4p and is not zero")
slopes = entries[-1, 1:] / rates[-1]  # the slope of each of the other two entries
check(np.abs(entries[:, 1:] - np.outer(rates, slopes)).max() < 1e-12
      and np.abs(slopes).min() > 1e-3,
      "T^x1_x5 and T^x1_x0 are proportional to a4p (zero only at a4p = 0)")
report("T^x4_x1", f"{entries[20, 0]:.6f}")
report("slopes d T^x1_x5/d a4p and d T^x1_x0/d a4p",
       f"{slopes[0]:.6f} and {slopes[1]:.6f}")
```

For 41 values of a_4' from -1 to 1 the cell computes the tensor of the same condensate at the same point and keeps three entries: $T^{x_4}{}_{x_1}$ (`T[4, 1]`), $T^{x_1}{}_{x_5}$ (`T[1, 5]`) and $T^{x_1}{}_{x_0}$ (`T[1, 0]`). The first

check confirms that $T^{x_4}{}_{x_1}$ is the same for every a_4' (it equals its value at the middle of the list, `entries[20, 0]`, where $a_4' = 0$) and is not zero. The second computes the slopes of the other two entries from the last value ($a_4' = 1$) and confirms that each entry is its slope times a_4' at all 41 values (`np.outer(rates, slopes)` is the table of all products), with slopes that are not zero. It prints $T^{x_4}{}_{x_1} = 0.835532$ and the slopes -0.012942 and -0.049288.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.6, 3.9))
fig.subplots_adjust(wspace=0.35)
left.plot(rates, entries[:, 0], label="$T^{x_4}{}_{x_1}$ (momentum flow)")
left.set_ylim(0.0, 1.2 * entries[20, 0])
left.set_xlabel("deflation rate $a_4'$")
left.set_ylabel("entry (energy per unit volume)")
left.set_title("Comes from $H$: independent of $a_4'$")
left.legend(fontsize=8)
right.plot(rates, entries[:, 1], label="$T^{x_1}{}_{x_5}$")
right.plot(rates, entries[:, 2], "--", label="$T^{x_1}{}_{x_0}$")
right.axhline(0.0, color="black", linewidth=0.8)
right.set_xlabel("deflation rate $a_4'$")
right.set_title("Proportional to $a_4'$")
right.legend(fontsize=8)
save_figure(fig, "offdiagonal_entries",
            "Three off-diagonal entries of the generic condensate of the previous "
            ...)
```

What Figure 09c.2 shows. Left: the momentum flow $T^{x_4}{}_{x_1}$ (energy per unit volume) against a_4' is a horizontal line at 0.835532, the value printed by the cell: it comes from the H part of the spin connection and from the term $3H\gamma^{(4)}\gamma^{(0)}$ of the condensate's time derivative (Section 9.26). Right: $T^{x_1}{}_{x_5}$ (solid) and $T^{x_1}{}_{x_0}$ (dashed) are straight lines through zero. The student should see that 30 of the 42 entries exist only because $a_4' \neq 0$, as the hand computation of $T^{x_1}{}_{x_5}$ in Section 9.26 showed.

In [8], the 15 three-gamma bilinears.

```
def bilinear_directions(nu, mu):
    """The three directions (a, b, c) of the bilinear that carries T^nu_mu."""
    directions = {nu, mu}
    if 4 in directions and 0 not in directions:
        directions.add(0)  # add x0
    elif 0 in directions and 4 not in directions:
        directions.add(4)  # add x4
    elif 4 not in directions and 0 not in directions:
        directions.add(4)  # add x4
    return tuple(sorted(directions))

def bilinear(column, directions):
    a, b, c = directions
    return bar(column) @ gamma[a] @ gamma[b] @ gamma[c] @ column
```

`bilinear_directions` encodes the rule of the record: the bilinear of the entry (ν, μ) has the directions ν, μ and the missing one of x_4, x_0 (or x_4 when neither occurs). `{nu, mu}` is a **set** (a collection without order and without repetitions); `.add` puts an element in; `elif` means "else

if"; `tuple(sorted(...))` returns the three directions in increasing order. `bilinear` computes $\bar{\Phi}\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$.

```
columns = [rng.normal(size=16) + 1j * rng.normal(size=16) for _ in range(3)]
tensors = [condensate_tensor(column, **POINT) for column in columns]
worst_ratio, used = 0.0, set()
for nu, mu in pairs:
    directions = bilinear_directions(nu, mu)
    used.add(directions)
    ratios = [tensors[n][nu, mu] / bilinear(columns[n], directions) for n in range(3)]
    worst_ratio = max(worst_ratio,
                      max(abs(r - ratios[0]) for r in ratios) / abs(ratios[0]))
```

Three more random columns give three more condensates at the same point. For each of the 42 pairs the loop divides the entry by its bilinear for each of the three columns; if the entry is a fixed multiple of the bilinear, the three ratios are equal. `worst_ratio` keeps the largest relative spread, and `used` collects the bilinears that occur.

```
check(worst_ratio < 1e-9 and len(used) == 15
      and recorded(A4_WL, "condensate_offdiagonal_are_three_gamma_bilinears") == "PASS"
      and recorded(A4_PY, "authorT16_condensate_offdiagonal_three_gamma") == "PASS",
      "each of the 42 entries is a fixed multiple of one of 15 three-gamma bilinears",
      record=f"{A4_WL}, check condensate_offdiagonal_are_three_gamma_bilinears; "
             f"{A4_PY}, check authorT16_condensate_offdiagonal_three_gamma")
for directions in sorted(used):
    say("bilinear Phibar gamma^(" + ") gamma^(".join(NAMES[d] for d in directions)
        + ") Phi")
```

The check confirms equal ratios and exactly 15 bilinears; the loop prints them: the nine $\bar{\Phi}\gamma^{(x_i)}\gamma^{(x_4)}\gamma^{(x_t)}\Phi$ and the six $\bar{\Phi}\gamma^{(x_j)}\gamma^{(x_4)}\gamma^{(x_0)}\Phi$ (written with the directions in increasing order).

In [9], the coefficients of the record.

```
import re  # regular expressions: patterns that find pieces of a text

import sympy as sp  # exact algebra with symbols

A4_RECORD = "Revision/field_equations_a4/a4-equations.json"
record_entries = json.loads(repository_file(A4_RECORD).read_text(encoding="utf-8"))[
    "fields"]["dirac16complex00"]["offDiagonalKinetic"]
cc, a4v, ad1, H_symbol = sp.symbols("cc a4v ad1 H", real=True)
AT_POINT = {cc: 1 / np.tan(POINT["z"]), a4v: POINT["a4"], ad1: POINT["a4p"],
            H_symbol: H}
worst_coefficient, groups = 0.0, {}  # groups: formula text -> its first entry
```

A **regular expression** is a pattern that finds pieces of a text; the module `re` provides them. The record file holds, under `fields`, `dirac16complex00`, `offDiagonalKinetic`, the list of the 42 entries with their bilinears and coefficients. The coefficients are Wolfram-Language formulas in the names `cc` ($\cot z$), `a4v` (a_4), `ad1` (a_4') and `H`; `AT_POINT` gives these names the values of the point.

```
for item in record_entries:
    # "K^x1_x4 (symmetrised)": upper index x1 (row nu), lower index x4 (column mu)
    nu, mu = [int(digit) for digit in re.findall(r"x(\d)", item["component"])]
    term = item["terms"][0]  # every entry of the record has exactly one term
    directions = [int(digit) for digit in re.findall(r"x(\d)", term["bilinear"])]
    formula = term["coefficient"]["input"]  # the Wolfram Language text
```

For each entry of the record, `re.findall(r"x(\d)", text)` finds every `x` followed by a digit and returns the digits (`\d` means one digit, the parentheses mark the part to return; the `r` before the string keeps the backslash). The component name gives ν and μ and the bilinear's name gives its three directions, all counted from 0. `formula` is the coefficient's text.

```
    coefficient = float(sp.sympify(
        formula.replace("E^", "E**").replace("^", "**"),
        locals={"E": sp.E, "cc": cc, "a4v": a4v, "ad1": ad1, "H": H_symbol},
    ).subs(AT_POINT))
    for column, T in zip([chi] + columns, [T_generic] + tensors):
        predicted = -coefficient * bilinear(column, tuple(directions))
        worst_coefficient = max(worst_coefficient, abs(T[nu, mu] - predicted))
    groups.setdefault(formula, (nu, mu, coefficient))
```

The formula is translated (`E^x` becomes `E**x`, and `^` becomes `**`), read by sympy, evaluated at the point (`.subs(AT_POINT)`) and turned into an ordinary number (`float`). For the generic column and the three random columns, the entry predicted by the record is minus the coefficient times the bilinear (off the diagonal $T = -K^{(\nu}{}_{\mu)}$, Section 9.26); the largest difference from the computed entry is kept. `groups` remembers the first entry of each distinct formula.

```
check(len(record_entries) == 42 and len(groups) == 10 and worst_coefficient < 1e-12
      and recorded(A4_PY, "json_offdiagonal_coefficients") == "PASS"
      and recorded(A4_PY, "offdiagonal_coefficients_representation_independent")
      == "PASS",
      "all 42 entries are -(record coefficient) x bilinear, for 4 columns",
      record=f"{A4_RECORD}, offDiagonalKinetic; {A4_PY}, checks "
             "json_offdiagonal_coefficients and "
             "offdiagonal_coefficients_representation_independent")
for nu, mu, coefficient in groups.values():
    say(f"T^{NAMES[nu]}_{NAMES[mu]} = -({coefficient:+.6f}) x its bilinear")
```

The check confirms 42 entries in the record, ten distinct coefficient formulas, and agreement within 10^{-12} for all 42 entries and four columns. The loop prints one entry of each group; for example `T^x1_x5 = -(-0.045985) x its bilinear`, the coefficient derived by hand in Section 9.26, and `T^x4_x1 = -(-2.723325) x its bilinear`, from the record's coefficient $-\frac{7}{4}e^{a_4}H\sin^{1/6} z$ ($\frac{7}{4}\cdot 1.6487213\cdot 0.9438743 = 2.723325$, rounded to six decimals), also derived by hand in Section 9.26. Each printed line names one entry of its group; the other entries of the group have the same coefficient with another 3-space index x_i or extra-time index x_t.

In [10], the record's witnesses.

```
import itertools  # all combinations and all sign choices of a list

P = [gamma[i] @ gamma[i + 4] for i in range(1, 4)]  # gamma^(x1) gamma^(x5), ...
```

The module `itertools` of Python's standard library provides the two tools used at the end of the cell: all combinations of a list and all choices of signs. `P` is the list of the three matrices $P_1 = \gamma^{(1)}\gamma^{(5)}$, $P_2 = \gamma^{(2)}\gamma^{(6)}$, $P_3 = \gamma^{(3)}\gamma^{(7)}$ of Section 9.26.

```
def witness(V_w, H_w):
    """The frequency omega (here freq), A, the unit vectors v1, v2 and the column
    Phi0 of the record's diagonal witness for (V_w, H_w)."""
    A_w = -g4 @ (V_w * I16 - 3 * H_w * g0)  # d4 Phi = A Phi
    freq = np.sqrt(V_w ** 2 - 9 * H_w ** 2)  # the frequency omega
    # The null space of A + i omega: the rows of the third SVD factor whose
    # singular value is zero, complex conjugated and written as columns.
    _, singular, rows = np.linalg.svd(A_w + 1j * freq * I16)
    space = rows[singular < 1e-9].conj().T  # 16 x 8: the eigenspace for -i omega
```

The function builds the matrix A and the angular frequency $\omega = \sqrt{V^2 - 9H^2}$. The columns v with $Av = -i\omega v$ are the solutions of $(A + i\omega)v = 0$, the **null space** of $A + i\omega$. The **singular value decomposition** (`np.linalg.svd`) writes any matrix as a product $U\,\mathrm{diag}(s)\,W$ of two matrices with perpendicular unit rows or columns and a list of non-negative numbers s, the singular values; the rows of W whose singular value is zero span the null space (after complex conjugation, written as columns). `rows[singular < 1e-9]` selects these rows; there are eight.

```
    found = []
    for sign in (-1, 1):
        projector = (I16 + sign * P[0]) @ (I16 + sign * P[1]) @ (I16 + sign * P[2]) / 8
        left_vectors, values, _ = np.linalg.svd(projector @ space)
        if np.sum(values > 1e-9) != 1:
            raise ValueError("the joint eigenvector is not unique")
        found.append(left_vectors[:, 0])  # a unit vector
    v1, v2 = found
    c = np.conj(bar(v1) @ v2)  # c = conj(v1^dagger C v2)
    return freq, A_w, v1, v2, v1 + c * v2
```

Because $P_k^2 = 1$, the matrix $\frac{1}{2}(1 \pm P_k)$ keeps the part of a column with $P_k = \pm 1$ and removes the rest (a **projector**); the product of the three, $\frac{1}{8}(1 \pm P_1)(1 \pm P_2)(1 \pm P_3)$, keeps exactly the columns with $P_1 = P_2 = P_3 = \pm 1$. Applied to the eight columns of the eigenspace it leaves a single direction (the check `np.sum(values > 1e-9) != 1` stops the notebook otherwise), and the first left factor of its singular value decomposition is a unit column along it: v_1 for the sign -1, v_2 for $+1$. Then $c = \overline{v_1^\dagger C v_2}$ and $\Phi_0 = v_1 + c v_2$. The function returns five results.

```
WITNESSES = [(5.0, 1.0), (5.0, 4 / 3), (-5.0, 1.0)]  # the record's (V, H)
witnesses = {pair: witness(*pair) for pair in WITNESSES}  # (V, H) -> the five
for (V_w, H_w), found in witnesses.items():
    say(f"witness (V, H) = ({V_w:g}, {H_w:.4g}): frequency omega = "
        f"sqrt(V^2 - 9 H^2) = {found[0]:.6f}")
```

The record's three pairs (V, H); `witness(*pair)` hands the two numbers over as two arguments. The cell prints the frequencies 4, 3 and 4 ($H = 4/3$ is printed as `1.333` by the format `.4g`, four significant digits).

```
def product_of(indices):
    """The product gamma^(a) gamma^(b) ... of the frame gammas with these indices."""
    result = I16
    for index in indices:
        result = result @ gamma[index]
    return result

subsets = [chosen for size in range(1, 9)
           for chosen in itertools.combinations(range(8), size)]  # 255 index sets
traceless = all(abs(np.trace(product_of(chosen))) < 1e-12 for chosen in subsets)
```

The rest of the cell checks Steps 1 and 3 of the construction in Section 9.26 with numbers. `product_of` multiplies the frame gammas whose indices it is given, from left to right, starting from the unit matrix. `itertools.combinations(range(8), size)` lists every choice of `size` different indices out of $0, \ldots, 7$, each in increasing order; for `size` from 1 to 8 these are $8+28+56+70+56+28+8+1 = 255 = 2^8 - 1$ choices. `np.trace` adds the diagonal entries of a matrix, and `traceless` is true when every one of the 255 products has trace 0 up to rounding, the lemma of Step 3.

```
dimensions_hold = True
for (V_w, H_w), (freq, A_w, v1, v2, phi0) in witnesses.items():
    # the dimension of the space of -i omega: 16 minus the rank of A + i omega
    dimension = 16 - np.linalg.matrix_rank(A_w + 1j * freq * I16, tol=1e-9)
    for signs in itertools.product((-1, 1), repeat=3):  # the eight sectors
        keeper = (I16 + 1j / freq * A_w) / 2  # keeps the space of -i omega
        for sign, P_k in zip(signs, P):
            keeper = keeper @ (I16 + sign * P_k) / 2  # keeps P_k = sign
        dimensions_hold = dimensions_hold and abs(np.trace(keeper) - 1) < 1e-12
    dimensions_hold = dimensions_hold and dimension == 8
check(len(subsets) == 255 and traceless and dimensions_hold,
      "255 gamma products have trace 0; space of -i omega: dim 8; each sector: dim 1")
```

For each witness, the **rank** of a matrix (`np.linalg.matrix_rank`, the number of its independent columns, counted here with the tolerance 10^{-9} for rounding) gives the dimension of the space of the eigenvalue $-i\omega$: the columns v with $(A + i\omega)v = 0$ form a space of dimension 16 minus the rank of $A + i\omega$ (Step 1 says 8). `itertools.product((-1, 1), repeat=3)` lists the eight choices of three signs $(\varepsilon_1, \varepsilon_2, \varepsilon_3)$; for each, `keeper` is the matrix $\Pi = \frac{1}{2}(1 + \frac{i}{\omega}A) \cdot \frac{1}{2}(1 + \varepsilon_1 P_1) \cdot \frac{1}{2}(1 + \varepsilon_2 P_2) \cdot \frac{1}{2}(1 + \varepsilon_3 P_3)$ of Step 2, built factor by factor (`1j / freq * A_w` is $\frac{i}{\omega}A$), and its trace must be 1 (Step 3). The check confirms the 255 traces, the dimension 8 and the 24 sector traces (eight sectors for each of the three witnesses), and prints `PASS 255 gamma products have trace 0; space of -i omega: dim 8; each sector: dim 1`.

In [11], the witnesses are condensates with a diagonal tensor.

```
grid = [(a4, a4p, z) for a4 in (-1.0, 0.0, 0.5) for a4p in (-0.5, 0.0, 0.25, 1.0)
        for z in (0.3, 0.8, 1.3)]  # 3 x 4 x 3 = 36 points
witness_columns = {}  # (V, H) -> Phi0
unit_S = {}  # (V, H) -> S of Phi0 built from v1 and v2 of length 1
for (V_w, H_w), (freq, A_w, v1, v2, phi0) in witnesses.items():
    S_w = (bar(phi0) @ phi0).real
```

```
    largest_bilinear = max(abs(bilinear(phi0, d)) for d in used)
    worst_off = 0.0  # the largest off-diagonal entry at the 36 points
    for a4, a4p, z in grid:
        T = condensate_tensor(phi0, a4, a4p, z, V_w, H_w)
        worst_off = max(worst_off, np.abs(T - np.diag(np.diag(T))).max())
```

`grid` lists 36 points: every combination of three values of a_4, four of a_4' (deflating, static and inflating) and three of z. For each witness the loop computes S, the largest of its 15 bilinears, and, at the 36 points, the largest entry off the diagonal of its tensor (`np.diag(np.diag(T))` is the diagonal matrix made of the diagonal of `T`, so `T - np.diag(np.diag(T))` keeps only the entries off the diagonal).

```
    check(np.abs(A_w @ phi0 + 1j * freq * phi0).max() < 1e-12
          and largest_bilinear < 1e-12 and abs(S_w) > 0.1 and worst_off < 1e-12,
          f"witness (V, H) = ({V_w:g}, {H_w:.4g}): omega = {freq:g}, the 15 "
          "bilinears vanish, S != 0, T diagonal at 36 points")
    witness_columns[(V_w, H_w)] = phi0
    unit_S[(V_w, H_w)] = S_w
    report(f"witness ({V_w:g}, {H_w:.4g}): omega, and S for unit v1, v2",
           f"{freq:g} and {S_w:.6f}")
```

Each check confirms four things: $A\Phi_0 = -i\omega\Phi_0$, so $\Phi = e^{-i\omega x_4}\Phi_0$ is an exact condensate; all 15 bilinears vanish; $S \neq 0$; and the tensor is diagonal at all 36 points. The cell prints $S = 1.28$, 0.72 and 1.28.

In [12], why S of a witness is never negative.

```
anticommute = all(np.abs(C @ P_k + P_k @ C).max() < 1e-12 for P_k in P)
symmetric = all(np.array_equal(P_k, P_k.T) for P_k in P)  # real: P^dagger = P^T
steps_hold, observation = True, True
for (V_w, H_w), (freq, A_w, v1, v2, phi0) in witnesses.items():
    s = bar(v1) @ v2  # s = v1^dagger C v2
    S_unit = unit_S[(V_w, H_w)]  # S of Phi0 with unit v1, v2 (previous cell)
    steps_hold = (steps_hold and abs(bar(v1) @ v1) < 1e-12
                  and abs(bar(v2) @ v2) < 1e-12
                  and abs(S_unit - 2 * abs(s) ** 2) < 1e-12)
    observation = observation and abs(S_unit - 2 * freq ** 2 / V_w ** 2) < 1e-12
```
