check(np.array_equal(B.real, np.zeros((16, 16))) and np.allclose(B, B.conj().T)
      and np.allclose(B @ B, np.eye(16)) and lead_passed("B_imaginary_hermitian"),
      "B = -i C gamma^(x4) is purely imaginary, Hermitian, B^2 = 1",
      record=f"{RECORD}, check B_imaginary_hermitian")
```

`B.real` is the array of the real parts, which must all be zero; `B.conj().T` is the conjugate transpose $B^\dagger$, and `np.allclose` compares two arrays entry by entry and accepts a difference up to 10^{-8} plus 10^{-5} times the size of the corresponding entry of the second array (numpy's default tolerances), far above rounding errors and far below the differences that matter here; `B @ B` must be the identity. Out [5] shows the three PASS lines, two of them with the record checks they reproduce.

In [6]: every matrix that obeys the condition, solved exactly.

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over the rationals
```

`sympy` computes with exact numbers and symbols. A `DomainMatrix` is sympy's fast matrix of exact numbers from a chosen **domain**: the rational numbers `QQ` (fractions) or the integers `ZZ`.

```
def conjugation_system(s, directions=COORDS):
    """Coefficient matrix of M conj(gamma^a) - s gamma^a M = 0 for the 256
    unknowns M_rc (read row by row), one block of 256 equations per direction."""
    blocks = []
    for x in directions:
        G_conj = np.conj(gamma[x]).astype(np.int64)  # (gamma^a)*, equal to gamma^a
        blocks.append(np.kron(I16, G_conj.T) - s * np.kron(gamma[x], I16))
    return np.vstack(blocks)
```

The unknown matrix M is read row by row as one column y of 256 numbers, $y_{16r+c} = M_{rc}$ (rows and columns counted from 0). The entry (r, c) of MG is $\sum_k M_{rk} G_{kc}$; as a linear function of y it is row $16r + c$ of the **Kronecker product** $1 \otimes G^T$ (`np.kron(I16, G_conj.T)`, the 256×256 block matrix whose block (r, r') is $\delta_{rr'} G^T$). The entry (r, c) of GM is $\sum_k G_{rk} M_{kc}$, row $16r + c$ of $G \otimes 1$ (`np.kron(gamma[x], I16)`). So each direction contributes 256 equations $(1 \otimes G^{*T} - s\, G \otimes 1)\, y = 0$. `np.conj` takes the complex conjugate, which changes nothing for the real gammas but keeps the code faithful to the condition $M(\gamma^a)^* = s\gamma^a M$. `np.vstack` stacks the blocks into one tall coefficient matrix with $8 \cdot 256 = 2048$ rows.

```
def exact_solutions(A):
    """A basis of all solutions y of A y = 0, each returned as a 16 x 16 matrix."""
    null = DomainMatrix.from_list(A.tolist(), sp.QQ).nullspace().to_Matrix()
    return [np.array(null.row(k).tolist()[0], dtype=object).reshape(16, 16)
            for k in range(null.rows)]
```

`A.tolist()` turns the numpy array into nested Python lists; `DomainMatrix.from_list(..., sp.QQ)` makes an exact matrix of rational numbers; `.nullspace()` computes, by exact Gaussian elimination, a basis of all solutions of $Ay = 0$ (one solution per row), and `.to_Matrix()` turns it into an ordinary sympy matrix. The list comprehension takes each basis row (`null.row(k)`), turns it into a numpy array of exact sympy numbers (`dtype=object`) and folds the 256 numbers back into a 16×16 matrix with `.reshape(16, 16)`. No rounding is involved anywhere: a solution can be neither hidden nor invented.

```
def proportional(X, Y):
    """True when X and Y are nonzero and X is a number times Y."""
    X = np.array(X, dtype=float).reshape(-1)
    Y = np.array(Y, dtype=float).reshape(-1)
    return bool(X.any() and Y.any() and np.linalg.matrix_rank(np.array([X, Y])) == 1)
```

Both matrices are written as rows of 256 decimal numbers (`reshape(-1)` makes one long row). Two nonzero rows are multiples of each other exactly when the 2×256 matrix made of them has **rank** 1 (only one independent row); `X.any()` is true when some entry is nonzero.

```
A_same, A_reversed = conjugation_system(+1), conjugation_system(-1)
M_same, M_reversed = exact_solutions(A_same), exact_solutions(A_reversed)
say(f"s = +1: {A_same.shape[0]} equations, {len(M_same)} independent solution(s)")
say(f"s = -1: {A_reversed.shape[0]} equations, {len(M_reversed)} independent "
    "solution(s)")
```

The two systems are built and solved; a comma on both sides assigns two values at once. `A_same.shape[0]` is the number of rows (equations). Out [6] prints 2048 equations and 1 independent solution for each sign.

```
check(len(M_same) == 1 and proportional(M_same[0], I16)
      and lead_passed("intertwiners_same_mass"),
      "s = +1 (same mass): the solutions are the multiples of the identity",
      record=f"{RECORD}, check intertwiners_same_mass")
check(len(M_reversed) == 1 and proportional(M_reversed[0], Gamma)
      and lead_passed("intertwiners_reversed_mass"),
      "s = -1 (mass reversed): the solutions are the multiples of Gamma",
      record=f"{RECORD}, check intertwiners_reversed_mass")
```

The solution space of each sign has dimension 1, and its basis matrix is a multiple of 1 (for $s = +1$) or of Γ (for $s = -1$): Theorem CC (a), reproducing the two record checks.

In [7]: each equation halves the solution space.

```
dimensions = {}
for s in (+1, -1):
    dims = [256]  # k = 0: no equation, every matrix is a solution
    for k in range(1, 9):
        A = conjugation_system(s, COORDS[:k])  # the first k directions only
        rank = DomainMatrix.from_list(A.tolist(), sp.ZZ).rank()  # exact rank
        dims.append(256 - rank)
    dimensions[s] = dims
    say(f"s = {s:+d}: dimensions for k = 0..8: {dims}")
```

For each sign and each $k = 1, \ldots, 8$ (`range(1, 9)` stops before 9), the system of the first k directions (`COORDS[:k]`, the first k names) is built. Its **rank**, the number of independent equations, is computed exactly over the integers; the number of free unknowns, the dimension of the solution space, is 256 minus the rank. `dims.append` adds it to the list. Out [7] prints $[256, 128, 64, 32, 16, 8, 4, 2, 1]$ for both signs.

```
check(dimensions[+1] == dimensions[-1] == [256 // 2 ** k for k in range(9)],
      "each gamma equation halves the solution space: 256, 128, ..., 2, 1")
```

`256 // 2 ** k` is the whole-number quotient $256/2^k$ (`**` is a power, `//` division without remainder). Python reads `a == b == c` as "a equals b and b equals c".

```
fig, ax = plt.subplots(figsize=(7.5, 4.4))
k_values = np.arange(9)
ax.semilogy(k_values, dimensions[+1], "o-", markersize=9,
            label="$s = +1$: $M$ commutes with the first $k$ gammas")
ax.semilogy(k_values, dimensions[-1], "s--", markersize=5,
            label="$s = -1$: $M$ anticommutes with the first $k$ gammas")
```

`np.arange(9)` is the array 0, 1, ..., 8. `semilogy` draws a curve with a logarithmic vertical axis, on which halving is a constant step. The style string `"o-"` means circles joined by a line, and the

style string made of the letter s and two hyphens means small squares joined by a dashed line; the squares are drawn smaller so that the circles of the first curve remain visible around them. `label` is the text of the legend.

```
ax.set_xticks(k_values, ["0"] + [f"{k}\n(+{x})" for k, x in zip(range(1, 9), COORDS)])
ax.set_yticks([1, 2, 4, 8, 16, 32, 64, 128, 256],
              ["1", "2", "4", "8", "16", "32", "64", "128", "256"])
ax.set_xlabel("number $k$ of gamma equations imposed (and the direction added)")
ax.set_ylabel("dimension of the solution space")
ax.set_title("Every equation halves the space of conjugation matrices")
ax.legend()
```

The tick labels of the horizontal axis show k and, below it (`\n` is a line break), the direction added. The vertical ticks are the powers of 2. Axis labels, a title and the legend follow.

```
save_figure(fig, "halving_solutions",
            "The dimension of the space of $16 \\times 16$ matrices $M$ that obey "
            "$M(\\gamma^a)^\\ast = s\\,\\gamma^a M$ for the first $k$ directions only "
            "(computed exactly as $256$ minus the rank of the equations), for "
            "$s = +1$ (circles) and $s = -1$ (squares); horizontal axis $k$ with "
            "the direction added, vertical axis the dimension on a logarithmic "
            "scale. Both sequences are $256/2^k$: every new gamma halves the "
            "freedom, and with all eight only one direction is left, the multiples "
            "of $1$ ($s = +1$) or of $\\Gamma$ ($s = -1$).")
```

Figure 21a.2. **What the figure shows.** Two identical straight staircases on the logarithmic axis, from 256 down to 1: every gamma equation removes exactly half of the remaining freedom, as Section 21.9 explains for the first step, until only the multiples of 1 or of Γ are left.

In [8]: the two charge-conjugation matrices and their transposition rules.

```
calC_plus = C  # M = 1
calC_minus = Gamma @ C  # M = Gamma
inv_plus = np.linalg.inv(calC_plus)  # the inverse matrix
inv_minus = np.linalg.inv(calC_minus)
```

$\mathcal{C} = MC$ with $M = 1$ and $M = \Gamma$ (Theorem CC (b)). `np.linalg.inv` computes the inverse matrix in decimal numbers.

```
check(all(np.allclose(inv_plus @ gamma[x] @ calC_plus, -gamma[x].T) for x in COORDS)
      and np.array_equal(calC_plus.T, calC_plus)
      and lead_passed("charge_conjugation_matrix_plus"),
      "calC_+ = C: calC_+^-1 gamma^a calC_+ = -(gamma^a)^T, real, symmetric",
      record=f"{RECORD}, check charge_conjugation_matrix_plus")
check(all(np.allclose(inv_minus @ gamma[x] @ calC_minus, gamma[x].T) for x in COORDS)
      and np.array_equal(calC_minus.T, calC_minus)
      and lead_passed("charge_conjugation_matrix_minus"),
      "calC_- = Gamma C: calC_-^-1 gamma^a calC_- = +(gamma^a)^T, real, symmetric",
      record=f"{RECORD}, check charge_conjugation_matrix_minus")
```

The transposition rules of Theorem CC (c) for all eight gammas, and the symmetry of both matrices (they are whole-number arrays, hence real).

```
def transposition_system(zeta):
    """Coefficient matrix of gamma^a X - zeta X (gamma^a)^T = 0 for all a."""
    return np.vstack([np.kron(gamma[x], I16) - zeta * np.kron(I16, gamma[x])
                      for x in COORDS])
```

The converse part of (c). With X read row by row as before, γX is `np.kron(gamma[x], I16)` applied to it, and the entry (r, c) of $X\gamma^T$ is $\sum_k X_{rk}\gamma_{ck}$, which is `np.kron(I16, gamma[x])` applied to it (the transpose of γ^T is γ).

```
X_minus = exact_solutions(transposition_system(-1))  # expected: multiples of C
X_plus = exact_solutions(transposition_system(+1))  # expected: multiples of Gamma C
check(len(X_minus) == 1 and proportional(X_minus[0], calC_plus)
      and len(X_plus) == 1 and proportional(X_plus[0], calC_minus),
      "gamma^a X = zeta X (gamma^a)^T: zeta = -1 only C, zeta = +1 only Gamma C")
```

Both systems are solved exactly: each has a one-dimensional solution space, spanned by C for $\zeta = -1$ and by ΓC for $\zeta = +1$. So the usual textbook definition by transposition rules gives the same two matrices. Out [8] shows the three PASS lines.

In [9]: the heat maps of the two matrices.

```
fig, axes = plt.subplots(1, 3, figsize=(11.5, 4.2))
heat_map(axes[0], calC_plus, r"$\mathcal{C}_+ = C$ (same mass)")
heat_map(axes[1], Gamma, r"chirality $\Gamma$", row_label=False)
image = heat_map(axes[2], calC_minus, r"$\mathcal{C}_- = \Gamma C$ (mass reversed)",
                 row_label=False)
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8, label="matrix entry")
```

One row of three panels. A string that starts with `r` is a **raw string**, in which a backslash is an ordinary character, convenient for LaTeX titles. The three matrices are drawn with the helper of In [4].

```
save_figure(fig, "conjugation_matrices",
            "Heat maps of the two charge-conjugation matrices and of the chirality "
            "that relates them: $\\mathcal{C}_+ = C$ (left, the conjugation that "
            "keeps the mass), $\\Gamma$ (middle) and $\\mathcal{C}_- = \\Gamma C$ "
            "(right, the conjugation that reverses the mass); horizontal axis the "
            "column, vertical axis the row, colour the entry (red $+1$, blue $-1$, "
            "pale $0$). $C$ and $\\Gamma C$ have their entries only in the two "
            "diagonal blocks, and they differ only by the sign of the upper half, "
            "where $\\Gamma = -1$.")
```

Figure 21a.3. **What the figure shows.** C and ΓC have one entry per row and column, all inside the two diagonal blocks (they are products of an even number of gammas, which keep the halves apart). The middle panel is the diagonal Γ: blue in the upper half, red in the lower. The right panel is the left one with the colours of the upper eight rows exchanged.

In [10]: the two reality conditions.

```
check(np.array_equal(I16 @ np.conj(I16), I16)
      and np.array_equal(Gamma @ np.conj(Gamma), I16)
      and lead_passed("majorana_conditions_consistent"),
      "M M* = 1 for M = 1 and M = Gamma: both reality conditions are consistent",
      record=f"{RECORD}, check majorana_conditions_consistent")
```

The consistency condition $MM^* = 1$ of Section 21.10 for both matrices, reproducing the record check.

```
rows = np.arange(1, 17)  # the component numbers 1, ..., 16
v = (np.cos(rows) + 0.5) + 1j * np.sin(2.0 * rows)  # a fixed complex column
psi_real = (v + np.conj(v)) / 2  # satisfies Psi = Psi*
psi_gamma = (v + Gamma @ np.conj(v)) / 2  # satisfies Psi = Gamma Psi*
```

`v` is a fixed complex column whose r-th entry is $\cos r + 0.5 + i \sin 2r$: an arbitrary but reproducible choice. $(v+v^*)/2$ is the real part of v, so it is real. For the second: $\Gamma\big((v+\Gamma v^*)/2\big)^* = (\Gamma v^* + \Gamma\Gamma v)/2 = (v + \Gamma v^*)/2$ (Γ is real and $\Gamma\Gamma = 1$), so `psi_gamma` obeys $\Psi = \Gamma\Psi^*$.

```
check(np.allclose(psi_real, np.conj(psi_real))
      and np.allclose(psi_gamma, Gamma @ np.conj(psi_gamma)),
      "the two example fields satisfy Psi = Psi* and Psi = Gamma Psi*")
```

The check confirms both conditions with numbers.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0), sharey=True)
for ax, psi, title in ((axes[0], psi_real, r"$\Psi = \Psi^*$ (condition of "
                        r"$\mathcal{C}_+$)"),
                       (axes[1], psi_gamma, r"$\Psi = \Gamma\Psi^*$ (condition of "
                        r"$\mathcal{C}_-$)")):
    ax.bar(rows - 0.2, psi.real, width=0.4, label="real part")
    ax.bar(rows + 0.2, psi.imag, width=0.4, label="imaginary part")
    ax.axvline(8.5, color="black", linewidth=0.8)
    ax.set_xticks([1, 4, 8, 12, 16])
    ax.set_xlabel("component number")
    ax.set_title(title)
    ax.legend(loc="lower left")
axes[0].set_ylabel("value of the component")
```

Two panels with a common vertical axis (`sharey=True`). The loop runs over two triples (panel, field, title). `ax.bar` draws bars: the real parts shifted 0.2 to the left of each component number, the imaginary parts 0.2 to the right, each 0.4 wide. A vertical line at 8.5 separates the two halves. Ticks, labels, title and legend (in the lower left corner) follow.

```
save_figure(fig, "reality_conditions",
            "One field satisfying each reality (Majorana) condition, made from the "
            "same complex column: left $\\Psi = \\Psi^\\ast$ (every imaginary part is "
            "zero), right $\\Psi = \\Gamma\\Psi^\\ast$ (components 1 to 8, where "
            "$\\Gamma = -1$, are purely imaginary; components 9 to 16, where "
```

```
"$\\Gamma = +1$, are real); horizontal axis the component number, "
"vertical axis the real part (left bar of each pair) and the imaginary "
"part (right bar). Both conditions can be imposed, because "
"$MM^\\ast = 1$ for $M = 1$ and for $M = \\Gamma$.")
```

Figure 21a.4. **What the figure shows.** On the left every second bar of a pair is missing (zero imaginary parts). On the right components 1 to 8 have only imaginary parts and components 9 to 16 only real parts, exactly as the condition $\Psi = \Gamma\Psi^*$ demands component by component.

In [11]: the exact solution of the record in the author's metric.

```
THEORY = {f["key"]: f["wl"] for f in json.loads(repository_file(
    "Revision/theory/field-theory.json").read_text(encoding="utf-8"))["formulas"]}
PY_THEORY = {c["name"]: c["verdict"].upper() for c in json.loads(repository_file(
    "Revision/theory/reports/python-field-theory.json").read_text(
    encoding="utf-8"))["checks"]}
```

The field-theory record holds a list of formulas, each with a key and its text in Wolfram notation (`"wl"`); `THEORY` maps each key to its text. The independent sympy report of the same record holds checks whose verdicts are written in small letters; `.upper()` turns them into capitals, so that `PY_THEORY[name]` is `"PASS"` for a passed check.

```
# the left side of the record's field equation, word for word (right side m + U')
FIELD_EQUATION_LEFT = (
    "Tan[z] g[x0] d0 Psi"
    " + E^-a4[x4] Sin[z]^(-1/6) (g[x1] d1 + g[x2] d2 + g[x3] d3) Psi + g[x4] d4 Psi"
    " + E^a4[x4] Sin[z]^(-1/6) (g[x5] d5 + g[x6] d6 + g[x7] d7) Psi"
    " + 3 H g[x0] Psi")
# item (i) of the record's formula exact_solutions, word for word
SOLUTION_I = (
    "(i) U = 0: Psi = Sin[z]^al (Cosh[k x4] + Sinh[k x4]/k M) chi, M = -m g[x4]"
    " + 3 H (2 al + 1) g[x4].g[x0], k^2 = 9 H^2 (2 al + 1)^2 - m^2 (any a4)")
```

Two strings, each written as several pieces in parentheses that Python joins: the left side of the field equation and item (i) of the exact solutions, exactly as this book writes them in Section 21.11, but in the record's notation (`g[x4]` is $\gamma^{(x4)}$, `d4` is ∂_4, `al` is α, `E^a4[x4]` is e^{a_4}, the dot is the matrix product).

```
left, right = THEORY["field_equation"].split(" = ")  # the two sides
say("record, exact solution " + SOLUTION_I)
check(left == FIELD_EQUATION_LEFT and right.startswith("(m + U")
      and THEORY["exact_solutions"].startswith(SOLUTION_I + "; "),
      "the record states the field equation and the exact solution (i) used here",
      record="Revision/theory/field-theory.json, formulas field_equation and "
      "exact_solutions")
```

`split(" = ")` cuts the record's equation at the equals sign into its two sides. The check compares the left side word for word, asks that the right side starts with the factor $m + U'$, and asks that the record's text of the exact solutions starts with item (i) followed by a semicolon. If the record is ever changed, this check fails and the notebook stops.

```
x4, z = sp.symbols("x4 z", real=True)  # the time x4 and the angle z = 6 H x0
H, alpha, m = sp.Rational(1, 6), 1, 2  # the parameters chosen above
b = 3 * H * (2 * alpha + 1)  # b = 3/2
w = sp.sqrt(m ** 2 - b ** 2)  # k = i w with w = sqrt(7)/2
```

`sp.symbols` makes two symbols that sympy treats as unknown real numbers. `sp.Rational(1, 6)` is the exact fraction 1/6. Then $b = 3 \cdot \frac{1}{6} \cdot 3 = \frac{3}{2}$ and $w = \sqrt{4 - 9/4} = \sqrt{7}/2$, both exact.

```
G = {x: sp.Matrix(gamma[x].tolist()) for x in COORDS}  # exact sympy matrices
Gamma_s = sp.Matrix(Gamma.tolist())
```

Exact sympy copies of the gammas and of Γ.

```
def M_of(mass):
    """M_m = -m gamma^(x4) + b gamma^(x4) gamma^(x0)."""
    return -mass * G["x4"] + b * G["x4"] * G["x0"]
```

The matrix M_m of the solution; for sympy matrices `*` is the matrix product.

```
def E(mass, field):
    """E_m[Psi] = gamma^(x4) d4 Psi + 6H tan z gamma^(x0) dz Psi + 3H gamma^(x0) Psi
    - m Psi (the field equation of the record for fields of x4 and z only)."""
    tan_z = sp.sin(z) / sp.cos(z)  # tan z written as sin z / cos z
    return (G["x4"] * field.diff(x4) + 6 * H * tan_z * G["x0"] * field.diff(z)
            + 3 * H * G["x0"] * field - mass * field)
```

The left side of the field equation for a field of x_4 and z only (step 4 of Section 21.11); `field.diff(x4)` is the exact partial derivative of every component.

```
# a fixed complex column chi with exact entries (j + i (17 - j)) / 16, j = 1..16
chi = sp.Matrix([sp.Rational(j, 16) + sp.I * sp.Rational(17 - j, 16)
                 for j in range(1, 17)])
U = sp.cos(w * x4) * sp.eye(16) + sp.sin(w * x4) / w * M_of(m)  # real 16 x 16
Psi = sp.sin(z) ** alpha * U * chi
```

`chi` is a column of 16 exact complex numbers, $(j + i(17 - j))/16$; `sp.I` is i. `U` is $\cos(wx_4)\,1 + \sin(wx_4)M_m/w$, the form the solution takes for imaginary k; it is real. `Psi` is the solution $\sin z\, U\chi$.

```
check(E(m, Psi).expand() == sp.zeros(16, 1)
      and sp.simplify(M_of(m) ** 2 + w ** 2 * sp.eye(16)) == sp.zeros(16, 16)
      and PY_THEORY["exact_solution_family_x4_x0"] == "PASS",
      "the record's exact solution solves the field equation (mass m = 2)",
      record="Revision/theory/reports/python-field-theory.json, check "
      "exact_solution_family_x4_x0")
```

`.expand()` multiplies out every product, and the result must be the zero column: the field equation holds exactly. The second test is $M_m^2 = -w^2 = k^2$ (step 2 of Section 21.11). Out [11] prints the record's text of the solution and the two PASS lines.

In [12]: the two conjugates, exactly.

```
Psi_conj = Psi.conjugate()  # Psi*: every entry complex-conjugated (x4, z are real)
Psi_gamma_conj = Gamma_s * Psi_conj  # Gamma Psi*
```

`.conjugate()` takes the complex conjugate of every component; since `x4` and `z` were declared real, sympy conjugates only the numbers i in χ.

```
def vanishes(vector):
    """True when every component expands to exactly zero (sympy multiplies out
    every product; cos z / cos z cancels automatically)."""
    return vector.expand() == sp.zeros(16, 1)

check(vanishes(E(m, Psi_conj)) and vanishes(E(-m, Psi_gamma_conj)),
      "Psi* solves the equation with mass +2, Gamma Psi* with mass -2 (exact)")
check(not vanishes(E(-m, Psi_conj)) and not vanishes(E(m, Psi_gamma_conj)),
      "negative controls: Psi* fails with -2, Gamma Psi* fails with +2")
```

The first check proves what Section 21.11 derived: Ψ^* solves the equation with the same mass $+2$, $\Gamma\Psi^*$ the one with the reversed mass -2. The second is a **negative control**, a test that must fail if the computation is meaningful: with the masses exchanged the equations do not hold.

In [13]: the conjugates along the time, numerically.

```
times = np.linspace(0.0, 8.0, 161)  # 161 times x4 from 0 to 8
z_fixed = np.pi / 4
```

`np.linspace(0, 8, 161)` gives 161 equally spaced times from 0 to 8 (steps of 0.05). The angle is fixed at $z = \pi/4$.

```
def numeric(expression):
    """Evaluate a sympy 16 x 1 expression of x4 at z = pi/4 for all times."""
    f = sp.lambdify((x4, z), expression, "numpy")
    return np.array([np.array(f(t, z_fixed), dtype=complex).reshape(16)
                     for t in times])

def size(expression):
    """|E| at every time: the length of the 16-component column."""
    return np.linalg.norm(numeric(expression), axis=1)
```

`sp.lambdify` turns an exact expression into a fast numerical function of x_4 and z. `numeric` evaluates it at every time and stacks the 161 columns into an array of shape 161×16. `size` computes for each time the length of the column, the square root of the sum of the squared moduli of its 16 entries (`np.linalg.norm` along `axis=1`, that is along each row of the array).

```
curves = {
    r"$|E_{+2}[\Psi^*]|$ (same mass)": size(E(m, Psi_conj)),
    r"$|E_{-2}[\Gamma\Psi^*]|$ (mass reversed)": size(E(-m, Psi_gamma_conj)),
    r"$|E_{-2}[\Psi^*]|$ (control)": size(E(-m, Psi_conj)),
```

```
    r"$|E_{+2}[\Gamma\Psi^*]|$ (control)": size(E(m, Psi_gamma_conj)),
}
floor = 1e-17  # added before taking the logarithm, so that 0 can be drawn
values = list(curves.values())
```

The four sizes, stored under their legend texts: the two solutions and the two controls. On a logarithmic axis zero cannot be drawn, so `floor` (10^{-17}) will be added. `values` is the list of the four arrays, in the order written.

```
say(f"largest |E| of the two solutions below 1e-12: "
    f"{max(values[0].max(), values[1].max()) < 1e-12}")
say(f"smallest |E| of the two controls: {min(values[2].min(), values[3].min()):.2f}")
field_size = size(Psi_conj)  # |Psi*| = |Gamma Psi*| at every time (Gamma permutes)
```

The first line prints True: both solutions give sizes below 10^{-12} at every time (rounding only). The second prints the smallest size of the controls, 9.67 (`:.2f` prints two decimals). `field_size` is the length of Ψ^* at every time; Γ only changes signs of components, so $\Gamma\Psi^*$ has the same length.

```
check(max(values[0].max(), values[1].max()) < 1e-12
      and np.allclose(values[2], 4 * field_size)
      and np.allclose(values[3], 4 * field_size),
      "numerically: the solutions give |E| below 1e-12, the controls |E| = 4 |field|")
```

The controls are exactly four times the length of the field, as Section 21.11 predicted ($E_{-2}[\Psi^*] = 4\Psi^*$).

```
B_c = B.astype(complex)  # the charge density is J^(x4) = Psi^dagger B Psi
density = {}
for field, label in ((Psi, r"$\Psi$"), (Psi_conj, r"$\Psi^*$"),
                     (Psi_gamma_conj, r"$\Gamma\Psi^*$")):
    values_f = numeric(field)  # shape (161, 16): the field at every time
    density[label] = np.einsum("tr,rc,tc->t", np.conj(values_f), B_c, values_f).real
d_psi, d_conj, d_gconj = density.values()
```

For each of the three fields the values at all times are computed, and `np.einsum("tr,rc,tc->t", ...)` forms, for each time t, the sum $\sum_{r,c} \Psi^*_r B_{rc} \Psi_c$: the letters name the indices of the three arrays, and the index after the arrow is the one kept. `.real` keeps the real part (the imaginary part is zero up to rounding, since B is Hermitian). The last line unpacks the three density arrays.

```
check(np.allclose(d_conj, -d_psi) and np.allclose(d_gconj, d_psi)
      and np.ptp(d_psi) > 0.1,
      "charge density: Psi* has -J^(x4), Gamma Psi* has +J^(x4) at every time")
```

Ψ^* carries the opposite charge density at every time and $\Gamma\Psi^*$ the same, as the table of Section 21.10 says for commuting components. `np.ptp` (peak to peak) is the largest minus the smallest value; requiring it above 0.1 makes sure the density is not trivially zero or constant.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.4))
for (label, values_d), style in zip(density.items(), ["-", "--", ":"]):
    axes[0].plot(times, values_d, style, linewidth=2, label=f"{label}")
axes[0].set_xlabel("time $x_4$")
axes[0].set_ylabel("charge density $\\Psi^\\dagger B\\Psi$ at $z = \\pi/4$")
axes[0].set_title("A solution and its two conjugates")
axes[0].legend(fontsize=8)
```

The left panel draws the three densities against the time, with a solid, a dashed and a dotted line (`density.items()` gives the pairs label and values).

```
for (label, values_e), style in zip(curves.items(), ["-", "--", "-.", ":"]):
    axes[1].semilogy(times, values_e + floor, style, label=label)
axes[1].set_xlabel("time $x_4$")
axes[1].set_ylabel("$|E|$ at $z = \\pi/4$ (log scale)")
axes[1].set_title("Which mass does each conjugate solve?")
axes[1].legend(fontsize=8)
```

The right panel draws the four sizes on a logarithmic axis, each raised by the floor.

```
save_figure(fig, "curved_solution_images",
            "Charge conjugation acting on an exact solution of the field equation "
            "in the author's metric ($H = 1/6$, $\\alpha = 1$, mass $m = 2$, valid "
            "for every history $a_4$). Left: the charge density "
            "$\\Psi^\\dagger B\\Psi$ of $\\Psi$ (solid), $\\Psi^\\ast$ (dashed) and "
            "$\\Gamma\\Psi^\\ast$ (dotted, on top of the solid curve) versus the "
            "time $x_4$ at $z = \\pi/4$ (pure numbers); $\\Psi^\\ast$ carries the "
            "opposite charge density. Right: the size $|E|$ of the left-hand "
            "side of the field equation versus $x_4$, logarithmic scale. $\\Psi^\\ast$ "
            "solves the equation with the same mass $+2$ and $\\Gamma\\Psi^\\ast$ the "
            "one with the reversed mass $-2$ ($|E|$ at rounding level, about "
            "$10^{-16}$), while the exchanged masses fail ($|E|$ equals four "
            "times the size of the field, about 10).")
```

Figure 21a.5. **What the figure shows.** Left: the dashed curve is the mirror image of the solid one in the horizontal axis (opposite charge density), and the dotted curve lies on the solid one. The densities are quadratic in $\cos(wx_4)$ and $\sin(wx_4)$ with $w = \sqrt{7}/2$, so they oscillate with the angular frequency $2w = \sqrt{7}$, a period of about 2.37. Right: the two solutions stay at the rounding level near 10^{-16} at the bottom, the two controls near 10 at the top: about seventeen orders of magnitude separate "solves" from "does not solve".

In [14]: the sign table of S and J.

```
def effective(Mmat, K, eps):
    """The matrix K' of the bilinear after Psi -> M Psi*, with the reorder sign eps."""
    return eps * (Mmat.conj().T @ K @ Mmat).T

def sign_of(Kp, K):
    """+1 if K' = K, -1 if K' = -K, 0 otherwise."""
    return 1 if np.allclose(Kp, K) else (-1 if np.allclose(Kp, -K) else 0)
```

`effective` is the rule $K' = \epsilon(M^\dagger K M)^T$ of Section 21.10. `sign_of` compares K' with K and $-K$ and returns the sign, or 0 when neither matches (which never happens here).

```
K_S = C.astype(complex)  # the scalar S = Psi^dagger C Psi
K_J = [-1j * (C @ gamma[x]) for x in COORDS]  # the currents J^a
measured = {}
```

The matrices of the scalar and of the eight currents; `measured` will collect the signs.

```
for label, Mmat in (("plus", I16), ("minus", Gamma)):
    for eps in (1, -1):
        sS = sign_of(effective(Mmat, K_S, eps), K_S)
        sJ = [sign_of(effective(Mmat, K, eps), K) for K in K_J]
        measured[f"{label},eps={eps}"] = [sS, sJ]
        kind = "commuting" if eps == 1 else "anticommuting"
        say(f"calC_{'+' if label == 'plus' else '-'}, {kind:13}: S -> {sS:+d} S, "
            f"J -> {sJ[0]:+d} J (all eight components alike: {len(set(sJ)) == 1})")
```

Two nested loops over the two matrices and the two kinds of components. For each case the sign of S and the list of the eight signs of the currents are stored under a key such as `"plus,eps=1"`, the spelling the record uses. The printed line uses a small conditional inside the f-string to write + or −, pads the kind to 13 characters (`{kind:13}`) so that the columns line up, and reports whether the eight current signs are all equal (`set(sJ)` has one element then). Out [14] prints the four rows of the table of Section 21.10.

```
detail = LEAD["bilinears_under_charge_conjugation"]["detail"]
recorded = json.loads(detail.split("measured: ", 1)[1])  # the record's own table
check(measured == recorded and lead_passed("bilinears_under_charge_conjugation"),
      "signs of S and J under calC_+ and calC_-, both statistics, equal the record",
      record=f"{RECORD}, check bilinears_under_charge_conjugation")
```

The record's check stores its own measured table in its detail text after the words "measured: ". `split("measured:  ", 1)[1]` takes the text after them, `json.loads` reads it as a dictionary, and the check demands that the notebook's table is identical to the record's.

In [15]: the signs of all 256 bilinears.

```
CASES = [("plus", I16, 1), ("plus", I16, -1), ("minus", Gamma, 1), ("minus", Gamma, -1)]
degree_signs = np.zeros((4, 9), dtype=int)  # rows: the four cases, columns: k
```

The four cases (matrix, kind of components) and an array of zeros with four rows and nine columns for the signs of the degrees $k = 0, \ldots, 8$.

```
for row, (label, Mmat, eps) in enumerate(CASES):
    for k in range(9):
        signs = {sign_of(effective(Mmat, C @ product(A), eps), C @ product(A))
                 for A in itertools.combinations(COORDS, k)}
        # one common sign for all products of degree k, else 0
        degree_signs[row, k] = signs.pop() if len(signs) == 1 else 0
```

`itertools.combinations(COORDS, k)` lists every choice of k different directions in the order $x_0, \ldots, x_7$; together over $k = 0, \ldots, 8$ these are the 256 products Γ_A (`product(A)`; the empty choice gives the identity). For each one the sign of the bilinear with the matrix $C\Gamma_A$ is computed, and the braces collect the signs into a **set**, which keeps each different value once. If all products of degree k share one sign, the set has one element and `pop()` takes it out; otherwise 0 is stored.

```
k_all = np.arange(9)
formula = np.array([(-1) ** (k_all * (k_all + 1) // 2),
                    -(-1) ** (k_all * (k_all + 1) // 2),
                    (-1) ** (k_all * (k_all - 1) // 2),
                    -(-1) ** (k_all * (k_all - 1) // 2)])
```

The four rows of the degree rules of Section 21.10: $(-1)^{k(k+1)/2}$ for $\mathcal{C}_+$, $(-1)^{k(k-1)/2}$ for $\mathcal{C}_-$, each with an extra minus sign for anticommuting components. numpy computes the power for all nine values of k at once.

```
for row, (label, _, eps) in enumerate(CASES):
    say(f"calC_{'+' if label == 'plus' else '-'}, eps = {eps:+d}: signs for k = 0..8: "
        + " ".join(f"{s:+d}" for s in degree_signs[row]))
check(np.array_equal(degree_signs, formula),
      "all 256 bilinears: the sign depends only on the degree k, as the formulas say")
```

The underscore `_` is a name for a value that is not used. Each row of measured signs is printed (Out [15]); the check demands that every sign was common to its degree (no 0) and equals the formula.

In [16]: the sign table as a picture.

```
fig, ax = plt.subplots(figsize=(9.0, 3.8))
ax.imshow(degree_signs, cmap=SIGNS, vmin=-1, vmax=1, aspect="auto")
for row in range(4):
    for k in range(9):
        ax.text(k, row, f"{degree_signs[row, k]:+d}", ha="center", va="center")
```

The 4×9 array is drawn as coloured squares (`aspect="auto"` lets the squares stretch to fill the panel), and `ax.text` writes each sign in the middle of its square (`ha` and `va` are the horizontal and vertical alignment).

```
ax.set_xticks(range(9), ["0\n($S$)", "1\n($J$)"] + [str(k) for k in range(2, 9)])
ax.set_yticks(range(4), [r"$\mathcal{C}_+$, commuting",
                         r"$\mathcal{C}_+$, anticommuting",
                         r"$\mathcal{C}_-$, commuting",
                         r"$\mathcal{C}_-$, anticommuting"])
ax.set_xlabel("degree $k$ (number of gamma factors in the bilinear)")
ax.set_title("Sign of every bilinear under the two charge conjugations")
ax.grid(False)
```

The column labels mark the scalar ($k = 0$) and the current ($k = 1$); `str(k)` writes a number as text. The row labels name the four cases.

```
save_figure(fig, "bilinear_signs",
            "The sign that each of the 256 bilinears $\\bar\\Psi\\gamma^{a_1}"
            "\\cdots\\gamma^{a_k}\\Psi$ acquires under $\\Psi \\to M\\Psi^\\ast$ "
            "($M = 1$ for $\\mathcal{C}_+$, $M = \\Gamma$ for $\\mathcal{C}_-$), "
            "for commuting and anticommuting components; horizontal axis the degree "
            "$k$, rows the four cases, colour and number the sign (red $+1$, blue "
            "$-1$). All products of the same degree share one sign. For commuting "
            "components $\\mathcal{C}_+$ keeps the scalar $S$ ($k = 0$) and "
            "reverses the current $J$ ($k = 1$); anticommuting components reverse "
            "every sign.")
```

Figure 21a.6. **What the figure shows.** Each row repeats a pattern of two equal signs followed by two opposite ones: $+, -, -, +, +, -, -, +, +$ for $\mathcal{C}_+$ with commuting components, shifted by one place for $\mathcal{C}_-$, and the colours exchanged for anticommuting components. The pattern has period 4 in k because $k(k+1)/2$ changes its parity in pairs.

In [17]: a numerical confirmation with numbers.

```
rng = np.random.default_rng(2101)  # a fixed seed: the same numbers in every run
psi = rng.normal(size=16) + 1j * rng.normal(size=16)  # a complex field value
```

`np.random.default_rng(2101)` makes a random-number generator started from the fixed **seed** 2101, so every run draws the same numbers. `rng.normal(size=16)` draws 16 numbers from the bell-shaped normal distribution; two such draws make a complex column.

```
def S_of(p):
    """S = Psi^dagger C Psi."""
    return np.conj(p) @ C @ p

def J_of(p):
    """The eight currents J^a = Psi^dagger (-i C gamma^a) Psi."""
    return np.array([np.conj(p) @ K @ p for K in K_J])
```

For a numpy column `p`, `np.conj(p) @ C @ p` is the number $\sum_{r,c} p_r^* C_{rc} p_c$.

```
for label, p in (("Psi", psi), ("Psi*", np.conj(psi)),
                 ("Gamma Psi*", Gamma @ np.conj(psi))):
    say(f"{label:10}: S = {S_of(p).real:+.4f}, J^(x4) = {J_of(p)[4].real:+.4f}")
```

For the three columns the scalar and the time current (`J_of(p)[4]`, position 4 is x_4) are printed with a sign and four decimals: Out [17] shows $S = +6.0205$ for all three and $J^{(x4)} = +6.4970$, -6.4970, $+6.4970$.

```
check(np.isclose(S_of(np.conj(psi)), S_of(psi))
      and np.allclose(J_of(np.conj(psi)), -J_of(psi))
      and np.isclose(S_of(Gamma @ np.conj(psi)), S_of(psi))
      and np.allclose(J_of(Gamma @ np.conj(psi)), J_of(psi)),
      "numbers: Psi* keeps S and reverses J; Gamma Psi* keeps S and J")
```

The commuting rows of the table, confirmed with numbers for all eight currents (`np.isclose` compares two numbers up to rounding).

In [18]: real fields, exactly.

```
r = sp.Matrix(sp.symbols("r1:17", real=True))  # a real field with symbolic entries
C_s = sp.Matrix(C.tolist())
antisymmetric = all(np.array_equal((C @ gamma[x]).T, -(C @ gamma[x])) for x in COORDS)
```

`sp.symbols("r1:17", real=True)` makes the 16 real symbols $r_1, \ldots, r_{16}$ (the range stops before 17); `sp.Matrix` puts them into a column, a real field with completely general components. `C_s` is the exact copy of C. The third line checks that all eight $C\gamma^a$ are antisymmetric.

```
currents_zero = all(sp.expand((-sp.I * r.T * C_s * G[x] * r)[0, 0]) == 0
                    for x in COORDS)
S_kept = sp.expand((Gamma_s * r).T * C_s * (Gamma_s * r) - r.T * C_s * r) == \
    sp.zeros(1, 1)
kinetic_reversed = all(np.array_equal(Gamma.T @ C @ gamma[x] @ Gamma, -(C @ gamma[x]))
                       for x in COORDS)
```

`(-sp.I * r.T * C_s * G[x] * r)[0, 0]` is the single entry of the 1×1 matrix $-ir^T C\gamma^a r$; expanded, it is exactly zero for every a: (F1). The second statement is broken over two lines by a backslash at the end of the first (a **line continuation**); it tests that $(\Gamma r)^T C(\Gamma r) - r^T C r$ is exactly zero, so Γ keeps S. The third tests $\Gamma^T C\gamma^a \Gamma = -C\gamma^a$ for all eight directions: (F3).

```
check(antisymmetric and currents_zero and S_kept and kinetic_reversed
      and lead_passed("real_fields_charge_conjugation"),
      "real fields: J^a = 0, calC_+ is the identity, Gamma keeps S and reverses "
      "every kinetic matrix C gamma^a",
      record=f"{RECORD}, check real_fields_charge_conjugation")
```

The four facts together reproduce the record check. (That $\mathcal{C}_+$ is the identity on a real field needs no computation: $\Psi^* = \Psi$.)

In [19]: real fields, in a picture.

```
psi_r = rng.normal(size=16)  # a real column
phi_r = rng.normal(size=16)  # a second real column
kinetic_before = np.array([psi_r @ C @ gamma[x] @ phi_r for x in COORDS])
kinetic_after = np.array([(Gamma @ psi_r) @ C @ gamma[x] @ (Gamma @ phi_r)
                          for x in COORDS])
S_before, S_after = psi_r @ C @ psi_r, (Gamma @ psi_r) @ C @ (Gamma @ psi_r)
```

Two real columns from the same generator (the next numbers it draws). Think of `phi_r` as the derivative of the field in the kinetic term. The eight **kinetic numbers** $\Psi^T C\gamma^a \Phi$ are computed before and after the map Γ, and so is the scalar: $S = \Psi^T C \Psi$ before and $(\Gamma\Psi)^T C(\Gamma\Psi)$ after. For a real column `psi_r @ C @ psi_r` is exactly $\Psi^T C \Psi$.

```
say(f"S before = {S_before:+.4f}, S after = {S_after:+.4f}")
check(np.allclose(kinetic_after, -kinetic_before) and np.isclose(S_after, S_before),
      "numbers: Gamma reverses the eight kinetic numbers and keeps S")
```

Out [19] prints $S = -6.5629$ before and after, and the check confirms that all eight kinetic numbers change sign.

```
fig, axes = plt.subplots(1, 2, figsize=(11.5, 4.3), width_ratios=[1, 1.4])
heat_map(axes[0], C @ gamma["x4"], r"$C\gamma^{(x4)}$ is antisymmetric")
positions = np.arange(8)
axes[1].bar(positions - 0.2, kinetic_before, width=0.4,
            label=r"$\Psi^T C\gamma^a\Phi$")
axes[1].bar(positions + 0.2, kinetic_after, width=0.4,
            label=r"$(\Gamma\Psi)^T C\gamma^a(\Gamma\Phi)$")
axes[1].axhline(0.0, color="black", linewidth=0.8)
axes[1].set_xticks(positions, COORDS)
axes[1].set_xlabel("direction $a$")
axes[1].set_ylabel("kinetic number")
axes[1].set_title(f"$\\Gamma$ reverses the kinetic numbers; $S$ = {S_before:.3f} "
                  "stays")
axes[1].legend()
```

Two panels, the right one 1.4 times as wide (`width_ratios`). Left: the heat map of $C\gamma^{(x4)}$. Right: pairs of bars for the eight kinetic numbers before and after the map, a black line at zero, the coordinate names as tick labels, and a title that includes the value of S with three decimals.

```
save_figure(fig, "real_fields",
            "Real fields. Left: heat map of the real matrix $C\\gamma^{(x4)}$ "
            "(horizontal axis the column, vertical axis the row, red $+1$, blue "
            "$-1$); it is antisymmetric, so $\\Psi^T C\\gamma^{(x4)}\\Psi = 0$ for "
            "every real $\\Psi$ and a real field carries no current. Right: the "
            "eight kinetic numbers $\\Psi^T C\\gamma^a\\Phi$ of two fixed real "
            "columns (left bars) and of their images under the real matrix "
            "$\\Gamma$ (right bars); horizontal axis the direction $a$, vertical "
            "axis the value (pure numbers). Every kinetic number changes sign "
            "while $S = \\Psi^T C\\Psi$ stays: with the mass reversed, $\\Gamma$ "
            "maps real solutions to real solutions.")
```

Figure 21a.7. **What the figure shows.** Left: every red square has a blue partner at the mirror position across the diagonal, the picture of antisymmetry, which is why a real field carries no current. Right: each pair of bars has equal height and opposite sign: Γ reverses the kinetic term while keeping the mass term, which is the same as keeping the kinetic term and reversing the mass, up to the overall sign of the Lagrangian.

In [20]: the record and the figure files.

check(summary["passed"] == summary["total"] == 12
      and all(lead_passed(name) for name in REPRODUCED_HERE),
      "the lead record passes 12 of 12; the nine checks reproduced here are in it")
```

The list of the nine record checks this notebook reproduced; the check asks that the lead report passes all 12 of its checks and holds each of the nine. (The other three concern the spin connection and the U(1) identity, reproduced in Notebook 21b, and the quantised field, reproduced in Notebook 21c.)

```
names = sorted(FIGURE_NUMBERS, key=FIGURE_NUMBERS.get)  # in the order of saving
check(len(names) == 7 and all(
    output_file(f"{FIGURE_FOLDER}/21a_{FIGURE_NUMBERS[n]}_{n}.png").is_file()
    for n in names), "the seven figure files of notebook 21a exist")
all_checks_passed()
```

`sorted(..., key=FIGURE_NUMBERS.get)` lists the figure names in the order of their numbers. The check asks that there are seven and that each file exists where it was written. The last line prints ALL 27 CHECKS PASSED (notebook 21a), the line you must see at the end.

21.16 The phase symmetry and Noether's current

Sakharov's first condition asks whether some process can change the number that counts matter minus antimatter. The theory of this book has no baryons; the only number of this kind it has is the U(1) charge Q of Section 21.7. This section finds the current that belongs to the phase symmetry, and Section 21.17 proves its exact local conservation law: the charge can change only by a flow through the boundary.

The symmetry. Under $\Psi \to e^{i\alpha}\Psi$ with a constant α, $\Psi^\dagger \to e^{-i\alpha}\Psi^\dagger$ (the conjugate of $e^{i\alpha}$ is $e^{-i\alpha}$), so every bilinear $\Psi^\dagger X \Psi$ is multiplied by $e^{-i\alpha}e^{i\alpha} = 1$, and $\mathcal{L}$, built from bilinears, does not change.

A phase that changes from point to point, line by line. Let $\alpha(x)$ be a function of the coordinates and write $\alpha_\mu = \partial_\mu \alpha$. For $\Psi' = e^{i\alpha}\Psi$:

$$D_\mu \Psi' = \partial_\mu(e^{i\alpha}\Psi) + \Omega_\mu e^{i\alpha}\Psi = e^{i\alpha}\big(D_\mu\Psi + i\alpha_\mu\Psi\big)$$

(product rule and chain rule, $\partial_\mu e^{i\alpha} = i\alpha_\mu e^{i\alpha}$; the number $e^{i\alpha}$ passes through the matrix Ω_μ). In the same way $\bar\Psi' = (e^{i\alpha}\Psi)^\dagger C = e^{-i\alpha}\bar\Psi$ and

$$D_\mu \bar\Psi' = \partial_\mu(e^{-i\alpha}\bar\Psi) - e^{-i\alpha}\bar\Psi\Omega_\mu = e^{-i\alpha}\big(D_\mu\bar\Psi - i\alpha_\mu\bar\Psi\big).$$

Inserting both into the kinetic term, the phases $e^{-i\alpha}e^{i\alpha} = 1$ cancel and

$$\tfrac{1}{2}\big(\bar\Psi'\gamma^\mu D_\mu\Psi' - (D_\mu\bar\Psi')\gamma^\mu\Psi'\big) = \tfrac{1}{2}\big(\bar\Psi\gamma^\mu(D_\mu\Psi + i\alpha_\mu\Psi) - (D_\mu\bar\Psi - i\alpha_\mu\bar\Psi)\gamma^\mu\Psi\big)$$

$$= \tfrac{1}{2}(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi) + i\alpha_\mu\bar\Psi\gamma^\mu\Psi$$

(the two terms with α_μ are equal and add: $\tfrac{1}{2}(i+i)=i$). Since $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, we have $\bar\Psi\gamma^\mu\Psi = iJ^\mu$ and $i\alpha_\mu\bar\Psi\gamma^\mu\Psi = i\cdot i\,\alpha_\mu J^\mu = -\alpha_\mu J^\mu$. The scalar S does not change. Hence, with the sum over μ,

$$\mathcal{L}' - \mathcal{L} = -\cos z\,\alpha_\mu J^\mu.$$

The current is the coefficient of $\partial_\mu\alpha$. This is **Noether's construction**. On a solution of the field equations the action $\int \mathcal{L}\,d^8x$ does not change to first order under any small change of the field that vanishes at the boundary (the principle of stationary action of Chapter 7). For a small α that vanishes at the boundary, $e^{i\alpha}\Psi$ is such a change, so

$$0 = \int (\mathcal{L}' - \mathcal{L})\,d^8x = -\int \cos z\,(\partial_\mu\alpha)J^\mu\,d^8x = \int \alpha\,\partial_\mu(\cos z\,J^\mu)\,d^8x$$

(the last step is integration by parts in each coordinate; the boundary term vanishes because α does). This holds for every such α, which is only possible if $\partial_\mu(\cos z\,J^\mu) = 0$ at every point inside the region: **the current is conserved on every solution**, as a **local** law (whether the total charge stays constant depends on what flows through the boundary, Sections 21.17 and 21.18). Notebook 21b checks the formula $\mathcal{L}' - \mathcal{L} = -\cos z\,\alpha_\mu J^\mu$ with numbers at one point of the author's metric, with the full spin connection, $m = 0.7$, $\lambda = 0.3$ and random field values: it finds $\mathcal{L} = -16.780795$, the same value after a constant phase, and $\mathcal{L}' - \mathcal{L} = +2.348835 = -\cos z\,\alpha_\mu J^\mu$ for a local phase (In [9]).

21.17 Exact local charge conservation in the author's metric

Noether's argument rests on the principle of stationary action. The Revision record also proves the conservation law directly, as an exact identity, and this section derives it line by line. Write the current as $J^\mu = \Psi^\dagger K^\mu\Psi$ with $K^\mu = -iC\gamma^\mu$ and the field equation as $E = \gamma^\mu D_\mu\Psi - V\Psi = 0$, with real $V = m + U'(S)$; the components are commuting here (the matrix identity found at the end contains no field, and the record checks the conservation law for both kinds of components: checks `commuting_current_conservation` and `grassmann_current_conservation` of `Revision /theory/reports/python-field-theory.json`).

Line 1 (product rule).

$$\partial_\mu(\cos z\,J^\mu) = \Psi^\dagger\big[\partial_\mu(\cos z\,K^\mu)\big]\Psi + \cos z\big[(\partial_\mu\Psi)^\dagger K^\mu\Psi + \Psi^\dagger K^\mu\partial_\mu\Psi\big].$$

Line 2 (the combination of the field equation). Consider $-i\cos z\,(\Psi^\dagger CE - E^\dagger C\Psi)$. Insert E; since the gammas and the Ω_μ are real, $E^\dagger = (\partial_\mu\Psi)^\dagger(\gamma^\mu)^T + \Psi^\dagger\Omega_\mu^T(\gamma^\mu)^T - V\Psi^\dagger$. The two terms with V give $-i\cos z\,(V\Psi^\dagger C\Psi - V\Psi^\dagger C\Psi) = 0$, because V is real.

Line 3 (the derivative terms). What remains of the derivative terms is $-i\cos z\,\big[\Psi^\dagger C\gamma^\mu\partial_\mu\Psi - (\partial_\mu\Psi)^\dagger(\gamma^\mu)^T C\Psi\big]$. By (R3), $(\gamma^\mu)^T C = -C\gamma^\mu$ (the scale factor $1/f_\mu$ is a number), so this is $-i\cos z\,\big[\Psi^\dagger C\gamma^\mu\partial_\mu\Psi + (\partial_\mu\Psi)^\dagger C\gamma^\mu\Psi\big] = \cos z\big[\Psi^\dagger K^\mu\partial_\mu\Psi + (\partial_\mu\Psi)^\dagger K^\mu\Psi\big]$: exactly the second part of line 1.

Line 4 (the spin-connection terms). They give $-i\cos z\,\Psi^\dagger\big[C\gamma^\mu\Omega_\mu - \Omega_\mu^T(\gamma^\mu)^TC\big]\Psi$.

Line 5 (the matrix identity). So $\partial_\mu(\cos z\,J^\mu) = -i\cos z\,(\Psi^\dagger CE - E^\dagger C\Psi)$ holds for every field as soon as the first part of line 1 equals line 4, that is (dividing by $-i$) as soon as the 16×16 **matrix identity**

$$\sum_\mu \partial_\mu\big(\cos z\,C\gamma^\mu\big) = \cos z\sum_\mu\big(C\gamma^\mu\Omega_\mu - \Omega_\mu^T(\gamma^\mu)^TC\big)$$

holds (and only then: two matrices that give the same bilinear for every column are equal when, as here, i times each is Hermitian).

Line 6 (conservation). On a solution $E=0$, so $\partial_\mu(\cos z\,J^\mu)=0$. Integrate over a region of the seven coordinates other than x_4 and over a time interval: by the fundamental theorem of calculus the charge $Q(x_4)=\int\cos z\,J^{(x4)}d^7x$ changes only by the **flux** of $\cos z\,J^\mu$ through the boundary of the region. With no flux, Q is constant. Whether the flux through the brane $z=\pi/2$ vanishes is not decided by the field equation: the record derives no boundary condition there, Section 21.18 shows an exact solution through whose brane charge flows, and Section 18.21 shows the same for the homogeneous solutions (there the charge of a patch of coordinate volume V_6 changes at the rate $-V_6q_0$, with the frame current q_0 running from -0.3454 to 0.3454 on the solution of Notebook 18c). The **no-flux condition** at the brane is therefore ASSUMED wherever it is used, and whether a junction condition at the brane implies it is OPEN.

The matrix identity in the author's metric, by hand. The left side is a sum over the eight directions of $\partial_\mu(\cos z/f_\mu)\,C\gamma^{(\mu)}$ (the curved gamma is $\gamma^{(\mu)}/f_\mu$).

- For $\mu = x_1, x_2, x_3, x_5, x_6, x_7$ the factor $\cos z/f_\mu$ depends only on x_4 and x_0, and it is differentiated along x_μ itself: zero.
- For $\mu = x_4$: $f_4 = 1$ and $\cos z$ does not depend on x_4: zero. (This is where the volume factor matters.)
- For $\mu = x_0$: $\cos z/f_0 = \cos z/\cot z = \sin z$, and $\partial_0\sin z = 6H\cos z$ (chain rule, $z = 6Hx_0$).

So the left side is $6H\cos z\,C\gamma^{(x0)}$. For the right side the record gives the spin connection (formula `Omega_components` of `Revision/theory/field-theory.json`; Chapters 6 and 8 derive it):

$$\Omega_{x_i} = \tfrac{1}{2}f_i\big(a_4'\gamma^{(xi)}\gamma^{(x4)} + H\gamma^{(xi)}\gamma^{(x0)}\big)\qquad (i=1,2,3),$$

$$\Omega_{x_t} = -\tfrac{1}{2}f_t\big(a_4'\gamma^{(x4)}\gamma^{(xt)} + H\gamma^{(xt)}\gamma^{(x0)}\big)\qquad (t=5,6,7),$$

and $\Omega_{x_4}=\Omega_{x_0}=0$, with $f_i = e^{a_4}\sin^{1/6}z$ and $f_t = e^{-a_4}\sin^{1/6}z$. Write $Y_\mu = \gamma^\mu\Omega_\mu$ (no sum). Since $\Omega_\mu^T(\gamma^\mu)^T = Y_\mu^T$ and, by (R3), $Y^TC = -CY$ for any combination Y of single gammas, each direction contributes $\cos z\,(CY_\mu - Y_\mu^TC) = 2\cos z\,CY_\mu$.

- Ordinary space, $i=1,2,3$: $Y_{x_i} = (\gamma^{(xi)}/f_i)\tfrac{1}{2}f_i\big(a_4'\gamma^{(xi)}\gamma^{(x4)} + H\gamma^{(xi)}\gamma^{(x0)}\big) = \tfrac{1}{2}\big(a_4'\gamma^{(x4)} + H\gamma^{(x0)}\big)$, because $\gamma^{(xi)}\gamma^{(xi)} = +1$. Contribution: $\cos z\,C\big(+a_4'\gamma^{(x4)} + H\gamma^{(x0)}\big)$.

- Extra times, $t = 5, 6, 7$: $Y_{x_t} = -\frac{1}{2}(a_4'\gamma^{(xt)}\gamma^{(x4)}\gamma^{(xt)} + H\gamma^{(xt)}\gamma^{(xt)}\gamma^{(x0)})$. Here $\gamma^{(xt)}\gamma^{(x4)}\gamma^{(xt)} = -\gamma^{(x4)}\gamma^{(xt)}\gamma^{(xt)} = \gamma^{(x4)}$ (anticommute, then $\gamma^{(xt)}\gamma^{(xt)} = -1$) and $\gamma^{(xt)}\gamma^{(xt)} = -1$, so $Y_{x_t} = \frac{1}{2}(-a_4'\gamma^{(x4)} + H\gamma^{(x0)})$. Contribution: $\cos z\, C(-a_4'\gamma^{(x4)} + H\gamma^{(x0)})$.

Adding the six contributions: the coefficient of $C\gamma^{(x4)}$ is $(3-3)a_4'\cos z = 0$ and that of $C\gamma^{(x0)}$ is $6H\cos z$. **Both sides equal $6H\cos z\, C\gamma^{(x0)}$, for every history a_4.** (The same six Ys add to $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)}$, the record's formula `gammaOmega_total`.) The identity is PROVED (lead check `u1_noether_matrix_identity` of `Revision/lead_checks/reports/charge-conjugation-and-u1.json`, which builds the connection from the metric with sympy and verifies the identity for a general $a_4(x_4)$; Notebook 21b repeats this, In [3] to In [5]).

Why the time-derivative terms cancel. Each inflating direction of space contributes $+a_4'$ to the coefficient of $C\gamma^{(x4)}$, each deflating extra time $-a_4'$. Suppose instead the extra times also inflated, with the scale factor $e^{+a_4}\sin^{1/6} z$ (a **control metric**, not the author's). Then each of the six contributes $+a_4'$, the right side has $6a_4'$ times the volume factor in front of $C\gamma^{(x4)}$, and the identity still holds, because now the volume factor is $\sqrt{|g|} = e^{6a_4}\cos z$ and the left side has the term $\partial_4(e^{6a_4}\cos z)\, C\gamma^{(x4)} = 6a_4'\, e^{6a_4}\cos z\, C\gamma^{(x4)}$. The identity holds in every metric; what is special about the author's metric is that $\sqrt{|g|} = e^{3a_4}e^{-3a_4}\cos z = \cos z$ does not depend on the time: **the deflation of the three extra times exactly compensates the inflation of the three space directions**, the volume of a slice stays constant, and no time-derivative term appears at all. Notebook 21b computes both metrics and draws the eight contributions (In [6] and In [7], figure 21b.1). A **negative control**: with the spin connection set to zero the right side vanishes but the left side does not, so without the spin connection the current would not be conserved (In [5], figure 21b.2).

statement	status	where it is verified
the current of the phase symmetry is $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, real; a constant phase leaves $\mathcal{L}$ unchanged	PROVED (Section 21.16); COMPUTED at a point	record formula `current`; Notebook 21b, In [2] and In [9]
the spin connection of the author's metric is real; it equals the record's formula; $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)}$	PROVED (sympy, general a_4)	lead check `spinor_connection_real`; formulas `Omega_components`, `gammaOmega_total`; Notebook 21b, In [4]
the U(1) matrix identity; both sides $6H\cos z\, C\gamma^{(x0)}$; fails without the connection	PROVED (sympy, general a_4)	lead check `u1_noether_matrix_identity`; Notebook 21b, In [5]
the a_4' terms cancel because the deflation keeps $\sqrt{\lvert g\rvert} = \cos z$; the control metric balances $6a_4'$ by its growing volume	PROVED (sympy)	Notebook 21b, In [6] (its own computation)

21.18 The charge of an exact solution: the flux through the brane, a constant charge, an indefinite density

The solution and its current. Take again the exact solution of Section 21.11 with $H = 1/6$, $\alpha = 1$, $m = 2$: $\Psi = \sin z\, U(x_4)\chi$ with the real matrix $U = \cos(wx_4) + \sin(wx_4)M/w$, $M =$

$-2\gamma^{(x4)} + \frac{3}{2}\gamma^{(x4)}\gamma^{(x0)}$, $w = \sqrt{7}/2$, and a fixed complex column χ (Notebook 21b uses one with exact rational entries). All eight components of its current are in general nonzero, but Ψ depends only on x_4 and z, so in the conservation law $\sum_\mu \partial_\mu(\cos z\, J^\mu) = 0$ only the terms with $\mu = x_4$ and $\mu = x_0$ survive. Their two densities are

$$\cos z\, J^{(x4)} = \cos z\, \Psi^\dagger B \Psi, \qquad \cos z\, J^{x0} = \cos z \tan z\, \Psi^\dagger K_0 \Psi = \sin z\, \Psi^\dagger K_0 \Psi, \quad K_0 = -iC\gamma^{(x0)},$$

because the curved gamma of x_0 is $\gamma^{(x0)}/f_0 = \tan z\, \gamma^{(x0)}$. With $H = 1/6$, $\partial_0 = \partial_z$, and the law reads $\partial_4(\cos z\, J^{(x4)}) + \partial_z(\cos z\, J^{x0}) = 0$; Notebook 21b checks it exactly (In [10]) and with finite differences (In [14]).

The charge balance, line by line. Since U is real, $\Psi^\dagger B \Psi = \sin^2 z\, \chi^\dagger U^T B U \chi = \sin^2 z\, f(x_4)$ with $f(x_4) = \chi^\dagger U^T B U \chi$, and in the same way $\Psi^\dagger K_0 \Psi = \sin^2 z\, g(x_4)$ with $g = \chi^\dagger U^T K_0 U \chi$.

Line 1. The charge of the patch (per unit of the other six coordinates) is $Q(x_4) = \int_0^{\pi/2} \cos z \sin^2 z\, dz\; f(x_4) = \frac{1}{3} f(x_4)$ (substitute $u = \sin z$, $du = \cos z\, dz$: $\int_0^1 u^2 du = \frac{1}{3}$).

Line 2. The flux density is $\sin z \cdot \sin^2 z\, g = \sin^3 z\, g(x_4)$: it is 0 at the tip $z = 0$ and $g(x_4)$ at the brane $z = \pi/2$.

Line 3. Integrate the conservation law over $0 < z < \pi/2$: $\frac{d}{dx_4} \int_0^{\pi/2} \cos z\, J^{(x4)} dz + \big[\sin^3 z\, g\big]_0^{\pi/2} = 0$ (the integral of a derivative is the difference of the end values), so $dQ/dx_4 = -g(x_4)$.

Line 4. Integrating from 0 to x_4:

$$Q(x_4) - Q(0) = -\int_0^{x_4} g(t)\, dt :$$

the charge of the patch changes exactly by what flows out through the brane. Notebook 21b checks this exactly with sympy (In [12]) and draws it (figure 21b.4); for its column χ the charge at $x_4 = 0$ is 0.178467.

A solution with zero flux. Since $M^2 = -w^2$ (Section 21.11, step 2, with $k^2 = -w^2$), define $P = \frac{1}{2}(1 - iM/w)$. Line by line:

- $P^2 = \frac{1}{4}(1 - 2iM/w + i^2M^2/w^2) = \frac{1}{4}(1 - 2iM/w + 1) = P$ (the square multiplied out; $i^2M^2/w^2 = (-1)(-w^2)/w^2 = 1$): P is a **projector**.
- $MP = \frac{1}{2}(M - iM^2/w) = \frac{1}{2}(M + iw) = iw\, \frac{1}{2}(1 - iM/w) = iwP$ (the same rule; $-iM^2/w = iw$; factor out iw, using $1/i = -i$).
- For $\chi_0 = P\chi$: $M\chi_0 = iw\chi_0$, hence $U\chi_0 = \big(\cos(wx_4) + i \sin(wx_4)\big)\chi_0 = e^{iwx_4}\chi_0$ (Euler's formula).

So $\Psi_0 = \sin z\, e^{iwx_4}\chi_0$ has a single frequency: a **stationary state**. Its charge density $\cos z \sin^2 z\, \chi_0^\dagger B \chi_0$ does not depend on the time (the phase e^{iwx_4} cancels against its conjugate), so by line 3 its flux through the brane is zero, and its charge is **constant**. For the column of Notebook 21b the constant is

$$Q_0 = -\frac{1424}{1875} - \frac{13\sqrt{7}}{1500} = -0.782397$$

(In [12], exact). It stays the same while the extra times deflate (figure 21b.6), and any other history gives the same constant: Ψ_0 does not depend on $x_1, x_2, x_3, x_5, x_6, x_7$, so it solves the field equation for every history a_4 (Section 21.11, step 4; record check `exact_solution_family_x4_x0`), and its charge density $\cos z \sin^2 z\, \chi_0^\dagger B \chi_0$ contains no a_4 (not even in the volume factor $\cos z$, because the deflation of the extra times compensates the inflation of space, Section 21.17). (The conservation law alone would not give this: a law that holds for every a_4 does not by itself make its constant independent of a_4.)

The charge density can be negative. $J^{(x4)} = \Psi^\dagger B \Psi$ is a quadratic expression with the matrix B, which has eight eigenvalues $+1$ and eight -1 (B is Hermitian, $B^2 = 1$ and its trace is 0; lead check `B_imaginary_hermitian` and record check `B_properties`). Writing $\Psi = \sum_j c_j v_j$ in orthonormal eigenvectors v_j of B gives $\Psi^\dagger B \Psi = \sum_{B=+1} |c_j|^2 - \sum_{B=-1} |c_j|^2$, which can have either sign; divided by $\Psi^\dagger \Psi = \sum |c_j|^2$ it lies between -1 and $+1$. *A worked example in flat space* ($H = 0$, a_4 constant). The field equation along the time is $\gamma^{(x4)} \partial_4 \Psi = m\Psi$. A **rest state** $\Psi = u\, e^{-imx_4}$ with $-i\gamma^{(x4)} u = u$ solves it: $\gamma^{(x4)} \partial_4 \Psi = \gamma^{(x4)} (-im) u\, e^{-imx_4} = m(-i\gamma^{(x4)} u) e^{-imx_4} = m\Psi$. It has the positive frequency m. Since C commutes with $\gamma^{(x4)}$ ((R3): x_4 is time-like) and $B = C(-i\gamma^{(x4)})$, B commutes with $-i\gamma^{(x4)}$ and maps the 8-dimensional space of such u into itself; there it has four eigenvalues $+1$ (eigenvector u_+) and four -1 (eigenvector u_-), as the notebook computes. For $u = \frac{3}{5} u_+ + \frac{4}{5} u_-$ (length 1, since $\frac{9}{25} + \frac{16}{25} = 1$) the charge density is $\frac{9}{25}(+1) + \frac{16}{25}(-1) = -\frac{7}{25}$: a positive-frequency field with a **negative** charge density (Notebook 21b, In [16]; figure 21b.7 shows that for 20000 random columns the normalised density takes both signs about equally often, a fraction 0.504 negative). The sign of the charge of a single field is therefore not fixed by the sign of its frequency; Chapter 10 explains what this means after quantisation (the Krein space).

statement	**status**	**where it is verified**
the exact solution solves the field equation (any a_4); local conservation for it	PROVED (sympy)	`Revision/theory/reports/python-field-theory.json`, checks `exact_solution_family_x4_x0`, `commuting_current_conservation`; Notebook 21b, In [10]
charge balance $Q(x_4) - Q(0) = -\int_0^{x_4} g$	PROVED (sympy); COMPUTED to 10^{-12} on 161 times	Notebook 21b, In [12] and In [13] (its own computation)
the stationary solution has zero flux and the constant charge $-1424/1875 - 13\sqrt{7}/1500 = -0.782397$	PROVED (sympy, exact)	Notebook 21b, In [12]
finite differences converge to the exact law with order 2	COMPUTED (ratios 3.966 to 4.000)	Notebook 21b, In [14]
B has signature (8,8); a positive-frequency rest state with charge density $-7/25$	PROVED (above); COMPUTED	Notebook 21b, In [16]

21.19 The pair-level bookkeeping: theorem T1 and the zero total charge

Theorem T1 of the Revision record (`Revision/docs/PAIR_CREATION_PROOFS.md`, its section 4; Chapter 18 gives the complete proof). For both fields, in every gravitational field taken as a fixed background, in particular the author's metric with the deflating extra times: for every configuration Ψ,

$$\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi], \qquad J^{\mu}[\Gamma\Psi] = -J^{\mu}[\Psi],$$

$\Gamma\Psi$ solves the field equations with (m, λ) if and only if Ψ solves them with $(-m, -\lambda)$, and the energy-momentum tensor is reversed as well.

The current part, line by line. $\overline{\Gamma\Psi} = (\Gamma\Psi)^{\dagger}C = \Psi^{\dagger}\Gamma^{\dagger}C = \Psi^{\dagger}\Gamma C = \Psi^{\dagger}C\Gamma = \bar{\Psi}\Gamma$ (the rule $(XY)^{\dagger} = Y^{\dagger}X^{\dagger}$; Γ is real and symmetric; Γ commutes with C by (R2)). Then $\overline{\Gamma\Psi}\gamma^{\mu}\Gamma\Psi = \bar{\Psi}\Gamma\gamma^{\mu}\Gamma\Psi = -\bar{\Psi}\gamma^{\mu}\Gamma\Gamma\Psi = -\bar{\Psi}\gamma^{\mu}\Psi$ (R1, then $\Gamma\Gamma = 1$). Multiplying by $-i$: $J^{\mu}[\Gamma\Psi] = -J^{\mu}[\Psi]$ at every point, for both kinds of components (Γ only multiplies each component by ± 1, so no components are reordered).

On the exact solution. For $\lambda = 0$, $\Gamma\Psi$ solves the equation with the mass -2: every term of E_m in Section 21.11 except the mass term contains one gamma, which anticommutes with Γ, so $E_{-m}[\Gamma\Psi] = -\Gamma E_m[\Psi] = 0$. Its charge density is the opposite of that of Ψ at every point, and the pair carries none (Notebook 21b, In [11], figure 21b.3). For the stationary solution the partner has the constant charge $+0.782397$ and the pair 0 (figure 21b.4, right). For five random columns at three times, $Q + Q' = 0$ to 10^{-12} while Q itself is nonzero (In [17], figure 21b.8).

What this says, exactly. A pair made of a solution Ψ with (m, λ) and its partner $\Gamma\Psi$ with $(-m, -\lambda)$, both in the same gravitational field, has total current zero and total charge zero, as **classical bilinears** (ordinary numbers for dirac16complex00, elements of the Grassmann algebra for dirac16complex). Record checks: `T1_current_primordial_commuting` and `T1_current_primordial_grassmann` of `Revision/pairing/reports/wolfram-pairing.json`, `T1.metric.commuting.current` of `Revision/pairing/reports/python-pairing.json`. Status: PROVED.

What it does not say (rule R3 of this book; the record's own list is in section 11.2 of `Revision/docs/PAIR_CREATION_PROOFS.md`):

- It does not create anything. T1 is a map between the solutions of two parameter sets. No equation of this theory produces a universe, or a pair of universes, from anything; no creation process, rate, probability or amplitude follows from these equations (Chapter 20).
- No equation forces the partner to exist: a single universe with the charge $Q \neq 0$ is an equally valid solution. If no charge flows through the brane (the ASSUMED no-flux condition, Sections 21.17 and 21.18), Q is constant, so its value is fixed by the initial data and is not explained.
- For $\lambda \neq 0$ the partner has the coupling $-\lambda$ as well; T1 is not a pairing of $+m$ with $-m$ at a fixed coupling.
- At the quantum level, the chirality image $\Gamma\Psi$ of the quantised field carries the Krein metric $-B$: it is the same quantum system, relabelled, and the identity $Q + Q' = 0$ is of the form $X + (-X) = 0$ within that one system. An independently quantised universe of mass $-m$ carries $+B$, cannot be identified with $\Gamma\Psi$, and its charge does not cancel ours (record checks

`Q_Krein_metric_of_images` and `Q_no_identification_of_independent_universes` of the Wolfram pairing report; Chapter 10).

- A T1 pair taken as the complete classical source of the author's metric is a zero source, and Einstein's equations then have no solution for $H > 0$ (corollary C1 of the record; check `einstein_no_vacuum_solution` of `Revision/field_equations_a4/reports/wolfram-a4-report.json`). So a T1 pair alone cannot even be the source of the author's universe.
- The member of mass $-m$ is not antimatter of our world: its negative mass is a parameter of a second field configuration. Nothing in this book says that antimatter has negative mass.

The idea that a universe and an anti-universe together are symmetric belongs to a class of ideas in the published literature; a published example is L. Boyle, K. Finn and N. Turok, "CPT-Symmetric Universe", Phys. Rev. Lett. 121, 251301 (2018), who propose that the universe after the big bang is the CPT image of the universe before it, so that the two epochs form a universe/anti-universe pair. Their proposal is cited only as an example of the class; this book neither uses nor tests it, and the pairing of this theory is of a different kind (both members exist at the same time x_4, related by the chirality matrix and $m \to -m$). Any scenario in which our universe is one member of such a pair is a **HYPOTHESIS** (Section 21.37).

21.20 Example: Notebook 21b follows the charge in the author's metric

Notebook 21b turns Sections 21.16 to 21.19 into exact computations. It reads the gammas, the lead report, the field-theory record and both pairing reports; it builds the canonical spin connection of the author's metric with sympy for an unspecified history $a_4(x_4)$ and checks it against the record; it verifies the U(1) matrix identity, its negative control and the control metric with inflating extra times; it checks the Noether current with a local phase at one point; it follows the charge of the record's exact solution (local conservation, the balance through the brane, a stationary solution of constant charge, a finite-difference test); it shows that the charge density is indefinite; and it does the pair-level bookkeeping of theorem T1. It runs in about 40 seconds; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/21b_charge_conservation.PROVENANCE.md`. It needs no Rust, prints 21 PASS lines and draws eight figures.

21.21 How to run Notebook 21b

Step 1. What this notebook does and what it needs.

Notebook 21b (Local U(1) charge conservation, the brane flux and the pair-level charge bookkeeping) is the file `Revision/textbook/notebooks/21b_charge_conservation.ipynb` of the repository Dirac_claude. It builds the canonical spin connection of the author's metric for a general history a4(x4) with sympy, checks that it is real, reduces the U(1) Noether identity to a 16 by 16 matrix identity and verifies it exactly (with a negative control without the spin connection and a control metric with inflating extra times, which shows that the a4 terms cancel because the deflating extra times keep the volume of a slice constant), checks the Noether current by a local phase change, follows the charge of an exact solution of the field equation in the author's metric (exact local conservation, second-order convergence of a finite-difference test, the charge balance with the flux

through the brane, a solution with zero flux and constant charge), shows that the charge density is indefinite, and does the pair-level bookkeeping of theorem T1: the chirality partner carries the opposite current, so the total charge of a pair is zero. Eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 21b_charge_conservation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 40 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21b_charge_conservation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 21b_charge_conservation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/21b.captions.json`
- `Revision/textbook/figures/21b_1_volume_balance.png`
- `Revision/textbook/figures/21b_2_noether_matrices.png`
- `Revision/textbook/figures/21b_3_charge_density_maps.png`
- `Revision/textbook/figures/21b_4_charge_balance.png`
- `Revision/textbook/figures/21b_5_local_conservation.png`
- `Revision/textbook/figures/21b_6_charge_through_deflation.png`
- `Revision/textbook/figures/21b_7_indefinite_charge.png`
- `Revision/textbook/figures/21b_8_pair_bookkeeping.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the eight figure files of notebook 21b exist
ALL 21 CHECKS PASSED (notebook 21b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/21b_charge_conservation.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 21b_charge_conservation.ipynb
python -m nbconvert --execute --inplace 21b_charge_conservation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`, `Revision/theory`, `Revision/pairing` or `Revision/lead_checks`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

21.22 Notebook 21b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/21b_charge_conservation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the

cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The first of Sakharov's three conditions for making more matter than antimatter
is that some process must **change** the number that counts matter minus
antimatter. The theory of this book contains no baryons; the only number of this
kind it has is the **U(1) charge** $Q$ of the field: the Lagrangian does not
change when the field is
multiplied by a constant phase $e^{i\alpha}$, and by Noether's theorem the charge
of this symmetry obeys a **local** conservation law: no process creates or
destroys it at any point of the patch $0 < z < \pi/2$ (off the brane), and the
charge of a region changes only by what flows through its boundary. This
notebook checks that law exactly in
the author's primordial metric, for **every** history $a_4(x_4)$, in particular
the one in which ordinary space inflates and the three extra times deflate
exponentially. It

1. builds the canonical spin connection of the author's metric with sympy and
   checks that it is real and gives $\gamma^\mu\Omega_\mu = 3H\gamma^{(x0)}$;
2. reduces the conservation law $\partial_\mu(\cos z\,J^\mu) = 0$ (on solutions)
   to one $16 \times 16$ matrix identity and verifies it exactly, with a negative
   control (no spin connection: the identity fails) and a control metric (the
   extra times inflating too), which shows **why** the time-derivative terms
   cancel: the deflation of the extra times keeps the volume of a slice constant;
3. checks the Noether current by changing the phase of a field from point to
   point;
4. follows the charge of an **exact solution** of the field equation in the
   author's metric: local conservation (exact, and a finite-difference test), the
   charge balance with the flux through the brane $z = \pi/2$, and a solution
   whose flux vanishes, so that its charge stays constant while the extra times
   deflate;
5. shows that the charge density $\Psi^\dagger B\Psi$ can be positive or negative;
6. does the **pair-level bookkeeping** of theorem T1: the chirality partner
   $\Gamma\Psi$ (a solution with the mass reversed) carries exactly the opposite
   current, so a pair has total charge zero.

Two checks reproduce `Revision/lead_checks/reports/charge-conjugation-and-u1.json`;
others reproduce the Revision field-theory and pairing records. Eight plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 21b (Local U(1) charge conservation, the brane flux and the pair-level charge
bookkeeping) is the file `Revision/textbook/notebooks/21b_charge_conservation.ipynb` of
the repository Dirac_claude. It builds the canonical spin connection of the author's
metric for a general history a4(x4) with sympy, checks that it is real, reduces the U(1)
```

Noether identity to a 16 by 16 matrix identity and verifies it exactly (with a negative control without the spin connection and a control metric with inflating extra times, which shows that the a4 terms cancel because the deflating extra times keep the volume of a slice constant), checks the Noether current by a local phase change, follows the charge of an exact solution of the field equation in the author's metric (exact local conservation, second-order convergence of a finite-difference test, the charge balance with the flux through the brane, a solution with zero flux and constant charge), shows that the charge density is indefinite, and does the pair-level bookkeeping of theorem T1: the chirality partner carries the opposite current, so the total charge of a pair is zero. Eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 21b_charge_conservation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 40 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 21b_charge_conservation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 21b_charge_conservation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/21b.captions.json‘
- ‘Revision/textbook/figures/21b_1_volume_balance.png‘
- ‘Revision/textbook/figures/21b_2_noether_matrices.png‘
- ‘Revision/textbook/figures/21b_3_charge_density_maps.png‘
- ‘Revision/textbook/figures/21b_4_charge_balance.png‘
- ‘Revision/textbook/figures/21b_5_local_conservation.png‘
- ‘Revision/textbook/figures/21b_6_charge_through_deflation.png‘
- ‘Revision/textbook/figures/21b_7_indefinite_charge.png‘
- ‘Revision/textbook/figures/21b_8_pair_bookkeeping.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS the eight figure files of notebook 21b exist
    ALL 21 CHECKS PASSED (notebook 21b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from

a copy outside the repository. Open the file
‘Revision/textbook/notebooks/21b_charge_conservation.ipynb‘ inside the folder
Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
"Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
active; do Step 4. If the environment is active and the message stays, the programs
jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
Start them through Python itself, in the folder of the notebook: the first command
below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 21b_charge_conservation.ipynb
python -m nbconvert --execute --inplace 21b_charge_conservation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
first run after the installation: this is a message, not an error; the run continues
and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
and Run All Cells; if it fails again, install the packages again with the pip commands
of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘, ‘Revision/theory‘,
‘Revision/pairing‘ or ‘Revision/lead_checks‘: the notebook was opened outside the
repository, or the repository is incomplete; clone the repository again and open the
notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 21b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 21b (Local U(1) charge conservation, the brane flux and the pair-level charge
# bookkeeping) is the file Revision/textbook/notebooks/21b_charge_conservation.ipynb of
# the repository Dirac_claude. It builds the canonical spin connection of the author’s
# metric for a general history a4(x4) with sympy, checks that it is real, reduces the
# U(1) Noether identity to a 16 by 16 matrix identity and verifies it exactly (with a
# negative control without the spin connection and a control metric with inflating extra
```

```
# times, which shows that the a4 terms cancel because the deflating extra times keep the
# volume of a slice constant), checks the Noether current by a local phase change,
# follows the charge of an exact solution of the field equation in the author's metric
# (exact local conservation, second-order convergence of a finite-difference test, the
# charge balance with the flux through the brane, a solution with zero flux and constant
# charge), shows that the charge density is indefinite, and does the pair-level
# bookkeeping of theorem T1: the chirality partner carries the opposite current, so the
# total charge of a pair is zero. Eight teaching plots. It needs a computer with Windows
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
```

```
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
```

```
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 21b_charge_conservation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 40
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 21b_charge_conservation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 21b_charge_conservation.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
```

```
#
# - Revision/textbook/figures/21b.captions.json
# - Revision/textbook/figures/21b_1_volume_balance.png
# - Revision/textbook/figures/21b_2_noether_matrices.png
# - Revision/textbook/figures/21b_3_charge_density_maps.png
# - Revision/textbook/figures/21b_4_charge_balance.png
# - Revision/textbook/figures/21b_5_local_conservation.png
# - Revision/textbook/figures/21b_6_charge_through_deflation.png
# - Revision/textbook/figures/21b_7_indefinite_charge.png
# - Revision/textbook/figures/21b_8_pair_bookkeeping.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the eight figure files of notebook 21b exist
#     ALL 21 CHECKS PASSED (notebook 21b)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/21b_charge_conservation.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
```

```
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 21b_charge_conservation.ipynb
#     python -m nbconvert --execute --inplace 21b_charge_conservation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra, Revision/theory,
#   Revision/pairing or Revision/lead_checks: the notebook was opened outside the
#   repository, or the repository is incomplete; clone the repository again and open the
#   notebook from its folder Revision/textbook/notebooks.
#

## 3. The words used in this notebook

- **Phase**: a complex number $e^{i\alpha} = \cos\alpha + i\sin\alpha$ of modulus
  1. Multiplying every component of $\Psi$ by the same $e^{i\alpha}$ is a
  **global U(1) transformation** (U(1) is the name of the group of these phases).
- **Symmetry, Noether's theorem**: when the Lagrangian does not change under a
  continuous transformation, there is a **current** $J^\mu$ whose divergence
  vanishes on every solution (a **local** conservation law); its time component
  integrated over space is the **charge** $Q$, which changes only by what flows
  through the boundary of the region (it is constant when nothing flows
  through it).
- **Current** $J^\mu = -i\bar\Psi\gamma^\mu\Psi$ (eight components, $\mu = x0,
  \dots, x7$), with $\bar\Psi = \Psi^\dagger C$ and the curved gammas
  $\gamma^\mu = e^\mu{}_a\gamma^a$; its time component is the **charge density**
  $J^{(x4)} = \Psi^\dagger B\Psi$, $B = -iC\gamma^{(x4)}$.
```

- **Divergence** $\partial_\mu(\cos z\,J^\mu) = \sum_\mu \partial(\cos z\,J^\mu) /\partial x_\mu$; $\cos z = \sqrt{|g|}$ is the volume factor of the author's metric.
- **Flux**: the amount of charge that flows through a surface per unit time; **charge balance**: the charge inside a region changes exactly by the flux through its boundary.
- **Vielbein** $e^a{}_\mu$: the eight scale factors f_a of the author's metric, $f_{1,2,3} = e^{a_4}\sin^{1/6}z$ (ordinary space), $f_4 = 1$ (the time), $f_{5,6,7} = e^{-a_4}\sin^{1/6}z$ (the deflating extra times), $f_0 = \cot z$ (the hidden direction), with $z = 6Hx_0$.
- **Spin connection** $\Omega_\mu = \tfrac12\omega_{\mu ab}S^{ab}$: the matrices that make the derivative $D_\mu = \partial_\mu + \Omega_\mu$ of a spinor covariant; $\omega_{\mu ab}$ are built from the vielbein and the Christoffel symbols, and $S^{ab} = \tfrac14[\gamma^a, \gamma^b]$.
- **Brane**: the end $z = \pi/2$ of the patch $0 < z < \pi/2$ of the hidden direction.
- **Chirality partner**: $\Gamma\Psi$ with $\Gamma = \gamma^{(x0)}\gamma^{(x1)} \cdots\gamma^{(x7)}$; by theorem T1 of the Revision pairing record it solves the field equation with the mass reversed.
- **Indefinite**: a quadratic expression that can take both signs.

Text cell:

```
## 4. The physical and mathematical situation

**The symmetry.** The Lagrangian of both fields of the Revision record is
$\mathcal{L} = \cos z\,[\tfrac12(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)
\gamma^\mu\Psi) - mS - U(S)]$ with $S = \bar\Psi\Psi$. Under $\Psi \to
e^{i\alpha}\Psi$ with a constant $\alpha$, $\Psi^\dagger \to e^{-i\alpha}
\Psi^\dagger$, so every bilinear $\Psi^\dagger X\Psi$ is multiplied by
$e^{-i\alpha}e^{i\alpha} = 1$: $\mathcal{L}$ does not change.

**The identity behind conservation**, line by line. Write the current as
$J^\mu = \Psi^\dagger K^\mu\Psi$ with $K^\mu = -iC\gamma^\mu$, and the field
equation as $E = \gamma^\mu D_\mu\Psi - V\Psi = 0$ with real $V = m + U'(S)$.

1. Product rule: $\partial_\mu(\cos z\,J^\mu) = \Psi^\dagger[\partial_\mu(\cos z
   \,K^\mu)]\Psi + \cos z\,[(\partial_\mu\Psi)^\dagger K^\mu\Psi + \Psi^\dagger
   K^\mu\partial_\mu\Psi]$.
2. The Revision record states the identity $\partial_\mu(\cos z\,J^\mu) = -i\cos
   z\,(\Psi^\dagger CE - E^\dagger C\Psi)$. Insert $E$: the $V$ terms give
   $-i\cos z\,(V\Psi^\dagger C\Psi - V\Psi^\dagger C\Psi) = 0$ because $V$ is real.
3. The derivative terms give $-i\cos z\,[\Psi^\dagger C\gamma^\mu\partial_\mu\Psi
   - (\partial_\mu\Psi)^\dagger(\gamma^\mu)^TC\Psi]$. With $(\gamma^\mu)^TC =
   -C\gamma^\mu$ (the gammas are real) this is $\cos z\,[\Psi^\dagger K^\mu
   \partial_\mu\Psi + (\partial_\mu\Psi)^\dagger K^\mu\Psi]$: exactly the second
   part of line 1.
4. The terms with the spin connection give $-i\cos z\,\Psi^\dagger[C\gamma^\mu
   \Omega_\mu - \Omega_\mu^T(\gamma^\mu)^TC]\Psi$.
5. So the identity holds for every field if and only if the first part of line 1
   equals line 4 for every $\Psi$, that is (dividing by $-i$) if and only if the
   $16 \times 16$ **matrix identity**
   $$\sum_\mu\partial_\mu(\cos z\,C\gamma^\mu) = \cos z\sum_\mu\big(C\gamma^\mu
```

```
   \Omega_\mu - \Omega_\mu^T(\gamma^\mu)^TC\big)$$
   holds. (Two Hermitian matrices that give the same value $\Psi^\dagger X\Psi$
   for every column $\Psi$ are equal.)
6. On a solution $E = 0$, so $\partial_\mu(\cos z\,J^\mu) = 0$. Integrating over
   a slab between two times and using the fundamental theorem of calculus, the
   charge $Q(x_4) = \int\cos z\,J^{(x4)}\,d^7x$ changes only by the flux of
   $\cos z\,J^\mu$ through the boundary of the region; with no flux, $Q$ is
   constant.

This notebook verifies the matrix identity of line 5 exactly, for a general
history $a_4(x_4)$ (so for the deflating one), and then watches lines 1 to 6 at
work on an exact solution.
```

Text cell:

```
## 5. The gammas and the Revision records

The next cell reads the eight gamma matrices of the Revision record (both as
whole-number numpy arrays and as exact sympy matrices), checks that they are eight
real $16 \times 16$ matrices with the Clifford relation of signature (4,4), builds
$C$, $\Gamma$, $B$ and the generators $S^{ab}$, and reads the Revision records
whose checks this notebook reproduces. It also checks that the record's formula
current defines the current and the charge density exactly as this notebook does.
```

## 6. The canonical spin connection of the author's metric

The next cell builds, with sympy, everything the spin connection needs, for an
unspecified function $a_4(x_4)$ (so the result holds for every history):

- the scale factors $f_a$ and the metric $g_{\mu\mu} = \eta_{aa}f_a^2$ (diagonal);
- the Christoffel symbols $\Gamma^l{}_{ij} = \tfrac12 g^{lm}(\partial_j g_{mi} +
  \partial_i g_{mj} - \partial_m g_{ij})$;
- the connection coefficients $\omega_\mu{}^a{}_b = f_a\,\big(\partial_\mu
  (\delta_{ab}/f_b) + \Gamma^a{}_{\mu b}/f_b\big)$ (the vielbein postulate
  $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu e_b{}^\nu + \Gamma^\nu{}_{\mu
  \lambda}e_b{}^\lambda)$ for the diagonal vielbein $e^a{}_\nu = f_a\delta^a_\nu$),
  lowered with $\eta$;
- $\Omega_\mu = \tfrac12\sum_{a,b}\omega_{\mu ab}S^{ab}$.

It is written as a function of the three scale factors of the extra times, so
that the same code can later build a *control* metric in which the extra times
inflate. (About 7 seconds.)
```

In [3]:

```
x = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7
H = sp.symbols("H", positive=True)  # the author's constant H > 0
```

```

Text cell:

```
The next cell checks three facts of the Revision record:

1. every entry of every $\Omega_\mu$ is a **real** expression (no imaginary unit;
   record check spinor_connection_real), and not all of them vanish;
```

```
2. $\Omega_\mu$ agrees with the record's formula Omega_components:
   $\Omega_{x_i} = \tfrac12 e^{a_4}\sin^{1/6}z\,(a_4'\gamma^{(xi)}\gamma^{(x4)} +
   H\gamma^{(xi)}\gamma^{(x0)})$ for $i = 1, 2, 3$, $\Omega_{x_t} = -\tfrac12
   e^{-a_4}\sin^{1/6}z\,(a_4'\gamma^{(x4)}\gamma^{(xt)} + H\gamma^{(xt)}
   \gamma^{(x0)})$ for $t = 5, 6, 7$, and $\Omega_{x_4} = \Omega_{x_0} = 0$ (the
   cell also checks that the record's text, in Wolfram notation with `g[x4]` for
   $\gamma^{(x4)}$, states exactly these pieces);
3. the contraction $\gamma^\mu\Omega_\mu = \sum_\mu f_\mu^{-1}\gamma^\mu
   \Omega_\mu = 3H\gamma^{(x0)}$ (record formula gammaOmega_total).
```

## 7. The U(1) identity as a matrix identity

The next cell computes both sides of the matrix identity of section 4, line 5:
$$\mathrm{LHS} = \sum_\mu\partial_\mu(\cos z\,C\gamma^\mu),\qquad
\mathrm{RHS} = \cos z\sum_\mu\big(C\gamma^\mu\Omega_\mu - \Omega_\mu^T
(\gamma^\mu)^TC\big),$$
checks that their difference simplifies to the zero matrix (record check
u1_noether_matrix_identity), and checks that the left side is exactly $6H\cos z\,
C\gamma^{(x0)}$. As a **negative control** it sets the spin connection to zero:
then the right side vanishes while the left side does not, so without the spin
connection the current would not be conserved.
```

In [5]:

```
cos_z = vol_dfl  # sqrt|g| = cos z
lhs = sum((sp.diff(cos_z / f_dfl[mu], x[mu]) * C_s * G[mu] for mu in range(8)),
          sp.zeros(16, 16))
pieces = [cos_z * (C_s * gamma_up[mu] * Omega[mu]
                   - Omega[mu].T * gamma_up[mu].T * C_s) for mu in range(8)]
rhs = sum(pieces, sp.zeros(16, 16))
check((lhs - rhs).applyfunc(sp.simplify) == sp.zeros(16, 16)
      and LEAD["u1_noether_matrix_identity"] == "PASS",
      "the U(1) Noether matrix identity holds exactly for a general history a4",
      record=f"{LEAD_FILE}, check u1_noether_matrix_identity")
check((lhs - 6 * H * sp.cos(z) * C_s * G[0]).applyfunc(sp.simplify)

     reproduces Revision/lead_checks/reports/charge-conjugation-and-u1.json, check
    u1_noether_matrix_identity
PASS the left side is exactly 6 H cos z C gamma^(x0)
PASS negative control: with Omega = 0 the right side is 0 but the left side is not
```

Text cell:

```
**Why the $a_4'$ terms cancel.** The next cell splits the right side into the
contributions of the eight directions. Each is a combination of $C\gamma^{(x4)}$
```

```
and $C\gamma^{(x0)}$; the cell extracts the two coefficients (divided by the
volume factor $\sqrt{|g|}$) by the trace formula $c = \mathrm{tr}(P\,Y^T)/16$ for
$P = c\,Y + \dots$ (the products of gammas are orthogonal under this trace). Each
direction of ordinary space contributes $+a_4'$ to the $C\gamma^{(x4)}$
coefficient, each deflating extra time $-a_4'$: they cancel. Then it repeats the
whole computation for a **control metric** in which the extra times *inflate*
($e^{+a_4}$): the identity still holds (it holds in every metric), but now the six
contributions add up to $6a_4'$, and the left side contains the same $6a_4'$,
because the volume factor $\sqrt{|g|} = e^{6a_4}\cos z$ grows. In the author's
metric $\sqrt{|g|} = e^{3a_4}e^{-3a_4}\cos z = \cos z$ does not depend on $x_4$:
**the deflation of the extra times exactly compensates the inflation of space**,
and the time-derivative terms drop out. (About 7 seconds.)
```

8. The Noether current from a local phase change

Noether's construction finds the current by making the phase depend on the point: $\Psi \to e^{i\alpha(x)}\Psi$. Then $D_\mu(e^{i\alpha}\Psi) = e^{i\alpha}(D_\mu\Psi + i(\partial_\mu\alpha)\Psi)$, and inserting this into the kinetic term gives, line by line,
$$\tfrac12\big(\bar\Psi\gamma^\mu(D_\mu\Psi + i\alpha_\mu\Psi) - (D_\mu\bar\Psi - i\alpha_\mu\bar\Psi)\gamma^\mu\Psi\big) = K + i\alpha_\mu\bar\Psi\gamma^\mu\Psi = K - \alpha_\mu J^\mu ,$$
with $\alpha_\mu = \partial_\mu\alpha$ and $\bar\Psi\gamma^\mu\Psi = iJ^\mu$. So $\mathcal{L}' - \mathcal{L} = -\cos z\,\alpha_\mu J^\mu$: the current is the coefficient of $\partial_\mu\alpha$. The next cell checks this with numbers at one point of the author's metric: it evaluates the full Lagrangian (with the spin connection, $m = 0.7$, $\lambda = 0.3$, $U = \tfrac\lambda2S^2$) for a fixed complex field value and fixed complex first derivatives, once as they are and once after the local phase change, and compares the difference with $-\cos z\, \alpha_\mu J^\mu$. With all $\alpha_\mu = 0$ (a constant phase) the Lagrangian does not change at all.

## 9. The charge of an exact solution in the author's metric

The Revision field-theory record (formula exact_solutions, item (i)) gives the
exact solution with $U = 0$
$$\Psi = \sin^\alpha z\,\Big(\cos(wx_4)\,1 + \frac{\sin(wx_4)}{w}M\Big)\chi,\quad
M = -m\gamma^{(x4)} + b\,\gamma^{(x4)}\gamma^{(x0)},\quad b = 3H(2\alpha + 1),$$
written here for $k^2 = b^2 - m^2 = -w^2 < 0$ (then $\cosh(kx_4) = \cos(wx_4)$
and $\sinh(kx_4)/k = \sin(wx_4)/w$). It does not depend on $x1, x2, x3, x5, x6,
x7$, so the factors $e^{\pm a_4}$ of the field equation multiply derivatives that
vanish: it solves the field equation for **every** history $a_4$, the deflating
one included. We take $H = 1/6$ (so $z = x_0$), $\alpha = 1$, $m = 2$, so $b =
3/2$ and $w = \sqrt7/2$, and a fixed complex column $\chi$ with exact rational
entries. The current has two nonzero components:
$$\cos z\,J^{(x4)} = \cos z\,\Psi^\dagger B\Psi,\qquad
\cos z\,J^{(x0)} = \cos z\tan z\,\Psi^\dagger K_0\Psi = \sin z\,\Psi^\dagger K_0
\Psi,\quad K_0 = -iC\gamma^{(x0)},$$
because $\gamma^{x0} = \gamma^{(x0)}/f_0 = \tan z\,\gamma^{(x0)}$. The next cell
checks that the record states item (i) word for word as used here (in Wolfram
notation, `al` is $\alpha$ and $k^2 = 9H^2(2\alpha + 1)^2 - m^2 = b^2 - m^2$),
builds $\Psi$, checks the field equation exactly, and checks the local
conservation law $\partial_4(\cos z\,J^{(x4)}) + \partial_z(\cos z\,J^{(x0)}) = 0$
exactly ($\partial_0 = \partial_z$ for $H = 1/6$).
```

## 10. The charge balance and a solution with zero flux

Integrate the conservation law over the patch $0 < z < \pi/2$ (for each unit of
the other six coordinates). Since $\Psi$ contains $\sin z$, the density is
$\cos z\,\sin^2z\,f(x_4)$ with $f = \chi^\dagger U^TBU\chi$, and the charge is
$$Q(x_4) = \int_0^{\pi/2}\cos z\,\sin^2 z\,dz\;f(x_4) = \tfrac13 f(x_4)$$
(substitute $u = \sin z$: $\int_0^1 u^2\,du = 1/3$). The flux $\sin^3z\,g(x_4)$,
$g = \chi^\dagger U^TK_0U\chi$, vanishes at the tip $z = 0$ and equals $g(x_4)$ at
the brane $z = \pi/2$. The fundamental theorem of calculus gives the **charge
balance**
$$Q(x_4) - Q(0) = -\int_0^{x_4} g(t)\,dt :$$
the charge of the patch changes exactly by what flows out through the brane. The
next cell checks this exactly (sympy integrates $g$ exactly).

Can the flux vanish? Since $M^2 = -w^2\,1$, the matrix $P = \tfrac12(1 - iM/w)$
satisfies $P^2 = P$ (a projector) and $MP = iwP$. For $\chi_0 = P\chi$ we get
$M\chi_0 = iw\chi_0$, hence $U\chi_0 = (\cos(wx_4) + i\sin(wx_4))\chi_0 =
e^{iwx_4}\chi_0$, and the solution $\Psi_0 = \sin z\,e^{iwx_4}\chi_0$ has a
single frequency: it is a **stationary state**. Its charge density
$\cos z\sin^2z\,\chi_0^\dagger B\chi_0$ does not depend on the time, so by the
conservation law its flux is zero, and its charge $Q$ is **constant**. The cell
checks this too, and that this constant is not zero.
```

## 11. The charge density can be negative

The charge density $J^{(x4)} = \Psi^\dagger B\Psi$ is a *quadratic form* with the
matrix $B$, which has eight eigenvalues $+1$ and eight eigenvalues $-1$
(signature (8,8)). Writing $\Psi$ in the eigenvectors of $B$ as $\Psi = \sum_j c_j
v_j$ gives $\Psi^\dagger B\Psi = \sum_{B = +1}|c_j|^2 - \sum_{B = -1}|c_j|^2$, which
can have either sign; divided by $\Psi^\dagger\Psi = \sum|c_j|^2$ it lies between
$-1$ and $+1$.

**A worked example in flat space** ($H = 0$, $a_4$ constant). The field equation
```

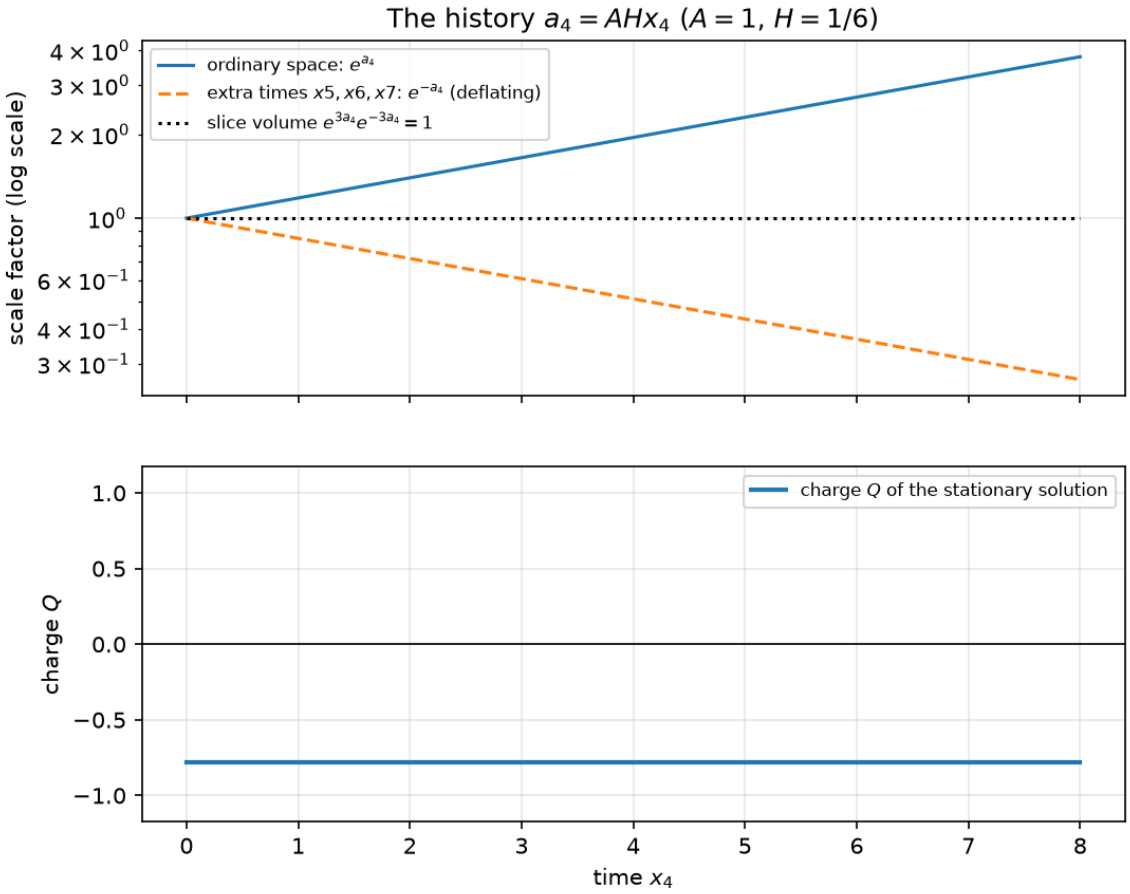

Figure 534: Top: the scale factors of the author's metric along the time x_4 for the linear history $a_4 = AHx_4$ with $A = 1$, $H = 1/6$ (chosen for the picture): ordinary space e^{a_4} grows, the three extra times e^{-a_4} deflate exponentially, and their product, the volume factor of a slice, stays 1 (logarithmic vertical scale). Bottom: the charge Q of the stationary exact solution versus x_4; it does not change while space inflates and the extra times deflate. The stationary solution solves the field equation for every history a_4 and its charge density contains no a_4, so the constant does not depend on this choice. (Notebook 21b, figure 6.)

```
along the time is $\gamma^{(x4)}\partial_4\Psi = m\Psi$. A *rest state* $\Psi =
u\,e^{-imx_4}$ with $-i\gamma^{(x4)}u = u$ solves it: $\gamma^{(x4)}(-im)u =
m(-i\gamma^{(x4)})u = mu$; it has the positive frequency $m$. Since $B =
C(-i\gamma^{(x4)})$ and $C$ commutes with $\gamma^{(x4)}$, $B$ maps the
8-dimensional space of such $u$ into itself and has there four eigenvalues $+1$
(vector $u_+$) and four $-1$ (vector $u_-$). For $u = \tfrac35u_+ + \tfrac45u_-$
(normalised) the charge density is $\tfrac{9}{25} - \tfrac{16}{25} =
-\tfrac{7}{25}$: a positive-frequency field with negative charge density. The
next cell computes this exactly from the gammas and draws the distribution of
$\Psi^\dagger B\Psi/\Psi^\dagger\Psi$ for 20000 random columns.
```

## 12. The pair-level charge bookkeeping
```

```
Theorem T1 of the Revision pairing record says: for every configuration $\Psi$ of
the theory with $(m, \lambda)$, the chirality partner $\Gamma\Psi$ is a
configuration of the theory with $(-m, -\lambda)$, and $J^\mu[\Gamma\Psi] =
-J^\mu[\Psi]$ at every point. Hence a pair $\{\Psi, \Gamma\Psi\}$ has total
charge $Q + Q' = 0$ **as classical bilinears**. The next cell checks the
pointwise statement with numbers for five random columns at three times, using
the exact solution's matrix $U(x_4)$: it computes $Q$ of $\Psi$, of $\Gamma\Psi$
and their sum, and draws them. (What this does *not* say: it does not make two
independently quantised universes cancel each other, and it does not create
anything; a single universe with charge $Q$ is an equally valid solution.)
```

In [17]:

```
U_f = sp.lambdify(x4, U_sol, "numpy")
columns = rng.normal(size=(5, 16)) + 1j * rng.normal(size=(5, 16))

## 14. What this notebook showed

- PROVED (exact, sympy, for a general history $a_4(x_4)$): the canonical spin
  connection of the author's metric is real and gives $\gamma^\mu\Omega_\mu =
  3H\gamma^{(x0)}$; the U(1) Noether identity reduces to the matrix identity
  $\sum_\mu\partial_\mu(\cos z\,C\gamma^\mu) = \cos z\sum_\mu(C\gamma^\mu
  \Omega_\mu - \Omega_\mu^T(\gamma^\mu)^TC)$, which holds; both sides equal
  $6H\cos z\,C\gamma^{(x0)}$. Without the spin connection it fails.
- PROVED: the $a_4'$ terms cancel because the three deflating extra times
  compensate the three inflating space directions, so that the volume factor
  $\sqrt{|g|} = \cos z$ does not depend on the time; in a control metric with
  inflating extra times they add to $6a_4'$ and are balanced by the growing
  volume.
- COMPUTED (numbers at a point): the Noether current of the phase symmetry is
  $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, real; a constant phase leaves the
  Lagrangian unchanged.
- PROVED for an exact solution of the Revision record in the author's metric:
  the local conservation law holds exactly; the charge of the patch changes only
  by the flux through the brane $z = \pi/2$; for a stationary (single-frequency)
  solution the flux vanishes and the charge is a nonzero constant, for every
  history $a_4$. A finite-difference test converges to the exact law with order 2.
- PROVED: the charge density $\Psi^\dagger B\Psi$ is indefinite (signature
  (8,8)); a positive-frequency rest state can carry the charge density $-7/25$.
- PROVED (theorem T1, reproduced): the chirality partner $\Gamma\Psi$ solves the
  equation with the mass reversed and carries exactly the opposite current, so
```

```
  the total charge of a pair is zero as classical bilinears.
- Consequence for Sakharov's first condition: no process of this theory creates
  or destroys U(1) charge at any point of the patch $0 < z < \pi/2$, off the
  brane (the local law). The charge of a universe
  changes only by what flows through its boundary, and the first solution of
  this notebook shows that charge does flow through the brane $z = \pi/2$. Only
  under a no-flux condition at the brane, which is ASSUMED and not derived
  (OPEN), is the charge of a universe constant and fixed by the initial data.
  This is a statement about the classical field equations; it is not a creation
  mechanism for anything.
```

21.23 Line-by-line walk-through of Notebook 21b

The notebook has 18 code cells, In [1] to In [18]. Each is explained below, line by line or in small groups of lines.

In [1], the set-up cell. It is the set-up cell of Notebook 21a, explained line by line in Section 21.15 under In [1], word for word except for two things: the comment lines at the top hold the run instructions of Notebook 21b (Section 21.21), and the line

```
NOTEBOOK_ID = "21b"  # this notebook: chapter 21, example b
```

names this notebook, so that its figures are called `21b_<k>_<name>.png`. The cell prints its one line, Set-up of notebook 21b complete.

In [2]: the gammas, C, Γ, B and the records.

```
import numpy as np  # numbers, arrays, matrices
import sympy as sp  # exact algebra and calculus
```

numpy for numbers and arrays, sympy for exact algebra and calculus (Section 21.15 explains both).

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = fixture["eta"]  # +1 space-like, -1 time-like, in the order x0..x7
gamma = [np.array(mat, dtype=np.int64) for mat in fixture["gamma"]]  # index 0..7
I16 = np.eye(16, dtype=np.int64)
```

The Revision record of the gammas is read as in Notebook 21a, but here the gammas are kept in a **list**, numbered from 0 in the order of the record, $x_0, \ldots, x_7$: `gamma[k]` is $\gamma^{(xk)}$, so `gamma[0]` is $\gamma^{(x0)}$ of the hidden direction and `gamma[4]` is $\gamma^{(x4)}$ of the time. `ETA` is the list of the eight signs in the same order.

```
real_ok = all(g.shape == (16, 16) and set(np.unique(g)) <= {-1, 0, 1} for g in gamma)
clifford_ok = all(np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                                 2 * (ETA[a] if a == b else 0) * I16)
                  for a in range(8) for b in range(8))
check(len(gamma) == 8 and real_ok and clifford_ok,
      "eight real 16 x 16 gamma matrices with the Clifford relation, signature (4,4)")
```

The same tests as In [3] of Notebook 21a, written with the numbers `a`, `b` from 0 to 7 (`range(8)`): eight real 16×16 matrices with entries -1, 0, $+1$ that obey the Clifford relation for all 64 pairs.

```
G = [sp.Matrix(g.tolist()) for g in gamma]  # exact sympy copies, G[k] = gamma^(xk)
C_s = G[0] * G[1] * G[2] * G[3]  # C = gamma^(x0) gamma^(x1) gamma^(x2) gamma^(x3)
C = np.array(C_s.tolist(), dtype=np.int64)
```

Exact sympy copies of the gammas; C is built exactly (`C_s`) and also kept as a whole-number numpy array (`C`).

```
Gamma = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5] \
    @ gamma[6] @ gamma[7]  # the chirality (index 0 is x0)
B = -1j * (C @ gamma[4])  # B = -i C gamma^(x4); index 4 is x4
K0 = -1j * (C @ gamma[0])  # the matrix of the x0 current: -i C gamma^(x0)
S_gen = [[(G[a] * G[b] - G[b] * G[a]) / 4 for b in range(8)] for a in range(8)]
```

The chirality is the product of all eight in the order $x_0, x_1, \ldots, x_7$; the backslash at the end of the first line continues the statement on the next. $B = -iC\gamma^{(x4)}$ and $K_0 = -iC\gamma^{(x0)}$ are the matrices of the charge density and of the x_0 current (Section 21.18). `S_gen[a][b]` is the exact generator S^{ab} for all 64 ordered pairs (zero when $a = b$).

```
LEAD_FILE = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
LEAD = {c["name"]: c["verdict"] for c in json.loads(
    repository_file(LEAD_FILE).read_text(encoding="utf-8"))["checks"]}
THEORY = {f["key"]: f for f in json.loads(repository_file(
    "Revision/theory/field-theory.json").read_text(encoding="utf-8"))["formulas"]}
PY_THEORY = {c["name"]: c["verdict"].upper() for c in json.loads(repository_file(
    "Revision/theory/reports/python-field-theory.json").read_text(
    encoding="utf-8"))["checks"]}
```

Four Revision records are read into dictionaries: the lead report (check name to verdict), the formulas of the field-theory record (key to the whole formula entry, so that `THEORY[key]["wl"]` is its text), and the verdicts of the sympy field-theory report, in capitals.

```
WL_PAIR = {c["name"]: c["verdict"] for c in json.loads(repository_file(
    "Revision/pairing/reports/wolfram-pairing.json").read_text(
    encoding="utf-8"))["checks"]}
PY_PAIR = {c["name"]: c["verdict"] for c in json.loads(repository_file(
    "Revision/pairing/reports/python-pairing.json").read_text(
    encoding="utf-8"))["checks"]}
```

The two pairing reports of the Revision record: the WolframScript verifier and the independent sympy checker. Their verdicts are already written as PASS.

```
clauses = THEORY["current"]["wl"].split("; ")  # the statements of the formula
say("record formula current: " + clauses[0] + "; " + clauses[2])
check(clauses[0] == "J^mu = -i Psibar gamma^mu Psi"
      and clauses[2] == "J^x4 = Psi^dagger B Psi",
      "the record defines J^mu = -i Psibar gamma^mu Psi and J^x4 = Psi^dagger B Psi",
      record="Revision/theory/field-theory.json, formula current")
```

The record's formula `current` is a list of statements separated by semicolons; `split("; ")` cuts it into them. The first defines the current and the third the charge density; the check demands that they are exactly the definitions this notebook uses. Out [2] prints the two statements and two PASS lines.

In [3]: the canonical spin connection for every history.

```
x = sp.symbols("x0:8", real=True)  # the coordinates x0, ..., x7
H = sp.symbols("H", positive=True)  # the author's constant H > 0
a4 = sp.Function("a4", real=True)(x[4])  # an unspecified history a4(x4)
z = 6 * H * x[0]  # z = 6 H x0
eta = sp.diag(*ETA)
```

Eight real symbols for the coordinates (`x[k]` is x_k: `x[0]` is x_0, `x[4]` is x_4), a positive symbol H, and an **unspecified function** $a_4(x_4)$: sympy knows nothing about it except that it depends on x_4, so every result below holds for every history, the deflating one included. `sp.diag(*ETA)` is the diagonal matrix η (the star passes the eight list entries as eight separate arguments).

```
def geometry(extra_sign):
    """Scale factors, volume factor and the eight matrices Omega_mu of the metric
    whose extra-time factors are exp(extra_sign a4) sin^(1/6) z (extra_sign = -1:
    the author's deflating extra times)."""
    f = ([sp.cot(z)] + [sp.exp(a4) * sp.sin(z) ** sp.Rational(1, 6)] * 3
         + [sp.Integer(1)]
         + [sp.exp(extra_sign * a4) * sp.sin(z) ** sp.Rational(1, 6)] * 3)
    g = sp.diag(*[ETA[a] * f[a] ** 2 for a in range(8)])  # the diagonal metric
    g_inv = g.inv()
```

The function builds the geometry of a metric whose three extra-time scale factors are $e^{\pm a_4}\sin^{1/6} z$: with `extra_sign = -1` the author's metric, with `+1` the control metric of Section 21.17. A list times 3 repeats the list three times, and `+` joins lists: `f` is the list of the eight scale factors. The metric is diagonal with $g_{aa} = \eta_{aa} f_a^2$, and `g.inv()` is its inverse.

```
    chris = [[[sp.simplify(sum(g_inv[l, m] * (sp.diff(g[m, i], x[j])
                                              + sp.diff(g[m, j], x[i])
                                              - sp.diff(g[i, j], x[m]))
                               for m in range(8)) / 2)
               for j in range(8)] for i in range(8)] for l in range(8)]
```

The Christoffel symbols $\Gamma^l{}_{ij} = \frac{1}{2}\sum_m g^{lm}(\partial_j g_{mi} + \partial_i g_{mj} - \partial_m g_{ij})$ (Chapter 3), stored so that `chris[l][i][j]` is $\Gamma^l{}_{ij}$: three nested list comprehensions, the innermost index written last. `sp.diff(expr, x[j])` is the exact partial derivative and `sp.simplify` tidies each result.

```
    e_inv = [1 / v for v in f]  # e_a^mu = 1 / f_a on the diagonal
    Omega = []
    for mu in range(8):
        om = sp.zeros(8, 8)  # omega_mu^a_b
        for a in range(8):
            for b_ in range(8):
```

```
            om[a, b_] = sp.simplify(f[a] * (sp.diff(e_inv[b_] if a == b_ else 0,
                                                   x[mu])
                                            + chris[a][mu][b_] * e_inv[b_]))
```

The inverse vielbein is diagonal with entries $1/f_a$. For each direction μ the 8×8 table ${\omega_\mu}^a{}_b$ of the canonical connection is computed from the **vielbein postulate** ${\omega_\mu}^a{}_b = e^a{}_\nu(\partial_\mu {e_b}^\nu + {\Gamma^\nu}_{\mu\lambda} {e_b}^\lambda)$; with the diagonal vielbein $e^a{}_\nu = f_a \delta^a_\nu$ and ${e_b}^\nu = \delta^\nu_b / f_b$ the sums collapse to ${\omega_\mu}^a{}_b = f_a(\partial_\mu(\delta_{ab}/f_b) + {\Gamma^a}_{\mu b}/f_b)$, which is the line in the loop (`e_inv[b_] if a == b_ else 0` is δ_{ab}/f_b; the letter `b_` avoids a clash with other names).

```
        om_low = eta * om  # omega_mu ab = eta_ac omega_mu^c_b
        Om = sp.zeros(16, 16)
        for a in range(8):
            for b_ in range(8):
                if om_low[a, b_] != 0:
                    Om += om_low[a, b_] * S_gen[a][b_] / 2
        Omega.append(Om.applyfunc(sp.simplify))
```

The first index is lowered with η (a matrix product), and the spinor connection $\Omega_\mu = \frac{1}{2}\sum_{a,b} \omega_{\mu ab} S^{ab}$ is summed (only the nonzero coefficients). `applyfunc(sp.simplify)` simplifies every entry, and the matrix is added to the list `Omega`.

```
    volume = sp.simplify(sp.prod(f))  # sqrt|g| = product of the scale factors
    return f, volume, Omega

f_dfl, vol_dfl, Omega = geometry(-1)  # the author's metric (deflating extra times)
say(f"sqrt|g| of the author's metric = {vol_dfl}")
```

`sp.prod(f)` multiplies the eight scale factors, which for a diagonal metric is $\sqrt{|\det g|}$. The function returns the three results, and it is called for the author's metric. Out [3] prints `cos(6*H*x0)`: the volume factor is $\cos z$, with no a_4 in it (Section 21.7). This cell takes about 7 seconds.

In [4]: the connection agrees with the record.

```
a4p = sp.Derivative(a4, x[4])  # a4' = d a4 / d x4
real_ok = all(not entry.has(sp.I) for Om in Omega for entry in Om)
nonzero = any(Om != sp.zeros(16, 16) for Om in Omega)
check(real_ok and nonzero and LEAD["spinor_connection_real"] == "PASS",
      "every entry of Omega_mu is real and not all vanish",
      record=f"{LEAD_FILE}, check spinor_connection_real")
```

`a4p` is the symbol of the derivative a_4'. `entry.has(sp.I)` asks whether an entry contains the imaginary unit; none does, so every Ω_μ is real. `any` asks that at least one Ω_μ is not the zero matrix. This reproduces the lead check that makes $\gamma^\mu D_\mu$ a real operator (Section 21.8, step 1).

```
s16 = sp.sin(z) ** sp.Rational(1, 6)
expected = []
```

```
for mu in range(8):
    if mu in (1, 2, 3):  # x1, x2, x3: inflating ordinary space
        expected.append(sp.exp(a4) * s16 / 2 * (a4p * G[mu] * G[4] + H * G[mu] * G[0]))
    elif mu in (5, 6, 7):  # x5, x6, x7: the deflating extra times
        expected.append(-sp.exp(-a4) * s16 / 2 * (a4p * G[4] * G[mu]
                                                  + H * G[mu] * G[0]))
    else:  # x4 and x0
        expected.append(sp.zeros(16, 16))
```

The record's formula `Omega_components` (Section 21.17), written out for each direction: `if`, `elif` ("else if") and `else` choose the right case.

```
record_text = THEORY["Omega_components"]["wl"]  # the record's statement
pieces_of_record = [  # the formula above, piece by piece, in the record's notation
    "Omega_xi = (1/2) E^a4[x4] Sin[6 H x0]^(1/6) (a4",
    "g[xi].g[x4] + H g[xi].g[x0]) (i = 1, 2, 3)",
    "Omega_xt = -(1/2) E^-a4[x4] Sin[6 H x0]^(1/6) (a4",
    "g[x4].g[xt] + H g[xt].g[x0]) (t = 5, 6, 7)",
    "Omega_x0 = Omega_x4 = 0"]
```

The record's text of the formula and five pieces of it in the record's notation. The pieces stop just before the derivative of a_4, which the record writes with a straight single quote; the notebook avoids writing that character.

```
check(all((Omega[mu] - expected[mu]).applyfunc(sp.simplify) == sp.zeros(16, 16)
          for mu in range(8))
      and all(piece in record_text for piece in pieces_of_record),
      "Omega_mu equals the record formula Omega_components",
      record="Revision/theory/field-theory.json, formula Omega_components")
```

Every computed Ω_μ minus the expected one simplifies to zero, and every piece occurs in the record's text (`in` asks whether one string occurs inside another).

```
gamma_up = [G[mu] / f_dfl[mu] for mu in range(8)]  # gamma^mu = gamma^a / f_a
contraction = sum((gamma_up[mu] * Omega[mu] for mu in range(8)), sp.zeros(16, 16))
check((contraction - 3 * H * G[0]).applyfunc(sp.simplify) == sp.zeros(16, 16)
      and THEORY["gammaOmega_total"]["wl"] == '3*H*gamma["x0"]',
      "gamma^mu Omega_mu = 3 H gamma^(x0) for every history a4",
      record="Revision/theory/field-theory.json, formula gammaOmega_total")
```

The curved gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$; `sum(..., sp.zeros(16, 16))` adds the eight products starting from the zero matrix. The contraction equals $3H\gamma^{(x0)}$, and the record's formula `gammaOmega_total` says the same. Out [4] shows the three PASS lines.

In [5]: the U(1) matrix identity.

```
cos_z = vol_dfl  # sqrt|g| = cos z
lhs = sum((sp.diff(cos_z / f_dfl[mu], x[mu]) * C_s * G[mu] for mu in range(8)),
          sp.zeros(16, 16))
```

```
pieces = [cos_z * (C_s * gamma_up[mu] * Omega[mu]
                   - Omega[mu].T * gamma_up[mu].T * C_s) for mu in range(8)]
rhs = sum(pieces, sp.zeros(16, 16))
```

The two sides of the identity of Section 21.17: the left side $\sum_\mu \partial_\mu(\cos z\, C\gamma^\mu) = \sum_\mu \partial_\mu(\cos z/f_\mu)\, C\gamma^{(\mu)}$, and the right side as the list of its eight contributions (kept for In [6]) and their sum.

```
check((lhs - rhs).applyfunc(sp.simplify) == sp.zeros(16, 16)
      and LEAD["u1_noether_matrix_identity"] == "PASS",
      "the U(1) Noether matrix identity holds exactly for a general history a4",
      record=f"{LEAD_FILE}, check u1_noether_matrix_identity")
check((lhs - 6 * H * sp.cos(z) * C_s * G[0]).applyfunc(sp.simplify)
      == sp.zeros(16, 16), "the left side is exactly 6 H cos z C gamma^(x0)")
check(lhs.applyfunc(sp.simplify) != sp.zeros(16, 16),
      "negative control: with Omega = 0 the right side is 0 but the left side is "
      "not")
```

The difference of the two sides simplifies to the zero matrix for the unspecified a_4: the identity holds for every history (reproducing the lead check). The left side equals $6H\cos z\, C\gamma^{(x0)}$, as computed by hand in Section 21.17. The negative control: without the spin connection the right side would be the zero matrix, and the left side is not zero, so the identity, and with it the conservation of the current, would fail.

In [6]: why the a_4' terms cancel.

```
CG4, CG0 = C_s * G[4], C_s * G[0]

def coefficients(matrix, volume):
    """The coefficients of C gamma^(x4) and C gamma^(x0) in matrix, divided by the
    volume factor (trace formula; checked to leave no remainder)."""
    c4 = sp.simplify((matrix * CG4.T).trace() / 16 / volume)
    c0 = sp.simplify((matrix * CG0.T).trace() / 16 / volume)
    remainder = (matrix - volume * (c4 * CG4 + c0 * CG0)).applyfunc(sp.simplify)
    return c4, c0, remainder == sp.zeros(16, 16)
```

The matrices $C\gamma^{(x4)}$ and $C\gamma^{(x0)}$ are signed permutation matrices, so each times its own transpose is 1, with trace 16, while the trace of one times the transpose of the other is 0 (they are orthogonal). So if a matrix is $P = c_4 C\gamma^{(x4)} + c_0 C\gamma^{(x0)}$, then $c_4 = \mathrm{tr}(P(C\gamma^{(x4)})^T)/16$, and likewise c_0. The function divides by the volume factor and checks that nothing else is left over (`remainder` is the zero matrix).

```
dfl = [coefficients(p, cos_z) for p in pieces]  # the author's metric
f_ctl, vol_ctl, Omega_ctl = geometry(+1)  # control: inflating extra times
gamma_up_ctl = [G[mu] / f_ctl[mu] for mu in range(8)]
pieces_ctl = [vol_ctl * (C_s * gamma_up_ctl[mu] * Omega_ctl[mu]
                         - Omega_ctl[mu].T * gamma_up_ctl[mu].T * C_s)
              for mu in range(8)]
lhs_ctl = sum((sp.diff(vol_ctl / f_ctl[mu], x[mu]) * C_s * G[mu] for mu in range(8)),
              sp.zeros(16, 16))
```

The coefficients of the eight contributions in the author's metric; then the whole computation again for the control metric (`geometry(+1)`): its curved gammas, its eight contributions and its left side. This takes about 7 seconds.

```
ctl = [coefficients(p, vol_ctl) for p in pieces_ctl]
lhs_c4, _, _ = coefficients(lhs_ctl, vol_ctl)  # control: the volume-growth term
lhs_c4_dfl, _, _ = coefficients(lhs, cos_z)  # author's metric: zero
say(f"control metric: sqrt|g| = {vol_ctl}")
```

The coefficients of the control contributions, and the $C\gamma^{(x4)}$ coefficient of each left side (the underscores discard the other two returned values). Out [6] first prints the control volume factor `exp(6*a4(x4))*cos(6*H*x0)`, which grows with a_4.

```
for mu in range(8):  # the coefficients in units of a4' (sympy divides exactly)
    say(f"{COORDS[mu]}: author's metric {str(sp.simplify(dfl[mu][0] / a4p)):>2} a4'"
        f" | control metric {str(sp.simplify(ctl[mu][0] / a4p)):>2} a4'")
```

For each direction the $C\gamma^{(x4)}$ coefficient divided by a_4' is printed for both metrics (`:>2` right-aligns the text in two characters). Out [6] shows $0, 1, 1, 1, 0, -1, -1, -1$ for the author's metric and $0, 1, 1, 1, 0, 1, 1, 1$ for the control (in the order $x_0, \ldots, x_7$).

```
expected_dfl = [0] + [a4p] * 3 + [0] + [-a4p] * 3  # +a4' space, -a4' extra times
expected_ctl = [0] + [a4p] * 3 + [0] + [a4p] * 3  # all six +a4'
check(all(c[2] for c in dfl + ctl)
      and all(sp.simplify(c[0] - e) == 0 for c, e in zip(dfl, expected_dfl))
      and all(sp.simplify(c[0] - e) == 0 for c, e in zip(ctl, expected_ctl))
      and sp.simplify(lhs_c4 - 6 * a4p) == 0 and sp.simplify(lhs_c4_dfl) == 0
      and (lhs_ctl - sum(pieces_ctl, sp.zeros(16, 16))).applyfunc(sp.simplify)
      == sp.zeros(16, 16),
      "a4' terms: +a4' (space) and -a4' (deflating extra times) cancel; the "
      "control metric balances 6 a4' by its growing volume")
```

One check for everything of the paragraph "Why the time-derivative terms cancel" of Section 21.17: no remainders; the expected coefficients in both metrics; the left side of the control has $6a_4'$ and that of the author's metric 0; and the identity holds in the control metric too.

In [7]: the volume balance as bars.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.3), sharey=True)
labels = COORDS + ["left side"]
for ax, data, lhs_value, title in (
        (axes[0], dfl, lhs_c4_dfl, "author's metric: extra times deflate"),
        (axes[1], ctl, lhs_c4, "control: extra times inflate")):
    heights = [float(sp.simplify(c[0] / a4p)) for c in data + [(lhs_value,)]]
```

Two panels, one per metric. The loop runs over two groups of four values. `data + [(lhs_value,)]` appends a one-element tuple to the eight coefficient triples, so that `c[0]` is also the left-side coefficient; each is divided by a_4' and turned into a decimal number with `float`.

```
    colours = ["#e34948" if h > 0 else ("#2a78d6" if h < 0 else "#999999")
               for h in heights[:8]] + ["#555555"]
    ax.bar(range(9), heights, color=colours)
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xticks(range(9), labels, rotation=30)
    ax.set_title(title + f"; sum of the eight = {round(sum(heights[:8]))}")
    ax.set_xlabel("direction $\\mu$ of the term")
axes[0].set_ylabel("coefficient of $C\\gamma^{(x4)}$ in units of $a_4'$")
```

Red bars for positive, blue for negative, grey for zero coefficients, and a dark bar for the left side. The tick labels are turned by 30 degrees; the title states the sum of the eight contributions (`heights[:8]`, rounded to a whole number).

```
save_figure(fig, "volume_balance",
            "Why the time-derivative terms of the U(1) identity cancel. Each bar is "
            "the coefficient of $C\\gamma^{(x4)}$, in units of $a_4'$ and divided by "
            "the volume factor, contributed by one direction $\\mu$ to the right "
            "side $\\cos z\\,\\sum_\\mu(C\\gamma^\\mu\\Omega_\\mu - \\Omega_\\mu^T"
            "(\\gamma^\\mu)^TC)$; the last bar is the coefficient of the left "
            "side. Left: the author's metric, in which ordinary space contributes "
            "$+1$ per direction and the deflating extra times $-1$ each; the sum "
            "and the left side are $0$. Right: a control metric with inflating "
            "extra times; the six contributions add to $6$, matched by the growing "
            "volume factor $e^{6a_4}\\cos z$ on the left side.")
```

Figure 21b.1. **What the figure shows.** Left: three red bars of height $+1$ (space) and three blue bars of height -1 (extra times), sum 0, and an empty left-side bar: the deflation cancels the inflation. Right: six red bars, sum 6, and a dark left-side bar of height 6: in a metric whose volume grows, the growth itself supplies the balancing term.

In [8]: the matrices of the identity as heat maps.

```
from matplotlib.colors import TwoSlopeNorm

sample = {a4p: 0.7, a4: 0.3, H: sp.Rational(1, 6), x[0]: 0.5}  # any point
```

`TwoSlopeNorm` maps numbers to colours with the middle colour at a chosen centre value. `sample` is a dictionary of values for a sample point: $a_4' = 0.7$, $a_4 = 0.3$, $H = 1/6$, $x_0 = 0.5$.

```
def sampled(matrix):
    """matrix / (H cos z) evaluated at the sample point, as numbers."""
    return np.array(sp.N((matrix / (H * sp.cos(z))).subs(a4p, 0.7).subs(sample))
                    .tolist(), dtype=float)
```

The matrix is divided by $H\cos z$; `.subs` replaces symbols by values. The derivative a_4' is replaced first, on its own, because replacing a_4 by a number inside the derivative would destroy it. `sp.N` turns the exact result into decimal numbers, and the result is a numpy array.

```
lhs_num, rhs_num = sampled(lhs), sampled(rhs)
say(f"LHS = RHS at the sample point to 1e-12: "
    f"{np.abs(lhs_num - rhs_num).max() < 1e-12}")
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.0))
norm = TwoSlopeNorm(vmin=-6, vcenter=0, vmax=6)  # blue negative, red positive
```

Both sides at the sample point; the printed line (True) confirms that they agree to 10^{-12}. Three panels; the colour scale runs from -6 (blue) through 0 to $+6$ (red).

```
for ax, matrix, title in ((axes[0], lhs_num, "left side / $(H\\cos z)$"),
                          (axes[1], rhs_num, "right side / $(H\\cos z)$"),
                          (axes[2], 0 * rhs_num, "right side, $\\Omega = 0$")):
    image = ax.imshow(matrix, cmap="RdBu_r", norm=norm)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.set_xlabel("column")
    ax.grid(False)
axes[0].set_ylabel("row")
fig.colorbar(image, ax=axes, shrink=0.8, label="matrix entry")
```

The three matrices: the left side, the right side, and the right side without the spin connection (the zero matrix, `0 * rhs_num`). `"RdBu_r"` is matplotlib's red-blue colour map reversed, so that positive numbers are red.

```
save_figure(fig, "noether_matrices",
            "The $16 \\times 16$ matrices of the U(1) identity in the author's "
            "metric, divided by $H\\cos z$: left side $\\sum_\\mu\\partial_\\mu"
            "(\\cos z\\,C\\gamma^\\mu)$ (left panel), right side $\\cos z\\sum_\\mu"
            "(C\\gamma^\\mu\\Omega_\\mu - \\Omega_\\mu^T(\\gamma^\\mu)^TC)$ (middle) "
            "and the right side of the negative control with the spin connection "
            "removed (right); horizontal axis the column, vertical axis the row, "
            "colour the entry (red positive, blue negative). The first two are the "
            "same matrix $6C\\gamma^{(x0)}$ for every history $a_4$; without the "
            "spin connection the right side would be zero and the current would "
            "not be conserved.")
```

Figure 21b.2. **What the figure shows.** The left and middle panels are identical: sixteen squares of value ± 6 arranged like the signed permutation matrix $C\gamma^{(x0)}$. The right panel is empty: without the connection nothing balances the left side.

In [9]: the Noether current from a local phase change.

```
point = {x[0]: 0.7, H: sp.Rational(1, 6)}  # z = 0.7 (H = 1/6, so z = x0)
A4_value, A4_slope = 0.4, 0.25  # a4 and a4' at the point (any values)
```

A point of the author's metric: $x_0 = 0.7$ with $H = 1/6$, so $z = 0.7$; and arbitrary values $a_4 = 0.4$, $a_4' = 0.25$ of the history there.

```
def at_point(expression):
    """A sympy expression evaluated at the point, as a numpy array of complex."""
    e = expression.subs(a4p, A4_slope).subs(a4, A4_value).subs(point)
    return np.array(sp.N(e).tolist(), dtype=complex) if hasattr(e, "tolist") \
        else complex(sp.N(e))
```

The values are substituted (the derivative first, as in In [8]). If the result is a matrix (it has the method `tolist`; `hasattr` asks this), it becomes a complex numpy array, otherwise a complex number; the backslash continues the line.

```
Om_num = [at_point(Om) for Om in Omega]  # Omega_mu at the point
f_num = [at_point(v).real for v in f_dfl]  # the scale factors at the point
g_up = [gamma[mu] / f_num[mu] for mu in range(8)]  # gamma^mu at the point
cos_num = np.cos(0.7)
m_val, lam = 0.7, 0.3
```

The spin connection, the scale factors and the curved gammas at the point, the volume factor $\cos 0.7$, and the mass and coupling $m = 0.7$, $\lambda = 0.3$.

```
rng = np.random.default_rng(2102)  # fixed seed: the same numbers in every run
psi = rng.normal(size=16) + 1j * rng.normal(size=16)  # Psi at the point
dpsi = rng.normal(size=(8, 16)) + 1j * rng.normal(size=(8, 16))  # d_mu Psi
alpha_mu = rng.normal(size=8)  # the slopes d_mu alpha of the phase
# drawn with x0 last, as before the move to x0..x7; the roll puts x0 first
dpsi, alpha_mu = np.roll(dpsi, 1, axis=0), np.roll(alpha_mu, 1)
```

A random-number generator with the fixed seed 2102 provides a complex field value, eight complex first derivatives (an 8×16 array, one row per direction) and eight slopes $\alpha_\mu = \partial_\mu \alpha$ of the phase. They are drawn in the order in which this notebook drew them before it moved to the author's coordinates, with the hidden direction last; `np.roll(..., 1, axis=0)` moves the last row to the front, so that row μ belongs to x_μ and every printed number stays the same. A Lagrangian density at one point depends only on these numbers.

```
def lagrangian(p, dp):
    """cos z [ (1/2)(Psibar gamma^mu D_mu Psi - (D_mu Psibar) gamma^mu Psi)
    - m S - (lambda/2) S^2 ] at the point, for the value p and derivatives dp."""
    bar = np.conj(p) @ C  # Psibar = Psi^dagger C
    kinetic = 0
    for mu in range(8):
        D = dp[mu] + Om_num[mu] @ p  # D_mu Psi
        Dbar = np.conj(dp[mu]) @ C - bar @ Om_num[mu]  # D_mu Psibar
        kinetic += (bar @ g_up[mu] @ D - Dbar @ g_up[mu] @ p) / 2
    S = bar @ p
    return cos_num * (kinetic - m_val * S - lam / 2 * S ** 2)
```

The Lagrangian density of the record, term by term: the Dirac adjoint $\bar\Psi = \Psi^\dagger C$ (a row); for each direction $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $D_\mu\bar\Psi = (\partial_\mu\Psi)^\dagger C - \bar\Psi\Omega_\mu$; the kinetic term summed over the eight directions (`+=` adds to the running total); the scalar S; and $\cos z\,[\,\text{kinetic} - mS - \frac{\lambda}{2}S^2\,]$.

```
phase = np.exp(1j * 0.9)  # e^(i alpha) at the point, alpha = 0.9
L0 = lagrangian(psi, dpsi)
L_const = lagrangian(phase * psi, phase * dpsi)  # constant phase: alpha_mu = 0
L_local = lagrangian(phase * psi, phase * (dpsi + 1j * alpha_mu[:, None] * psi))
J = np.array([-1j * (np.conj(psi) @ C @ g_up[mu] @ psi) for mu in range(8)])
```

Three evaluations: the field as it is; after a constant phase $e^{0.9i}$ (value and derivatives multiplied by it); and after a local phase, whose derivatives are $e^{i\alpha}(\partial_\mu\Psi + i\alpha_\mu\Psi)$ (Section 21.16). `alpha_mu[:, None]` turns the eight slopes into a column, so that the product with the 16 components gives an 8×16 array, one row per direction. `J` holds the eight components of the current at the point.

```
say(f"L = {L0.real:+.6f} (imaginary part below 1e-12: {abs(L0.imag) < 1e-12}); "
    f"after a constant phase {L_const.real:+.6f}")
say(f"L' - L = {(L_local - L0).real:+.6f};  -cos z alpha_mu J^mu = "
    f"{(-cos_num * alpha_mu @ J).real:+.6f}")
```

Out [9] prints $\mathcal{L} = -16.780795$ with an imaginary part below 10^{-12} (the Lagrangian is real), the same value after a constant phase, and $\mathcal{L}' - \mathcal{L} = +2.348835 = -\cos z\,\alpha_\mu J^\mu$ (`alpha_mu @ J` is the sum $\sum_\mu \alpha_\mu J^\mu$).

```
check(abs(L0.imag) < 1e-12 and abs(L_const - L0) < 1e-12
      and abs((L_local - L0) - (-cos_num * alpha_mu @ J)) < 1e-12
      and np.allclose(J.imag, 0),
      "L is real and phase invariant; a local phase changes it by -cos z "
      "(d_mu alpha) J^mu with J^mu = -i Psibar gamma^mu Psi real")
```

The four statements to 10^{-12}, including that all eight current components are real.

In [10]: the exact solution and local conservation.

```
x4, zz = sp.symbols("x4 z", real=True)  # the time and the angle z = x0
Hn, al, m_sol = sp.Rational(1, 6), 1, 2
b_sol = 3 * Hn * (2 * al + 1)  # 3/2
w = sp.sqrt(m_sol ** 2 - b_sol ** 2)  # sqrt(7)/2
M_sol = -m_sol * G[4] + b_sol * G[4] * G[0]
U_sol = sp.cos(w * x4) * sp.eye(16) + sp.sin(w * x4) / w * M_sol  # a real matrix
```

New symbols for the time and the angle (the name `zz` keeps `z` of In [3] intact), the parameters $H = 1/6$, $\alpha = 1$, $m = 2$, and $b = 3/2$, $w = \sqrt{7}/2$, M and U of Section 21.11, exactly.

```
chi_values = [(0.62, -0.31), (0.15, 0.88), (-0.47, 0.26), (0.93, -0.05),
              (-0.21, -0.64), (0.38, 0.12), (0.07, -0.93), (-0.85, 0.44),
              (0.51, 0.69), (-0.12, -0.27), (0.29, 0.58), (-0.66, 0.03),
              (0.44, -0.72), (0.81, 0.35), (-0.39, -0.18), (0.24, 0.97)]
chi = sp.Matrix([sp.Rational(round(100 * re), 100) + sp.I * sp.Rational(
    round(100 * im), 100) for re, im in chi_values])  # exact rational entries
Psi = sp.sin(zz) ** al * U_sol * chi
```

Sixteen pairs (real part, imaginary part) with two decimals; `round(100 * re)` makes the whole number of hundredths, and `sp.Rational(..., 100)` the exact fraction, so χ has exact entries such as $31/50 - 31i/100$. `Psi` is the exact solution $\sin z\, U\chi$.

```
tan_z = sp.sin(zz) / sp.cos(zz)
E = (G[4] * Psi.diff(x4) + 6 * Hn * tan_z * G[0] * Psi.diff(zz)
     + 3 * Hn * G[0] * Psi - m_sol * Psi)  # the field equation, U = 0
SOLUTION_I = (  # item (i) of the record's formula exact_solutions, word for word
    "(i) U = 0: Psi = Sin[z]^al (Cosh[k x4] + Sinh[k x4]/k M) chi, M = -m g[x4]"
    " + 3 H (2 al + 1) g[x4].g[x0], k^2 = 9 H^2 (2 al + 1)^2 - m^2 (any a4)")
```

The left side of the field equation $E_m[\Psi]$ of Section 21.11 (step 4) with $m = 2$, and the record's text of the solution, word for word, as in Notebook 21a.

```
check(E.expand() == sp.zeros(16, 1)
      and THEORY["exact_solutions"]["wl"].startswith(SOLUTION_I + "; ")
      and PY_THEORY["exact_solution_family_x4_x0"] == "PASS",
      "the record's exact solution solves the field equation (m = 2)",
      record="Revision/theory/reports/python-field-theory.json, check "
      "exact_solution_family_x4_x0")
```

The solution solves the equation exactly; the record states it as used here; the record's own check passed.

```
B_s = -sp.I * C_s * G[4]
K0_s = -sp.I * C_s * G[0]
density = sp.cos(zz) * (Psi.H * B_s * Psi)[0, 0]  # cos z J^(x4)
flux = sp.sin(zz) * (Psi.H * K0_s * Psi)[0, 0]  # cos z J^(x0)
divergence = sp.expand(sp.diff(density, x4) + sp.diff(flux, zz))
```

Exact B and K_0; `Psi.H` is sympy's conjugate transpose $\Psi^\dagger$. The two densities of Section 21.18, $\cos z\, \Psi^\dagger B \Psi$ and $\sin z\, \Psi^\dagger K_0 \Psi$, and the divergence $\partial_4(\ldots) + \partial_z(\ldots)$, the only two terms of the conservation law that do not vanish for this solution.

```
check(sp.simplify(divergence) == 0
      and PY_THEORY["commuting_current_conservation"] == "PASS",
      "d4(cos z J^(x4)) + dz(cos z J^(x0)) = 0 exactly for the exact solution",
      record="Revision/theory/reports/python-field-theory.json, check "
      "commuting_current_conservation")
```

The divergence simplifies to exactly zero, as Section 21.17 proved in general. (The text cell before this code cell says that "the current has two nonzero components"; precisely, all eight components of this solution's current are nonzero, but only these two enter the conservation law, because the others do not depend on their own coordinate. The computation is unaffected.)

In [11]: the chirality partner and the density maps.

```
Gamma_s = sp.Matrix(Gamma.tolist())
partner = Gamma_s * Psi
E_partner = (G[4] * partner.diff(x4) + 6 * Hn * tan_z * G[0] * partner.diff(zz)
             + 3 * Hn * G[0] * partner + m_sol * partner)  # mass -2
density_p = sp.cos(zz) * (partner.H * B_s * partner)[0, 0]
flux_p = sp.sin(zz) * (partner.H * K0_s * partner)[0, 0]
```

The partner $\Gamma\Psi$, the left side of the field equation with the mass -2 (the mass term $-(-2)\Gamma\Psi = +2\Gamma\Psi$), and the partner's two densities.

```
check(E_partner.expand() == sp.zeros(16, 1)
      and sp.expand(density_p + density) == 0 and sp.expand(flux_p + flux) == 0
      and WL_PAIR["T1_current_primordial_commuting"] == "PASS"
      and PY_PAIR["T1.metric.commuting.current"] == "PASS",
      "Gamma Psi solves the equation with mass -2 and carries the opposite "
      "current: the pair's total current is zero",
      record="Revision/pairing/reports/wolfram-pairing.json, check "
      "T1_current_primordial_commuting")
```

Theorem T1 on this solution (Section 21.19): the partner solves the equation with the reversed mass, and its densities are exactly the negatives of those of Ψ; both pairing reports hold the corresponding checks with the verdict PASS.

```
density_f = sp.lambdify((x4, zz), density, "numpy")
times = np.linspace(0.0, 8.0, 161)
angles = np.linspace(0.0, np.pi / 2, 91)
T, Z = np.meshgrid(times, angles)  # every pair (time, angle)
rho = np.real(density_f(T, Z))  # the charge density of Psi
```

The density becomes a fast function; 161 times from 0 to 8 and 91 angles from 0 to $\pi/2$; `np.meshgrid` makes two arrays that together list every pair (time, angle); `rho` is the density at all of them.

```
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.0), sharey=True)
limit = np.abs(rho).max()
for ax, values, title in ((axes[0], rho, "$\\Psi$ (mass $+2$)"),
                          (axes[1], -rho, "$\\Gamma\\Psi$ (mass $-2$)"),
                          (axes[2], rho - rho, "sum of the pair")):
    image = ax.pcolormesh(T, Z, values, cmap="RdBu_r", vmin=-limit, vmax=limit,
                          shading="auto")
    ax.set_title(title)
    ax.set_xlabel("time $x_4$")
axes[0].set_ylabel("angle $z = 6Hx_0$ (brane at $\\pi/2$)")
fig.colorbar(image, ax=axes, shrink=0.85, label="charge density $\\cos z\\,J^{(x4)}$")
```

Three colour maps over the plane of time and angle (`pcolormesh` colours each small cell by its value; the colour scale is symmetric about zero). The partner's map is drawn as `-rho`, which the check above proved equal to its density; the third map is the sum, zero.

```
save_figure(fig, "charge_density_maps",
            "The charge density $\\cos z\\,J^{(x4)}$ of an exact solution of the "
            "field equation in the author's metric ($H = 1/6$, $\\alpha = 1$, mass "
            "$+2$; left), of its chirality partner $\\Gamma\\Psi$ (a solution with "
            "mass $-2$; middle) and of the pair (right); horizontal axis the time "
            "$x_4$, vertical axis the angle $z = 6Hx_0$ from the tip $0$ to the "
            "brane $\\pi/2$, colour the density (red positive, blue negative, pure "
            "numbers). The partner carries exactly the opposite density at every "
            "point, so the pair carries none.")
```

Figure 21b.3. **What the figure shows.** Left: for this column the density is mostly negative: dark blue bands, separated by faint red ones, repeat in time with the oscillation of the solution (period about 2.37), and every band fades out towards the tip $z = 0$ (the factor $\sin^2 z$) and towards the brane $z = \pi/2$ (the factor $\cos z$). Middle: the same picture with red and blue exchanged. Right: a uniform pale panel: the pair's density is zero everywhere.

In [12]: the charge balance and the stationary solution.

```
t = sp.symbols("t", real=True)
f_of = sp.expand((U_sol * chi).H * B_s * (U_sol * chi))[0, 0]  # f(x4)
g_of = sp.expand((U_sol * chi).H * K0_s * (U_sol * chi))[0, 0]  # g(x4)
Q_of = f_of / 3
```

The functions $f(x_4) = \chi^\dagger U^T B U \chi$ and $g(x_4) = \chi^\dagger U^T K_0 U \chi$ of Section 21.18 (the conjugate transpose of the real U times χ is $\chi^\dagger U^T$), and the charge $Q = f/3$.

```
balance = sp.simplify(Q_of - Q_of.subs(x4, 0)
                      + sp.integrate(g_of.subs(x4, t), (t, 0, x4)))
check(balance == 0, "charge balance: Q(x4) - Q(0) = - (flux through the brane), "
      "exactly")
```

`sp.integrate(g_of.subs(x4, t), (t, 0, x4))` is the exact integral $\int_0^{x_4} g(t)\,dt$ (the variable renamed to t). The balance $Q(x_4) - Q(0) + \int_0^{x_4} g = 0$ holds exactly.

```
P_stat = (sp.eye(16) - sp.I * M_sol / w) / 2  # projector onto M chi = i w chi
chi0 = P_stat * chi  # the single-frequency part of chi
g0 = sp.simplify(sp.expand((U_sol * chi0).H * K0_s * (U_sol * chi0))[0, 0])
Q0 = sp.simplify(sp.expand((U_sol * chi0).H * B_s * (U_sol * chi0))[0, 0] / 3)
```

The projector $P = \frac{1}{2}(1 - iM/w)$, the stationary column $\chi_0 = P\chi$, its flux function g_0 and its charge Q_0.

```
check((P_stat * P_stat - P_stat).applyfunc(sp.simplify) == sp.zeros(16, 16)
      and (M_sol * chi0 - sp.I * w * chi0).applyfunc(sp.simplify) == sp.zeros(16, 1)
      and g0 == 0 and Q0.free_symbols == set() and Q0 != 0,
      "the stationary solution sin z exp(i w x4) chi0: zero flux, constant nonzero Q")
```

$P^2 = P$; $M\chi_0 = iw\chi_0$; the flux is exactly zero; `Q0.free_symbols == set()` means that Q_0 contains no symbol at all, so it does not depend on the time; and it is not zero.

```
report("charge of the general solution at x4 = 0",
       f"{float(sp.re(Q_of.subs(x4, 0))):.6f}")
report("constant charge of the stationary solution", f"{Q0} = {float(Q0):.6f}")
```

Out [12] prints RESULT lines: $Q(0) = 0.178467$ for the general column and $Q_0 = -1424/1875 - 13\sqrt{7}/1500 = -0.782397$ (sympy writes the square root as `sqrt(7)`).

In [13]: the balance in a figure.

```
Q_f = sp.lambdify(x4, Q_of, "numpy")
g_f = sp.lambdify(x4, g_of, "numpy")
integral_f = sp.lambdify(x4, sp.integrate(g_of.subs(x4, t), (t, 0, x4)), "numpy")
Q_vals = np.real(Q_f(times))
rhs_vals = np.real(Q_f(0.0) - integral_f(times))
```

Fast functions for the charge, the flux and its integral; the charge at the 161 times and the prediction $Q(0) - \int_0^{x_4} g$.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.3))
axes[0].plot(times, Q_vals, linewidth=3, label="charge $Q(x_4)$ of the patch")
axes[0].plot(times, rhs_vals, "--", color="black",
             label="$Q(0) - \\int_0^{x_4}$ flux")
axes[0].plot(times, np.real(g_f(times)), ":", label="flux $g(x_4)$ through the brane")
axes[0].set_xlabel("time $x_4$")
axes[0].set_ylabel("charge, flux (pure numbers)")
axes[0].set_title("General solution: charge flows through the brane")
```

The left panel: the charge as a thick line, the prediction as a thin black dashed line on top of it, and the flux as a dotted line.

```
top = 1.9 * np.abs(np.real(g_f(times))).max()  # room for the legend above
axes[0].set_ylim(-1.2 * np.abs(np.real(g_f(times))).max(), top)
axes[0].legend(fontsize=8, loc="upper right")
```

The vertical range is set from -1.2 to 1.9 times the largest flux, which leaves room for the legend at the top.

```
Q0_value = float(Q0)
axes[1].plot(times, np.full_like(times, Q0_value), linewidth=2,
             label="$Q$ of $\\Psi$ (mass $+2$)")
axes[1].plot(times, np.full_like(times, -Q0_value), "--", linewidth=2,
             label="$Q$ of $\\Gamma\\Psi$ (mass $-2$)")
axes[1].plot(times, np.zeros_like(times), ":", color="black", linewidth=2,
             label="total charge of the pair")
axes[1].set_xlabel("time $x_4$")
axes[1].set_title("Zero flux: the charge is constant")
axes[1].set_ylim(-1.3 * abs(Q0_value), 2.2 * abs(Q0_value))  # legend fits on top
axes[1].legend(fontsize=8, loc="upper right")
```

The right panel: three constant lines (`np.full_like(times, value)` is an array of the same length filled with one value): the stationary charge, the partner's opposite charge (Section 21.19) and the pair's zero total.

```
check(np.max(np.abs(Q_vals - rhs_vals)) < 1e-12,
      "numerically: Q(x4) and Q(0) minus the integrated flux agree to 1e-12")
```

The balance holds to 10^{-12} at all 161 times.

```
save_figure(fig, "charge_balance",
            "The charge balance of exact solutions in the author's metric ($H = "
            "1/6$, $\\alpha = 1$, mass $2$). Left: for a general column $\\chi$, "
            "the charge $Q(x_4)$ of the patch $0 < z < \\pi/2$ (thick line), the "
            "prediction $Q(0) - \\int_0^{x_4} g$ of the conservation law (dashed, "
            "on top of it) and the flux $g$ through the brane (dotted), versus the "
            "time $x_4$. Right: for the stationary solution $\\sin z\\,e^{iwx_4}"
            "\\chi_0$ the flux vanishes, its charge is constant, its chirality "
            "partner "
            "carries the opposite constant charge and the pair carries none. All "
            "quantities per unit of the other six coordinates (pure numbers).")
```

Figure 21b.4. **What the figure shows.** Left: the charge rises and falls; wherever the flux (dotted) is positive the charge decreases and wherever it is negative the charge increases, and the dashed prediction lies exactly on the thick line. Right: two horizontal lines at ∓ 0.782397 and the zero line between them.

In [14]: a finite-difference test.

```
flux_f = sp.lambdify((x4, zz), flux, "numpy")
steps = 0.2 / 2.0 ** np.arange(7)  # 0.2, 0.1, ..., 0.003125
t0, z0 = 1.3, 0.7
```

The flux as a fast function; seven steps h that halve each time; the test point $(x_4, z) = (1.3, 0.7)$.

```
residuals = np.array([abs(np.real(
    (density_f(t0 + h, z0) - density_f(t0 - h, z0)) / (2 * h)
    + (flux_f(t0, z0 + h) - flux_f(t0, z0 - h)) / (2 * h))) for h in steps])
ratios = residuals[:-1] / residuals[1:]
```

For each step the divergence is computed with **central differences**, $\partial F \approx (F(x+h) - F(x-h))/(2h)$, whose error is proportional to h^2 (Chapter 2). `residuals[:-1] / residuals[1:]` divides each residual by the next one (`[:-1]` is all but the last, `[1:]` all but the first).

```
say("residuals: " + ", ".join(f"{r:.2e}" for r in residuals))
say("ratios when h is halved: " + ", ".join(f"{q:.3f}" for q in ratios))
check(np.all(np.abs(ratios - 4.0) < 0.05),
      "finite differences: the residual falls by 4 when h is halved (order 2)")
```

Out [14] prints the residuals from 3.68×10^{-3} down to 9.10×10^{-7} (`.2e` is scientific notation with two decimals) and the ratios 3.966, 3.991, 3.998, 3.999, 4.000, 4.000: halving h divides the residual by 4, the signature of order 2 converging to the exact value zero.

```
fig, ax = plt.subplots(figsize=(7.0, 4.4))
ax.loglog(steps, residuals, "o-", label="|central-difference divergence|")
ax.loglog(steps, residuals[0] * (steps / steps[0]) ** 2, "--",
          label="slope 2: proportional to $h^2$")
ax.set_xlabel("step $h$")
ax.set_ylabel("residual of the conservation law")
ax.set_title("A numerical test converges to the exact law")
ax.legend()
```

A plot with both axes logarithmic (`loglog`), the residuals and a reference line proportional to h^2 through the first point.

```
save_figure(fig, "local_conservation",
            "The local conservation law $\\partial_4(\\cos z\\,J^{(x4)}) + "
            "\\partial_z(\\cos z\\,J^{(x0)}) = 0$ tested with central differences "
            "of step $h$ at the point $x_4 = 1.3$, $z = 0.7$ for the exact solution "
            "of the author's metric; horizontal axis the step $h$, vertical axis "
            "the size of the computed divergence, both on logarithmic scales "
            "(pure numbers). The points follow the dashed line of slope 2: the "
            "error of the difference formula, proportional to $h^2$, is all there "
            "is; the exact divergence is zero.")
```

Figure 21b.5. **What the figure shows.** Seven points on a straight line of slope 2, lying on the dashed reference line: what a computer measures as a nonzero divergence is only the error of the difference formula.

In [15]: the charge while the extra times deflate.

```
a4_vals = times / 6.0  # a4 = A H x4 with A = 1, H = 1/6
fig, axes = plt.subplots(2, 1, figsize=(8.0, 6.4), sharex=True)
axes[0].semilogy(times, np.exp(a4_vals), label="ordinary space: $e^{a_4}$")
axes[0].semilogy(times, np.exp(-a4_vals), "--",
                 label="extra times $x5, x6, x7$: $e^{-a_4}$ (deflating)")
axes[0].semilogy(times, np.exp(3 * a4_vals) * np.exp(-3 * a4_vals), ":",
                 color="black", label="slice volume $e^{3a_4}e^{-3a_4} = 1$")
```

The linear history $a_4 = AHx_4$ with $A = 1$ and $H = 1/6$, chosen only for the picture. Two panels stacked vertically with a common time axis; the upper one draws, on a logarithmic axis, the growth factor of space, the shrinking factor of the extra times and the product of the cubes, which is exactly 1.

```
axes[0].set_ylabel("scale factor (log scale)")
axes[0].set_title("The history $a_4 = AHx_4$ ($A = 1$, $H = 1/6$)")
axes[0].legend(fontsize=8)
axes[1].plot(times, np.full_like(times, Q0_value), linewidth=2,
```

```
             label="charge $Q$ of the stationary solution")
axes[1].set_ylim(-1.5 * abs(Q0_value), 1.5 * abs(Q0_value))
axes[1].axhline(0.0, color="black", linewidth=0.8)
axes[1].set_xlabel("time $x_4$")
axes[1].set_ylabel("charge $Q$")
axes[1].legend(fontsize=8)
```

Labels and legend of the upper panel; the lower panel draws the constant charge of the stationary solution and the zero line.

```
save_figure(fig, "charge_through_deflation",
            "Top: the scale factors of the author's metric along the time $x_4$ "
            "for the linear history $a_4 = AHx_4$ with $A = 1$, $H = 1/6$ "
            "(chosen for the picture): ordinary space $e^{a_4}$ grows, the three "
            "extra times $e^{-a_4}$ deflate exponentially, and their product, the "
            "volume factor of a slice, stays $1$ (logarithmic vertical scale). "
            "Bottom: the charge $Q$ of the stationary exact solution versus $x_4$; "
            "it does not change while space inflates and the extra times deflate. "
            "The stationary solution solves the field equation for every "
            "history $a_4$ and its charge density contains no $a_4$, so the "
            "constant does not depend on this choice.")
```

Figure 21b.6. **What the figure shows.** Top: two straight lines on the logarithmic scale, one rising and one falling at the same rate, and a flat dotted line at 1 between them. Bottom: a flat line at -0.782: the charge is untouched by the deflation.

In [16]: the charge density is indefinite.

```
from fractions import Fraction

eig_B = np.linalg.eigvalsh(B)
plus_space = (I16 - 1j * gamma[4]) / 2  # projector onto -i gamma^(x4) = +1
```

`Fraction` (a Python module for exact fractions) is used to print the result. `np.linalg.eigvalsh` computes the eigenvalues of a Hermitian matrix in increasing order. `plus_space` is $\frac{1}{2}(1 + (-i\gamma^{(x4)}))$, the projector onto the eigenvectors of $-i\gamma^{(x4)}$ with eigenvalue $+1$ (the rest states of Section 21.18).

```
# B restricted to that space: an 8-dimensional block, eigenvalues +-1
values, vectors = np.linalg.eigh(plus_space @ B @ plus_space)
u_plus = vectors[:, np.argmax(values)]  # a vector with -i g4 u = u, B u = +u
u_minus = vectors[:, np.argmin(values)]  # a vector with -i g4 u = u, B u = -u
```

`np.linalg.eigh` returns the eigenvalues and an orthonormal set of eigenvectors (the columns of `vectors`). The matrix PBP has the eigenvalues of B restricted to the rest-state space and zeros elsewhere; `np.argmax` and `np.argmin` give the positions of the largest ($+1$) and smallest (-1) eigenvalue, and `vectors[:, k]` is column `k`.

```
u = 0.6 * u_plus + 0.8 * u_minus  # 3/5 and 4/5
rest_density = np.conj(u) @ B @ u
restricted = np.linalg.eigvalsh(plus_space @ B @ plus_space)
```

The worked example $u = \frac{3}{5}u_+ + \frac{4}{5}u_-$, its charge density $u^\dagger B u$, and the eigenvalues of PBP once more for the check.

```
check(np.allclose(sorted(eig_B), [-1] * 8 + [1] * 8)
      and np.allclose(-1j * gamma[4] @ u, u)
      and np.sum(restricted > 0.5) == 4 and np.sum(restricted < -0.5) == 4
      and abs(rest_density - (-7 / 25)) < 1e-12,
      "B has signature (8,8); a positive-frequency rest state has charge density "
      "-7/25")
report("charge density of the rest state 3/5 u+ + 4/5 u-",
       Fraction(round(rest_density.real * 25), 25))
```

B has eight eigenvalues -1 and eight $+1$; u is a rest state; the restricted block has four eigenvalues $+1$ and four -1 (`np.sum` of a true-false array counts the trues); the density is $-7/25$. The RESULT line prints the density as the exact fraction $-7/25$ (25 times the density, rounded to a whole number, over 25).

```
samples = rng.normal(size=(20000, 16)) + 1j * rng.normal(size=(20000, 16))
ratio = (np.einsum("nr,rc,nc->n", np.conj(samples), B, samples).real
         / np.einsum("nr,nr->n", np.conj(samples), samples).real)
say(f"fraction of random columns with negative charge density: "
    f"{np.mean(ratio < 0):.3f}")
```

20000 random complex columns (from the generator of In [9], which continues its sequence). For each, `einsum` computes $\Psi^\dagger B \Psi$ and $\Psi^\dagger \Psi$, and `ratio` is their quotient. `np.mean(ratio < 0)` is the fraction of negative ones: Out [16] prints 0.504.

```
check(ratio.min() >= -1 - 1e-12 and ratio.max() <= 1 + 1e-12
      and 0.4 < np.mean(ratio < 0) < 0.6,
      "random columns: the ratio lies in [-1, 1] and takes both signs")
fig, ax = plt.subplots(figsize=(7.5, 4.3))
ax.hist(ratio, bins=60, range=(-1, 1), color="#7a8fb3")
ax.axvline(-7 / 25, color="#e34948", linewidth=2,
           label="rest state with positive frequency: $-7/25$")
ax.set_xlabel("$\\Psi^\\dagger B\\Psi / \\Psi^\\dagger\\Psi$")
ax.set_ylabel("number of random columns")
ax.set_title("The charge density is indefinite")
ax.legend(fontsize=8)
```

The ratio lies between -1 and $+1$ (Section 21.18) and is negative for between 40 and 60 per cent of the columns. `ax.hist` draws a **histogram**: the interval from -1 to 1 is cut into 60 bins and each bar counts the columns whose ratio falls into it. A red vertical line marks $-7/25$.

```
save_figure(fig, "indefinite_charge",
            "Histogram of the normalised charge density $\\Psi^\\dagger B\\Psi / "
            "\\Psi^\\dagger\\Psi$ for 20000 random complex columns $\\Psi$ (fixed "
            "seed); horizontal axis the ratio, from $-1$ to $+1$, vertical axis the "
            "number of columns in each of 60 bins. Because $B$ has eight "
            "eigenvalues $+1$ and eight $-1$, the ratio takes both signs equally "
            "often. The red line marks the worked example: a flat-space rest "
            "state of positive frequency with charge density $-7/25$.")
```

Figure 21b.7. **What the figure shows.** A bell-shaped histogram centred at zero and symmetric: the charge density of a random field is positive or negative with equal probability, and the red line shows that a field of positive frequency can lie on the negative side.

In [17]: the pair-level bookkeeping.

```
U_f = sp.lambdify(x4, U_sol, "numpy")
columns = rng.normal(size=(5, 16)) + 1j * rng.normal(size=(5, 16))
check_times = [0.0, 2.5, 5.0]
totals, charges = [], []
```

The matrix $U(x_4)$ as a fast function, five random complex columns χ, three test times, and two empty lists.

```
for col in columns:
    u_t = [np.array(U_f(tt), dtype=float) @ col for tt in check_times]
    q_psi = [np.conj(v) @ B @ v / 3 for v in u_t]  # Q = f / 3 for alpha = 1
    q_par = [np.conj(Gamma @ v) @ B @ (Gamma @ v) / 3 for v in u_t]
    charges.append((q_psi[0].real, q_par[0].real))
    totals += [abs(a + b_) for a, b_ in zip(q_psi, q_par)]
```

For each column and each time, $v = U(x_4)\chi$ and the charge $Q = v^\dagger B v/3$ of the solution $\sin z\, U\chi$ (Section 21.18, line 1), and the charge of the partner Γv. The charges at the first time are kept for the figure; the sizes of the totals $Q + Q'$ are collected.

```
check(max(totals) < 1e-12 and min(abs(c[0]) for c in charges) > 1e-3,
      "five random columns at three times: Q + Q(partner) = 0, Q itself nonzero")
```

All 15 totals vanish to 10^{-12}, while every single charge is far from zero.

```
fig, ax = plt.subplots(figsize=(8.0, 4.3))
idx = np.arange(5)
ax.bar(idx - 0.25, [c[0] for c in charges], width=0.25, label="$Q$ of $\\Psi$")
ax.bar(idx, [c[1] for c in charges], width=0.25, label="$Q$ of $\\Gamma\\Psi$")
ax.plot(idx + 0.25, [c[0] + c[1] for c in charges], "D", color="black",
        label="total of the pair (zero)")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(idx, [f"column {k + 1}" for k in idx])
ax.set_ylabel("charge $Q$ at $x_4 = 0$")
ax.set_title("Theorem T1: the partner carries the opposite charge")
ax.legend(fontsize=8)
```

For each column two bars (the charges of Ψ and of $\Gamma\Psi$) and a black diamond (`"D"`) at their total.

```
save_figure(fig, "pair_bookkeeping",
            "Pair-level charge bookkeeping for five random columns $\\chi$ in the "
            "exact solution of the author's metric: the charge $Q$ of $\\Psi$ "
            "(left bar of each group), of its chirality partner $\\Gamma\\Psi$, a "
```

```
        "solution with the mass reversed (right bar), and their total (black "
        "diamond, zero); horizontal axis the column, vertical axis the charge at "
        "$x_4 = 0$ per unit of the other six coordinates (pure numbers). The "
        "charges of single universes can have either sign and any size; only "
        "the pair adds to zero.")
```

Figure 21b.8. **What the figure shows.** Pairs of bars of equal height and opposite sign, some positive first and some negative first, and five diamonds on the zero line: the pair-level statement of theorem T1. The figure shows a property of pairs of solutions; it does not show that such pairs are made (Section 21.19).

In [18]: the figure files.

```
names = sorted(FIGURE_NUMBERS, key=FIGURE_NUMBERS.get)
check(len(names) == 8 and all(
    output_file(f"{FIGURE_FOLDER}/21b_{FIGURE_NUMBERS[n]}_{n}.png").is_file()
    for n in names), "the eight figure files of notebook 21b exist")
all_checks_passed()
```

As in the last cell of Notebook 21a: the eight figure files exist, and the last line prints ALL 21 CHECKS PASSED (notebook 21b).

21.24 Reflections and the chirality: P, T and Γ

Sakharov's second condition speaks of C, P and T. Sections 21.8 to 21.10 found the matrices of charge conjugation. This section collects what the Revision record proves about the reflections, which play the roles of P and T, and about the chirality Γ. All statements are from the pairing record (`Revision/docs/PAIR_CREATION_PROOFS.md`, its sections 3 and 5; Chapter 18 gives the complete proofs); the one-line derivations are repeated here.

Reflections. The reflection R_n of a frame direction n reverses that direction and keeps the others: it is the diagonal matrix with -1 in place n and $+1$ elsewhere. Reflecting a space-like direction (x_0, x_1, x_2 or x_3) is a **parity**-type operation (P); reflecting the time x_4 is **time reversal** (T); reflecting an extra time x_5, x_6, x_7 is a time-reversal-type operation of an extra time. On the spinor, the reflection of the direction n is carried by the matrix $P_n = \Gamma\gamma^{(n)}$, which is plus or minus the product of the seven other gammas, hence an element of Pin(4,4) (record check `T2_Pn_in_Pin44`), and which acts on the gammas exactly as R_n (check `T2_Pn_covers_the_reflection`).

What a reflection does to the scalar, in one line. With the real matrix $\gamma^{(n)}$ (so $(\gamma^{(n)})^\dagger = (\gamma^{(n)})^T$) and (R3) in the form $(\gamma^a)^T C = -C\gamma^a$:

$$S[\gamma^{(n)}\Psi] = \Psi^\dagger (\gamma^{(n)})^T C \gamma^{(n)} \Psi = -\Psi^\dagger C \gamma^{(n)}\gamma^{(n)}\Psi = -\eta_{nn}\, S[\Psi],$$

because $\gamma^{(n)}\gamma^{(n)} = \eta_{nn}$. So a space-like reflection reverses the mass term and a time-like one keeps it. The record also proves (checks `T2_kernels_gamma_n_with_frame_reflection` of the Wolfram pairing report and `T2.general_field.reflection_table` of the sympy pairing report) that the kinetic term is multiplied by $+\eta_{nn}$ when the frame is reflected along. The result for the eight directions:

direction	η_{nn}	S under $\gamma^{(n)}$	kinetic term	parameters and Lagrangian
x_1, x_2, x_3 (P type)	$+1$	$-S$	kept	$(-m, \lambda)$, $+\mathcal{L}$ (T2 type)
x_4 (T)	-1	$+S$	reversed	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)
x_5, x_6, x_7	-1	$+S$	reversed	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)
x_0 (P type)	$+1$	$-S$	kept	$(-m, \lambda)$, $+\mathcal{L}$ (T2 type)

Every reflection maps the theory with mass m to a theory with mass $-m$. In the author's metric only the reflection of x_0 is realised by a map of the space onto itself, the mirror across the brane $z = \pi/2$, and that uses the ASSUMED Z2 construction (theorem T2 of the record; Chapter 18); the reflections of x_1, x_2, x_3 are statements about frames. For a space-like reflection the charge density is unchanged (record, statement T2c), so the T2 partner has equal, not opposite, charge.

The chirality. Γ is the product of all eight gammas, the spinor image of reflecting all eight directions at once. It keeps S and reverses every kinetic term and every current (Sections 21.10 and 21.19): theorem T1.

The Krein signs. After quantisation the matrix B fixes the canonical anticommutator (Section 21.25). A constant map $\Psi \to M\Psi$ turns it into $MBM^\dagger$, and the record proves $MBM^\dagger = \sigma_M B$ with a sign σ_M (check `Q_Krein_metric_of_images`). For the chirality, line by line: $\Gamma B \Gamma^\dagger = \Gamma B \Gamma = -iC\Gamma\gamma^{(x4)}\Gamma = -iC(-\gamma^{(x4)}) = -B$ (Γ is real and symmetric; it commutes with C, (R2), and anticommutes with $\gamma^{(x4)}$, (R1)). So $\sigma_\Gamma = -1$: the chirality image of a quantised field carries the Krein metric $-B$. For the single gammas the record finds $\sigma = +1$ for x_0, x_1, x_2, x_3, x_4 and -1 for x_5, x_6, x_7.

statement	status	where it is verified
$P_n = \Gamma\gamma^{(n)}$ is in Pin(4,4) and covers the reflection R_n	PROVED	`Revision/pairing/reports/wolfram-pairing.json`, checks `T2_Pn_in_Pin44`, `T2_Pn_covers_the_reflection`
$S[\gamma^{(n)}\Psi] = -\eta_{nn}S$; the table of the eight reflections	PROVED	the same report, `T2_character_of_Pn`, `T2_kernels_gamma_n_with_frame_reflection`; `Revision/pairing/reports/python-pairing.json`, `T2.general_field.reflection_table`
$\Gamma B \Gamma = -B$ and the Krein signs of the reflections	PROVED	`Revision/pairing/reports/wolfram-pairing.json`, check `Q_Krein_metric_of_images`

21.25 The quantised field: which conjugation keeps the canonical anticommutator

From numbers to operators. After **canonical quantisation** (Chapter 10) the 16 components of the field dirac16complex are no longer numbers but **operators** Ψ_A, $A = 1, \ldots, 16$: rules that turn one state of the quantum system into another. Two operators need not commute. The **anticommutator** of two operators is $\{X, Y\} = XY + YX$. The Revision record (`Revision /theory/field-theory.json`, formula `quantisation`) fixes, on a slice of constant time x_4,

$$\{\Psi_A(x), \Psi_C^\dagger(y)\} = B_{AC}\, \delta^7(x-y)/\cos z, \qquad \{\Psi_A(x), \Psi_C(y)\} = 0,$$

the **canonical anticommutator**, which the Lagrangian dictates. Because B has eight negative eigenvalues, $\Psi^\dagger$ cannot be the ordinary (Hilbert) adjoint of Ψ: the state space carries an indefinite form, a **Krein space**. The record realises the rule in the **positive representation** $\Psi_A = b_A$, $\Psi_C^\dagger = \sum_D b_D^* B_{DC}$, where b_A and b_A^* are ordinary fermion operators (Section 21.26). **Its scope.** This representation realises the anticommutation rule of the 16 components at one point on an ordinary (positive) space of 2^{16} states; it says nothing about the energy. A positive Fock space on which the normal-ordered Hamiltonian is non-negative is constructed in the record only for single good-sector momenta (no dependence on the extra times) with frozen coefficients: the Wolfram check `Fock_space_good_sector_example` and the sympy check `good_sector_positive_fock_realisation` of the field-theory record, whose reports are in the folder `Revision/theory/reports/`. In the author's metric the curved good-sector mode operator is Hermitian only up to a boundary term at the brane $z = \pi/2$, and without a boundary condition there the good sector has complex frequencies (for $U = 0$) whenever $m^2 < 9H^2$ (checks `good_sector_hermiticity_up_to_the_brane_flux` and `good_sector_x0_independent_modes_without_boundary_condition` of `Revision/theory/reports/wolfram-scope.json`). A positive-norm Hilbert space for the full field in the deflating background is not established (OPEN). In this section the delta function plays no role and is left out: everything is said for one point.

The question. Charge conjugation of the quantised field must turn Ψ into a new field built from the adjoints, $\Psi' = M\Psi^{\dagger T}$, that is $\Psi'_A = \sum_B M_{AB}\Psi_B^\dagger$ with a constant matrix M. For Ψ' to be a field of the **same** quantum theory it must obey the **same** canonical rule.

The condition, line by line. The adjoint of Ψ'_C is $\Psi_C'^\dagger = \sum_D M_{CD}^* \Psi_D$ (the adjoint of a number times an operator conjugates the number; the adjoint of $\Psi^\dagger$ is Ψ).

Line 1. $\{\Psi'_A, \Psi_C'^\dagger\} = \sum_{B,D} M_{AB} M_{CD}^* \{\Psi_B^\dagger, \Psi_D\}$ (the anticommutator is linear in each of its two slots).

Line 2. $\{\Psi_B^\dagger, \Psi_D\} = \{\Psi_D, \Psi_B^\dagger\} = B_{DB} = (B^T)_{BD}$ (the anticommutator is symmetric, $XY + YX = YX + XY$; then the canonical rule).

Line 3. So $\{\Psi'_A, \Psi_C'^\dagger\} = \sum_{B,D} M_{AB}(B^T)_{BD}(M^\dagger)_{DC} = (MB^TM^\dagger)_{AC}$ (the definition of the matrix product, with $M_{CD}^* = (M^\dagger)_{DC}$).

Line 4. Ψ' obeys the canonical rule if and only if

$$MB^TM^\dagger = B.$$

Which M satisfy it. B is Hermitian and purely imaginary, so $B^T = (B^\dagger)^* = B^* = -B$. For $M = \Gamma$: $\Gamma B^T \Gamma^\dagger = -\Gamma B \Gamma = -(-B) = B$ (Section 21.24): **the condition holds**. For $M = 1$: $B^T = -B \neq B$: **it fails**. More generally, for the family $M(t) = \cos t\, 1 + \sin t\, \Gamma$, which is real and symmetric:

$$M(t)\, B^T M(t)^\dagger = -M(t) B M(t) = -\big(\cos^2 t\, B + \cos t \sin t\, (\Gamma B + B\Gamma) + \sin^2 t\, \Gamma B \Gamma\big)$$

(the product multiplied out). Γ anticommutes with B (Γ commutes with C and anticommutes with $\gamma^{(x4)}$), so the middle term vanishes, and $\Gamma B \Gamma = -B$. Hence

$$M(t)\, B^T M(t)^\dagger = -(\cos^2 t - \sin^2 t)\, B = -\cos(2t)\, B,$$

which equals B only when $\cos 2t = -1$, that is $t = \pi/2$ or $3\pi/2$: $M = \pm\Gamma$. The size of the failure is $|1 + \cos 2t|$ times the size of B, which is 4 (the square root of the sum of the squares of its 16 entries of modulus 1); at $t = 0$ it is 8. A multiple $c\,\Gamma$ gives $|c|^2 B$, so it works exactly when $|c| = 1$, a phase. Notebook 21c computes all of this (In [4], figure 21c.2), reproducing the lead check `quantum_charge_conjugation_unitary_type`.

Which mass? A conjugation must also map solutions to solutions. The intertwiner condition of Section 21.8, the definition of a charge-conjugation matrix, is enough for this (though not necessary: for $V = 0$ the projector P_- also does it, Section 21.8), and by Theorem CC the only matrices that obey it are the multiples of 1 (same mass) and of Γ (mass reversed). So for the quantised field **the only charge-conjugation matrix that keeps the canonical anticommutator gives $\Psi \to \Gamma \Psi^{\dagger T}$ (times a phase), and it reverses the mass.** The same-mass candidate $\Psi \to \Psi^{\dagger T}$ would turn B into $-B$.

21.26 Particles and holes; the mass reversed, the spectra equal

Fermion modes from zero. A **fermion mode** is a place that holds at most one particle: it is either empty (0) or occupied (1). Sixteen modes have $2^{16} = 65536$ states, one for each list of 16 zeros and ones. The **annihilation operator** b_j empties mode j (and gives zero if it is already empty); the **creation operator** b_j^* fills it (and gives zero if it is already full). To make operators of different modes anticommute, each action on mode j also multiplies by (-1) raised to the number of occupied modes before j (the **Jordan-Wigner** sign rule). With it, $\{b_j, b_k^*\} = \delta_{jk}$ and $\{b_j, b_k\} = 0$. The number operator $b_j^* b_j$ is 1 on states where mode j is occupied and 0 otherwise, and $N = \sum_j b_j^* b_j$ counts the occupied modes. Notebook 21c builds these operators explicitly on all 65536 states (In [5]).

The charge counts the occupied modes. In the positive representation the charge operator is

$$Q = \sum_{A,C} \Psi^\dagger_A B_{AC} \Psi_C = \sum_{A,C,D} b^*_D B_{DA} B_{AC} b_C = \sum_{D,C} b^*_D (B^2)_{DC} b_C = \sum_D b^*_D b_D = N$$

(insert $\Psi^\dagger_A = \sum_D b^*_D B_{DA}$ and $\Psi_C = b_C$; the sum over A is a matrix product; $B^2 = 1$).

The charge of the conjugated field, line by line, for $\Psi' = \Gamma \Psi^{\dagger T}$. Since Γ is diagonal and real, $\Psi'_C = \Gamma_{CC} \Psi^\dagger_C$ and $\Psi'^\dagger_A = \Gamma_{AA} \Psi_A$.

Line 1. $Q' = \sum_{A,C} \Psi'^{\dagger}_A B_{AC} \Psi'_C = \sum_{A,C} \Gamma_{AA} B_{AC} \Gamma_{CC}\, \Psi_A \Psi^{\dagger}_C = \sum_{A,C} (\Gamma B \Gamma)_{AC} \Psi_A \Psi^{\dagger}_C$ (insert; the numbers Γ_{AA} and Γ_{CC} commute with the operators; for a diagonal Γ, $\Gamma_{AA} B_{AC} \Gamma_{CC} = (\Gamma B \Gamma)_{AC}$).

Line 2. $\Gamma B \Gamma = -B$ (Section 21.24), so $Q' = -\sum_{A,C} B_{AC} \Psi_A \Psi^{\dagger}_C$.

Line 3. The canonical rule gives $\Psi_A \Psi^{\dagger}_C = B_{AC} - \Psi^{\dagger}_C \Psi_A$, so $Q' = -\sum_{A,C} B^2_{AC} + \sum_{A,C} \Psi^{\dagger}_C (B^T)_{CA} \Psi_A$ (with $B_{AC} = (B^T)_{CA}$).

Line 4. $\sum_{A,C} B^2_{AC} = \mathrm{tr}(BB^T) = \mathrm{tr}(B(-B)) = -\mathrm{tr}(B^2) = -16$, and $B^T = -B$ turns the second sum into $-Q$. Hence

$$Q' = 16 - Q.$$

The valid conjugate counts the **empty** modes. Up to the constant 16, which does not change any difference of charges, it **reverses the charge**: $Q' - 8 = -(Q - 8)$. Particles and holes are exchanged. The same four lines with $M = 1$ (no factors Γ, so no sign in line 2) give $Q'' = \sum_{A,C} B_{AC} \Psi_A \Psi^{\dagger}_C = -16 + Q$: the invalid same-mass candidate would not even reverse the charge, it would shift it. Notebook 21c checks these three operator identities on a random state of the 16 modes (In [8], figure 21c.4). This operator result is the quantum counterpart of the anticommuting rows of the table of Section 21.10: the valid conjugation reverses the charge and the mass; the same-mass candidate keeps the charge (up to a shift). Normal ordering subtracts the vacuum value ($Q = N = 0$ in the empty state, so Q' has the vacuum value 16 and Q'' the value -16) and gives $:Q':= -Q$ and $:Q'':= Q$: it adds no sign, as the corrected detail text of the record's check `bilinears_under_charge_conjugation` states (Section 21.10).

The mass is reversed, the spectra are equal. In flat 4+4 space ($H = 0$, a_4 constant) a plane wave $u\, e^{ik\cdot x}$, with the momenta k_a along the seven directions other than the time, evolves by $i\, \partial_4 u = h_m(k) u$ with the **one-particle Hamiltonian** of the record

$$h_m(k) = -im\gamma^{(x4)} - \gamma^{(x4)} \sum_{a \neq x4} k_a \gamma^{(a)}.$$

Four facts, each derived in a few lines (write $K = \sum_{a \neq x4} k_a \gamma^{(a)}$, so $h = -\gamma^{(x4)}(im + K)$):

- *The square.* $h^2 = \gamma^{(x4)}(im+K)\gamma^{(x4)}(im+K) = \gamma^{(x4)}\gamma^{(x4)}(im-K)(im+K) = -(-m^2-K^2) = m^2 + K^2$ ($\gamma^{(x4)}$ anticommutes with every gamma in K; $\gamma^{(x4)}\gamma^{(x4)} = -1$; the cross terms $imK - Kim$ cancel). By the Clifford relation $K^2 = \sum_a k_a^2 \eta^{aa}$ (the products of different gammas cancel in pairs). Hence $h^2 = w^2\, 1$ with $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$: the frequencies are $\pm w$ (record check `Q_one_particle_flat_dispersion`).
- *The chirality.* $\Gamma h_m \Gamma = -im\Gamma\gamma^{(x4)}\Gamma - \Gamma\gamma^{(x4)}K\Gamma = im\gamma^{(x4)} - \gamma^{(x4)}K = h_{-m}(k)$ (R1 for the single gamma, R2 for the pair): the Hamiltonians of $+m$ and $-m$ are **similar**, so their spectra are **identical**, not opposite (record check `Q_one_particle_maps`).
- *The conjugated mode.* The conjugated field contains Γu^*. Conjugating the evolution gives $-i\, \partial_4 u^* = h^* u^*$, that is $i\, \partial_4 u^* = -h^* u^*$, and multiplying by Γ (with $\Gamma\Gamma = 1$): $i\, \partial_4 (\Gamma u^*) = -\Gamma h^* \Gamma\, (\Gamma u^*)$. Now $h^*_m = im\gamma^{(x4)} - \gamma^{(x4)}K$ (only the i changes sign), so $-\Gamma h^*_m \Gamma = -(-im\gamma^{(x4)} - \gamma^{(x4)}K) = h_{-m}(-k)$: **the conjugated mode is a mode of the theory with the reversed mass** (and the reversed momentum, as $e^{-ik\cdot x}$ says).

- *Krein self-adjointness.* $BhB = h^\dagger$, hence $Bh = h^\dagger B$ ($B^2 = 1$). Derivation: with $(-i)^2 = -1$ and $C\gamma^{(x4)} = \gamma^{(x4)}C$, $BhB = -(C\gamma^{(x4)})h(C\gamma^{(x4)})$; the mass part gives $-(C\gamma^{(x4)})(-im\gamma^{(x4)})(C\gamma^{(x4)}) = imC\gamma^{(x4)}\gamma^{(x4)}C\gamma^{(x4)} = -im\gamma^{(x4)}$ (using $\gamma^{(x4)}\gamma^{(x4)} = -1$ and $CC = 1$) and the momentum part gives $K^T\gamma^{(x4)}$ (using $CKC = -K^T$); and $h^\dagger = im(\gamma^{(x4)})^T - K^T(\gamma^{(x4)})^T = -im\gamma^{(x4)} + K^T\gamma^{(x4)}$, the same (record check `mode_hamiltonian_B_selfadjoint_dispersion` of the sympy field-theory report).

Krein inertia. For a real frequency w each eigenspace of h has dimension 8, and the form $u^\dagger Bu$ restricted to it has four positive and four negative directions: **Krein inertia** (4,4). For an imaginary frequency the eigenspace is **Krein-neutral**: if $hu = wu$ and $hv = wv$, then $w\,u^\dagger Bv = u^\dagger Bhv = u^\dagger h^\dagger Bv = (hu)^\dagger Bv = w^* u^\dagger Bv$, so $(w - w^*)u^\dagger Bv = 0$, and the form vanishes when w is not real (record check `Q_one_particle_complex_and_zero_frequencies_Krein_neutral`). Imaginary frequencies occur when the extra-time momenta dominate, $k_5^2 + k_6^2 + k_7^2 > m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2$; these modes grow exponentially in time (the ill-posedness of the extra times, Chapter 8). The record's eight samples (`Revision/pairing/pairing-theory.json`, data `one_particle_flat`), which Notebook 21c reproduces (In [10]):

m	**momenta** $(k_0, \ldots, k_7)$	w	**dimensions of the $\pm w$ eigenspaces**	**Krein inertia on $+w$ and $-w$**
± 2	(4, 1, 2, 0, 0, 0, 0, 0)	5	8 and 8	(4,4) and (4,4)
± 3	(0, 0, 0, 0, 0, 0, 0, 0)	3	8 and 8	(4,4) and (4,4)
± 1	(0, 1, 0, 0, 0, 0, 0, 0)	$\sqrt{2} = 1.414214$	8 and 8	(4,4) and (4,4)
± 2	(0, 0, 0, 0, 0, 1, 0, 0)	$\sqrt{3} = 1.732051$	8 and 8	(4,4) and (4,4)

(Each row stands for two samples of the record, $+m$ and $-m$, with identical results. The entry k_4 is not used. Check: for the first row $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 = 4 + 16 + 1 + 4 = 25$.)

statement	**status**	**where it is verified**
the canonical anticommutator $B_{AC}\delta/\cos z$ and the positive representation	record statement, checked word for word	`Revision/theory/field-theory.json`, formula `quantisation`; Notebook 21c, In [2]
$MB^TM^\dagger = B$ holds for $M = \Gamma$, gives $-B$ for $M = 1$; in the family $\cos t + \sin t\,\Gamma$ only $t = \pi/2, 3\pi/2$	PROVED (above); COMPUTED	lead check `quantum_charge_conjugation_unitary_type`; Notebook 21c, In [4]
with explicit operators on 65536 states: $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$; $\Gamma\Psi^{\dagger T}$ gives B, $\Psi^{\dagger T}$ gives $-B$	COMPUTED (all 256 pairs, to rounding)	`Revision/theory/reports/python-field-theory.json`, check `canonical_anticommutator_B`; Notebook 21c, In [6]

What this does **not** do: no regularised quantum field theory in signature (4,4) is constructed here, no positive-norm Hilbert space for the full field is established (Section 21.25), the statements concern the anticommutator and the one-particle problem, and nothing in them creates particles, antiparticles or universes.

21.27 Example: Notebook 21c conjugates the quantised field

Notebook 21c turns Sections 21.25 and 21.26 into computations. It reads the gammas, the lead report, the field-theory record and its sympy report, and the pairing record; it checks the properties of B; it computes $MB^TM^\dagger$ for $M = \Gamma$, $M = 1$ and the family $\cos t\, 1 + \sin t\, \Gamma$; it builds 16 fermion modes with the Jordan-Wigner rule and measures all 256 anticommutators of three fields with explicit operators on 65536 states; it checks $Q' = 16 - Q$; it proves the one-particle facts with sympy, reproduces the eight samples of the pairing record and scans the momenta into the region of growing modes. It runs in about 30 seconds; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/21c_quantum_conjugation.PROVENANCE.md`. It needs no Rust, prints 17 PASS lines and draws six figures.

21.28 How to run Notebook 21c

Step 1. What this notebook does and what it needs.

Notebook 21c (The conjugation of the quantised field: M B^T M^dagger = B) is the file `Revision/textbook/notebooks/21c_quantum_conjugation.ipynb` of the repository Dirac_claude. It derives the condition M B^T M^dagger = B that a conjugation Psi to M Psi^dagger T must satisfy to preserve the canonical anticommutator of the quantised field dirac16complex (B = -i C gamma^(x4), the Krein matrix), finds that it holds for M = Gamma and fails for M = 1 (and, among the matrices cos t + sin t Gamma, only for Gamma), verifies this with explicit fermion operators on the 65536 states of 16 modes (Jordan-Wigner construction in the positive representation of the Revision record), shows that the valid conjugation turns the charge Q into 16 - Q (particles into holes), proves with sympy that it maps the one-particle Hamiltonian of mass m to that of mass -m, and reproduces the one-particle samples of the Revision pairing record: equal spectra for +m and -m, Krein inertia (4,4) at real frequencies, Krein-neutral growing modes at large extra-time momentum.

Six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 21c_quantum_conjugation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21c_quantum_conjugation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 21c_quantum_conjugation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/21c.captions.json`
- `Revision/textbook/figures/21c_1_krein_matrix.png`
- `Revision/textbook/figures/21c_2_which_conjugation.png`
- `Revision/textbook/figures/21c_3_operator_anticommutators.png`
- `Revision/textbook/figures/21c_4_charge_of_states.png`
- `Revision/textbook/figures/21c_5_dispersion_pm_mass.png`
- `Revision/textbook/figures/21c_6_krein_inertia_scan.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 21c exist
ALL 17 CHECKS PASSED (notebook 21c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/21c_quantum_conjugation.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 21c_quantum_conjugation.ipynb
python -m nbconvert --execute --inplace 21c_quantum_conjugation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`, `Revision/theory`, `Revision/pairing` or `Revision/lead_checks`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.
- "MemoryError" in the cells of section 7: the operators act on columns of 65536 complex numbers (1 MB each); close other programs and run the notebook again.

21.29 Notebook 21c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/21c_quantum_conjugation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the

cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

After *quantisation* the 16 components of the field dirac16complex are no longer
numbers but **operators** $\Psi_A$ ($A = 1, \dots, 16$), and the Revision record
fixes how they combine: on a slice of constant time $x_4$,
$$\{\Psi_A(x), \Psi^\dagger_C(y)\} = B_{AC}\,\delta^7(x - y)/\cos z,\qquad
B = -iC\gamma^{(x4)} ,$$
the **canonical anticommutator**. A charge conjugation of the quantised field must
turn $\Psi$ into a new field $\Psi' = M\Psi^{\dagger T}$ (built from the adjoint
operators, arranged as a column, times a constant matrix $M$) that obeys **the
same** rule; otherwise $\Psi'$ is not a field of the same quantum theory. This
notebook

1. derives the condition $MB^TM^\dagger = B$ and shows: it holds for
   $M = \Gamma$, it fails for $M = 1$ (that choice gives $-B$), and among all
   matrices $\cos t\,1 + \sin t\,\Gamma$ it holds only for $\pm\Gamma$
   (record check quantum_charge_conjugation_unitary_type);
2. builds the 16 field operators explicitly, as $65536 \times 65536$ operators on
   the states of 16 fermion modes, and measures all 256 anticommutators of
   $\Psi$, of $\Gamma\Psi^{\dagger T}$ and of $\Psi^{\dagger T}$;
3. shows that the valid conjugation counts the *empty* modes: its charge is
   $16 - Q$, the charge reversed up to a constant (particles become holes);
4. proves with sympy that the conjugated field obeys the field equation with the
   **mass reversed**, and that nevertheless the one-particle spectra of the masses
   $+m$ and $-m$ are identical; it reproduces the eight samples of the Revision
   pairing record (frequencies, dimensions, Krein inertia) and scans the
   extra-time momentum into the region of growing modes.

Six teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 21c (The conjugation of the quantised field: M B^T M^dagger = B) is the file
‘Revision/textbook/notebooks/21c_quantum_conjugation.ipynb‘ of the repository
Dirac_claude. It derives the condition M B^T M^dagger = B that a conjugation Psi to M
Psi^dagger T must satisfy to preserve the canonical anticommutator of the quantised field
dirac16complex (B = -i C gamma^(x4), the Krein matrix), finds that it holds for M = Gamma
and fails for M = 1 (and, among the matrices cos t + sin t Gamma, only for Gamma),
verifies this with explicit fermion operators on the 65536 states of 16 modes
(Jordan-Wigner construction in the positive representation of the Revision record), shows
that the valid conjugation turns the charge Q into 16 - Q (particles into holes), proves
with sympy that it maps the one-particle Hamiltonian of mass m to that of mass -m, and
reproduces the one-particle samples of the Revision pairing record: equal spectra for +m
and -m, Krein inertia (4,4) at real frequencies, Krein-neutral growing modes at large
```

extra-time momentum. Six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
```

```
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 21c_quantum_conjugation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21c_quantum_conjugation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 21c_quantum_conjugation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/21c.captions.json‘
- ‘Revision/textbook/figures/21c_1_krein_matrix.png‘
- ‘Revision/textbook/figures/21c_2_which_conjugation.png‘
- ‘Revision/textbook/figures/21c_3_operator_anticommutators.png‘
- ‘Revision/textbook/figures/21c_4_charge_of_states.png‘
- ‘Revision/textbook/figures/21c_5_dispersion_pm_mass.png‘
- ‘Revision/textbook/figures/21c_6_krein_inertia_scan.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of notebook 21c exist
ALL 17 CHECKS PASSED (notebook 21c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/21c_quantum_conjugation.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 21c_quantum_conjugation.ipynb
      python -m nbconvert --execute --inplace 21c_quantum_conjugation.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘, ‘Revision/theory‘, ‘Revision/pairing‘ or ‘Revision/lead_checks‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.
- "MemoryError" in the cells of section 7: the operators act on columns of 65536 complex numbers (1 MB each); close other programs and run the notebook again.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 21c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 21c (The conjugation of the quantised field: M B^T M^dagger = B) is the file
# Revision/textbook/notebooks/21c_quantum_conjugation.ipynb of the repository
# Dirac_claude. It derives the condition M B^T M^dagger = B that a conjugation Psi to M
# Psi^dagger T must satisfy to preserve the canonical anticommutator of the quantised
# field dirac16complex (B = -i C gamma^(x4), the Krein matrix), finds that it holds for M
# = Gamma and fails for M = 1 (and, among the matrices cos t + sin t Gamma, only for
# Gamma), verifies this with explicit fermion operators on the 65536 states of 16 modes
# (Jordan-Wigner construction in the positive representation of the Revision record),
# shows that the valid conjugation turns the charge Q into 16 - Q (particles into holes),
# proves with sympy that it maps the one-particle Hamiltonian of mass m to that of mass
# -m, and reproduces the one-particle samples of the Revision pairing record: equal
# spectra for +m and -m, Krein inertia (4,4) at real frequencies, Krein-neutral growing
# modes at large extra-time momentum. Six teaching plots. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
```

```
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the

#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
```

```
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 21c_quantum_conjugation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 21c_quantum_conjugation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 21c_quantum_conjugation.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/21c.captions.json
# - Revision/textbook/figures/21c_1_krein_matrix.png
# - Revision/textbook/figures/21c_2_which_conjugation.png
# - Revision/textbook/figures/21c_3_operator_anticommutators.png
# - Revision/textbook/figures/21c_4_charge_of_states.png
# - Revision/textbook/figures/21c_5_dispersion_pm_mass.png
# - Revision/textbook/figures/21c_6_krein_inertia_scan.png
#
# It changes no other file of the repository; running it headless or saving it in
```

```
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the six figure files of notebook 21c exist
#     ALL 17 CHECKS PASSED (notebook 21c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/21c_quantum_conjugation.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 21c_quantum_conjugation.ipynb
#     python -m nbconvert --execute --inplace 21c_quantum_conjugation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event

## 3. The words used in this notebook

- **Operator**: a rule that turns one state of a quantum system into another; with
  a basis of the states it is a (large) matrix. Operators need not commute:
  $XY \ne YX$ in general.
- **Anticommutator** $\{X, Y\} = XY + YX$.
- **Fermion modes, occupation**: a fermion mode is either empty (0) or occupied
  (1); 16 modes have $2^{16} = 65536$ states, each a list of 16 zeros and ones.
  The **annihilation operator** $b_j$ empties mode $j$ (and gives zero if it is
  already empty), the **creation operator** $b_j^*$ fills it; they obey
  $\{b_j, b_k^*\} = \delta_{jk}$ and $\{b_j, b_k\} = 0$. The sign rule that makes
  them anticommute is the **Jordan-Wigner** rule: acting on mode $j$ gives the
  factor $(-1)$ to the power of the number of occupied modes before $j$.
- **Hilbert adjoint** $X^*$: the conjugate transpose of the matrix of $X$ in an
  ordinary (positive) inner product.
- **Canonical anticommutator**: the rule $\{\Psi_A, \Psi^\dagger_C\} = B_{AC}$
  (times the delta function) that canonical quantisation of the Lagrangian gives.
  Because $B$ has eight eigenvalues $+1$ and eight $-1$, $\Psi^\dagger$ cannot be
  the Hilbert adjoint of $\Psi$; the Revision record realises it as $\Psi^\dagger
  = b^*B$ (the **positive representation**: $\Psi_A = b_A$, $\Psi^\dagger_C =
  \sum_D b^*_D B_{DC}$).
- **Krein matrix, Krein form**: $B$, and the indefinite form $u^\dagger Bv$;
  **Krein inertia** $(p, n)$ of a space: the numbers of positive and negative
  eigenvalues of the form restricted to it; **Krein-neutral**: the form vanishes
  on the space.
```

```
- **Charge operator** $Q = \sum_{A,C}\Psi^\dagger_A B_{AC}\Psi_C$ (the integral
  of the charge density $\Psi^\dagger B\Psi$ for one point).
- **One-particle Hamiltonian** $h_m(k)$: the $16 \times 16$ matrix that gives the
  time evolution $i\,\partial_4 u = h_m(k)u$ of a plane wave $u\,e^{ik\cdot x}$ in
  flat 4+4 space; its eigenvalues are the **frequencies** $\pm w$.
- **Extra-time momentum** $k_5, k_6, k_7$: the momentum along the extra times;
  the **good sector** has $k_5 = k_6 = k_7 = 0$.
```

Text cell:

```
## 4. The physical and mathematical situation

**The condition, line by line.** Let $\Psi' = M\Psi^{\dagger T}$, that is
$\Psi'_A = \sum_B M_{AB}\Psi^\dagger_B$, with a constant matrix $M$. Its adjoint
is $\Psi'^\dagger_C = \sum_D M^*_{CD}\Psi_D$ (the adjoint of a product of a number
and an operator conjugates the number, and the adjoint of $\Psi^\dagger$ is
$\Psi$).

1. $\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{B,D}M_{AB}M^*_{CD}\{\Psi^\dagger_B,
   \Psi_D\}$, because the anticommutator is linear in each slot.
2. $\{\Psi^\dagger_B, \Psi_D\} = \{\Psi_D, \Psi^\dagger_B\} = B_{DB} =
   (B^T)_{BD}$.
3. Hence $\{\Psi'_A, \Psi'^\dagger_C\} = \sum_{B,D}M_{AB}(B^T)_{BD}(M^\dagger)_{DC}
   = (MB^TM^\dagger)_{AC}$.
4. So $\Psi'$ obeys the canonical rule if and only if
   $$MB^TM^\dagger = B .$$

$B$ is Hermitian and purely imaginary, so $B^T = (B^\dagger)^* = B^* = -B$, and the
condition reads $MBM^\dagger = -B$. For $M = \Gamma$: $\Gamma B\Gamma =
-iC\Gamma\gamma^{(x4)}\Gamma = +iC\gamma^{(x4)} = -B$ (because $\Gamma$ commutes
with $C$ and anticommutes with $\gamma^{(x4)}$), so the condition **holds**. For
$M = 1$: $B = -B$ is **false**.

**Which mass?** A conjugation must also map solutions of the field equation to
solutions. The classical analysis of the charge-conjugation matrices (Notebook
21a) defines them by the intertwiner condition $M(\gamma^a)^* = s\,\gamma^a M$
(the definition of the Revision record), which is enough for this, and shows
that the only matrices obeying it are the multiples of $1$ (same mass) and of
$\Gamma$ (mass reversed). (Other matrices can also map solutions to solutions:
for $V = 0$ the projector $P_-$ does, Notebook 05c.) So for the quantised field
the only charge-conjugation matrix that keeps the canonical anticommutator gives
$\Psi \to \Gamma\Psi^{\dagger T}$ (times a phase), and it **reverses the mass**.
Section 9 checks this directly on the one-particle Hamiltonian.
```

Text cell:

```
## 5. The gammas and the Krein matrix B

The next cell reads the eight gamma matrices of the Revision record, checks that
they are eight real $16 \times 16$ matrices with the Clifford relation of
signature (4,4), builds $C$, the chirality $\Gamma$ and $B = -iC\gamma^{(x4)}$,
and reads the Revision records used below. It also checks that the record's
```

formula quantisation states the canonical anticommutator and the positive
representation exactly as this notebook uses them.

## 6. Which conjugation keeps the anticommutator?

The next cell computes $MB^TM^\dagger$ for $M = \Gamma$ and $M = 1$ and compares
with the Revision record (check quantum_charge_conjugation_unitary_type). Then it
looks at the whole family $M(t) = \cos t\,1 + \sin t\,\Gamma$ for $t$ from $0$ to
$2\pi$ and computes the size of the mismatch $\|M(t)B^TM(t)^\dagger - B\|$ (the
square root of the sum of the squared moduli of the 256 entries): it vanishes
only at $t = \pi/2$ and $t = 3\pi/2$, where $M = \pm\Gamma$. Finally it checks
that a multiple $c\,\Gamma$ works exactly when $|c| = 1$ (a phase).
```

## 7. The anticommutators with explicit operators

The next cell builds 16 fermion modes on a computer. A state of the 16 modes is a
column of $2^{16} = 65536$ complex numbers, one for each occupation pattern; the
pattern of basis state number $n$ is the binary digits of $n$ (bit $j$ is the
occupation of mode $j$). The annihilation operator $b_j$ moves the amplitude of
each pattern with bit $j$ set to the pattern with bit $j$ cleared, multiplied by
$(-1)^{(\text{number of occupied modes below } j)}$; the creation operator $b_j^*$
does the reverse. Instead of storing $65536 \times 65536$ matrices, the cell stores
these index lists and applies the operators to columns.

Then the field operators of the positive representation of the Revision record:
$\Psi_A = b_A$ and $\Psi^\dagger_C = \sum_D b_D^*B_{DC}$. Every column of $B$ has
exactly one nonzero entry, so $\Psi^\dagger_C$ is a single creation operator times
$\pm i$. The cell first checks the basic rules $\{b_j, b_k^*\} = \delta_{jk}$ for a
few pairs.
```

```
## 8. The valid conjugation counts the empty modes

The charge operator of the field is $Q = \sum_{A,C}\Psi^\dagger_AB_{AC}\Psi_C$. In
the positive representation $\Psi^\dagger B\Psi = b^*B\,B\,b = b^*b$ (since
$B^2 = 1$): $Q$ is the **number of occupied modes**. For the conjugated field
$\Psi' = \Gamma\Psi^{\dagger T}$, line by line:

1. $Q' = \sum_{A,C}\Psi'^\dagger_AB_{AC}\Psi'_C = \sum_{A,C}\Gamma_{AA}\Gamma_{CC}
   B_{AC}\,\Psi_A\Psi^\dagger_C = \sum_{A,C}(\Gamma B\Gamma)_{AC}\Psi_A
   \Psi^\dagger_C$ ($\Gamma$ is diagonal and real).
2. $\Gamma B\Gamma = -B$, so $Q' = -\sum B_{AC}\Psi_A\Psi^\dagger_C$.
3. The anticommutator gives $\Psi_A\Psi^\dagger_C = B_{AC} - \Psi^\dagger_C
   \Psi_A$, so $Q' = -\sum_{A,C}B_{AC}^2 + \sum_{A,C}\Psi^\dagger_C(B^T)_{CA}
   \Psi_A$.
4. $\sum B_{AC}^2 = \mathrm{tr}(BB^T) = -\mathrm{tr}(B^2) = -16$ and $B^T = -B$,
```

```
   so $Q' = 16 - Q$.

The conjugate counts the **empty** modes: up to the constant 16 (which does not
change any difference of charges), it **reverses the charge**, $Q' - 8 = -(Q -
8)$, as particles and holes are exchanged. The same steps with $M = 1$ give
$Q'' = Q - 16$: the invalid candidate would not even reverse the charge. The next
cell checks the three operator identities on the random state and draws the
charges of the 17 kinds of basis states (0 to 16 occupied modes).
```

## 9. The mass is reversed, the spectra are equal

In flat 4+4 space a plane wave $u\,e^{ik\cdot x}$ ($k$ the momenta $k_0, k_1, k_2,
k_3, k_5, k_6, k_7$ along the directions other than the time) evolves by
$i\,\partial_4u = h_m(k)u$ with the one-particle Hamiltonian of the Revision
pairing record
$$h_m(k) = -im\gamma^{(x4)} - \gamma^{(x4)}\sum_{a \ne x4}k_a\gamma^a .$$
The conjugated field contains $\Gamma u^*$: taking the complex conjugate of the
evolution equation gives $i\,\partial_4u^* = -h_m(k)^*u^*$, and multiplying by
$\Gamma$ gives $i\,\partial_4(\Gamma u^*) = -\Gamma h_m(k)^*\Gamma\,(\Gamma u^*)$
```

```
(since $\Gamma^2 = 1$). The next cell proves with sympy, for symbolic $m$ and $k$:

1. $-\Gamma h_m(k)^*\Gamma = h_{-m}(-k)$: the conjugated mode is a mode of the
   theory with the **reversed mass** (and the reversed momentum, as $e^{-ik\cdot
   x}$ says);
2. $\Gamma h_m(k)\Gamma = h_{-m}(k)$: the two Hamiltonians are *similar*, so the
   one-particle spectra of the masses $+m$ and $-m$ are **identical**, not opposite
   (record check Q_one_particle_maps);
3. $h_m(k)^2 = w^2\,1$ with $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 -
   k_6^2 - k_7^2$ (record check Q_one_particle_flat_dispersion): the frequencies
   are $\pm w$;
4. $Bh_m = h_m^\dagger B$ for real $m$ and $k$: $h_m$ is self-adjoint for the Krein
   form (Revision check mode_hamiltonian_B_selfadjoint_dispersion).
```

```
**Scans.** The next cell computes the sixteen eigenvalues of $h_{+m}(k)$ and of
$h_{-m}(k)$ for $m = 1$ along two lines of momenta: along ordinary space ($k_1$
from $-3$ to $3$, all other momenta zero), where $w = \sqrt{1 + k_1^2}$ is real;
and along an extra time ($k_5$ from $-3$ to $3$), where $w^2 = 1 - k_5^2$ becomes
negative for $|k_5| > 1$: the frequencies become imaginary, $\pm i\sqrt{k_5^2 -
1}$, and the modes grow exponentially in time (the ill-posedness of the extra
times). It checks that the spectra of $+m$ and $-m$ agree at every point.

One warning about the two points $k_5 = \pm1$ of the scan. There $w = 0$ and
$h_m^2 = 0$: every eigenvalue is exactly 0, but $h_m$ itself is not the zero
matrix, and such a matrix cannot be brought to diagonal form. For a matrix of this
kind the computer's eigenvalues are accurate only to about the square root of the
rounding unit, about $10^{-8}$, instead of about $10^{-15}$. The function
`spectrum` rounds the eigenvalues to 9 decimals (so that equal values sort in the
same order); the cell compares the two spectra to $10^{-8}$ at all other points
and checks separately that at $k_5 = \pm1$ all 32 computed eigenvalues are
smaller than $10^{-6}$.
```

```

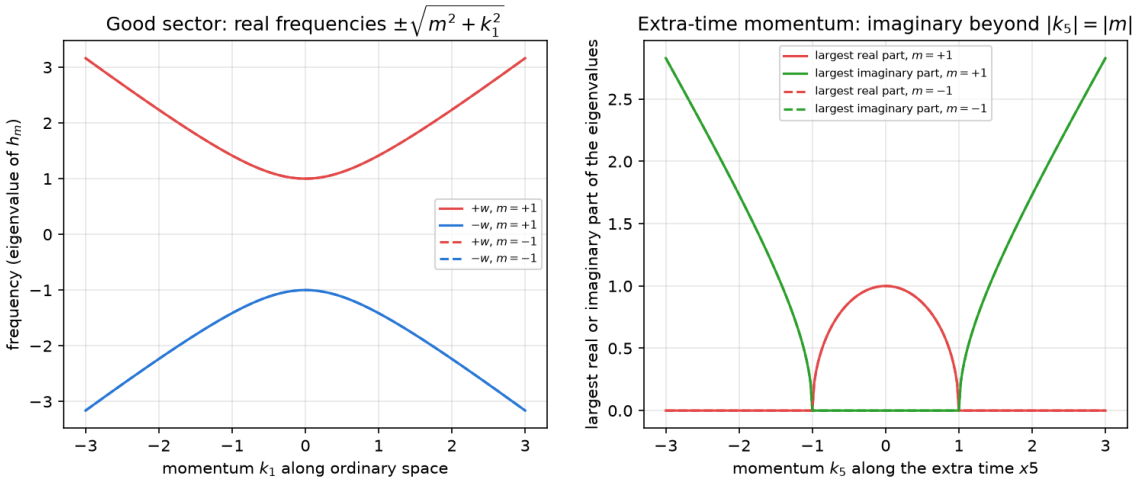

Figure 541: One-particle frequencies of the flat 4+4 Hamiltonian $h_m(k)$ for $m = +1$ (solid) and $m = -1$ (dashed, on top of the solid lines). Left: versus the momentum k_1 along ordinary space; the frequencies $\pm\sqrt{1+k_1^2}$ are real and the same for both masses. Right: versus the momentum k_5 along an extra time; for $|k_5| < 1$ the largest real part is $\sqrt{1-k_5^2}$, for $|k_5| > 1$ the frequencies are imaginary, $\pm i\sqrt{k_5^2-1}$ (green), and the modes grow in time. Horizontal axes the momentum, vertical axes the frequency (pure numbers, units with $m = 1$). (Notebook 21c, figure 5.)

```
$u^\dagger Bu$ takes both signs on it. For an imaginary frequency the record
proves that the eigenspace is **Krein-neutral**: from $Bh = h^\dagger B$,
$w\,u^\dagger Bv = u^\dagger Bhv = (hu)^\dagger Bv = w^*u^\dagger Bv$, so
$(w - w^*)u^\dagger Bv = 0$ and the form vanishes when $w$ is not real. The next
cell computes the inertia of the eigenspace of the eigenvalue with the largest
real part (or, beyond $|k_5| = 1$, the largest imaginary part) along the $k_5$
scan and checks both statements (record check
Q_one_particle_complex_and_zero_frequencies_Krein_neutral).

```
## 11. What this notebook showed

- PROVED (exact matrix algebra, reproducing the Revision record): a conjugation
  $\Psi \to M\Psi^{\dagger T}$ of the quantised field keeps the canonical
  anticommutator $\{\Psi, \Psi^\dagger\} = B\,\delta$ if and only if
  $MB^TM^\dagger = B$; this holds for $M = \Gamma$ (times a phase) and fails for
  $M = 1$, which gives $-B$. Among $\cos t\,1 + \sin t\,\Gamma$ only $\pm\Gamma$
  works.
- COMPUTED (explicit operators on the 65536 states of 16 fermion modes, in the
  positive representation of the Revision record): all 256 anticommutators of
  $\Psi$, of $\Gamma\Psi^{\dagger T}$ and of $\Psi^{\dagger T}$ act as the numbers
  $B$, $B$ and $-B$.
- PROVED: the valid conjugation counts the empty modes, $Q' = 16 - Q$: up to a
  constant it reverses the charge (particles and holes exchanged).
- PROVED (sympy, symbolic $m$ and $k$): the conjugated field evolves with the
  **reversed mass**, $-\Gamma h_m(k)^*\Gamma = h_{-m}(-k)$; at the same time
  $\Gamma h_m\Gamma = h_{-m}$, so the one-particle spectra of $+m$ and $-m$ are
  identical, not opposite.
- Reproduced: the eight one-particle samples of the pairing record; Krein inertia
  (4,4) at every real frequency of the scan; Krein-neutral eigenspaces for the
  growing extra-time modes.
- Consequence: for the quantised field dirac16complex the conjugation that is
  compatible with canonical quantisation is $\Psi \to \Gamma\Psi^{\dagger T}$,
  which maps the theory with mass $m$ to the theory with mass $-m$; the same-mass
  candidate is not compatible. This is a statement about the anticommutator and
  the field equation; no regularised quantum field theory in signature (4,4) is
  constructed here, and nothing in it creates particles, antiparticles or
  universes.
```

21.30 Line-by-line walk-through of Notebook 21c

The notebook has 13 code cells, In [1] to In [13].

In [1], the set-up cell. It is the set-up cell of Notebook 21a, explained line by line in Section 21.15 under In [1], except that the comment lines at the top hold the run instructions of Notebook 21c (Section 21.28) and that the line

```
NOTEBOOK_ID = "21c"  # this notebook: chapter 21, example c
```

names this notebook. The cell prints Set-up of notebook 21c complete.

In [2]: the gammas, B and the records.

```
import numpy as np  # numbers, arrays, matrices
import sympy as sp  # exact algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # "x0", ..., "x7"
ETA = fixture["eta"]
gamma = [np.array(mat, dtype=np.int64) for mat in fixture["gamma"]]  # x0 .. x7
I16 = np.eye(16, dtype=np.int64)
```

The packages and the Revision gammas, kept in a list numbered from 0 as in Notebook 21b (`gamma[4]` is $\gamma^{(x4)}$, `gamma[0]` is $\gamma^{(x0)}$).

```
check(len(gamma) == 8
      and all(g.shape == (16, 16) and set(np.unique(g)) <= {-1, 0, 1} for g in gamma)
      and all(np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                             2 * (ETA[a] if a == b else 0) * I16)
              for a in range(8) for b in range(8)),
      "eight real 16 x 16 gamma matrices with the Clifford relation, signature (4,4)")
```

The same test as in Notebooks 21a and 21b, written as one check: eight real signed-entry matrices that obey the Clifford relation.

```
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # C = g(x0) g(x1) g(x2) g(x3)
Gamma = C @ gamma[4] @ gamma[5] @ gamma[6] @ gamma[7]  # the chirality
B = -1j * (C @ gamma[4])  # the Krein matrix B = -i C gamma^(x4)
```

C, then Γ as C times the four time-like gammas (the same product $\gamma^{(x0)}\gamma^{(x1)}\cdots\gamma^{(x7)}$), and B.

```
def load_checks(path):
    """name -> verdict (upper case) of a Revision report."""
    entries = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
    return {c["name"]: c["verdict"].upper() for c in entries}
```

A helper that reads a Revision report and returns the dictionary from check name to verdict, in capitals.

```
LEAD_FILE = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
LEAD = load_checks(LEAD_FILE)
PY_THEORY = load_checks("Revision/theory/reports/python-field-theory.json")
WL_PAIR = load_checks("Revision/pairing/reports/wolfram-pairing.json")
THEORY = {f["key"]: f for f in json.loads(repository_file(
    "Revision/theory/field-theory.json").read_text(encoding="utf-8"))["formulas"]}
PAIRING = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                     .read_text(encoding="utf-8"))
```

The lead report, the sympy field-theory report, the Wolfram pairing report, the formulas of the field-theory record, and the whole pairing record `Revision/pairing/pairing-theory.json`, whose one-particle samples are used in In [10].

```
clauses = THEORY["quantisation"]["wl"].split("; ")  # the statements of the formula
rule = next(c for c in clauses if c.startswith("{Psi_A(x), Psi^dagger_C(y)}"))
positive = next(c for c in clauses if c.startswith("positive representation"))
say("record: " + rule)
say("record: " + positive)
```

The record's formula `quantisation` is cut at its semicolons. `next(c for c in clauses if ...)` returns the first statement that satisfies the condition: the one that starts with the anticommutator and the one that starts with the words positive representation. Out [2] prints both.

```
check(rule.endswith("= B_AC delta^7(x - y)/Cos[z]")
      and positive == "positive representation chi = Psi^dagger B, "
      "{Psi_A, chi_C} = delta_AC",
      "the record's anticommutator B_AC delta / cos z and positive representation",
      record="Revision/theory/field-theory.json, formula quantisation")
```

The check demands that the record states the canonical rule with $B_{AC}\delta^7/\cos z$, and the positive representation with $\chi = \Psi^\dagger B$ and $\{\Psi_A, \chi_C\} = \delta_{AC}$. (Since $B^2 = 1$, $\chi = \Psi^\dagger B$ means $\Psi^\dagger = \chi B$: with $\Psi_A = b_A$ and $\chi_C = b_C^*$ this is the representation of Section 21.25.)

In [3]: the properties of B.

```
eigenvalues = np.linalg.eigvalsh(B)  # eigenvalues of a Hermitian matrix, sorted
check(np.array_equal(B.real, np.zeros((16, 16))) and np.allclose(B, B.conj().T)
      and np.allclose(B @ B, np.eye(16)) and abs(np.trace(B)) < 1e-12
      and np.allclose(eigenvalues, [-1] * 8 + [1] * 8)
      and LEAD["B_imaginary_hermitian"] == "PASS"
      and PY_THEORY["B_properties"] == "PASS",
      "B is purely imaginary, Hermitian, B^2 = 1, trace 0: signature (8,8)",
      record=f"{LEAD_FILE}, check B_imaginary_hermitian")
check(np.allclose(B.T, -B), "B^T = -B")
```

The eigenvalues in increasing order; B is purely imaginary, Hermitian, squares to 1, has trace 0 (`np.trace` adds the diagonal), so eight eigenvalues -1 and eight $+1$; two record checks say the same. The second check is $B^T = -B$, used in Section 21.25.

```
from matplotlib.colors import LinearSegmentedColormap

SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.3), width_ratios=[1, 1.3])
```

The blue-white-red colour map of Notebook 21a, and a figure with two panels, the right one wider.

```
image = axes[0].imshow(B.imag, cmap=SIGNS, vmin=-1, vmax=1)
axes[0].set_title("imaginary part of $B = -iC\\gamma^{(x4)}$")
```

```
axes[0].set_xticks([0, 7, 15], ["1", "8", "16"])
axes[0].set_yticks([0, 7, 15], ["1", "8", "16"])
axes[0].set_xlabel("column")
axes[0].set_ylabel("row")
axes[0].grid(False)
fig.colorbar(image, ax=axes[0], ticks=[-1, 0, 1], shrink=0.8)
```

The left panel draws the imaginary part of B (`B.imag`) as a heat map, with a colour bar.

```
axes[1].bar(np.arange(1, 17), eigenvalues,
            color=["#2a78d6"] * 8 + ["#e34948"] * 8)
axes[1].set_xlabel("eigenvalue number (sorted)")
axes[1].set_ylabel("eigenvalue of $B$")
axes[1].set_title("eight eigenvalues $-1$, eight $+1$")
```

The right panel draws the sixteen eigenvalues as bars, the first eight blue and the last eight red.

```
save_figure(fig, "krein_matrix",
            "The Krein matrix $B = -iC\\gamma^{(x4)}$ of the canonical "
            "anticommutator. Left: its imaginary part as a heat map (its real part "
            "is zero; horizontal axis the column, vertical axis the row, red $+1$, "
            "blue $-1$); every row and column has one entry, and the nonzero "
            "entries join the two chiral halves. Right: its sixteen eigenvalues in "
            "increasing order, eight $-1$ and eight $+1$ (signature (8,8)); "
            "because of the eight negative eigenvalues the field adjoint cannot be "
            "an ordinary Hilbert adjoint.")
```

Figure 21c.1. **What the figure shows.** Left: sixteen coloured squares, one per row and column, all in the off-diagonal blocks (B contains one gamma, $\gamma^{(x4)}$, times the block-diagonal C). Right: a staircase of eight bars at -1 and eight at $+1$.

In [4]: which conjugation keeps the anticommutator.

```
def mismatch(M):
    """|| M B^T M^dagger - B ||: zero when M keeps the canonical anticommutator."""
    return np.linalg.norm(M @ B.T @ M.conj().T - B)
```

The size of the failure of the condition of Section 21.25; `np.linalg.norm` of a matrix is the square root of the sum of the squared moduli of all its entries.

```
q_gamma = Gamma @ B.T @ Gamma.T  # M = Gamma (real, so M^dagger = M^T)
q_one = B.T  # M = 1
check(np.allclose(q_gamma, B) and np.allclose(q_one, -B)
      and LEAD["quantum_charge_conjugation_unitary_type"] == "PASS",
      "M B^T M^dagger = +B for M = Gamma and = -B for M = 1",
      record=f"{LEAD_FILE}, check quantum_charge_conjugation_unitary_type")
```

$MB^TM^\dagger$ for $M = \Gamma$ (real, so its conjugate transpose is its transpose) and for $M = 1$: $+B$ and $-B$, as the lead check records.

```
t_values = np.linspace(0.0, 2 * np.pi, 721)  # steps of half a degree
family = [np.cos(t) * np.eye(16) + np.sin(t) * Gamma for t in t_values]
mismatches = np.array([mismatch(M) for M in family])
zeros = t_values[mismatches < 1e-12]
say("t where the mismatch vanishes (in units of pi): "
    + ", ".join(f"{t / np.pi:.3f}" for t in zeros))
```

721 values of t from 0 to 2π (steps of $2\pi/720$, half a degree), the matrices $\cos t\,1 + \sin t\,\Gamma$ and their mismatches. `t_values[mismatches < 1e-12]` keeps only the values of t where the mismatch is below 10^{-12} (an array indexed by a true-false array keeps the entries marked true). Out [4] prints 0.500 and 1.500, that is $t = \pi/2$ and $3\pi/2$.

```
phases_ok = all(abs(mismatch(c * Gamma)) < 1e-12 for c in (1j, np.exp(0.3j), -1))
scales_bad = all(mismatch(c * Gamma) > 1 for c in (0.5, 2.0))
check(np.allclose(zeros / np.pi, [0.5, 1.5]) and phases_ok and scales_bad,
      "in the family cos t + sin t Gamma only t = pi/2, 3pi/2 work; c Gamma works "
      "exactly for |c| = 1")
```

Multiples $c\,\Gamma$ with $|c| = 1$ ($c = i$, $e^{0.3i}$, -1) work; $c = 0.5$ and $c = 2$ fail (they give $|c|^2 B$). The check combines the three findings.

```
fig, ax = plt.subplots(figsize=(8.0, 4.3))
ax.plot(t_values / np.pi, mismatches)
ax.plot([0.5, 1.5], [0, 0], "o", color="#e34948", markersize=9,
        label="$M = \\pm\\Gamma$: mismatch zero")
ax.plot([0.0, 1.0, 2.0], [mismatch(np.eye(16))] * 3, "s", color="#2a78d6",
        label="$M = \\pm 1$: mismatch $\\|{-B} - B\\| = 8$")
ax.set_xlabel("$t / \\pi$ in $M(t) = \\cos t\\,1 + \\sin t\\,\\Gamma$")
ax.set_ylabel("$\\|M B^T M^\\dagger - B\\|$")
ax.set_title("Only $\\pm\\Gamma$ keeps the canonical anticommutator")
ax.legend(fontsize=8)
```

The mismatch against t/π, red dots at the two zeros, and blue squares at $t = 0, \pi, 2\pi$, where $M = \pm 1$ and the mismatch is $\|-B - B\| = 2 \cdot 4 = 8$.

```
save_figure(fig, "which_conjugation",
            "The mismatch $\\|M B^T M^\\dagger - B\\|$ (the size of the failure of "
            "the canonical anticommutator) for the conjugations $\\Psi \\to "
            "M\\Psi^{\\dagger T}$ with $M = \\cos t\\,1 + \\sin t\\,\\Gamma$; "
            "horizontal axis $t/\\pi$ from $0$ to $2$, vertical axis the mismatch "
            "(pure number). It vanishes only at $t = \\pi/2$ and $3\\pi/2$, that is "
            "for $M = \\pm\\Gamma$ (red dots); the same-mass choice $M = \\pm 1$ "
            "(blue squares) gives $-B$ instead of $B$, a mismatch of $\\|2B\\| = 8$.")
```

Figure 21c.2. **What the figure shows.** The curve $4|1 + \cos 2t|$ of Section 21.25: it starts at 8, falls to zero at $t = \pi/2$, rises to 8 at $t = \pi$, falls to zero at $3\pi/2$ and returns to 8. Only the two isolated points $M = \pm\Gamma$ are allowed.

In [5]: sixteen fermion modes on a computer.

```
MODES, STATES = 16, 2 ** 16
index = np.arange(STATES)  # basis state numbers 0 .. 65535
occupied_count = np.zeros(STATES, dtype=np.int64)  # number of occupied modes
for j in range(MODES):
    occupied_count += (index >> j) & 1  # >> shifts the bits; & 1 reads bit j
```

A state of the 16 modes is a column of 65536 complex numbers, one **amplitude** per occupation pattern; basis state number n has the pattern given by the binary digits (**bits**) of n: bit j is the occupation of mode j (counted from 0). The operator written as two greater-than signs shifts the binary digits of every number j places to the right, and `& 1` (bitwise and with 1) keeps the last digit: together they read bit j. Adding these bits over all modes gives, for each basis state, the number of occupied modes.

```
OPS = []  # for each mode j: the states where j is occupied, and the sign factors
for j in range(MODES):
    filled = ((index >> j) & 1).astype(bool)
    below = index & ((1 << j) - 1)  # the bits of the modes below j
    parity = np.zeros(STATES, dtype=np.int64)
    for i in range(j):
        parity += (below >> i) & 1
    OPS.append((index[filled], index[~filled], np.where(parity % 2 == 0, 1.0, -1.0)))
```

For each mode j: `filled` marks the states in which mode j is occupied. The operator written as two less-than signs shifts digits to the left, so `1` shifted by `j` places is 2^j, and $2^j - 1$ has ones exactly in the bits $0, \ldots, j-1$; the bitwise and with it keeps the bits of the modes below j. `parity` counts the occupied modes below j, and `np.where(parity % 2 == 0, 1.0, -1.0)` turns an even count into the sign $+1$ and an odd one into -1: the Jordan-Wigner sign of Section 21.26. The list `OPS` stores, for each mode, the states where it is occupied (`index[filled]`), those where it is empty (`~` negates the true-false array) and the signs.

```
def annihilate(j, v):
    """b_j v: empty mode j (with the Jordan-Wigner sign)."""
    filled, _, sign = OPS[j]
    out = np.zeros_like(v)
    out[filled ^ (1 << j)] = sign[filled] * v[filled]
    return out
```

The annihilation operator applied to a state `v`: the amplitude of every pattern with mode j occupied is moved, with its sign, to the pattern with bit j cleared (`^` is the bitwise exclusive or, which flips bit j); every other amplitude of the result is zero. Instead of storing a 65536×65536 matrix, the notebook stores these index lists.

```
def create(j, v):
    """b_j^* v: fill mode j (with the Jordan-Wigner sign)."""
    _, empty, sign = OPS[j]
    out = np.zeros_like(v)
    out[empty | (1 << j)] = sign[empty] * v[empty]
    return out
```

The creation operator does the reverse: amplitudes of patterns with mode j empty move to the pattern with bit j set (`|` is the bitwise or). The sign depends only on the modes below j, which the move does not change.

```
rng = np.random.default_rng(2103)  # fixed seed: the same state in every run
v = rng.normal(size=STATES) + 1j * rng.normal(size=STATES)
v /= np.linalg.norm(v)  # a random normalised state of the 16 modes
```

A random state of the 16 modes, scaled to length 1 (`/=` divides in place).

```
basic = all(np.allclose(annihilate(j, create(k, v)) + create(k, annihilate(j, v)),
                        (1.0 if j == k else 0.0) * v)
            for j, k in [(0, 0), (3, 3), (15, 15), (0, 1), (4, 9), (15, 2)])
check(basic, "Jordan-Wigner operators: {b_j, b_k^*} = delta_jk on a random state")
```

The rule $\{b_j, b_k^*\} = \delta_{jk}$, tested on the random state for six pairs: $b_j b_k^* v + b_k^* b_j v$ must be v for $j = k$ and zero otherwise.

In [6]: the anticommutators of three fields.

```
B_column = [int(np.flatnonzero(B[:, c])[0]) for c in range(16)]  # row of the entry
```

Every column of B has exactly one nonzero entry; `np.flatnonzero` lists the positions of the nonzero entries of column `c` (`B[:, c]`), and the first one is kept. So $\Psi_C^\dagger = \sum_D b_D^* B_{DC}$ is a single creation operator times $B_{DC} = \pm i$.

```
def psi(A, u):
    """Psi_A = b_A."""
    return annihilate(A, u)

def psi_dagger(Cc, u):
    """Psi^dagger_C = sum_D b_D^* B_DC (a single term)."""
    D = B_column[Cc]
    return B[D, Cc] * create(D, u)
```

The field operators of the positive representation applied to a state. (The letter `Cc` avoids a clash with the matrix `C`.)

```
def field_pair(M):
    """For the conjugate M Psi^{dagger T} with diagonal M: the maps u -> Psi'_A u
    and u -> Psi'^dagger_C u (Psi'_A = M_AA Psi^dagger_A, Psi'^dagger_C =
    conj(M_CC) Psi_C)."""
    d = np.diag(M)
    return (lambda A, u: d[A] * psi_dagger(A, u),
            lambda Cc, u: np.conj(d[Cc]) * psi(Cc, u))
```

For a diagonal matrix M (both Γ and 1 are diagonal), the conjugate field is $\Psi'_A = M_{AA}\Psi_A^\dagger$ and its adjoint $\Psi_C'^\dagger = M_{CC}^*\Psi_C$. `np.diag(M)` takes the diagonal, and `lambda` defines a small unnamed function; the function returns the pair of them.

```
def anticommutator_matrix(first, second):
    """N_AC with {first_A, second_C} v = N_AC v, and whether it acts as a number."""
    N = np.zeros((16, 16), dtype=complex)
    number_like = True
    for A in range(16):
        for Cc in range(16):
            w = first(A, second(Cc, v)) + second(Cc, first(A, v))
            N[A, Cc] = np.vdot(v, w)  # v^dagger w
            number_like &= np.allclose(w, N[A, Cc] * v)
    return N, number_like
```

For each of the 256 pairs (A, C) the anticommutator is applied to the random state, $w = XYv + YXv$; `np.vdot(v, w)` is $v^\dagger w$, the number N_{AC}; and `number_like` stays true only if $w = N_{AC}v$ for every pair, that is, if the anticommutator acts on the state as a plain number (`&=` combines with "and").

```
N_psi, ok_psi = anticommutator_matrix(psi, psi_dagger)
N_same, ok_same = anticommutator_matrix(psi, psi)  # {Psi_A, Psi_C}
N_gamma, ok_gamma = anticommutator_matrix(*field_pair(Gamma))
N_one, ok_one = anticommutator_matrix(*field_pair(np.eye(16)))
```

Four measurements: $\{\Psi_A, \Psi_C^\dagger\}$, $\{\Psi_A, \Psi_C\}$, and the anticommutators of the conjugate fields with $M = \Gamma$ and $M = 1$ (the star unpacks the returned pair into the two arguments). In all, 1024 anticommutators of operators on 65536 states; this takes about 10 seconds.

```
check(ok_psi and ok_same and np.allclose(N_psi, B) and np.allclose(N_same, 0)
      and PY_THEORY["canonical_anticommutator_B"] == "PASS",
      "operators: {Psi_A, Psi^dagger_C} = B_AC and {Psi_A, Psi_C} = 0 (256 pairs)",
      record="Revision/theory/reports/python-field-theory.json, check "
      "canonical_anticommutator_B")
check(ok_gamma and ok_one and np.allclose(N_gamma, B) and np.allclose(N_one, -B),
      "operators: Gamma Psi^{dagger T} has +B, Psi^{dagger T} has -B")
```

The positive representation obeys the canonical rule; the valid conjugate $\Gamma\Psi^{\dagger T}$ obeys it too; the same-mass candidate $\Psi^{\dagger T}$ obeys it with $-B$. This is Section 21.25 confirmed with explicit operators.

In [7]: the measured anticommutators as heat maps.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.2))
for ax, N, title in ((axes[0], N_psi, "$\\{\\Psi_A, \\Psi^\\dagger_C\\}$"),
                     (axes[1], N_gamma, "$\\Psi' = \\Gamma\\Psi^{\\dagger T}$"),
                     (axes[2], N_one, "$\\Psi'' = \\Psi^{\\dagger T}$")):
    image = ax.imshow(N.imag, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.set_xlabel("$C$")
    ax.grid(False)
axes[0].set_ylabel("$A$")
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.8,
             label="imaginary part of the anticommutator")
```

Three heat maps of the imaginary parts of the measured 16×16 matrices (their real parts are zero), with C along the horizontal and A along the vertical axis.

```
save_figure(fig, "operator_anticommutators",
            "The anticommutators $\\{X_A, Y^\\dagger_C\\}$ measured with explicit "
            "operators on the 65536 states of 16 fermion modes (imaginary parts; "
            "the real parts are zero; horizontal axis $C$, vertical axis $A$, red "
            "$+1$, blue $-1$). Left: the field $\\Psi$ of the positive "
            "representation, which gives the Krein matrix $B$. Middle: the "
            "conjugate $\\Gamma\\Psi^{\\dagger T}$, which gives $B$ again, so it is "
            "a field of the same quantum theory. Right: the same-mass candidate "
            "$\\Psi^{\\dagger T}$, which gives $-B$ (every colour reversed), so it is "
            "not.")
```

Figure 21c.3. **What the figure shows.** The left and middle panels are the same picture, the heat map of B of figure 21c.1; the right panel is that picture with red and blue exchanged.

In [8]: the valid conjugation counts the empty modes.

```
def charge(first_dagger, second, u):
    """sum_AC first_dagger_A B_AC second_C u (only the 16 nonzero B_AC)."""
    out = np.zeros_like(u)
    for Cc in range(16):
        A = B_column[Cc]  # the row of the nonzero entry of column C
        out += first_dagger(A, B[A, Cc] * second(Cc, u))
    return out
```

The charge operator $\sum_{A,C} X^\dagger_A B_{AC} Y_C$ applied to a state; since each column of B has one nonzero entry, the double sum has only 16 terms.

```
conj_g, conj_g_dagger = field_pair(Gamma)
conj_1, conj_1_dagger = field_pair(np.eye(16))
Q_v = charge(psi_dagger, psi, v)
Qp_v = charge(conj_g_dagger, conj_g, v)
Qpp_v = charge(conj_1_dagger, conj_1, v)
```

The two conjugate fields and their adjoints, and the three charges Q, Q' (valid conjugate) and Q'' (same-mass candidate) applied to the random state.

```
check(np.allclose(Q_v, occupied_count * v)
      and np.allclose(Qp_v, (16 - occupied_count) * v)
      and np.allclose(Qpp_v, (occupied_count - 16) * v),
      "Q = number of occupied modes, Q' = 16 - Q (Gamma), Q'' = Q - 16 (M = 1)")
```

`occupied_count * v` multiplies each amplitude by the number of occupied modes of its basis state: that is how the number operator N acts. The check proves, on this state, $Q = N$, $Q' = 16 - N$ and $Q'' = N - 16$ (Section 21.26).

```
n = np.arange(17)
fig, ax = plt.subplots(figsize=(8.0, 4.4))
ax.plot(n, n - 8, "o-", label="$Q - 8$ of the field $\\Psi$")
ax.plot(n, (16 - n) - 8, "s-", label="$Q' - 8$ of $\\Gamma\\Psi^{\\dagger T}$ "
        "(valid)")
ax.plot(n, (n - 16) + 8, "^--", color="#999999",
        label="$Q'' + 8$ of $\\Psi^{\\dagger T}$ (invalid)")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("number of occupied modes in the basis state")
ax.set_ylabel("charge (shifted by the constant 8)")
ax.set_title("The valid conjugation reverses the charge")
ax.legend(fontsize=8)
```

For a basis state with $n = 0, \dots, 16$ occupied modes the three charges are n, $16 - n$ and $n - 16$; they are drawn shifted by the constant 8 (minus 8 for the first two, plus 8 for the third), so that a reversal shows as a mirror image in the horizontal axis.

```
save_figure(fig, "charge_of_states",
            "The charge of the basis states of 16 fermion modes, measured by three "
            "fields; horizontal axis the number of occupied modes (0 to 16), "
            "vertical axis the charge shifted by a constant (minus 8 for $\\Psi$ "
            "and $\\Gamma\\Psi^{\\dagger T}$, plus 8 for $\\Psi^{\\dagger T}$; "
            "pure numbers). "
            "The field $\\Psi$ counts the occupied modes; the valid conjugate "
            "$\\Gamma\\Psi^{\\dagger T}$ counts the empty ones, $Q' = 16 - Q$, so "
            "the shifted charge is exactly reversed (particles and holes "
            "exchanged); the invalid candidate $\\Psi^{\\dagger T}$ would give "
            "$Q - 16$, not a reversal.")
```

Figure 21c.4. **What the figure shows.** A rising line (Ψ) and a falling line (the valid conjugate) that cross at $n = 8$: the charge reversed about its middle. The grey dashed line of the invalid candidate lies exactly on the rising line: shifted back by the constant, it measures the same charge as Ψ, not the opposite.

In [9]: the mass is reversed, the spectra are equal.

```
m = sp.symbols("m", real=True)
k = sp.symbols("k0:8", real=True)  # k[a] along xa; k[4] (the x4 entry) is not used
G = [sp.Matrix(g.tolist()) for g in gamma]
Gamma_s, B_s = sp.Matrix(Gamma.tolist()), -sp.I * sp.Matrix(C.tolist()) * G[4]
```

A real symbol for the mass, eight real symbols $k_0, \dots, k_7$ for the momenta (`k[a]` along x_a; `k[4]`, along the time, is not used), exact gammas, Γ and B.

```
def h(mass, momenta):
    """h_m(k) = -i m gamma^(x4) - gamma^(x4) sum_(a != x4) k_a gamma^a."""
    total = -sp.I * mass * G[4]
    for a in range(8):
        if a != 4:
            total -= momenta[a] * G[4] * G[a]
    return total
```

The one-particle Hamiltonian of Section 21.26, built term by term (`-=` subtracts from the running total; `!=` means "not equal").

```
zero = sp.zeros(16, 16)
h_m = h(m, k)
minus_k = [-q for q in k]
w2 = m ** 2 + k[0] ** 2 + k[1] ** 2 + k[2] ** 2 + k[3] ** 2 - k[5] ** 2 - k[6] ** 2 \
    - k[7] ** 2
```

The zero matrix, $h_m(k)$ with symbolic mass and momenta, the reversed momenta, and w^2 (the backslash continues the line).

```
check((-Gamma_s * h_m.conjugate() * Gamma_s - h(-m, minus_k)).expand() == zero,
      "-Gamma conj(h_m(k)) Gamma = h_(-m)(-k): the conjugated mode has the reversed "
      "mass")
check((Gamma_s * h_m * Gamma_s - h(-m, k)).expand() == zero
      and WL_PAIR["Q_one_particle_maps"] == "PASS",
      "Gamma h_m(k) Gamma = h_(-m)(k): equal spectra for +m and -m",
      record="Revision/pairing/reports/wolfram-pairing.json, check "
      "Q_one_particle_maps")
```

The first two facts of Section 21.26, proved exactly for every real mass and momentum: the conjugated mode evolves with the reversed mass, and the Hamiltonians of $\pm m$ are similar.

```
check((h_m * h_m - w2 * sp.eye(16)).expand() == zero
      and (B_s * h_m - h_m.H * B_s).expand() == zero
      and WL_PAIR["Q_one_particle_flat_dispersion"] == "PASS"
      and PY_THEORY["mode_hamiltonian_B_selfadjoint_dispersion"] == "PASS",
      "h_m(k)^2 = w^2 1 and B h_m = h_m^dagger B",
      record="Revision/pairing/reports/wolfram-pairing.json, check "
      "Q_one_particle_flat_dispersion")
```

The square and the Krein self-adjointness (`h_m.H` is $h^\dagger$), with the two record checks.

In [10]: the eight samples of the pairing record.

```
def numeric_h(mass, momenta):
    """h_m(k) as a numpy array."""
    total = -1j * mass * gamma[4].astype(complex)
    for a in range(8):
        if a != 4:
            total = total - momenta[a] * (gamma[4] @ gamma[a])
    return total
```

The same Hamiltonian with numbers instead of symbols.

```
def eigenspace_facts(H_mat, w):
    """Dimension and Krein inertia (positive, negative) of the eigenspace of w."""
    P = (np.eye(16) + H_mat / w) / 2  # projector onto the eigenvalue +w (w != 0)
```

```
    U_, s_, _ = np.linalg.svd(P)
    V = U_[:, s_ > 1e-9]  # orthonormal basis of the range of P
    form = np.linalg.eigvalsh(V.conj().T @ B @ V)
    return V.shape[1], (int(np.sum(form > 1e-9)), int(np.sum(form < -1e-9)))
```

Since $h^2 = w^2$, the matrix $P = \frac{1}{2}(1 + h/w)$ is the projector onto the eigenvectors of h with eigenvalue w ($P^2 = \frac{1}{4}(1 + 2h/w + h^2/w^2) = \frac{1}{4}(2 + 2h/w) = P$). The **singular value decomposition** `np.linalg.svd` writes P as a product of three matrices; the columns of the first that belong to nonzero singular values form an orthonormal basis V of the eigenspace. The form $u^\dagger B u$ restricted to the eigenspace is the matrix $V^\dagger B V$; its eigenvalues are counted by sign. The function returns the dimension (the number of columns of V) and the Krein inertia.

```
rows_ok = True
for sample in PAIRING["data"]["one_particle_flat"]["samples"]:
    H_mat = numeric_h(sample["m"], sample["k"])
    w = float(sp.sympify(sample["w"].replace("Sqrt[", "sqrt(").replace("]", ")")))
    w_here = np.sqrt(np.max(np.linalg.eigvals(H_mat @ H_mat).real))
    dim_p, inertia_p = eigenspace_facts(H_mat, w_here)
    dim_m, inertia_m = eigenspace_facts(H_mat, -w_here)
```

For each sample of the record: the Hamiltonian; the record's frequency, written in Wolfram notation such as `Sqrt[2]`, which `.replace` turns into `sqrt(2)` and `sp.sympify` reads as a number; the frequency computed here as the square root of the largest eigenvalue of h^2; and the dimensions and inertias of both eigenspaces.

```
    same = (abs(w_here - w) < 1e-12 and dim_p == sample["dim_plus_w"]
            and dim_m == sample["dim_minus_w"]
            and list(inertia_p) == sample["B_inertia_plus_w"]
            and list(inertia_m) == sample["B_inertia_minus_w"])
    rows_ok &= same
```

Every number is compared with the record (the inertia, a pair, is turned into a list for the comparison).

```
    k_text = ",".join(str(q) for q in sample["k"])
    say(f"m = {sample['m']:+d}, k = ({k_text}): w = {w_here:.6f}, dims {dim_p} "
        f"{dim_m}, inertia ({inertia_p[0]},{inertia_p[1]}) "
        f"({inertia_m[0]},{inertia_m[1]}), same: {same}")
```

One printed line per sample: Out [10] shows the eight rows of the table of Section 21.26, each ending with "same: True".

```
check(rows_ok and WL_PAIR["Q_one_particle_Krein_signatures"] == "PASS",
      "all eight one-particle samples of the pairing record reproduced",
      record="Revision/pairing/reports/wolfram-pairing.json, check "
      "Q_one_particle_Krein_signatures")
```

All eight samples agree with the record.

In [11]: the spectra along two lines of momenta.

```
def spectrum(mass, k1=0.0, k5=0.0):
    """The 16 eigenvalues of h_m with momenta k1 (x1) and k5 (x5), sorted."""
    momenta = [0, k1, 0, 0, 0, k5, 0, 0]  # k0, ..., k7
    values = np.linalg.eigvals(numeric_h(mass, momenta))
    return np.sort_complex(np.round(values, 9))
```

The sixteen eigenvalues of h_m with a momentum k_1 along ordinary space and k_5 along an extra time (the list `momenta` holds $k_0, \ldots, k_7$, so k_1 stands at position 1 and k_5 at position 5), rounded to 9 decimals (so that equal values sort in the same order) and sorted (`np.sort_complex` sorts by real part, then by imaginary part).

```
scan = np.linspace(-3.0, 3.0, 241)  # steps of 0.025; contains k5 = -1 and +1
spec_k1 = {s: np.array([spectrum(s, k1=q) for q in scan]) for s in (1, -1)}
spec_k5 = {s: np.array([spectrum(s, k5=q) for q in scan]) for s in (1, -1)}
exceptional = np.abs(np.abs(scan) - 1.0) < 1e-9  # the two points k5 = -1, +1
```

241 momenta from -3 to 3; the spectra for $m = +1$ and $m = -1$ along k_1 and along k_5; and a true-false array that marks the two points $k_5 = \pm 1$, where $w = 0$.

```
check(np.allclose(spec_k1[1], spec_k1[-1], rtol=0, atol=1e-8)
      and np.allclose(spec_k5[1][~exceptional], spec_k5[-1][~exceptional],
                      rtol=0, atol=1e-8)
      and np.abs(spec_k5[1][exceptional]).max() < 1e-6
      and np.abs(spec_k5[-1][exceptional]).max() < 1e-6
      and np.allclose(np.abs(spec_k1[1].real).max(axis=1), np.sqrt(1 + scan ** 2)),
      "scans: identical spectra for m = +1 and m = -1; w = sqrt(1 + k1^2)")
```

The spectra of $m = +1$ and $m = -1$ agree to 10^{-8} at every point (`rtol=0, atol=1e-8` means an absolute tolerance only), except at the two points $k_5 = \pm 1$. There $h^2 = 0$ although $h \neq 0$: such a matrix cannot be brought to diagonal form, and a computer finds its eigenvalues only to about the square root of the rounding unit, about 10^{-8}; the check therefore asks only that all 32 computed eigenvalues there are below 10^{-6}. Finally the largest real part along k_1 is $\sqrt{1 + k_1^2}$.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.4))
for s, style, label in ((1, "-", "$m = +1$"), (-1, "--", "$m = -1$")):
    axes[0].plot(scan, spec_k1[s].real.max(axis=1), style, color="#e34948",
                 label=f"$+w$, {label}")
    axes[0].plot(scan, spec_k1[s].real.min(axis=1), style, color="#2a78d6",
                 label=f"$-w$, {label}")
    axes[1].plot(scan, spec_k5[s].real.max(axis=1), style, color="#e34948",
                 label=f"largest real part, {label}")
    axes[1].plot(scan, spec_k5[s].imag.max(axis=1), style, color="#2ca02c",
                 label=f"largest imaginary part, {label}")
```

For both masses (solid and dashed lines): along k_1 the largest and smallest eigenvalue ($\pm w$); along k_5 the largest real part and the largest imaginary part.

```
axes[0].set_xlabel("momentum $k_1$ along ordinary space")
axes[0].set_ylabel("frequency (eigenvalue of $h_m$)")
```

```
axes[0].set_title("Good sector: real frequencies $\\pm\\sqrt{m^2 + k_1^2}$")
axes[0].legend(fontsize=7)
axes[1].set_xlabel("momentum $k_5$ along the extra time $x5$")
axes[1].set_ylabel("largest real or imaginary part of the eigenvalues")
axes[1].set_title("Extra-time momentum: imaginary beyond $|k_5| = |m|$")
axes[1].legend(fontsize=7)
```

Labels, titles and legends of the two panels.

```
save_figure(fig, "dispersion_pm_mass",
            "One-particle frequencies of the flat 4+4 Hamiltonian $h_m(k)$ for "
            "$m = +1$ (solid) and $m = -1$ (dashed, on top of the solid lines). "
            "Left: versus the momentum $k_1$ along ordinary space; the frequencies "
            "$\\pm\\sqrt{1 + k_1^2}$ are real and the same for both masses. Right: "
            "versus the momentum $k_5$ along an extra time; for $|k_5| < 1$ the "
            "largest real part is $\\sqrt{1 - k_5^2}$, for $|k_5| > 1$ the "
            "frequencies are imaginary, $\\pm i\\sqrt{k_5^2 - 1}$ (green), and the "
            "modes grow in time. Horizontal axes the momentum, vertical axes the "
            "frequency (pure numbers, units with $m = 1$).")
```

Figure 21c.5. **What the figure shows.** Left: two hyperbola-like curves $\pm\sqrt{1+k_1^2}$, the dashed ones exactly on the solid ones. Right: a red half-circle $\sqrt{1-k_5^2}$ between $k_5 = -1$ and 1, and outside it green curves $\sqrt{k_5^2-1}$ rising from zero: imaginary frequencies, growing modes, the same for both masses.

In [12]: the Krein inertia along the extra-time scan.

```
def leading_inertia(k5):
    """Dimension and Krein inertia of the eigenspace of the leading eigenvalue."""
    H_mat = numeric_h(1, [0, 0, 0, 0, 0, k5, 0, 0])  # k5 along x5
    w2_here = 1 - k5 ** 2
    w = np.sqrt(w2_here) if w2_here > 0 else 1j * np.sqrt(-w2_here)
    return eigenspace_facts(H_mat, w)
```

For $m = 1$ and momentum k_5: $w^2 = 1 - k_5^2$, and the leading eigenvalue is $w = \sqrt{w^2}$ when $w^2 > 0$ and $w = i\sqrt{-w^2}$ otherwise; the projector of In [10] works for an imaginary w as well, since still $h^2 = w^2$.

```
k5_scan = scan[np.abs(np.abs(scan) - 1.0) > 1e-6]  # leave out w = 0 at |k5| = 1
facts = [leading_inertia(q) for q in k5_scan]
positive = np.array([f[1][0] for f in facts])
negative = np.array([f[1][1] for f in facts])
dims = np.array([f[0] for f in facts])
real_region = np.abs(k5_scan) < 1
```

The scan without the two points of zero frequency (where the projector would divide by zero); the dimension and the counts of positive and negative directions for each momentum; and a mark for the region of real frequencies.

```
check(np.all(dims == 8)
      and np.all(positive[real_region] == 4) and np.all(negative[real_region] == 4)
      and np.all(positive[~real_region] == 0) and np.all(negative[~real_region] == 0)
      and WL_PAIR["Q_one_particle_complex_and_zero_frequencies_Krein_neutral"]
      == "PASS",
      "inertia (4,4) at real frequencies, Krein-neutral at imaginary frequencies",
      record="Revision/pairing/reports/wolfram-pairing.json, check "
      "Q_one_particle_complex_and_zero_frequencies_Krein_neutral")
```

Every eigenspace has dimension 8; for real frequencies the inertia is (4,4); for imaginary frequencies there are no positive and no negative directions: the form vanishes on the eigenspace (Section 21.26).

```
fig, ax = plt.subplots(figsize=(8.0, 4.3))
ax.plot(k5_scan, positive, "o", markersize=6, markerfacecolor="none",
        label="positive directions of the form")  # open circles
ax.plot(k5_scan, negative, "x", markersize=4,
        label="negative directions of the form")  # crosses inside the circles
ax.axvspan(-3, -1, color="#f2d0a9", alpha=0.5, label="imaginary frequency")
ax.axvspan(1, 3, color="#f2d0a9", alpha=0.5)
ax.set_xlim(-3, 3)
ax.set_ylim(-0.5, 8.5)
ax.set_xlabel("momentum $k_5$ along the extra time $x5$ ($m = 1$)")
ax.set_ylabel("Krein inertia of the 8-dimensional eigenspace")
ax.set_title("Inertia (4,4) for real frequencies, neutral for growing modes")
ax.legend(fontsize=8, loc="upper center")
```

The two counts against k_5: open circles for the positive and small crosses for the negative directions (they coincide, so the crosses sit inside the circles); `axvspan` shades the two regions of imaginary frequency.

```
save_figure(fig, "krein_inertia_scan",
            "The Krein inertia of the 8-dimensional eigenspace of the leading "
            "eigenvalue of $h_m(k)$, $m = 1$, along the momentum $k_5$ of an extra "
            "time: the numbers of positive (circles) and negative (crosses) "
            "eigenvalues of the form $u^\\dagger Bu$ restricted to it; horizontal "
            "axis $k_5$, vertical axis the counts. For $|k_5| < 1$ (real "
            "frequency) the inertia is (4,4); in the shaded regions $|k_5| > 1$ the "
            "frequency is imaginary, the mode grows, and the form vanishes on the "
            "whole eigenspace (Krein-neutral).")
```

Figure 21c.6. **What the figure shows.** In the middle, between $k_5 = -1$ and 1, a row of circles with crosses at height 4; in the two shaded regions the same marks at height 0. A growing mode carries no Krein charge of either sign.

In [13]: the figure files.

```
names = sorted(FIGURE_NUMBERS, key=FIGURE_NUMBERS.get)
check(len(names) == 6 and all(
    output_file(f"{FIGURE_FOLDER}/21c_{FIGURE_NUMBERS[n]}_{n}.png").is_file()
    for n in names), "the six figure files of notebook 21c exist")
all_checks_passed()
```

The six figure files exist, and the last line prints ALL 17 CHECKS PASSED (notebook 21c).

21.31 Sakharov's conditions applied to this theory

Sections 21.3 to 21.6 taught the three conditions on toy models; Sections 21.7 to 21.30 derived the facts of the theory. This section puts them together, condition by condition. Each status is set by a check of the Revision record; Notebook 21d reads every one of these verdicts before it draws the scorecard (Section 21.37).

Condition 1: a process must change the number. The theory has no baryons; its only number of this kind is the U(1) charge Q. Section 21.17 proved that $\partial_\mu(\cos z\, J^\mu) = 0$ on every solution, in the author's metric with an arbitrary history $a_4(x_4)$, the deflating one included (lead check `u1_noether_matrix_identity`). So the charge of a region changes only by the flux through its boundary: no process creates or destroys charge at any point inside the patch $0 < z < \pi/2$, that is, off the brane, where the law is proved. A flux through the brane $z = \pi/2$ does change the charge of the patch (Section 21.18; on the homogeneous solutions of Section 18.21 at the rate $-V_6 q_0$), and the record does not describe where that charge goes: with the Z2 mirror glued on, the mirror patch changes its charge at the same rate and with the same sign (Section 18.21), so gluing does not stop the change. Only with no flux (the no-flux condition, ASSUMED, not derived) is the charge of one universe constant. In the language of the decay model of Section 21.5: every process of the theory has channels of the **same** charge, $\mathcal{B}_1 = \mathcal{B}_2$, so the net charge made by N pairs, $N(r - \bar{r})(\mathcal{B}_1 - \mathcal{B}_2)$, is zero; the rate model of Section 21.6 then starts with $\epsilon = 0$ and ends with $a = 0$, however slow the decays and however far from equilibrium (Notebook 21d, In [13]). **Condition 1 FAILS for every process inside the patch (PROVED: the local law); for the total charge of a universe it fails under the no-flux condition at the brane, which is ASSUMED (whether a junction condition at the brane implies it is OPEN).** For the quantised field this holds at the level of the canonical field equations; no regularised quantum field theory in signature (4,4) is constructed in the record, and no anomaly (a quantum breaking of a classical conservation law) is computed: OPEN.

Condition 2: C and CP must be violated. For the commuting field dirac16complex00 the same-mass charge conjugation $\Psi \to \Psi^c = \Psi^*$ is an exact symmetry. Proof, line by line:

- Every term of $\mathcal{L}$ is a sum of products $\Psi_r^* X_{rc} \Phi_c$ with a real matrix X (built from C, the gammas, the scale factors and the Ω_μ) and with Φ the field or one of its derivatives, or a product of two such sums (the term $\frac{\lambda}{2} S^2$), times the real $\cos z$ (Section 21.7).
- Replacing Ψ by Ψ^* turns $\Psi_r^* X_{rc} \Phi_c$ into $\Psi_r X_{rc} \Phi_c^* = (\Psi_r^* X_{rc} \Phi_c)^*$ (commuting numbers may be reordered; X_{rc} is real; the conjugate of a product is the product of the conjugates).
- So $\mathcal{L}[\Psi^*] = (\mathcal{L}[\Psi])^*$, and $\mathcal{L}$ is real (record checks `L_real_C` of `Revision/theory/reports/wolfram-field-theory.json` and `commuting_lagrangian_real` of the sympy report): $\mathcal{L}[\Psi^*] = \mathcal{L}[\Psi]$.

The map keeps the Lagrangian, hence maps solutions to solutions of the same theory, and it reverses every current (Section 21.10). By Proposition 2 of Section 21.5 a C-symmetric start can then develop no average charge asymmetry, even if condition 1 were met. Notebook 21d checks $\mathcal{L}[\Psi^*] = \mathcal{L}[\Psi] = -11.2851368126$ at one point of the author's metric with the record's spin connection (In [14]). For

the quantised field dirac16complex no same-mass charge-conjugation matrix is compatible with canonical quantisation: the only one that is, giving $\Psi \to \Gamma\Psi^{\dagger T}$, reverses the mass (Section 21.25). The maps Γ and $\Gamma\Psi^*$ also reverse the mass: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = \mathcal{L}_{m,\lambda}[\Gamma\Psi^*] = -\mathcal{L}_{-m,-\lambda}[\Psi] = 8.4767165144$ at the same point (In [14]; theorem T1, record check `T1_Lagrangian_primordial_commuting`). Whether particle and antiparticle processes of this theory happen at different rates (C and CP violation in rates) is **NOT COMPUTED**: the record computes no reaction rates at all. The status of condition 2 is therefore different for the two fields. For the commuting field dirac16complex00 condition 2 **FAILS (PROVED)**: $\mathcal{C}_+$ is an exact symmetry that reverses the charge, so Proposition 2 applies (the reality of the gammas, of C and of the Ω_μ: lead checks `representation_real` and `spinor_connection_real`; the reversal of the current: lead check `bilinears_under_charge_conjugation`). For the quantised field dirac16complex it is **NOT COMPUTED**: no rates are computed, and the only charge-conjugation matrix compatible with its quantisation reverses the mass (lead check `quantum_charge_conjugation_unitary_type`).

Condition 3: a departure from thermal equilibrium. The Revision record contains no computation of reaction rates or of a departure from equilibrium. Its Kohn-Sham states (Chapters 14 and 15) are instantaneous states along the history $a_4 = AHx_4$, and that history is a **prescribed background**: the Kohn-Sham states violate the source conditions of the a_4 equations, so the history is not a dynamical consequence of the field (record check `ks_history_is_a_prescribed_background` of `Revision/field_equations_a4/reports/ks-source-conditions.json`; Chapter 17). **NOT COMPUTED.**

The conclusion. Since condition 1 fails exactly inside the patch, conditions 2 and 3 cannot help there: whatever the rates and however far from equilibrium, no process of the theory as built makes a net charge at any point inside the patch $0 < z < \pi/2$ of one universe, and under the ASSUMED no-flux condition the total charge of the universe cannot change either. The flow through the brane is the one open door: the record neither excludes it nor describes it as a process (OPEN).

Sakharov condition	**this theory**	**status**	**record check**
1. a process changes the number	the local law $\partial_\mu(\cos z\, J^\mu) = 0$ holds for every a_4; the total Q is constant only under the no-flux condition at the brane	inside the patch: FAILS (PROVED); total charge: FAILS under the no-flux condition (ASSUMED; OPEN)	`u1_noether_matrix_identity`
2. C and CP violated	the commuting field: $\mathcal{C}_+$ is exact and reverses the charge, so a C-symmetric start keeps zero charge; the quantised field has only the mass-reversing conjugation; no rates computed	dirac16complex00: FAILS (PROVED: $\mathcal{C}_+$ exact, Proposition 2); dirac16complex: NOT COMPUTED (no rates; only the mass-reversing conjugation)	`representation_real`, `spinor_connection_real`, `bilinears_under_charge_conjugation`, `quantum_charge_conjugation_unitary_type`

Sakharov condition	this theory	status	record check
3. out of equilibrium	no rate computed; the Kohn-Sham history is a prescribed background	NOT COMPUTED	`ks_history_is_a_prescribed_background`

21.32 What a charge-violating term would look like

Condition 1 could be met only by adding to the theory a term that is **not** invariant under $\Psi \to e^{i\alpha}\Psi$. The simplest candidates are **Majorana-type mass terms** $\Psi^T M \Psi$ with a constant 16×16 matrix M, built from Ψ twice and without $\Psi^\dagger$. Under $\Psi \to e^{i\alpha}\Psi$ such a term is multiplied by $e^{i\alpha}e^{i\alpha} = e^{2i\alpha}$: it carries U(1) charge 2. This section finds every such term that respects the rotations and boosts of the theory. It is a statement about possible additions to the theory, not about the theory as built.

The condition, line by line. A rotation or boost acts as $\Psi \to R\Psi$ with $R = e^{\theta S^{ab}}$. The term is invariant when $(R\Psi)^T M (R\Psi) = \Psi^T R^T M R \Psi$ equals $\Psi^T M \Psi$ for every Ψ, that is $R^T M R = M$. For a small angle θ, $R = 1 + \theta S + \dots$ (the dots are terms with θ^2 and higher powers), and

$$R^T M R = (1 + \theta S^T) M (1 + \theta S) + \dots = M + \theta\,(S^T M + M S) + \dots ,$$

so the term of first order must vanish:

$$(S^{ab})^T M + M S^{ab} = 0 \qquad \text{for all 28 generators } S^{ab}.$$

For the 256 entries of M these are $28 \times 256 = 7168$ linear equations.

Their solutions. First, $C S^{ab} C = -(S^{ab})^T$ for $a \neq b$:

$$C S^{ab} C = \tfrac{1}{2} C\gamma^a C C \gamma^b C = \tfrac{1}{2}\big(-(\gamma^a)^T\big)\big(-(\gamma^b)^T\big) = \tfrac{1}{2}(\gamma^b\gamma^a)^T = -\tfrac{1}{2}(\gamma^a\gamma^b)^T = -(S^{ab})^T$$

(insert $CC = 1$ in the middle; (R3) twice; the transpose of a product reverses the order; $\gamma^b\gamma^a = -\gamma^a\gamma^b$ for $a \neq b$). Then the condition $S^T M + M S = 0$ with $S^T = -CSC$ reads $-CSCM + MS = 0$; multiplying from the left by C gives $-SCM + CMS = 0$, that is

$$(CM)\, S^{ab} = S^{ab}\, (CM) \qquad \text{for all } S^{ab}:$$

M solves the equations exactly when CM commutes with every generator. The matrices that commute with all 28 generators form a space of dimension 2, spanned by 1 and Γ (equivalently by the projectors onto the two chiral halves; record check `spin_commutant_dimension_2` of `Revision/algebra/reports/python-algebra.json`: the 16 components split under Spin(4,4) into two inequivalent halves). Hence $CM = c_1 1 + c_2 \Gamma$, and multiplying by C: $M = c_1 C + c_2 C\Gamma$. **The invariant Majorana-type matrices are exactly the combinations of C and $C\Gamma$.** Notebook 21d solves the 7168 equations exactly and finds a space of dimension 2 spanned by them (In [16]); it also checks a finite rotation-boost R, built with $e^{\theta S} = \cos(\theta/2) + 2\sin(\theta/2)S$ when $S^2 = -\frac{1}{4}$

(a rotation) and $e^{\theta S} = \cosh(\theta/2) + 2\sinh(\theta/2)S$ when $S^2 = +\frac{1}{4}$ (a boost). (These follow from the power series of the exponential, as Euler's formula does, because $(2S)^2 = -1$ or $+1$. And $S^2 = \frac{1}{4}\gamma^a\gamma^b\gamma^a\gamma^b = -\frac{1}{4}\eta^{aa}\eta^{bb}$: a rotation when the two directions are both space-like or both time-like, a boost otherwise.)

For anticommuting components these terms vanish, line by line. With $\Psi_r\Psi_c = -\Psi_c\Psi_r$ and hence $\Psi_r\Psi_r = 0$:

$$\Psi^T M \Psi = \sum_{r,c} \Psi_r M_{rc} \Psi_c = \sum_{r<c} (M_{rc} - M_{cr}) \Psi_r \Psi_c$$

(the diagonal terms vanish; a term with $r > c$ is rewritten as $-M_{rc}\Psi_c\Psi_r$ and the summation letters renamed). Only the antisymmetric part of M survives. C is symmetric (R3) and so is $C\Gamma$ ($(C\Gamma)^T = \Gamma^T C^T = \Gamma C = C\Gamma$ by (R2)). So **the field dirac16complex has no Majorana-type mass term at all.** For the commuting field dirac16complex00 the terms $\Psi^T C\Psi$ and $\Psi^T C\Gamma\Psi$ are nonzero and carry charge 2 (In [16] and In [17], figure 21d.7). Adding one of them to the Lagrangian (together with its complex conjugate, to keep $\mathcal{L}$ real) would break the U(1) symmetry and let the charge change in steps of 2. That this would be consistent, or that nature contains such a term, is a HYPOTHESIS that nothing in the Revision record examines; for the anticommuting field a charge-violating term would need derivatives, more fields or new structures, which are not classified here (OPEN).

statement	status	where it is verified
invariance needs $S^T M + MS = 0$; solutions exactly the span of C and $C\Gamma$	PROVED (above); the 7168 equations solved exactly	`Revision/algebra/reports/python-algebra.json`, check `spin_com mutant_dimension_2`; Notebook 21d, In [16]
a finite rotation-boost keeps C and $C\Gamma$	COMPUTED (to rounding)	Notebook 21d, In [16]
C, $C\Gamma$ symmetric: no Majorana-type mass term for anticommuting components; charge 2 for commuting ones	PROVED (above); COMPUTED	Notebook 21d, In [16] and In [17]

21.33 Example: Notebook 21d computes the three conditions and the scorecard

Notebook 21d computes the worked examples of Sections 21.3, 21.5, 21.6, 21.31 and 21.32 and draws the scorecard. It counts $\mathcal{B}$, L and Q_{el} in four processes with exact fractions; it proves the net baryon number of the decay model with sympy; it checks the equilibrium surplus and evaluates the worked example; it solves the rate model in closed form with the incomplete gamma function and integrates it with RK4; then it turns to the theory: it applies condition 1 with the record's verdict, evaluates the record's Lagrangian at a point of the author's metric for Ψ, Ψ^*, $\Gamma\Psi$ and $\Gamma\Psi^*$, solves for every invariant Majorana-type matrix, and builds the scorecard from the PASS verdicts of the record. It uses no measured number. It runs in about 20 seconds; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/21d_sakharov_scorecard.PROVENANCE.md`. It needs no Rust, prints 19 PASS lines and draws eight figures.

21.34 How to run Notebook 21d

Step 1. What this notebook does and what it needs.

Notebook 21d (Sakharov's three conditions and the scorecard of this theory) is the file `Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb` of the repository Dirac_claude. It teaches the three conditions that a process making more matter than antimatter must meet (Sakharov 1967) with exact toy computations of its own: the bookkeeping of baryon number, lepton number and electric charge in four processes; a decay model whose net baryon number is the product of the baryon-number violation and the particle-antiparticle difference of the decay probabilities (derived with sympy); the Fermi-Dirac occupations of particles and antiparticles, which agree when the chemical potential vanishes; and a two-equation rate model of decays out of equilibrium whose final asymmetry is found in closed form and by Runge-Kutta integration. No measured number is used. It then applies the three conditions to this theory with the verdicts of the Revision record: the exact local conservation law of the U(1) charge, the same-mass conjugation of the commuting field as an exact symmetry of the Lagrangian of the record at a point of the author's metric, the mass-reversing conjugation of the quantised field, the two invariant Majorana-type mass matrices C and C Gamma (charge 2, absent for anticommuting components), and draws the scorecard: the theory as built does not solve the matter-antimatter problem. Eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 21d_sakharov_scorecard.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21d_sakharov_scorecard.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 21d_sakharov_scorecard.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/21d.captions.json`
- `Revision/textbook/figures/21d_1_bookkeeping.png`
- `Revision/textbook/figures/21d_2_decay_asymmetry.png`
- `Revision/textbook/figures/21d_3_equilibrium_occupations.png`
- `Revision/textbook/figures/21d_4_rate_model_histories.png`
- `Revision/textbook/figures/21d_5_washout_efficiency.png`
- `Revision/textbook/figures/21d_6_lagrangian_maps.png`
- `Revision/textbook/figures/21d_7_majorana_terms.png`
- `Revision/textbook/figures/21d_8_scorecard.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the eight figure files of notebook 21d exist
ALL 19 CHECKS PASSED (notebook 21d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 21d_sakharov_scorecard.ipynb
python -m nbconvert --execute --inplace 21d_sakharov_scorecard.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`, `Revision/theory`, `Revision/pairing`, `Revision/lead_checks` or `Revision/field_equations_a4`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

21.35 Notebook 21d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The part of the universe we can observe is made of **matter** (protons, neutrons,
electrons); **antimatter** (antiprotons, positrons, ...) appears only for short
times, made in collisions. Why there is more matter than antimatter is an open
question of physics. In 1967 Andrei Sakharov showed that any process that makes
more matter than antimatter out of a symmetric start must meet **three
conditions**. This notebook

1. counts the conserved numbers (baryon number $B$, lepton number $L$, electric
   charge $Q$) in four processes, and shows what a violation of $B$ looks like;
2. computes, with sympy, the net baryon number made by the decays of a toy
   particle and its antiparticle: it is the product of the **violation of $B$**
   (condition 1) and of the **difference between particle and antiparticle**
   (condition 2, C and CP violation);
3. shows with the Fermi-Dirac occupations that in **thermal equilibrium** without
   a conserved $B$ particles and antiparticles are equally common, and solves a
   two-equation rate model, in closed form and with the Runge-Kutta method, in
   which an asymmetry survives only when the decays happen **out of equilibrium**
   (condition 3);
4. applies the three conditions to the theory of this book, using the verdicts of
   the Revision record: the U(1) charge obeys an exact local conservation law
   (condition 1 fails inside the patch $0 < z < \pi/2$, off the brane; the total
   charge is constant only under the ASSUMED no-flux condition at the brane
   $z = \pi/2$),
   the same-mass conjugation is an exact symmetry of the commuting field, the
   quantised field has only the mass-reversing conjugation, and no departure from
   equilibrium has been computed;
5. finds every Majorana-type mass matrix that a charge-violating term could use
   (exactly two, $C$ and $C\Gamma$; both vanish for anticommuting components);
6. draws the **scorecard**: the theory as built does not solve the
```

```
   matter-antimatter problem.

The toy computations use no measured number. Eight teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 21d (Sakharov's three conditions and the scorecard of this theory) is the file
‘Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb‘ of the repository
Dirac_claude. It teaches the three conditions that a process making more matter than
antimatter must meet (Sakharov 1967) with exact toy computations of its own: the
bookkeeping of baryon number, lepton number and electric charge in four processes; a
decay model whose net baryon number is the product of the baryon-number violation and the
particle-antiparticle difference of the decay probabilities (derived with sympy); the
Fermi-Dirac occupations of particles and antiparticles, which agree when the chemical
potential vanishes; and a two-equation rate model of decays out of equilibrium whose
final asymmetry is found in closed form and by Runge-Kutta integration. No measured
number is used. It then applies the three conditions to this theory with the verdicts of
the Revision record: the exact local conservation law of the U(1) charge, the same-mass
conjugation of the commuting field as an exact symmetry of the Lagrangian of the record
at a point of the author's metric, the mass-reversing conjugation of the quantised field,
the two invariant Majorana-type mass matrices C and C Gamma (charge 2, absent for
anticommuting components), and draws the scorecard: the theory as built does not solve
the matter-antimatter problem. Eight teaching plots. It needs a computer with Windows 11,
macOS or Linux, an internet connection for the installation, the program Git, and Python
3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 21d_sakharov_scorecard.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21d_sakharov_scorecard.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 21d_sakharov_scorecard.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/21d.captions.json‘
- ‘Revision/textbook/figures/21d_1_bookkeeping.png‘
- ‘Revision/textbook/figures/21d_2_decay_asymmetry.png‘
- ‘Revision/textbook/figures/21d_3_equilibrium_occupations.png‘
- ‘Revision/textbook/figures/21d_4_rate_model_histories.png‘
- ‘Revision/textbook/figures/21d_5_washout_efficiency.png‘
- ‘Revision/textbook/figures/21d_6_lagrangian_maps.png‘
- ‘Revision/textbook/figures/21d_7_majorana_terms.png‘
- ‘Revision/textbook/figures/21d_8_scorecard.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the

notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS the eight figure files of notebook 21d exist
    ALL 19 CHECKS PASSED (notebook 21d)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 21d_sakharov_scorecard.ipynb
      python -m nbconvert --execute --inplace 21d_sakharov_scorecard.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘, ‘Revision/theory‘, ‘Revision/pairing‘, ‘Revision/lead_checks‘ or ‘Revision/field_equations_a4‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then

it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 21d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 21d (Sakharov's three conditions and the scorecard of this theory) is the file
# Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb of the repository
# Dirac_claude. It teaches the three conditions that a process making more matter than
# antimatter must meet (Sakharov 1967) with exact toy computations of its own: the
# bookkeeping of baryon number, lepton number and electric charge in four processes; a
# decay model whose net baryon number is the product of the baryon-number violation and
# the particle-antiparticle difference of the decay probabilities (derived with sympy);
# the Fermi-Dirac occupations of particles and antiparticles, which agree when the
# chemical potential vanishes; and a two-equation rate model of decays out of equilibrium
# whose final asymmetry is found in closed form and by Runge-Kutta integration. No
# measured number is used. It then applies the three conditions to this theory with the
# verdicts of the Revision record: the exact local conservation law of the U(1) charge,
# the same-mass conjugation of the commuting field as an exact symmetry of the Lagrangian
# of the record at a point of the author's metric, the mass-reversing conjugation of the
# quantised field, the two invariant Majorana-type mass matrices C and C Gamma (charge 2,
# absent for anticommuting components), and draws the scorecard: the theory as built does
# not solve the matter-antimatter problem. Eight teaching plots. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
```

```
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
```

```
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~

#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 21d_sakharov_scorecard.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
```

```
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 21d_sakharov_scorecard.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 21d_sakharov_scorecard.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/21d.captions.json
# - Revision/textbook/figures/21d_1_bookkeeping.png
# - Revision/textbook/figures/21d_2_decay_asymmetry.png
# - Revision/textbook/figures/21d_3_equilibrium_occupations.png
# - Revision/textbook/figures/21d_4_rate_model_histories.png
# - Revision/textbook/figures/21d_5_washout_efficiency.png
# - Revision/textbook/figures/21d_6_lagrangian_maps.png
# - Revision/textbook/figures/21d_7_majorana_terms.png
# - Revision/textbook/figures/21d_8_scorecard.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the eight figure files of notebook 21d exist
#     ALL 19 CHECKS PASSED (notebook 21d)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
```

```
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/21d_sakharov_scorecard.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 21d_sakharov_scorecard.ipynb
#     python -m nbconvert --execute --inplace 21d_sakharov_scorecard.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra, Revision/theory,
#   Revision/pairing, Revision/lead_checks or Revision/field_equations_a4: the notebook
#   was opened outside the repository, or the repository is incomplete; clone the
#   repository again and open the notebook from its folder Revision/textbook/notebooks.
#

## 3. The words used in this notebook

- **Quark**: a constituent of protons and neutrons. The up quark $u$ has electric
  charge $+2/3$, the down quark $d$ has $-1/3$ (in units of the proton charge);
  every quark has **baryon number** $B = 1/3$. An **antiquark** ($\bar u$, $\bar d$)
  has the opposite numbers.
- **Baryon**: a particle made of three quarks, such as the proton $p = uud$ and the
  neutron $n = udd$ ($B = 1$); a **meson** (pion $\pi$) is a quark and an antiquark
  ($B = 0$).
- **Lepton number** $L$: $+1$ for the electron $e^-$ and the neutrino $\nu_e$,
  $-1$ for the positron $e^+$ and the antineutrino $\bar\nu_e$, $0$ for quarks and
  the photon $\gamma$.
- **Conserved number**: a number whose total before a process equals its total
  after it, in every process that happens.
- **Branching probability**: the probability that a decaying particle decays in one
  particular way (one **channel**).
- **C** (charge conjugation): the exchange of particles and antiparticles; **CP**:
  C combined with a mirror reflection of space. A theory **violates** C (or CP)
  when the exchanged process does not happen with the same probability.
- **Thermal equilibrium** at temperature $T$: the state that a system reaches when
  its reactions run forwards and backwards equally often. **Fermi-Dirac
  occupation**: the probability $f(E) = 1/(e^{(E - \mu)/T} + 1)$ that a state of
  energy $E$ holds a fermion; $\mu$ is the **chemical potential** of a conserved
  number (Boltzmann's constant is 1).
- **Rate**: a number per unit time; here the time is measured in units of the
  cooling time of the toy universe.
- **U(1) charge** $Q$ of the field of this theory: the number that belongs to the phase
  symmetry $\Psi \to e^{i\alpha}\Psi$, $Q = \int\cos z\,\Psi^\dagger B\Psi\,d^7x$.
  Its local conservation law is PROVED (chapter 21); the total $Q$ is constant only
  if no charge flows through the brane $z = \pi/2$, and this no-flux condition is
  ASSUMED.
- **Majorana-type term**: a term $\Psi^TM\Psi$ built from $\Psi$ twice (no
  $\Psi^\dagger$); under $\Psi \to e^{i\alpha}\Psi$ it is multiplied by
  $e^{2i\alpha}$, so it carries U(1) charge 2.
- **Status labels**: PROVED (exact), COMPUTED (numerical), ASSUMED (an input),
  HYPOTHESIS (not derived), OPEN (not answered), NOT COMPUTED (no computation
  exists).
```

Text cell:

```
## 4. The physical and mathematical situation

**Sakharov's three conditions** (A. D. Sakharov, 1967; quoted here as known
physics, and illustrated by the toy computations of this notebook). Suppose the
universe starts with equal amounts of matter and antimatter. To end with more
matter,

1. some process must **change the baryon number** $B$ (otherwise the total $B$,
```

```
   zero at the start, stays zero);
2. **C and CP must be violated** (otherwise every process that makes baryons has a
   mirror process that makes the same number of antibaryons at the same rate);
3. these processes must happen **out of thermal equilibrium** (in equilibrium a
   number that is not conserved has zero chemical potential, and particles and
   antiparticles are equally common).

**The theory of this book** has no quarks and no baryons. The only number of this
kind it has is the U(1) charge $Q$ of its field; the Revision record proves that
$Q$ obeys an exact local conservation law at every point of the patch
$0 < z < \pi/2$ (off the brane $z = \pi/2$) in the author's metric, for every
history $a_4(x_4)$, in particular the one in which the three extra times
$x5, x6, x7$ deflate exponentially: inside the patch, charge can only flow from
one place to another. The total $Q$ of a universe is constant only if no charge
flows through the brane $z = \pi/2$; this no-flux condition is ASSUMED, not
derived. The notebook first teaches the three conditions on toy models and then
asks, condition by condition, what this theory does.

**Honesty.** The toy models (a decay model and a rate model) are illustrations
with ASSUMED equations; they are not part of this theory. Every statement about
this theory comes from a check of the Revision record that the notebook reads, or
from a computation of the notebook that reproduces one.
```

Text cell:

```
## 5. The Revision records

The next cell reads the verdicts of the Revision reports that this notebook uses:
the lead checks of charge conjugation and U(1) conservation, the pairing record,
the algebra record and the record of the Kohn-Sham source conditions. It prints
the verdicts of the checks the scorecard will rest on.
```

## 6. Counting conserved numbers

The next cell computes $B$ and $Q$ of the proton, the neutron, the antiproton and
the three pions from their quark content (exact fractions), adds the leptons and
the photon, and counts $B$, $L$ and $Q$ before and after four processes:

- neutron decay $n \to p + e^- + \bar\nu_e$ (observed);
- proton-antiproton annihilation $p + \bar p \to \pi^+ + \pi^- + \pi^0$
  (observed);
- pair creation near a proton, $\gamma + p \to p + e^- + e^+$ (observed);
- proton decay $p \to e^+ + \pi^0$ (searched for and never observed; it is the
  kind of process that condition 1 asks for).

It checks that the first three conserve all three numbers and that proton decay
would change $B$ and $L$ by $-1$ each, while $Q$ and the difference $B - L$ stay.
```

In [3]:

```
QUARK = {"u": (Fraction(1, 3), Fraction(2, 3)),  # (B, Q) of the up quark
         "d": (Fraction(1, 3), Fraction(-1, 3))}  # (B, Q) of the down quark
```

```

## 7. Conditions 1 and 2: a decay model

A heavy toy particle $X$ decays in two ways: with probability $r$ into a channel of
baryon number $B_1$, with probability $1 - r$ into a channel of baryon number
$B_2$. Its antiparticle $\bar X$ decays into the antichannels (baryon numbers
$-B_1$, $-B_2$) with probabilities $\bar r$ and $1 - \bar r$. (Ordinary quantum
field theory makes the *total* decay rates of $X$ and $\bar X$ equal; the
branching probabilities $r$ and $\bar r$ can differ only if C and CP are
violated.) Start with $N$ particles $X$ and $N$ antiparticles $\bar X$; line by
line:

1. One $X$ makes on average $rB_1 + (1 - r)B_2$ baryons.
2. One $\bar X$ makes on average $-\bar rB_1 - (1 - \bar r)B_2$.
3. The total is $N[rB_1 + (1 - r)B_2 - \bar rB_1 - (1 - \bar r)B_2] =
   N[(r - \bar r)B_1 - (r - \bar r)B_2] = N(r - \bar r)(B_1 - B_2)$.

The net baryon number is a **product**: it vanishes if $B_1 = B_2$ (then $X$
carries a conserved baryon number: **condition 1** fails) or if $r = \bar r$
(particle and antiparticle behave alike: **condition 2** fails). The next cell
checks this with sympy and evaluates one example: $X \to qq$ ($B_1 = 2/3$) and
$X \to \bar q\bar\ell$ ($B_2 = -1/3$) with $r = 0.6$, $\bar r = 0.5$.
```

In [5]:

```
r, rbar, B1, B2, N = sp.symbols("r rbar B1 B2 N", real=True)
from_X = r * B1 + (1 - r) * B2  # average baryon number made by one X
from_Xbar = -rbar * B1 - (1 - rbar) * B2  # by one antiparticle
net = sp.expand(N * (from_X + from_Xbar))  # N particles and N antiparticles
check(sp.expand(net - N * (r - rbar) * (B1 - B2)) == 0,
      "net baryon number = N (r - rbar) (B1 - B2) exactly")
example = net.subs({N: 1, B1: sp.Rational(2, 3), B2: sp.Rational(-1, 3),
                    r: sp.Rational(3, 5), rbar: sp.Rational(1, 2)})
report("net baryon number per pair X, Xbar for r = 0.6, rbar = 0.5", example)
check(example == sp.Rational(1, 10)
      and net.subs(B2, B1) == 0 and net.subs(rbar, r) == 0,
      "example 1/10 per pair; zero when B1 = B2 or when r = rbar")
```

Out [5]:

```
## 8. Condition 3: equilibrium

In thermal equilibrium at temperature $T$ a state of energy $E$ holds a particle of
baryon number $+1$ with probability $f_+ = 1/(e^{(E - \mu)/T} + 1)$ and the
antiparticle (baryon number $-1$, the same mass, hence the same energy) with
probability $f_- = 1/(e^{(E + \mu)/T} + 1)$; $\mu$ is the chemical potential of
the baryon number. Line by line:

1. $f_+ - f_- = \dfrac{e^{(E + \mu)/T} - e^{(E - \mu)/T}}{(e^{(E - \mu)/T} + 1)
   (e^{(E + \mu)/T} + 1)}$ (common denominator).
```

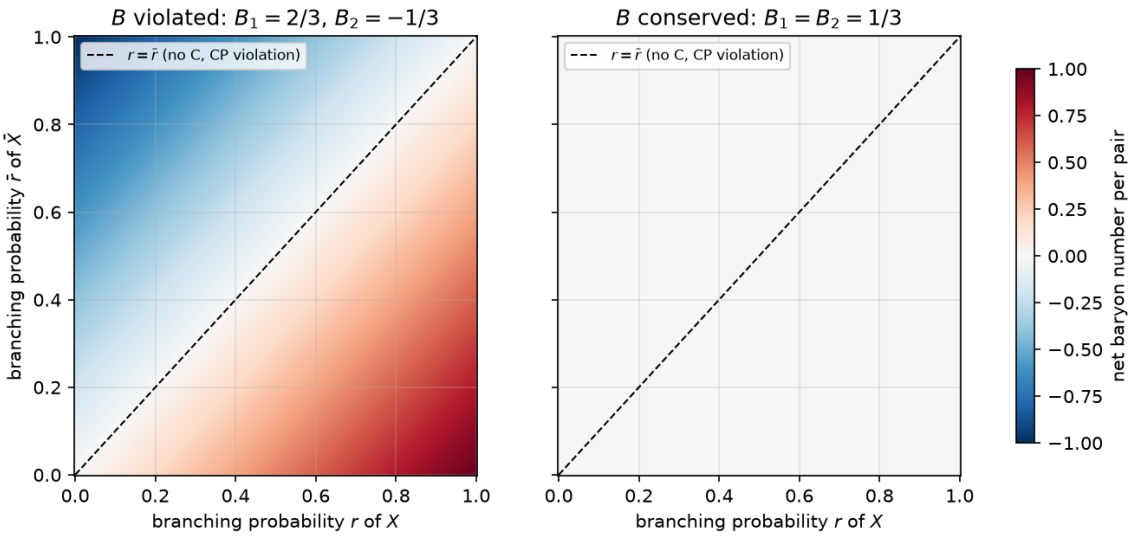

Figure 544: The net baryon number $(r - \bar{r})(B_1 - B_2)$ made by the decays of one toy particle X and its antiparticle, versus the branching probability r of X (horizontal) and $\bar{r}$ of $\bar{X}$ (vertical), colour the net number (red positive, blue negative). Left: channels with $B_1 = 2/3$ and $B_2 = -1/3$ (baryon number violated); the net number vanishes only on the diagonal $r = \bar{r}$. Right: channels with equal baryon number; the net number is zero everywhere. An asymmetry needs both conditions 1 and 2. (Notebook 21d, figure 2.)

```
2. Multiply out the denominator: $e^{2E/T} + e^{(E - \mu)/T} + e^{(E + \mu)/T} +
   1$; divide numerator and denominator by $e^{E/T}$:
   $f_+ - f_- = \dfrac{2\sinh(\mu/T)}{2\cosh(E/T) + 2\cosh(\mu/T)} =
   \dfrac{\sinh(\mu/T)}{\cosh(E/T) + \cosh(\mu/T)}$.
3. If reactions that change $B$ run back and forth in equilibrium, $B$ is not
   conserved and has no chemical potential: $\mu = 0$, so $\sinh 0 = 0$ and
   $f_+ = f_-$ for **every** energy. No asymmetry.

The next cell checks the formula of line 2 with sympy and evaluates the worked
example $E = 2T$: at $\mu = 0$ both occupations are $1/(e^2 + 1)$; a chemical
potential $\mu = 0.1T$ would give a surplus of particles.
```

```
## 9. Condition 3: decays out of equilibrium (a rate model)

A toy universe cools; the time $t$ is measured in units of its cooling time. Let
```

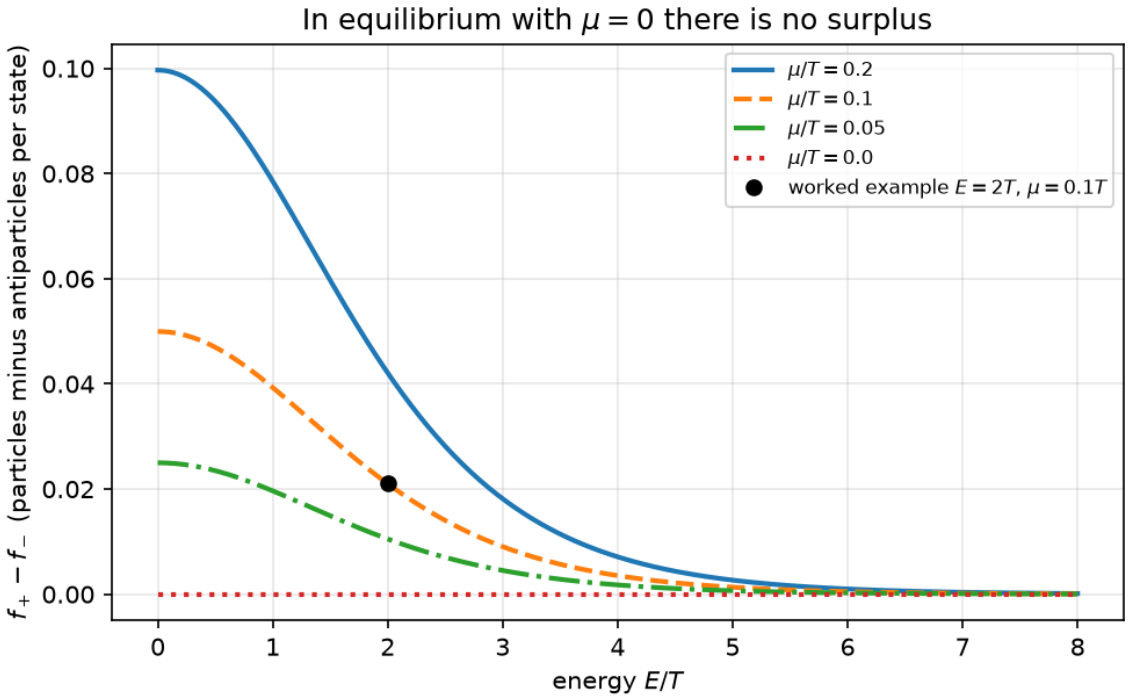

Figure 545: The surplus $f_+ - f_- = \sinh(\mu/T)/(\cosh(E/T)+\cosh(\mu/T))$ of particles over antiparticles per quantum state in thermal equilibrium, versus the energy E/T of the state (horizontal) for the chemical potentials $\mu/T = 0.2, 0.1, 0.05, 0$ (pure numbers). The dot is the worked example $E = 2T$, $\mu = 0.1T$. When the reactions that change the baryon number are in equilibrium, $\mu = 0$ and the surplus vanishes at every energy (dotted line). (Notebook 21d, figure 3.)

```
$n(t)$ be the number of heavy pairs $X$, $\bar X$ (per unit volume, in units of
their starting number) and $n_{eq}(t) = e^{-t}$ the number that equilibrium would
have (heavy particles become rare as the temperature falls). Decays and inverse
decays pull $n$ towards $n_{eq}$ at the rate $K$; each net decay of a pair makes
$\epsilon$ baryons (the number of section 7); inverse decays, which need $X$
particles in equilibrium, erase the asymmetry $a$ at the rate $Kn_{eq}$. The
ASSUMED model is
$$\frac{dn}{dt} = -K(n - n_{eq}),\qquad \frac{da}{dt} = \epsilon K(n - n_{eq})
- Kn_{eq}\,a,\qquad n(0) = 1,\ a(0) = 0 .$$

**Solving it exactly**, line by line.

1. Write $n = n_{eq} + \Delta$. Since $dn_{eq}/dt = -e^{-t}$, the first equation
   becomes $d\Delta/dt = -K\Delta + e^{-t}$ with $\Delta(0) = 0$.
2. Its solution is $\Delta(t) = (e^{-t} - e^{-Kt})/(K - 1)$ (for $K \ne 1$;
   differentiate to check: $(-e^{-t} + Ke^{-Kt})/(K - 1) = -K\Delta + e^{-t}$).
3. With $W(t) = K(1 - e^{-t})$, so $dW/dt = Kn_{eq}$, the second equation is
   $d(a\,e^{W})/dt = \epsilon K\Delta\,e^{W}$ (product rule), hence
   $a(t) = \epsilon\int_0^t K\Delta(s)\,e^{W(s) - W(t)}\,ds$.
4. As $t \to \infty$, $W(t) \to K$ and $W(s) - K = -Ke^{-s}$, so the final
   asymmetry is $a(\infty) = \epsilon\,\eta(K)$ with the **efficiency**
   $\eta(K) = \int_0^\infty K\Delta(s)\,e^{-Ke^{-s}}\,ds$.
5. Substitute $y = e^{-s}$ ($ds = -dy/y$):
   $\eta(K) = \frac{K}{K - 1}\int_0^1(1 - y^{K-1})\,e^{-Ky}\,dy$.
6. $\int_0^1 e^{-Ky}dy = (1 - e^{-K})/K$, and with $u = Ky$,
   $\int_0^1 y^{K-1}e^{-Ky}dy = K^{-K}\gamma(K, K)$, where $\gamma(s, x) =
   \int_0^x u^{s-1}e^{-u}du$ is the *lower incomplete gamma function* (mpmath's
   `gammainc(s, 0, x)`):
   $$\eta(K) = \frac{K}{K - 1}\Big(\frac{1 - e^{-K}}{K} - K^{-K}\gamma(K, K)\Big).$$

The next cell checks lines 1 to 3 with sympy and defines $\eta(K)$ with mpmath
(30 digits).
```

The next cell computes the efficiency $\eta(K) = a(\infty)/\epsilon$ for 24 rates
from $K = 0.01$ to $K = 1000$ with the closed form and draws it with the three RK4
results. It checks the two limits: $\eta \to 1$ for slow decays, and $\eta =
1/(K - 1)$ up to the exponentially small term $K^{-K}\gamma(K, K)$ for fast ones,
so the asymmetry disappears as the decays approach equilibrium.
```

## 10. This theory, condition 1: no process changes the U(1) charge locally
```

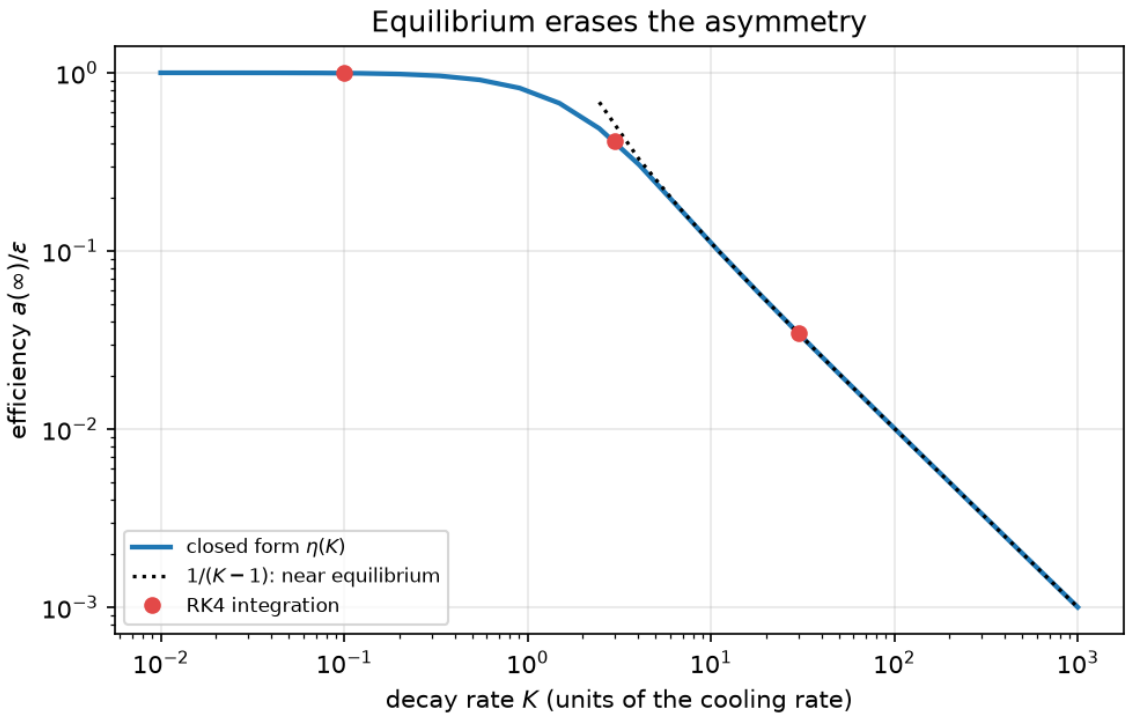

Figure 547: The efficiency $\eta(K) = a(\infty)/\epsilon$ of the rate model: the fraction of the asymmetry made by the decays that survives, versus the decay rate K, both on logarithmic scales (pure numbers). Solid: the closed form with the incomplete gamma function; dots: the RK4 integrations; dotted: the limit $1/(K-1)$. Slow decays (out of equilibrium) keep almost all of it; the closer the decays are to equilibrium (large K), the less survives: condition 3. (Notebook 21d, figure 5.)

```
The Revision record proves (check u1_noether_matrix_identity) the exact local
conservation law $\partial_\mu(\cos z\,J^\mu) = 0$ on every solution, at every
point of the patch $0 < z < \pi/2$ (off the brane), in the author's metric with an
arbitrary history $a_4(x_4)$: charge can only flow from one place to another, and
the U(1) charge $Q = \int\cos z\,\Psi^\dagger B\Psi\,d^7x$ of a universe changes
only by what flows through its boundary. At the brane $z = \pi/2$ the record does
not exclude such a flow (notebook 21b follows an exact solution whose charge
changes by the flux through the brane); the no-flux condition that would make $Q$
constant is ASSUMED, not derived. In the language of section 7: every process of
this theory, at any point of the patch $0 < z < \pi/2$, has channels of the
**same** charge, $B_1 = B_2$, so the factor $(B_1 - B_2)$ is zero, and the rate
model then starts with $\epsilon = 0$ and ends with $a = 0$, whatever the rates
and however far from equilibrium. The next cell checks that the record holds this
verdict and evaluates the decay formula and the rate model with this input.
```

## 11. This theory, condition 2: the conjugations

Condition 2 asks whether particle and antiparticle behave differently. The next
cell evaluates the Lagrangian of the Revision record,
$$\mathcal{L}_{m,\lambda}[\Psi] = \cos z\,\Big[\tfrac12\sum_\mu\big(\bar\Psi
\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi\big) - mS -
\tfrac\lambda2S^2\Big],\quad S = \bar\Psi\Psi,\quad \bar\Psi = \Psi^\dagger C,$$
with $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$, $D_\mu\bar\Psi =
\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, the record's spin connection
$\Omega_\mu$ (formula Omega_components) and the curved gammas $\gamma^\mu =
\gamma^{(\mu)}/f_\mu$, at one point of the author's metric ($H = 1/6$,
$z = 0.7$, $a_4 = 0.4$, $a_4' = 0.25$), for a fixed commuting field value
```

```
$\Psi$ and fixed first derivatives $\partial_\mu\Psi$ (random numbers with a fixed
seed), $m = 0.7$, $\lambda = 0.3$. It compares four numbers:

1. $\mathcal{L}_{m,\lambda}[\Psi]$ and $\mathcal{L}_{m,\lambda}[\Psi^*]$: they are
   **equal**, so the same-mass conjugation $\mathcal{C}_+$ ($\Psi^c = \Psi^*$) is
   an exact symmetry of the commuting field dirac16complex00. (Why: every matrix
   in $\mathcal{L}$, that is $C$, the gammas and $\Omega_\mu$, is real, so
   replacing $\Psi$ by $\Psi^*$ turns $\mathcal{L}$ into its complex conjugate;
   and $\mathcal{L}$ is real.) The map also reverses every current, so it turns
   every solution into a solution of the same theory with the opposite charge. A
   start in which every field configuration and its conjugate are equally likely
   therefore keeps the average charge zero at all times: for the commuting field
   **condition 2 fails** (PROVED).
2. $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$
   (theorem T1, record check T1_Lagrangian_primordial_commuting) and the same for
   $\Gamma\Psi^*$ (the conjugation $\mathcal{C}_-$): these maps reverse the mass.

For the **quantised** field dirac16complex the record proves (check
quantum_charge_conjugation_unitary_type) that the only conjugation compatible with
the canonical anticommutator is $\Psi \to \Gamma\Psi^{\dagger T}$, which reverses
the mass: within one universe of mass $m$ there is no same-mass conjugation of the
quantised field. Whether its particles and antiparticles react at different rates
is NOT COMPUTED: the record computes no reaction rates.

## 12. What a charge-violating term would look like

Condition 1 could be met only by adding to the theory a term that is not
invariant under $\Psi \to e^{i\alpha}\Psi$. The simplest candidates are
**Majorana-type mass terms** $\Psi^TM\Psi$ with a constant $16 \times 16$ matrix
```

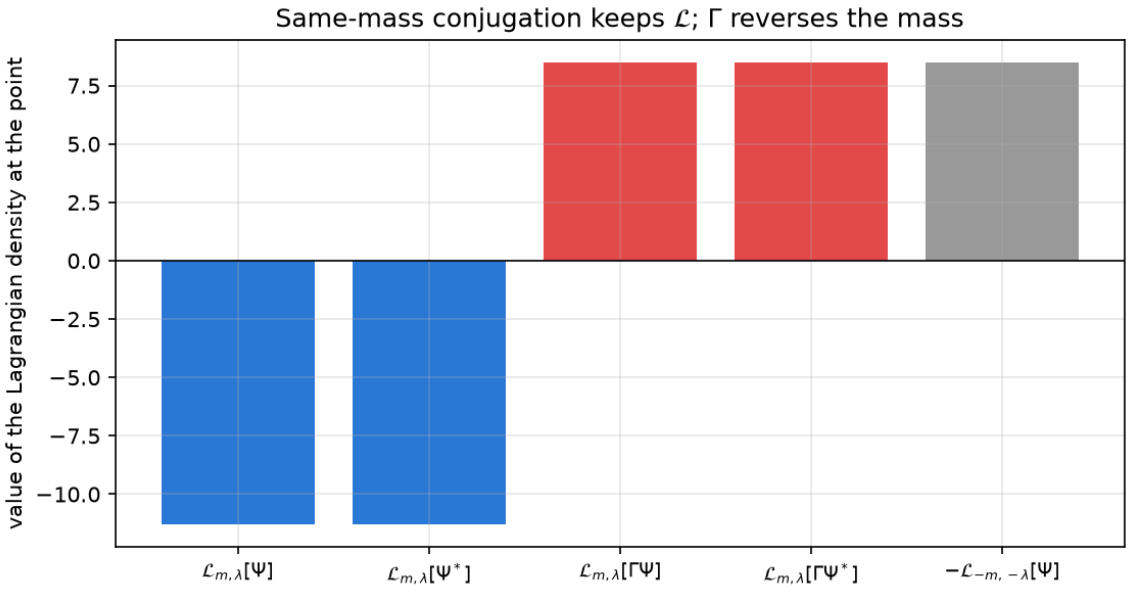

Figure 548: The Lagrangian density of the Revision record for the commuting field at one point of the author's metric ($H = 1/6$, $z = 0.7$, $a_4 = 0.4$, $a_4' = 0.25$, $m = 0.7$, $\lambda = 0.3$, a fixed field value and fixed first derivatives): for Ψ and its same-mass conjugate Ψ^* (blue, equal), for the images $\Gamma\Psi$ and $\Gamma\Psi^*$ (red) and for minus the Lagrangian of the reversed mass and coupling (grey); vertical axis the value (pure numbers). The red bars equal the grey one: Γ maps the theory with (m, λ) to the theory with $(-m, -\lambda)$. (Notebook 21d, figure 6.)

```
$M$. Such a term must still be invariant under the rotations and boosts of
Spin(4,4), $\Psi \to R\Psi$ with $R = e^{\theta S^{ab}}$, that is $R^TMR = M$; for
small $\theta$ this is
$$(S^{ab})^TM + MS^{ab} = 0\quad\text{for all 28 generators } S^{ab} .$$
The next cell solves these $28 \cdot 256 = 7168$ linear equations exactly (as in
the search for the charge-conjugation matrices) and finds a two-dimensional space
spanned by $C$ and $C\Gamma$. (This reproduces the Revision algebra check
spin_commutant_dimension_2: $M$ solves the equations exactly when $CM$ commutes
with every $S^{ab}$, because $CS^{ab}C = -(S^{ab})^T$.) It also checks a finite
transformation $R$ (a product of three rotations and boosts, built from
$e^{\theta S} = \cos(\theta/2) + 2\sin(\theta/2)S$ when $S^2 = -\tfrac14$ and
$\cosh(\theta/2) + 2\sinh(\theta/2)S$ when $S^2 = +\tfrac14$).

**For anticommuting components these terms vanish.** With $\Psi_r\Psi_c =
-\Psi_c\Psi_r$ and $\Psi_r\Psi_r = 0$, $\Psi^TM\Psi = \sum_{r<c}(M_{rc} -
M_{cr})\Psi_r\Psi_c$ keeps only the antisymmetric part of $M$; $C$ and $C\Gamma$
are symmetric, so the field dirac16complex has **no** Majorana-type mass term. For
the commuting field dirac16complex00 they survive and carry charge 2.

(Notebook 21d, figure 7.)

```
## 13. The scorecard

The next cell builds the scorecard of this theory from the verdicts of the
Revision record (each status is set only if the record holds the named check
with the verdict PASS) and draws it as a table. Condition 1 has two parts: it
fails for every process inside the patch (the local law, PROVED), and for the
total charge of a universe only under the no-flux condition at the brane
(ASSUMED). Condition 2 has two statuses: it
fails for the commuting field (its same-mass conjugation is exact, section 11;
the record checks that the gammas, $C$ and $\Omega_\mu$ are real and that the
conjugation reverses the current), and it is not computed for the quantised field
(no rates; its only conjugation reverses the mass). Condition 3: the Revision
record contains no computation of reaction rates or of a departure from
equilibrium; its Kohn-Sham history is a prescribed background (record check
ks_history_is_a_prescribed_background), not a dynamical history.
```

## 15. What this notebook showed

- ASSUMED (known physics, quoted): Sakharov's three conditions; the quark content
  and the numbers $B$, $L$, $Q$ of the particles.
- COMPUTED (exact fractions): the three observed processes conserve $B$, $L$ and
  $Q$; proton decay $p \to e^+\pi^0$ would change $B$ and $L$ by $-1$ each and
  keep $B - L$.
- PROVED (sympy) for the toy decay model: the net baryon number is $N(r - \bar r)
  (B_1 - B_2)$, zero unless both condition 1 and condition 2 hold; example $1/10$
  per pair.
- PROVED: in equilibrium $f_+ - f_- = \sinh(\mu/T)/(\cosh(E/T) + \cosh(\mu/T))$,
  zero for $\mu = 0$.
- PROVED (closed form, checked by RK4 to $10^{-7}$) for the ASSUMED rate model:
  the surviving fraction of the asymmetry is $\eta(K)$, near 1 for slow decays and
  $1/(K - 1)$ for fast ones: condition 3.
- This theory (Revision record): the U(1) charge obeys an exact local
  conservation law (u1_noether_matrix_identity), so no process of the theory can
  make a net charge at any point of the patch $0 < z < \pi/2$ (off the brane) of
  one universe, whatever the rates and however far from equilibrium: condition 1
  FAILS there (PROVED). The total charge of a universe is constant only under the
  no-flux condition at the brane $z = \pi/2$, which is ASSUMED, not derived
  (OPEN). The same-mass conjugation is an exact symmetry of the commuting field
  (COMPUTED here at a point of the author's metric) that reverses the charge, so
  condition 2 FAILS for the commuting field (PROVED); the quantised field has
  only the mass-reversing conjugation (quantum_charge_conjugation_unitary_type),
  and C and CP violation in its rates is NOT COMPUTED; no departure from
  equilibrium is computed (the Kohn-Sham history is a prescribed background).
- PROVED (exact linear algebra): the only Spin(4,4)-invariant Majorana-type mass
  matrices are $C$ and $C\Gamma$; both are symmetric, so the anticommuting field
  has no such term; for the commuting field they carry U(1) charge 2.
- The pair-level statement (theorem T1, PROVED for classical bilinears): the
  partner of mass $-m$ carries the opposite current, so a pair has total charge
  zero. That pairs of universes exist, or were created, is a HYPOTHESIS (the
  universe/anti-universe class of ideas; a published example is L. Boyle, K. Finn
  and N. Turok, Phys. Rev. Lett. 121, 251301 (2018)); this theory does not derive
  it.
- **The theory as built does not solve the matter-antimatter problem.** What would
  be needed (OPEN): baryons in the theory; a charge-violating interaction (for the
  commuting field a Majorana-type term like the ones found here; the
  anticommuting field has no invariant mass-type term, so it would need terms
  with derivatives, more fields or new background structures, which are not
```

```
  classified here); CP violation in reaction rates; and a computed departure from
  equilibrium along a dynamical history of the deflating extra times.
```

21.36 Line-by-line walk-through of Notebook 21d

The notebook has 20 code cells, In [1] to In [20].

In [1], the set-up cell. It is the set-up cell of Notebook 21a, explained line by line in Section 21.15 under In [1], except that the comment lines at the top hold the run instructions of Notebook 21d (Section 21.34) and that the line

```
NOTEBOOK_ID = "21d"  # this notebook: chapter 21, example d
```

names this notebook. The cell prints Set-up of notebook 21d complete.

In [2]: the verdicts of the Revision record.

```
from fractions import Fraction  # exact fractions such as 1/3

import mpmath  # numbers with many digits and special functions
import numpy as np  # numbers, arrays, matrices
import sympy as sp  # exact algebra
```

`Fraction` computes with exact fractions such as 1/3; `mpmath` computes with as many digits as asked and knows special functions such as the incomplete gamma function of Section 21.6.

```
def load_checks(path):
    """name -> verdict (upper case) of every check of a Revision report."""
    entries = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
    return {c["name"]: c["verdict"].upper() for c in entries}
```

The helper of Notebook 21c: a Revision report becomes a dictionary from check name to verdict in capitals.

```
LEAD_FILE = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
PAIR_FILE = "Revision/pairing/reports/wolfram-pairing.json"
ALGEBRA_FILE = "Revision/algebra/reports/python-algebra.json"
KS_FILE = "Revision/field_equations_a4/reports/ks-source-conditions.json"
LEAD, PAIR = load_checks(LEAD_FILE), load_checks(PAIR_FILE)
ALGEBRA, KS = load_checks(ALGEBRA_FILE), load_checks(KS_FILE)
```

The four reports on which the scorecard rests: the lead checks of charge conjugation and U(1) conservation, the Wolfram pairing report, the sympy algebra report, and the record of the Kohn-Sham source conditions of the a_4 equations.

```
USED = [(LEAD_FILE, LEAD, "u1_noether_matrix_identity"),
        (LEAD_FILE, LEAD, "representation_real"),
```

```
        (LEAD_FILE, LEAD, "spinor_connection_real"),
        (LEAD_FILE, LEAD, "bilinears_under_charge_conjugation"),
        (LEAD_FILE, LEAD, "quantum_charge_conjugation_unitary_type"),
        (PAIR_FILE, PAIR, "T1_current_primordial_commuting"),
        (PAIR_FILE, PAIR, "T1_current_primordial_grassmann"),
        (PAIR_FILE, PAIR, "T1_Lagrangian_primordial_commuting"),
        (ALGEBRA_FILE, ALGEBRA, "spin_commutant_dimension_2"),
        (KS_FILE, KS, "ks_history_is_a_prescribed_background")]
for path, verdicts, name in USED:
    say(f"record {path.split('/')[-1]}: {name} = {verdicts[name]}")
```

The ten record checks the notebook will use, each as a triple (file, its verdicts, check name). Two of them, `representation_real` (the gammas, C and the S^{ab} are real) and `spinor_connection_real` (every entry of every Ω_μ is real), are the facts on which the exact same-mass conjugation of the commuting field rests (Section 21.31); the scorecard of In [18] uses them. The loop prints the file name (`split` cuts the path at every slash, and the index `[-1]` takes the last part), the check name and its verdict: Out [2] shows ten lines, all PASS.

In [3]: counting conserved numbers.

```
QUARK = {"u": (Fraction(1, 3), Fraction(2, 3)),  # (B, Q) of the up quark
         "d": (Fraction(1, 3), Fraction(-1, 3))}  # (B, Q) of the down quark
```

The baryon number and electric charge of the up and down quarks, as exact fractions.

```
def hadron(quarks="", antiquarks=""):
    """(B, L, Q) of a particle made of the given quarks and antiquarks."""
    B = sum(QUARK[x][0] for x in quarks) - sum(QUARK[x][0] for x in antiquarks)
    Q = sum(QUARK[x][1] for x in quarks) - sum(QUARK[x][1] for x in antiquarks)
    return (B, Fraction(0), Q)
```

A particle made of quarks: a string such as `"uud"` is read letter by letter, the numbers of its quarks are added and those of its antiquarks subtracted (the addition rule of Section 21.3); the lepton number is 0. The function returns the triple $(\mathcal{B}, L, Q_{\mathrm{el}})$.

```
PARTICLE = {"p": hadron("uud"), "n": hadron("udd"), "pbar": hadron("", "uud"),
            "pi+": hadron("u", "d"), "pi-": hadron("d", "u"), "pi0": hadron("u", "u"),
            "e-": (0, 1, -1), "e+": (0, -1, 1), "nubar": (0, -1, 0), "gamma": (0, 0, 0)}
```

The particles of the four processes with their triples: the proton, neutron, antiproton and pions from their quark content (the neutral pion as $u\bar{u}$), the leptons and the photon directly.

```
PROCESSES = [("neutron decay", ["n"], ["p", "e-", "nubar"]),
             ("annihilation", ["p", "pbar"], ["pi+", "pi-", "pi0"]),
             ("pair creation", ["gamma", "p"], ["p", "e-", "e+"]),
             ("proton decay", ["p"], ["e+", "pi0"])]
changes, totals = {}, {}  # process -> changes of (B, L, Q); totals before, after
```

The four processes, each with its name, the particles before and the particles after; two empty dictionaries for the results.

```
for label, before, after in PROCESSES:
    total_before = [sum(PARTICLE[x][k] for x in before) for k in range(3)]
    total_after = [sum(PARTICLE[x][k] for x in after) for k in range(3)]
    totals[label] = (total_before, total_after)
    changes[label] = [a - b for a, b in zip(total_after, total_before)]
    say(f"{label:14}: {' + ' '.join(before):10} -> {' + ' '.join(after):15} "
        f"change of (B, L, Q) = ({', '.join(str(c) for c in changes[label])})")
```

For each process the three totals before and after (for each $k = 0, 1, 2$ the sum of the k-th number over the particles), and the changes, after minus before. The printed line pads the name to 14 and the two lists to 10 and 15 characters. Out [3] shows the changes $(0, 0, 0)$ for the three observed processes and $(-1, -1, 0)$ for proton decay.

```
check(PARTICLE["p"] == (1, 0, 1) and PARTICLE["n"] == (1, 0, 0)
      and PARTICLE["pi+"][2] == 1 and PARTICLE["pi0"] == (0, 0, 0),
      "quark content: p has (B, L, Q) = (1, 0, 1), n (1, 0, 0), pi+ charge 1")
check(all(changes[p[0]] == [0, 0, 0] for p in PROCESSES[:3])
      and changes["proton decay"] == [-1, -1, 0],
      "three observed processes conserve B, L, Q; proton decay changes B and L by -1")
```

The quark-content values of Section 21.3, and the bookkeeping: the first three processes (`PROCESSES[:3]`) conserve all three numbers, proton decay would change $\mathcal{B}$ and L by -1.

In [4]: the bookkeeping as a picture.

```
REACTIONS = ["$n \\to p\\,e^-\\bar\\nu_e$", "$p\\,\\bar p \\to \\pi^+\\pi^-\\pi^0$",
             "$\\gamma\\,p \\to p\\,e^-e^+$", "$p \\to e^+\\pi^0$ (never seen)"]
table = np.array([[float(totals[p[0]][side][k]) for k in range(3)
                   for side in (0, 1)] for p in PROCESSES])  # rows: processes
```

The reactions written in LaTeX for the row labels. `table` has one row per process and six columns: for each of the three numbers its total before (`side` 0) and after (`side` 1), as decimal numbers.

```
fig, ax = plt.subplots(figsize=(10.0, 4.2))
ax.imshow(table, cmap="RdBu_r", vmin=-2.5, vmax=2.5, aspect="auto")
for row in range(len(PROCESSES)):
    for col in range(6):
        value = table[row, col]
        ax.text(col, row, "0" if value == 0 else f"{value:+.0f}", ha="center",
                va="center", fontsize=11)
```

The table as coloured squares (red positive, blue negative), with each total written in its square with its sign (`+.0f`: a sign and no decimals).

```
        if col % 2 == 1 and table[row, col] != table[row, col - 1]:  # a change
            for c in (col - 1, col):
                ax.add_patch(plt.Rectangle((c - 0.46, row - 0.44), 0.92, 0.88,
                                           fill=False, linewidth=2.5))
```

In every "after" column (the odd column numbers) the total is compared with the "before" column to its left; if they differ, a black frame (`plt.Rectangle` with lower-left corner, width and height, not filled) is drawn around both squares.

```
ax.set_xticks(range(6), ["$B$ before", "$B$ after", "$L$ before", "$L$ after",
                         "$Q$ before", "$Q$ after"])
ax.set_yticks(range(len(PROCESSES)), [f"{p[0]}\n{r}" for p, r in
                                      zip(PROCESSES, REACTIONS)], fontsize=9)
for x in (1.5, 3.5):
    ax.axvline(x, color="black", linewidth=1)
ax.grid(False)
ax.set_title("Bookkeeping: only proton decay would change $B$ (and $L$)")
```

Column labels, row labels (the process name and, below it, the reaction), two vertical lines that separate the three numbers, and a title.

```
save_figure(fig, "bookkeeping",
            "The totals of the baryon number $B$, the lepton number $L$ and the "
            "electric charge $Q$ before and after four processes (rows): neutron "
            "decay, proton-antiproton annihilation into three pions and pair "
            "creation near a proton (all observed), and proton decay into a "
            "positron and a pion (never observed); columns the number and the side "
            "of the process, colour and figure the total (red positive, blue "
            "negative, pure numbers). Black frames mark the numbers that change: "
            "only proton decay would change $B$ and $L$, the kind of process that "
            "Sakharov's first condition requires.")
```

Figure 21d.1. **What the figure shows.** Three rows in which each "after" square has the colour of its "before" square, and one row, proton decay, with two framed pairs: $\mathcal{B}$ from $+1$ to 0 and L from 0 to -1.

In [5]: the decay model.

```
r, rbar, B1, B2, N = sp.symbols("r rbar B1 B2 N", real=True)
from_X = r * B1 + (1 - r) * B2  # average baryon number made by one X
from_Xbar = -rbar * B1 - (1 - rbar) * B2  # by one antiparticle
net = sp.expand(N * (from_X + from_Xbar))  # N particles and N antiparticles
```

Five real symbols (r, $\bar{r}$, $\mathcal{B}_1$, $\mathcal{B}_2$, N), the two averages of Section 21.5, and the multiplied-out net baryon number.

```
check(sp.expand(net - N * (r - rbar) * (B1 - B2)) == 0,
      "net baryon number = N (r - rbar) (B1 - B2) exactly")
```

The factorised form of Section 21.5 holds exactly.

```
example = net.subs({N: 1, B1: sp.Rational(2, 3), B2: sp.Rational(-1, 3),
                    r: sp.Rational(3, 5), rbar: sp.Rational(1, 2)})
```

```
report("net baryon number per pair X, Xbar for r = 0.6, rbar = 0.5", example)
check(example == sp.Rational(1, 10)
      and net.subs(B2, B1) == 0 and net.subs(rbar, r) == 0,
      "example 1/10 per pair; zero when B1 = B2 or when r = rbar")
```

The worked example with exact fractions: $1/10$ per pair (printed as a RESULT line). Replacing $\mathcal{B}_2$ by $\mathcal{B}_1$, or $\bar{r}$ by r, gives exactly zero: the two conditions.

In [6]: the decay model as a map.

```
grid = np.linspace(0.0, 1.0, 201)  # values of r and rbar from 0 to 1
R, RBAR = np.meshgrid(grid, grid)
net_f = sp.lambdify((r, rbar, B1, B2), net.subs(N, 1), "numpy")
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.4), sharey=True)
```

201 values from 0 to 1 for each probability, all their pairs, and the net number per pair ($N = 1$) as a fast function.

```
for ax, (b1, b2), title in ((axes[0], (2 / 3, -1 / 3), "$B$ violated: $B_1 = 2/3$, "
                               "$B_2 = -1/3$"),
                              (axes[1], (1 / 3, 1 / 3), "$B$ conserved: "
                               "$B_1 = B_2 = 1/3$")):
    values = net_f(R, RBAR, b1, b2) + 0 * R  # + 0 * R: an array even when constant
    image = ax.pcolormesh(R, RBAR, values, cmap="RdBu_r", vmin=-1, vmax=1,
                          shading="auto")
```

Two cases: channels of baryon number $2/3$ and $-1/3$, and two channels of the same baryon number $1/3$. In the second case the expression is the constant zero, and a function that returns a constant returns a single number; adding `0 * R` turns it into an array of the right shape. `pcolormesh` colours the plane of $(r, \bar{r})$.

```
    ax.plot([0, 1], [0, 1], "--", color="black", linewidth=1,
            label="$r = \\bar r$ (no C, CP violation)")
    ax.set_xlabel("branching probability $r$ of $X$")
    ax.set_title(title)
    ax.legend(fontsize=8, loc="upper left")
axes[0].set_ylabel("branching probability $\\bar r$ of $\\bar X$")
fig.colorbar(image, ax=axes, shrink=0.85, label="net baryon number per pair")
```

A dashed diagonal marks $r = \bar{r}$; labels, legend and colour bar follow.

```
save_figure(fig, "decay_asymmetry",
            "The net baryon number $(r - \\bar r)(B_1 - B_2)$ made by the decays of "
            "one toy particle $X$ and its antiparticle, versus the branching "
            "probability $r$ of $X$ (horizontal) and $\\bar r$ of $\\bar X$ "
            "(vertical), colour the net number (red positive, blue negative). Left: "
            "channels with $B_1 = 2/3$ and $B_2 = -1/3$ (baryon number violated); "
            "the net number vanishes only on the diagonal $r = \\bar r$. Right: "
            "channels with equal baryon number; the net number is zero everywhere. "
            "An asymmetry needs both conditions 1 and 2.")
```

Figure 21d.2. **What the figure shows.** Left: red below the diagonal ($r > \bar{r}$), blue above it, white on it; the colour is strongest in the corners, where $r - \bar{r} = \pm 1$. Right: uniformly white: without a change of baryon number no asymmetry, whatever the probabilities.

In [7]: the equilibrium occupations.

```
E_T, mu_T = sp.symbols("E_T mu_T", real=True)  # E / T and mu / T
f_plus = 1 / (sp.exp(E_T - mu_T) + 1)
f_minus = 1 / (sp.exp(E_T + mu_T) + 1)
difference = sp.sinh(mu_T) / (sp.cosh(E_T) + sp.cosh(mu_T))
```

Symbols for E/T and μ/T, the two Fermi-Dirac occupations and the formula of Section 21.5 for their difference.

```
check(sp.simplify((f_plus - f_minus - difference).rewrite(sp.exp)) == 0,
      "f+ - f- = sinh(mu/T) / (cosh(E/T) + cosh(mu/T)) exactly")
```

`.rewrite(sp.exp)` writes sinh and cosh with exponentials; the difference then simplifies to zero: the line-by-line derivation of Section 21.5 is confirmed.

```
at_zero = [float(f.subs({E_T: 2, mu_T: 0})) for f in (f_plus, f_minus)]
at_tenth = [float(f.subs({E_T: 2, mu_T: sp.Rational(1, 10)}))
            for f in (f_plus, f_minus)]
report("f+ = f- at E = 2T, mu = 0", f"{at_zero[0]:.6f}")
report("f+, f- at E = 2T, mu = 0.1 T", f"{at_tenth[0]:.6f}, {at_tenth[1]:.6f}")
report("surplus of particles per state", f"{at_tenth[0] - at_tenth[1]:.6f}")
```

The worked example: both occupations at $E = 2T$, $\mu = 0$, and at $\mu = 0.1T$. Out [7] prints 0.119203; 0.130108 and 0.109097; and the surplus 0.021012.

```
check(at_zero[0] == at_zero[1] and abs(at_zero[0] - 1 / (np.exp(2) + 1)) < 1e-15
      and at_tenth[0] > at_tenth[1],
      "mu = 0: equal occupations 1/(e^2 + 1); mu > 0: more particles")
```

At $\mu = 0$ the two occupations are equal to $1/(e^2 + 1)$; at $\mu > 0$ particles are more common.

In [8]: the surplus against the energy.

```
energies = np.linspace(0.0, 8.0, 321)  # E / T from 0 to 8
diff_f = sp.lambdify((E_T, mu_T), difference, "numpy")
fig, ax = plt.subplots(figsize=(7.5, 4.3))
for mu_value, style in ((0.2, "-"), (0.1, "--"), (0.05, "-."), (0.0, ":")):
    ax.plot(energies, diff_f(energies, mu_value) + 0 * energies, style, linewidth=2,
            label=f"$\\mu/T = {mu_value}$")
```

321 energies from 0 to $8T$, the surplus as a fast function, and one curve for each of four chemical potentials (with `+ 0 * energies` for the same reason as in In [6]).

```
ax.plot([2.0], [at_tenth[0] - at_tenth[1]], "o", color="black",
        label="worked example $E = 2T$, $\\mu = 0.1T$")
ax.set_xlabel("energy $E/T$")
ax.set_ylabel("$f_+ - f_-$ (particles minus antiparticles per state)")
ax.set_title("In equilibrium with $\\mu = 0$ there is no surplus")
ax.legend(fontsize=8)
```

A black dot at the worked example, axis labels, title and legend.

```
save_figure(fig, "equilibrium_occupations",
            "The surplus $f_+ - f_- = \\sinh(\\mu/T)/(\\cosh(E/T) + \\cosh(\\mu/T))$ "
            "of particles over antiparticles per quantum state in thermal "
            "equilibrium, versus the energy $E/T$ of the state (horizontal) for the "
            "chemical potentials $\\mu/T = 0.2, 0.1, 0.05, 0$ (pure numbers). The "
            "dot is the worked example $E = 2T$, $\\mu = 0.1T$. When the reactions "
            "that change the baryon number are in equilibrium, $\\mu = 0$ and the "
            "surplus vanishes at every energy (dotted line).")
```

Figure 21d.3. **What the figure shows.** Three curves that start near $\tanh(\mu/2T)$ at $E = 0$ and fall towards zero for large energies, the higher the larger μ; the curve for $\mu = 0$ is the horizontal axis itself.

In [9]: the rate model in closed form.

```
t, s_, K_s, eps_s = sp.symbols("t s K epsilon", positive=True)
Delta = (sp.exp(-t) - sp.exp(-K_s * t)) / (K_s - 1)  # line 2
W = K_s * (1 - sp.exp(-t))  # line 3
```

Positive symbols for the time and the rate (two further symbols, for s and ϵ, are created but not used below), and the two functions $\Delta(t)$ and $W(t)$ of Section 21.6.

```
line2_ok = (sp.simplify(sp.diff(Delta, t) - (-K_s * Delta + sp.exp(-t))) == 0
            and Delta.subs(t, 0) == 0)
line3_ok = sp.simplify(sp.diff(W, t) - K_s * sp.exp(-t)) == 0
check(line2_ok and line3_ok, "rate model: Delta(t) and W(t) solve lines 1 to 3")
mpmath.mp.dps = 30  # work with 30 significant digits
```

Δ solves $d\Delta/dt = -K\Delta + e^{-t}$ with $\Delta(0) = 0$, and $dW/dt = Ke^{-t}$: lines 1 to 3. mpmath is told to work with 30 significant digits.

```
def efficiency(K):
    """eta(K) = K/(K - 1) ((1 - e^-K)/K - K^-K gamma(K, K)), K != 1."""
    K = mpmath.mpf(K)
    incomplete = mpmath.gammainc(K, 0, K)  # the lower incomplete gamma(K, K)
    return float(K / (K - 1) * ((1 - mpmath.exp(-K)) / K - K ** (-K) * incomplete))

for K in (0.1, 3.0, 30.0):
    say(f"K = {K:5}: eta = {efficiency(K):.10f}")
```

The closed form of line 6. `mpmath.mpf` makes a 30-digit number; `mpmath.gammainc(K, 0, K)` is $\int_0^K u^{K-1}e^{-u}du = \gamma(K, K)$. The result is returned as an ordinary decimal number. Out [9] prints $\eta = 0.9955325865$, 0.4110164748 and 0.0344827586 for $K = 0.1$, 3 and 30.

In [10]: the rate model integrated with RK4.

```
def integrate(K, eps=1.0, erase=True, keep_every=50):
    """RK4 for (n, a) from t = 0 to 60 + 40/K; returns the final state and the
    history (every keep_every-th step)."""
    t_end = 60.0 + 40.0 / K  # long enough for n and n_eq to be negligible
    steps = int(np.ceil(t_end / min(0.1 / K, 0.02)))  # step below 0.1/K
    dt = t_end / steps
```

The integration runs to $t = 60 + 40/K$, by which time n and n_{eq} are negligible (for slow decays n approaches n_{eq} only on the time scale $1/K$). The step is at most $0.1/K$ and at most 0.02; `np.ceil` rounds the number of steps up to a whole number, and `dt` is the exact step.

```
    def rates(time, y):
        n_eq = np.exp(-time)
        return np.array([-K * (y[0] - n_eq),
                         eps * K * (y[0] - n_eq) - (K * n_eq * y[1] if erase else 0)])
```

The right sides of the two equations of Section 21.6 for the state $y = (n, a)$; with `erase=False` the erasing term is left out.

```
    y, time, history = np.array([1.0, 0.0]), 0.0, [(0.0, 1.0, 0.0)]
    for step in range(steps):
        k1 = rates(time, y)
        k2 = rates(time + dt / 2, y + dt / 2 * k1)
        k3 = rates(time + dt / 2, y + dt / 2 * k2)
        k4 = rates(time + dt, y + dt * k3)
        y = y + dt / 6 * (k1 + 2 * k2 + 2 * k3 + k4)
        time += dt
        if (step + 1) % keep_every == 0:
            history.append((time, y[0], y[1]))
    return y, np.array(history)
```

The classical fourth-order **Runge-Kutta method** (Chapter 2): from the start $n = 1$, $a = 0$, each step evaluates the slopes at the beginning, twice in the middle and at the end of the step, and advances with their weighted average; the error over a fixed time falls like dt^4. Every 50th state is kept for the figure.

```
RATES = (0.1, 3.0, 30.0)
runs = {K: integrate(K) for K in RATES}
for K in RATES:
    say(f"K = {K:5}: RK4 a(infinity) = {runs[K][0][1]:.10f}, "
        f"closed form {efficiency(K):.10f}")
check(all(abs(runs[K][0][1] - efficiency(K)) < 1e-7 for K in RATES),
      "RK4 agrees with the closed form eta(K) to 1e-7 for K = 0.1, 3, 30")
```

The three integrations with $\epsilon = 1$; the final asymmetry (`runs[K][0][1]`, the second entry of the final state) is printed next to the closed form. Out [10] shows agreement to 10 decimals for $K = 0.1$ and 30 and to 5×10^{-10} for $K = 3$ (0.4110164753 against 0.4110164748); the check demands 10^{-7}.

```
no_cp, _ = integrate(3.0, eps=0.0)
no_erase, _ = integrate(3.0, erase=False)
check(no_cp[1] == 0.0 and abs(no_erase[1] - 1.0) < 1e-9,
      "controls: eps = 0 gives a = 0 exactly; without erasing a(infinity) = eps")
```

The two controls of Section 21.6: with $\epsilon = 0$ the asymmetry stays exactly zero; without the erasing term the final asymmetry is $\epsilon = 1$.

In [11]: the histories.

```
fig, axes = plt.subplots(2, 1, figsize=(8.0, 6.6), sharex=True)
times = np.linspace(0.0, 60.0, 601)
axes[0].semilogy(times, np.exp(-times), color="black", linewidth=1,
                 label="equilibrium $n_{eq} = e^{-t}$")
```

Two panels stacked vertically; the top one draws $n_{eq} = e^{-t}$ on a logarithmic axis from $t = 0$ to 60.

```
for K, style in zip(RATES, ["-", "--", ":"]):
    history = runs[K][1]
    shown = history[history[:, 0] <= 60.0]
    axes[0].semilogy(shown[:, 0], shown[:, 1], style, linewidth=2,
                     label=f"$n$, $K = {K}$")
    axes[1].plot(shown[:, 0], shown[:, 2], style, linewidth=2, label=f"$K = {K}$")
```

For each rate the stored history (columns: time, n, a), restricted to $t \leq 60$ (`history[:, 0] <= 60.0` marks the rows to keep); n in the top panel, a in the bottom one.

```
axes[0].set_ylim(1e-12, 2.0)
axes[0].set_ylabel("heavy pairs (log scale)")
axes[0].legend(fontsize=8, loc="lower left")
axes[1].set_xlabel("time $t$ (units of the cooling time)")
axes[1].set_ylabel("asymmetry $a/\\epsilon$")
axes[1].set_ylim(0.0, 1.05)
axes[1].legend(fontsize=8, loc="center right", bbox_to_anchor=(1.0, 0.68))
```

Axis ranges, labels and legends; `bbox_to_anchor` places the lower legend at the right edge, 68 per cent of the way up.

```
save_figure(fig, "rate_model_histories",
            "The rate model of decays out of equilibrium for three decay rates $K$. "
            "Top: the number $n$ of heavy pairs (coloured) and the equilibrium "
            "value $n_{eq} = e^{-t}$ (thin black), logarithmic scale. Bottom: the "
            "asymmetry $a/\\epsilon$. Horizontal axis the time in units of the "
            "cooling time (pure numbers). Slow decays ($K = 0.1$) happen late, "
            "far from equilibrium, when nothing erases their product: almost the "
            "whole $\\epsilon$ survives. Fast decays ($K = 30$) keep $n$ close to "
            "$n_{eq}$, and the inverse decays erase almost everything.")
```

Figure 21d.4. **What the figure shows.** Top: for $K = 3$ and $K = 30$ the curves of n lie on or just above the black line of equilibrium; for $K = 0.1$ the curve stays far above it and falls only slowly, like e^{-Kt}. Bottom: all three asymmetries rise steadily to their final values (they never decrease in this model): nearly 1 for $K = 0.1$, 0.41 for $K = 3$ and only $1/29$ for $K = 30$, because the faster the decays, the more of their product the inverse decays erase while it is being made.

In [12]: the efficiency for all rates.

```
K_grid = np.logspace(-2.0, 3.0, 24)  # 24 rates; K = 1 is not among them
eta = np.array([efficiency(K) for K in K_grid])
check(eta[0] > 0.99 and abs(efficiency(1000.0) * 999.0 - 1.0) < 1e-12
      and np.all(np.diff(eta) < 0),
      "efficiency: near 1 for K = 0.01, exactly 1/(K - 1) at K = 1000, decreasing")
```

`np.logspace(-2, 3, 24)` gives 24 rates from 10^{-2} to 10^{3}, equally spaced on a logarithmic scale (the formula has $K - 1$ in a denominator, and $K = 1$ is not among them). The efficiency is above 0.99 for $K = 0.01$, equals $1/999$ at $K = 1000$ to 10^{-12} relative accuracy (the exponentially small terms are invisible), and decreases from each rate to the next (`np.diff` gives the differences of neighbours).

```
fig, ax = plt.subplots(figsize=(7.5, 4.4))
ax.loglog(K_grid, eta, "-", linewidth=2, label="closed form $\\eta(K)$")
ax.loglog(K_grid[K_grid > 2], 1 / (K_grid[K_grid > 2] - 1), ":", color="black",
          label="$1/(K - 1)$: near equilibrium")
ax.loglog(RATES, [runs[K][0][1] for K in RATES], "o", color="#e34948",
          label="RK4 integration")
ax.set_xlabel("decay rate $K$ (units of the cooling rate)")
ax.set_ylabel("efficiency $a(\\infty)/\\epsilon$")
ax.set_title("Equilibrium erases the asymmetry")
ax.legend(fontsize=8, loc="lower left")
```

Both axes logarithmic: the closed form, the fast-decay limit $1/(K - 1)$ for $K > 2$, and the three RK4 results as red dots.

```
save_figure(fig, "washout_efficiency",
            "The efficiency $\\eta(K) = a(\\infty)/\\epsilon$ of the rate model: the "
            "fraction of the asymmetry made by the decays that survives, versus "
            "the decay rate $K$, both on logarithmic scales (pure numbers). Solid: "
            "the closed form with the incomplete gamma function; dots: the RK4 "
            "integrations; dotted: the limit $1/(K - 1)$. Slow decays (out of "
            "equilibrium) keep almost all of it; the closer the decays are to "
            "equilibrium (large $K$), the less survives: condition 3.")
```

Figure 21d.5. **What the figure shows.** A flat plateau near 1 for small rates that bends down into a straight line of slope -1 for large rates, on which the dotted limit lies; the three red dots sit on the curve.

In [13]: this theory, condition 1.

```
Q_channel = sp.Symbol("Q_channel")  # the common charge of every channel
eps_theory = net.subs({N: 1, B1: Q_channel, B2: Q_channel})  # B1 = B2
a_theory, _ = integrate(0.1, eps=float(eps_theory))  # slow decays, far from equil.
```

In this theory every channel of every process carries the same charge (Section 21.31): the decay formula with $\mathcal{B}_1 = \mathcal{B}_2$ gives the net charge per pair, and the rate model is run with that ϵ and the slowest rate, as far from equilibrium as in In [10].

```
say(f"net charge per pair with equal channels: {eps_theory}; rate model: "
    f"a(infinity) = {a_theory[1]}")
check(LEAD["u1_noether_matrix_identity"] == "PASS" and eps_theory == 0
      and a_theory[1] == 0.0,
      "local U(1) law: no process makes a net charge at any point of the patch "
      "0 < z < pi/2, condition 1 fails there (total charge: no flux through the "
      "brane ASSUMED)",
      record=f"{LEAD_FILE}, check u1_noether_matrix_identity")
```

Out [13] prints a net charge 0 and $a(\infty) = 0.0$; the check also demands the record's verdict PASS for the local conservation law $\partial_\mu(\cos z\, J^\mu) = 0$. Its label says what that verdict gives: no process makes a net charge at any point of the patch $0 < z < \pi/2$ (the local law is proved there, off the brane $z = \pi/2$), so condition 1 fails there; for the total charge of a universe the no-flux condition at the brane is needed in addition, and it is ASSUMED (Section 21.31). The label is one text made of three string pieces that stand next to each other, and `record=` names the record file and check on the PASS line.

In [14]: this theory, condition 2: the Lagrangian at a point.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
gamma = [np.array(mat, dtype=np.int64) for mat in fixture["gamma"]]  # x0 .. x7
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # C = g(x0) g(x1) g(x2) g(x3)
Gamma = C @ gamma[4] @ gamma[5] @ gamma[6] @ gamma[7]  # the chirality
```

The Revision gammas, C and Γ, as in Notebook 21c.

```
THEORY = {f["key"]: f["wl"] for f in json.loads(repository_file(
    "Revision/theory/field-theory.json").read_text(encoding="utf-8"))["formulas"]}
lagrangian_text = ("L = Cos[z] [ (1/2) sum_mu (Psibar gammaˆmu D_mu Psi - (D_mu "
                   "Psibar) gammaˆmu Psi) - m S - U(S) ]")
omega_text = ["(1/2) Eˆa4[x4] Sin[6 H x0]ˆ(1/6) (a4",
              "g[xi].g[x4] + H g[xi].g[x0]) (i = 1, 2, 3)",
              "-(1/2) Eˆ-a4[x4] Sin[6 H x0]ˆ(1/6) (a4",
              "g[x4].g[xt] + H g[xt].g[x0]) (t = 5, 6, 7)", "Omega_x0 = Omega_x4 = 0"]
record_ok = (THEORY["Lagrangian"].startswith(lagrangian_text)
             and all(piece in THEORY["Omega_components"] for piece in omega_text))
```

The record's formulas; the beginning of its Lagrangian and pieces of its spin connection, in the record's notation, which the notebook uses below; `record_ok` is true when the record states them so.

```
H, z, a4, a4p = 1 / 6, 0.7, 0.4, 0.25  # the point of the author's metric
s16 = np.sin(z) ** (1 / 6)
f = [1 / np.tan(z)] + [np.exp(a4) * s16] * 3 + [1.0] + [np.exp(-a4) * s16] * 3
```

A point of the author's metric, now with plain numbers: $H = 1/6$, $z = 0.7$, $a_4 = 0.4$, $a_4' = 0.25$; and the eight scale factors there ($1/\tan z = \cot z$).

```
Omega = []  # the record's formula Omega_components at the point
for mu in range(8):
    if mu in (1, 2, 3):  # x1, x2, x3
        Omega.append(np.exp(a4) * s16 / 2 * (a4p * gamma[mu] @ gamma[4]
                                             + H * gamma[mu] @ gamma[0]))
    elif mu in (5, 6, 7):  # x5, x6, x7: the deflating extra times
        Omega.append(-np.exp(-a4) * s16 / 2 * (a4p * gamma[4] @ gamma[mu]
                                               + H * gamma[mu] @ gamma[0]))
    else:  # x4 and x0
        Omega.append(np.zeros((16, 16)))
gamma_up = [gamma[mu] / f[mu] for mu in range(8)]  # curved gammas at the point
```

The record's spin connection (Section 21.17) evaluated at the point, and the curved gammas.

```
def lagrangian(p, dp, m, lam):
    """The record's Lagrangian at the point for the field value p and the eight
    first derivatives dp[mu] (commuting components)."""
    bar = np.conj(p) @ C  # Psibar = Psi^dagger C
    kinetic = 0.0
    for mu in range(8):
        D = dp[mu] + Omega[mu] @ p  # D_mu Psi
        Dbar = np.conj(dp[mu]) @ C - bar @ Omega[mu]  # D_mu Psibar
        kinetic += (bar @ gamma_up[mu] @ D - Dbar @ gamma_up[mu] @ p) / 2
    S = bar @ p
    return np.cos(z) * (kinetic - m * S - lam / 2 * S ** 2)
```

The Lagrangian density of the record at the point, as in In [9] of Notebook 21b, with the mass and the coupling as arguments.

```
rng = np.random.default_rng(2104)  # fixed seed: the same numbers in every run
psi = rng.normal(size=16) + 1j * rng.normal(size=16)
dpsi = rng.normal(size=(8, 16)) + 1j * rng.normal(size=(8, 16))
dpsi = np.roll(dpsi, 1, axis=0)  # drawn with x0 last, as before; now x0 first
m_value, lam_value = 0.7, 0.3
```

A fixed random field value and eight derivatives (seed 2104), $m = 0.7$, $\lambda = 0.3$. The derivatives are drawn with the hidden direction last, as before the move to the author's coordinates, and `np.roll` moves that row to the front (row μ belongs to x_μ), so every printed number stays the same.

```
values = {
    "L[Psi]": lagrangian(psi, dpsi, m_value, lam_value),
    "L[Psi*]": lagrangian(np.conj(psi), np.conj(dpsi), m_value, lam_value),
```

```
    "L[Gamma Psi]": lagrangian(Gamma @ psi, dpsi @ Gamma.T, m_value, lam_value),
    "L[Gamma Psi*]": lagrangian(Gamma @ np.conj(psi), np.conj(dpsi) @ Gamma.T,
                                m_value, lam_value),
    "-L_(-m,-lambda)[Psi]": -lagrangian(psi, dpsi, -m_value, -lam_value)}
```

Five numbers: the Lagrangian of Ψ; of Ψ^* (value and derivatives conjugated); of $\Gamma\Psi$, whose derivatives are $\Gamma\partial_\mu\Psi$ (each row of `dpsi` times Γ^T from the right is Γ times that row); of $\Gamma\Psi^*$; and minus the Lagrangian of Ψ with the reversed parameters.

```
for label, value in values.items():
    say(f"{label:21}: {value.real:+.10f} (imaginary part below 1e-12: "
        f"{abs(value.imag) < 1e-12})")
```

Out [14] prints -11.2851368126 for $\mathcal{L}[\Psi]$ and $\mathcal{L}[\Psi^*]$ and $+8.4767165144$ for the other three, all real.

```
check(record_ok and all(abs(v.imag) < 1e-12 for v in values.values())
      and abs(values["L[Psi*]"] - values["L[Psi]"]) < 1e-12,
      "commuting field: L[Psi*] = L[Psi], the same-mass conjugation is exact")
check(abs(values["L[Gamma Psi]"] - values["-L_(-m,-lambda)[Psi]"]) < 1e-12
      and abs(values["L[Gamma Psi*]"] - values["-L_(-m,-lambda)[Psi]"]) < 1e-12
      and PAIR["T1_Lagrangian_primordial_commuting"] == "PASS",
      "L[Gamma Psi] = L[Gamma Psi*] = -L_(-m,-lambda)[Psi]: these maps reverse m",
      record=f"{PAIR_FILE}, check T1_Lagrangian_primordial_commuting")
```

The same-mass conjugation keeps the Lagrangian (Section 21.31); Γ and $\Gamma\Psi^*$ map it to minus the Lagrangian with $(-m, -\lambda)$ (theorem T1).

```
check(LEAD["bilinears_under_charge_conjugation"] == "PASS"
      and LEAD["quantum_charge_conjugation_unitary_type"] == "PASS",
      "record: calC_+ keeps S and reverses J (commuting); the quantised field has "
      "only the mass-reversing conjugation",
      record=f"{LEAD_FILE}, check quantum_charge_conjugation_unitary_type")
```

The two record verdicts on which row 2 of the scorecard rests.

In [15]: the five Lagrangian values as bars.

```
fig, ax = plt.subplots(figsize=(8.5, 4.3))
labels = ["$\\mathcal{L}_{m,\\lambda}[\\Psi]$", "$\\mathcal{L}_{m,\\lambda}[\\Psi^*]$",
          "$\\mathcal{L}_{m,\\lambda}[\\Gamma\\Psi]$",
          "$\\mathcal{L}_{m,\\lambda}[\\Gamma\\Psi^*]$",
          "$-\\mathcal{L}_{-m,-\\lambda}[\\Psi]$"]
colours = ["#2a78d6", "#2a78d6", "#e34948", "#e34948", "#999999"]
ax.bar(range(5), [v.real for v in values.values()], color=colours)
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(range(5), labels, fontsize=9)
ax.set_ylabel("value of the Lagrangian density at the point")
ax.set_title("Same-mass conjugation keeps $\\mathcal{L}$; $\\Gamma$ reverses the mass")
```

Five bars with LaTeX labels: blue for Ψ and Ψ^*, red for the two images, grey for the comparison value.

```
save_figure(fig, "lagrangian_maps",
            "The Lagrangian density of the Revision record for the commuting field "
            "at one point of the author's metric ($H = 1/6$, $z = 0.7$, $a_4 = 0.4$, "
            "$a_4' = 0.25$, $m = 0.7$, $\\lambda = 0.3$, a fixed field value and "
            "fixed first derivatives): for $\\Psi$ and its same-mass conjugate "
            "$\\Psi^\\ast$ (blue, equal), for the images $\\Gamma\\Psi$ and "
            "$\\Gamma\\Psi^\\ast$ (red) and for minus the Lagrangian of the reversed "
            "mass and coupling (grey); vertical axis the value (pure numbers). The "
            "red bars equal the grey one: $\\Gamma$ maps the theory with $(m, "
            "\\lambda)$ to the theory with $(-m, -\\lambda)$.")
```

Figure 21d.6. **What the figure shows.** Two equal blue bars below zero (-11.29) and three equal bars above zero ($+8.48$).

In [16]: the invariant Majorana-type matrices.

```
from sympy.polys.matrices import DomainMatrix  # exact matrices over the rationals

I16 = np.eye(16, dtype=np.int64)
pairs = [(a, b) for a in range(8) for b in range(a + 1, 8)]  # the 28 generators
S2 = {(a, b): gamma[a] @ gamma[b] for a, b in pairs}  # 2 S^ab = gamma^a gamma^b
```

The exact solver of Notebook 21a, the identity, the 28 pairs of directions and, for each, $2S^{ab} = \gamma^a\gamma^b$ (twice the generator: whole numbers, and the factor 2 does not change the solutions of the homogeneous equations).

```
# unknown M read row by row: S^T M -> kron(S^T, 1), M S -> kron(1, S^T)
system = np.vstack([np.kron(S.T, I16) + np.kron(I16, S.T) for S in S2.values()])
null = DomainMatrix.from_list(system.tolist(), sp.QQ).nullspace().to_Matrix()
basis = np.array([np.array(null.row(k).tolist()[0], dtype=float)
                  for k in range(null.rows)])  # each row: one solution, 256 numbers
```

With M read row by row as in Notebook 21a, S^TM is `np.kron(S.T, I16)` applied to it and MS is `np.kron(I16, S.T)` applied to it; the 28 blocks of 256 equations are stacked and solved exactly. Each row of `basis` is one solution, 256 decimal numbers.

```
CG = C @ Gamma
span_ok = all(np.linalg.matrix_rank(np.vstack([basis, M.reshape(1, -1)])) == 2
              for M in (C, CG))
say(f"{system.shape[0]} equations; dimension of the solution space: {null.rows}")
```

$C\Gamma$; and `span_ok` is true when adding C (or $C\Gamma$) as a third row to the two basis rows leaves the rank at 2, that is, when each lies in the space of solutions. Out [16] prints 7168 equations and dimension 2.

```
check(null.rows == 2 and span_ok
      and all(np.array_equal(C @ S @ C, -S.T) for S in S2.values())
      and ALGEBRA["spin_commutant_dimension_2"] == "PASS",
      "invariant Majorana-type matrices: a 2-dimensional space spanned by C, C Gamma",
      record=f"{ALGEBRA_FILE}, check spin_commutant_dimension_2")
```

The space has dimension 2 and is spanned by C and $C\Gamma$; the identity $CSC = -S^T$ of Section 21.32 holds for all 28 generators; the algebra record's commutant has dimension 2.

```
ETA = [1, 1, 1, 1, -1, -1, -1, -1]

def exp_generator(a, b, theta):
    """exp(theta S^ab) for S^ab = gamma^a gamma^b / 2 (a rotation or a boost)."""
    S = S2[(a, b)] / 2
    if ETA[a] * ETA[b] == 1:  # S^2 = -1/4: a rotation
        return np.cos(theta / 2) * np.eye(16) + 2 * np.sin(theta / 2) * S
    return np.cosh(theta / 2) * np.eye(16) + 2 * np.sinh(theta / 2) * S  # a boost
```

The signs of the frame metric, and the finite transformation $e^{\theta S^{ab}}$ by the formulas of Section 21.32: a rotation when the two directions have the same sign of η, a boost otherwise.

```
R = exp_generator(1, 2, 0.7) @ exp_generator(1, 4, 0.4) @ exp_generator(0, 5, 1.1)
check(np.allclose(R.T @ C @ R, C) and np.allclose(R.T @ CG @ R, CG)
      and not np.allclose(R.T @ R, np.eye(16)),
      "a finite rotation-boost R keeps C and C Gamma (R^T M R = M), not the identity")
```

A product of a rotation in the plane of x_1, x_2 (angle 0.7), a boost in the plane of x_1, x_4 (0.4) and a boost in the plane of x_0, x_5 (1.1; the same boost as -1.1 in the plane of x_5, x_0, because $S^{x_0 x_5} = -S^{x_5 x_0}$). It keeps C and $C\Gamma$ ($R^T M R = M$), while $R^T R$ is not the identity: the invariance is not an accident of an orthogonal R.

```
symmetric = np.array_equal(C, C.T) and np.array_equal(CG, CG.T)
psi_c = rng.normal(size=16) + 1j * rng.normal(size=16)  # a commuting field value
alpha = 0.9
phase_ok = all(np.isclose((np.exp(1j * alpha) * psi_c) @ M @ (np.exp(1j * alpha)
                                                              * psi_c),
                          np.exp(2j * alpha) * (psi_c @ M @ psi_c)) for M in (C, CG))
check(symmetric and phase_ok and abs(psi_c @ C @ psi_c) > 0.1,
      "C, C Gamma symmetric: zero for anticommuting components; for commuting "
      "ones nonzero, charge 2")
```

Both matrices are symmetric, so the terms vanish for anticommuting components (Section 21.32). For a commuting field value (the generator of In [14] continues), the term $\Psi^T M \Psi$ is multiplied by $e^{2i\alpha}$ when Ψ is multiplied by $e^{i\alpha}$ ($\alpha = 0.9$): charge 2; and $\Psi^T C \Psi$ is not zero.

In [17]: the two matrices and the phase of the term.

```
from matplotlib.colors import LinearSegmentedColormap
```

```
SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.2), width_ratios=[1, 1, 1.3])
```

The blue-white-red colour map and three panels, the last one wider.

```
for ax, M, title in ((axes[0], C, "$C$ (symmetric)"),
                     (axes[1], CG, "$C\\Gamma$ (symmetric)")):
    image = ax.imshow(M, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.set_xlabel("column")
    ax.axhline(7.5, color="black", linewidth=0.8)
    ax.axvline(7.5, color="black", linewidth=0.8)
    ax.grid(False)
axes[0].set_ylabel("row")
```

Heat maps of C and $C\Gamma$ with the lines that separate the two halves.

```
alphas = np.linspace(0.0, np.pi, 91)
majorana = np.array([(np.exp(1j * x) * psi_c) @ C @ (np.exp(1j * x) * psi_c)
                     for x in alphas])
scalar = np.array([np.conj(np.exp(1j * x) * psi_c) @ C @ (np.exp(1j * x) * psi_c)
                   for x in alphas])
base = np.angle(majorana[0])
```

91 phases α from 0 to π; for each, the Majorana-type term $\Psi^T C \Psi$ and the scalar $\Psi^\dagger C \Psi$ of the rotated field. `np.angle` gives the phase of a complex number; `base` is the phase of the term at $\alpha = 0$.

```
axes[2].plot(alphas, np.unwrap(np.angle(majorana)) - base, linewidth=2,
             label="$\\Psi^T C\\Psi$: phase $2\\alpha$ (charge 2)")
axes[2].plot(alphas, np.angle(scalar) - np.angle(scalar[0]), "--", linewidth=2,
             label="$\\Psi^\\dagger C\\Psi$: unchanged (charge 0)")
axes[2].set_xlabel("phase $\\alpha$ of $\\Psi \\to e^{i\\alpha}\\Psi$")
axes[2].set_ylabel("change of the phase of the term")
axes[2].legend(fontsize=8)
axes[2].set_title("A Majorana-type term carries charge 2")
```

The change of the phase of each term against α. `np.angle` returns values between $-\pi$ and π, so the phase of the Majorana-type term jumps by 2π when it passes π; `np.unwrap` removes these jumps.

```
save_figure(fig, "majorana_terms",
            "Left and middle: heat maps of the only two matrices $M$ for which a "
            "Majorana-type term $\\Psi^T M\\Psi$ is invariant under the rotations and "
            "boosts of Spin(4,4), $C$ and $C\\Gamma$ (horizontal axis the column, "
            "vertical axis the row, red $+1$, blue $-1$); both are symmetric, so "
            "the term vanishes for anticommuting components. Right: the change of "
            "the phase of $\\Psi^T C\\Psi$ (solid) and of $\\Psi^\\dagger C\\Psi$ "
```

```
            "(dashed) for a commuting field under $\\Psi \\to e^{i\\alpha}\\Psi$, "
            "versus $\\alpha$ (radians): the Majorana-type term turns twice as "
            "fast, it carries U(1) charge 2 and would break the U(1) symmetry "
            "and with it the local conservation law of the charge.")
```

Figure 21d.7. **What the figure shows.** Left and middle: two block-diagonal patterns, each its own mirror image across the diagonal (symmetric). Right: a straight line of slope 2, reaching 2π at $\alpha = \pi$, and a flat dashed line at zero.

In [18]: the scorecard from the record's verdicts.

```
def status(passed, text):
    """The status text when the record check passed, otherwise UNSUPPORTED."""
    return text if passed else "UNSUPPORTED"
```

A status is written only if the record check behind it passed; otherwise the row would read UNSUPPORTED (and the check below would fail).

```
ROWS = [
    ("1. a process changes the number",
     "local U(1) law d_mu(cos z J^mu) = 0 for every history a4: no process inside "
     "the patch changes Q; the total Q is constant only if no charge flows "
     "through the brane z = pi/2 (ASSUMED, not derived)",
     status(LEAD["u1_noether_matrix_identity"] == "PASS",
            "inside the patch: FAILS (PROVED); total: no flux ASSUMED"),
     "u1_noether_matrix_identity"),
```

Each row has four entries: the condition, what this theory has, the status, and the record check. Row 1 has two parts (Section 21.31): condition 1 fails for every process inside the patch, proved by the U(1) identity (the local law, written in plain letters: `d_mu(cos z J^mu) = 0` is $\partial_\mu(\cos z\, J^\mu) = 0$); for the total charge of a universe the no-flux condition at the brane is needed, and the status says that it is ASSUMED. The status text is written only if the lead check `u1_noether_matrix_identity` has the verdict PASS.

```
    ("2. C and CP violated",
     "commuting field: the same-mass conjugation is an exact symmetry that "
     "reverses the charge, so a C-symmetric start keeps zero charge; quantised "
     "field: the only conjugation, Gamma, reverses the mass; no rates computed",
     status(all(LEAD[name] == "PASS" for name in (
         "representation_real", "spinor_connection_real",
         "bilinears_under_charge_conjugation",
         "quantum_charge_conjugation_unitary_type")),
         "commuting: FAILS (PROVED); quantised: NOT COMPUTED"),
     "representation_real, spinor_connection_real, "
     "bilinears_under_charge_conjugation, quantum_charge_conjugation_unitary_type"),
```

Row 2 has two statuses, one for each field (Section 21.31). For the commuting field dirac16complex00 condition 2 fails: the same-mass conjugation is exact (all matrices of $\mathcal{L}$ are real) and reverses the charge, so by Proposition 2 of Section 21.5 a start in which every configuration and its conjugate are

equally likely keeps zero average charge. For the quantised field dirac16complex it is not computed. `all(...)` is `True` only when every one of the four named lead checks has the verdict PASS: `representation_real` and `spinor_connection_real` (the reality of the gammas, of C and of the Ω_μ), `bilinears_under_charge_conjugation` (the conjugation reverses the current) and `quantum_charge_conjugation_unitary_type` (the quantised field has only the mass-reversing conjugation). Python joins two string pieces that stand next to each other into one text: the last entry is the list of the four checks.

```
    ("3. out of equilibrium",
     "no rate computed; the Kohn-Sham history is a prescribed background",
     status(KS["ks_history_is_a_prescribed_background"] == "PASS", "NOT COMPUTED"),
     "ks_history_is_a_prescribed_background"),
```

Row 3: not computed; the only history of the record is a prescribed background.

```
    ("pair level (theorem T1)",
     "the partner Gamma Psi of mass -m carries the opposite current: total charge 0",
     status(PAIR["T1_current_primordial_commuting"] == "PASS"
            and PAIR["T1_current_primordial_grassmann"] == "PASS",
            "PROVED (classical bilinears)"),
     "T1_current_primordial_commuting, T1_current_primordial_grassmann"),
```

The pair-level row: proved for classical bilinears, for both fields.

```
    ("verdict",
     "no process makes a net charge at any point of the patch 0 < z < pi/2 of one "
     "universe (nor a total charge, under the ASSUMED no-flux condition at the "
     "brane); no baryons in the theory",
     status(LEAD["u1_noether_matrix_identity"] == "PASS", "PROBLEM NOT SOLVED"),
     "the checks above")]
for row in ROWS:
    say(f"{row[0]:34} | {row[2]}")
```

The verdict row (its second entry is again one text, made of three string pieces that stand next to each other), and a loop that prints the condition (padded to 34 characters) and the status of each row: Out [18].

```
check([row[2] for row in ROWS] == [
          "inside the patch: FAILS (PROVED); total: no flux ASSUMED",
          "commuting: FAILS (PROVED); quantised: NOT COMPUTED",
          "NOT COMPUTED", "PROVED (classical bilinears)", "PROBLEM NOT SOLVED"],
      "scorecard: every status is backed by a PASS verdict of the Revision record")
```

The five statuses must be exactly these, which is possible only if every record check behind them passed. The list of the five expected texts opens with `[` at the end of the first line and is written one or more texts per line.

In [19]: the scorecard as a figure.

```
COLOURS = {"inside the patch: FAILS (PROVED); total: no flux ASSUMED": "#f4c7c3",
           "commuting: FAILS (PROVED); quantised: NOT COMPUTED": "#f2e2b8",
           "NOT COMPUTED": "#e3e3e3", "PROVED (classical bilinears)": "#cfe8c4",
           "PROBLEM NOT SOLVED": "#f4c7c3"}
fig, ax = plt.subplots(figsize=(13.0, 6.2))
ax.set_xlim(0, 13.0)
ax.set_ylim(0, len(ROWS) + 1)
ax.axis("off")
```

A pale background colour for each status (red for the failure of condition 1, whose status names its two parts, and for the verdict, yellow for the two statuses of condition 2, fails for the commuting field and not computed for the quantised one, grey for not computed, green for proved). The figure is used as a drawing area with coordinates from 0 to 13 across and 0 to 6 up; `ax.axis("off")` hides the axes.

```
columns = [(0.1, 2.4, "Sakharov condition"), (2.6, 4.3, "this theory"),
           (7.1, 2.3, "status"), (9.5, 3.5, "Revision record check")]
for x0, width, heading in columns:
    ax.text(x0, len(ROWS) + 0.5, heading, fontsize=11, fontweight="bold",
            va="center")
```

The four columns, each with its left edge, its width and its heading; the headings are written in bold in the top line.

```
for k, row in enumerate(ROWS):
    y = len(ROWS) - k - 0.5  # the first row at the top
    ax.add_patch(plt.Rectangle((0.0, y - 0.48), 13.0, 0.96, color=COLOURS[row[2]],
                               zorder=0))
    for (x0, width, _), text in zip(columns, row):
        chars = int(width * 11.5)  # about 11 characters per unit of width
        ax.text(x0, y, textwrap.fill(text, chars, break_long_words=False),
                fontsize=8.5, va="center")  # long check names stay whole
ax.set_title("Sakharov's conditions applied to the theory as built", fontsize=12)
```

For each row, from the top down: a coloured band across the whole width (`zorder=0` puts it behind the text), and the four entries, each broken into lines that fit its column (`textwrap.fill` of the set-up cell; `break_long_words=False` keeps long check names whole).

```
save_figure(fig, "scorecard",
            "The scorecard of the theory as built against Sakharov's three "
            "conditions, with the status of each row and the Revision record "
            "check it rests on (each status is set by the notebook only when the "
            "record holds that check with the verdict PASS). Condition 1 fails "
            "for every process inside the patch (the local U(1) law holds for "
            "every history $a_4$), so there conditions 2 and 3 cannot help; the "
            "total charge of a universe is constant only under the no-flux "
            "condition at the brane $z = \\pi/2$, which is ASSUMED; condition 2 "
            "also fails for the "
            "commuting field (its same-mass conjugation is exact) and is not "
            "computed for the quantised field; the pair-level statement of theorem "
```

```
        "T1 is exact but creates nothing. The theory does not solve the "
        "matter-antimatter problem.")
```

Figure 21d.8. **What the figure shows.** A table of five coloured rows: red for condition 1 (fails inside the patch; for the total charge the no-flux condition is ASSUMED) and for the verdict (problem not solved), yellow for condition 2 (fails for the commuting field, not computed for the quantised field), grey for condition 3 (not computed), green for the pair level (proved for classical bilinears), each with the record checks it rests on.

In [20]: the figure files.

```
names = sorted(FIGURE_NUMBERS, key=FIGURE_NUMBERS.get)
check(len(names) == 8 and all(
    output_file(f"{FIGURE_FOLDER}/21d_{FIGURE_NUMBERS[n]}_{n}.png").is_file()
    for n in names), "the eight figure files of notebook 21d exist")
all_checks_passed()
```

The eight figure files exist, and the last line prints ALL 19 CHECKS PASSED (notebook 21d).

21.37 The scorecard, pairs of universes as a hypothesis, and what would be needed

The scorecard. Figure 21d.8 and the table of Section 21.31 put the three conditions side by side. Condition 1 fails exactly for every process inside the patch, and for the total charge of a universe under the ASSUMED no-flux condition at the brane; condition 2 fails exactly for the commuting field and is not computed for the quantised field; condition 3 is not computed; and conditions 2 and 3 could not help while condition 1 fails; the pair-level statement is exact but creates nothing. **The theory as built does not solve the matter-antimatter problem.** It contains no baryons, no process of it changes the charge at any point inside the patch $0 < z < \pi/2$ of one universe (the total charge could change only by a flow through the brane, which the record neither excludes nor describes), and it predicts no value of the baryon-to-photon ratio η_B.

Pairs of universes, stated as a hypothesis. Theorem T1 suggests a picture of the kind described at the end of Section 21.19: our universe carries some charge, and a partner universe of mass $-m$ carries the opposite charge, so that the pair as a whole is symmetric. The picture rests on three statements, each of which is a **HYPOTHESIS**: nothing in the Revision record derives it.

- **H1 (HYPOTHESIS).** Our universe is one member of a T1 pair: two configurations in the same gravitational field, Ψ with the parameters (m, λ) and its partner $\Gamma\Psi$ with $(-m, -\lambda)$, in this correlated configuration.
- **H2 (HYPOTHESIS).** The configuration has a nonzero charge, $Q \neq 0$. Given H1, the partner has $-Q$ by theorem T1; the content of H2 is $Q \neq 0$, and nothing computes its value or its sign.
- **H3 (HYPOTHESIS, not derivable within the theory).** The U(1) charge of the field is the baryon number (or the difference of baryon and lepton numbers). The theory contains no quarks, baryons or leptons, so this cannot be derived from it.

What would follow, and only for classical fields. If H1, H2 and H3 held, the two charges would add to zero at every time (theorem T1), each would be separately constant under the ASSUMED no-flux condition at the brane (Sections 21.17 and 21.18), and the baryon excess of one member would be balanced by the opposite excess of the other.

What the picture does not do.

- It does not produce an asymmetry. Under the no-flux condition each charge is constant, so a nonzero charge today is the same as a nonzero charge at the start: the asymmetry is an initial condition, put in by H2. Without that condition a charge could change only by a flow through the brane, which the record does not describe; no asymmetry is computed either way.
- It does not predict η_B: neither the size nor the sign of the charge is computed, nor the photons to which η_B refers.
- It does not meet Sakharov's conditions; it replaces them by an assumed correlated configuration.
- At the quantum level there is no cancellation between two independently quantised universes: the chirality image is the same quantum system with the Krein metric $-B$, and an independent universe of mass $-m$ carries $+B$ and its own charge (Section 21.19).
- It does not show that pairs are created (Chapter 20), and it does not say that antimatter has negative mass.
- It is a statement about a model in signature (4,4), with four time-like directions, while observed spacetime has one time; applying it to "our universe" is a further assumption.

A published example of the class of universe/anti-universe ideas is the CPT-symmetric universe of Boyle, Finn and Turok, Phys. Rev. Lett. 121, 251301 (2018) (Section 21.19); it is cited as an example of the class only.

What would have to be added (all OPEN; none of these ingredients is present in the theory, none is claimed to be natural, and none has been shown to be sufficient):

- *Baryons.* Couplings of the field to the quarks and leptons of the Standard Model of particle physics, or another link between the U(1) charge and the baryon number (H3).
- *A charge-violating interaction* (condition 1). For the commuting field the candidates found in Section 21.32 are the Majorana-type terms $\Psi^T C\Psi$ and $\Psi^T C\Gamma\Psi$ (each with its complex conjugate), of charge 2. For the anticommuting field no Majorana-type mass term exists; a charge-violating term would need derivatives, more fields or new structures, which are not classified here. A remark derived here but not checked by the record: if one such term $g\,\Psi^T M\Psi$ (plus its conjugate) is added, the rotation $\Psi \to e^{i\alpha}\Psi$ changes its coefficient to $g\,e^{2i\alpha}$, so the phase of a single coefficient can be removed by renaming the field; only relative phases between several such terms could be a source of CP violation.
- *C and CP violation in rates* (condition 2): rates of processes of the extended theory, computed and shown to differ between particles and antiparticles.

- *A departure from equilibrium* (condition 3): a dynamical history in which the charge-violating processes run out of equilibrium, for example during the deflation of the extra times, with their rates. The record has only instantaneous Kohn-Sham states along a prescribed history; the time-dependent problem and the back-reaction on a_4 are OPEN (Chapters 15, 17 and 22).
- *A computed* η_B: only with all of the above could a value be computed and compared with the observed $\eta_B \approx 6.1 \times 10^{-10}$ of Section 21.4.

21.38 What we proved, what we computed, what we assumed

statement	**status**	**where it is verified**
the observed excess of matter: $\Omega_b h^2 = 0.0224 \pm 0.0001$, $\eta_B \approx 6.1 \times 10^{-10}$; no antimatter domains	ASSUMED (quoted observations)	the literature cited in Section 21.4
Sakharov's three conditions (Propositions 1 and 2; the equilibrium surplus)	PROVED (Section 21.5) for the stated assumptions; the Fermi-Dirac law and equal particle and antiparticle masses quoted (ASSUMED)	Notebook 21d, In [7]
decay model $N(r - \bar{r})(\mathcal{B}_1 - \mathcal{B}_2)$; rate model $\eta(K)$ in closed form	PROVED for the ASSUMED toy models; COMPUTED (RK4 to 10^{-7})	Notebook 21d, In [5], In [9] to In [12]
the gammas are eight real 16×16 signed permutation matrices with signature (4,4); C, Γ, B, S^{ab} as stated	PROVED	`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, `representation_real`, `B_imaginary_hermitian`; Notebook 21a, In [3], In [5]
charge conjugation is a matrix: with the intertwiner condition as the definition (the record's), exactly $\mathcal{C}_+ = C$ (same mass) and $\mathcal{C}_- = \Gamma C$ (mass reversed); their transposition rules; both reality conditions consistent	PROVED	the same report, `intertwiners_same_mass`, `intertwiners_reversed_mass`, `charge_conjugation_matrix_plus`, `charge_conjugation_matrix_minus`, `majorana_conditions_consistent`; Notebook 21a, In [6] to In [10]
the intertwiner condition is enough, not necessary: for $V = 0$ the matrix $P_- C$ maps every solution to a solution without obeying it	PROVED	Section 21.8 (derivation); Section 5.28
each gamma equation halves the solution space	COMPUTED exactly	Notebook 21a, In [7]
signs of S, J and of all 256 bilinears for both statistics	PROVED	the same report, `bilinears_under_charge_conjugation`; Notebook 21a, In [14], In [15]

statement	status	where it is verified
real fields: $J=0$, $\mathcal{C}_+$ the identity, Γ the only nontrivial real map among the matrices that obey the intertwiner condition, with the mass reversed	PROVED	the same report, `real_fields_charge_conjugation`; Notebook 21a, In [18]
on the record's exact solution (any a_4): Ψ^* solves with $+m$, $\Gamma\Psi^*$ with $-m$	PROVED	`Revision/theory/reports/python-field-theory.json`, `exact_solution_family_x4_x0`; Notebook 21a, In [11] to In [13]
the Noether current $J^\mu=-i\bar\Psi\gamma^\mu\Psi$	PROVED (Section 21.16); COMPUTED at a point	record formula `current`; Notebook 21b, In [9]
exact local U(1) conservation law $\partial_\mu(\cos z\, J^\mu)=0$ in the author's metric for every a_4; the a_4' terms cancel because $\sqrt{\lvert g\rvert}=\cos z$	PROVED	lead check `u1_noether_matrix_identity`; Notebook 21b, In [5], In [6]
charge balance through the brane; a stationary solution with the constant charge $-1424/1875-13\sqrt{7}/1500=-0.782397$	PROVED (sympy)	Notebook 21b, In [10] to In [13]
the charge density is indefinite; a rest state of positive frequency with density $-7/25$	PROVED	Notebook 21b, In [16]
theorem T1: the partner $\Gamma\Psi$ has $(-m,-\lambda)$ and the opposite current; a pair has total charge 0 as classical bilinears	PROVED	`Revision/pairing/reports/wolfram-pairing.json`, `T1_current_primordial_commuting`, `T1_current_primordial_grassmann`, `T1_Lagrangian_primordial_commuting`; Notebook 21b, In [11], In [17]; Notebook 21d, In [14]
the reflections (P, T types) and their Krein signs	PROVED in the record	the Wolfram pairing report, `T2_Pn_in_Pin44`, `T2_character_of_Pn`, `Q_Krein_metric_of_images`
quantised field: of the charge-conjugation matrices only the one giving $\Psi\to\Gamma\Psi^{\dagger T}$ keeps the canonical anticommutator; it reverses the mass	PROVED	lead check `quantum_charge_conjugation_unitary_type`; Notebook 21c, In [4], In [6]
$Q'=16-Q$ (charge reversed up to a constant); $Q''=Q-16$ for the same-mass candidate	PROVED (Section 21.26); COMPUTED with explicit operators	Notebook 21c, In [8]

statement	status	where it is verified
one-particle spectra of $\pm m$ identical; inertia (4,4) at real, Krein-neutral at imaginary frequencies	PROVED	Wolfram pairing report, `Q_one_particle_maps`, `Q_one_particle_Krein_signatures`, `Q_one_particle_complex_and_zero_frequencies_Krein_neutral`; Notebook 21c, In [9] to In [12]
the same-mass conjugation is an exact symmetry of the commuting field	PROVED (Section 21.31); COMPUTED at a point	`Revision/theory/reports/wolfram-field-theory.json`, `L_real_C`; Notebook 21d, In [14]
invariant Majorana-type matrices: exactly C and $C\Gamma$; none for anticommuting components	PROVED	`Revision/algebra/reports/python-algebra.json`, `spin_commutant_dimension_2`; Notebook 21d, In [16]
the total charge of a universe is constant (no flux through the brane $z = \pi/2$)	ASSUMED (not derived; it fails on the exact solution of Section 21.18 with the general column χ and on the solution of Notebook 18c in Section 18.21, although the stationary solution of Section 21.18 has zero flux; OPEN)	Notebook 21b, In [12]; Notebook 18c
Sakharov condition 1	FAILS inside the patch (PROVED); for the total charge FAILS under the ASSUMED no-flux condition	lead check `u1_noether_matrix_identity`; Notebook 21d, In [13]
Sakharov condition 2 (C and CP violation)	dirac16complex00: FAILS (PROVED: $\mathcal{C}_+$ exact, Proposition 2); dirac16complex: NOT COMPUTED (no rates; only the mass-reversing conjugation)	lead checks `representation_real`, `spinor_connection_real`, `bilinears_under_charge_conjugation`, `quantum_charge_conjugation_unitary_type`; Notebook 21d, In [14], In [18]
Sakharov condition 3 (departure from equilibrium)	NOT COMPUTED	`Revision/field_equations_a4/reports/ks-source-conditions.json`, `ks_history_is_a_prescribed_background`
our universe is one member of a pair; the U(1) charge is the baryon number	HYPOTHESIS	Section 21.37
a creation process, rate or amplitude for universes, in pairs or otherwise	not derived by any equation of the record	Chapter 20; `Revision/docs/PAIR_CREATION_PROOFS.md`, its section 11.2

statement	status	where it is verified
a regularised quantum theory in signature (4,4); anomalies of the U(1) symmetry	OPEN	not constructed in the record
normal ordering adds no sign: $:Q':=-Q$, $:Q'':=Q$ (the same-mass candidate keeps the charge)	PROVED (Section 21.26); COMPUTED with explicit operators; the record's detail text states the same since its correction of 2026-10-08 (no Fock-space computation there)	lead check `bilinears_under_charge_conjugation`, its detail text; Notebook 21c, In [8]

In one sentence. In this theory charge conjugation is a matrix, the charge obeys an exact local conservation law while the extra times deflate (its total is constant only under the ASSUMED no-flux condition at the brane), a solution and its chirality partner carry opposite charges, and nothing in the theory as built can make more matter than antimatter.

21.39 Exercises

1. **Bookkeeping.** Count Q_{el}, $\mathcal{B}$ and L before and after (a) the annihilation $p+\bar{p}\to\pi^+ +\pi^-$ and (b) the hypothetical decay $n\to p+e^-$ without the antineutrino. Which numbers are conserved?

2. **The decay model.** For $N=1000$ pairs, $r=0.51$, $\bar{r}=0.49$, $\mathcal{B}_1=\frac{2}{3}$, $\mathcal{B}_2=-\frac{1}{3}$, compute the net baryon number with the formula of Section 21.5. Then repeat with $\mathcal{B}_1=\mathcal{B}_2=\frac{1}{3}$ and with $r=\bar{r}=0.5$.

3. **The equilibrium surplus.** Show that at $E=0$ the surplus f_+-f_- of Section 21.5 equals $\tanh(\mu/2T)$, and evaluate it for $\mu=0.1T$. Then show that for E much larger than T and μ it is approximately $2\sinh(\mu/T)\,e^{-E/T}$.

4. **The rate model at $K=2$.** Use $\gamma(2,x)=1-(1+x)e^{-x}$ to compute the efficiency $\eta(2)$ exactly, and check it against the values $\eta(0.1)$ and $\eta(3)$ of Notebook 21d.

5. **Why C is not one of the matrices M.** Show that C commutes with the four time-like gammas and anticommutes with the four space-like ones. Explain why this does not contradict $\mathcal{C}_+=C$.

6. **Real fields carry no current.** For the 2×2 antisymmetric matrix A with $A_{12}=1$, $A_{21}=-1$ and $A_{11}=A_{22}=0$, compute u^TAu for a real column $u=(u_1,u_2)$ and $u^\dagger Au$ for a complex one. What does this say about the current of a real and of a complex field?

7. **The charge of the general exact solution.** For the exact solution $\Psi=\sin^\alpha z\,U(x_4)\chi$ of Section 21.11 with any $\alpha>-\frac{1}{2}$, show that the charge of the patch is $Q(x_4)=f(x_4)/(2\alpha+1)$ with $f=\chi^\dagger U^T BU\chi$.

8. **A half-way conjugation.** Compute $MB^TM^\dagger$ for $M=(1+\Gamma)/\sqrt{2}$, and explain with the formula of Section 21.25 why the result is the zero matrix.

9. **Anticommuting components and a 2×2 Majorana term.** For two anticommuting components Ψ_1, Ψ_2 and the matrix M with entries $M_{11}=a$, $M_{12}=b$, $M_{21}=c$, $M_{22}=d$, compute $\Psi^T M \Psi$. When does it vanish?

21.40 Answers to the exercises

1. (a) Before: $Q_{\text{el}} = 1-1=0$, $\mathcal{B}=1-1=0$, $L=0$. After: $Q_{\text{el}}=1-1=0$, $\mathcal{B}=0+0=0$, $L=0$. All three are conserved (such annihilations into two pions are observed). (b) Before: $Q_{\text{el}}=0$, $\mathcal{B}=1$, $L=0$. After: $Q_{\text{el}}=1-1=0$, $\mathcal{B}=1+0=1$, $L=0+1=1$. The charge and the baryon number are conserved, the lepton number would change by $+1$: this is why the observed decay contains the antineutrino ($L=-1$), as the table of Section 21.3 shows.

2. With the formula $N(r-\bar{r})(\mathcal{B}_1-\mathcal{B}_2)$: $1000\times(0.51-0.49)\times(\frac{2}{3}+\frac{1}{3}) = 1000\times 0.02\times 1 = 20$ baryons. With $\mathcal{B}_1=\mathcal{B}_2$ the last factor is 0, and with $r=\bar{r}$ the middle factor is 0: no net baryon number in either case (conditions 1 and 2 of Section 21.5).

3. At $E=0$, $\cosh 0=1$, so $f_+ - f_- = \sinh(\mu/T)/(1+\cosh(\mu/T))$. With $u=\mu/2T$ and the double-angle formulas $\sinh 2u = 2\sinh u\cosh u$ and $1+\cosh 2u = 2\cosh^2 u$ (both follow from the definitions with exponentials), this is $2\sinh u\cosh u/(2\cosh^2 u) = \tanh u = \tanh(\mu/2T)$. For $\mu=0.1T$: $\tanh 0.05 = 0.049958$ (to six decimals). For large E, $\cosh(E/T) = (e^{E/T}+e^{-E/T})/2 \approx e^{E/T}/2$, which is much larger than $\cosh(\mu/T)$; so $f_+ - f_- \approx \sinh(\mu/T)/(e^{E/T}/2) = 2\sinh(\mu/T)\,e^{-E/T}$: the surplus dies out exponentially with the energy, as figure 21d.3 shows.

4. With $K=2$: $K/(K-1)=2$, $(1-e^{-2})/2$, $K^{-K}=\frac{1}{4}$ and $\gamma(2,2)=1-3e^{-2}$. So

$$\eta(2) = 2\Big(\frac{1-e^{-2}}{2} - \frac{1-3e^{-2}}{4}\Big) = (1-e^{-2}) - \frac{1-3e^{-2}}{2} = \frac{1}{2} + \frac{e^{-2}}{2} = 0.567668$$

(multiply out; collect the constants $1-\frac{1}{2}$ and the terms with e^{-2}, $-1+\frac{3}{2}=\frac{1}{2}$; $e^{-2}=0.135335$). It lies between $\eta(0.1)=0.9955$ and $\eta(3)=0.4110$, as it must, since η decreases with K (Notebook 21d, In [12]). (The formula $\gamma(2,x)=\int_0^x ue^{-u}du = 1-(1+x)e^{-x}$ follows by integration by parts.)

5. $C=\gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$. Moving a time-like $\gamma^{(t)}$ through C passes four different gammas, each costing a sign: $(-1)^4=+1$, so they commute. Moving a space-like gamma that occurs in C passes the three other factors (three signs) and itself (no sign): $(-1)^3=-1$, so they anticommute. Hence C satisfies neither $C\gamma^a = +\gamma^a C$ for all a nor $C\gamma^a=-\gamma^a C$ for all a: it is not one of the matrices M of Theorem CC. There is no contradiction: the charge-conjugation matrix is $\mathcal{C}=MC$, and $\mathcal{C}_+ = C$ belongs to $M=1$. The map is $\Psi^c = \mathcal{C}_+\bar{\Psi}^T = C\,C\Psi^* = \Psi^*$; the matrix C appears twice, once in $\mathcal{C}_+$ and once in the Dirac adjoint, and $CC=1$.

6. $u^T A u = u_1A_{12}u_2 + u_2A_{21}u_1 = u_1u_2 - u_2u_1 = 0$ for real (indeed for any commuting) numbers. For a complex column, $u^\dagger A u = u_1^*u_2 - u_2^*u_1$, and since $u_2^*u_1$ is the conjugate of $u_1^*u_2$, this is $2i\,\text{Im}(u_1^*u_2)$, which is nonzero in general (for $u=(1,i)$ it is $2i$). The current is $J^a = -i\Psi^\dagger(C\gamma^a)\Psi$ with the antisymmetric $C\gamma^a$: it vanishes for every real field (fact F1 of Section 21.10) and is in general nonzero, and real ($-i\cdot 2i\,\text{Im} = 2\,\text{Im}$), for a complex field. A real field carries no U(1) charge.

7. Since U is real, $\Psi^\dagger B\Psi = \sin^{2\alpha}z\,\chi^\dagger U^T B U\chi = \sin^{2\alpha}z\,f(x_4)$. The charge of the patch is $\int_0^{\pi/2}\cos z\,\sin^{2\alpha}z\,dz\,f(x_4)$. Substitute $u=\sin z$, $du=\cos z\,dz$, limits 0 and 1: $\int_0^1 u^{2\alpha}du = 1/(2\alpha+1)$ (the power rule of integration, valid for $2\alpha>-1$). So $Q=f/(2\alpha+1)$; for $\alpha=1$ this is the $f/3$ of Section 21.18.

8. $M = (1+\Gamma)/\sqrt{2}$ is $\cos t\, 1 + \sin t\, \Gamma$ with $t = \pi/4$. By Section 21.25, $M(t) B^T M(t)^\dagger = -\cos(2t) B$, and $\cos(\pi/2) = 0$: the result is the zero matrix. Directly: M is real and symmetric, so $M B^T M^\dagger = -MBM = -\frac{1}{2}(B + \Gamma B + B\Gamma + \Gamma B \Gamma) = -\frac{1}{2}(B + 0 - B) = 0$, because $\Gamma B = -B\Gamma$ and $\Gamma B \Gamma = -B$. In fact $(1+\Gamma)/2$ is the projector onto the components 9 to 16, and B joins the two halves (figure 21c.1), so $\frac{1+\Gamma}{2} B \frac{1+\Gamma}{2} = 0$: such an M would give a field whose anticommutator vanishes, which is not a field of the theory at all.

9. $\Psi^T M \Psi = a\Psi_1\Psi_1 + b\Psi_1\Psi_2 + c\Psi_2\Psi_1 + d\Psi_2\Psi_2$ (the sum over the four entries). For anticommuting components $\Psi_1\Psi_1 = \Psi_2\Psi_2 = 0$ and $\Psi_2\Psi_1 = -\Psi_1\Psi_2$, so $\Psi^T M \Psi = (b-c)\Psi_1\Psi_2$. It vanishes exactly when $b = c$, that is, when M is symmetric. This is the 2×2 case of Section 21.32: since C and $C\Gamma$ are symmetric, the anticommuting field dirac16complex has no Majorana-type mass term.

22 Open problems and how a student could attack them

Every earlier chapter of this book marked the questions it could not answer with the label OPEN, and every starting point it could not derive with the label ASSUMED. This last chapter of Part V collects the most important of them and treats each one as a research problem for a student who has worked through Chapters 0 to 21. For each problem it says exactly what is asked, what the Revision record already proves or computes about it, why it is hard, what a first step could be, and in which files of the repository the work would start. For one of the problems, the question of how fast the three extra times x_5, x_6, x_7 may deflate before the instantaneous Kohn-Sham states of Chapters 14 and 15 stop describing the gas, the chapter carries out the first step completely, with Notebook 22a, as an example of what such a step looks like in practice. Nothing in this chapter is claimed to be solved.

22.1 What this chapter does

Why a chapter of open problems. A theory is finished when every question it raises has an answer. The theory of this book is not finished, and the honesty rule of Chapter 0 forbids pretending that it is. The Revision record proves some statements exactly (the pairing theorems, the field equations for a_4, the exact reduction of the Kohn-Sham problem), computes others numerically with measured errors (the Kohn-Sham states along the deflating history), and leaves the rest open. An open problem is not a failure of the record: it is the place where new work can begin, and pushing against the edges of a theory is one of the best ways to understand it. This chapter lists the edges.

The five parts of each problem. For each problem the chapter gives:

1. **the question**, put as precisely as possible, together with what would count as an answer;
2. **what is known**, every statement with its label and with the record file and check that verify it;
3. **why it is hard**: which obstacle is known, and which step nobody has taken;
4. **a first step** that a student could take with what this book teaches;
5. **where to start**: the files of the repository that already exist.

The problems.

problem	sections	status	where it arose
1. The creation question: are universes created, in pairs or otherwise?	22.4	OPEN; the pairing maps T1, T2, Q, T3 and the corollary C1 are PROVED	Chapters 18 to 20
2. Beyond the instantaneous Kohn-Sham states: the time-dependent problem	22.5 to 22.13	OPEN; a first estimate for the free field is COMPUTED in Notebook 22a	Chapters 14 and 15
3. The back-reaction of the gas on a_4	22.14	OPEN; no recorded Kohn-Sham state is an admissible source	Chapters 12 and 17
4. The Z2 brane and its junction conditions	22.15	the Z2 mirror is ASSUMED; its junction conditions are OPEN	Chapters 14, 18 and 19
5. The dark-sector hypotheses	22.16 to 22.24	HYPOTHESIS, INVESTIGATED by the record and established in neither form; the observer's density ASSUMED; the remaining questions OPEN; Notebook 22b reproduces the record's numbers	Chapters 9, 12 and 15
6. Matter and antimatter	22.25	not solved by the theory as built; every scenario is a HYPOTHESIS	Chapter 21
7. Smaller open items	22.26	OPEN, CHOSEN or CONVENTION, as listed there	several chapters

The problems are linked. The time-dependent problem (Problem 2) needs the history of a_4, which the back-reaction (Problem 3) would determine; both T2 and T3 of Chapters 18 and 19 rest on the Z2 brane (Problem 4); the dark-sector results of the record (Problem 5) are read on the prescribed history and rest on an ASSUMED observer density, and an equation of state that is a consequence of the coupled equations needs Problem 3 again; and a creation process (Problem 1) would need a dynamical geometry, which none of the equations of the record provides. A student is well advised to start with a problem whose first step is a finite calculation: Problem 2, whose first step this chapter carries out, or the first steps of Problems 3 and 4.

The notebooks of this chapter. Notebook 22a is the worked example of Problem 2. It reads the adiabaticity measure Q of the 75 recorded ground states, shows that Q grows exactly in proportion to the deflation rate, reproduces the record's Q with the solver's shooting method written again in Python, collapses every slice and every momentum shell onto one curve with the exact rescaling

identity, measures the jumps into the negative-energy branch, and solves the exact time evolution of one sector of the free field for deflation rates from 0.25 to 251. It draws eight figures, needs no Rust, and ends with the line ALL 20 CHECKS PASSED (notebook 22a). Notebook 22b is the worked example of Problem 5: it reads the committed outputs of the Revision dark-sector record, reproduces its key numbers (the observer identities on the computed history, the radiation-like Kohn-Sham gas, the dark-matter-like bulk band, the condensate, the mixtures and the models of dirac16complex00 against the observed values), each asserted against its record file and check, draws five figures, needs no Rust, and ends with the line ALL 28 CHECKS PASSED (notebook 22b).

The status of every statement. Every statement carries one of the five labels of Chapter 0: PROVED (exact, with the record file and check where the Revision record verifies it), COMPUTED (a number of a numerical computation, with its measured uncertainty and the file or notebook cell that holds it), ASSUMED (a starting point that is not derived), HYPOTHESIS (an idea that is stated and examined but not established) and OPEN (a question nobody has answered). Three special cases of ASSUMED, used as in Chapters 14 to 17, appear here as well: PRESCRIBED BACKGROUND (the history $a_4 = AHx_4$, given and not solved for), CHOSEN (a numerical or boundary choice, such as the tip of the hidden direction) and CONVENTION (a rule fixed by agreement, such as which levels count as particles). A few derivations of this chapter are the book's own and are not checked by a Revision verifier; each of them is written out line by line and says so.

What this chapter does not do. It does not solve any of the problems it lists. In particular, and in the words of the honesty rule: that the big bang creates universes in pairs is NOT proved, and no creation process, rate, amplitude or big-bang dynamics follows from the equations of the record (Section 22.4); the theory as built does NOT solve the matter-antimatter problem (Section 22.25); and the record's investigation of the dark-sector hypotheses establishes neither of them (Sections 22.16 to 22.24).

Notation and units. The author's coordinates are $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates with the scale factor $e^{a_4} \sin^{1/6} z$; x_4 is the time; x_5, x_6, x_7 are the three extra times, which deflate exponentially with the scale factor $e^{-a_4} \sin^{1/6} z$; x_0 is the hidden space direction, with $z = 6Hx_0$ between 0 and $\pi/2$. The signature is (4,4): $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$. The hidden coordinate of the Kohn-Sham chapters is $y = \ln(\sin z)/(6H)$; it runs from the **tip** $y = -L$ (with $L = 3$) to the **brane** $y = 0$. A **slice** is one instant of the history, and $a_{4,0}$ is the value of a_4 there; the record's history is $a_4 = AHx_4$ with $A = 1$, on the background $b_4 = 1$ of the second function $b_4(x_4)$ of the author's metric of 2026-10-14 (Chapter 3), on which the Kohn-Sham record works. In all numbers $H = 1$ and $m = 1$, so energies and momenta are in units of m, lengths and times in units of $1/H$. A state of the record is named like N688_lamm2_a00: $N = 688$ quanta, the coupling $-\lambda_2$ (the tags lam0, lamp1, lamm1, lamp2, lamm2 stand for $\lambda = 0, +\lambda_1, -\lambda_1, +\lambda_2, -\lambda_2$), the slice $a_{4,0} = 0.0$ (the two digits are ten times the slice).

22.2 The words of this chapter

Most words of this chapter were defined in earlier chapters; they are repeated here in plain words so that the chapter can be read on its own.

- **Open problem**: a question that neither the Revision record nor this book answers, put precisely enough that one can recognise an answer.

- **Test field** and **back-reaction**: a field that is computed in a gravitational field given in advance, which the field itself does not change, is a test field. The change of the gravitational field caused by the energy and momentum of the field is its back-reaction. All Kohn-Sham results of the record are test-field results.

- **Prescribed background**: the history $a_4 = AHx_4$ used by the Kohn-Sham chapters. It is given, not solved for: the computed Kohn-Sham states cannot be its source in the field equations for a_4 (Chapter 17).

- **Rate** A and **e-fold**: on the history $a_4 = AHx_4$ the extra-time scale factor $e^{-a_4}\sin^{1/6} z$ shrinks by the factor $e = 2.718\ldots$ (one e-fold) in the time $1/(AH)$; the rate A is the number of e-folds per unit of time $1/H$.

- **Instantaneous** (or **adiabatic**) **state**: the ground state of the Kohn-Sham Hamiltonian of one slice, computed as if the slice lasted forever. The word **adiabatic** also describes an evolution that is so slow that every particle stays in its instantaneous level.

- **Time-dependent Kohn-Sham problem**: the problem in which the orbitals evolve in the time x_4 under the Hamiltonian of each moment, with the potentials recomputed at every moment from the evolving densities.

- **Sector**: one momentum shell n_2 (3-momentum of length $k = 0.25\sqrt{n_2}$), one block type $j = \pm 1$ and one brane parity (even or odd). The exact evolution never moves a particle from one sector to another. The **Fermi shell** of a state is its highest occupied shell.

- **Level**, **orbital** and **label**: a level ε and its orbital φ solve $h\varphi = \varepsilon\varphi$ for the Hamiltonian h of one slice. The label n is the integer that numbers the levels of one sector in order: $n = 0$ is the **band level** (bound to the brane; the occupied level of the Fermi shell), $n = 1, 2, \ldots$ are the **bulk levels** above it, and $n = -1, -2, \ldots$ are the levels of negative energy, the **negative branch**, which the record's filling convention treats as the normal-ordered sea that holds no particles.

- **Amplitude** and **probability**: when an orbital is written as a sum $\sum_n c_n\varphi_n$ of instantaneous orbitals, the complex number c_n is the amplitude of level n and $|c_n|^2$ the probability to find the particle in level n.

- **Basis**: a set of orbitals in which every orbital is written as a sum. A **truncated** basis keeps only some of them; a computation **converges** when its result stops changing as more are kept.

- **Dressing**: the small admixture of other levels that a particle carries while the background keeps moving. **Adiabaticity measure** Q: the size of this admixture to first order (Section 22.7). $G = Q/A$ is Q per unit rate.

- **Redshifted momentum** $q = ke^{-a_{4,0}}$: the 3-momentum as the deflating history sees it (Section 22.7).

- **Sudden limit**: the limit of an infinitely fast change, in which the orbital has no time to change at all (Section 22.8). **Breakdown**: the instantaneous picture breaks down when the probability that a particle is NOT in its instantaneous level stops being small.

- **Brane**: the end $y = 0$ (that is $z = \pi/2$) of the hidden direction. **Z2 mirror** (or **orbifold**): the construction that continues the universe beyond the brane by its mirror image. **Kink**:

a point where a function is continuous but its slope jumps. **Junction condition**: the rule that ties the jump of the slopes of the metric (or of a field) across a surface to the energy and momentum concentrated on that surface. **Tension**: the energy per unit area of a surface, which acts like a negative pressure along it.

- **Equation of state** w: the ratio p/ρ of a pressure to the energy density. **CPL parametrisation**: the formula $w(a) = w_0 + w_a(1 - a)$ for an equation of state that changes with the scale factor a of the observed universe. **Phantom**: $w < -1$.
- **Null energy condition** along a direction: $\rho + p \geq 0$, with p the pressure of that direction.
- **Einstein-Hilbert Lagrangian**: the Lagrangian density $\sqrt{|g|}R$ of the geometry, with R the Ricci scalar; varying its action with respect to the metric gives Einstein's equations without a source.
- **Quantum cosmology** and **wave function of the universe**: a quantum theory in which a few numbers that describe the whole geometry, such as a scale factor, are quantum variables; its wave function is a function of these numbers. The **Wheeler-DeWitt equation** is the equation this wave function must obey. The **tunnelling proposal** and the **no-boundary proposal** are two proposed boundary conditions that pick one solution of it; they are named in this chapter, not used.
- **Bogoliubov method**: a way to count the quanta of a field that a changing background creates: one compares the modes of the field before and after the change, and the part of a positive-energy mode of the start that has turned into negative-energy modes of the end measures the creation. It is quoted in this chapter, not derived or applied.
- **Hypothesis**: an idea that is stated and examined but not established; here, every scenario that goes beyond what the record proves or computes.

22.3 How to work on an open problem

The Revision record answered every question it did answer by one procedure, and a student who attacks an open problem should follow it, because it is what makes an answer trustworthy.

1. **Write the question down precisely**, with what would count as an answer and what would not. The specification `Revision/SPEC.md` is an example: section 7 asks for instantaneous Kohn-Sham states and says in the same sentence that the time-dependent problem is OPEN.
2. **Derive the result by hand**, line by line, as this book does.
3. **Verify every exact statement with two programs that share no code.** The record uses a Wolfram Language verifier and an independent Python checker built on sympy for each exact statement, each writing a report with a name, a verdict and a detail for every check. Include **negative controls**: inputs that must fail, so that a check that passes everything is caught.
4. **Compute every number with two independent methods** and compare them with tolerances fixed before the comparison, as the cross-check of Chapter 16 does. Repeat every run to show that it gives the same bytes.

5. **Never weaken a check to make it pass.** A failing check is information; the task is to find out why it fails (Chapter 16 tells how the first cross-check failed and what it found).

6. **Write down what is proved, what is computed, what is assumed and what is not claimed**, and label every statement.

The tools that already exist, and that the first steps below use, are these:

tool	what it does	where
exact verifiers (Wolfram Language)	prove identities with exact numbers and symbols and write a report	the files ending in `.wls` in the folders `Revision/algebra/wolfram`, `Revision/theory/wolfram`, `Revision/pairing/wolfram`, `Revision/field_equations_a4/wolfram`
independent exact checkers (Python, sympy)	the same statements without Wolfram code	the files whose names start with `check_` in the folders `Revision/algebra/python`, `Revision/theory/python`, `Revision/pairing/python`, `Revision/field_equations_a4/python`
the lead's checks	three further independent checks (the energy-momentum divergence, the Einstein and Gauss-Bonnet equations for a_4, charge conjugation and the U(1) charge)	the folder `Revision/lead_checks`
the Kohn-Sham theory	the exact reduction, the functional, the boundary conditions, the adiabaticity measure	`Revision/kohn_sham/ks-theory.json` with the verifiers in `Revision/kohn_sham/theory`
the Rust Kohn-Sham solver	shooting with RK4 and a Pruefer count, self-consistency, the adiabaticity table	the crate `Revision/kohn_sham/solver`
the reference solver and the cross-check	a second method and the comparison with tolerances fixed in advance	`Revision/kohn_sham/reference/run_reference.py`, `Revision/kohn_sham/checker/crosscheck_ks.py`
the source-condition checker	the Kohn-Sham states as sources of the equations for a_4	`Revision/field_equations_a4/python/check_ks_source_conditions.py`
the notebooks of this book	every example, built and checked byte for byte	`Revision/textbook/notebooks` and the tool `Revision/textbook/tools/nbkit.py`

22.4 Problem 1: the creation question

The question. The author asked for a proof "that Universes of masses {+mass, -mass} are created in pairs" (`Revision/README.md`), and the request for this book repeats it as "the big bang creates universes in pairs". As an open problem the question is: is there a theory in which the creation of a universe, or of a pair of universes of masses $+m$ and $-m$, is a process with a computable amplitude, probability or rate; and if so, what is it, and does it create pairs? An answer would be such a theory together with the computed number; a correspondence between solutions, however exact, is not an answer, because it says nothing about whether either solution comes into being.

What is known.

- PROVED (Chapter 18; `Revision/pairing/reports/wolfram-pairing.json` and `Revision /pairing/reports/python-pairing.json`): theorem T1, the chirality map Γ: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$, so Γ maps every solution with (m, λ) to a solution with $(-m, -\lambda)$, with the energy-momentum tensor $T \to -T$ and the current $J \to -J$, in every gravitational field taken as a fixed background, for both fields.
- PROVED (same reports): theorem T2, Γ combined with a Pin(4,4) reflection of character -1, maps (m, λ) to $(-m, \lambda)$ with $\mathcal{L} \to +\mathcal{L}$; in the author's field it is the mirror across the Z2 brane (an ASSUMED construction), and the partner has EQUAL, not opposite, energy-momentum.
- PROVED (same reports): the quantum reading Q for dirac16complex: the chirality image carries the Krein metric $-B$ and is the same quantum system written in other variables; two universes quantised independently of each other carry $+B$ each, and their generators add without cancelling.
- PROVED (Chapter 19): theorem T3, every self-consistent instantaneous Kohn-Sham state with (m, λ, θ) has a partner with $(-m, +\lambda, \pi - \theta)$ with equal levels, occupations, energies and energy-momentum profiles (ASSUMED Z2 brane). The two reports are `wolfram-t3.json` and `python-t3.json` in the folder `Revision/pairing/kohn_sham/reports`.
- PROVED (Chapter 20): corollary C1, a T1 pair taken as the complete classical source of the author's metric is a zero source, and in Einstein gravity the author's metric then has no solution for $H > 0$. The derivation is short and is given below.
- The record itself lists what these theorems do not establish: the report `Revision/pairing /reports/python-pairing.json` holds, under its key `not_established`, twelve items. Among them: no creation process (nothing in these equations produces a universe, a pair of universes or a change of the number of universes); no rate, probability or amplitude (no wave function of the universe, path integral or tunnelling computation is part of the theorems); no dynamical necessity (a single universe of mass $+m$ is an equally valid solution without its partner); the vanishing total energy-momentum of a T1 pair is not a cancellation between two independently quantised universes; and the gravitational back-reaction is not part of the theorems.
- OPEN: whether any universe is CREATED, in pairs or otherwise. The equations of the record are field equations on a gravitational field that is given, and their canonical quantisation; no creation process, rate, amplitude or big-bang dynamics follows from them.

Corollary C1 in Einstein gravity, line by line. The field equations for a_4 in Einstein gravity (Chapter 12; `Revision/field_equations_a4/a4-equations.json`, key `einstein`) contain the x_4 component and the x_0 component

$$3(a_4')^2 + 21H^2 + \Lambda = -\kappa\rho, \qquad -3(a_4')^2 + 15H^2 + \Lambda = \kappa p_0,$$

where $a_4' = da_4/dx_4$, Λ is the cosmological constant, κ the gravitational coupling, ρ the energy density and p_0 the pressure of the source along x_0. By T1 the two members of a pair have $T' = -T$, so the total source $T + T'$ vanishes: $\rho = 0$ and $p_0 = 0$.

$$3(a_4')^2 + 21H^2 + \Lambda = 0, \qquad -3(a_4')^2 + 15H^2 + \Lambda = 0.$$

Rule: insert $\rho = 0$ and $p_0 = 0$ into the two components.

$$36H^2 + 2\Lambda = 0.$$

Rule: add the two equations; the terms $3(a_4')^2$ and $-3(a_4')^2$ cancel.

$$6(a_4')^2 + 6H^2 = 0.$$

Rule: subtract the second equation from the first; Λ cancels.

$$(a_4')^2 = -H^2.$$

Rule: divide by 6 and subtract H^2 from both sides.

The square of a real number is never negative, and $-H^2 < 0$ for $H > 0$. So no real history $a_4(x_4)$ exists: the only solutions of the two equations are the complex slopes $a_4' = \pm iH$ with $\Lambda = -18H^2$. PROVED: `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `einstein_no_vacuum_solution`; `Revision/field_equations_a4/reports/python-a4-report.json`, check `einstein_no_vacuum`; and independently `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, check `no_vacuum_for_H_positive`, which also lists the complex solutions. The consequence: a T1 pair cannot by itself be the source of the author's universe in Einstein gravity. This is a statement about sources in one common geometry; it is not a derivation that a geometry, or a pair, is created.

Why it is hard.

- *The geometry has no dynamics of its own in the record.* Every theorem of Chapters 18 to 20 is a statement about fields in a gravitational field that is given (hypothesis H1 of T1). Without a dynamical geometry there is no process "a universe appears", and no state "no universe" from which it could appear.
- *A universe is not a particle in a fixed background.* To speak of the creation of universes one needs a quantum theory in which the geometry itself is a quantum variable, such as the quantum cosmology of a few variables of the metric (the Wheeler-DeWitt equation, the

tunnelling and the no-boundary proposals). In plain words: **quantum cosmology** treats a few numbers that describe the whole geometry, such as a scale factor, as quantum variables; its **wave function of the universe** is a function of these numbers, and the **Wheeler-DeWitt equation** is the equation that this wave function must obey, the analogue for a geometry of the Schroedinger equation of a particle. That equation alone does not fix the wave function; it needs a boundary condition, and the **tunnelling proposal** (A. Vilenkin) and the **no-boundary proposal** (J. B. Hartle and S. W. Hawking) are two proposed boundary conditions of this kind. They are named here, not used. None of these is formulated for this 8-dimensional theory, and in signature (4,4) both the classical and the quantum side bring their own difficulties: modes with momentum along the extra times grow instead of oscillating (Chapter 8), and the quantised field has an indefinite (Krein) inner product (Chapter 10).

- *Nothing forces the partner to exist.* T1, T2 and T3 relate the solutions of two parameter sets. A single universe of mass $+m$ is an equally valid solution.
- *The cancelling pair has no home in Einstein gravity.* By C1 a T1 pair as the complete source of one common geometry leaves no solution for $H > 0$. A T2 pair does not cancel at all: its two members carry equal energy-momentum.

A first step. (a) Redo the derivation of C1 above, and its version for Einstein-Gauss-Bonnet gravity, in which vacuum solutions of the linear form $a_4 = AHx_4 + a_0$ exist exactly for $0 < \alpha_2 H^2 \leq 1/40$ (Chapter 12; checks `linear_member_vacuum_factor` and `einstein_gauss_bonnet_vacuum_linear` of both reports in `Revision/field_equations_a4/reports`). (b) Prepare the classical side of a reduced quantum model. From the four independent components of the Einstein tensor in the record (`Revision/field_equations_a4/a4-equations.json`, key `lovelockTensors.E1`) the student can compute the Ricci scalar of the author's metric; this is a derivation of this book, from the record's components. The record's field-theory verifier computes the same R from the metric directly: the detail of its check `curvature_nonzero_flat_only_formally` in `Revision/theory/reports/python-field-theory.json` states $R = 6(a_4'^2 - 7H^2)$, and its comparison `ricci_scalar` with the Wolfram verifier has the verdict agree. The trace of the Einstein tensor adds three 3-space components, the time component, three extra-time components and the hidden component:

$$G^{\mu}{}_{\mu} = 3\big(-3(a_4')^2 + a_4'' + 15H^2\big) + \big(3(a_4')^2 + 21H^2\big) + 3\big(-3(a_4')^2 - a_4'' + 15H^2\big) + \big(-3(a_4')^2 + 15H^2\big).$$

Rule: the trace is the sum of the eight diagonal components $G^{x_0}{}_{x_0} + \cdots + G^{x_7}{}_{x_7}$, and the record gives $G^{x_1}{}_{x_1} = G^{x_2}{}_{x_2} = G^{x_3}{}_{x_3}$ and $G^{x_5}{}_{x_5} = G^{x_6}{}_{x_6} = G^{x_7}{}_{x_7}$.

$$G^{\mu}{}_{\mu} = -18(a_4')^2 + 126H^2.$$

Rule: collect terms: $(a_4')^2$ appears with $-9 + 3 - 9 - 3 = -18$, a_4'' with $3 - 3 = 0$, and H^2 with $45 + 21 + 45 + 15 = 126$.

$$G^{\mu}{}_{\mu} = R - \tfrac{8}{2}R = -3R.$$

Rule: $G^{\mu}{}_{\nu} = R^{\mu}{}_{\nu} - \frac{1}{2}R\,\delta^{\mu}_{\nu}$; the trace of $R^{\mu}{}_{\nu}$ is R, and the trace of δ^{μ}_{ν} in eight dimensions is 8.

$$R = 6(a_4')^2 - 42H^2.$$

Rule: divide $-18(a_4')^2 + 126H^2 = -3R$ by -3.

The second derivative a_4'' has dropped out: the inflation of 3-space and the deflation of the extra times enter with opposite signs. The **Einstein-Hilbert Lagrangian** is the Lagrangian density $\sqrt{|g|}R$ of the geometry itself: when its action is varied with respect to the components of the metric, the Euler-Lagrange equations (Chapter 7) are Einstein's equations without a source (with a source, the Lagrangian of the matter is added). With $\sqrt{|g|} = \cos z$ independent of a_4 (Chapter 12), the Einstein-Hilbert Lagrangian $\sqrt{|g|}R$ of the author's metric contains a_4 only through $(a_4')^2$, which is the starting point of a reduced quantum model with the one variable a_4. Quantising such a model is a HYPOTHESIS-level programme of quantum cosmology; even if it is carried out, it gives a wave function of a_4, not a process that changes the number of universes, and both the boundary condition of that wave function and the meaning of "two universes" in it would have to be supplied. (c) Study the one kind of creation that could occur within the record's own equations, the creation of quanta of the field inside ONE universe by the changing background (OPEN: the record computes no such process), which in ordinary Dirac theory is the jump of a particle from a filled negative level to an empty positive one (the Bogoliubov method, introduced for expanding universes by L. Parker, Phys. Rev. 183, 1057 (1969); quoted, not derived here). Notebook 22a measures how strongly the deflating background couples the negative branch to the positive one in the free field (Section 22.13); whether such jumps mean the creation of pairs of quanta in the 4+4 quantisation with its Krein metric is OPEN, and they have nothing to do with the creation of universes.

Where to start. The proofs and their limits: `Revision/docs/PAIR_CREATION_PROOFS.md` (its section 11 lists what is proved and what is not), `Revision/pairing/pairing-theory.json` (key `not_established`), the verifiers `Revision/pairing/wolfram/verify_pairing.wls` and `Revision/pairing/python/check_pairing.py`; the equations for a_4: `Revision/field_equations_a4/a4-equations.json` with its two verifiers; the lead's check `Revision/lead_checks/einstein_gauss_bonnet_a4.py`, which has its own curvature code.

22.5 Problem 2: beyond the instantaneous Kohn-Sham states

The question. Chapters 14 and 15 computed instantaneous Kohn-Sham states: at each slice $a_{4,0}$ of the history $a_4 = AHx_4$ the solver finds the ground state of the Hamiltonian of that one instant, as if the background stood still. But the background does not stand still: the three extra times deflate, 3-space inflates, and the Hamiltonian changes with x_4. The open problem has two levels. First: how fast would the extra times have to deflate before the instantaneous states stop describing the gas, and what happens then? Second: solve the self-consistent time-dependent Kohn-Sham problem, in which the orbitals evolve in x_4 and the potentials follow the evolving densities. An answer to the first is an estimate of the breakdown rate with a measured error; an answer to the second is a solver for the time-dependent problem, checked like the solvers of Chapters 15 and 16.

What is known.

- PROVED: the reduction of the field equation to the hidden coordinate is exact also when a_4 depends on x_4; in each sector the orbital obeys $i\,\partial\chi/\partial x_4 = h(x_4)\chi$ with a Hermitian h, and the momentum, the block and the brane parity are conserved, so particles can only jump between

levels of the same sector. The record states this in `Revision/kohn_sham/ks-theory.json` under the keys `sectorAndAnsatz.exactReduction` and `adiabaticity.exactEvolution`, and both theory reports in the folder `Revision/kohn_sham/reports` verify it with their check `hamiltonian_16_hermitian`.

- PROVED: the identity behind the adiabaticity measure Q (Sections 22.6 and 22.7); check `adiabatic_offdiagonal_identity` of the report `ks-theory-python.json` in the same folder.
- COMPUTED: at the record's rate $A = 1$ the largest Q of each of the 75 ground states is at most 0.0935 (largest value 0.0934532, state N688_lamm2_a00), and $Q = 0$ exactly for $N = 8$; the column `transition_probability_estimate_Q2` gives Q^2, at most 0.0087335 (the record's name for Q^2; Section 22.7 explains how this book reads it). The table is `adiabaticity.csv` in the folder `Revision/kohn_sham/results/adiabatic`.
- COMPUTED: for the 15 series of the record (three particle numbers, five couplings) the set of occupied levels does not change between neighbouring slices (the tables `fermi-level-crossings.csv` and `history.json` of the same folder). But the record also shows that this is not always so: for $N = 696$ at $\lambda = 0$ the brane-band levels redshift below the $k = 0$ bulk level along the history, the instantaneous ground state changes its occupied levels, and the state continued adiabatically from $a_{4,0} = 0$ lies above the instantaneous ground state by 3.657, 6.053, 7.612 and 8.623 (units of m) at the slices 0.5, 1, 1.5 and 2. This is the table `crossing-demo.csv` of the same folder, checked by `adiabatic_crossing_flag_demonstration` of the solver's report `Revision/kohn_sham/reports/ks-rust-solver.json`.
- PRESCRIBED BACKGROUND: the history itself (`Revision/kohn_sham/results/adiabatic/history.json`, key `status`).
- OPEN: the non-adiabatic (time-dependent) problem (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.caveat`).

Why it is hard. With interaction the effective mass $M = m + \frac{15}{16}\lambda S$ and the potential $v = -\lambda n/16$ depend on the densities of all occupied orbitals of all sectors (Chapter 14), so the evolution of one sector depends on all the others at every moment, and a gas of 688 quanta occupies many sectors. The functional itself is a question: the simplest choice, the ground-state functional evaluated with the densities of each moment, is the adiabatic approximation of time-dependent density functional theory, whose foundation in ordinary quantum mechanics is the theorem of E. Runge and E. K. U. Gross (Phys. Rev. Lett. 52, 997 (1984); quoted, not derived here); nobody has established its analogue for the 4+4 field with its Krein metric. When levels of different sectors cross the Fermi level, the instantaneous ground state and the evolved state part ways, as the case $N = 696$ shows. The negative branch is coupled to the positive one by the moving background, and how such jumps are to be read in the quantised theory is OPEN. And the history is prescribed: a full answer would also need Problem 3.

A first step: an estimate in the free field. In the free field ($\lambda = 0$) the mass is $M = m$ and $v = 0$ in every sector, so the sectors do not influence each other and the evolution equation of one sector is the complete, exact time evolution of the free field in that sector. That makes an exact first step possible. Sections 22.6 to 22.8 derive the equations it needs, Notebook 22a solves them (Sections 22.9 to 22.12), and Section 22.13 collects what it found and how a student could go on.

22.6 The amplitude equations, line by line

The setting. Take one sector. Its orbital is a pair of complex functions $\chi(y, x_4) = (\chi_1, \chi_2)$ on $-L \le y \le 0$. Its evolution equation is (`Revision/kohn_sham/ks-theory.json`, keys `adiabaticity.exactEvolution` and `blockEquation.hamiltonian`)

$$i\,\frac{\partial \chi}{\partial x_4} = h\,\chi, \qquad h = j\Big[-i\sigma_1\frac{d}{dy} + M\sigma_2 + \kappa k\sigma_3\Big] + v, \qquad \kappa = e^{-Hy-a_4(x_4)},$$

where $j = \pm 1$ is the block type, k the length of the 3-momentum, and σ_1, σ_2, σ_3 the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The factor κk is the 3-momentum as the orbital feels it: 3-space has the scale factor e^{Hy+a_4} in the hidden coordinate (Chapter 14), and a fixed coordinate momentum k corresponds to the physical momentum k divided by that scale factor. As the history goes on, a_4 grows and κk shrinks: the momenta redshift.

The inner product and Hermiticity. For two orbitals φ and ψ write $\langle\varphi|\psi\rangle = \int_{-L}^{0} \varphi^\dagger \psi\, dy$, where $\varphi^\dagger$ is the row of the complex conjugates of the components of φ. An operator h is **Hermitian** when $\langle\varphi|h\psi\rangle = \langle h\varphi|\psi\rangle$ for all orbitals that obey the boundary conditions; the Kohn-Sham h is (checks `hamiltonian_16_hermitian` and `bc_self_adjoint_boundary_term` of `Revision/kohn_sham/reports/ks-theory-python.json`). Its first consequence is that the total probability does not change. Write $\dot\chi = \partial\chi/\partial x_4$:

$$\frac{d}{dx_4}\langle\chi|\chi\rangle = \langle\dot\chi|\chi\rangle + \langle\chi|\dot\chi\rangle.$$

Rule: the product rule, applied inside the integral to $\chi^\dagger\chi$.

$$\frac{d}{dx_4}\langle\chi|\chi\rangle = \langle -ih\chi|\chi\rangle + \langle\chi| -ih\chi\rangle = i\langle h\chi|\chi\rangle - i\langle\chi|h\chi\rangle.$$

Rule: the evolution equation gives $\dot\chi = -ih\chi$; a factor $-i$ in the left slot comes out complex-conjugated as $+i$ (the left slot carries the dagger), in the right slot as $-i$.

$$\frac{d}{dx_4}\langle\chi|\chi\rangle = 0.$$

Rule: h is Hermitian, so the two terms are equal and cancel.

The instantaneous orbitals. At each slice the levels ε_n and orbitals φ_n solve $h\varphi_n = \varepsilon_n\varphi_n$ with the boundary conditions of the record (the regular tip, $b(-L) = 0$; the even brane parity, $b(0) = 0$, or the odd one). They are **orthonormal**: $\langle\varphi_m|\varphi_n\rangle = 1$ for $m = n$ and 0 otherwise. In the free field they depend on x_4 only through a_4, so we write $\varphi_n(y; a_4)$ and $\varepsilon_n(a_4)$. In the **real form** of the record (`Revision/kohn_sham/ks-theory.json`, key `blockEquation.realForm`) every orbital can be written $\varphi = (a, ib)$ with two real functions $a(y)$ and $b(y)$, which obey for $j = +1$

$$a' = Ma - (\kappa k + \varepsilon - v)\, b, \qquad b' = (\varepsilon - v - \kappa k)\, a - Mb,$$

where the prime is d/dy; in the free field $M = 1$ and $v = 0$. Then $\varphi^\dagger \varphi = a^2 + b^2$, and for two orbitals $\varphi_m^\dagger \sigma_3 \varphi_n = a_m a_n - b_m b_n$.

The equations for the amplitudes. Write ∂_a for the derivative with respect to a_4 at fixed y, and a dot for d/dx_4.

Line 1. Assume that the instantaneous orbitals form a basis, and write the evolving orbital as

$$\chi(y, x_4) = \sum_n c_n(x_4)\, \varphi_n(y; a_4(x_4)).$$

Rule: the expansion in a basis; the amplitudes c_n carry the time dependence that the orbitals of the slice do not. (A computer keeps finitely many levels; Notebook 22a keeps 20 and measures what the others would change.)

Line 2.

$$i\dot\chi = i \sum_n \Big[\dot c_n\, \varphi_n + c_n\, \dot a_4\, \partial_a \varphi_n \Big].$$

Rule: the product rule for each term $c_n \varphi_n$, and the chain rule for φ_n, which depends on x_4 through $a_4(x_4)$: $d\varphi_n/dx_4 = \dot a_4\, \partial_a \varphi_n$.

Line 3.

$$h\chi = \sum_n c_n\, \varepsilon_n\, \varphi_n.$$

Rule: h acts on each term (it is linear), and $h\varphi_n = \varepsilon_n \varphi_n$.

Line 4. Set line 2 equal to line 3, multiply from the left by $\varphi_m^\dagger$ and integrate over y:

$$i\dot c_m + i\dot a_4 \sum_n K_{mn} c_n = \varepsilon_m c_m, \qquad K_{mn} = \langle \varphi_m | \partial_a \varphi_n \rangle.$$

Rule: by orthonormality $\langle \varphi_m | \varphi_n \rangle$ is 1 for $n = m$ and 0 otherwise, so of the first and the last sum only the term $n = m$ survives; the middle sum keeps all terms and defines the numbers K_{mn}.

Line 5.

$$\dot c_m = -i\varepsilon_m c_m - \dot a_4 \sum_n K_{mn} c_n.$$

Rule: subtract $i\dot a_4 \sum_n K_{mn} c_n$ from both sides and multiply by $-i$ (because $1/i = -i$). This is the equation that Notebook 22a integrates. It says that the amplitudes turn with the frequencies ε_m and are mixed by the motion of the background, with the strength $\dot a_4 K_{mn}$.

Line 6. To compute K_{mn} for $m \neq n$, differentiate the eigenvalue equation $h\varphi_n = \varepsilon_n \varphi_n$ with respect to a_4:

$$(\partial_a h)\varphi_n + h\,\partial_a \varphi_n = (\partial_a \varepsilon_n)\varphi_n + \varepsilon_n\,\partial_a \varphi_n.$$

Rule: the product rule on both sides.

$$\langle \varphi_m | \partial_a h | \varphi_n \rangle + \varepsilon_m K_{mn} = 0 + \varepsilon_n K_{mn}.$$

Rule: multiply from the left by $\varphi_m^\dagger$ and integrate; h is Hermitian and its levels are real, so $\langle \varphi_m | h\psi \rangle = \langle h\varphi_m | \psi \rangle = \varepsilon_m \langle \varphi_m | \psi \rangle$ with $\psi = \partial_a \varphi_n$; and $\langle \varphi_m | \varphi_n \rangle = 0$ for $m \neq n$.

$$K_{mn} = \frac{\langle m | \partial_a h | n \rangle}{\varepsilon_n - \varepsilon_m} \qquad (m \neq n).$$

Rule: subtract $\varepsilon_m K_{mn}$ and divide by $\varepsilon_n - \varepsilon_m$, which is not zero for different levels of one sector; $\langle m | X | n \rangle$ is short for $\langle \varphi_m | X \varphi_n \rangle$. PROVED: check `adiabatic_offdiagonal_identity` of `Revision/kohn_sham/reports/ks-theory-python.json`.

Line 7. $K_{nn} = 0$:

$$1 = \langle \varphi_n | \varphi_n \rangle = \int (a_n^2 + b_n^2)\, dy \quad \Longrightarrow \quad 0 = 2 \int (a_n \partial_a a_n + b_n \partial_a b_n)\, dy = 2K_{nn}.$$

Rule: differentiate the normalisation with respect to a_4 (the derivative of the constant 1 is 0); with $\varphi_n = (a_n, i b_n)$ and real a_n, b_n the integrand of K_{nn} is $a_n \partial_a a_n + (-i b_n)(i \partial_a b_n) = a_n \partial_a a_n + b_n \partial_a b_n$.

Line 8. In the free field only κ depends on a_4, and

$$\partial_a \kappa = \partial_a e^{-Hy - a_4} = -\kappa, \qquad \partial_a h = -j\kappa k\, \sigma_3.$$

Rule: the derivative of e^{-a_4} with respect to a_4 is $-e^{-a_4}$; $M = 1$ and $v = 0$ do not depend on a_4. PROVED: the record states $\partial_a h_j = -j\kappa k \sigma_3$ for frozen potentials (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.derivative`) and verifies it with the check `adiabatic_hellmann_feynman` of `Revision/kohn_sham/reports/ks-theory-python.json`. Lines 1 to 5 and line 7 are derivations of this book, which no Revision check covers.

$$\langle m | \partial_a h | n \rangle = -k\, e^{-a_4} \int_{-L}^{0} e^{-Hy}\, (a_m a_n - b_m b_n)\, dy \qquad (j = +1).$$

Rule: $\kappa = e^{-Hy} e^{-a_4}$ (the rule $e^{s+t} = e^s e^t$), and $\varphi_m^\dagger \sigma_3 \varphi_n = a_m a_n - b_m b_n$ in the real form.

The total probability in the amplitudes. By orthonormality $\langle \chi | \chi \rangle = \sum_n |c_n|^2$, and it is 1 at all times by the conservation law above. Notebook 22a uses this as a test of its numerics: the computed $\sum_n |c_n|^2$ must stay 1.

22.7 What the adiabaticity measure Q measures, and two exact rules

The dressing. Let the history run at the constant rate $\dot{a}_4 = AH$, and let the particle be in level 0. If the other amplitudes are small, only the term $n = 0$ matters on the right of line 5 ("first order"), and over a short time the levels and the numbers K_{m0} hardly change. The amplitude of level 0 then turns as $c_0 = e^{-i\varepsilon_0 x_4}$. Try, for every $m \neq 0$, an amplitude that turns together with it, $c_m = \alpha_m e^{-i\varepsilon_0 x_4}$ with a constant α_m:

$$-i\varepsilon_0\,\alpha_m e^{-i\varepsilon_0 x_4} = -i\varepsilon_m\,\alpha_m e^{-i\varepsilon_0 x_4} - AH\,K_{m0}\,e^{-i\varepsilon_0 x_4}.$$

Rule: the left side is $\dot{c}_m$ (the derivative of $e^{-i\varepsilon_0 x_4}$ is $-i\varepsilon_0 e^{-i\varepsilon_0 x_4}$); the right side is line 5 with only $n = 0$ kept and $\dot{a}_4 = AH$.

$$i(\varepsilon_m - \varepsilon_0)\,\alpha_m = -AH\,K_{m0}.$$

Rule: divide by $e^{-i\varepsilon_0 x_4}$, which is never zero, and add $i\varepsilon_m\alpha_m$ to both sides.

$$\alpha_m = \frac{iAH\,K_{m0}}{\varepsilon_m - \varepsilon_0}.$$

Rule: divide by $i(\varepsilon_m - \varepsilon_0)$ and use $-1/i = i$.

$$|\alpha_m| = AH\,\frac{|\langle m|\partial_a h|0\rangle|}{(\varepsilon_0 - \varepsilon_m)^2}.$$

Rule: insert line 6, $K_{m0} = \langle m|\partial_a h|0\rangle/(\varepsilon_0 - \varepsilon_m)$, and take the absolute value ($|i| = 1$).

This is exactly the record's adiabaticity measure Q_{0m} (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.measure`: $Q_{nm} = AH|\langle n|\partial_a h|m\rangle|/(\varepsilon_n - \varepsilon_m)^2$ for n occupied and m empty in the same sector). So Q has a plain meaning: it is the amplitude, and Q^2 the probability, of the admixture of level m that a particle carries while the background moves, as long as Q is much smaller than 1. This admixture is the dressing. It is not a transition: when the motion stops slowly, the dressing disappears again. The record itself calls Q^2 the leading-order transition probability (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.measure`). For a constant rate this book reads it instead as the probability of the dressing; this reading is a derivation of this book, not of the record, and Notebook 22a tests it numerically in In [14]: at $A = 0.3$ the exact evolution, started in the dressed state, agrees with $\sum_m Q_{0m}^2$ within 15 percent. Only when the motion is started or stopped abruptly is Q^2 of the size of a real transition: the abrupt start at $A = 1$ in Figure 22a.6 (right) leaves up to about three times the dressing.

Exact rule 1: Q grows in proportion to the rate. The levels, orbitals and matrix elements of a slice depend only on $a_{4,0}$, not on how fast a_4 changes. The rate enters Q only through the factor AH. Hence $Q(A) = A\,Q(A = 1)$ exactly, and the naive criterion "breakdown when Q reaches 1" puts the breakdown at the rate $A = 1/Q_{max}$, where Q_{max} is the record's largest Q at $A = 1$.

Exact rule 2: one variable is enough. In the free field a_4 enters h only through the product

$$\kappa k = e^{-Hy - a_{4,0}}\,k = e^{-Hy}\left(k\,e^{-a_{4,0}}\right) = e^{-Hy}\,q, \qquad q = k\,e^{-a_{4,0}}.$$

Rule: $e^{s+t} = e^s e^t$, and the factors are regrouped. So the Hamiltonian of momentum k at the slice $a_{4,0}$ is the Hamiltonian of momentum q at the slice 0: same levels, same orbitals. This is the rescaling identity of the record (`Revision/kohn_sham/ks-theory.json`, key `rescalingIdentity`; PROVED: check `rescaling_identity` of `Revision/kohn_sham/reports/ks-theory-python.json`; COMPUTED by the solver: check `free_rescaling_relation_and_band_monotone` of `Revision/kohn_sham/reports/ks-rust-solver.json`, which finds the two sides equal to 0.0). By line 8 the matrix element is $-q \int e^{-Hy}(a_m a_n - b_m b_n)\, dy$ with the orbitals of momentum q at slice 0. Therefore, for $\lambda = 0$,

$$\frac{Q}{A} = G(q),$$

one function of one variable for every shell and every slice. We call q the **redshifted momentum**. As the history goes on, the q of every shell slides from k towards 0.

22.8 The sudden limit, two histories and three estimates of the breakdown

The adiabatic and the sudden limit. At a very small rate the particle stays in its instantaneous level, up to the dressing (the **adiabatic limit**). At a very large rate the opposite happens. Suppose that a_4 jumps from the value s_1 to the value s_2 in a time interval of length τ, and let τ go to zero. Integrating $\dot{\chi} = -ih\chi$ over the interval changes χ by at most τ times the largest size of $h\chi$ on it, which goes to zero with τ. So just after the jump the orbital is still the orbital $\varphi_0(s_1)$ of the start. Expanded in the orbitals of the new slice,

$$\varphi_0(s_1) = \sum_n \langle \varphi_n(s_2) | \varphi_0(s_1) \rangle \, \varphi_n(s_2),$$

Rule: the expansion of line 1 at the slice s_2; the amplitudes follow by multiplying with $\varphi_n(s_2)^\dagger$ and integrating (orthonormality).

and the probability that the particle is no longer in level 0 is

$$P_{sudden} = 1 - \left| \langle \varphi_0(s_2) | \varphi_0(s_1) \rangle \right|^2 = 1 - \Big(\int_{-L}^{0} \left(a_0(s_2) a_0(s_1) + b_0(s_2) b_0(s_1) \right) dy \Big)^2 .$$

Rule: the probability of level 0 is the square of the absolute value of its amplitude, and the probabilities of all levels add up to 1; in the real form the overlap is a real integral. The sudden limit depends only on how much the band orbital itself changes between the two slices. In the language of line 5, an infinitely fast passage is line 5 without the term $-i\varepsilon_m c_m$, which has no time to act; Notebook 22a computes the sudden limit both ways.

Time measured in units of the passage. Let a passage from $a_4 = 0$ to $a_4 = 2$ (the span of the record's slices) last the time T, and write $x_4 = Tu$ with u running from 0 to 1. Then

$$\frac{dc_m}{du} = T \, \frac{dc_m}{dx_4} = -iT\varepsilon_m c_m - \frac{da_4}{du} \sum_n K_{mn} c_n .$$

Rule: the chain rule, $dc/du = (dx_4/du)(dc/dx_4) = T\,dc/dx_4$, applied to line 5, and $T\dot{a}_4 = da_4/du$ by the same rule.

The smooth passage. The first history of Notebook 22a is

$$a_4(u) = 2\Big[u - \frac{\sin(2\pi u)}{2\pi}\Big].$$

At $u = 0$ it is 0 and at $u = 1$ it is 2, because $\sin 0 = \sin 2\pi = 0$. Its rate:

$$\frac{da_4}{du} = 2\big[1 - \cos(2\pi u)\big] = 4\sin^2(\pi u).$$

Rule: the derivative of $\sin(2\pi u)/(2\pi)$ is $\cos(2\pi u)$; then the identity $1 - \cos 2\theta = 2\sin^2\theta$ with $\theta = \pi u$.

$$\frac{da_4}{dx_4} = \frac{1}{T}\,\frac{da_4}{du} = \frac{4}{T}\sin^2(\pi u).$$

Rule: the chain rule with $du/dx_4 = 1/T$. The rate starts at 0, rises to its peak $4/T$ at $u = 1/2$ (where $\sin^2(\pi/2) = 1$) and falls back to 0. With $H = 1$ the peak rate is $A = 4/T$, so a passage with peak rate A lasts $T = 4/A$. Because the rate vanishes at both ends, the particle carries no dressing at the start and at the end: whatever probability has left level 0 at the end is a real transition.

The constant rate. The second history is the record's kind, $a_4 = 2u$, with the constant rate $da_4/dx_4 = 2/T = A$, so $T = 2/A$. Here the particle carries the dressing all the time, and the test is whether the exact evolution reproduces the first-order dressing $\sum_m Q_{0m}^2$ of Section 22.7.

First order for the smooth passage. Write $c_m = d_m\, e^{-iT\int_0^u \varepsilon_m\,du'}$, which removes the fast turning of each amplitude, and keep on the right of the u-equation only $c_0 = e^{-iT\int_0^u \varepsilon_0\,du'}$:

$$\frac{dd_m}{du} = -\frac{da_4}{du}\,K_{m0}\,e^{iT\int_0^u(\varepsilon_m-\varepsilon_0)\,du'}.$$

Rule: the product rule gives $dc_m/du = (dd_m/du - iT\varepsilon_m d_m)\,e^{-iT\int\varepsilon_m}$; the term $-iT\varepsilon_m c_m$ of the equation cancels the second part; dividing by $e^{-iT\int\varepsilon_m}$ and inserting c_0 gives the right side.

$$d_m(1) = -\int_0^1 \frac{da_4}{du}\,K_{m0}\,e^{iT\int_0^u(\varepsilon_m-\varepsilon_0)\,du'}\,du, \qquad P^{(1)} = \sum_{m\neq 0}|d_m(1)|^2.$$

Rule: integrate from $u = 0$, where $d_m = 0$ (the particle starts in level 0), to $u = 1$; $|c_m| = |d_m|$ because the exponential has absolute value 1. For a slow passage (large T) the fast-turning exponential makes the integral small: the transitions die out. This is a derivation of this book; Notebook 22a tests it against the exact evolution.

Three estimates of the breakdown. The instantaneous picture breaks down when the probability P that a particle is not in its instantaneous level stops being small. Notebook 22a compares three estimates of the rate at which that happens:

1. the naive estimate: Q reaches 1, that is $A = 1/Q_{max}$ (exact rule 1);

2. the first-order estimate: the dressing probability $(AQ_0)^2$ reaches the sudden value P_{sudden} of the passage from $a_{4,0} = 0$ to 2, that is $A = \sqrt{P_{sudden}}/Q_0$, where Q_0 is the record's largest Q of the free state $N = 688$ at the slice 0;

3. the exact evolution: the rate $A_{1/2}$ at which the exact P of the smooth passage reaches half of P_{sudden}.

22.9 Example: when does the instantaneous picture break down (Notebook 22a)

Notebook 22a carries out the first step of Problem 2. It reads the table `Revision/kohn_sham/results/adiabatic/adiabaticity.csv` (the largest Q of each of the 75 ground states), `Revision/kohn_sham/results/adiabatic/history.json` (the status of the history), `Revision/kohn_sham/results/ground/levels` (the level tables), `Revision/kohn_sham/results/parameters.json` (the units and numerical parameters) and `Revision/kohn_sham/ks-theory.json`. It writes the solver's shooting method again in Python for the free block, reproduces the record's levels and Q, draws the one curve $G(q)$ of exact rule 2, measures the jumps into the negative branch, and integrates the amplitude equation of Section 22.6 in a basis of 20 instantaneous levels for the smooth passage and the constant rate of Section 22.8. Everything that is computed beyond the record is computed for the free field ($\lambda = 0$) and for one sector: $j = +1$, even brane parity, the Fermi shell $n_2 = 11$ of $N = 688$. It needs only numpy and matplotlib, takes about a minute (the build and check runs of 2026-10-08 recorded in its provenance file took 18.5 and 15.6 seconds; on a computer busy with other work it takes longer), draws eight figures and ends with the line ALL 20 CHECKS PASSED (notebook 22a).

22.10 How to run Notebook 22a

Step 1. What this notebook does and what it needs.

Notebook 22a (When does the instantaneous Kohn-Sham picture break down) is the file `Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb` of the repository Dirac_claude. It estimates how fast the three extra times would have to deflate before the instantaneous Kohn-Sham states of dirac16complex stop describing the gas: it reads the adiabaticity measure Q of the 75 recorded ground states and shows that Q grows exactly in proportion to the rate, reproduces Q of the free Fermi-shell sectors with the solver's shooting method, collapses every slice and shell onto one curve with the exact rescaling identity, measures the jumps into the negative-energy branch, and solves the exact time evolution of the free Fermi-shell sector of N = 688 in a basis of 20 instantaneous levels for rates from 0.25 to 251, compared with the first-order estimate and the sudden limit. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell

(or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is

a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 22a_adiabatic_breakdown.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 22a_adiabatic_breakdown.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 22a_adiabatic_breakdown.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/22a.captions.json`

- `Revision/textbook/figures/22a_1_naive_rates.png`
- `Revision/textbook/figures/22a_2_one_curve.png`
- `Revision/textbook/figures/22a_3_across_the_gap.png`
- `Revision/textbook/figures/22a_4_sector_levels.png`
- `Revision/textbook/figures/22a_5_smooth_passage.png`
- `Revision/textbook/figures/22a_6_constant_rate.png`
- `Revision/textbook/figures/22a_7_sudden_ceiling.png`
- `Revision/textbook/figures/22a_8_convergence.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 20 CHECKS PASSED (notebook 22a)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.

- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 22a_adiabatic_breakdown.ipynb
python -m nbconvert --execute --inplace 22a_adiabatic_breakdown.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

22.11 Notebook 22a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The Kohn-Sham states of dirac16complex in the Revision record are **instantaneous**
states: at each slice $a_{4,0}$ of the history $a_4 = A H x_4$ the solver finds the
ground state of the Hamiltonian of that one instant. The record measures how good
this picture is with the adiabaticity measure $Q$ and finds $Q_{max} \le 0.0935$ at
the record's rate $A = 1$. Behind this number lies one of the OPEN problems of this
chapter, the time-dependent problem: **how fast would the three extra times $x_5$,
$x_6$, $x_7$ have to deflate before the instantaneous picture breaks down, and what
happens then?** This notebook makes that estimate in six steps:
```

- it reads Q_{max} of all 75 ground states of the record, shows why Q grows exactly in proportion to the rate A, and computes the naive breakdown rate $1/Q_{max}$ of every state;
- it solves again, with the Rust solver's shooting method written in vectorised Python, the Fermi-shell sectors of the free states $N = 136$ and $N = 688$ at the five slices and reproduces the record's Q_{max}, energy difference and matrix element;
- with the exact rescaling identity it collapses every slice and every shell onto ONE curve: Q/A against the redshifted momentum $q = k e^{-a_{4,0}}$;
- it measures the jumps across the gap into the negative-energy branch, which the record's filling convention leaves out;
- it solves the exact time evolution of one sector of the free field (where the evolution equation is exact) in a basis of 20 instantaneous levels, for rates from $A = 0.25$ to $A = 251$, and compares it with the first-order estimate and with the sudden limit;
- it collects the breakdown estimates in one table.

It draws eight figures and needs no Rust. Units: $H = m = 1$, as in the record.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 22a (When does the instantaneous Kohn-Sham picture break down) is the file ‘Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb‘ of the repository Dirac_claude. It estimates how fast the three extra times would have to deflate before the instantaneous Kohn-Sham states of dirac16complex stop describing the gas: it reads the adiabaticity measure Q of the 75 recorded ground states and shows that Q grows exactly in proportion to the rate, reproduces Q of the free Fermi-shell sectors with the solver's shooting method, collapses every slice and shell onto one curve with the exact rescaling identity, measures the jumps into the negative-energy branch, and solves the exact time evolution of the free Fermi-shell sector of N = 688 in a basis of 20 instantaneous levels for rates from 0.25 to 251, compared with the first-order estimate and the sudden limit. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the

installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 22a_adiabatic_breakdown.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 1 minute on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 22a_adiabatic_breakdown.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 22a_adiabatic_breakdown.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/22a.captions.json‘
- ‘Revision/textbook/figures/22a_1_naive_rates.png‘
- ‘Revision/textbook/figures/22a_2_one_curve.png‘
- ‘Revision/textbook/figures/22a_3_across_the_gap.png‘
- ‘Revision/textbook/figures/22a_4_sector_levels.png‘
- ‘Revision/textbook/figures/22a_5_smooth_passage.png‘
- ‘Revision/textbook/figures/22a_6_constant_rate.png‘
- ‘Revision/textbook/figures/22a_7_sudden_ceiling.png‘
- ‘Revision/textbook/figures/22a_8_convergence.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it

runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 20 CHECKS PASSED (notebook 22a)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 22a_adiabatic_breakdown.ipynb
  python -m nbconvert --execute --inplace 22a_adiabatic_breakdown.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues

  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 22a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 22a (When does the instantaneous Kohn-Sham picture break down) is the file
# Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb of the repository
# Dirac_claude. It estimates how fast the three extra times would have to deflate before
# the instantaneous Kohn-Sham states of dirac16complex stop describing the gas: it reads
# the adiabaticity measure Q of the 75 recorded ground states and shows that Q grows
# exactly in proportion to the rate, reproduces Q of the free Fermi-shell sectors with
# the solver’s shooting method, collapses every slice and shell onto one curve with the
# exact rescaling identity, measures the jumps into the negative-energy branch, and
# solves the exact time evolution of the free Fermi-shell sector of N = 688 in a basis of
# 20 instantaneous levels for rates from 0.25 to 251, compared with the first-order
# estimate and the sudden limit. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
```

```
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
```

```
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 22a_adiabatic_breakdown.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 1 minute
# on a typical laptop. Scroll to the end and compare the last printed lines with the
# lines in the step "What the notebook writes and what you must see" below. To keep the
```

```
# results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the
# menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 22a_adiabatic_breakdown.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 22a_adiabatic_breakdown.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/22a.captions.json
# - Revision/textbook/figures/22a_1_naive_rates.png
# - Revision/textbook/figures/22a_2_one_curve.png
# - Revision/textbook/figures/22a_3_across_the_gap.png
# - Revision/textbook/figures/22a_4_sector_levels.png
# - Revision/textbook/figures/22a_5_smooth_passage.png
# - Revision/textbook/figures/22a_6_constant_rate.png
# - Revision/textbook/figures/22a_7_sudden_ceiling.png
# - Revision/textbook/figures/22a_8_convergence.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 20 CHECKS PASSED (notebook 22a)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
```

```
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/22a_adiabatic_breakdown.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 22a_adiabatic_breakdown.ipynb
#     python -m nbconvert --execute --inplace 22a_adiabatic_breakdown.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================

## 3. The words used in this notebook

- **Slice** $a_{4,0}$: one instant of the history, named by its value of $a_4$.
  **History**: $a_4 = A H x_4$; the extra times shrink by the factor $e = 2.718...$
  (one **e-fold**) in the time $1/(AH)$. **Rate** $A$: how many e-folds per unit of
  time $1/H$; the record uses $A = 1$.
- **Sector**: one 3-momentum shell $n_2$ ($k = 0.25\sqrt{n_2}$), one block type
  $j$ and one brane parity. The exact evolution never moves a particle out of its
  sector. **Fermi shell**: the highest occupied shell of a state.
- **Instantaneous level and orbital**: a solution $h\varphi = \varepsilon\varphi$
  of the Hamiltonian $h$ of one slice. **Label** $n$: the integer that numbers the
  levels of a sector: $n = 0$ is the **band level** (bound to the brane, occupied in
  the Fermi shell), $n = 1, 2, ...$ the **bulk levels** above it (empty), $n = -1,
  -2, ...$ the levels of negative energy, the **negative branch** (in the record's
  convention the normal-ordered sea, not populated).
- **Amplitude** $c_n$: a complex number with $|c_n|^2$ = the probability to find
  the particle in level $n$. **Matrix element** $\langle m|X|n\rangle$: the integral
  $\int \varphi_m^\dagger X \varphi_n\,dy$.
- **Adiabatic**: so slow that the particle stays in its instantaneous level.
  **Sudden**: so fast that the orbital has no time to change at all.
- **Dressing**: the small admixture of other levels that a particle carries while
  the background keeps moving; **adiabaticity measure** $Q$: the amplitude of that
  admixture to first order (derived in section 4). $G(q) = Q/A$: $Q$ per unit rate.
- **Redshifted momentum** $q = k e^{-a_{4,0}}$: the 3-momentum as the deflating
  history sees it (section 4, exact rule 2).
- **Breakdown rate**: a rate at which the probability that a particle is NOT in its
  instantaneous level stops being small.
- **First order**: an approximation that keeps only terms linear in the small
  amplitudes. **Basis**: the set of instantaneous levels in which the evolving
  orbital is expanded; a **truncated** basis keeps only some of them, and
  **convergence** means the result stops changing when more are kept.
- **Unitary**: an evolution that keeps the total probability equal to 1.
- **RK4**: the classical Runge-Kutta method of order 4 for differential equations.
  **Bisection**: finding a root by halving an interval that contains it.
  **Vectorised**: one numpy operation acts on whole arrays of cases at once.
- **Chebyshev interpolation**: the polynomial through the values of a function at
  the Chebyshev nodes $s_j = 1 + \cos\theta_j$, $\theta_j = \pi(j + 1/2)/N$; for
  smooth functions it is accurate to many digits.
```

Text cell:

```
## 4. The physical and mathematical situation

**The background.** In the author's metric the three space directions $x_1, x_2,
x_3$ grow with the factor $e^{a_4}$ and the three extra times $x_5, x_6, x_7$ shrink
with $e^{-a_4}$ (both times $\sin^{1/6} z$); $x_4$ is the time and $x_0$ the hidden
direction, written with $y = \ln(\sin z)/(6H)$ from the tip $y = -L$ to the brane
$y = 0$. The record's history is $a_4 = A H x_4$ with $A = 1$, labelled a PRESCRIBED
BACKGROUND (it is not a solution of the $a_4$ equations with the Kohn-Sham source),
on the background $b_4 = 1$ of the second function $b_4(x_4)$ of the author's metric
of 2026-10-14, on which the Kohn-Sham record works.
Here $H = m = 1$ as in the record, and $A$ is the only thing we change.
```

The exact evolution. In each sector the Kohn-Sham orbital $\chi(y, x_4)$, with two real functions a and b in $\chi = (a, i b)$, obeys exactly (ks-theory.json, adiabaticity.exactEvolution)

$$i\,\frac{\partial\chi}{\partial x_4} = h\,\chi, \qquad
h = j\left[-i\sigma_1\frac{d}{dy} + M\sigma_2 + \kappa k\sigma_3\right] + v,
\qquad \kappa = e^{-Hy - a_4(x_4)}.$$

Without interaction ($\lambda = 0$) $M = m = 1$ and $v = 0$, and this equation is the complete time evolution of the free field in the sector; with interaction M and v depend on the state itself (self-consistent time-dependent Kohn-Sham theory, OPEN). This notebook solves the free case exactly, in the sector $j = +1$, even brane parity, of the Fermi shell $n_2 = 11$ of $N = 688$.

The equations for the amplitudes, line by line.

1. Write the orbital as a sum over the instantaneous orbitals, $\chi = \sum_n c_n(x_4)\,\varphi_n(a_4(x_4))$, with $\int\varphi_m^\dagger \varphi_n\,dy = 1$ for $m = n$ and 0 otherwise.
2. Left side: by the product rule and the chain rule, $i\partial_{x_4}\chi = i\sum_n[\dot c_n\varphi_n + c_n\dot a_4\,\partial_a \varphi_n]$; the dot is d/dx_4 and $\partial_a = \partial/\partial a_4$.
3. Right side: $h\chi = \sum_n c_n\varepsilon_n\varphi_n$, because every φ_n is an instantaneous orbital.
4. Multiply both sides by $\varphi_m^\dagger$ and integrate over y; the orthonormality of line 1 keeps $n = m$ in the first and last sums: $i\dot c_m + i\dot a_4\sum_n K_{mn}c_n = \varepsilon_m c_m$, with $K_{mn} = \int\varphi_m^\dagger\,\partial_a\varphi_n\,dy$.
5. Solve for the derivative: $\dot c_m = -i\varepsilon_m c_m - \dot a_4\sum_n K_{mn}c_n$. This is the equation the notebook integrates.
6. K_{mn} for $m \ne n$: differentiate $h\varphi_n = \varepsilon_n\varphi_n$ with respect to a_4: $(\partial_a h)\varphi_n + h\,\partial_a\varphi_n = (\partial_a\varepsilon_n)\varphi_n + \varepsilon_n\partial_a\varphi_n$. Multiply by $\varphi_m^\dagger$ and integrate; h is Hermitian, so $\int\varphi_m^\dagger h\,\psi\,dy = \varepsilon_m\int\varphi_m^\dagger\psi\,dy$: $\langle m|\partial_a h|n\rangle + \varepsilon_m K_{mn} = \varepsilon_n K_{mn}$, hence $K_{mn} = \langle m|\partial_a h|n\rangle/(\varepsilon_n - \varepsilon_m)$.
7. $K_{nn} = 0$: a and b are real, so $\int\varphi_n^\dagger\varphi_n\,dy = \int(a^2 + b^2)\,dy = 1$; its derivative is $2\int(a\,\partial_a a + b\,\partial_a b)\,dy = 2K_{nn} = 0$.
8. For $\lambda = 0$ only κ depends on a_4, and $\partial_a\kappa = -\kappa$, so $\partial_a h = -j\kappa k\sigma_3$ and, for $j = +1$ and $H = 1$, $\langle m|\partial_a h|n\rangle = -k e^{-a_4}\int e^{-y}(a_m a_n - b_m b_n)\,dy$ (with $\chi = (a, ib)$, $\chi_m^\dagger\sigma_3\chi_n = a_m a_n - b_m b_n$).

What Q measures. Start in level 0 at the constant rate $\dot a_4 = AH$. To first order (the other amplitudes small) line 5 reads $\dot c_m = -i\varepsilon_m c_m - AH K_{m0}c_0$ with $c_0 = e^{-i\varepsilon_0 x_4}$. Try $c_m = \alpha_m e^{-i\varepsilon_0 x_4}$ with a constant α_m: then $-i\varepsilon_0\alpha_m = -i\varepsilon_m\alpha_m - AHK_{m0}$, so $\alpha_m = iAHK_{m0}/(\varepsilon_m - \varepsilon_0)$: an admixture of level m that travels with the particle. By line 6 its size is

$$|\alpha_m| = AH\,\frac{|\langle m|\partial_a h|0\rangle|}{(\varepsilon_0 -

```
\varepsilon_m)^2} = Q_{0m},$$

the record's adiabaticity measure. So $Q$ is the amplitude, and $Q^2$ the
probability, with which the moving particle is NOT in its instantaneous level, as
long as $Q \ll 1$. This admixture is the **dressing**. (The record calls $Q^2$
the leading-order transition probability; reading it for a constant rate as the
probability of the dressing is this notebook's derivation, tested in section 14.)

**Exact rule 1: Q grows in proportion to the rate.** The levels, orbitals and
matrix elements of a slice depend on $a_{4,0}$, not on how fast $a_4$ changes; only
the factor $AH$ of $Q$ does. So $Q(A) = A\,Q(A = 1)$ exactly.

**Exact rule 2: one variable is enough.** $a_4$ enters $h$ only through
$\kappa k = e^{-Hy}(k e^{-a_4})$ (the rescaling identity of ks-theory.json, checked
by the solver). With the redshifted momentum $q = k e^{-a_{4,0}}$ the levels and
orbitals of momentum $k$ at the slice $a_{4,0}$ are those of momentum $q$ at the
slice $0$, and $\langle m|\partial_a h|n\rangle = -q\int e^{-y}(a_m a_n - b_m b_n)
\,dy$. Hence for $\lambda = 0$: $Q/A = G(q)$, one function of one variable for
every shell and every slice.

**The two limits.** At a small rate the particle stays in its instantaneous level,
up to the dressing (the adiabatic limit). At a very large rate the orbital has no
time to change: at the end it is still the orbital $\varphi_0$ of the start (the
sudden limit), and the probability that it has left level 0 is
$P_{sudden} = 1 - |\int\varphi_0(\mathrm{end})^\dagger\varphi_0(\mathrm{start})
\,dy|^2$.

**What we call breakdown.** The instantaneous picture breaks down when the
probability $P$ that a particle is not in its instantaneous level stops being
small. Three estimates are compared: the naive one, $Q = 1$, that is
$A = 1/Q_{max}$; the rate at which $Q^2$ reaches the sudden value $P_{sudden}$; and
the exact evolution.

**Status.** The record's $Q$ values are COMPUTED (Revision record). The curves,
the time evolution and the breakdown rates of this notebook are COMPUTED here for
the free field ($\lambda = 0$) in one sector, with measured numerical errors. The
self-consistent time-dependent problem ($\lambda \ne 0$) is OPEN, the history is a
PRESCRIBED BACKGROUND, the Z2 brane is ASSUMED, and the meaning of jumps into the
negative branch is OPEN.
```

```
## 5. The record: Q of the 75 ground states

The next cell reads three Revision records: the table `adiabaticity.csv` (one row
per ground state: $N = 8, 136, 688$; the couplings $\lambda = 0, \pm\lambda_1,
\pm\lambda_2$, tags lam0, lamp1, lamm1, lamp2, lamm2; the five slices), the file
`history.json` with the status of the history, and `ks-theory.json`. It prints the
largest $Q_{max}$ and the record's formula for $Q$, and checks the label of the
history and the two facts the record states: $Q_{max} \le 0.0935$, and $Q_{max} = 0$
exactly for $N = 8$ (only the $k = 0$ zero modes are occupied, and there
$\partial_a h = 0$).
```

## 6. Q grows in proportion to the rate: the naive breakdown rates

By exact rule 1 of section 4, a history $A$ times faster than the record's has
$Q = A\,Q_{max}$. The naive criterion "breakdown when $Q$ reaches 1" therefore puts
the breakdown at the rate $A = 1/Q_{max}$. The next cell computes this rate for the
50 states with $Q_{max} > 0$ and draws it against the slice (left; the five
couplings differ so little that they are drawn as a thin band around the free
state $\lambda = 0$), and draws $Q = A\,Q_{max}$ against $A$ for the free state
$N = 688$ at the five slices (right): straight lines of slope 1 on logarithmic axes.
```

## 7. The solver's shooting method, vectorised

To go beyond the record we need the levels and orbitals ourselves. The next cell
reads the record's numerical parameters from `parameters.json` (the units, the tip
cutoff $L = 3$, the 900 RK4 steps) and defines five functions for the free block
($j = +1$, $M = 1$, $v = 0$, even brane parity):

- `shoot(eps, q)` integrates the block equation $a' = a - (q e^{-y} + \varepsilon)
  b$, $b' = (\varepsilon - q e^{-y})a - b$ (the real form of $h\varphi =
```

```
  \varepsilon\varphi$, ks-theory.json blockEquation.realForm) from the tip, where
  $b = 0$, to the brane with RK4, for whole arrays of energies and momenta at once,
  and follows the **Pruefer angle** $\theta = \mathrm{atan2}(b, a)$ continuously;
  the phase $\Phi = \theta(0)$ grows with $\varepsilon$, and the level with label
  $n$ is where $\Phi = n\pi$ (then $b(0) = 0$, the even brane condition);
- `levels(labels, q)` finds these levels by bisection to $10^{-13}$, the solver's
  root tolerance;
- `orbitals(eps, q)` returns the normalised orbitals on the fine grid of step ends
  and midpoints (midpoints by cubic Hermite interpolation, norm by Simpson's rule,
  as in the solver);
- `couplings(q, a, b)` returns the matrix of $\langle m|\partial_a h|n\rangle =
  -q\int e^{-y}(a_m a_n - b_m b_n)\,dy$ (line 8 of section 4);
- `per_unit_rate(eps, matrix)` returns $G_{nm} = |\langle n|\partial_a h|m\rangle|
  /(\varepsilon_n - \varepsilon_m)^2$, that is $Q/A$.
```

## 8. The Fermi shells of the record, solved again

The record's largest $Q$ of the free states is always the jump from the band level
(label 0) to the first bulk level (label 1) in the Fermi shell: $n_2 = 4$
($k = 0.5$) for $N = 136$ and $n_2 = 11$ ($k = 0.829$) for $N = 688$. The next cell
solves the labels 0, 1, 2 of these sectors for the ten free states, **at the slice
0 with the redshifted momentum** $q = k e^{-a_{4,0}}$ (exact rule 2 of section 4),
compares the 30 levels with the record's level tables, and compares $Q$, the energy
difference and the matrix element with the record's columns `Q_max`,
`Q_max_delta_eps` and `Q_max_matrix_element`. Agreement at every slice is at the
same time a test of the rescaling identity.
```

## 10. Jumps across the gap into the negative branch

The record's $Q$ counts only jumps between levels of positive energy: its filling
convention treats the negative branch as the normal-ordered sea, which is not
populated. But the moving background couples the two branches too, through the
same matrix elements. In ordinary Dirac theory a jump from a filled negative level
to an empty positive one is the creation of a particle-antiparticle pair OF THE
FIELD, inside one universe; whether that reading holds in the 4+4 quantisation with
```

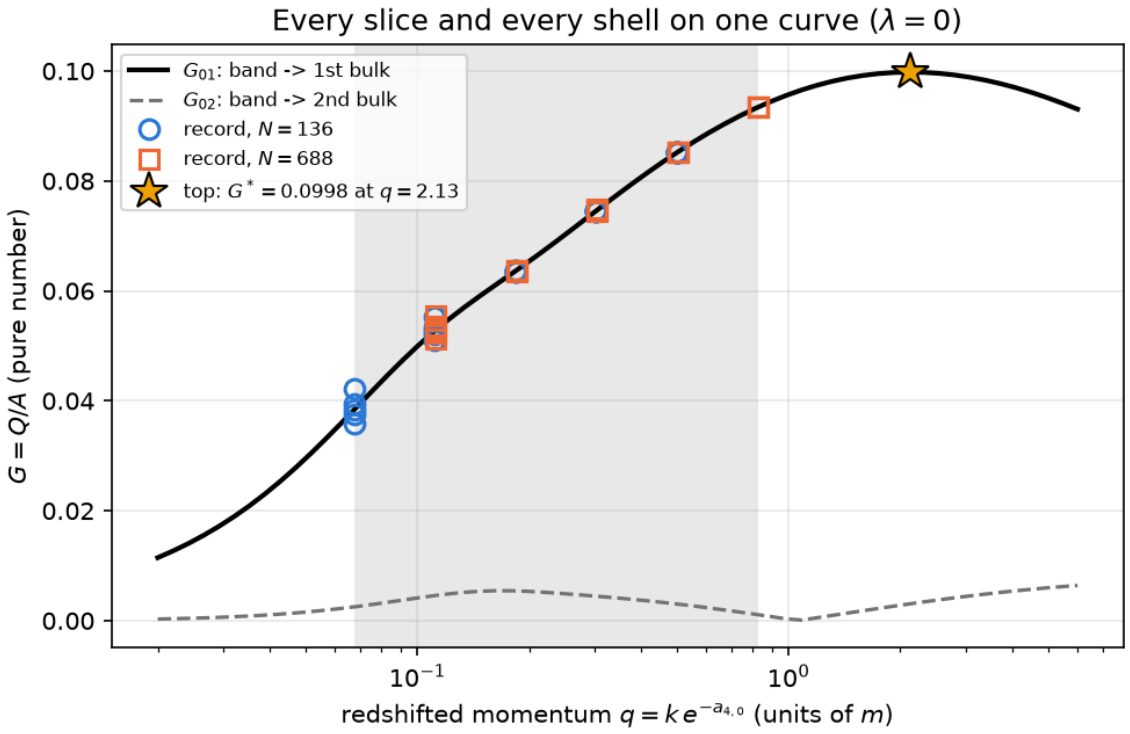

Figure 552: The adiabaticity measure per unit rate, $G = Q/A$ (vertical axis, pure number), of the jump from the band level to the first (black) and second (grey, dashed) bulk level of a free sector, against the redshifted momentum $q = ke^{-a_{4,0}}$ (horizontal axis, logarithmic, units of m). Open symbols: the recorded Q_{max} of the 50 states with $N = 136$ (circles) and $N = 688$ (squares), each at the q of its Fermi shell; the five couplings overlap. The grey band is the range of the record; the star is the top of the curve, the largest Q/A of the jump to the first bulk level for every shell and slice with $0.02 \leq q \leq 6$ (all states of the record). (Notebook 22a, figure 2.)

its Krein metric is OPEN, and it has nothing to do with the creation of universes. The next cell draws, from the same table $G_{nm}(q)$, the jumps from the negative levels -1 and -2 to the bulk levels and to the band level, next to the band jump of section 9, and finds the largest jump from a negative to a positive bulk level.

(Notebook 22a, figure 3.)

11. The Fermi-shell sector along the recorded span

For the time evolution we need the levels and the matrix K_{mn} not at a few slices but at every instant. The next cell takes the Fermi-shell sector of $N = 688$ ($n_2 = 11$, $k = 0.829$, 96 particles in its band level), solves 20 labels (-9 to 10) at 56 Chebyshev nodes of the span $a_{4,0} = 0$ to 2, and builds the interpolating Chebyshev polynomials of every level and every matrix element: the coefficients are $c_k = (2/N)\sum_j f(s_j)\cos(k\theta_j)$, with c_0 halved. It then checks the interpolation against a direct solution at five other points, and checks that the interpolated Q at the five slices equals the record's.

In [9]:

```
K11 = 0.25 * math.sqrt(11.0)  # the Fermi-shell momentum of N = 688 (units of m)

```

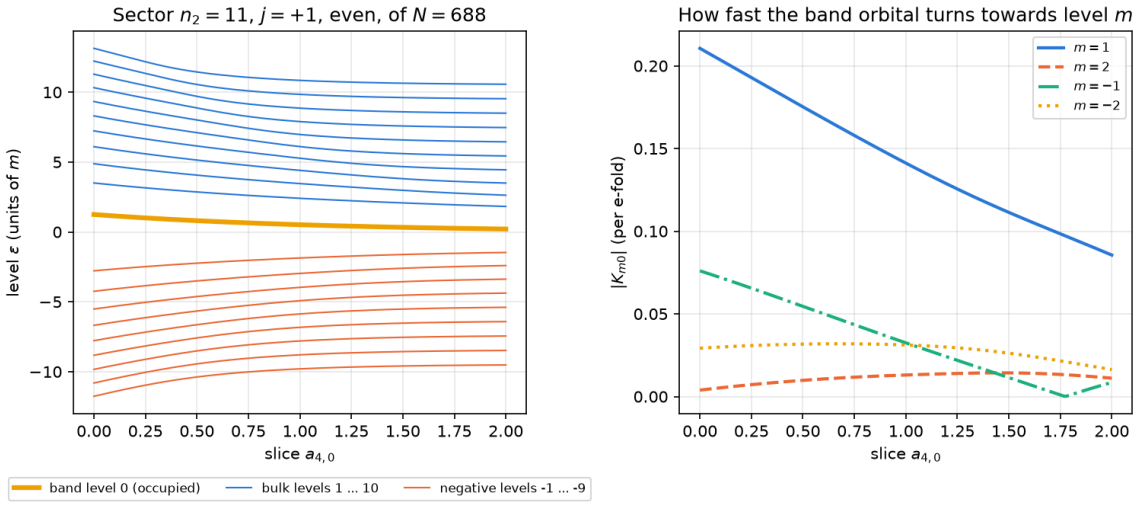

Figure 554: Left: the 20 instantaneous levels (vertical axis, units of m) of the free Fermi-shell sector of $N = 688$ against the slice $a_{4,0}$ (horizontal axis): the occupied band level (thick) falls as the 3-momentum redshifts, the bulk levels above it and the negative levels below it move towards their values at $k = 0$. Right: $|K_{m0}|$, how far the band orbital turns towards level m per e-fold (vertical axis), for $m = 1, 2, -1, -2$; all are below 0.25, so the band orbital changes slowly. (Notebook 22a, figure 4.)

## 12. The exact time evolution in the basis of instantaneous levels

Now we integrate line 5 of section 4, $\dot c_m = -i\varepsilon_m c_m - \dot a_4
\sum_n K_{mn}c_n$, in the basis of the 20 levels. We write the time as $x_4 = T u$
with $u$ running from 0 to 1, so that $dc/du = -iT\varepsilon c - (da_4/du)\,K c$;
$T$ is the duration of the passage. The next cell defines:

- `frame(s)`: the levels and the matrix $K_{mn} = \langle m|\partial_a h|n\rangle
  /(\varepsilon_n - \varepsilon_m)$ ($K_{nn} = 0$) at the slices $s$, from the
  Chebyshev fits;
- `passage(...)`: RK4 for $dc/du$ on a fine grid of 4000 steps of $u$ (it may use
  every second, fourth, ... point for fewer steps);
- `steps_needed(T)`: the smallest number of steps for which the fastest phase
  turns by at most 0.2 radian per step;
- the two histories: a **smooth passage** $a_4 = 2[u - \sin(2\pi u)/(2\pi)]$, whose
  rate $da_4/dx_4 = (4/T)\sin^2(\pi u)$ starts at zero, rises to its peak $A = 4/T$
  in the middle and falls back to zero; and the **constant rate** $a_4 = 2u$ of the
  record's kind, with $A = 2/T$.
```

## 13. A smooth passage at every rate

The smooth passage starts and ends with the rate zero, so there is no dressing at
the ends: whatever probability $P = 1 - |c_0|^2$ has left the band level at the end
is a real transition. The next cell runs the passage for 31 peak rates $A$ from
$0.25$ to $251$ (ten per factor 10), checks that the total probability stays 1,
computes the sudden limit twice (in the basis, with $T = 0$, and directly from the
overlap of the two band orbitals at $a_{4,0} = 0$ and $2$), and computes the
first-order estimate $P^{(1)} = \sum_m |d_m|^2$ with $d_m = -\int_0^1 (da_4/du)
K_{m0}\,e^{iT\int_0^u(\varepsilon_m - \varepsilon_0)\,du'}\,du$ (line 5 with $c_0 =
1$ on the right side, written for $d_m = c_m e^{iT\int\varepsilon_m du}$). Finally
it finds the rate $A_{1/2}$ at which $P$ reaches half the sudden value.
```

## 14. A constant rate: the dressing that Q measures

Section 4 showed that at a constant rate the particle carries the dressing
$\alpha_m = iAK_{m0}/(\varepsilon_m - \varepsilon_0)$, of total probability
$\sum_m Q_{0m}^2$. The next cell tests this with the exact evolution at the
constant rates $A = 0.3$, $1$ and $3$ over the span $a_{4,0} = 0$ to $2$: it starts
in the dressed state (level 0 plus the admixtures $\alpha_m$, normalised) and
compares the exact $P(a_4)$ with $\sum_m Q_{0m}(a_4)^2$ at 101 points. At $A = 1$
it also starts in the bare level 0, to show the extra transition caused by
switching the motion on abruptly.
```

In [14]:

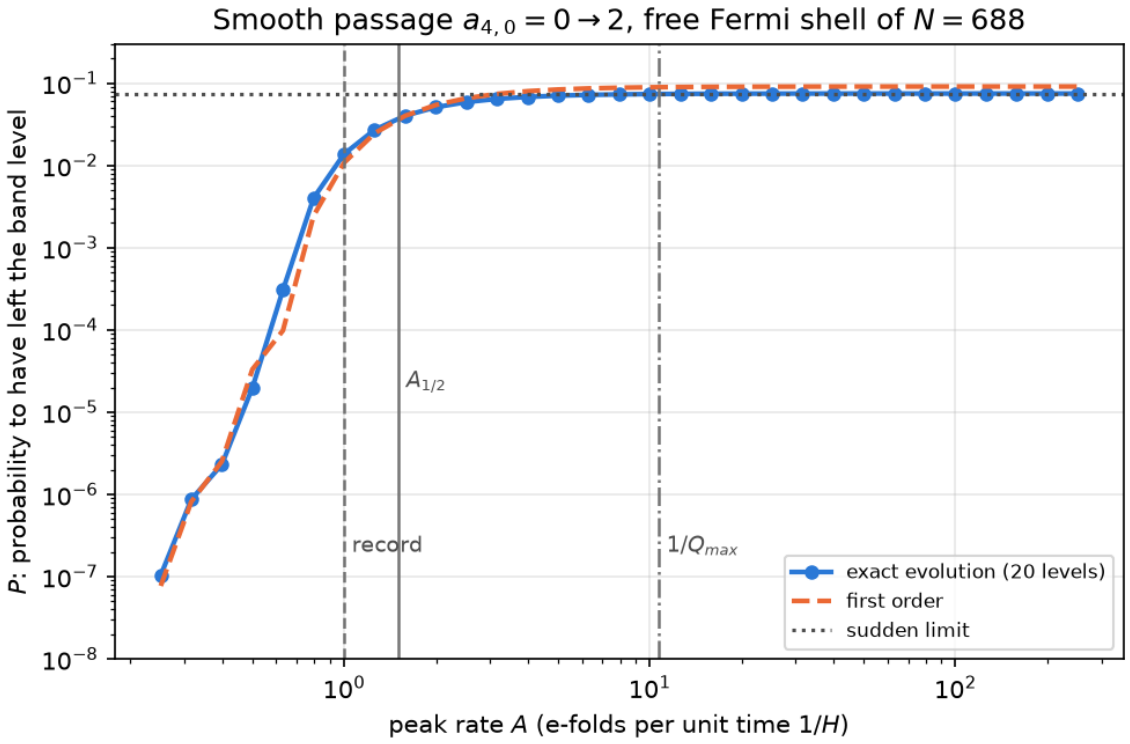

Figure 555: The probability P that the particle of the band level has left it at the end of a smooth passage from $a_{4,0} = 0$ to 2 (vertical axis, logarithmic), against the peak rate A (horizontal axis, logarithmic): exact evolution in the basis of 20 instantaneous levels (blue), the first-order estimate (orange, dashed) and the sudden limit (dotted). Vertical lines: the record's rate $A = 1$, the rate $A_{1/2}$ at which P reaches half the sudden limit, and the naive breakdown rate $1/Q_{max}$. The gas stops following its level near $A = 1$, about seven times below the naive estimate ($A_{1/2} = 1.5$ against $1/Q_{max} = 10.7$), but P never exceeds the sudden limit of about 7.5 percent. PASS the sudden limit grows with the end slice and stays below 0.11 up to 6
```

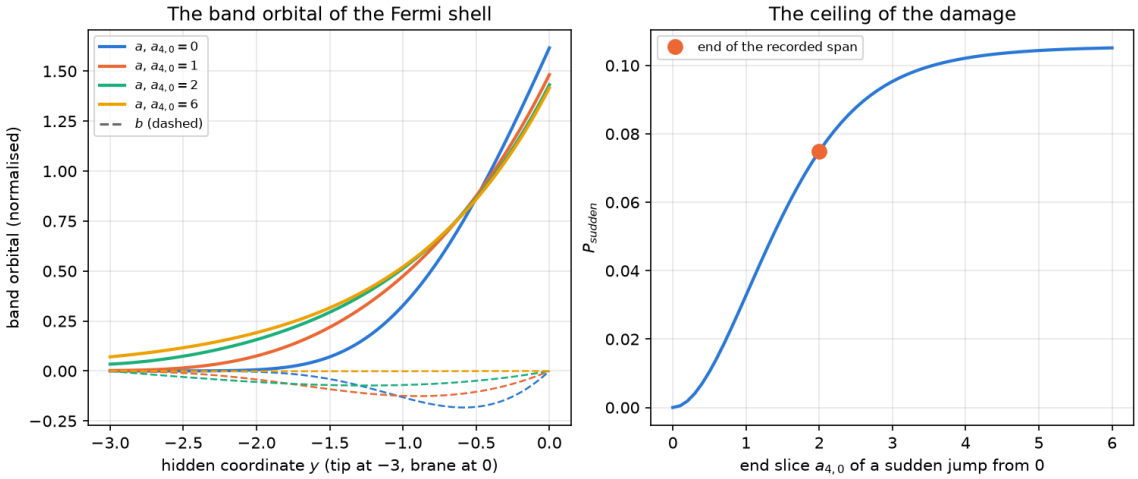

Figure 557: Left: the band orbital of the Fermi shell of $N = 688$, components a (solid) and b (dashed), against the hidden coordinate y (horizontal axis) at the slices $a_{4,0} = 0$, 1, 2, 6: as the momentum redshifts, b shrinks and the orbital approaches the brane zero mode e^{y}. Right: the sudden limit P_{sudden} (vertical axis) of a jump from $a_{4,0} = 0$ to the end slice (horizontal axis); it grows and levels off near 0.105: even an instant jump to the far future leaves almost 90 percent of the particles in the band level. (Notebook 22a, figure 7.)

Text cell:

```
The last numerical question is how good the truncated basis and the time steps
are. The next cell repeats the sudden limit and the smooth passages at $A = 1$ and
$A = 3$ with smaller bases (the labels $-l ... l$ and $-l ... l + 1$, from 3 to 20
levels), draws the differences to the reference (the direct overlap for the sudden
limit, the 20-level result for $A = 1$ and $3$), and repeats three passages with
twice or half the number of steps.
```

## 17. What this notebook showed

- The record's adiabaticity measure $Q$ is, in this notebook's reading (the record
  calls $Q^2$ the leading-order transition probability), the first-order amplitude
  of the dressing that a moving particle carries; by an exact argument it grows in
  proportion to the rate $A$ of the history. At the record's rate $A = 1$,
  $Q_{max} \le 0.0935$ for all 75 states (COMPUTED, Revision record), so the naive
  breakdown "$Q = 1$" would need $A \ge 10.7$.
- The solver's shooting method, written again in vectorised Python, reproduces the
```

```
  record's levels and $Q$ of the free Fermi shells; with the exact rescaling
  identity every slice and every shell falls on ONE curve $Q/A = G(q)$, whose top
  is $G^* = 0.0998$ at $q = 2.13$ (COMPUTED here): for a particle in the band level
  of every shell and slice with $0.02 \le q \le 6$ (all states of the record) the
  naive breakdown rate is at least $A = 10.0$.
- Jumps across the gap into the negative branch, which the record leaves out, are
  weaker than the top of the band jump (below 0.05 per unit rate; the strongest,
  $-1 \to$ bulk 1, peaks near $q = 0.11$) but stronger than the band jump itself
  below $q$ of about 0.1; their reading as pair creation of the field in 4+4
  dimensions is OPEN, and they say nothing about the creation of universes.
- The exact evolution of the free Fermi-shell sector of $N = 688$ (20-level basis,
  converged to a few millionths) tells a sharper story: the gas stops following its
  instantaneous level already near $A = 1$ ($A_{1/2} \approx 1.5$ for a smooth
  passage), about seven times below the naive estimate ($1/Q_{max} = 10.7$); but
  the damage is capped by the sudden limit, 7.5 percent over the recorded span and
  about 10.5 percent even for an instant jump to $a_{4,0} = 6$, because the band
  orbital itself changes slowly.
  At the record's rate the probability to find a Fermi-shell particle outside its
  instantaneous level is about 1 percent (COMPUTED here).
- What remains OPEN: the self-consistent time-dependent Kohn-Sham problem with
  interaction, the meaning of the negative branch, the history itself (a PRESCRIBED
  BACKGROUND, without back-reaction) and the ASSUMED Z2 brane. A student could
  attack the first by starting from the record's self-consistent states and
  recomputing the potentials $M$ and $v$ at every time step from the evolving
  orbitals of all occupied sectors (time-dependent Kohn-Sham theory), then
  repeating sections 13 and 14 with them.
```

22.12 Line-by-line walk-through of Notebook 22a

The notebook has 17 code cells, In [1] to In [17]. This section explains every line of every one of them, in order. In the notebook each code cell is preceded by a text cell that says what the cell does; the printed output of each cell is in Section 22.11 under the label Out [k], and the eight figures are shown there with their captions. For each figure this section adds what the student should see and why.

In [1], the set-up cell. It is the same in every notebook of the book except for the notebook's name. Its first 231 lines repeat the complete run instructions of Section 22.10 as **comment lines**: every line that starts with `#` is skipped by Python and is there only so that the notebook file carries its own instructions. A line of dashes and the title THE SET-UP between two lines of `=` signs mark where the code begins.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "22a"  # this notebook: chapter 22, example a
```

`import` loads a **module** (a part of Python or of an installed package) so that the cell can use it; the text after `#` on each line is a comment that says what the module is for. `json` reads the text format JSON in which most Revision records are stored. `os` gives access to the operating system, here to read an environment variable. `textwrap` breaks long printed text into lines. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system. `matplotlib` is the plotting package and `matplotlib.pyplot` its drawing functions, called `plt` by convention. `Image` and `display` show a saved picture below a cell. The last line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"22a"`; the figure files are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description that Python keeps but does not run. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. The list `[here, *here.parents]` holds this folder followed by its parent, the parent of that, and so on (the star unpacks the parents into the list), and the `for` loop takes them one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back; if no folder does, `raise` stops the notebook with an error message that says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))

def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
```

```
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path

def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`REPO` is the repository folder; it is never printed, because it differs from computer to computer while the printed output must be the same everywhere. `os.environ.get(name, default)` reads an **environment variable** (a named text that a program receives from the computer) or returns the default; when you run the notebook the variable TEXTBOOK_OUTPUT_ROOT is not set, so `OUTPUT_ROOT` is the repository, while the book's checking tool sets it to a scratch folder so that a check never changes the repository. `repository_file` gives the full path of a repository file for reading; `output_file` gives the full path at which to write one, after creating its folder (`mkdir` with `parents=True` creates missing parent folders as well, and `exist_ok=True` makes it do nothing if the folder exists). `say` prints a text in lines of at most 89 characters, continuation lines indented by four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})

FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

`matplotlib.rcdefaults()` returns to the built-in plotting settings, so that the figures are the same on every computer, and `plt.rcParams.update` sets the default figure size (7.0 by 4.2 inches), the letter size (10 points) and a faint grid. The braces `{...}` make a **dictionary**: pairs of a key and a value, written `key: value`. A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/22a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary `{}` into the captions file; `newline="\n"` stores the same line end on every operating system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
```

```
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` numbers the figures 1, 2, 3, ... in the order in which they are saved (`setdefault` returns the number already stored for this name, or stores one more than the count so far), saves the figure as a PNG file with 150 dots per inch, cut to its content and without the program's name inside (so that two runs write the same bytes), closes it, records its caption in the captions file (`json.dumps` turns the dictionary into JSON text, one entry per line, keys sorted), shows the saved picture below the cell, and prints where it was saved. The caption given to it is the caption that the book prints under the figure.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")

def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`PASSED` is an empty **list** (an ordered collection, in square brackets). `check` is the function behind every check of the notebook: if the statement `condition` is false, `raise AssertionError(...)` stops the notebook with an error that names the check; if it is true, the name is appended to `PASSED`

and the line PASS followed by the name is printed, and a second line names the Revision record when the argument `record` is given (`None` is Python's word for "nothing"). Python's own `assert` statement is not used, because Python started with the option `-O` skips it. `report` prints a key number as a line that starts with RESULT. `all_checks_passed` prints the last line of the notebook with the number of checks that passed (`len` is the length of a list). The last statement prints the one output line of In [1].

In [2], the record: Q of the 75 ground states.

```
import csv  # reads the tables (CSV files) of the Revision record
import math  # exp, sqrt and log of single numbers

import numpy as np  # arrays of numbers and their arithmetic
from numpy.polynomial import chebyshev  # Chebyshev polynomials (section 11)
```

Four more modules: `csv` reads tables stored as CSV files (comma-separated values: one line per row, the entries separated by commas); `math` computes the exponential, square root and logarithm of single numbers; `numpy`, called `np`, holds **arrays** (tables of numbers of any shape) and computes with whole arrays at once; and `chebyshev` evaluates sums of Chebyshev polynomials, which In [9] uses.

```
ADIABATIC = "Revision/kohn_sham/results/adiabatic/adiabaticity.csv"
HISTORY = "Revision/kohn_sham/results/adiabatic/history.json"
THEORY = "Revision/kohn_sham/ks-theory.json"
SLICES = [0.0, 0.5, 1.0, 1.5, 2.0]  # the slices a4,0 of the record
TAGS = ["lam0", "lamp1", "lamm1", "lamp2", "lamm2"]  # 0, +-lambda_1, +-lambda_2
PALETTE = ["#2a78d6", "#eb6834", "#1baf7a", "#eda100", "#e87ba4", "#008300",
           "#4a3aa7", "#e34948"]  # the colours of the figures, in a fixed order
```

Three names for the repository paths of the records the cell reads; the five slices of the record; the five coupling tags; and eight colours, written as hexadecimal codes, which every figure uses in this fixed order (blue, orange, green, yellow, pink, dark green, violet, red).

```
def state_id(n, a4, tag="lam0"):
    """The record's name of a ground state, for example N688_lam0_a05."""
    return f"N{n}_{tag}_a{round(10 * a4):02d}"
```

`state_id` builds the record's name of a state: for $n = 688$, $a_4 = 0.5$ and the default tag lam0 it returns `N688_lam0_a05`. Inside the braces of the f-string, `round(10 * a4)` turns the slice into the whole number 5, and the format `:02d` writes it with two digits, padded by a zero.

```
with open(repository_file(ADIABATIC), newline="", encoding="utf-8") as handle:
    record = {row["id"]: row for row in csv.DictReader(handle)}
history = json.loads(repository_file(HISTORY).read_text(encoding="utf-8"))
theory = json.loads(repository_file(THEORY).read_text(encoding="utf-8"))
```

`with open(...) as handle:` opens the table and closes it again when the indented line has run. `csv.DictReader` reads it row by row, each row a dictionary from the column names of the first line (`id`, `N`, `lambda_tag`, `Q_max`, `Q_max_pair`, ...) to the texts of that row. The braces with `for` inside make a **dictionary comprehension**: `record` maps each state's name (column `id`) to its row. `json.loads` turns the text of the two JSON files into Python dictionaries.

```
q_max = {(n, tag, a4): float(record[state_id(n, a4, tag)]["Q_max"])
         for n in (8, 136, 688) for tag in TAGS for a4 in SLICES}
largest = max(q_max.values())
n8_zero = all(q_max[(8, tag, a4)] == 0.0 for tag in TAGS for a4 in SLICES)
```

`q_max` maps every triple (particle number, tag, slice), a **tuple** written in round brackets, to the number in the column `Q_max` of that state; `float` turns the text into a number. The two lines of the comprehension run over the 3 particle numbers, the 5 tags and the 5 slices: 75 states. `largest` is the largest of all 75 values. `all(...)` is true when every one of the 25 values for $N = 8$ is exactly zero.

```
report("ground states in the record", len(record))
report("largest Q_max at the rate A = 1", f"{largest:.10f}")
say("The record's measure: " + theory["adiabaticity"]["measure"])
```

Out [2] shows 75 states and the largest value 0.0934532439, printed with ten digits after the point (format `.10f`), and then the record's own definition of Q from the key `adiabaticity.measure` of `ks-theory.json`: the formula derived in Section 22.7, with the remark that Q^2 is the leading-order transition probability.

```
check(history["status"].startswith("PRESCRIBED BACKGROUND")
      and theory["adiabaticity"]["historyStatus"].startswith("PRESCRIBED BACKGROUND"),
      "the history a4 = A H x4 is labelled a PRESCRIBED BACKGROUND",
      record=f"{HISTORY}, key status, and {THEORY}, adiabaticity.historyStatus")
check(len(record) == 75 and largest <= 0.0935 and n8_zero,
      "75 states, Q_max <= 0.0935, and Q_max = 0 exactly for N = 8",
      record=f"{ADIABATIC}, column Q_max")
```

The first check requires that both records begin their statement of the history with the words PRESCRIBED BACKGROUND (`startswith` tests the beginning of a string): the notebook works on a background that is given, not solved for, and says so. The second check requires the 75 rows, the bound 0.0935 and the exact zeros for $N = 8$. Those zeros have a reason: the eight quanta of $N = 8$ occupy only the zero modes at $k = 0$, and at $k = 0$ the derivative $\partial_a h = -j\kappa k\sigma_3$ of Section 22.6 vanishes.

In [3], Q grows in proportion to the rate (Figure 22a.1).

```
naive = {key: 1.0 / value for key, value in q_max.items() if value > 0.0}
weakest = min(naive, key=naive.get)  # the state that reaches Q = 1 first
rates = np.geomspace(0.1, 100.0, 200)  # rates A for the right panel
```

By exact rule 1 of Section 22.7, Q reaches 1 at the rate $A = 1/Q_{max}$. `naive` maps every state with $Q_{max} > 0$ (the 50 states with $N = 136$ and 688) to this rate. `min(naive, key=naive.get)` returns the key whose value is smallest: the state that would reach $Q = 1$ first. `np.geomspace(0.1 , 100.0, 200)` makes 200 rates from 0.1 to 100, equally spaced on a logarithmic scale (each one the same factor larger than the one before).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2), layout="constrained")
for colour, marker, n in ((PALETTE[0], "o", 136), (PALETTE[1], "s", 688)):
    band = np.array([[naive[(n, tag, a4)] for a4 in SLICES] for tag in TAGS])
    left.fill_between(SLICES, band.min(axis=0), band.max(axis=0), color=colour,
                      alpha=0.25, lw=0)  # the spread over the five couplings
    left.plot(SLICES, band[0], "-", color=colour, marker=marker, ms=8, lw=2.0,
              label=f"$N = {n}$")
```

`plt.subplots(1, 2, ...)` makes a figure with two panels side by side, `left` and `right`, 10 by 4.2 inches, with the layout adjusted automatically. For $N = 136$ (blue circles) and $N = 688$ (orange squares) the loop builds `band`, an array with one row per tag and one column per slice. `fill_between` shades the area between the smallest and the largest value of each column (`axis=0` takes the minimum down the columns), that is, the spread over the five couplings, a quarter opaque (`alpha=0.25`) and without border (`lw=0`). `left.plot` draws the first row, the free state lam0, as a line with markers of size 8.

```
left.axhline(1.0, color="0.3", lw=1.2, ls=":")
left.text(0.05, 1.12, "the record's rate $A = 1$", fontsize=8, color="0.3")
left.set_yscale("log")
left.set_ylim(0.7, 50.0)
left.set_xlabel("slice $a_{4,0}$")
left.set_ylabel("naive breakdown rate $1/Q_{max}$")
left.set_title("Rate at which $Q$ would reach 1")
left.legend(fontsize=8)
```

A dotted horizontal line at $A = 1$, the record's rate, with a small label; a logarithmic vertical axis from 0.7 to 50; the axis labels, the title and the legend. Text between dollar signs is set as mathematics by matplotlib.

```
for colour, a4 in zip(PALETTE, SLICES):
    right.plot(rates, rates * q_max[(688, "lam0", a4)], color=colour, lw=2.0,
               label=f"$a_{{4,0}} = {a4}$")
right.axhline(1.0, color="0.3", lw=1.2, ls=":")
right.axvline(1.0, color="0.3", lw=1.2, ls="--")
right.text(1.08, 0.012, "record: $A = 1$", fontsize=8, color="0.3")
right.set_xscale("log")
right.set_yscale("log")
right.set_xlabel("rate $A$ (e-folds of the extra times per unit time $1/H$)")
right.set_ylabel("$Q = A\\,Q_{max}$")
right.set_title("$N = 688$, $\\lambda = 0$: $Q$ grows like $A$")
right.legend(fontsize=8)
```

`zip` pairs the first five colours with the five slices. For each slice the right panel draws $Q = A\,Q_{max}$ of the free state $N = 688$ against the 200 rates. In the f-string the doubled braces `{{4,0}}` print single braces, so the label reads $a_{4,0} = 0.5$ and so on. A dotted line marks $Q = 1$, a dashed vertical line the record's rate; both axes are logarithmic. In a normal Python string a backslash starts an escape, so `\\,` and `\\lambda` are written with two backslashes to give matplotlib the single backslash of `\,` (a thin space) and of `\lambda`.

```
save_figure(fig, "naive_rates",
            "Left: the naive breakdown rate $1/Q_{max}$ (vertical axis, logarithmic) "
            "of the ground states $N = 136$ (blue circles) and $N = 688$ (orange "
            "squares) against the slice $a_{4,0}$ (horizontal axis); the lines are "
            "the free states, the shaded bands the spread over the five couplings, "
            "the dotted line the record's rate $A = 1$. Right: $Q = A\\,Q_{max}$ "
            "against the rate $A$ for the free state $N = 688$ at the five slices "
            "(both axes logarithmic); $Q$ reaches 1 (dotted) only above $A = 10$. "
            "The naive estimate says the record's history is at least ten times "
            "too slow to break the instantaneous picture.")
report(f"naive breakdown rate 1/Q_max of {state_id(weakest[0], weakest[2], weakest[1])}",
       f"{naive[weakest]:.4f}")
check(naive[weakest] > 10.0,
      "every recorded state keeps Q below 1 up to the rate A = 10",
      record=f"{ADIABATIC}, column Q_max")
```

`save_figure` saves Figure 22a.1 with its caption (Python joins strings written next to each other into one). The report names the weakest state, N688_lamm2_a00 (the tuple `weakest` is (688, "lamm2", 0.0), so `weakest[0]` is the particle number, `weakest[2]` the slice and `weakest[1]` the tag), and its naive breakdown rate 10.7005 (Out [3]). The check requires that every recorded state keeps Q below 1 up to the rate $A = 10$.

What the student should see in Figure 22a.1, and why. On the left every point lies far above the dotted line: the naive breakdown rate is between 10.7 (N688_lamm2_a00) and 27.8 (N136_lamm2_a20; 26.05 for the free state N136 at the slice 2), so by this measure the record's history is at least ten times too slow to disturb the instantaneous picture. Both curves rise with the slice: as the history goes on, the momentum of the Fermi shell redshifts, $q = ke^{-a_{4,0}}$ falls, and Q/A falls with it (Figure 22a.2 shows why). The shaded bands are thin: the five couplings change Q_{max} by at most about ten percent. On the right the five lines are straight with slope 1 on the logarithmic axes, which is exact rule 1: ten times the rate gives ten times Q. They cross the dotted line $Q = 1$ between $A = 10.7$ and $A = 18.9$.

In [4], the solver's shooting method, vectorised.

```
PARAMETERS = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                        .read_text(encoding="utf-8"))
L = PARAMETERS["physics"]["L_tipCutoff"]  # the tip cutoff y = -L
STEPS = PARAMETERS["numerics"]["rk4Steps"]  # RK4 steps from the tip to the brane
POINTS = 2 * STEPS + 1  # the fine grid: step ends and step midpoints
STEP = L / STEPS  # the length of one RK4 step in y
```

The cell reads the record's parameter file and takes from it the tip cutoff $L = 3$ and the number of RK4 steps, 900, with which the Rust solver integrates from the tip $y = -L$ to the brane $y = 0$. RK4 evaluates the equation at the start, the middle and the end of every step, so the notebook keeps a **fine grid** of $2 \cdot 900 + 1 = 1801$ points: the 901 step ends and the 900 midpoints. One step has the length $3/900 = 1/300$.

```
Y = -L * ((POINTS - 1 - np.arange(POINTS)) / (POINTS - 1))  # y from -L to 0
EW = np.exp(-Y)  # e^{-Hy} with H = 1, so kappa k = q e^{-y} with q = k e^{-a4,0}
SIMPSON = np.full(POINTS, 2.0 * STEP / 6.0)  # Simpson weights on the fine grid:
```

```
SIMPSON[1::2] = 4.0 * STEP / 6.0  # midpoints carry 4/6 of a step,
SIMPSON[0] = SIMPSON[-1] = STEP / 6.0  # the two ends 1/6
```

`np.arange(POINTS)` is the array $0, 1, \ldots, 1800$; the formula turns it into the 1801 values of y, from -3 at index 0 to 0 at the last index, equally spaced. `EW` holds e^{-y} at every point: with $H = 1$ the momentum term of Section 22.6 is $\kappa k = qe^{-y}$ (exact rule 2). `SIMPSON` holds the weights of **Simpson's rule**: the integral of a function over one step is $\frac{h}{6}(f_{start} + 4f_{middle} + f_{end})$ with h the step length, and adding these over all steps gives every midpoint the weight $4h/6$, every inner step end $2h/6$ (it belongs to two steps), and the two outer ends $h/6$. `np.full` fills an array with one value, `SIMPSON[1::2]` selects every second entry starting at index 1 (the midpoints), and the index `-1` means the last entry. An integral is then `np.sum(SIMPSON * f)`.

```
check(PARAMETERS["physics"]["H"] == 1.0 and PARAMETERS["physics"]["m"] == 1.0
      and L == 3.0 and STEPS == 900 and PARAMETERS["physics"]["dk"] == 0.25,
      "the record's units H = m = 1, tip cutoff L = 3, lattice step 0.25, 900 steps",
      record="Revision/kohn_sham/results/parameters.json, physics and numerics")
```

The check requires the record's units $H = m = 1$, $L = 3$, the lattice step $\Delta k = 0.25$ of the 3-momenta and 900 steps, the numbers on which everything below relies (Out [4]).

```
def shoot(eps, q, store=False):
    """Integrate the free block equation from the tip to the brane for the arrays
    eps (energies) and q (redshifted momenta) at once.  Returns the phase
    Phi = theta(0) and, if store is True, the list of (a, b) at the step ends."""
    a, b = np.ones_like(eps), np.zeros_like(eps)  # tip: b(-L) = 0, a(-L) = 1
    theta, raw = np.zeros_like(eps), np.zeros_like(eps)  # the angle, last atan2
    ends = [(a, b)] if store else None
```

`shoot` solves the real form of the free block equation of Section 22.6 ($j = +1$, $M = 1$, $v = 0$), $a' = a - (qe^{-y} + \varepsilon)b$, $b' = (\varepsilon - qe^{-y})a - b$, for a trial energy ε, from the tip to the brane. It is **vectorised**: `eps` and `q` are arrays, and every line acts on all their entries at once, so one call solves hundreds of cases. At the tip it starts with $a = 1$, $b = 0$ (`np.ones_like` and `np.zeros_like` make arrays of ones and zeros of the same shape as `eps`); $b(-L) = 0$ is the record's regular tip condition, and the size of a is irrelevant because the equation is linear. `theta` will hold the **Pruefer angle**, the angle of the point (a, b) in the plane, followed continuously; `raw` holds the angle of the previous step; `ends` collects the values (a, b) at the step ends when `store` is true.

```
    for i in range(STEPS):
        k0, k1, k2 = q * EW[2 * i], q * EW[2 * i + 1], q * EW[2 * i + 2]
        p1a, p1b = a - (k0 + eps) * b, (eps - k0) * a - b  # (a', b') at the start
        aa, bb = a + 0.5 * STEP * p1a, b + 0.5 * STEP * p1b
        p2a, p2b = aa - (k1 + eps) * bb, (eps - k1) * aa - bb  # at the midpoint
        aa, bb = a + 0.5 * STEP * p2a, b + 0.5 * STEP * p2b
        p3a, p3b = aa - (k1 + eps) * bb, (eps - k1) * aa - bb  # midpoint again
        aa, bb = a + STEP * p3a, b + STEP * p3b
        p4a, p4b = aa - (k2 + eps) * bb, (eps - k2) * aa - bb  # at the end
        a = a + STEP / 6.0 * (p1a + 2.0 * p2a + 2.0 * p3a + p4a)  # the RK4 step
        b = b + STEP / 6.0 * (p1b + 2.0 * p2b + 2.0 * p3b + p4b)
```

The loop takes the 900 steps. `k0`, `k1`, `k2` are qe^{-y} at the start, the middle and the end of step `i` (fine-grid indices $2i$, $2i+1$, $2i+2$). Then comes the classical **Runge-Kutta rule of order 4** (RK4, Chapter 2): the first slope `p1` from the equation at the start; a half step with it to the midpoint and the second slope `p2` there; a half step with `p2` and the third slope `p3`, again at the midpoint; a full step with `p3` and the fourth slope `p4` at the end; and the new values as the start plus one step times the weighted mean $(p_1 + 2p_2 + 2p_3 + p_4)/6$. Each line computes the two components a and b side by side.

```
        new = np.arctan2(b, a)  # the angle of the point (a, b), in (-pi, pi]
        turn = new - raw  # how far the angle turned in this step, brought back
        turn = np.where(turn > np.pi, turn - 2.0 * np.pi, turn)  # into (-pi, pi]
        turn = np.where(turn <= -np.pi, turn + 2.0 * np.pi, turn)
        theta, raw = theta + turn, new  # the angle, followed continuously
        if store:
            ends.append((a, b))
    return theta, ends
```

`np.arctan2(b, a)` is the angle of the point (a, b), between $-\pi$ and π. When the point circles around the origin this angle jumps by 2π as it passes π; the next three lines remove such jumps: the turn of one step is brought back into the range $(-\pi, \pi]$ (`np.where(condition, x, y)` takes `x` where the condition holds and `y` elsewhere), and adding the turns gives the angle followed continuously. The steps are short, so the true turn of one step is far below π and this is safe. At the brane, $\Phi = \theta(0)$ is the phase of the orbital. Chapter 15 showed for the Rust solver why this counts levels: Φ grows with ε, and $b(0) = 0$, the even brane condition, holds exactly when Φ is a whole multiple of π; the level with label n is the energy with $\Phi = n\pi$. The function returns the phases and, if asked, the stored values.

```
def levels(labels, q):
    """The level with label n (Phi = n pi) for every pair (label, q): bisection on
    [-40, 40], halving the bracket until it is shorter than 1e-13."""
    target = np.pi * np.asarray(labels, dtype=float)
    q = np.asarray(q, dtype=float)
    low, high = np.full(q.shape, -40.0), np.full(q.shape, 40.0)
    while np.max(high - low) > 1e-13:  # 50 halvings of the length 80
        middle = 0.5 * (low + high)
        above = shoot(middle, q)[0] > target  # Phi grows with eps
        low, high = np.where(above, low, middle), np.where(above, middle, high)
    return 0.5 * (low + high)
```

`levels` finds, for every pair of a label n and a momentum q, the energy at which $\Phi = n\pi$, by **bisection** (Chapter 2): every level lies in the bracket $[-40, 40]$; the phase is computed in the middle of the bracket; if it is above the target, the level lies in the lower half, otherwise in the upper half; the bracket is halved until it is shorter than 10^{-13}, the root tolerance of the Rust solver. Starting from the length 80 this takes 50 halvings, because $80/2^{50} \approx 7 \times 10^{-14}$. All pairs are bisected together, one vectorised call of `shoot` per halving. The answer is the middle of the last bracket.

```
def orbitals(eps, q):
    """The normalised orbitals (a, b) on the fine grid, one row per (eps, q)."""
    ends = shoot(eps, q, store=True)[1]
```

```
    a_e = np.array([pair[0] for pair in ends]).T  # rows: orbitals; columns: ends
    b_e = np.array([pair[1] for pair in ends]).T
    kap = q[:, None] * EW[None, 0::2]  # kappa k at the step ends
    da = a_e - (kap + eps[:, None]) * b_e  # the derivatives at the step ends
    db = (eps[:, None] - kap) * a_e - b_e
```

`orbitals` integrates again at the found levels, this time storing a and b at the 901 step ends, and arranges them as arrays with one row per orbital and one column per step end (`.T` transposes, that is, exchanges rows and columns). `q[:, None] * EW[None, 0::2]` multiplies a column of momenta with a row of the values e^{-y} at the step ends (`0::2` takes every second fine-grid point from index 0), which gives the table qe^{-y} for every orbital and every step end; `None` adds a dimension of length 1 so that numpy repeats the column and the row (**broadcasting**). `da` and `db` are the derivatives a' and b' from the block equation at every step end.

```
    a, b = np.zeros((len(eps), POINTS)), np.zeros((len(eps), POINTS))
    a[:, 0::2], b[:, 0::2] = a_e, b_e
    # cubic Hermite midpoint: (left + right)/2 + STEP (left' - right')/8
    a[:, 1::2] = 0.5 * (a_e[:, :-1] + a_e[:, 1:]) + STEP / 8.0 * (da[:, :-1] - da[:, 1:])
    b[:, 1::2] = 0.5 * (b_e[:, :-1] + b_e[:, 1:]) + STEP / 8.0 * (db[:, :-1] - db[:, 1:])
    norm = np.sqrt(np.sum(SIMPSON * (a * a + b * b), axis=1))  # Simpson's rule
    return a / norm[:, None], b / norm[:, None]
```

The orbitals are needed on the whole fine grid. The step ends are copied into the even columns. The midpoints are filled by **cubic Hermite interpolation**: the cubic polynomial with the values f_0, f_1 and the slopes f_0', f_1' at the two ends of a step of length h has, in the middle, the value $(f_0 + f_1)/2 + h(f_0' - f_1')/8$ (Exercise 3 of Section 22.28 derives it); `a_e[:, :-1]` are the left ends of all steps and `a_e[:, 1:]` the right ends. This is what the Rust solver does. Finally each orbital is **normalised**: its norm $\sqrt{\int (a^2 + b^2)\, dy}$ is computed with Simpson's rule (`axis=1` sums along each row), and both components are divided by it, so that $\int (a^2 + b^2)\, dy = 1$.

```
def couplings(q, a, b):
    """The matrix <m| d_a h |n> = -q int e^{-y} (a_m a_n - b_m b_n) dy of the
    orbitals (rows of a and b) of one sector at the redshifted momentum q."""
    weight = SIMPSON * EW  # Simpson weights times e^{-y}
    return -q * ((a * weight) @ a.T - (b * weight) @ b.T)
```

`couplings` computes the matrix of line 8 of Section 22.6 in its rescaled form (exact rule 2), $\langle m|\partial_a h|n\rangle = -q \int e^{-y}(a_m a_n - b_m b_n)\, dy$, for all pairs of orbitals of one sector at once. `@` is the matrix product: `(a * weight) @ a.T` has in row m and column n the sum over the grid of $a_m\, w\, a_n$, which is the Simpson integral of $e^{-y} a_m a_n$.

```
def per_unit_rate(eps, matrix):
    """G[n, m] = |<n| d_a h |m>| / (eps_n - eps_m)^2 = Q / A (0 for n = m)."""
    gap = eps[:, None] - eps[None, :]
    safe = np.where(gap == 0.0, 1.0, gap)  # 1 on the diagonal: no division by 0
    return np.where(gap == 0.0, 0.0, np.abs(matrix) / safe ** 2)
```

`per_unit_rate` turns the levels and the coupling matrix into the table $G_{nm} = |\langle n|\partial_a h|m\rangle|/(\varepsilon_n - \varepsilon_m)^2$, which is Q/A by Section 22.7. `gap` is the table of all differences of levels; on the diagonal it is zero, so `safe` puts 1 there before dividing, and the result is set to 0 there.

In [5], the Fermi shells of the record, solved again.

```
LEVELS = "Revision/kohn_sham/results/ground/levels"
SHELL = {136: 4, 688: 11}  # the Fermi shell n2 of each N
fermi = [(n, a4) for n in (136, 688) for a4 in SLICES]  # the ten free states
q_fermi = np.array([0.25 * math.sqrt(SHELL[n]) * math.exp(-a4) for n, a4 in fermi])
eps_fermi = levels(np.tile([0, 1, 2], 10), np.repeat(q_fermi, 3)).reshape(10, 3)
```

In the record the largest Q of every free state is the jump from the band level to the first bulk level of its Fermi shell: $n_2 = 4$, $k = 0.25\sqrt{4} = 0.5$, for $N = 136$, and $n_2 = 11$, $k = 0.25\sqrt{11} = 0.829$, for $N = 688$. `fermi` lists the ten free states (two particle numbers, five slices) and `q_fermi` their redshifted momenta $q = ke^{-a_{4,0}}$. `np.tile([0, 1, 2], 10)` repeats the labels ten times and `np.repeat(q_fermi, 3)` repeats each momentum three times, so the two arrays list the 30 pairs (label, q); one call of `levels` solves all 30, and `.reshape(10, 3)` arranges them as ten rows of three levels. Every level is solved at the slice 0 with the redshifted momentum, as exact rule 2 allows.

```
worst_level, compared = 0.0, 0
for (n, a4), row in zip(fermi, eps_fermi):
    path = repository_file(f"{LEVELS}/{state_id(n, a4)}.csv")
    with open(path, newline="", encoding="utf-8") as handle:
        for entry in csv.DictReader(handle):
            sector = (int(entry["n2"]), int(entry["j"]), entry["parity"])
            if sector == (SHELL[n], 1, "even") and int(entry["label"]) <= 2:
                difference = float(entry["eps"]) - row[int(entry["label"])]
                worst_level = max(worst_level, abs(difference))
                compared += 1
```

For each of the ten states the loop opens the record's level table (for example `N688_lam0_a00.csv`, one row per level with the columns `n2`, `j`, `parity`, `label`, `eps`, ...), picks the rows of the Fermi-shell sector with $j = +1$ and even parity and a label of at most 2, and compares the recorded level with the one just computed; `worst_level` keeps the largest difference and `compared` counts the comparisons.

```
a_f, b_f = orbitals(eps_fermi[:, :2].ravel(), np.repeat(q_fermi, 2))
worst_q, same_pair, q_free = 0.0, True, {}
say("   N  a4,0        q      eps_0      eps_1   Q (here)   Q_max (record)")
```

`eps_fermi[:, :2]` takes the labels 0 and 1 of every row and `.ravel()` lines them up into one array of 20 levels; `orbitals` returns their 20 orbitals, two consecutive rows per state. The last line prints the header of the table of Out [5].

```
for i, (n, a4) in enumerate(fermi):
    matrix = couplings(q_fermi[i], a_f[2 * i:2 * i + 2], b_f[2 * i:2 * i + 2])
    gap = eps_fermi[i, 1] - eps_fermi[i, 0]
```

```
    q_free[(n, a4)] = abs(matrix[0, 1]) / gap ** 2  # Q at the rate A = 1
    row = record[state_id(n, a4)]
    for value, column in ((q_free[(n, a4)], "Q_max"), (gap, "Q_max_delta_eps"),
                          (abs(matrix[0, 1]), "Q_max_matrix_element")):
        worst_q = max(worst_q, abs(value / float(row[column]) - 1.0))
```

`enumerate` numbers the states $i = 0, \dots, 9$. For each one, `couplings` gives the 2×2 matrix of the band orbital and the first bulk orbital (rows $2i$ and $2i+1$), `gap` is $\varepsilon_1 - \varepsilon_0$, and $Q = |\langle 0|\partial_a h|1\rangle|/(\varepsilon_1 - \varepsilon_0)^2$ at the rate $A = 1$ (with $H = 1$). The inner loop compares three numbers with the record's three columns, Q, the energy difference and the matrix element, as relative differences, and keeps the largest.

```
    pair = f"{SHELL[n]}:+1:even:0 -> {SHELL[n]}:+1:even:1"
    same_pair = same_pair and row["Q_max_pair"] == pair
    recorded = float(row["Q_max"])
    say(f"{n:4d}  {a4:4.1f}  {q_fermi[i]:7.4f}  {eps_fermi[i, 0]:9.6f}"
        f"  {eps_fermi[i, 1]:9.6f}  {q_free[(n, a4)]:.7f}  {recorded:.7f}")
```

The record names the pair of levels of its largest Q in the column `Q_max_pair`, written as shell, block type, parity and label of both levels; `same_pair` stays true only if every state names the band level and the first bulk level of its Fermi shell. The last statement prints one row of the table: the formats `4d`, `4.1f`, `7.4f`, `9.6f` and `.7f` give whole numbers of width 4 and numbers with 1, 4, 6 and 7 digits after the point.

```
report("levels compared with the record", compared)
report("largest |eps(here) - eps(record)|", f"{worst_level:.1e}")
report("largest relative difference of Q, delta eps, matrix element", f"{worst_q:.1e}")
check(compared == 30 and worst_level < 1e-12,
      "the 30 levels of the Fermi-shell sectors equal the record's within 1e-12",
      record=f"{LEVELS}/N136_lam0_a*.csv and N688_lam0_a*.csv, column eps")
check(worst_q < 1e-9,
      "Q_max, its energy difference and matrix element reproduced within 1e-9",
      record=f"{ADIABATIC}, columns Q_max, Q_max_delta_eps, Q_max_matrix_element; "
             "computed at the slice 0 with q = k e^(-a4,0), the rescaling identity "
             "of Revision/kohn_sham/reports/ks-rust-solver.json, check "
             "free_rescaling_relation_and_band_monotone")
check(same_pair,
      "the recorded pair is band level -> first bulk level of the Fermi shell",
      record=f"{ADIABATIC}, column Q_max_pair")
```

Out [5] shows the table and the results: 30 levels compared, the largest difference 8.8×10^{-14}, and the largest relative difference of Q, of the energy difference and of the matrix element 1.3×10^{-13}. For example, for $N = 688$ at the slice 0 the band level is $\varepsilon_0 = 1.247113$, the first bulk level $\varepsilon_1 = 3.500518$, and $Q = 0.0934506$ both here and in the record. The three checks require the 30 levels within 10^{-12}, the three columns within 10^{-9} (relative), and the recorded pair. Because every level was computed at the slice 0 with the momentum $ke^{-a_{4,0}}$, the agreement at all five slices is at the same time a test of the rescaling identity, which the second check names.

In [6], one curve for every slice and every shell.

```
Q_GRID = np.geomspace(0.02, 6.0, 61)  # redshifted momenta q (units of m)
CURVE = np.arange(-3, 5)  # the labels -3 ... 4 of the sector
BAND = 3  # the position of label 0 in CURVE
q_rows = np.repeat(Q_GRID, len(CURVE))  # one row per (q, label)
curve_eps = levels(np.tile(CURVE, len(Q_GRID)), q_rows)
curve_a, curve_b = orbitals(curve_eps, q_rows)
curve_eps = curve_eps.reshape(len(Q_GRID), len(CURVE))
```

By exact rule 2 the free Q/A of a sector is one function $G(q)$. The cell computes it at 61 momenta from 0.02 to 6, equally spaced on a logarithmic scale. `CURVE` holds the eight labels $-3, -2, \ldots, 4$, and label 0 sits at position 3 of this array (`BAND`). The $61 \times 8 = 488$ levels and orbitals are computed in one call each and the levels are arranged as 61 rows of 8.

```
G = np.array([per_unit_rate(curve_eps[i], couplings(
    Q_GRID[i], curve_a[8 * i:8 * i + 8], curve_b[8 * i:8 * i + 8]))
    for i in range(len(Q_GRID))])  # G[i, n, m]: Q per unit rate at Q_GRID[i]
del curve_a, curve_b  # the orbitals are no longer needed
```

For each momentum the eight orbitals give an 8×8 coupling matrix and from it the table G_{nm}; `G` stacks the 61 tables into one array with three indices: the momentum, n and m. `del` deletes the orbitals (488 rows of 1801 numbers each) to free memory.

```
g01 = G[:, BAND, BAND + 1]  # band level -> first bulk level
top = int(np.argmax(g01))
fine_q = np.linspace(Q_GRID[top - 1], Q_GRID[top + 1], 41)  # around the top
fine_eps = levels(np.tile([0, 1], 41), np.repeat(fine_q, 2)).reshape(41, 2)
fine_a, fine_b = orbitals(fine_eps.ravel(), np.repeat(fine_q, 2))
fine_g = np.array([per_unit_rate(fine_eps[i], couplings(
    fine_q[i], fine_a[2 * i:2 * i + 2], fine_b[2 * i:2 * i + 2]))[0, 1]
    for i in range(41)])
g_star, q_star = float(fine_g.max()), float(fine_q[int(np.argmax(fine_g))])
```

`g01` is the curve of the band jump, $G_{01}(q)$. `np.argmax` gives the position of its largest value on the coarse grid. Around it, between the two neighbouring grid points, `np.linspace` makes 41 equally spaced momenta, and the labels 0 and 1 are solved again there; `fine_g` is G_{01} on this fine grid, and its largest value G^* and the momentum q^* where it is reached are kept.

```
report("largest Q per unit rate of the band jump, G*", f"{g_star:.5f}")
report("at the redshifted momentum q*", f"{q_star:.3f}")
report("naive breakdown rate of the band level, 0.02 <= q <= 6, 1/G*",
       f"{1.0 / g_star:.3f}")
report("largest G of the jumps band -> bulk 2, 3, 4 on the grid",
       ", ".join(f"{G[:, BAND, BAND + m].max():.5f}" for m in (2, 3, 4)))
```

Out [6]: $G^* = 0.09979$ at $q^* = 2.128$, and $1/G^* = 10.021$. The last line prints, for the jumps from the band level to the second, third and fourth bulk levels, the largest value on the 61 momenta of the grid: `G[:, BAND, BAND + m]` is the column of the jump to label m, `.max()` its largest entry, and `", ".join(...)` writes the three numbers separated by commas; Out [6] shows 0.00640, 0.00249 and

0.00087. What this establishes, and only this: every shell at every slice whose redshifted momentum lies between 0.02 and 6 sits somewhere on the one curve, and that includes every state of the record (their q lie between $0.5e^{-2} = 0.068$ and 0.829). For all of them the jump from the band level to the first bulk level never has Q/A above G^*, the jumps to the second, third and fourth bulk levels stay below 0.0065, 0.0025 and 0.0009, and so the naive breakdown rate of the band level is at least $1/G^* = 10.021$ (COMPUTED here, free field, for the labels up to 4). Beyond $q = 6$ the curve was not computed, and nothing is claimed there.

In [7], drawing the one curve (Figure 22a.2).

```
fig, ax = plt.subplots(figsize=(7.5, 4.5))
ax.plot(Q_GRID, g01, color="black", lw=2.0, label="$G_{01}$: band -> 1st bulk")
ax.plot(Q_GRID, G[:, BAND, BAND + 2], color="0.45", lw=1.5, ls="--",
        label="$G_{02}$: band -> 2nd bulk")
q_low, q_high = float(q_fermi.min()), float(q_fermi.max())
ax.axvspan(q_low, q_high, color="0.85", alpha=0.6, lw=0)  # the recorded range
```

One panel, 7.5 by 4.5 inches. The black line is G_{01}, the grey dashed line G_{02} (band level to second bulk level). `axvspan` shades the range of momenta that the record's Fermi shells cover, from the smallest to the largest of the ten values of `q_fermi`.

```
for colour, marker, n in ((PALETTE[0], "o", 136), (PALETTE[1], "s", 688)):
    for tag in TAGS:
        xs = [0.25 * math.sqrt(SHELL[n]) * math.exp(-a4) for a4 in SLICES]
        ys = [q_max[(n, tag, a4)] for a4 in SLICES]
        ax.plot(xs, ys, marker, color=colour, ms=8, mfc="none", mew=1.5,
                label=f"record, $N = {n}$" if tag == "lam0" else None)
ax.plot([q_star], [g_star], "*", color=PALETTE[3], ms=16, mec="black",
        label=f"top: $G^* = {g_star:.4f}$ at $q = {q_star:.2f}$")
```

For both particle numbers and all five couplings the record's Q_{max} (at $A = 1$, so equal to Q/A) is drawn as open markers (`mfc="none"`: no fill; `mew`: the width of the marker's edge) at the redshifted momentum of its Fermi shell; only the free states get a legend entry (the expression `... if tag == "lam0" else None` gives the label or nothing). A yellow star with a black edge marks the top of the curve.

```
ax.set_xscale("log")
ax.set_xlabel("redshifted momentum $q = k\\,e^{-a_{4,0}}$ (units of $m$)")
ax.set_ylabel("$G = Q/A$ (pure number)")
ax.set_title("Every slice and every shell on one curve ($\\lambda = 0$)")
ax.legend(fontsize=8, loc="upper left")
save_figure(fig, "one_curve",
            "The adiabaticity measure per unit rate, $G = Q/A$ (vertical axis, pure "
            "number), of the jump from the band level to the first (black) and "
            "second (grey, dashed) bulk level of a free sector, against the "
            "redshifted momentum $q = k e^{-a_{4,0}}$ (horizontal axis, "
            "logarithmic, units of $m$). Open symbols: the recorded $Q_{max}$ of "
            "the 50 states with $N = 136$ (circles) and $N = 688$ (squares), each "
            "at the $q$ of its Fermi shell; the five couplings overlap. The grey "
            "band is the range of the record; the star is the top of the curve, "
```

```
            "the largest $Q/A$ of the jump to the first bulk level for every "
            "shell and slice with $0.02 \\le q \\le 6$ (all states of the record).")
```

A logarithmic horizontal axis, the labels, the title, the legend in the upper left corner, and `save_figure` saves Figure 22a.2. In the caption, `\\le` gives matplotlib's and the book's sign $\leq$ (less than or equal); the doubled backslash is needed in a normal Python string, as explained for In [3].

```
spread = max(abs(q_max[(n, tag, a4)] / q_max[(n, "lam0", a4)] - 1.0)
             for n in (136, 688) for tag in TAGS for a4 in SLICES)
report("largest relative change of Q_max by the interaction", f"{spread:.4f}")
check(largest < g_star < 0.1,
      "the top of the curve lies above every recorded Q_max and below 0.1")
check(spread < 0.15, "the interaction changes Q_max by less than 15 percent",
      record=f"{ADIABATIC}, column Q_max, all couplings")
```

`spread` is the largest relative difference between the Q_{max} of an interacting state and that of the free state with the same particle number and slice: 0.0980, that is, 9.8 percent (Out [7]). The first check requires $Q_{max} < G^* < 0.1$ for all recorded states (Python allows the chain `a < b < c`); the second that the interaction changes Q_{max} by less than 15 percent.

What the student should see in Figure 22a.2, and why. The black curve rises from about 0.011 at $q = 0.02$ to its top 0.0998 at $q = 2.13$ and falls slowly beyond. All ten free states of the record lie exactly on it, at five different slices and two different shells: this is exact rule 2 at work, the deflating history moves each shell along the one curve towards smaller q. The interacting states lie close to the curve; the largest scatter is at the smallest q (the shell of $N = 136$ at the slice 2), where the interaction changes Q by up to ten percent. The whole recorded range (grey) lies left of the top, which is why Q falls along the history in Figure 22a.1. The dashed curve of the second bulk level stays below 0.007 and touches zero near $q = 1.1$, where its matrix element passes through zero: the band level couples mainly to its nearest neighbour.

In [8], jumps across the gap into the negative branch (Figure 22a.3).

```
def g_pair(n, m):
    """G of the jump from label n to label m along Q_GRID."""
    return G[:, BAND + n, BAND + m]

sea = np.max([g_pair(n, m) for n in (-3, -2, -1) for m in (1, 2, 3, 4)], axis=0)
sea_top = int(np.argmax(sea))
```

The record's Q counts only jumps between levels of positive energy, because its filling convention treats the negative branch as the normal-ordered sea, which holds no particles. But the moving background couples the two branches through the same matrix elements, and the table `G` already contains them. `g_pair(n, m)` returns the curve of the jump from label n to label m (the label is shifted by `BAND` to its position in the array). `sea` is, at each momentum, the largest of the twelve jumps from a negative level (-3, -2, -1) to a bulk level (1 to 4), and `sea_top` the position of its maximum.

```
fig, ax = plt.subplots(figsize=(7.5, 4.5))
ax.plot(Q_GRID, g01, color="black", lw=2.0, label="band 0 -> bulk 1 (record's Q)")
```

```
for colour, style, (n, m) in zip(PALETTE, ("-", "--", "-.", ":"),
                                 ((-1, 1), (-1, 2), (-2, 1), (-1, 0))):
    kind = "band" if m == 0 else "bulk"
    ax.plot(Q_GRID, g_pair(n, m), color=colour, lw=2.0, ls=style,
            label=f"negative {n} -> {kind} {m}")
```

The black band jump of In [7] for comparison, and four jumps across the gap, each with its own colour and line style (solid, dashed, dash-dotted, dotted): from -1 to the bulk levels 1 and 2, from -2 to bulk 1, and from -1 to the band level 0.

```
ax.set_xscale("log")
ax.set_xlabel("redshifted momentum $q = k\\,e^{-a_{4,0}}$ (units of $m$)")
ax.set_ylabel("$G = Q/A$ (pure number)")
ax.set_title("Jumps across the gap between the two branches ($\\lambda = 0$)")
ax.legend(fontsize=8)
save_figure(fig, "across_the_gap",
            "The adiabaticity measure per unit rate $G = Q/A$ (vertical axis) of "
            "jumps from the negative levels $-1$ and $-2$ of a free sector to the "
            "bulk levels 1 and 2 and to the band level 0 (coloured), compared "
            "with the band jump of the record (black), against the redshifted "
            "momentum $q$ (horizontal axis, logarithmic, units of $m$). The jumps "
            "across the gap stay below 0.05 per unit rate; the strongest of them "
            "($-1 \\to$ bulk 1) peaks near $q = 0.11$ at 0.049 and exceeds the "
            "band jump only below $q$ of about 0.1; their reading as pair "
            "creation of the field is OPEN.")
report("largest G of a jump negative level -> bulk level", f"{sea[sea_top]:.5f}")
report("at the redshifted momentum", f"{Q_GRID[sea_top]:.4f}")
check(sea[sea_top] < 0.5 * g_star,
      "every jump across the gap is weaker than half the top of the band jump")
```

The axes, the title, the legend and Figure 22a.3; in its caption `\\to` gives the arrow $\to$. Out [8] gives the strongest jump from a negative to a bulk level, $G = 0.04887$ at $q = 0.1107$, and the check requires it to be below half of G^*.

What the student should see in Figure 22a.3, and why. The strongest jump across the gap, from -1 to bulk 1 (blue), rises to its peak 0.0489 near $q = 0.11$ and falls on both sides; below about $q = 0.1$ it is stronger than the band jump of the record, above it is weaker, and at large q it is far weaker. The other jumps across the gap stay below 0.025; the jumps from -1 to the band level and from -2 to bulk 1 pass through zero near $q = 0.15$. So in the free field the moving background does couple the negative branch to the positive one, at a strength comparable to the band jump at small momenta. In ordinary Dirac theory a jump from a filled negative level to an empty positive one is the creation of a particle-antiparticle pair OF THE FIELD, inside one universe. Whether that reading holds in the 4+4 quantisation with its Krein metric is OPEN, and it has nothing to do with the creation of universes.

In [9], the Fermi-shell sector along the recorded span.

```
K11 = 0.25 * math.sqrt(11.0)  # the Fermi-shell momentum of N = 688 (units of m)
END = 2.0  # the recorded span of slices, a4,0 = 0 ... 2
NODES = 56  # Chebyshev nodes on the span
BASIS = np.arange(-9, 11)  # 20 labels: nine negative, the band level, ten bulk
SIZE, ZERO = len(BASIS), 9  # ZERO: the position of label 0 (the band level)
```

For the time evolution the levels and the matrix K_{mn} are needed at every instant, not only at five slices. The cell takes the Fermi-shell sector of $N = 688$ ($n_2 = 11$, $k = 0.829$, $j = +1$, even parity; its band level holds 96 quanta, the degeneracy $4 \cdot 24$ of the shell in the record's level table), the span $a_{4,0} = 0$ to 2, 56 interpolation nodes, and a basis of 20 labels, -9 to 10; label 0 is at position 9.

```
angles = np.pi * (np.arange(NODES) + 0.5) / NODES  # theta_j of the nodes
nodes_s = 0.5 * END * (1.0 + np.cos(angles))  # the nodes as slices a4,0
q_nodes = np.repeat(K11 * np.exp(-nodes_s), SIZE)  # one row per (node, label)
node_eps = levels(np.tile(BASIS, NODES), q_nodes)
node_a, node_b = orbitals(node_eps, q_nodes)
node_eps = node_eps.reshape(NODES, SIZE)
```

The **Chebyshev nodes** are the slices $s_j = 1 + \cos\theta_j$ with $\theta_j = \pi(j + \frac{1}{2})/56$, $j = 0, \ldots, 55$ (`0.5 * END` is 1). They crowd towards the two ends of the span, which is what makes polynomial interpolation through them accurate. At each node the 20 levels and orbitals are solved: $56 \cdot 20 = 1120$ levels in one call, each at the slice 0 with the momentum ke^{-s_j}.

```
node_m = np.array([couplings(K11 * math.exp(-s), node_a[SIZE * i:SIZE * (i + 1)],
                             node_b[SIZE * i:SIZE * (i + 1)])
                   for i, s in enumerate(nodes_s)])
del node_a, node_b  # the orbitals are no longer needed
```

At each node the 20×20 matrix $\langle m|\partial_a h|n\rangle$ of the 20 orbitals of that node; `node_m` stacks the 56 matrices. The orbitals are then deleted.

```
def chebyshev_coefficients(values):
    """c_k = (2/NODES) sum_j values_j cos(k theta_j), c_0 halved: the polynomial
    through the values at the nodes (one column per function)."""
    table = np.cos(np.outer(np.arange(NODES), angles))  # cos(k theta_j)
    coefficients = 2.0 / NODES * table @ values.reshape(NODES, -1)
    coefficients[0] *= 0.5
    return coefficients
```

A function f on the span is approximated by the polynomial $\sum_{k=0}^{55} c_k T_k(x)$, where $x = s - 1$ runs from -1 to 1 and T_k is the Chebyshev polynomial of degree k, defined by $T_k(\cos\theta) = \cos(k\theta)$. The coefficients that make the polynomial pass exactly through the values at the 56 nodes are $c_k = \frac{2}{56}\sum_j f(s_j)\cos(k\theta_j)$, with c_0 halved. `np.outer` makes the table of all products $k\theta_j$, and the matrix product with the values computes all sums at once; `values.reshape(NODES, -1)` arranges any array of values as 56 rows (one per node) and as many columns as there are functions (`-1` lets numpy count them).

```
FIT_EPS = chebyshev_coefficients(node_eps)  # 20 levels
FIT_M = chebyshev_coefficients(node_m)  # 400 matrix elements

def interpolated(s):
    """Levels (one row per point s) and coupling matrices from the fits."""
    x = 2.0 * np.asarray(s, dtype=float) / END - 1.0  # a4,0 = 0 ... 2 -> -1 ... 1
```

```
    eps = chebyshev.chebval(x, FIT_EPS).T
    matrix = chebyshev.chebval(x, FIT_M).T.reshape(len(x), SIZE, SIZE)
    return eps, matrix
```

Coefficients for the 20 levels and for the $20 \cdot 20 = 400$ matrix elements. `interpolated` maps the slices to $x = 2s/2 - 1$, evaluates all the polynomials there with `chebval`, which returns one row per function and one column per point, transposes, and arranges the matrix elements again as 20×20 matrices, one per point.

```
test_s = np.array([0.03, 0.25, 0.77, 1.31, 1.97])  # five points between the nodes
test_q = np.repeat(K11 * np.exp(-test_s), SIZE)
test_eps = levels(np.tile(BASIS, 5), test_q)
test_a, test_b = orbitals(test_eps, test_q)
fit_eps, fit_m = interpolated(test_s)
error_eps = float(np.max(np.abs(fit_eps - test_eps.reshape(5, SIZE))))
error_m = max(float(np.max(np.abs(fit_m[i] - couplings(
    K11 * math.exp(-s), test_a[SIZE * i:SIZE * (i + 1)],
    test_b[SIZE * i:SIZE * (i + 1)])))) for i, s in enumerate(test_s))
```

The test of the interpolation: at five slices that are not nodes, the levels and matrices are solved directly and compared with the interpolated ones; `error_eps` and `error_m` are the largest differences.

```
slice_eps, slice_m = interpolated(SLICES)
slice_q = [abs(slice_m[i, ZERO, ZERO + 1]) / (slice_eps[i, ZERO + 1]
           - slice_eps[i, ZERO]) ** 2 for i in range(5)]
worst_slice = max(abs(slice_q[i] / q_max[(688, "lam0", a4)] - 1.0)
                  for i, a4 in enumerate(SLICES))
```

A second test: Q of the band jump computed from the interpolated levels and matrices at the five slices of the record, compared with the record's Q_{max} of the free state $N = 688$.

```
report("largest interpolation error of a level", f"{error_eps:.1e}")
report("largest interpolation error of a matrix element", f"{error_m:.1e}")
report("largest relative difference of the interpolated Q to the record",
       f"{worst_slice:.1e}")
check(error_eps < 1e-9 and error_m < 1e-7,
      "the Chebyshev fits reproduce levels within 1e-9 and couplings within 1e-7")
check(worst_slice < 1e-8, "the interpolated Q at the five slices equals the record's",
      record=f"{ADIABATIC}, column Q_max of N688_lam0_a00 ... a20")
```

Out [9]: the interpolation reproduces the levels to 7.3×10^{-11} and the matrix elements to 6.4×10^{-9}, and the interpolated Q at the five slices agrees with the record to 1.4×10^{-13} (relative). The two checks require 10^{-9}, 10^{-7} and 10^{-8}.

In [10], the levels of the sector and how fast the band orbital turns (Figure 22a.4).

```
s_plot = np.linspace(0.0, END, 201)
eps_plot, m_plot = interpolated(s_plot)
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.4), layout="constrained")
```

```
for i, label in enumerate(BASIS):
    if label == 0:
        left.plot(s_plot, eps_plot[:, i], color=PALETTE[3], lw=3.0,
                  label="band level 0 (occupied)")
    else:
        colour = PALETTE[0] if label > 0 else PALETTE[1]
        left.plot(s_plot, eps_plot[:, i], color=colour, lw=1.0)
```

201 slices across the span, the interpolated levels and matrices there, and two panels. On the left every one of the 20 levels is drawn against the slice: the band level thick and yellow, the bulk levels blue and the negative levels orange.

```
left.plot([], [], color=PALETTE[0], lw=1.0, label="bulk levels 1 ... 10")
left.plot([], [], color=PALETTE[1], lw=1.0, label="negative levels -1 ... -9")
left.set_xlabel("slice $a_{4,0}$")
left.set_ylabel("level $\\varepsilon$ (units of $m$)")
left.set_title("Sector $n_2 = 11$, $j = +1$, even, of $N = 688$")
left.legend(fontsize=8, loc="upper center", bbox_to_anchor=(0.5, -0.15), ncol=3)
```

Two empty plots (`[]`, no points) create one legend entry each for the nineteen thin lines; the legend is placed below the panel in three columns (`bbox_to_anchor` gives its position relative to the panel).

```
for colour, style, label in zip(PALETTE, ("-", "--", "-.", ":"), (1, 2, -1, -2)):
    m = ZERO + label
    turn = np.abs(m_plot[:, m, ZERO]) / np.abs(eps_plot[:, ZERO] - eps_plot[:, m])
    right.plot(s_plot, turn, color=colour, ls=style, lw=2.0, label=f"$m = {label}$")
right.set_xlabel("slice $a_{4,0}$")
right.set_ylabel("$|K_{m0}|$ (per e-fold)")
right.set_title("How fast the band orbital turns towards level $m$")
right.legend(fontsize=8)
```

On the right, for the levels $m = 1, 2, -1, -2$, the number $|K_{m0}| = |\langle m|\partial_a h|0\rangle|/|\varepsilon_0 - \varepsilon_m|$ of line 6 of Section 22.6. It says how far the band orbital turns towards level m per unit change of a_4, that is, per e-fold of the extra times.

```
save_figure(fig, "sector_levels",
            "Left: the 20 instantaneous levels (vertical axis, units of $m$) of the "
            "free Fermi-shell sector of $N = 688$ against the slice $a_{4,0}$ "
            "(horizontal axis): the occupied band level (thick) falls as the 3-"
            "momentum redshifts, the bulk levels above it and the negative levels "
            "below it move towards their values at $k = 0$. Right: $|K_{m0}|$, how "
            "far the band orbital turns towards level $m$ per e-fold (vertical "
            "axis), for $m = 1, 2, -1, -2$; all are below 0.25, so the band orbital "
            "changes slowly.")
```

`save_figure` saves Figure 22a.4. This cell prints nothing else.

What the student should see in Figure 22a.4, and why. On the left the band level falls from 1.247 at the slice 0 to 0.206 at the slice 2 (the values of Out [5]): as q redshifts towards 0 it approaches

the zero mode, the level $\varepsilon = 0$ of the brane-bound orbital at $k = 0$. The bulk levels fall and the negative levels rise, all towards their values at $k = 0$; the gap between the band level and the first bulk level stays above 1.6 (at the slice 2 it is $1.823448 - 0.205760 = 1.617688$, Out [5]). On the right $|K_{10}|$ falls from 0.21 to about 0.09 along the span; the turning towards the negative level -1 starts at about 0.08 and passes through zero near the slice 1.8; the others stay below about 0.035. All are well below 1: the band orbital changes slowly per e-fold, which is why the instantaneous picture works as well as it does.

In [11], the exact time evolution in the basis of instantaneous levels.

```
U_STEPS = 4000  # the finest number of RK4 steps of one passage, u = 0 ... 1
U = np.linspace(0.0, 1.0, 2 * U_STEPS + 1)  # the fine grid: step ends, midpoints
CHOICES = [200, 400, 500, 1000, 2000, 4000]  # step numbers that divide U_STEPS
OFF = ~np.eye(SIZE, dtype=bool)  # every pair n != m
SPAN = float(np.ptp(node_eps))  # the largest energy difference of the basis
```

The passage is integrated in the variable $u = x_4/T$ of Section 22.8, from 0 to 1, with RK4. The finest integration uses 4000 steps; `U` is its fine grid of 8001 points (step ends and midpoints), on which the levels and matrices are tabulated once. A coarser integration may use 200, 400, 500, 1000 or 2000 steps; these numbers divide 4000, so their step ends and midpoints are points of the same fine grid. `np.eye(SIZE, dtype=bool)` is the 20×20 table that is true on the diagonal, and `~` turns true into false and back, so `OFF` selects the pairs $m \neq n$. `np.ptp` ("peak to peak") is the largest value minus the smallest: `SPAN` is the largest difference between any two levels of the basis at any node, 24.89 (Out [11]).

```
def frame(s):
    """Levels e[i, n] and the matrix k[i, m, n] = <m| d_a n> at the slices s[i]."""
    e, matrix = interpolated(s)
    gap = e[:, None, :] - e[:, :, None]  # gap[i, m, n] = eps_n - eps_m
    k = np.zeros_like(matrix)
    k[:, OFF] = matrix[:, OFF] / gap[:, OFF]  # line 6 of section 4; K_nn = 0
    return e, k
```

`frame` gives, at a list of slices, the levels and the matrices $K_{mn} = \langle m|\partial_a h|n\rangle/(\varepsilon_n - \varepsilon_m)$ (line 6 of Section 22.6; the comment refers to section 4 of the notebook, which derives it), with $K_{nn} = 0$ (line 7). The array `gap` holds $\varepsilon_n - \varepsilon_m$ in position $[i, m, n]$, which the two `None` arrange by broadcasting; only the off-diagonal entries are divided.

```
def steps_needed(duration):
    """The smallest step number of CHOICES with duration * SPAN / steps <= 0.2."""
    for steps in CHOICES:
        if duration * SPAN / steps <= 0.2:
            return steps
    return CHOICES[-1]
```

In the variable u the amplitudes turn with the frequencies $T\varepsilon_m$, so in one step of length $1/N$ a phase changes by up to about $T \cdot \mathrm{SPAN}/N$. `steps_needed` returns the smallest step number of `CHOICES` that keeps this below 0.2 radian, and the finest one when none does.

```
def passage(duration, e, k, rate, start, steps, keep=0):
    """RK4 for dc/du = -i duration e(u) c - rate(u) k(u) c from u = 0 to 1.
    e, k and rate are given on the fine grid U. Returns the final amplitudes and,
    if keep > 0, the list of the amplitudes after every keep steps."""
    stride = U_STEPS // steps  # fine-grid points per half step
    h = 1.0 / steps
    c = start.astype(complex)
    kept = [c]
```

`passage` integrates the equation $dc/du = -iT\varepsilon(u)c - (da_4/du)K(u)c$ of Section 22.8 for the vector c of the 20 amplitudes. The arguments are the duration T, the levels `e` and matrices `k` on the fine grid, the rate da_4/du on the fine grid, the starting amplitudes, the number of steps, and how often to keep the amplitudes. A step of length $h = 1/N$ spans $2 \cdot 4000/N$ intervals of the fine grid, so half a step spans `stride` $= 4000/N$ of them (`//` is division of whole numbers). `astype(complex)` makes the amplitudes complex numbers.

```
    def slope(i, c):
        return -1j * duration * e[i] * c - rate[i] * (k[i] @ c)

    for step in range(steps):
        i = 2 * stride * step  # the start of this step on the fine grid
        s1 = slope(i, c)
        s2 = slope(i + stride, c + 0.5 * h * s1)
        s3 = slope(i + stride, c + 0.5 * h * s2)
        s4 = slope(i + 2 * stride, c + h * s3)
        c = c + h / 6.0 * (s1 + 2.0 * s2 + 2.0 * s3 + s4)
        if keep and (step + 1) % keep == 0:
            kept.append(c)
    return c, kept
```

`slope(i, c)` is the right side of the equation at the fine-grid point i; `1j` is Python's i, and `e[i] * c` multiplies each amplitude by its own level. Each step is the RK4 rule of In [4], with the slopes at the start (fine point i), twice at the middle ($i+$ `stride`) and at the end ($i + 2$ `stride`). After every `keep` steps the amplitudes are stored (`%` is the remainder of a division). The function returns the final amplitudes and the stored ones.

```
S_SMOOTH = END * (U - np.sin(2.0 * np.pi * U) / (2.0 * np.pi))  # a4 along it
RATE_SMOOTH = 2.0 * END * np.sin(np.pi * U) ** 2  # its derivative d a4 / d u
E_SMOOTH, K_SMOOTH = frame(S_SMOOTH)
S_LINEAR = END * U  # the constant rate: a4 = END u
RATE_LINEAR = np.full_like(U, END)
E_LINEAR, K_LINEAR = frame(S_LINEAR)
```

The two histories of Section 22.8 on the fine grid: the smooth passage $a_4 = 2[u - \sin(2\pi u)/(2\pi)]$ with $da_4/du = 4\sin^2(\pi u)$, and the constant rate $a_4 = 2u$ with $da_4/du = 2$; for each, `frame` tabulates the levels and the matrices K at all 8001 points.

```
START = np.zeros(SIZE, dtype=complex)
START[ZERO] = 1.0  # the particle starts in the band level
report("largest energy difference of the basis", f"{SPAN:.4f}", "m")
```

The starting amplitudes: 1 for the band level, 0 for the 19 others. The report prints `SPAN` with its unit m.

In [12], a smooth passage at every rate.

```
RATES = 10.0 ** np.linspace(-0.6, 2.4, 31)  # peak rates A from 0.25 to 251
excited, norm_error = [], 0.0
for rate in RATES:
    duration = 2.0 * END / rate  # T = 4/A: the peak rate is A
    c, _ = passage(duration, E_SMOOTH, K_SMOOTH, RATE_SMOOTH, START,
                   steps_needed(duration))
    excited.append(1.0 - abs(c[ZERO]) ** 2)  # probability to have left level 0
    norm_error = max(norm_error, abs(float(np.vdot(c, c).real) - 1.0))
excited = np.array(excited)
```

31 peak rates $A = 10^{-0.6}, \ldots, 10^{2.4}$, that is from 0.251 to 251, ten per factor 10; the seventh is 1 (up to rounding in the last digit: the computer stores 1.0000000000000002) and the eleventh $10^{0.4} = 2.51$. For each the passage lasts $T = 4/A$ (Section 22.8), and the probability that the particle has left the band level at the end is $P = 1 - |c_0|^2$. It counts every other level of the basis, the negative ones included. `np.vdot(c, c)` is $\sum_n |c_n|^2$, the total probability, and `norm_error` keeps its largest distance from 1. The underscore `_` receives the stored amplitudes, which are not needed here.

```
c, _ = passage(0.0, E_SMOOTH, K_SMOOTH, RATE_SMOOTH, START, 400)  # infinitely fast
sudden_basis = 1.0 - abs(c[ZERO]) ** 2
q_ends = np.array([K11, K11 * math.exp(-END)])  # the band level at a4,0 = 0 and 2
ends_a, ends_b = orbitals(levels([0, 0], q_ends), q_ends)
overlap = float(np.sum(SIMPSON * (ends_a[0] * ends_a[1] + ends_b[0] * ends_b[1])))
sudden = 1.0 - overlap ** 2  # the sudden limit from the two orbitals directly
```

The sudden limit, twice. First in the basis: with the duration $T = 0$ the term $-iT\varepsilon c$ vanishes and only the transport by K remains, which is the infinitely fast passage of Section 22.8. Second directly: the band orbitals at the slices 0 and 2 (momenta k and ke^{-2}), their overlap $\int (a_0 a_2 + b_0 b_2)\, dy$ by Simpson's rule, and $P_{sudden} = 1 - \text{overlap}^2$.

```
du = 1.0 / (2 * U_STEPS)  # the spacing of the fine grid U
gaps = E_SMOOTH - E_SMOOTH[:, [ZERO]]  # eps_m - eps_0 along the passage
phase = np.vstack([np.zeros((1, SIZE)), np.cumsum(0.5 * (gaps[1:] + gaps[:-1]) * du,
                                                  axis=0)])  # trapezoid rule
weights = np.full(len(U), 2.0 * du / 3.0)  # Simpson weights on U
weights[1::2] = 4.0 * du / 3.0
weights[0] = weights[-1] = du / 3.0
drive = (weights * RATE_SMOOTH)[:, None] * K_SMOOTH[:, :, ZERO]  # da4/du K_m0
first = np.array([float(np.sum(np.abs(np.sum(drive * np.exp(
    1j * (2.0 * END / rate) * phase), axis=0)) ** 2)) for rate in RATES])
```

The first-order estimate $P^{(1)} = \sum_m |d_m(1)|^2$ of Section 22.8. `gaps` holds $\varepsilon_m - \varepsilon_0$ at every fine point (`[:, [ZERO]]` keeps the column as a column, so the subtraction works row by row). `phase` is $\int_0^u (\varepsilon_m - \varepsilon_0)\, du'$ at every fine point, built by the **trapezoid rule**: each interval adds its length times the mean of the values at its two ends, and `np.cumsum` adds these up one after the other

(`np.vstack` puts the starting row of zeros on top). `weights` are Simpson's weights for the 8000 intervals of length `du` of the grid `U` (here written for pairs of intervals: $du/3$, $4du/3$, $2du/3$). `drive` holds $(da_4/du)K_{m0}$ times the weights, one column per level m. For each rate the integral $d_m(1)$ is the weighted sum of `drive` times $e^{iT\cdot\text{phase}}$ with $T = 4/A$; the absolute squares are added over m. The column $m = 0$ contributes nothing, because $K_{00} = 0$.

```
above = int(np.argmax(excited >= 0.5 * sudden))  # first rate past half the limit
x0, x1 = math.log(RATES[above - 1]), math.log(RATES[above])
y0, y1 = excited[above - 1] - 0.5 * sudden, excited[above] - 0.5 * sudden
rate_half = math.exp(x0 - y0 * (x1 - x0) / (y1 - y0))  # straight line in log A
```

`excited >= 0.5 * sudden` is an array of true and false, and `np.argmax` of it is the position of the first true: the first rate at which P has reached half the sudden limit. Between that rate and the one before, the difference $P - P_{sudden}/2$ is replaced by a straight line in $\ln A$, and its zero is $A_{1/2}$: the line through (x_0, y_0) and (x_1, y_1) crosses zero at $x = x_0 - y_0(x_1 - x_0)/(y_1 - y_0)$, and $A_{1/2} = e^x$.

```
report("largest |total probability - 1|", f"{norm_error:.1e}")
report("sudden limit: overlap / basis", f"{sudden:.6f} / {sudden_basis:.6f}")
report("P at A = 0.25, 1, 2.51, 251",
       ", ".join(f"{excited[i]:.3e}" for i in (0, 6, 10, 30)))
report("rate at which P reaches half the sudden limit, A_1/2", f"{rate_half:.3f}")
check(norm_error < 1e-9, "the evolution keeps the total probability 1 within 1e-9")
check(abs(sudden_basis / sudden - 1.0) < 1e-3,
      "the sudden limit of the 20-level basis equals the direct overlap within 0.1%")
check(abs(excited[-1] / sudden - 1.0) < 1e-3 and excited[0] < 1e-6
      and bool(np.all(excited <= sudden * (1.0 + 1e-3))),
      "P rises from below 1e-6 at A = 0.25 to the sudden limit at A = 251, never above")
```

Out [12]: the total probability stays 1 to 1.2×10^{-11}; the sudden limit is 0.074906 from the overlap and 0.074902 in the basis; P is 1.04×10^{-7} at $A = 0.25$, 0.0138 at $A = 1$, 0.0590 at $A = 2.51$ and 0.0749 at $A = 251$; and $A_{1/2} = 1.508$. (`", ".join(...)` writes the four numbers separated by commas; the format `.3e` writes a number with three digits after the point and a power of ten.) The three checks require the conservation of probability, the agreement of the two sudden limits within 0.1 percent, and that P rises from below 10^{-6} to the sudden limit without ever exceeding it by more than 0.1 percent. That P never exceeds the sudden limit is a COMPUTED finding for this sector and this passage, not a theorem.

In [13], drawing the smooth passage (Figure 22a.5).

```
fig, ax = plt.subplots(figsize=(7.5, 4.6))
ax.plot(RATES, excited, "o-", color=PALETTE[0], ms=5, lw=2.0,
        label="exact evolution (20 levels)")
ax.plot(RATES, first, "--", color=PALETTE[1], lw=2.0, label="first order")
ax.axhline(sudden, color="0.3", ls=":", lw=1.5, label="sudden limit")
```

The exact P (blue, with markers), the first-order estimate (orange, dashed) and the sudden limit (dotted horizontal line).

```
for value, style, text, height in ((1.0, "--", "record", 2e-7),
                                   (rate_half, "-", "$A_{1/2}$", 2e-5),

            "$A_{1/2}$ at which $P$ reaches half the sudden limit, and the naive "
            "breakdown rate $1/Q_{max}$. The gas stops following its level near "
            "$A = 1$, about seven times below the naive estimate ($A_{1/2} = 1.5$ "
            "against $1/Q_{max} = 10.7$), but $P$ never exceeds the sudden limit "
            "of about 7.5 percent.")
```

Both axes logarithmic, the vertical one from 10^{-8} to 0.3; labels, title and legend; Figure 22a.5.

What the student should see in Figure 22a.5, and why. At small rates P is tiny (10^{-7} at $A = 0.25$) and rises very steeply, by about five powers of ten up to $A = 1$: a slow passage leaves the particle in its level, and the fast-turning phases of Section 22.8 suppress the transitions the more strongly the slower the passage. Near $A = 1$, where $P = 0.0138$, the rise slows down, and from about $A = 5$ on the curve is nearly flat at the sudden limit 0.0749: there the passage is so fast that the orbital has no time to adapt at all. The first-order estimate follows the exact curve up to about $A = 1$ (with the same small wiggles, which come from the oscillating phases) and then overshoots the sudden limit, because at large rates the amplitudes are no longer small. The three vertical lines tell the story of the breakdown: the gas stops following its level near $A_{1/2} = 1.51$, about seven times below the naive estimate 10.7; but however fast the passage, at most about 7.5 percent of the particles leave the band level over the recorded span.

In [14], a constant rate: the dressing that Q measures (Figure 22a.6).

```
MARKS = np.arange(0, 2 * U_STEPS + 1, 2 * U_STEPS // 100)  # 101 points of U

def dressed(rate):
    """Level 0 with the first-order admixtures i A K_m0 / (eps_m - eps_0)."""
```

```
    e, k = E_LINEAR[0], K_LINEAR[0]
    c = START.copy()
    for m in range(SIZE):
        if m != ZERO:
            c[m] = 1j * rate * k[m, ZERO] / (e[m] - e[ZERO])
    return c / np.linalg.norm(c)
```

`MARKS` are 101 points of the fine grid, every 80th, at $u = 0, 0.01, \ldots, 1$. `dressed(rate)` builds the dressed state of Section 22.7 at the start of the constant-rate history: amplitude 1 for the band level and $\alpha_m = iAK_{m0}/(\varepsilon_m - \varepsilon_0)$ for every other level (with $H = 1$), divided by its length `np.linalg.norm(c)` $= \sqrt{\sum |c_n|^2}$ so that the total probability is 1.

```
def dressing(rate):
    """The first-order estimate sum_m Q_0m^2 at the 101 marks."""
    e, k = E_LINEAR[MARKS], K_LINEAR[MARKS]
    total = np.zeros(len(MARKS))
    for m in range(SIZE):
        if m != ZERO:  # Q_0m = A |K_m0| / |eps_m - eps_0|
            total += (rate * k[:, m, ZERO] / (e[:, m] - e[:, ZERO])) ** 2
    return total
```

`dressing(rate)` is the first-order dressing probability $\sum_{m \neq 0} Q_{0m}^2$ at the 101 marks, with $Q_{0m} = A|K_{m0}|/|\varepsilon_m - \varepsilon_0|$, which equals the formula of Section 22.7 by line 6. The sum runs over all 19 other levels of the basis, the negative ones included; the matrix K is real, so its square needs no absolute value.

```
runs = {}
for rate in (0.3, 1.0, 3.0):
    duration = END / rate  # T = 2/A for the constant rate A
    steps = steps_needed(duration)
    _, kept = passage(duration, E_LINEAR, K_LINEAR, RATE_LINEAR, dressed(rate),
                      steps, keep=steps // 100)
    runs[rate] = np.array([1.0 - abs(c[ZERO]) ** 2 for c in kept])
steps = steps_needed(END)
_, kept = passage(END, E_LINEAR, K_LINEAR, RATE_LINEAR, START, steps, keep=steps // 100)
bare = np.array([1.0 - abs(c[ZERO]) ** 2 for c in kept])
s_marks = S_LINEAR[MARKS]
```

For the constant rates $A = 0.3$, 1 and 3 the history lasts $T = 2/A$; the evolution starts in the dressed state, and the amplitudes are kept after every hundredth of the steps, which gives the same 101 points as `MARKS`. `runs[rate]` holds $P = 1 - |c_0|^2$ at these points. At $A = 1$ ($T = 2$) a second run starts in the bare level 0 instead: that is an abrupt start of the motion. `s_marks` are the values of a_4 at the marks.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2), layout="constrained")
for colour, rate in zip(PALETTE, (0.3, 1.0, 3.0)):
    left.plot(s_marks, runs[rate], color=colour, lw=2.0, label=f"exact, $A = {rate}$")
    left.plot(s_marks, dressing(rate), color=colour, lw=1.5, ls="--")
left.plot([], [], color="0.4", ls="--", label="first order $\\sum_m Q_{0m}^2$")
```

```
left.set_yscale("log")
left.set_ylim(3e-5, 0.3)
left.set_xlabel("$a_4$ along the constant-rate history")
left.set_ylabel("$P$: probability outside the band level")
left.set_title("Dressed start: exact against first order")
left.legend(fontsize=8, loc="lower left")
```

The left panel: for each rate the exact P (solid) and the first-order dressing (dashed, same colour) against a_4; one empty plot gives the legend entry for the dashed lines; a logarithmic vertical axis from 3×10^{-5} to 0.3.

```
right.plot(s_marks, runs[1.0], color=PALETTE[1], lw=2.0, label="dressed start")
right.plot(s_marks, bare, color=PALETTE[0], lw=2.0, ls="-.", label="bare start")
right.plot(s_marks, dressing(1.0), color="0.4", lw=1.5, ls="--",
           label="first order $\\sum_m Q_{0m}^2$")
right.set_xlabel("$a_4$ along the constant-rate history")
right.set_ylabel("$P$")
right.set_title("$A = 1$: dressed and bare start")
right.legend(fontsize=8)
```

The right panel, with a linear vertical axis: at $A = 1$ the dressed start, the bare start and the first-order dressing.

```
save_figure(fig, "constant_rate",
            "Left: the probability $P$ that the particle is not in its "
            "instantaneous band level (vertical axis, logarithmic) along a history "
            "of constant rate $A = 0.3$, $1$, $3$ from $a_4 = 0$ to $2$ "
            "(horizontal axis), exact (solid) and the first-order dressing "
            "$\\sum_m Q_{0m}^2$ (dashed), starting in the dressed state. At $A = "
            "0.3$ they agree; at $A = 1$ the exact $P$ stays near 0.009 while the "
            "estimate falls; at $A = 3$ first order fails. Right: $A = 1$ with the "
            "dressed start and with the bare start (an abrupt start of the motion), "
            "which leaves about three times more.")
deviation = float(np.max(np.abs(runs[0.3] / dressing(0.3) - 1.0)))
report("A = 0.3: largest relative difference exact / first order", f"{deviation:.3f}")
report("A = 1: exact P at a4 = 0 and 2", f"{runs[1.0][0]:.5f}, {runs[1.0][-1]:.5f}")
report("A = 1: first-order dressing at a4 = 0 and 2",
       f"{dressing(1.0)[0]:.5f}, {dressing(1.0)[-1]:.5f}")
report("A = 1, bare start: largest P", f"{bare.max():.5f}")
check(deviation < 0.15, "at A = 0.3 the exact P agrees with the first-order dressing "
      "within 15 percent at all 101 points")
```

Figure 22a.6 and the numbers of Out [14]: at $A = 0.3$ the exact P and the first-order dressing differ by at most 11.3 percent; at $A = 1$ the exact P is 0.00904 at the start and 0.00730 at the end, while the first-order dressing falls from 0.00912 to 0.00289; the bare start at $A = 1$ reaches 0.02787. The check requires agreement within 15 percent at $A = 0.3$.

What the student should see in Figure 22a.6, and why. On the left the blue pair ($A = 0.3$) lies almost on top of each other and falls from about 8×10^{-4} to 2.6×10^{-4}: at a small rate the particle carries exactly the dressing that Q measures, and the dressing shrinks along the history because Q

falls as the momentum redshifts. At $A = 1$ the exact curve stays near 0.009 while the dressing falls to 0.003; the difference is, in the reading suggested by Section 22.7, probability that has really left the band level, not dressing that would disappear if the motion stopped slowly (the notebook does not separate the two by a computation of its own). At $A = 3$ the exact P stays near 0.075, the size of the sudden limit, and the first-order dressing is no guide. On the right, the abrupt (bare) start at $A = 1$ shakes the particle: P rises from 0 to 0.028 near $a_4 = 1.6$, about three times the dressing, because starting the motion suddenly is itself a sudden change.

In [15], how far the sudden limit reaches (Figure 22a.7).

```
ENDS = np.linspace(0.0, 6.0, 61)  # end slices of a sudden jump from a4,0 = 0
ends_q = K11 * np.exp(-ENDS)
band_a, band_b = orbitals(levels(np.zeros(61), ends_q), ends_q)
ceiling = 1.0 - (band_a @ (SIMPSON * band_a[0]) + band_b @ (SIMPSON * band_b[0])) ** 2
```

The sudden limit caps the damage, and it depends on how much the band orbital itself changes. The cell computes the band orbital of the Fermi shell at 61 end slices from 0 to 6, three times beyond the record's span (free field, computed here), and the sudden limit $1 - (\int \varphi_0(s)^\dagger \varphi_0(0)\, dy)^2$ of a jump from 0 to each of them. `band_a @ (SIMPSON * band_a[0])` computes in one matrix product the Simpson integrals of $a_0(s)a_0(0)$ for all 61 end slices.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2), layout="constrained")
for colour, index in zip(PALETTE, (0, 10, 20, 60)):
    left.plot(Y, band_a[index], color=colour, lw=2.0,
              label=f"$a$, $a_{{4,0}} = {ENDS[index]:.0f}$")
    left.plot(Y, band_b[index], color=colour, lw=1.2, ls="--")
left.plot([], [], color="0.4", ls="--", label="$b$ (dashed)")
left.set_xlabel("hidden coordinate $y$ (tip at $-3$, brane at 0)")
left.set_ylabel("band orbital (normalised)")
left.set_title("The band orbital of the Fermi shell")
left.legend(fontsize=8)
```

The left panel draws the two components of the band orbital, a solid and b dashed, against y at the end slices 0, 1, 2 and 6 (the indices 0, 10, 20, 60 of `ENDS`).

```
right.plot(ENDS, ceiling, color=PALETTE[0], lw=2.0)
right.plot([END], [sudden], "o", color=PALETTE[1], ms=9,
           label="end of the recorded span")
right.set_xlabel("end slice $a_{4,0}$ of a sudden jump from 0")
right.set_ylabel("$P_{sudden}$")
right.set_title("The ceiling of the damage")
right.legend(fontsize=8)
```

The right panel: the sudden limit against the end slice, with an orange dot at the end of the recorded span, the value of In [12].

```
save_figure(fig, "sudden_ceiling",
            "Left: the band orbital of the Fermi shell of $N = 688$, components "
            "$a$ (solid) and $b$ (dashed), against the hidden coordinate $y$ "
```

```
            "(horizontal axis) at the slices $a_{4,0} = 0$, $1$, $2$, $6$: as the "
            "momentum redshifts, $b$ shrinks and the orbital approaches the brane "
            "zero mode $e^{y}$. Right: the sudden limit $P_{sudden}$ (vertical "
            "axis) of a jump from $a_{4,0} = 0$ to the end slice (horizontal "
            "axis); it grows and levels off near 0.105: even an instant jump to "
            "the far future leaves almost 90 percent of the particles in the band "
            "level.")
report("sudden limit for the end slices 2, 4, 6",
       ", ".join(f"{ceiling[i]:.4f}" for i in (20, 40, 60)))
check(np.all(np.diff(ceiling) > -1e-12) and ceiling[-1] < 0.11
      and abs(ceiling[20] - sudden) < 1e-12,
      "the sudden limit grows with the end slice and stays below 0.11 up to 6")
```

Figure 22a.7 and Out [15]: the sudden limit is 0.0749, 0.1021 and 0.1051 for the end slices 2, 4 and 6. The check requires that it never decreases (`np.diff` gives the differences of neighbours), that it stays below 0.11, and that its value at the slice 2 equals the sudden limit of In [12].

What the student should see in Figure 22a.7, and why. On the left the band orbital is concentrated near the brane: a grows towards $y = 0$ and b is small and negative. As the slice grows, b shrinks towards zero and a spreads a little towards the tip, approaching the zero mode $(e^y, 0)$, the exact brane-bound orbital of momentum 0 (Chapter 14). The orbitals of the slices 2 and 6 are already close to each other. On the right the sudden limit rises steeply at first and then levels off near 0.105: the orbital cannot move further than to the zero mode, so even an instantaneous jump to the far future leaves almost 90 percent of the particles in the band level.

In [16], how many levels are needed (Figure 22a.8).

```
sizes, errors = [], {"sudden": [], 1.0: [], 3.0: []}
results = {}
for low in range(1, 10):
    for high in (low, low + 1):
        chosen = np.where((BASIS >= -low) & (BASIS <= high))[0]
        zero = int(np.where(BASIS[chosen] == 0)[0][0])
        e, k = E_SMOOTH[:, chosen], K_SMOOTH[:, chosen][:, :, chosen]
        start = np.zeros(len(chosen), dtype=complex)
        start[zero] = 1.0
        sizes.append(len(chosen))
```

A truncated basis can only be trusted if the results stop changing as it grows. The loop builds smaller bases from the labels $-l, \ldots, l$ and $-l, \ldots, l+1$ for $l = 1, \ldots, 9$, that is, of $3, 4, 5, \ldots, 20$ levels. `np.where(condition)[0]` gives the positions where the condition holds (`&` is "and" for arrays); `zero` is the position of label 0 within the chosen labels; `e` and `k` keep the columns, and for K also the rows, of the chosen levels; `start` puts the particle into the band level.

```
        c, _ = passage(0.0, e, k, RATE_SMOOTH, start, 400)
        errors["sudden"].append(abs(1.0 - abs(c[zero]) ** 2 - sudden))
        for rate in (1.0, 3.0):
            duration = 2.0 * END / rate
            c, _ = passage(duration, e, k, RATE_SMOOTH, start, steps_needed(duration))
            results[(len(chosen), rate)] = 1.0 - abs(c[zero]) ** 2
for rate in (1.0, 3.0):
```

```
    errors[rate] = [abs(results[(size, rate)] - results[(SIZE, rate)])
                    for size in sizes]
```

For each basis: the sudden limit, compared with the direct overlap of In [12], and the smooth passages at $A = 1$ and $A = 3$. Their errors are measured against the result of the full 20-level basis.

```
halving = 0.0
for rate in (RATES[0], 1.0, 10.0):
    duration = 2.0 * END / rate
    steps = steps_needed(duration)
    other = 2 * steps if steps < U_STEPS else steps // 2
    p_one, p_two = (1.0 - abs(passage(duration, E_SMOOTH, K_SMOOTH, RATE_SMOOTH, START,
                                      n)[0][ZERO]) ** 2 for n in (steps, other))
    halving = max(halving, abs(p_one - p_two))
```

The second numerical question, the time steps: three passages ($A = 0.25$, 1, 10) are repeated with twice the number of steps (or half of it, when the finest number is already in use), and `halving` keeps the largest change of P. The parentheses around the expression with `for` make a **generator**, whose two values are assigned to `p_one` and `p_two`.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
ax.plot(sizes, errors["sudden"], "o-", color=PALETTE[0], lw=2.0, ms=6,
        label="sudden limit (against the direct overlap)")
for colour, marker, rate in ((PALETTE[1], "s", 1.0), (PALETTE[2], "^", 3.0)):
    ax.plot(sizes[:-1], errors[rate][:-1], marker + "--", color=colour, lw=1.5, ms=6,
            label=f"$A = {rate:.0f}$ (against 20 levels)")
ax.set_yscale("log")
ax.set_xticks(range(3, 21))
ax.set_xlabel("number of instantaneous levels in the basis")
ax.set_ylabel("$|P - P_{reference}|$")
ax.set_title("Convergence with the size of the basis")
ax.legend(fontsize=8)
```

The errors against the size of the basis on a logarithmic axis, with a tick at every size from 3 to 20. For $A = 1$ and 3 the last point (the 20-level basis itself, whose error is zero by definition) is left out (`[:-1]`), because zero has no place on a logarithmic axis.

```
save_figure(fig, "convergence",
            "The error of the probability $P$ (vertical axis, logarithmic) against "
            "the number of instantaneous levels kept in the basis (horizontal "
            "axis), for the sudden limit (blue, against the direct overlap of the "
            "two orbitals) and for the smooth passages at $A = 1$ and $A = 3$ "
            "(against the 20-level result). The errors fall steadily; with 20 "
            "levels the sudden limit is right to a few millionths.")
report("sudden limit: error with 20 levels", f"{errors["sudden"][-1]:.1e}")
report("A = 1: change from 18 to 20 levels", f"{errors[1.0][-3]:.1e}")
report("largest change of P when the steps are doubled or halved", f"{halving:.1e}")
check(errors["sudden"][-1] < 1e-5 and errors[1.0][-3] < 1e-6,
      "the 20-level basis is converged: sudden limit within 1e-5, A = 1 within 1e-6")
check(halving < 1e-9, "doubling or halving the time steps changes P by less than 1e-9")
```

Figure 22a.8 and Out [16]: with 20 levels the sudden limit is right to 4.2×10^{-6}; at $A = 1$ going from 18 to 20 levels changes P by 2.4×10^{-8} (`errors[1.0][-3]` is the entry of the 18-level basis, the third from the end of the list of sizes); and doubling or halving the time steps changes P by at most 3.0×10^{-11}. The two checks require 10^{-5}, 10^{-6} and 10^{-9}.

What the student should see in Figure 22a.8, and why. All three error curves fall by several powers of ten as levels are added, with small ups and downs where a newly added level happens to matter little. The sudden limit converges most slowly (from 7×10^{-3} with 3 levels to a few millionths with 20), because a sudden jump excites all levels at once, while a passage at a finite rate mostly reaches the nearby levels; the passage at $A = 1$ converges fastest. These measured errors are the uncertainties of the COMPUTED probabilities of In [12] and In [14]: they are thousands of times smaller than the effects the figures show.

In [17], the breakdown estimate.

```
q_first = q_max[(688, "lam0", 0.0)]  # the largest Q of the free Fermi shell, A = 1
estimates = [
    ("naive: Q = 1 for the weakest recorded state", naive[weakest]),
    ("naive: Q = 1 for the band level, 0.02 <= q <= 6", 1.0 / g_star),
    ("first order: Q^2 reaches the sudden limit", math.sqrt(sudden) / q_first),
    ("exact: P reaches half the sudden limit", rate_half),
]
```

The four estimates of the breakdown rate of Section 22.8: the naive one for the weakest recorded state ($1/Q_{max}$, In [3]); the naive one for the band level of every shell and slice with redshifted momentum $0.02 \le q \le 6$ ($1/G^*$, In [6]); the first-order one, the rate at which $(AQ_0)^2$ reaches the sudden limit, $A = \sqrt{P_{sudden}}/Q_0$ with $Q_0 = 0.0934506$, the record's Q_{max} of the free state $N = 688$ at the slice 0; and the exact $A_{1/2}$ (In [12]). `estimates` is a list of pairs (text, value).

```
say("breakdown estimate                                    rate A")
for label, value in estimates:
    say(f"{label:50s} {value:9.3f}")
report("P at the record's rate A = 1, constant rate (dressed start)",
       f"{runs[1.0].min():.4f} ... {runs[1.0].max():.4f}")
report("P at the peak rate A = 1, smooth passage", f"{excited[6]:.4f}")
report("sudden limit over the span 0 ... 2, the most P reaches in the scan",
       f"{sudden:.4f}")
```

The table of Out [17], each text padded to 50 characters (`:50s`) and each rate printed with three digits after the point in a field of width 9: 10.701, 10.021, 2.929 and 1.508. Then the probability that a particle of the Fermi shell is outside its instantaneous level at the record's rate: between 0.0073 and 0.0092 along the constant-rate history with the dressed start, 0.0138 at the end of the smooth passage with peak rate 1; and the sudden limit 0.0749, the most that P reached in the scan of In [12].

```
NAMES = ["naive_rates", "one_curve", "across_the_gap", "sector_levels",
         "smooth_passage", "constant_rate", "sudden_ceiling", "convergence"]
missing = [name for number, name in enumerate(NAMES, start=1)
           if not output_file(f"{FIGURE_FOLDER}/22a_{number}_{name}.png").is_file()]
check(missing == [], "every figure file of this notebook exists")
all_checks_passed()
```

The last check requires that all eight figure files exist (`enumerate(NAMES, start=1)` numbers the names from 1, and the file of figure k is `22a_k_name.png`), and the last line prints ALL 20 CHECKS PASSED (notebook 22a): two checks in In [2], one each in In [3] and In [4], three in In [5], two in In [7], one in In [8], two in In [9], three in In [12], one each in In [14] and In [15], two in In [16] and one in In [17].

22.13 What Notebook 22a found, and how a student could continue

The results. Every number below is printed by the notebook in the cell named; the uncertainties are the ones the notebook measures.

result	value	status	where
largest Q of the record at $A = 1$	0.0934532 (N688_lamm2_a00)	COMPUTED (Revision record)	Out [2]; `adiabaticity.csv`
naive breakdown rate $1/Q_{max}$ of the weakest recorded state	10.70	COMPUTED from the record	Out [3]
record's levels and Q of the free Fermi shells, reproduced	to 8.8×10^{-14} and 1.3×10^{-13} (relative)	COMPUTED here	Out [5]
top of the curve $G(q) = Q/A$ of the band jump	$G^* = 0.09979$ at $q^* = 2.128$	COMPUTED here ($\lambda = 0$)	Out [6]
naive breakdown rate of the band level of every shell with $0.02 \le q \le 6$ (all states of the record), $1/G^*$	10.02	COMPUTED here ($\lambda = 0$)	Out [6]
largest change of Q_{max} by the interaction	9.8 percent (N136_lamp2_a20)	COMPUTED from the record	Out [7]
strongest jump from a negative level to a bulk level, per unit rate	0.0489 at $q = 0.111$	COMPUTED here; its reading OPEN	Out [8]
P at the end of the smooth passage with peak rate $A = 1$	0.0138	COMPUTED here	Out [12]
rate $A_{1/2}$ at which P reaches half the sudden limit	1.508, between the scan rates 1.259 and 1.585	COMPUTED here	Out [12]
sudden limit of the span $a_{4,0} = 0$ to 2	0.074906 (overlap), 0.074902 (20-level basis)	COMPUTED here	Out [12]
P along the constant rate $A = 1$, dressed start	0.0073 to 0.0092	COMPUTED here	Out [14], Out [17]

result	value	status	where
sudden limit for the end slices 4 and 6	0.1021 and 0.1051	COMPUTED here ($\lambda = 0$, beyond the record's span)	Out [15]
numerical errors	total probability 1.2×10^{-11}; basis: sudden limit 4.2×10^{-6}, $A = 1$ 2.4×10^{-8}; time steps 3.0×10^{-11}	measured	Out [12], Out [16]

The rate $A_{1/2}$ comes from a straight-line interpolation in $\ln A$ between two rates of the scan (ten per factor 10); that P crosses half the sudden limit between the scan rates $10^{0.1} = 1.259$ and $10^{0.2} = 1.585$ is certain, and the interpolated value 1.508 lies between them; the interpolation error itself is not measured.

What the results mean. Four statements, each for the free field ($\lambda = 0$) in the sector computed, follow from the table.

- In this book's reading (Section 22.7; the record calls Q^2 the leading-order transition probability), the record's Q measures the dressing, and the numbers confirm this reading: at a small rate ($A = 0.3$) a particle carries the dressing $\sum_m Q_{0m}^2$, and the exact evolution agrees with it within 11.3 percent along the whole span (Out [14]).
- The naive criterion "Q reaches 1" overestimates the breakdown rate about sevenfold (10.7 against 1.508). The reason is visible in the derivation of Section 22.7: what can leave the level is a probability, Q^2 to first order, and what it should be compared with is not 1 but the largest probability that can leave at all, the sudden limit 0.0749. The first-order estimate built on that comparison, $A = 2.929$, is within a factor of two of the exact $A_{1/2}$.
- The damage is capped: however fast the passage, at most about 7.5 percent of the particles of the Fermi shell leave the band level over the record's span, and at most about 10.5 percent even for a jump to the slice 6, because the band orbital itself changes little (Figure 22a.7).
- At the record's rate $A = 1$, about one percent of the Fermi-shell particles are outside their instantaneous level (0.7 to 0.9 percent along the constant-rate history, 1.4 percent at the end of the smooth passage). The instantaneous picture is therefore a fair first approximation at $A = 1$ for this sector, but the record's history is not deep inside the adiabatic regime: the gas stops following its levels at rates only about 1.5 times larger.

What the notebook does not show. It treats the free field only, one sector only ($j = +1$, even parity, the Fermi shell of $N = 688$), and one particle at a time; it does not include the interaction, the other sectors, the many-body state or the thermal states. The probability P counts the negative levels of the basis among the levels a particle can leave to; how that part is to be read in the quantised theory is part of the OPEN question of the negative branch. The history is a PRESCRIBED BACKGROUND, and the Z2 brane is ASSUMED.

A consequence for Fermi-level crossings, from the record's own statement. The exact evolution conserves the momentum, the block and the brane parity, so particles jump only between

levels of the same sector (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.exactEvolution`). In the free field, therefore, the number of particles in every sector stays what it was at the start. When levels of different sectors cross the Fermi level, as in the record's example $N = 696$ (Section 22.5), the evolving gas cannot move its particles into the sector that the instantaneous ground state would fill: at best, in the adiabatic limit, it becomes the adiabatically continued state of the record, which lies above the instantaneous ground state by up to 8.623 (units of m) at the slice 2 (`Revision/kohn_sham/results/adiabatic/crossing-demo.csv`). Whether interactions beyond the mean field (collisions, which the functional of the record does not contain) let the gas relax towards the instantaneous ground state is OPEN.

How a student could continue.

1. *Other shells and sectors.* By exact rule 2 the free evolution of a shell of momentum k from the slice s_1 to the slice s_2 depends only on how $q = ke^{-a_4}$ moves from ke^{-s_1} to ke^{-s_2}. Repeat In [9] to In [16] for the Fermi shell of $N = 136$ ($k = 0.5$), for the odd brane parity and for the block type $j = -1$, and draw the breakdown rate as a function of k.

2. *The interacting problem.* Write a time-dependent Kohn-Sham solver: evolve every occupied orbital of every sector with a method that conserves probability exactly, and at every time step recompute the densities $n(y)$ and $S(y)$ and from them $M = m + \frac{15}{16}\lambda S$ and $v = -\lambda n/16$ (`Revision/kohn_sham/ks-theory.json`, key `exchange.kohnShamPotentials`). Tests fixed in advance: for $\lambda = 0$ it must reproduce Notebook 22a; the particle number must be conserved; at a very small rate the gas must stay close to the record's instantaneous states; and the energy balance must follow the identity $dE/da_4 = -3\,(2\mathrm{Vol}_7)\int e^{6Hy}(p_3 - p_t)\,dy$ of the record (key `emt.energyChange`) up to the dressing.

3. *Crossings.* Follow the record's example $N = 696$ through its Fermi-level crossing with the evolution of item 2, and measure how far the evolved gas stays from the instantaneous ground state.

4. *The negative branch.* Formulate the jumps of Figure 22a.3 in the quantised theory: compare the modes of the field before and after a passage (the Bogoliubov method), and find out whether, with the Krein metric of Chapter 10, they describe the creation of pairs of quanta of positive norm. This is OPEN, and it concerns quanta inside one universe, not universes.

Where to start. The builder of the notebook, `Revision/textbook/notebooks/src/22a_adiabatic_breakdown.py`; the theory, `Revision/kohn_sham/ks-theory.json` (keys `adiabaticity`, `exchange`, `emt`); the Rust solver in `Revision/kohn_sham/solver` with its README; the folder `Revision/kohn_sham/results/adiabatic` (`adiabaticity.csv`, `crossing-demo.csv`, `fermi-level-crossings.csv`, `history.json`); the reference solver `Revision/kohn_sham/reference/run_reference.py` for a second method.

22.14 Problem 3: the back-reaction of the gas on a_4

The question. Every Kohn-Sham result of the record is a test-field result: the gas lives on the history $a_4 = AHx_4$, which is prescribed. The open problem is to solve the gas and the geometry together: a history $a_4(x_4)$ (or a more general metric) and gas states such that the gas is a solution in that geometry and its energy-momentum tensor is the source of that geometry in the field equations.

An answer is such a solution, with its numbers checked as in Chapter 16, or a proof, under stated assumptions, that none exists.

What is known.

- PROVED (Chapter 12; `Revision/field_equations_a4/a4-equations.json`, key `generalSource`; both reports in `Revision/field_equations_a4/reports`): for the author's metric the Einstein-Lovelock equations reduce to the constraint (the x_4 component), the evolution equation $a_4'' F(a_4') = \kappa(p_3 - p_t)$, the hidden ($x_0$) equation and conditions on the source: every component of the source must be independent of x_0, the source must obey $p_3 + p_t = 2p_0$, and its mixed x_4-x_0 components must vanish. The left-hand sides of the equations are free of x_0 (key `generalSource.x0_dependence`; independently `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, check `einstein_x0_independent`), and that is why the source must be free of x_0 too.

- PROVED: the linear member $a_4 = AHx_4 + a_0$ needs $p_3 = p_t = p_0$ and a constant ρ (check `linear_member_equal_pressures` of both reports).

- PROVED (Chapter 12; key `b4` of `a4-equations.json`; `wolfram-a4-report.json`, with the checks `b4_offdiagonal_factorises`, `b4_einstein_offdiagonal_forces_b4_constant` and `b4_identity_x1_plus_x5_minus_2x0`): with the second function $b_4(x_4)$ of the author's metric the coupled problem has one more unknown. The mixed equation reads $\kappa q_{40} = \cot z\,(b_4'/b_4)\,Q$ with $Q = \frac{3}{2}H$ in Einstein gravity, so there a source with $T^{x_4}{}_{x_0} = 0$ forces a constant b_4; and the algebraic condition becomes $\kappa(p_3 + p_t - 2p_0) = \frac{1}{4}(b_4'/b_4)^2 + b_4''/(2b_4)$ in Einstein gravity. A coupled solution may therefore use b_4 to meet the source conditions; this too is OPEN for the gas.

- PROVED: in Einstein gravity every source obeys $\kappa(\rho + p_0) = -6\big((a_4')^2 + H^2\big)$ (check `einstein_null_energy_x0` of both reports; `Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json`, check `einstein_null_energy`). The derivation is given below.

- COMPUTED: no recorded Kohn-Sham state is an admissible source. The report is `ks-source-conditions.json` in the folder `Revision/field_equations_a4/reports`, and its checks say why. Check `ks_profiles_depend_on_x0`: for every state with a nonzero energy-momentum tensor the energy density varies along the hidden coordinate, by at least 0.0497 of the largest component (smallest case N136_lamm2_a20). Check `ks_profiles_violate_algebraic_condition`: $\max_y |p_3 + p_t - 2p_0| / \max |T|$ lies between 2.09 and 3.99. Check `ks_integrals_violate_algebraic_condition`: even the source integrated over the hidden direction violates $p_3 + p_t = 2p_0$; the ratio $(\int p_3 + \int p_t)/(2\int p_0)$ is never 1 (closest 0.414, N688_lamm2_a00). Check `ks_history_is_a_prescribed_background`: along the history the integrated energy changes, for example $\int \rho = 80.28$, 32.38, 12.45 for N136_lam0 at the slices 0, 1 and 2, and $p_3 \neq p_t$, while the linear member needs a constant ρ and equal pressures.

- PROVED and COMPUTED, the energy exchange: along the history the energy of the gas changes as $dE/da_4 = -3\,(2\mathrm{Vol}_7)\int_{-L}^{0} e^{6Hy}(p_3 - p_t)\,dy$, where Vol_7 is the coordinate volume of 3-space and the extra times. The identity is the key `emt.energyChange` of `Revision/kohn_sham/ks-theory.json`, verified by the check `adiabatic_hellmann_feynman` of the theory report `ks-theory-python.json`. The record computes both sides: for N688_lam0_a00 the finite difference of the energies gives -597.9157012757526 and the energy-momentum integral -597.9157012806555 (the columns `dE_da4_finite_difference` and `dE_da4_emt` of

`adiabaticity.csv`). In a coupled solution this energy would have to be exchanged with the geometry.

- Chapter 12 constructs three exact solutions of the coupled equations of Einstein gravity and a homogeneous condensate of the classical field dirac16complex00, two of them with the extra times deflating as e^{-Hx_4} (Notebook 12d; a computation of this book under the assumptions stated there, not a Revision record). For that classical, homogeneous source the back-reaction is solved. For the quantised gas it is OPEN.

The null combination in Einstein gravity, line by line. The constraint and the hidden equation of Einstein gravity (`Revision/field_equations_a4/a4-equations.json`, key `einstein`) are

$$3(a_4')^2 + 21H^2 + \Lambda = -\kappa\rho, \qquad -3(a_4')^2 + 15H^2 + \Lambda = \kappa p_0.$$

$$\kappa\rho = -3(a_4')^2 - 21H^2 - \Lambda.$$

Rule: multiply the constraint by -1.

$$\kappa(\rho + p_0) = -3(a_4')^2 - 21H^2 - \Lambda - 3(a_4')^2 + 15H^2 + \Lambda = -6(a_4')^2 - 6H^2.$$

Rule: add the hidden equation; Λ cancels, $-3-3=-6$ and $-21+15=-6$.

The right-hand side is negative for every real history when $H > 0$. So in Einstein gravity, with a positive coupling κ, every source of the author's metric must have $\rho + p_0 < 0$ everywhere: it must violate the null energy condition along the hidden direction. This holds for every a_4 and every Λ; any candidate source, a time-dependent Kohn-Sham gas included, must meet it, or the gravity theory must contain more than the Einstein term.

Why it is hard. The metric of the record fixes the dependence on x_0 completely ($\sin^{1/3} z$ and $\cot^2 z$), and leaves only one free function, $a_4(x_4)$. A gas bound to the brane, whose density falls off towards the tip, cannot be the source of such a metric: its energy-momentum depends on y. A coupled solution therefore needs a more general metric, whose factors depend on y and on x_4; the field equations then become partial differential equations in two variables, and the Kohn-Sham reduction of Chapter 14, which used the exact warp e^{Hy}, must be redone for the new metric at every step. In addition, the brane enters (Problem 4), the couplings α_2, α_3, Λ and κ are unknown, and in Einstein gravity the source must violate the null energy condition along x_0, as just shown.

A first step. (a) Redo the derivation above, and its Einstein-Gauss-Bonnet version from the general null combination of the record (`Revision/field_equations_a4/a4-equations.json`, key `generalSource.nullCombinations`). (b) Check the energy-exchange identity on the record's numbers (Exercise 7 of Section 22.28). (c) Write down a more general metric that keeps the symmetries of the author's metric (3-space isotropic, the three extra times isotropic) but lets the factors depend on y and x_4, for example $ds^2 = e^{2\mathcal{A}(y,x_4)}(dx_1^2 + dx_2^2 + dx_3^2) - e^{2\mathcal{B}(y,x_4)}(dx_5^2 + dx_6^2 + dx_7^2) - e^{2\mathcal{C}(y,x_4)}dx_4^2 + dy^2$, which contains the author's metric as $\mathcal{A} = Hy + a_4$, $\mathcal{B} = Hy - a_4$, $\mathcal{C} = 0$ (this ansatz is a suggestion of this book, a HYPOTHESIS about a useful next step, not a result). Compute its Einstein tensor with two independent programs, as the record does for the author's

metric, and find which conditions it puts on a source. (d) Only then ask whether a Kohn-Sham gas can satisfy them, starting with the free gas.

Where to start. `Revision/field_equations_a4/README.md` and its verifiers; `Revision/field_equations_a4/python/check_ks_source_conditions.py` and its report; the lead's independent curvature code `Revision/lead_checks/einstein_gauss_bonnet_a4.py`; the profiles `Revision/kohn_sham/results/ground/profiles` and the integrals `Revision/kohn_sham/results/ground/emt-integrals.csv`; the GKD and Lovelock programs of Chapter 11 in `Revision/gkd_lovelock`.

22.15 Problem 4: the Z2 brane and its junction conditions

The question. The hidden direction ends at $z = \pi/2$, the brane. The record continues the universe beyond it by its mirror image, the Z2 construction: the field on the mirror patch $\pi/2 < z < \pi$ is the reflected field. This is ASSUMED. The open problem is to derive it, or to replace it, from field equations: which conditions must the metric and the field satisfy at the brane (the **junction conditions**), what energy and momentum must sit on the brane itself, and is the mirror the right continuation? An answer is a set of junction conditions derived from the field equations of gravity and of the field, with the brane's energy-momentum, checked like every other exact statement of the record.

What is known.

- PROVED: the map $z \to \pi - z$ (that is, $x_0 \to \pi/(6H) - x_0$) is an isometry of the author's metric: every component takes the same value at z and at $\pi - z$ (`Revision/pairing/reports/python-pairing.json`, check `geometry.mirror_isometry`; `Revision/pairing/reports/wolfram-pairing.json`, check `T2_mirror_is_isometry`).
- PROVED: in the coordinate x_0 the metric is degenerate at the brane: $g_{00} = \cot^2 z$ and $\sqrt{|g|} = \cos z$ vanish at $z = \pi/2$ (`Revision/pairing/reports/python-pairing.json`, check `geometry.brane_degenerate`).
- ASSUMED (`Revision/kohn_sham/ks-theory.json`, key `boundaryConditions.brane`): the Z2 mirror (orbifold) at $y = 0$, with the mirror warp $e^{-H|y|}$; continuity of the mirrored field gives the two brane parities, $b(0) = 0$ (even) and $a(0) = 0$ (odd), which both stop the current along y (checks `bc_brane_parity_conditions`, `bc_mirror_map_PA` and `bc_mirror_parities_of_densities` of `Revision/kohn_sham/reports/ks-theory-python.json`). PROVED under this assumption: the doubled problem is symmetric under the mirror exactly when the mirror copy carries $(-m, +\lambda)$ (`Revision/pairing/kohn_sham/reports/python-t3.json`, check `T3.z2_mirror_copy_carries_minus_m_plus_lambda`).
- What rests on it: theorem T2 in the author's field (the mirror pairing), theorem T3, and every Kohn-Sham number of the record (the densities are those of the doubled system, each patch with the weight 1/2; key `densities.total`).
- NOT established, as the record says itself: "no junction condition, brane tension or matching of the field across it is derived" (`Revision/pairing/reports/python-pairing.json`, key `not_established`). OPEN.

The brane in the coordinate y, line by line. The two derivations of this paragraph and the next are written out by the book from statements of the record. The first, the line element in the coordinate y, is verified by the record's checks `geometry_hidden_coordinate` and `geometry_warped_form` of `Revision/kohn_sham/reports/ks-theory-python.json`; the second, the kink of the mirror warp, is the book's own, and no Revision verifier checks it as such. The record's hidden coordinate is $y = \ln(\sin z)/(6H)$, with $dy = \cot z\, dx_0$ (`Revision/kohn_sham/ks-theory.json`, key `geometry.hiddenCoordinate`).

$$\cot^2 z\, dx_0^2 = dy^2.$$

Rule: square both sides of $dy = \cot z\, dx_0$.

$$\sin z = e^{6Hy}, \qquad \sin^{1/3} z = e^{2Hy}.$$

Rule: solve $y = \ln(\sin z)/(6H)$ for $\sin z$ (multiply by $6H$, then apply the exponential), and raise both sides to the power $1/3$.

$$ds^2 = e^{2Hy}\big[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2 + dx_7^2)\big] - dx_4^2 + dy^2.$$

Rule: insert both lines into the author's metric (the record's key `geometry.lineElement`; check `geometry_warped_form` of `Revision/kohn_sham/reports/ks-theory-python.json`).

At the brane $y = 0$ every coefficient of this line element is finite and nonzero ($e^0 = 1$). The zero of g_{00} in the coordinate x_0 belongs to that coordinate: $dx_0 = \tan z\, dy$, and $\tan z$ grows without bound as $z \to \pi/2$, so near the brane one unit of y corresponds to ever more units of x_0. In the same way $\sqrt{|g|}$ is $e^{6Hy} = \sin z$ in the coordinate y, and $\sin z \cdot \cot z = \cos z$ in the coordinate x_0 (rule: a volume element changes by the factor $|dy/dx_0| = \cot z$). What makes the brane special is therefore not a singularity of the geometry but the end of the coordinate range: y cannot exceed 0, because $\sin z$ cannot exceed 1. To go on, a continuation must be chosen, and the Z2 mirror is one choice.

The mirror has a kink, line by line. On the patch the warp factor of the six directions $x_1, x_2, x_3, x_5, x_6, x_7$ is $W(y) = e^{Hy}$ (key `geometry.warp`). The mirror continues it to $W(y) = e^{-H|y|}$ on $-L \le y \le L$ (key `boundaryConditions.brane`).

$$W'(y) = He^{Hy} \ \ (y < 0), \qquad W'(y) = -He^{-Hy} \ \ (y > 0).$$

Rule: for $y < 0$, $|y| = -y$ and $W = e^{Hy}$; for $y > 0$, $|y| = y$ and $W = e^{-Hy}$; differentiate each.

$$W'(0^-) = H, \qquad W'(0^+) = -H.$$

Rule: let y go to 0 from below and from above; $e^0 = 1$. The function W is continuous at $y = 0$ (both sides give 1) but its slope jumps by $-2H$: W has a kink.

$$\int_{-\epsilon}^{\epsilon} W''(y)\, dy = W'(\epsilon) - W'(-\epsilon) = -He^{-H\epsilon} - He^{-H\epsilon} = -2He^{-H\epsilon} \ \to \ -2H \quad (\epsilon \to 0).$$

Rule: the fundamental theorem of calculus (the integral of a derivative is the difference of the values at the ends), then the two slopes above, then $e^{-H\epsilon} \to 1$.

The integral of W'' over an interval around the brane does not shrink to zero with the interval: the second derivative of W has a part concentrated on the brane. The curvature of a metric contains the second derivatives of its components, so the curvature of the doubled metric has a part concentrated on the brane, and the field equations can then only hold if the source has a part concentrated there too: energy and momentum that live on the brane. Which energy density and which pressures, in which directions, the field equations demand is exactly what the junction conditions would say. Nobody has derived them for this metric: OPEN.

Why it is hard. The brane is a 7-dimensional surface whose own signature is (3,4): three space directions x_1, x_2, x_3 and four times x_4, x_5, x_6, x_7. The junction conditions of general relativity (W. Israel, Nuovo Cimento B 44, 1 (1966); quoted, not derived here) are formulated for surfaces in ordinary spacetime; the Lovelock terms of Chapter 11 change them; and the warp multiplies only six of the seven brane directions, because x_4 is not warped. For the field, the record's parities come from continuity of the mirrored field; other continuations are possible, and T2 and T3 depend on this one.

A first step. (a) Redo the two derivations above. (b) Compute the curvature of the doubled metric with $W = e^{-H|y|}$, keeping the concentrated parts, with two independent programs (the lead's curvature code in `Revision/lead_checks/einstein_gauss_bonnet_a4.py` is one starting point); write down the brane energy-momentum that Einstein's equations then require, and check whether it is a pure tension (the same negative pressure in every brane direction) or whether the unwarped time x_4 makes it different in different directions. (c) Integrate the field equation of the spinor across the brane in the same way and compare the resulting matching conditions with the record's parities $b(0) = 0$ and $a(0) = 0$. (d) Solve the Kohn-Sham problem of Chapter 15 with another brane condition and measure how much the levels and energies change.

Where to start. The Kohn-Sham theory record `Revision/kohn_sham/ks-theory.json`, with its keys `geometry` and `boundaryConditions`, and the two verifiers of this record in the folder `Revision/kohn_sham/theory`. For the mirror pairing, the pairing record `Revision/pairing/pairing-theory.json`, the T3 record `t3-theory.json` in the folder `Revision/pairing/kohn_sham`, and section 5.4 of the document `Revision/docs/PAIR_CREATION_PROOFS.md`, which proves T2 with the mirror.

22.16 Problem 5: the dark-sector hypotheses

The question. The author's request contains two hypotheses, quoted from `Revision/README.md`: "Hypothesis: dirac16complex provides a possible physical mechanism for a time-varying dark energy equation of state and/or a possible physical mechanism for a time-varying dark matter equation of state, both of which you will investigate." and "Hypothesis00: dirac16complex00 provides [the same], both of which you will investigate." (the brackets are those of the README, which abridges the repeated sentence). The problem is to investigate them: compute the equation of state that an observer in 3-space would see as the extra times deflate and 3-space inflates, its change in time, and compare it with the observations. An answer is such a computation with its uncertainties, and an honest statement of what each field can and cannot produce.

What is known now. Status: both hypotheses have been INVESTIGATED by the Revision

record, and neither is established. The investigation lives in two folders, `Revision/dark_sector/dirac16complex` (four scripts whose reports hold 30, 5, 13 and 9 checks, all PASS) and `Revision/dark_sector/dirac16complex00` (two independent implementations with 49 and 28 checks, all PASS), and it is written up in the registered document `Revision/docs/DARK_SECTOR_HYPOTHESES.md`. Sections 22.17 to 22.19 teach what the record finds, Notebook 22b (Section 22.20) reproduces its key numbers from the committed outputs, and Section 22.24 lists what remains open. The short answer, every item with the assumption it rests on:

1. The energy density ρ_4 that a 3-space observer assigns to 3-space is not fixed by the field equations; it is an ASSUMPTION, and the record states three definitions, called A, B and C (Section 22.17). Every verdict moves by exactly -1 between A and B on one side and C on the other.

2. dirac16complex, dark matter: a time-varying equation of state that falls from $1/3$ toward 0 (dark-matter-like) is present in the theory for quanta of the massive bulk band, but NOT in the computed Kohn-Sham ground states, whose gas is radiation-like under A and B (Section 22.18).

3. dirac16complex, dark energy: only under C, with w_{eff} between -0.707107 and -0.671895 and a slope of thawing sign far smaller than the observed one; nothing computed comes near the observed pair $(w_0, w_a) = (-0.861, -0.60)$, and no computed state crosses $w = -1$.

4. dirac16complex00, dark matter: a gas of positive-energy modes without extra-time momentum has the dark-matter-like law from $1/3$ to 0 under B (Section 22.19).

5. dirac16complex00, dark energy: only under C; the observed numbers are reproduced only by models whose parameters were CHOSEN to reproduce them, and a crossing of $w = -1$ only with a ghost-like component of negative energy.

6. On the prescribed history $a_4 = AHx_4$ the observer's expansion itself reads $w = -1$ exactly, with no time variation (Section 22.17).

In the words of the record: it "establishes neither Hypothesis nor Hypothesis00". Both remain HYPOTHESES.

The observed numbers. They come from a private document of the author, and the book quotes them only as `Revision/README.md` states them: the parametrisation $w(a) = w_0 + w_a(1 - a)$ (CPL, after Chevallier, Polarski and Linder), the constant-w fit $w = -0.764$, and $(w_0, w_a) = (-0.861, -0.60)$; in this convention thawing means $w_a < 0$. The record calls them the **Unite values**. In that document H is the Hubble rate and a the scale factor of the observed universe; they are not the H and a_4 of the author's metric.

What the CPL numbers say, line by line.

$$w(1) = w_0 + w_a \cdot 0 = w_0 = -0.861.$$

Rule: today the scale factor is $a = 1$, so $1 - a = 0$.

$$w(0) = w_0 + w_a = -0.861 - 0.60 = -1.461.$$

Rule: in the far past $a \to 0$, so $1 - a \to 1$.

$$w_0 + w_a(1-a) = -1 \quad \Longleftrightarrow \quad 1 - a = \frac{-1 - w_0}{w_a} = \frac{-0.139}{-0.60} = 0.231667 \quad \Longleftrightarrow \quad a = 0.768333 = \frac{461}{600}.$$

Rule: subtract w_0 from both sides and divide by w_a; then subtract from 1 ($0.231667 = 139/600$). The record checks this crossing exactly (`Revision/dark_sector/dirac16complex00/reports/python-derive-eos.json`, check `unite_crossing_point`).

So the fitted w falls below -1 for $a < 461/600$. What that requires:

$$w < -1,\ \rho > 0 \quad \Longleftrightarrow \quad p < -\rho \quad \Longleftrightarrow \quad \rho + p < 0.$$

Rule: multiply $w = p/\rho < -1$ by the positive number ρ (the direction of an inequality is kept), then add ρ to both sides.

A fluid of positive energy density with $w < -1$ (called **phantom**) violates the null energy condition. Section 22.19 shows what in this theory can produce such a reading, and at what price.

22.17 The observer's density and the equation of state, line by line

Why an assumption is needed. The observations are made in four dimensions, three of space and one of time; the theory lives in eight. An observer who sees only x_1, x_2, x_3 and the time x_4 must turn the energy of a state, which is spread over all seven other directions, into an energy per unit volume of 3-space. Over the hidden direction x_0 the record averages with the weight $\sqrt{|g|} = \cos z$, which does not depend on x_4 (check `observer_hidden_average_commutes` of `python-derive-eos.json`). Over the three extra times there is no unique choice, because they are time-like: an observer does not move through them as through a space direction. The record therefore states three definitions and decides between none of them.

The proper 7-volume does not change, line by line. The proper length of a step dx along a direction is $\sqrt{|g_{xx}|}\,dx$; the proper volume of a small box is the product of the proper lengths of its sides.

$$\left(e^{a_4} \sin^{1/6} z\right)^3 = e^{3a_4} \sin^{1/2} z.$$

Rule: the three directions x_1, x_2, x_3 each have the factor $e^{a_4} \sin^{1/6} z$; a product of three equal factors is the third power, and $3 \cdot \frac{1}{6} = \frac{1}{2}$. This is the proper 3-volume per unit coordinate volume: it inflates like e^{3a_4}.

$$\left(e^{-a_4} \sin^{1/6} z\right)^3 = e^{-3a_4} \sin^{1/2} z.$$

Rule: the same for the three extra times, whose factor is $e^{-a_4} \sin^{1/6} z$. The proper extra-time volume deflates like e^{-3a_4}.

$$e^{3a_4} \sin^{1/2} z \cdot e^{-3a_4} \sin^{1/2} z \cdot \cot z = \sin z \cot z = \cos z.$$

Rule: multiply by the factor $\sqrt{g_{00}} = \cot z$ of the hidden direction; $e^{3a_4}e^{-3a_4} = e^0 = 1$, $\sin^{1/2} z \sin^{1/2} z = \sin z$, and $\sin z \cdot \cos z / \sin z = \cos z$. The proper 7-volume element of a slice $x_4 =$ const is $\cos z$: the inflation of 3-space is compensated exactly by the deflation of the extra times (`Revision/dark_sector/dirac16complex/reports/derivation-checks.json`, checks `proper_3_and_extra_time_volume_scalings` and `proper_7_volume_element_independent_of_a4`).

The energy balance, line by line. Let E be the energy of a state, the proper 7-volume integral of the energy density ρ, and P_3, P_t, P_0 the integrals of the pressures of 3-space, of the extra times and of the hidden direction. The record re-derives the conservation law $\nabla_\mu T^\mu{}_\nu = 0$ from the author's metric for a diagonal energy-momentum tensor that depends on x_4 and x_0; its x_4 component reads (checks `conservation_x4_identity` and `conservation_x4_author_metric`)

$$\frac{\partial \rho}{\partial x_4} = -3a_4' \, (p_3 - p_t).$$

$$\frac{dE}{dx_4} = \int \cos z \, \frac{\partial \rho}{\partial x_4} = -3a_4' \int \cos z \, (p_3 - p_t) = -3a_4' \, (P_3 - P_t).$$

Rule: integrate over a slice with the weight $\cos z$; because the weight does not depend on x_4, the derivative can be taken outside the integral; a_4' does not depend on the position and comes out of the integral.

$$\frac{dE}{da_4} = \frac{dE/dx_4}{da_4/dx_4} = -3 \, (P_3 - P_t) = -3X, \qquad X = P_3 - P_t.$$

Rule: the chain rule, $dE/dx_4 = (dE/da_4)(da_4/dx_4)$, divided by $a_4' = da_4/dx_4$ (check `integrated_identity_dE_da4`). So the energy of a state changes as 3-space inflates exactly by the difference of the two pressures: positive pressure in 3-space takes energy away, as for a gas in an expanding box, and negative pressure along the extra times does the same.

The three definitions. They differ in how the extra times are counted:

- **(A)** the extra times are compact, with a fixed coordinate period (closed time-like directions): $\rho_4 = E/(\text{proper 3-volume}) \propto E \, e^{-3a_4}$;
- **(B)** the extra times are not compact, and ρ_4 is taken per unit extra-time COORDINATE volume: again $\rho_4 \propto E \, e^{-3a_4}$;
- **(C)** ρ_4 is taken per unit PROPER 7-volume (equivalently per unit proper extra-time volume): $\rho_4 \propto E$.

All three are written as $\rho_4 \propto E \, e^{-3(1-s)a_4}$, with $s = 0$ for A and B and $s = 1$ for C. Status: ASSUMPTION. Which of them, if any, describes a physical observer is OPEN (Section 22.24). The record for dirac16complex00 calls the same two scalings N1 (the scaling of A and B) and N2 (that of C).

The equation of state read from a dilution. For a 4-dimensional observer a fluid with a constant equation of state w thins out as $\rho \propto a^{-3(1+w)}$ (radiation, $w = 1/3$, as a^{-4}; dust, $w = 0$, as

a^{-3}; a cosmological constant, $w=-1$, not at all). Turned around, this defines the equation of state that the observer infers from any dilution:

$$\ln\rho = -3(1+w)\ln a + \text{const} \quad\Longrightarrow\quad \frac{d\ln\rho}{d\ln a} = -3(1+w) \quad\Longrightarrow\quad w = -1 - \frac{1}{3}\frac{d\ln\rho}{d\ln a}.$$

Rule: take the logarithm of $\rho = c\,a^{-3(1+w)}$ (the logarithm of a product is the sum of the logarithms, and $\ln a^n = n\ln a$), differentiate with respect to $\ln a$, then divide by -3 and subtract 1. Applied to ρ_4 it defines $w_{\text{eff}} = -1 - \frac{1}{3}\,d\ln\rho_4/d\ln a$.

The observer identities, line by line. The observer's scale factor is $a = e^{a_4 - a_{4,\text{today}}}$ (normalised to $a=1$ at a chosen today, a free parameter).

$$\ln a = a_4 - a_{4,\text{today}} \quad\Longrightarrow\quad d\ln a = da_4.$$

Rule: the logarithm undoes the exponential; $a_{4,\text{today}}$ is a constant.

$$\ln\rho_4 = \text{const} + \ln E - 3(1-s)a_4.$$

Rule: the logarithm of $c\,E\,e^{-3(1-s)a_4}$.

$$\frac{d\ln\rho_4}{d\ln a} = \frac{1}{E}\frac{dE}{da_4} - 3(1-s) = -\frac{3X}{E} - 3 + 3s.$$

Rule: differentiate with respect to a_4 (which is $\ln a$ up to a constant); $d\ln E/da_4 = (dE/da_4)/E$, and the energy balance $dE/da_4 = -3X$.

$$w_{\text{eff}} = -1 - \frac{1}{3}\Big(-\frac{3X}{E} - 3 + 3s\Big) = -1 + \frac{X}{E} + 1 - s = \frac{X}{E} - s.$$

Rule: insert into the definition of w_{eff} and multiply out.

$$w_{\text{eff}}(A) = w_{\text{eff}}(B) = \frac{X}{E}, \qquad w_{\text{eff}}(C) = \frac{X}{E} - 1.$$

Rule: $s=0$ for A and B, $s=1$ for C. These are exact (checks `w_eff_A_equals_X_over_E`, `w_eff_B_equals_w_eff_A`, `w_eff_C_equals_X_over_E_minus_1` and `w_eff_general_normaliser` of `derivation-checks.json`; for dirac16complex00, `observer_N1_weff_identity` and `observer_N2_weff_identity` of `python-derive-eos.json`). Notebook 22b tests them on the computed Kohn-Sham history (In [3]).

How every verdict depends on the assumption. The same state reads differently under each definition (the rows are records of `Revision/docs/DARK_SECTOR_HYPOTHESES.md`, section 3.2, derived in Sections 22.18 and 22.19):

state	w_{eff} **under A, B**	w_{eff} **under C**	**ratio** p_3/ρ
homogeneous condensate	0, dust-like	-1, cosmological-constant-like	$\lambda S/(2m+\lambda S)$, constant
massless quanta	1/3, radiation	$-2/3$	1/3
massive quanta, flat limit	$1/3 \to 0$	$-2/3 \to -1$	as under A, B
Kohn-Sham gas, $N = 688$, $\lambda = 0$	0.2929 to 0.3183	-0.7071 to -0.6817	0.2929 to 0.3183

The ratio p_3/ρ, the 8-dimensional equation of state, does not depend on the normalisation at all. INTERPRETATION (labelled, as in the record): supernova distances measure the dilution-inferred w_{eff} of a 4-dimensional observer, which agrees with the ratio only when no energy is exchanged with the extra times.

The expansion seen by the observer. An observer who reads the scale factor $a = e^{a_4}$ and the time $t = x_4$ and uses the 4-dimensional Friedmann equations infers $w_{\text{exp}} = -1 - \frac{2}{3}\, a_4''/(a_4')^2$ (check `expansion_inferred_w`). On the history $a_4 = AHx_4$ of the Kohn-Sham record, $a_4' = AH$ is constant and $a_4'' = 0$, so $w_{\text{exp}} = -1$ exactly: the expansion itself has no time-varying equation of state. This is also the only history that a condensate allows as a source: a condensate has $p_3 = p_t$, so the evolution equation $a_4'' F(a_4') = \kappa(p_3 - p_t)$ of Section 22.14 gives $a_4'' F(a_4') = 0$ at every time, and because F is a polynomial in a_4' that is not identically zero this forces $a_4'' = 0$ (the theorem of Chapter 12, key `theoremLinear` of `Revision/field_equations_a4/a4-equations.json`).

When is a reading phantom?

$$w_{\text{eff}}(C) < -1 \quad\Longleftrightarrow\quad \frac{X}{E} - 1 < -1 \quad\Longleftrightarrow\quad \frac{X}{E} < 0.$$

Rule: add 1 to both sides. With $E > 0$ this needs $X < 0$, that is $P_t > P_3$: a pressure along the extra times larger than the pressure of 3-space; otherwise it needs $E < 0$ together with $X > 0$, a state of negative energy. Under A and B the same condition gives $w_{\text{eff}} < 0$ (check `phantom_conditio n`, which verifies the identity $w_{\text{eff}}(C) + 1 = X/E$, not the origin of a negative E). For a single plane-wave mode of real frequency the record proves $X \geq 0$ (check `flat_mode_X_nonnegative`): its 3-space pressure is ≥ 0 and its extra-time pressure ≤ 0, so both make X larger, not smaller.

22.18 dirac16complex: the Kohn-Sham gas, the bulk band, the condensate and the mixtures

The Kohn-Sham history. The record runs the Revision Rust Kohn-Sham solver of Chapter 15 at the 41 slices $a_{4,0} = 0, 0.05, \ldots, 2$ for $N = 8$, 136 and 688 quanta and the five couplings $\lambda = 0, \pm\lambda_1, \pm\lambda_2$: 615 runs, with $H = m = 1$, $L = 3$, the tip angle $\theta = 0$ and temperature $T = 0$ (`Revision/dark_sector/dirac16complex/reports/ks-history-run.json`, 5 checks). It reproduces the 75 committed states of Chapter 15 with relative deviation 0 (check `committe d_slices_reproduced`), and the occupied levels are the same at all 41 slices of every series (check `occupied_labels_fixed_along_history`), so the instantaneous ground states are the adiabatically continued states. The history is a PRESCRIBED BACKGROUND: the gas is a test field without back-reaction (Section 22.14). The record's script `compute_eos.py` evaluates w_{eff} for the three definitions, the tangents, the fits, the condensate and the mixtures (13 checks), and an independent

second computation, `independent_free_gas.py` (Chebyshev collocation, no solver output used except for the final comparison), reproduces the solver's energies over 82 states to 1.897×10^{-12} and $w_{\text{eff}} = X/E$ to 1.492×10^{-12} (9 checks).

The gas is radiation-like. The occupied levels lie on the brane band, which is massless at zero 3-momentum (the brane zero mode, slope $c\,e^{-a_4}$ with $c = 1.9051482536$ at small k; check `brane_band_slope`). So the gas redshifts like radiation: $d\ln E/da_4$ goes from -0.8787 at $a_4 = 0$ to -0.9549 at $a_4 = 2$ for $N = 688$, $\lambda = 0$, toward the radiation value -1. Over all series with $N = 136$ and 688, X/E lies between 0.292893 and 0.328105 and rises monotonically toward 1/3 (checks `gas_radiation_like_band` and `gas_X_over_E_rises_toward_one_third` of `eos-checks.json`; Notebook 22b, In [3] and Figure 22b.1). For $N = 688$, $\lambda = 0$: $w_{\text{eff}}(A) = w_{\text{eff}}(B)$ goes from 0.2929 to 0.3183 and $w_{\text{eff}}(C)$ from -0.7071 to -0.6817. The pressure of the hidden direction gives P_0/E from 0.3535 to 0.6482: a pressure, but not one that the 3-space observer sees as pressure.

The CPL tangents of the gas. With $a = e^{a_4 - a_{4,\text{today}}}$, $da = a\,da_4$, so at $a = 1$ the slope dw/da equals dw/da_4 and the tangent is $w_0 = w_{\text{eff}}$ at $a_{4,\text{today}}$, $w_a = -dw_{\text{eff}}/da_4$ there. For $N = 688$, $\lambda = 0$ (`Revision/dark_sector/dirac16complex/outputs/eos-summary.json`; Notebook 22b, Out [4]):

$a_{4,\text{today}}$	**0.5**	**1**	**1.5**	**2**
w_0 under C	-0.7037	-0.6982	-0.6907	-0.6817
w_a (every definition)	-0.00905	-0.01292	-0.01701	-0.01775

(w_0 under A and B is the value under C plus 1; w_a is the same in every definition, because the definitions differ by the constant s.) Over all series with $N = 136$ and 688 the tangent w_a lies between -0.020523 and -0.008894, the least-squares fits give w_a between -0.030371 and -0.018132, and $w_{\text{eff}}(C)$ lies between -0.707107 and -0.671895 (check `gas_cpl_thawing_sign_small`). The sign is that of thawing; the size is smaller than the observed 0.60 by a factor of about 20 or more. For $N = 8$ with $\lambda \neq 0$ only the brane zero modes are occupied: E is constant and $P_3 = P_t$, so $w_{\text{eff}}(A) = 0$ and $w_{\text{eff}}(C) = -1$, constant, with $E < 0$ for $\lambda > 0$ (check `n8_interacting_zero_modes_constant`); for $N = 8$ with $\lambda = 0$, $E = 0$ and there is no equation of state. The negative E at $\lambda > 0$ comes from the interaction energy of the record's functional, Hartree plus the uniform-gas exchange of Chapter 13: with the exact Fock exchange in its place, solved self-consistently (the exact-Fock variant of the Kohn-Sham record, `Revision/kohn_sham/results/exx/exact-fock-variant.csv`), the same $N = 8$ states have $|E| \leq 2.04 \times 10^{-13}$. So this negative E is a property of the approximate functional, and good-sector states with $E < 0$ are not established beyond it (`Revision/docs/DARK_SECTOR_HYPOTHESES.md`, section 4.7).

The dark-matter-like law, line by line. In the flat limit (no warp) a quantum of mass M and fixed coordinate momentum k has the physical momentum k/a and the energy $\omega = \sqrt{M^2 + k^2/a^2}$, with $a = e^{a_4}$. With the number of quanta fixed, $E \propto \omega$, and the energy balance gives $X/E = -\frac{1}{3}\,d\ln E/da_4$.

$$\ln \omega = \tfrac{1}{2} \ln \left(M^2 + k^2 e^{-2a_4}\right).$$

Rule: $\ln \sqrt{x} = \frac{1}{2} \ln x$, and $1/a^2 = e^{-2a_4}$.

$$\frac{d\ln\omega}{da_4} = \frac{1}{2}\cdot\frac{-2k^2e^{-2a_4}}{M^2+k^2e^{-2a_4}} = -\frac{k^2}{M^2a^2+k^2}.$$

Rule: the chain rule, $d\ln f/da_4 = f'/f$, with $d(e^{-2a_4})/da_4 = -2e^{-2a_4}$; then multiply numerator and denominator by $a^2 = e^{2a_4}$.

$$w_{\text{eff}}(A) = \frac{X}{E} = \frac{k^2}{3\,(M^2a^2+k^2)}.$$

Rule: multiply by $-\frac{1}{3}$. For $a \to 0$ the momentum term dominates and $w_{\text{eff}} \to 1/3$ (radiation); for $a \to \infty$ the mass dominates and $w_{\text{eff}} \to 0$ (dust): a time-varying, dark-matter-like equation of state (check `massive_mode_w_eff_law`; for $M = 0$ it is $1/3$ at every time, check `massless_mode_w_eff`). In the author's metric the record finds this law for the massive **bulk band** (odd brane parity; its edge at zero momentum is $\varepsilon(0) = 1.292292828069$): the lowest odd-parity level of the shell $n_2 = 1$ has $w_{\text{eff}}(A)$ falling monotonically from 0.239626 at $a_4 = -3$ to 2.268×10^{-3} at $a_4 = 4$, while the brane-band level of the same shell stays between 0.291594 and 0.333275, tending to $1/3$ (`Revision/dark_sector/dirac16complex/reports/independent-checks.json`, checks `bulk_band_dark_matter_law` and `brane_band_radiation_law`; Notebook 22b, In [5] and Figure 22b.2). At late times the bulk level falls like $1/a$ rather than like $1/a^2$: the ratio $w(4)/w(3.75) = 0.765177$ is close to $e^{-0.25} = 0.778801$, which the record reads as a term of $\varepsilon(k)$ linear in small k. The computed ground states ($N \le 688$, $T = 0$) are filled below the bulk edge and do not populate the bulk band. COMPUTED; that such quanta are present in the universe is not established.

The condensate, line by line. A homogeneous condensate is an exact solution of both fields, with $S = \bar{\Psi}\Psi$ constant (Chapter 9), and

$$\rho = mS + \tfrac{\lambda}{2}S^2, \qquad p_3 = p_t = p_0 = \tfrac{\lambda}{2}S^2$$

(checks `condensate_rho_p` and `condensate_satisfies_both_identities` of `derivation-checks.json`).

$$X = P_3 - P_t = 0 \quad\Longrightarrow\quad w_{\text{eff}}(A) = w_{\text{eff}}(B) = 0, \qquad w_{\text{eff}}(C) = -1.$$

Rule: equal pressures give $X = 0$; insert into the observer identities. The condensate is dust-like under A and B and cosmological-constant-like under C, constant in time in both (check `condensate_w_eff`).

$$\frac{p}{\rho} = \frac{\frac{\lambda}{2}S^2}{mS+\frac{\lambda}{2}S^2} = \frac{\lambda S/m}{2+\lambda S/m} = \frac{u}{2+u}, \qquad u = \frac{\lambda S}{m}.$$

Rule: divide numerator and denominator by $mS/2$. The ratio is constant (check `condensate_ratio_w`).

$$\frac{u}{2+u} = -0.764 \implies u = -0.764\,(2+u) \implies 1.764\,u = -1.528,$$

$$u = -\frac{1.528}{1.764} = -\frac{382}{441} = -0.866213151927.$$

Rule: multiply by $2+u$, bring $-0.764u$ to the left, divide by 1.764; 1528/1764 reduces by 4 to 382/441. Then $\rho/(mS) = 1 + u/2 = 250/441 = 0.566893424036$, so $\rho > 0$ exactly when $mS > 0$ (check `condensate_ratio_equal_unite_constant_w`; Notebook 22b, In [6]). This value of u is CHOSEN to give -0.764: one parameter tuned to one number, and it is the 8-dimensional ratio, not the observer's w_{eff}, which is 0 or -1.

$$\frac{u}{2+u} < -1 \quad \Longleftrightarrow \quad -2 < u < -1.$$

Rule: if $2+u > 0$, multiply by it: $u < -2-u$, so $u < -1$, and with $u > -2$ the window $-2 < u < -1$; if $2+u < 0$, multiplying reverses the inequality: $u > -2-u$, so $u > -1$, which contradicts $u < -2$. The ratio is phantom exactly in this window (`python-derive-eos.json`, check `condensate_phantom_interval`; Figure 22b.3), and the CHOSEN $u = -0.866$ lies outside it.

Mixtures with a condensate, line by line. Take a radiation-like gas, $X_g = E_g/3$, so that $dE_g/da_4 = -E_g$ and $E_g \propto e^{-a_4} \propto 1/a$, and add a condensate with $X_c = 0$ and E_c constant. Let $r = E_g/E_c = r_0/a$, with r_0 its value today.

$$w_{\text{eff}}(A) = \frac{X_g + X_c}{E_g + E_c} = \frac{E_g/3}{E_g + E_c} = \frac{1}{3}\,\frac{r}{1+r}.$$

Rule: the observer identity for the whole mixture; divide numerator and denominator by E_c.

$$\frac{dw}{da} = \frac{1}{3}\,\frac{1}{(1+r)^2}\,\frac{dr}{da} = -\frac{1}{3}\,\frac{r_0}{a^2(1+r)^2} \quad \Longrightarrow \quad w_0 = \frac{r_0}{3(1+r_0)}, \qquad w_a = \frac{r_0}{3(1+r_0)^2} > 0.$$

Rule: the quotient rule gives $d(r/(1+r))/dr = 1/(1+r)^2$, and $dr/da = -r_0/a^2$; at $a = 1$, $r = r_0$, and $w_a = -dw/da$. The mixture is **freezing**: as the gas redshifts, w moves toward the condensate's value (check `mixture_radiation_condensate_cpl`). The same holds under C, with w_0 lowered by 1.

$$\frac{r_0}{3(1+r_0)} - 1 = -0.861 \implies r_0 = 0.417\,(1+r_0) \implies r_0 = \frac{417}{583} = 0.715266,$$

$$w_a = \frac{r_0}{3(1+r_0)^2} = \frac{0.139}{1+r_0} = 0.081037.$$

Rule: add 1 and multiply by 3 ($3 \cdot 0.139 = 0.417$); collect r_0; for w_a use $r_0/(3(1+r_0)) = 0.139$, and $0.139 \cdot 583/1000 = 0.081037$. So r_0 is CHOSEN for $w_0 = -0.861$, and the slope then has the wrong sign: $+0.081037$, not -0.60 (check `mixture_C_matching_w0_unite`). With the computed gas $N = 688$, $\lambda = 0$ and today at $a_{4,\text{today}} = 2$, under C (`eos-checks.json`; Notebook 22b, In [7] and Figure 22b.4):

- the gas share 0.436703 is CHOSEN so that $w_{\text{eff}}(C) = -0.861$ today; then $w_a = 0.067014 > 0$, freezing (check `mixture_C_w0_unite_has_positive_wa`);

- the gas share 0.6807148417136 is CHOSEN so that the constant-w proxy over $1/3 \le a \le 1$ equals -0.764; the CPL fit of that mixture is $(w_0, w_a) = (-0.7841, 0.0603)$, opposite in the sign of w_a to the observed fit (check `mixture_C_constant_w_unite_reachable_only_with_freezing_cpl`);
- in the ratio definition, with a condensate of any constant ratio between -3 and 1, any gas share and $a_{4,\text{today}} \in \{0.5, 1, 1.5, 2\}$, no mixture comes closer to the observed pair than 0.600001 (check `ratio_mixture_scan_cannot_reach_unite_wa`).

Phantom and the crossing of -1. No computed state of dirac16complex crosses $w = -1$: every computed state with $E \neq 0$ has $X \ge 0$, and all of them have $E > 0$ except the $N = 8$, $\lambda > 0$ states, which have $E < 0$ (from the uniform-gas exchange functional; with the exact Fock exchange $|E| \le 2.04 \times 10^{-13}$, as stated above) and $X = 0$ exactly; the 41 $N = 8$, $\lambda = 0$ states have $E = 0$ and no equation of state (`Revision/docs/DARK_SECTOR_HYPOTHESES.md`, section 5.5). Modes of dirac16complex with extra-time momentum lie outside the good sector and are OPEN.

22.19 dirac16complex00: modes of both energy signs, the populations and the models M1 to M5

Modes and their energies. dirac16complex00 is a classical field of 16 commuting complex components. A plane wave $\Phi = u\, e^{i(kx_1 + qx_5 - \omega x_4)}$ with 3-momentum k and extra-time momentum q (physical momenta in a frozen local frame) obeys $\omega u = hu$ with $h^2 = (m^2 + k^2 - q^2)\, I_{16}$, so

$$\omega^2 = m^2 + k^2 - q^2$$

(check `mode_dispersion_h_squared`): the extra times are time-like, and q enters with the opposite sign to k. The charge density is the Krein form $Q = \Phi^\dagger B \Phi$ of Chapter 10, conserved by the frozen-frame evolution (check `mode_generator_B_selfadjoint`); in the field theory the U(1) charge obeys a PROVED local conservation law, and its total is constant only under the ASSUMED no-flux condition at $z = \pi/2$ (Section 22.25). For the three test cases $(m, k, q) = (3, 4, 0)$, $(5, 0, 3)$ and $(4, 4, 4)$, with $\omega = \pm 5, \pm 4, \pm 4$, every real-frequency eigenspace has dimension 8 and a Krein form of signature (4,4), and on it $\rho = \omega Q$ exactly (checks `mode_krein_inertia_*` and `mode_emt_*`; the second implementation finds $\rho = +1.25$ and -1.25 at $\omega = 1.25$ for $Q = +1$ and -1, check `B_krein_signed_energy`). The three test cases are illustrations, not a proof of a general statement. The general statement is Theorem 10.1 of Chapter 10, the one-particle Krein-inertia theorem of the pairing record, which holds for the plane waves of flat 4+4 space and of the frozen local frame used here (PROVED: `Revision/pairing/reports/wolfram-pairing.json`, check `Q_one_particle_Krein_inertia_real_frequencies`; `Revision/pairing/reports/python-pairing.json`, check `Q.one_particle_Krein_inertia_proof`): at EVERY real frequency each eigenspace has dimension 8 and a Krein form of signature (4,4), so it holds waves with $Q > 0$ and waves with $Q < 0$. With $\rho = \omega Q$, the energy of a single wave, which the record checks exactly on the three test cases, the two signs of Q are two signs of the energy. So at every real frequency there are modes of BOTH energy signs: the classical energy of this field is unbounded below. A component of negative classical energy is called **ghost-like**; it is not an established physical state.

Growing modes. For $q^2 > m^2 + k^2$ the frequency is imaginary and the mode grows (Chapter 8). In the deflating field the physical extra-time momentum is qa, which grows with a, so every mode

with $q \neq 0$ reaches a **turning point** $a_{\rm turn}$, where $\omega = 0$, and grows after it: the deflation drives the growth. The field-equation implementation B measures, past the turning point $a_{\rm turn} = 1.8433886$, the growth rate 0.54337468 against the adiabatic estimate 0.55114035 (check `B_growth_rate`).

The adiabatic gas, line by line. In the deflating local model (the warp frozen at one hidden position: an APPROXIMATION) a mode has $\omega^2 = m^2 + k^2/a^2 - q^2a^2$, its Krein charge is an adiabatic invariant, and its energy density is $\rho_i = \omega_i Q_i \propto \omega_i$. Under B the observer identity gives $w_{\rm eff}(B) = -\frac{1}{3}\, d\ln\rho_i/d\ln a = -\frac{1}{3}\, d\ln\omega_i/d\ln a$.

$$\ln\omega = \tfrac{1}{2}\ln\left(m^2 + k^2a^{-2} - q^2a^2\right), \qquad \frac{d\ln\omega}{d\ln a} = \frac{-k^2a^{-2} - q^2a^2}{\omega^2}.$$

Rule: as in Section 22.18, with $d(a^{-2})/d\ln a = -2a^{-2}$ and $d(a^2)/d\ln a = 2a^2$; the factor $\frac{1}{2}$ cancels the factors 2.

$$\varepsilon_i = w_{\rm eff}(B)_i = \frac{k^2/a^2 + q^2a^2}{3\,\omega_i^2} \;\geq\; 0.$$

Rule: multiply by $-\frac{1}{3}$; both terms of the numerator are ≥ 0, and $\omega^2 > 0$ for a real frequency. The extra-time momentum RAISES ε: its pressure is negative, which increases X (checks `wkb_mode_gas_conservation`, `wkb_epsilon_sign_free`). For a mixture of components (check `mixture_weighted_average`):

$$w_{\rm eff}(B) = \frac{\sum_i \varepsilon_i\rho_i}{\sum_i \rho_i}, \qquad w_{\rm eff}(C) = \frac{\sum_i \varepsilon_i\rho_i}{\sum_i \rho_i} - 1.$$

No crossing without a ghost. If every $\rho_i \geq 0$, the first fraction is an average of numbers $\varepsilon_i \geq 0$ with weights $\rho_i \geq 0$, so it is ≥ 0: $w_{\rm eff}(B) \geq 0$ and $w_{\rm eff}(C) \geq -1$ at every a at which every component has a real frequency. A mode with $q \neq 0$ loses its real frequency past its turning point $a_{\rm turn}$, where the theorem does not apply. A crossing of -1 needs the numerator to change sign, that is a component with $\rho_i < 0$: negative classical energy, a ghost-like component. PROVED within the adiabatic model (`Revision/dark_sector/dirac16complex00/eos-theory.json`, key `wkb.theorem`). The only phantom value without negative energy is the constant ratio of a condensate with $-2 < u < -1$ (Section 22.18), which is not the observer's $w_{\rm eff}$.

The models. Each model is normalised to total energy density 1 at $a = 1$ and read under C unless stated. The parameters marked CHOSEN were fixed so that the model reproduces an observed number; that number is then an input, NOT an output (`eos-theory.json`, key `models`):

model	content	CHOSEN parameters
M1	condensate, an exact solution	$u = \lambda S/m$; the ratio is -0.764 at $u = -382/441$ (CHOSEN)
M2	positive-energy gas with $q = 0$	$k^2/(k^2+m^2) = 417/1000$ at $a = 1$, CHOSEN for $w_0 = -0.861$
M3	one positive-energy extra-time mode, $k = 0$	$s = q^2/m^2 = 417/1417$, CHOSEN for $w_0 = -0.861$

model	content	CHOSEN parameters
M4	condensate plus a positive extra-time mode	$s = 264037/403037$ and the mode share $\Omega_q = 57963/264037$, both CHOSEN so that the tangent is $(-0.861, -0.60)$
M5	as M4 plus a GHOST-LIKE part: massless modes of negative energy $-G/a$	$G = 3/10$ (a stated choice); s and Ω_q CHOSEN so that the fit over $1/2 \le a \le 1$ is $(-0.861, -0.60)$

M2 line by line, with $r = k^2/m^2$ and $q = 0$: $\varepsilon = (r/a^2)/(3(1+r/a^2)) = r/(3(r+a^2))$; at $a = 1$ this is $\frac{1}{3}\, r/(1+r) = \frac{1}{3}\, k^2/(k^2+m^2)$, and setting it to 0.139 (so that $w_{\text{eff}}(C) = -0.861$) gives $k^2/(k^2+m^2) = 0.417$. Its derivative is $dw/da = -\frac{2}{3}\, ra/(r+a^2)^2$, so $w_a = \frac{2}{3}\, r/(1+r)^2 = \frac{2}{3} \cdot 0.417 \cdot 0.583 = 0.162074$ (using $r/(1+r) = 0.417$ and $1/(1+r) = 0.583$): freezing (check `M2_tangent_exact`). Under B the same model has $w_{\text{eff}} = \frac{1}{3}\, k^2/(k^2+m^2a^2)$, from 1/3 to 0: the dark-matter-like law of dirac16complex00. M3 with $k = 0$: $w_{\text{eff}}(C) = -1 + \frac{1}{3}\, sa^2/(1-sa^2)$, which is ≥ -1 for $a < a_{\text{turn}}$, where $1 - sa^2 > 0$; at $a = 1$, $s/(1-s) = 0.417$ gives $s = 417/1417$, and $w_a = -\frac{2}{3}\, s/(1-s)^2 = -0.393926$: thawing; the turning point is at $a_{\text{turn}} = 1/\sqrt{s} = 1.8434$ (check `M3_tangent_exact`). Past it the frequency of the mode is imaginary, the mode grows (check `B_growth_rate`), and its energy density becomes large and negative (implementation B: $\rho/Q = -2.9228317 \times 10^{61}$ at $a = 2.2$, `Revision/dark_sector/dirac16complex00/results/independent-numerics.json`), so the bound $w_{\text{eff}}(C) \ge -1$ does not extend past a_{turn}.

The resulting CPL numbers under C (tangent; least-squares fit over $1/2 \le a \le 1$; the constant-w proxy, the mean of $w(a)$ over that range; records `M2_tangent_exact` to `M5_without_ghost_no_crossing` of `python-derive-eos.json`; Notebook 22b, In [8] and Figure 22b.5):

model	tangent w_0	tangent w_a	fit w_0	fit w_a	proxy	crosses -1 on $1/3 \le a \le 1$?
M1	-1	0	-1	0	-1	no
M2	-0.861	$+0.162074$	-0.8655	0.2173	-0.8112	no
M3	-0.861	-0.393926	-0.8734	-0.2196	-0.9283	no
M4	-0.861	-0.600	-0.8832	-0.2203	-0.9383	no
M5	-0.8396	-1.0399	-0.861	-0.600	-1.011	at $a = 0.7791$

The last column is the record's search for a crossing on $1/3 \le a \le 1$; it says nothing about $a > 1$. Past the turning point a_{turn} of an extra-time mode (M3: 1.8434, M4: 1.2355, M5: 1.3271) the frequency of that mode is imaginary and the theorem above does not apply.

- M4: $s = 0.6551$, $\Omega_q = 0.2195$. Its w does not cross -1 on $1/300 \le a \le 1$: the smallest $w_{\text{eff}}(C)$ over $a = 1/300, \ldots, 1$ is -0.999999214228 (check `M4_never_phantom`); by the theorem above, $w_{\text{eff}}(C) \ge -1$ holds up to the turning point of its extra-time mode. The phantom past $w_0 + w_a = -1.461$ belongs to the straight CPL line, not to the model. Its extra-time mode reaches its turning point at $a_{\text{turn}} = 1.2355$ and then grows without bound; past a_{turn}

its frequency is imaginary, the theorem above does not apply, and $w \geq -1$ is not established there. Under B or in the ratio, M4 is not dark energy ($w \geq 0$).

- M5: $s = 0.5678$, $\Omega_q = 0.5947$, condensate share 0.7053; its w crosses -1 at $a = 0.7791$ (the observed line at 0.7683), and without its ghost-like part it does not cross on $1/3 \leq a \leq 1$, nor, by the theorem above, before the turning point $a_{\text{turn}} = 1.3271$ of its extra-time mode; past that point this is not established (checks `M5_crosses_minus_1`, `M5_without_ghost_no_crossing`). INTERPRETATION, as in the record: because s and Ω_q were chosen so that the fit equals the observed line, a crossing close to the line's crossing is expected and is not an independent agreement.
- Implementation B rebuilds M2 to M5 from solutions of the full 16-component field equation with the author's gammas and agrees with A to within 0.00083082726 in every tangent, fit and proxy; it finds the M5 crossing at $a = 0.77905405$ (check `B_vs_A_M5_crossing` of `python-independent-numerics.json`).

The constant-w proxy is not the supernova fit. Applied to the observed CPL line itself, the mean of $w(a)$ is -1.011 over $1/2 \leq a \leq 1$ and -1.061 over $1/3 \leq a \leq 1$ (check `unite_line_fit_proxy`), not -0.764: the supernova constant-w fit weights the data, which no part of the record computes.

The comparison with the observed values. Every match is labelled with the number of parameters CHOSEN for it:

observed value	**dirac16complex**	**dirac16complex00**	**by construction?**
constant $w = -0.764$	condensate ratio at $u = -382/441$; mixture under C with gas share 0.6807 (proxy; slope $+0.0603$)	condensate ratio at $u = -382/441$, $\lambda < 0$	yes: one parameter for one number
$w_0 = -0.861$	mixture under C with gas share 0.436703: $w_a = 0.067014$, freezing	M2 ($w_a = +0.162074$), M3 ($w_a = -0.393926$)	yes: one parameter for one number
$(w_0, w_a) = (-0.861, -0.60)$	not reached: gas $\lvert w_a \rvert \leq 0.030371$; ratio mixtures never closer than 0.600001	M4 tangent exactly; M5 fit exactly	yes: two parameters for two numbers
crossing of -1 at $a = 0.7683$	no crossing in any computed state	only M5, with a ghost-like part: $a = 0.7791$	the fit by construction; the ghost share a stated choice

A model with as many tuned parameters as matched numbers reproduces them by construction and is NOT a prediction. Nothing in the record selects the populations of M2 to M5, the mixture shares or the condensate's u. What is NOT tuned are the signs and the ranges: for positive-energy content of real frequency $w_{\text{eff}}(C) \geq -1$ in the adiabatic model (for an extra-time mode only before its turning point); every computed state of dirac16complex has $X \geq 0$; the computed gas has the

thawing sign with $|w_a| \leq 0.030371$; gas-condensate mixtures are freezing; M4, tuned to the observed tangent, does not cross -1 before its turning point $a_{\text{turn}} = 1.2355$ (checked on $1/300 \leq a \leq 1$).

22.20 Example: the dark-sector numbers, reproduced from the record (Notebook 22b)

Notebook 22b reads the committed outputs of the dark-sector record: the table `Revision/dark_sector/dirac16complex/outputs/eos-history.csv` (energy, pressures and dw_{eff}/da_4 of the 14 Kohn-Sham series with nonzero energy, 41 slices each), the summary `eos-summary.json` and the independent free-gas output `independent-free-gas.json` in the same folder, and the model record `Revision/dark_sector/dirac16complex00/eos-theory.json` with the field-equation results `results/independent-numerics.json` of the same folder; and it checks that every check of the six check reports of the dark-sector record is PASS (the four of `Revision/dark_sector/dirac16complex`, among them the report `ks-history-run.json` of the 615 runs of the Kohn-Sham solver, and the two of `Revision/dark_sector/dirac16complex00`). It then tests the energy balance and the observer identities of Section 22.17 on the computed history, reproduces the band and the tangents of the gas, the bulk and brane bands, the condensate ratio and its phantom window, the mixture laws, and the models M2 to M5 with their crossings, each number asserted against its record file and check, and draws five figures. It needs only numpy and matplotlib, takes a few seconds (the build and check runs of 2026-10-08 recorded in its provenance file took 7.5 and 7.4 seconds; on a computer busy with other work it takes longer) and ends with the line ALL 28 CHECKS PASSED (notebook 22b).

22.21 How to run Notebook 22b

Step 1. What this notebook does and what it needs.

Notebook 22b (The dark-sector hypotheses: what the Revision record finds) is the file `Revision/textbook/notebooks/22b_dark_sector.ipynb` of the repository Dirac_claude. It reads the committed outputs and reports of the Revision dark-sector record for dirac16complex and dirac16complex00 and reproduces their key numbers: the observer identities w_eff(A) = w_eff(B) = X/E and w_eff(C) = X/E - 1 on the Kohn-Sham history, the radiation-like band of the Kohn-Sham gas and its CPL tangents, the dark-matter-like law of the massive bulk band, the condensate ratio, the gas and condensate mixtures, and the models M2 to M5 of dirac16complex00 against the Unite CPL values, every tuned parameter labelled CHOSEN. Every reproduced number is checked against its record file and check, and five teaching figures are drawn. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at

a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are

those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 22b_dark_sector.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 22b_dark_sector.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 22b_dark_sector.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/22b.captions.json`

- `Revision/textbook/figures/22b_1_gas_three_definitions.png`
- `Revision/textbook/figures/22b_2_bulk_and_brane_bands.png`
- `Revision/textbook/figures/22b_3_condensate_ratio.png`
- `Revision/textbook/figures/22b_4_mixtures_against_unite.png`
- `Revision/textbook/figures/22b_5_models_against_unite.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 28 CHECKS PASSED (notebook 22b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/22b_dark_sector.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 22b_dark_sector.ipynb
python -m nbconvert --execute --inplace 22b_dark_sector.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

22.22 Notebook 22b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/22b_dark_sector.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The author asked that two hypotheses be investigated: that dirac16complex
(Hypothesis) and dirac16complex00 (Hypothesis00) provide a possible physical
mechanism for a time-varying dark-energy and/or dark-matter equation of state. The
Revision record has investigated them, in the folders
‘Revision/dark_sector/dirac16complex‘ and ‘Revision/dark_sector/dirac16complex00‘.
This notebook reads the committed outputs and reports of that record and reproduces
its key numbers, each one checked against its record file and check:

- the observer identities $w_{\rm eff}(A) = w_{\rm eff}(B) = X/E$ and
  $w_{\rm eff}(C) = X/E - 1$, tested on the computed Kohn-Sham history, together
  with the energy balance $dE/da_4 = -3X$;
- the Kohn-Sham gas of dirac16complex: radiation-like, $X/E$ rising toward $1/3$,
  and its CPL tangents (small, thawing sign);
- the massive bulk band, which shows the dark-matter-like fall from about $1/3$
  toward 0, and the brane band, which does not;
- the condensate: its constant ratio $p/\rho = u/(2 + u)$ with $u = \lambda S/m$, and
```

```
  the value of $u$ CHOSEN to give the Unite constant $w = -0.764$;
- mixtures of the gas with a condensate: freezing, never the Unite slope;
- the models M2 to M5 of dirac16complex00: their tangents and fits against the
  Unite CPL line, every tuned parameter labelled CHOSEN, and the crossing of
  $w = -1$, which happens only with a ghost-like component.

It draws five figures and needs no Rust. Units: $H = m = 1$, as in the record.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 22b (The dark-sector hypotheses: what the Revision record finds) is the file
‘Revision/textbook/notebooks/22b_dark_sector.ipynb‘ of the repository Dirac_claude. It
reads the committed outputs and reports of the Revision dark-sector record for
dirac16complex and dirac16complex00 and reproduces their key numbers: the observer
identities w_eff(A) = w_eff(B) = X/E and w_eff(C) = X/E - 1 on the Kohn-Sham history, the
radiation-like band of the Kohn-Sham gas and its CPL tangents, the dark-matter-like law
of the massive bulk band, the condensate ratio, the gas and condensate mixtures, and the
models M2 to M5 of dirac16complex00 against the Unite CPL values, every tuned parameter
labelled CHOSEN. Every reproduced number is checked against its record file and check,
and five teaching figures are drawn. It needs a computer with Windows 11, macOS or Linux,
an internet connection for the installation, the program Git, and Python 3.12 or newer
(the notebooks were built with Python 3.14.5) with these packages at exactly these
versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10,
nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook
itself imports numpy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:
```

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in

this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 22b_dark_sector.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the

address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 22b_dark_sector.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 22b_dark_sector.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/22b.captions.json‘
- ‘Revision/textbook/figures/22b_1_gas_three_definitions.png‘
- ‘Revision/textbook/figures/22b_2_bulk_and_brane_bands.png‘
- ‘Revision/textbook/figures/22b_3_condensate_ratio.png‘
- ‘Revision/textbook/figures/22b_4_mixtures_against_unite.png‘
- ‘Revision/textbook/figures/22b_5_models_against_unite.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 28 CHECKS PASSED (notebook 22b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/22b_dark_sector.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 22b_dark_sector.ipynb
      python -m nbconvert --execute --inplace 22b_dark_sector.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 22b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
```

```
#
# Notebook 22b (The dark-sector hypotheses: what the Revision record finds) is the file
# Revision/textbook/notebooks/22b_dark_sector.ipynb of the repository Dirac_claude. It
# reads the committed outputs and reports of the Revision dark-sector record for
# dirac16complex and dirac16complex00 and reproduces their key numbers: the observer
# identities w_eff(A) = w_eff(B) = X/E and w_eff(C) = X/E - 1 on the Kohn-Sham history,
# the radiation-like band of the Kohn-Sham gas and its CPL tangents, the dark-matter-like
# law of the massive bulk band, the condensate ratio, the gas and condensate mixtures,
# and the models M2 to M5 of dirac16complex00 against the Unite CPL values, every tuned
# parameter labelled CHOSEN. Every reproduced number is checked against its record file
# and check, and five teaching figures are drawn. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
```

```
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 22b_dark_sector.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 22b_dark_sector.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 22b_dark_sector.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
```

```
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/22b.captions.json
# - Revision/textbook/figures/22b_1_gas_three_definitions.png
# - Revision/textbook/figures/22b_2_bulk_and_brane_bands.png
# - Revision/textbook/figures/22b_3_condensate_ratio.png
# - Revision/textbook/figures/22b_4_mixtures_against_unite.png
# - Revision/textbook/figures/22b_5_models_against_unite.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 28 CHECKS PASSED (notebook 22b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/22b_dark_sector.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
```

```
#     python -m jupyterlab 22b_dark_sector.ipynb
#     python -m nbconvert --execute --inplace 22b_dark_sector.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#

## 3. The words used in this notebook

- **Equation of state** $w$: a pressure divided by an energy density. **Observer**:
  someone who, like us, measures only the three space directions $x_1, x_2, x_3$
  and the time $x_4$.
- **$\rho_4$**: the energy density that this observer assigns to 3-space. It is NOT
  fixed by the field equations; the record states three definitions: (A) the extra
  times are closed with a fixed coordinate period, $\rho_4 \propto E e^{-3a_4}$;
  (B) $\rho_4$ per unit extra-time coordinate volume, $\rho_4 \propto E e^{-3a_4}$;
  (C) $\rho_4$ per unit proper 7-volume, $\rho_4 \propto E$. This is an
  ASSUMPTION about the observer.
- **$E, P_3, P_t$**: the energy and the integrated pressures of 3-space and of the
  extra times of one state; **$X = P_3 - P_t$**.
- **$w_{\rm eff}$**: the equation of state the observer infers from how fast
  $\rho_4$ thins out, $w_{\rm eff} = -1 - \frac{1}{3}\,d\ln\rho_4/d\ln a$, with the
  observer's scale factor $a = e^{a_4 - a_{4,\rm today}}$.
- **Radiation-like**: $w_{\rm eff} = 1/3$; **dust-like** (dark-matter-like):
  $w_{\rm eff} = 0$; **cosmological-constant-like**: $w = -1$; **phantom**:
  $w < -1$.
- **CPL**: $w(a) = w_0 + w_a(1 - a)$. **Tangent**: $w_0 = w(1)$ and
```

```
  $w_a = -dw/da$ at $a = 1$. **Fit**: the least-squares straight line in $1 - a$
  over a range of $a$. **Thawing**: $w_a < 0$; **freezing**: $w_a > 0$.
- **Unite values**: the supernova fits quoted by the record, $w = -0.764$ (constant
  $w$) and $(w_0, w_a) = (-0.861, -0.60)$.
- **CHOSEN**: a parameter fixed so that a model reproduces a Unite number; that
  number is then an input, NOT a prediction.
- **Ghost-like component**: a component of negative classical energy.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's metric has the 3-space scale factor $e^{a_4}\sin^{1/6}z$ and the
extra-time scale factor $e^{-a_4}\sin^{1/6}z$: as $a_4$ grows, 3-space inflates and
the three extra times $x_5, x_6, x_7$ deflate exponentially. The proper 7-volume
element is $\cos z$, independent of $a_4$, and for a homogeneous source the
conservation law gives exactly (record `derivation-checks.json`)
$$\frac{dE}{da_4} = -3X, \qquad X = P_3 - P_t .$$
With $\rho_4 \propto E e^{-3(1-s)a_4}$ ($s = 0$ for A and B, $s = 1$ for C) and
$d\ln a = da_4$:
$$w_{\rm eff} = -1 - \frac{1}{3}\left(\frac{1}{E}\frac{dE}{da_4} - 3(1 - s)\right)
= -1 + \frac{X}{E} + 1 - s = \frac{X}{E} - s .$$
The Kohn-Sham states are instantaneous ground states along the PRESCRIBED
BACKGROUND $a_4 = AHx_4$ (a test field without back-reaction), with the ASSUMED Z2
brane. The models of dirac16complex00 are adiabatic (WKB) gases of plane-wave modes,
an APPROXIMATION that the record measures with a second implementation.
```

Text cell:

```
## 5. The records

The next cell loads the modules, reads the six check reports of the dark-sector
record and checks that every one of their checks is PASS, then reads the table of
the Kohn-Sham history and the four output files whose numbers the later cells
reproduce.

## 6. The observer's equation of state on the Kohn-Sham gas

The next cell tests the energy balance $dE/da_4 = -3X$ on the computed history
(fourth-order differences of $E$ against $X$ from the solver's integrals), then
computes $w_{\rm eff}$ directly from its definition, by differentiating
$\ln\rho_4$ for the definitions A, B and C, and compares with $X/E$ and $X/E - 1$.
It checks the band of $X/E$ over all gas series and that $X/E$ rises with $a_4$,
and draws the histories (Figure 1).
```

## 9. The condensate

A homogeneous condensate is an exact solution of both fields, with
$\rho = mS + \lambda S^2/2$ and $p_3 = p_t = p_0 = \lambda S^2/2$, all constant.
So $X = 0$: $w_{\rm eff} = 0$ under A and B (dust-like), $-1$ under C. Its ratio is
$p/\rho = u/(2 + u)$ with $u = \lambda S/m$. The next cell computes, with exact
fractions, the value $u = -382/441$ that the record CHOSE so that the ratio equals
$-0.764$, checks the phantom window, and draws the ratio (Figure 3).
```

In [6]:

```

## 10. Mixtures of the gas with a condensate

For a radiation-like gas ($X = E/3$, $E \propto 1/a$) plus a condensate ($X = 0$,
$E$ constant) with energy ratio $r = r_0/a$, the record derives exactly
$w_{\rm eff}(A) = \frac{1}{3}r/(1 + r)$, so $w_0 = r_0/(3(r_0 + 1))$ and
$w_a = r_0/(3(r_0 + 1)^2) > 0$: freezing. The next cell evaluates this law at the
$r_0$ CHOSEN for $w_{\rm eff}(C) = -0.861$ today, then mixes the computed gas
N688_lam0 with a condensate (today $a_{4,\rm today} = 2$), with the gas share CHOSEN
for $w_{\rm eff}(C) = -0.861$, and draws mixtures against the Unite line (Figure 4).
```

## 11. The models M2 to M5 of dirac16complex00

Each component of an adiabatic (WKB) gas of dirac16complex00 has an energy
density $\rho_i$ and $\varepsilon_i = (k^2/a^2 + q^2a^2)/(3\omega_i^2) \ge 0$ with
$\omega^2 = m^2 + k^2/a^2 - q^2a^2$; a mixture has
$w_{\rm eff}(C) = \sum_i\varepsilon_i\rho_i/\sum_i\rho_i - 1$. The record's models
(normalised to total energy 1 at $a = 1$): M2 a good-sector gas ($q = 0$), M3 one
extra-time mode ($k = 0$), M4 a condensate plus an extra-time mode, M5 the same plus
a GHOST-LIKE component of negative energy $-G/a$. The next cell rebuilds them,
checks their tangents, the M5 fit, the crossings of $-1$ and the agreement of the
field-equation implementation B, and draws them against the Unite line (Figure 5).
```

In [8]:

```
def model(a, components):

## 13. What this notebook showed

- The observer's density $\rho_4$ is an ASSUMPTION. On the computed history the
  dilution gives exactly $w_{\rm eff} = X/E$ under A and B and $X/E - 1$ under C, so
  every verdict moves by exactly $-1$ between the definitions.
- The Kohn-Sham gas of dirac16complex is radiation-like: $X/E$ between 0.292893
  and 0.328105, rising toward $1/3$; under C it lies between $-0.707107$ and
  $-0.671895$ with small tangent slopes of thawing sign ($w_a$ between $-0.020523$
  and $-0.008894$), far from the Unite $w_a = -0.60$.
- The dark-matter-like fall from about $1/3$ toward 0 belongs to the massive bulk
  band (0.239626 to 0.002268), which the computed ground states do not populate.
- A condensate is dust-like (A, B) or cosmological-constant-like (C); its ratio is
  $-0.764$ only at the CHOSEN $u = -382/441$. Gas and condensate mixtures are
  freezing ($w_a = 0.067014$ for the CHOSEN share 0.436703).
```

```
- The dirac16complex00 models reproduce the Unite tangent (M4) and fit (M5) because
  their parameters were CHOSEN to; a crossing of $-1$ needs the ghost-like
  component (M5). None of these matches is a prediction.
- OPEN: which $\rho_4$ describes a real observer; a self-consistent history with an
  admissible source; populated bulk-band or thermal states; what would select the
  populations; a fit to supernova data.
```

22.23 Line-by-line walk-through of Notebook 22b

The notebook has 9 code cells, In [1] to In [9]. This section explains every line of In [2] to In [9], in order; the printed output of each cell is in Section 22.22 under the label Out [k], and the five figures are shown there with their captions. For each figure this section adds what the student should see and why.

In [1], the set-up cell. It is the set-up cell of every notebook of this book, with the name `"22b"`; Section 22.12 explains each of its lines for Notebook 22a, and only the name differs. Its comment lines repeat the run instructions of Section 22.21. Its code finds the repository folder (`REPO`), decides where files are written (`OUTPUT_ROOT`), and defines the helpers the later cells use: `repository_file(relative)` gives the path of a repository file for reading; `output_file(relative)` the path at which to write one; `say(text)` prints in lines of at most 89 characters; `save_figure(fig, name, caption)` saves a figure as `Revision/textbook/figures/22b_<k>_<name>.png`, records its caption, shows it and prints where it was saved, numbering the figures in the dictionary `FIGURE_NUMBERS`; `check(condition, name, record)` stops the notebook if the condition is false and otherwise prints PASS with the name, and a second line naming the Revision record when `record` is given; `report(label, value)` prints a line RESULT label = value; `all_checks_passed()` prints the last line. The folder name `FIGURE_FOLDER` is `"Revision/textbook/figures"`, and `NOTEBOOK_ID` is `"22b"`. It prints one line.

In [2], the records.

```
import csv  # reads the CSV tables of the Revision record
from fractions import Fraction  # exact fractions such as -382/441

import numpy as np  # arrays of numbers and their arithmetic
```

Three modules: `csv` reads tables stored as CSV files (comma-separated values: one line per row, the entries separated by commas); `Fraction` computes with exact fractions such as $-382/441$, without any rounding; `numpy`, called `np`, holds **arrays** (tables of numbers) and computes with whole arrays at once.

```
D16 = "Revision/dark_sector/dirac16complex"  # the record of dirac16complex
D00 = "Revision/dark_sector/dirac16complex00"  # the record of dirac16complex00
PALETTE = ["#2a78d6", "#eb6834", "#1baf7a", "#eda100", "#e87ba4", "#008300",
           "#4a3aa7", "#e34948"]  # the colours of the figures, in a fixed order
```

Two names for the two folders of the dark-sector record, used in every path below, and eight colours written as hexadecimal codes (blue, orange, green, yellow, pink, dark green, violet, red), which the figures use in this order.

```
def read_json(relative):
    """Read a JSON record of the repository into a Python dictionary."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))
```

`read_json` reads a JSON file of the repository: `repository_file` gives its full path, `.read_text` reads it as text, and `json.loads` turns the text into a Python **dictionary** (pairs of a key and a value).

```
REPORTS = {"derive": f"{D16}/reports/derivation-checks.json",
           "history": f"{D16}/reports/ks-history-run.json",
           "eos": f"{D16}/reports/eos-checks.json",
           "independent": f"{D16}/reports/independent-checks.json",
           "derive00": f"{D00}/reports/python-derive-eos.json",
           "numerics00": f"{D00}/reports/python-independent-numerics.json"}
EXPECTED = {"derive": 30, "history": 5, "eos": 13, "independent": 9,
            "derive00": 49, "numerics00": 28}  # the checks each report holds
```

The six check reports of the dark-sector record, each under a short key, and the number of checks each one holds according to the record's own document (`Revision/docs/DARK_SECTOR_HYPOTHESES.md`, section 11.1): the derivation (`derive`, 30 checks), the 615 runs of the Kohn-Sham solver along the prescribed history (`history`, 5 checks: every run succeeded, the committed states are reproduced, the occupied levels stay the same at all 41 slices, and the conservation law along y of Chapter 15 and the particle number hold in every state), the equation of state of the Kohn-Sham gas (`eos`, 13), the independent free-gas computation (`independent`, 9), and the two implementations for dirac16complex00 (`derive00`, 49, and `numerics00`, 28). A string that starts with `f` is an **f-string**: each name in braces is replaced by its value, so `f"{D16}/reports/eos-checks.json"` is the full repository path.

```
for key, relative in REPORTS.items():
    entries = read_json(relative)["checks"]
    passed = [entry for entry in entries if entry["verdict"] == "PASS"]
    say(f"{relative}: {len(passed)} of {len(entries)} checks PASS")
    check(len(passed) == len(entries) == EXPECTED[key],
          f"all {EXPECTED[key]} checks of the report {key} are PASS",
          record=f"{relative}, all checks")
```

The loop takes the reports one after the other. `entries` is the list of checks of one report, each a dictionary with the keys `name`, `verdict` and `detail`; the **list comprehension** in square brackets keeps those whose verdict is PASS. The cell prints the count, and the check requires that every check passed and that the count is the expected one (the chained comparison `a == b == c` is true when all three are equal). These are the lines of Out [2] that name the six reports.

```
with open(repository_file(f"{D16}/outputs/eos-history.csv"), newline="",
          encoding="utf-8") as handle:
    rows = list(csv.DictReader(handle))
COLUMNS = ["N", "a4", "E", "P3", "Pt", "dw_eff_da4"]
SERIES = {}  # series name -> {column name: numpy array over the slices}
for name in sorted({row["series"] for row in rows}):
    mine = [row for row in rows if row["series"] == name]
```

```
    SERIES[name] = {column: np.array([float(row[column]) for row in mine])
                    for column in COLUMNS}
```

`with open(...) as handle:` opens the table of the Kohn-Sham history and closes it when the indented line has run; `csv.DictReader` reads it row by row, each row a dictionary from the column names of the first line to the texts of that row, and `list` collects all rows. `COLUMNS` names the six columns the notebook uses: the number of quanta N, the slice a_4, the energy E, the integrated pressures P_3 and P_t, and the record's derivative dw_{eff}/da_4. The braces with `for` inside, `{row["series"] for row in rows}`, make a **set** of the series names (each name once), which `sorted` puts in alphabetical order so that every run treats them in the same order. For each series, `mine` keeps its rows, and the inner dictionary comprehension makes, for each column, a numpy array of the numbers of that column (`float` turns a text into a number).

```
GAS = [name for name in SERIES if SERIES[name]["N"][0] in (136, 688)]
summary = read_json(f"{D16}/outputs/eos-summary.json")
free_gas = read_json(f"{D16}/outputs/independent-free-gas.json")
theory00 = read_json(f"{D00}/eos-theory.json")
numerics00 = read_json(f"{D00}/results/independent-numerics.json")
```

`GAS` lists the ten series of the gas proper, those with $N = 136$ or 688 (the four series with $N = 8$ hold only brane zero modes). The other four lines read the summary of the equation of state of dirac16complex, the independent free-gas computation, the model record of dirac16complex00 (implementation A) and the results of its field-equation implementation B.

```
say(f"{len(rows)} rows read: {len(SERIES)} series, {len(GAS)} of them with "
    "N = 136 or 688")
check(all(len(SERIES[name]["a4"]) == 41 for name in SERIES)
      and all(np.all(np.diff(SERIES[name]["a4"]) > 0) for name in SERIES),
      "every series has 41 slices in increasing order of a4")
```

The cell prints the counts (574 rows, 14 series, 10 gas series) and checks that every series has 41 slices and that a_4 increases along each (`np.diff` gives the differences of neighbouring entries; `np.all(... > 0)` is true when all are positive). The finite differences of the next cells rely on this order.

In [3], the observer's equation of state on the gas.

```
def x_over_e(name):
    """X/E = (P3 - Pt)/E of one series at its 41 slices."""
    return (SERIES[name]["P3"] - SERIES[name]["Pt"]) / SERIES[name]["E"]
```

`x_over_e` returns the array of $X/E = (P_3 - P_t)/E$ of one series; numpy subtracts and divides the arrays entry by entry.

```
gas = SERIES["N688_lam0"]  # the gas of N = 688 quanta with lambda = 0
a4, E = gas["a4"], gas["E"]
X = gas["P3"] - gas["Pt"]
h = a4[1] - a4[0]  # the step 0.05 between two slices
```

The series N688_lam0 is the main example. `a4` and `E` are its slices and energies, `X` its $X = P_3 - P_t$, and `h` the distance between two neighbouring slices, 0.05.

```
def derivative(f):
    """df/da4 at the slices 2 to 38: fourth-order central differences."""
    return (f[:-4] - 8 * f[1:-3] + 8 * f[3:-1] - f[4:]) / (12 * h)
```

`derivative` computes df/da_4 from the values of f at the slices by the **fourth-order central difference** $f'(x) \approx [f(x-2h) - 8f(x-h) + 8f(x+h) - f(x+2h)]/(12h)$, whose error shrinks like h^4 (Chapter 2 treats the order of a numerical method). The four **slices** of the array do the shifting: `f[:-4]` holds the entries 0 to 36, that is $f(x-2h)$ for the slices 2 to 38; `f[1:-3]` the entries 1 to 37, $f(x-h)$; `f[3:-1]` the entries 3 to 39, $f(x+h)$; and `f[4:]` the entries 4 to 40, $f(x+2h)$. So the result holds the derivative at the interior slices 2 to 38; the two slices at each end have no two neighbours on both sides.

```
worst = 0.0  # the largest relative violation of dE/da4 = -3X
for name in GAS:
    E_n = SERIES[name]["E"]
    X_n = SERIES[name]["P3"] - SERIES[name]["Pt"]
    violation = np.max(np.abs(derivative(E_n) + 3 * X_n[2:-2])) / np.max(np.abs(E_n))
    worst = max(worst, violation)
report("largest |dE/da4 + 3X|/max|E| over the 10 gas series", f"{worst:.3e}")
check(f"{worst:.3e}" == "1.235e-07", "the energy balance dE/da4 = -3X on the data",
      record=f"{D16}/reports/eos-checks.json, "
             "check conservation_dE_da4_equals_minus_3X")
```

The energy balance of Section 22.17, $dE/da_4 = -3X$, tested on the data. For each gas series the loop differentiates the solver's energies E and compares with $-3X$ from the solver's pressure integrals, at the interior slices (`X_n[2:-2]` drops the two end entries on each side, to match). The violation is measured relative to the largest energy of the series, and `worst` keeps the largest violation over the ten series. Printed with three digits it is 1.235×10^{-7}, the number of the record's check (Out [3]): the two sides agree to about seven digits, the accuracy of the solver and of the finite differences. The format `:.3e` writes a number in scientific notation with three digits after the point.

```
rho4_AB = E * np.exp(-3 * a4)  # definitions A and B: rho4 ~ E e^(-3 a4)
rho4_C = E  # definition C: rho4 ~ E
w_AB = -1 - derivative(np.log(rho4_AB)) / 3  # -1 - (1/3) d ln rho4/d ln a
w_C = -1 - derivative(np.log(rho4_C)) / 3
```

The observer's density under the definitions A and B ($E\,e^{-3a_4}$, up to a constant factor, which does not change a logarithmic derivative) and under C (E). The next two lines compute $w_{\text{eff}} = -1 - \frac{1}{3}\,d\ln\rho_4/d\ln a$ directly from its definition, with $d\ln a = da_4$: `np.log` takes the natural logarithm of every entry, and `derivative` differentiates it.

```
error_AB = np.max(np.abs(w_AB - (X / E)[2:-2]))
error_C = np.max(np.abs(w_C - (X / E - 1)[2:-2]))
report("largest |w_eff(A, B) - X/E| from the dilution", f"{error_AB:.1e}")
report("largest |w_eff(C) - (X/E - 1)| from the dilution", f"{error_C:.1e}")
```

```
check(max(error_AB, error_C) < 1e-7,
      "w_eff(A) = w_eff(B) = X/E and w_eff(C) = X/E - 1 on the data",
      record=f"{D16}/reports/derivation-checks.json, checks "
             "w_eff_A_equals_X_over_E and w_eff_C_equals_X_over_E_minus_1")
```

The dilution-inferred values are compared with the identities X/E and $X/E - 1$ of Section 22.17. Both differences are at most 1.7×10^{-8} (Out [3]): on the computed history the identities hold to the accuracy of the differences. The record proves them exactly with sympy; this is the numerical test.

```
ratios = np.concatenate([x_over_e(name) for name in GAS])
report("X/E of N688_lam0 at a4 = 0 and a4 = 2", f"{X[0] / E[0]:.4f}, "
       f"{X[-1] / E[-1]:.4f}")
report("X/E over all gas series, smallest and largest",
       f"{ratios.min():.6f}, {ratios.max():.6f}")
report("w_eff(C) over all gas series, smallest and largest",
       f"{ratios.min() - 1:.6f}, {ratios.max() - 1:.6f}")
```

`np.concatenate` joins the ten arrays of X/E into one array of 410 numbers. The cell prints X/E of N688_lam0 at the first and the last slice (0.2929 and 0.3183; `X[-1]` is the last entry), the smallest and largest X/E of all gas series (0.292893 and 0.328105), and the same moved down by 1, the range under C (-0.707107 to -0.671895).

```
check(f"{ratios.min():.6f}" == "0.292893" and f"{ratios.max():.6f}" == "0.328105",
      "the gas is radiation-like: X/E in [0.292893, 0.328105]",
      record=f"{D16}/reports/eos-checks.json, check gas_radiation_like_band")
check(all(np.all(np.diff(x_over_e(name)) > 0) for name in GAS),
      "X/E rises with a4 in every gas series (toward 1/3, not toward 0)",
      record=f"{D16}/reports/eos-checks.json, "
             "check gas_X_over_E_rises_toward_one_third")
```

The two checks compare the band with the six digits of the record's check, and require that X/E increases from each slice to the next in every gas series: the gas approaches radiation, it does not fall toward dust.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
for colour, name in zip(PALETTE, ["N136_lam0", "N688_lam0", "N688_lamp2"]):
    left.plot(SERIES[name]["a4"], x_over_e(name), color=colour, label=name)
    right.plot(SERIES[name]["a4"], x_over_e(name) - 1, color=colour, label=name)
```

`plt.subplots(1, 2, ...)` makes a figure with two panels side by side, 9.0 by 3.8 inches, and names them `left` and `right`. `zip` pairs the first three colours with three series; each series is drawn in the left panel as X/E (definitions A and B) and in the right panel as $X/E - 1$ (definition C), with its name as the label of the legend.

```
left.axhline(1 / 3, color="black", linestyle="--", linewidth=0.8,
             label="radiation, 1/3")
right.axhline(-2 / 3, color="black", linestyle="--", linewidth=0.8,
              label="1/3 - 1")
left.set_title("definitions A and B: $w_{eff} = X/E$")
right.set_title("definition C: $w_{eff} = X/E - 1$")
```

`axhline` draws a horizontal line across a panel: the radiation value 1/3 on the left (dashed: the line style written as two minus signs) and the same value moved down by 1, $-2/3$, on the right. The titles name the definitions; text between dollar signs is set as mathematics.

```
for ax in (left, right):
    ax.set_xlabel("$a_4$ along the prescribed history")
    ax.legend(fontsize=8)
left.set_ylabel("$w_{eff}$")
save_figure(fig, "gas_three_definitions",
            "The equation of state $w_{eff}$ that a 3-space observer infers from "
...)
```

Both panels get the label of the horizontal axis and a legend; the left one the label of the vertical axis. `save_figure` saves the figure as Figure 22b.1 with its caption (shortened here; the full caption is printed under the figure in Section 22.22). **What to see:** the two panels have the same shape, moved by exactly 1. On the left, every curve rises toward the dashed radiation line, the larger gas ($N = 688$) a little lower than the smaller one, and the interaction (λ_2, green) changes almost nothing. On the right, the same curves lie between -0.71 and -0.67: far above -1, and rising, which is the thawing sign. The physics of the gas is the same in both panels; only the ASSUMED definition of the observer's density differs.

In [4], the CPL tangents of the gas.

```
TODAY = [0.5, 1.0, 1.5, 2.0]  # the four choices of a4,today of the record
index = [int(round(t / h)) for t in TODAY]  # their positions in the slice list
recorded = {entry["series"]: entry for entry in summary["series"]}
say("a4,today   w0 under C   wa (every definition)")
differences = []
```

The four values of $a_{4,\mathrm{today}}$ that the record uses, and their positions in the list of slices: $0.5/0.05 = 10$, then 20, 30 and 40 (`round` removes the tiny error of the division, and `int` makes a whole number). `recorded` maps each series name to its entry of the summary. The cell prints a header line and starts an empty list `differences`.

```
for t, i, entry in zip(TODAY, index, recorded["N688_lam0"]["cplTangent"]):
    w0 = X[i] / E[i] - 1  # w_eff(C) today
    wa = -gas["dw_eff_da4"][i]  # w_a = -dw/da at a = 1, and da = da4 there
    say(f"{t:8.1f}   {w0:10.4f}   {wa:12.5f}")
    differences += [abs(w0 - entry["w_eff_C"]["w0"]), abs(wa - entry["w_eff_C"]["wa"])]
check(max(differences) < 1e-12, "the CPL tangents of N688_lam0",
      record=f"{D16}/outputs/eos-summary.json, key cplTangent of N688_lam0")
```

For each choice of today, the tangent of Section 22.18: w_0 is $w_{\mathrm{eff}}(C) = X/E - 1$ at that slice, and $w_a = -dw_{\mathrm{eff}}/da_4$ there, read from the record's column `dw_eff_da4` (the derivative of X/E; under C the constant -1 does not change it). The format `8.1f` writes a number in 8 places with one digit after the point. The two numbers are compared with the summary's tangent of the same series; `+=` appends both differences to the list. The table of Out [4] is the table of Section 22.18.

```
tangents = [-SERIES[name]["dw_eff_da4"][i] for name in GAS for i in index]
report("tangent wa of every gas series, smallest and largest",
       f"{min(tangents):.6f}, {max(tangents):.6f}")
check(f"{min(tangents):.6f}" == "-0.020523" and f"{max(tangents):.6f}" == "-0.008894"
      and f"{ratios.min() - 1:.6f}" == "-0.707107"
      and f"{ratios.max() - 1:.6f}" == "-0.671895",
      "every gas tangent wa is negative (thawing sign) and far below 0.60",
      record=f"{D16}/reports/eos-checks.json, check gas_cpl_thawing_sign_small")
```

The tangent w_a of every gas series at every choice of today (40 numbers; the comprehension with two `for` runs over both). The smallest is -0.020523 and the largest -0.008894: all negative, the thawing sign, and at most about one thirtieth of the observed 0.60. The check compares them, and the range of $w_{\text{eff}}(C)$ from In [3], with the six digits of the record's check.

In [5], the bulk band and the brane band.

```
bulk = free_gas["bulkBand_n2_1"]  # the lowest massive (odd-parity) level, shell 1
brane = free_gas["braneBand_n2_1"]  # the brane-band level of the same shell
a4_band = np.array([point["a4"] for point in bulk])
w_bulk = np.array([point["w_eff_A_B"] for point in bulk])
w_brane = np.array([point["w_eff_A_B"] for point in brane])
```

The independent free-gas output holds two lists of points, one for the lowest level of the massive bulk band of the shell $n_2 = 1$ and one for the brane-band level of the same shell, each point a dictionary with the slice `a4` and the value `w_eff_A_B` of w_{eff} under A and B. The three arrays collect the slices (-3 to 4 in steps of 0.25) and the two curves.

```
report("w_eff(A) of the bulk level at a4 = -3 and a4 = 4",
       f"{w_bulk[0]:.6f}, {w_bulk[-1]:.3e}")
report("ratio w(4)/w(3.75) of the bulk level", f"{w_bulk[-1] / w_bulk[-2]:.6f}")
report("w_eff(A) of the brane level, smallest and largest",
       f"{w_brane.min():.6f}, {w_brane.max():.6f}")
```

The first and last value of the bulk level (0.239626 and 2.268×10^{-3}), the ratio of its last two values (0.765177, which Section 22.18 compares with $e^{-0.25}$), and the range of the brane level (0.291594 to 0.333275).

```
check(a4_band[0] == -3 and a4_band[-1] == 4 and np.all(np.diff(w_bulk) < 0)
      and f"{w_bulk[0]:.6f}" == "0.239626" and f"{w_bulk[-1]:.3e}" == "2.268e-03",
      "the bulk level falls from 0.239626 to 2.268e-03 (dark-matter-like)",
      record=f"{D16}/reports/independent-checks.json, check bulk_band_dark_matter_law")
check(f"{w_brane.min():.6f}" == "0.291594" and f"{w_brane.max():.6f}" == "0.333275",
      "the brane level stays between 0.291594 and 0.333275 (radiation-like)",
      record=f"{D16}/reports/independent-checks.json, check brane_band_radiation_law")
```

The first check requires the range of slices, that the bulk level falls at every step (all differences negative), and its two end values as the record's check states them; the second the range of the brane level.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
ax.plot(a4_band, w_bulk, "o-", color=PALETTE[1], markersize=3,
        label="bulk band (massive), one level")
ax.plot(a4_band, w_brane, "s-", color=PALETTE[0], markersize=3,
        label="brane band (massless at k = 0), one level")
ax.plot(a4, X / E, color=PALETTE[2], linewidth=2.5, label="the gas N688_lam0")
```

One panel. The bulk level is drawn in orange with small circles (`"o-"`: points joined by lines), the brane level in blue with small squares, and the gas N688_lam0 of In [3] as a thick green line over its range $0 \le a_4 \le 2$.

```
ax.axhline(1 / 3, color="black", linestyle="--", linewidth=0.8)
ax.axhline(0.0, color="black", linestyle=":", linewidth=0.8)
ax.set_xlabel("$a_4$")
ax.set_ylabel("$w_{eff}$ under definitions A and B")
ax.legend(fontsize=8)
save_figure(fig, "bulk_and_brane_bands",
            "Which quanta of dirac16complex behave like dark matter. Horizontal "
...)
```

The radiation value 1/3 (dashed) and the dust value 0 (dotted), the axis labels, the legend, and Figure 22b.2. **What to see:** only the orange curve goes from near radiation toward dust, the dark-matter-like behaviour of the flat-limit law of Section 22.18. The blue curve dips slightly and then climbs to 1/3, and the green gas, which consists of brane-band quanta, follows the blue behaviour. The time-varying dark-matter-like equation of state exists in the theory, but in a band that the computed states leave empty.

In [6], the condensate.

```
u = Fraction(-382, 441)  # lambda S/m, CHOSEN so that the ratio is -0.764
ratio = u / (2 + u)  # p/rho = (lambda S^2/2)/(m S + lambda S^2/2) = u/(2 + u)
density = 1 + u / 2  # rho/(m S)
report("the ratio u/(2 + u) at u = -382/441", f"{ratio} = {float(ratio)}")
report("rho/(m S) = 1 + u/2", f"{density} = {float(density):.12f}")
```

`Fraction(-382, 441)` is the exact fraction $-382/441$; arithmetic with it stays exact. The ratio $u/(2+u)$ of Section 22.18 comes out as the fraction $-191/250 = -0.764$, and $\rho/(mS) = 1 + u/2 = 250/441 = 0.566893424036$ (Out [6]; `float` turns a fraction into a decimal number).

```
check(ratio == Fraction(-764, 1000)
      and abs(float(u) - summary["condensate"]["u_for_ratio_minus_0p764"]) < 1e-12,
      "the condensate ratio is -0.764 at u = -382/441 (one CHOSEN parameter)",
      record=f"{D16}/reports/derivation-checks.json, "
             "check condensate_ratio_equal_unite_constant_w")
```

The ratio must equal $-764/1000$ exactly (`Fraction` reduces it to $-191/250$ and compares exactly), and u must agree with the value the summary records.

```
grid = np.linspace(-3.0, 1.0, 4001)
grid = grid[np.abs(grid + 2) > 1e-9]  # leave out the pole u = -2
below = grid / (2 + grid) < -1  # where the ratio is phantom
check(np.array_equal(below, (grid > -2) & (grid < -1)),
      "the ratio is below -1 exactly for -2 < u < -1",
      record=f"{D00}/reports/python-derive-eos.json, "
             "check condensate_phantom_interval")
```

A test of the phantom window derived in Section 22.18 on 4001 values of u from -3 to 1 (step 0.001). The second line removes the value $u = -2$, where the ratio has a zero denominator: the condition in square brackets is an array of true and false, and indexing with it keeps the entries where it is true. `below` marks where the ratio is below -1; `(grid > -2) & (grid < -1)` marks the window (the operator between the two conditions means "and", applied entry by entry); `np.array_equal` requires that the two markings agree at every point.

```
fig, ax = plt.subplots(figsize=(7.0, 4.2))
for part in (grid[grid < -2], grid[grid > -2]):
    ax.plot(part, part / (2 + part), color=PALETTE[0])
ax.axvspan(-2, -1, color=PALETTE[7], alpha=0.12, label="phantom ratio, -2 < u < -1")
```

The ratio is drawn in two pieces, left and right of the pole, so that no line jumps across it. `axvspan` shades the vertical band $-2 < u < -1$ in pale red (`alpha=0.12` makes it nearly transparent).

```
ax.axhline(0.0, color="black", linestyle="--", linewidth=0.8,
           label="$w_{eff}$, definitions A and B")
ax.axhline(-1.0, color="black", linestyle=":", linewidth=0.8,
           label="$w_{eff}$, definition C")
ax.plot([float(u)], [float(ratio)], "o", color=PALETTE[1],
        label="CHOSEN: u = -382/441 gives -0.764")
ax.set_ylim(-4.0, 4.0)
```

The two values that the observer infers for any condensate, 0 (A, B; dashed) and -1 (C; dotted), and the CHOSEN point in orange; `set_ylim` shows the vertical range -4 to 4, so that the steep branches near the pole are cut off.

```
ax.set_xlabel("$u = \\lambda S/m$")
ax.set_ylabel("ratio $p/\\rho$")
ax.legend(fontsize=8, loc="lower right")
save_figure(fig, "condensate_ratio",
            "The constant ratio $p/\\rho = u/(2 + u)$ of a homogeneous condensate "
...)
```

The axis labels (the doubled backslash `\\` puts one backslash into the text, which the mathematics needs before `lambda` and `rho`), the legend in the lower right corner, and Figure 22b.3. **What to see:** the ratio can take any value, and the value -0.764 is one point on the curve, reached by choosing u; it says nothing about the observer, whose two readings are the horizontal lines, the same for every u. Left of the pole the ratio is above 1, right of it the curve climbs from far below through the phantom band to -1 at $u = -1$, to 0 at $u = 0$ and on toward 1.

In [7], the mixtures.

```
r0 = Fraction(417, 583)  # gas/condensate energy today, CHOSEN for w0(C) = -0.861
w0_exact = r0 / (3 * (r0 + 1)) - 1  # w_eff(C) today
wa_exact = r0 / (3 * (r0 + 1) ** 2)  # w_a of the exact law: positive (freezing)
report("exact law: w0 under C and wa", f"{w0_exact}, {float(wa_exact):.6f}")
check(w0_exact == Fraction(-861, 1000) and f"{float(wa_exact):.6f}" == "0.081037",
      "radiation plus condensate with w0(C) = -0.861 has wa = 0.081037 > 0",
      record=f"{D16}/reports/derivation-checks.json, "
             "check mixture_C_matching_w0_unite")
```

The exact law of Section 22.18 for a radiation-like gas plus a condensate, with exact fractions: at the CHOSEN $r_0 = 417/583$, w_0 under C is exactly $-861/1000$ and $w_a = 0.081037$, positive (`**` is the power).

```
def mixture_w_C(share):
    """w_eff(C) of the gas N688_lam0 plus a condensate along the history; the gas
    has the energy share "share" today (a4 = 2)."""
    condensate = E[-1] * (1 - share) / share  # constant condensate energy
    return X / (E + condensate) - 1
```

`mixture_w_C` mixes the computed gas with a condensate and returns $w_{\text{eff}}(C)$ at all 41 slices. Today is the last slice, $a_4 = 2$. If the gas has the share `share` of the energy today, the condensate energy is $E_c = E(2)(1 - \text{share})/\text{share}$ (from $E(2)/(E(2) + E_c) = \text{share}$), constant in time. The condensate adds energy but no X, so the mixture has $w_{\text{eff}}(C) = X/(E + E_c) - 1$.

```
share = 0.139 / (X[-1] / E[-1])  # CHOSEN: gives w_eff(C) = -0.861 today
w_mix = mixture_w_C(share)
```

Today $w_{\text{eff}}(C) = \text{share} \cdot X/E - 1$, so $w_{\text{eff}}(C) = -0.861$ needs share $= 0.139/(X/E)$ at $a_4 = 2$: $0.139/0.3183 = 0.436703$. This share is CHOSEN; `w_mix` is the mixture's history.

```
# w_a = -dw/da4 at a4 = 2, one-sided fourth-order differences (as the record)
wa_mix = -(3 * w_mix[-5] - 16 * w_mix[-4] + 36 * w_mix[-3] - 48 * w_mix[-2]
           + 25 * w_mix[-1]) / (12 * h)
recorded_mix = summary["mixture_C_w0_minus_0p861"]
```

At the last slice there are no neighbours on the right, so the derivative uses the **one-sided fourth-order difference** $f'(x) \approx [3f(x-4h) - 16f(x-3h) + 36f(x-2h) - 48f(x-h) + 25f(x)]/(12h)$, the same stencil as the record; `w_mix[-5]` is the fifth entry from the end. The minus sign makes it w_a. `recorded_mix` is the record's entry for this mixture.

```
report("gas share today for w_eff(C) = -0.861 (CHOSEN)", f"{share:.6f}")
report("w0 and wa of that mixture under C", f"{w_mix[-1]:.3f}, {wa_mix:.6f}")
check(abs(share - recorded_mix["gas_fraction_today"]) < 1e-12
      and abs(wa_mix - recorded_mix["wa"]) < 1e-10 and wa_mix > 0,
      "the computed gas mixture with w0(C) = -0.861 is freezing, wa = 0.067014",
      record=f"{D16}/reports/eos-checks.json, check mixture_C_w0_unite_has_positive_wa")
```

The share 0.436703 and $(w_0, w_a) = (-0.861, 0.067014)$ are printed and compared with the record: w_a is positive, freezing, the opposite sign to the observed -0.60.

```
a_obs = np.exp(a4 - 2.0)  # the observer scale factor, a = 1 today (a4 = 2)
fig, ax = plt.subplots(figsize=(7.0, 4.2))
for colour, part in zip(PALETTE, [0.25, share, 0.75, 1.0]):
    ax.plot(a_obs, mixture_w_C(part), color=colour,
            label=f"gas share today {part:.3f}")
ax.plot(a_obs, -0.861 - 0.60 * (1 - a_obs), "k--", label="Unite CPL line")
ax.axhline(-1.0, color="black", linestyle=":", linewidth=0.8)
```

The observer's scale factor $a = e^{a_4 - 2}$ runs from $e^{-2} = 0.135$ to 1 over the history. Four mixtures are drawn against it, with the gas shares 0.25, the CHOSEN 0.437, 0.75 and 1 (pure gas), together with the observed CPL line (the style `"k"` followed by two minus signs: black and dashed) and the value -1 (dotted).

```
ax.set_xlabel("observer scale factor $a = e^{a_4 - 2}$")
ax.set_ylabel("$w_{eff}$ under definition C")
ax.legend(fontsize=8)
save_figure(fig, "mixtures_against_unite",
            "Mixtures of the computed Kohn-Sham gas N688_lam0 with a condensate, "
...)
```

Labels, legend and Figure 22b.4. **What to see:** every curve that contains condensate slopes DOWN toward -1 as a grows, because the gas redshifts and the condensate's -1 takes over; the observed line slopes UP. The orange curve meets the observed line at $a = 1$ (that is how its share was chosen) and leaves it at once in the opposite direction. No choice of the share turns one slope into the other.

In [8], the models of dirac16complex00.

```
def model(a, components):
    """The total energy density and the sum of eps_i rho_i of a WKB model at a
    (a number or an array).  Each component is (kind, weight at a = 1, s)."""
    a = np.asarray(a, dtype=float)
    rho_total, eps_rho = np.zeros_like(a), np.zeros_like(a)
    for kind, weight, s in components:
```

`model` evaluates the adiabatic gas of Section 22.19 at the scale factor `a`, which may be one number or an array (`np.asarray` makes an array of it either way). A model is a list of components, each a **tuple** `(kind, weight, s)`: what it is, its energy density at $a = 1$, and its parameter. `rho_tota l` will hold $\sum_i \rho_i$ and `eps_rho` the sum $\sum_i \varepsilon_i \rho_i$; `np.zeros_like(a)` makes arrays of zeros of the shape of `a`.

```
        if kind == "condensate":  # rho constant, eps = 0
            rho, eps = weight + 0 * a, 0 * a
        elif kind == "kmode":  # q = 0 and s = k^2/(k^2 + m^2) at a = 1
            r = s / (1 - s)  # k^2/m^2
            rho = weight * np.sqrt((r / a**2 + 1) / (r + 1))  # omega(a)/omega(1)
            eps = (r / a**2) / (3 * (r / a**2 + 1))
```

A condensate (with $\lambda = 0$) has constant energy density and $\varepsilon = 0$; adding `0 * a` gives the numbers the shape of `a`. A gas of modes with $q = 0$ (`"kmode"`) is described by $s = k^2/(k^2 + m^2)$ at $a = 1$;

$r = s/(1-s)$ is then k^2/m^2. Its energy density is $\rho_i \propto \omega = m\sqrt{1 + r/a^2}$, scaled to the weight at $a = 1$, and $\varepsilon = (k^2/a^2)/(3\omega^2) = (r/a^2)/(3(r/a^2 + 1))$, the formula of Section 22.19 with $q = 0$ and $m = 1$.

```
        elif kind == "qmode":  # k = 0 and s = q^2/m^2 at a = 1
            rho = weight * np.sqrt((1 - s * a**2) / (1 - s))
            eps = s * a**2 / (3 * (1 - s * a**2))
        else:  # "ghost": massless modes of NEGATIVE classical energy
            rho, eps = -weight / a, 1 / 3 + 0 * a
```

An extra-time mode with $k = 0$ (`"qmode"`), $s = q^2/m^2$ at $a = 1$: $\omega = m\sqrt{1 - sa^2}$, so ρ_i is the weight times $\sqrt{(1 - sa^2)/(1 - s)}$, and $\varepsilon = sa^2/(3(1 - sa^2))$. The ghost-like component: massless modes ($\varepsilon = 1/3$) of NEGATIVE energy density $-G/a$, with G the weight.

```
        rho_total = rho_total + rho
        eps_rho = eps_rho + eps * rho
    return rho_total, eps_rho
```

Each component adds its ρ_i and its $\varepsilon_i\rho_i$ to the two sums, which the function returns.

```
def w_model(a, components):
    """w_eff under definition C: sum eps_i rho_i / sum rho_i - 1."""
    rho_total, eps_rho = model(a, components)
    return eps_rho / rho_total - 1
```

`w_model` is the mixture formula of Section 22.19 under C.

```
def tangent(components, d=1e-3):
    """CPL tangent w0 = w(1), wa = -dw/da at a = 1 (fourth-order differences)."""
    f = [float(w_model(1 + k * d, components)) for k in (-2, -1, 1, 2)]
    slope = (f[0] - 8 * f[1] + 8 * f[2] - f[3]) / (12 * d)  # dw/da at a = 1
    return float(w_model(1.0, components)), -slope
```

`tangent` returns $w_0 = w(1)$ and $w_a = -dw/da$ at $a = 1$; the slope is the fourth-order central difference of In [3], with the step $d = 10^{-3}$ in a.

```
M5_RECORD = theory00["models"]["M5_with_ghost_component"]
G = float(Fraction(M5_RECORD["parameters"]["G"]))  # ghost share 3/10, a choice
s5 = float(M5_RECORD["parameters"]["s"])  # CHOSEN with q5 to fit the Unite line
q5 = float(M5_RECORD["parameters"]["Omega_q"])
c5 = float(M5_RECORD["parameters"]["Omega_c"])
```

The parameters of M5 are read from the record: the ghost share $G = 3/10$ (stored as the text `"3/10"`, which `Fraction` reads), and s, the mode share Ω_q and the condensate share Ω_c, which the record found by solving the two fit conditions (stored with 12 digits).

```
MODELS = {"M2": [("kmode", 1.0, 417 / 1000)],  # s CHOSEN: w0 = -0.861
          "M3": [("qmode", 1.0, 417 / 1417)],  # s CHOSEN: w0 = -0.861
          "M4": [("condensate", 1 - 57963 / 264037, 0.0),  # both CHOSEN:
                 ("qmode", 57963 / 264037, 264037 / 403037)],  # tangent = Unite
          "M5": [("condensate", c5, 0.0), ("qmode", q5, s5), ("ghost", G, 0.0)]}
```

The four models of the table of Section 22.19, each as a list of components with its CHOSEN parameters. The weights of M4 and M5 add up to 1 at $a = 1$: $(1 - \Omega_q) + \Omega_q = 1$, and $\Omega_c + \Omega_q - G = 0.705325 + 0.594675 - 0.3 = 1$.

```
EXPECTED_WA = {"M2": 81037 / 500000, "M3": -196963 / 500000, "M4": -0.6}
RECORD_CHECK = {"M2": "M2_tangent_exact", "M3": "M3_tangent_exact",
                "M4": "M4_tangent_equals_unite"}
for name in ("M2", "M3", "M4"):
    w0, wa = tangent(MODELS[name])
    report(f"{name} tangent (w0, wa) under C", f"({w0:.6f}, {wa:.6f})")
    check(abs(w0 + 0.861) < 1e-12 and abs(wa - EXPECTED_WA[name]) < 1e-8,
          f"the tangent of {name}",
          record=f"{D00}/reports/python-derive-eos.json, check {RECORD_CHECK[name]}")
```

The exact tangent slopes of the record ($81037/500000 = 0.162074$, $-196963/500000 = -0.393926$ and -0.6) and the names of the record's checks. For each model the cell computes the tangent and checks $w_0 = -0.861$ to 10^{-12} and w_a to 10^{-8}, the accuracy of the finite difference. Out [8] prints $(-0.861, 0.162074)$, $(-0.861, -0.393926)$ and $(-0.861, -0.600000)$.

```
a_fit = np.linspace(0.5, 1.0, 101)  # 101 points of a in [1/2, 1], as the record
wa_fit, w0_fit = np.polyfit(1 - a_fit, w_model(a_fit, MODELS["M5"]), 1)
report("M5 least-squares fit over a in [1/2, 1]", f"({w0_fit:.6f}, {wa_fit:.6f})")
check(abs(w0_fit + 0.861) < 1e-9 and abs(wa_fit + 0.6) < 1e-9,
      "the M5 fit equals the Unite pair (by construction)",
      record=f"{D00}/reports/python-derive-eos.json, check M5_fit_equals_unite")
```

The least-squares fit of M5, as in the record: 101 equally spaced values of a from $1/2$ to 1, and `np.polyfit(x, y, 1)` finds the straight line $y = c_1 x + c_0$ closest to the points (the sum of the squared vertical distances is smallest) and returns $[c_1, c_0]$. With $x = 1 - a$ the line is $w_0 + w_a(1 - a)$, so $c_1 = w_a$ and $c_0 = w_0$. The fit is the observed pair to 10^{-9}: by construction, since s and Ω_q were chosen for exactly this.

```
def crossings(components):
    """The values of a in [1/3, 1] where w = -1 (400 intervals, then bisection)."""
    points = np.linspace(1 / 3, 1, 401)
    values = w_model(points, components) + 1
    found = []
```

`crossings` finds where $w = -1$ between $a = 1/3$ and 1: it divides the range into 400 intervals (401 points) and evaluates $w + 1$, which changes sign at a crossing.

```
    for low, high, v_low, v_high in zip(points, points[1:], values, values[1:]):
        if v_low * v_high < 0:
```

```
            for _ in range(60):  # halve the interval 60 times
                middle = (low + high) / 2
                v_middle = float(w_model(middle, components) + 1)
                if v_low * v_middle <= 0:
                    high = middle
                else:
                    low, v_low = middle, v_middle
            found.append((low + high) / 2)
    return found
```

`zip(points, points[1:], ...)` runs over neighbouring pairs of points with their values. Where the product of the two values is negative, the sign changes inside the interval, and **bisection** narrows it: the middle is evaluated, and the half in which the sign still changes is kept (if the left value and the middle value have opposite signs or the middle is zero, the crossing is in the left half, so `high` moves to the middle; otherwise in the right half). After 60 halvings the interval is 2^{-60} times its original width 1/600, far below the precision of the numbers, and its middle is recorded. The underscore `_` is the name of a loop variable that is not used.

```
cross_M5 = crossings(MODELS["M5"])
no_ghost = [("condensate", 1 - q5, 0.0), ("qmode", q5, s5)]  # M5 without ghost
lowest_M4 = float(np.min(w_model(np.arange(1, 301) / 300, MODELS["M4"])))
crossing_A = float(M5_RECORD["N2"]["crossings_of_minus_1_in_[1/3,1]"][0])
crossing_B = numerics00["models"]["M5_with_ghost_component"]["crossing_N2"]
M4_RECORD = theory00["models"]["M4_condensate_plus_extra_time_mode"]
```

The crossings of M5; the same model with its ghost-like part removed (the condensate share becomes $1-\Omega_q$, so that the total is 1 again); the smallest w of M4 at $a = 1/300, 2/300, \ldots, 1$ (`np.arange(1, 301)` gives the whole numbers 1 to 300); the record's crossing from implementation A (stored as a text in a list) and from the field-equation implementation B; and the record's entry for M4.

```
report("M5 crosses w = -1 at a", f"{cross_M5[0]:.11f}")
report("the same crossing from the field equation (implementation B)",
       f"{crossing_B}")
report("lowest w_eff(C) of M4 for a = 1/300 to 1", f"{lowest_M4:.12f}")
```

Out [8] prints the crossing $a = 0.77909966367$, implementation B's 0.77905405, and the lowest w of M4, -0.999999214228: above -1.

```
check(len(cross_M5) == 1 and abs(cross_M5[0] - crossing_A) < 1e-10,
      "M5 crosses -1 once, at a = 0.7791",
      record=f"{D00}/reports/python-derive-eos.json, check M5_crosses_minus_1")
check(crossings(no_ghost) == [] and crossings(MODELS["M4"]) == []
      and abs(lowest_M4 - float(M4_RECORD["min_w_N2_on_(0,1]"])) < 1e-11,
      "no crossing on 1/3 <= a <= 1 without the ghost: M5 without it, and M4",
      record=f"{D00}/reports/python-derive-eos.json, checks "
             "M5_without_ghost_no_crossing and M4_never_phantom")
check(abs(crossing_B - cross_M5[0]) < 1e-4,
      "implementation B finds the M5 crossing within 1e-4",
      record=f"{D00}/reports/python-independent-numerics.json, "
             "check B_vs_A_M5_crossing")
```

Three checks: M5 crosses -1 exactly once, where the record says; neither M5 without its ghost-like part nor M4 crosses on $1/3 \le a \le 1$, the range that `crossings` searches (an empty list `[]`), and the lowest value of M4 on $1/300 \le a \le 1$ is the record's; and the field-equation implementation B agrees on the crossing within 10^{-4} (the difference is 4.6×10^{-5}, the accuracy of B's numerical solution).

```
a_plot = np.linspace(1 / 3, 1.0, 300)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
LABELS = {"M2": "M2, gas (1 CHOSEN)", "M3": "M3, extra-time mode (1 CHOSEN)",
          "M4": "M4 (2 CHOSEN)", "M5": "M5 (2 CHOSEN, ghost-like part)"}
for colour, name in zip(PALETTE, MODELS):
    left.plot(a_plot, w_model(a_plot, MODELS[name]), color=colour,
              label=LABELS[name])
```

300 values of a from $1/3$ to 1 and a figure with two panels. The labels state for each model how many parameters were CHOSEN. The loop draws $w_{\mathrm{eff}}(C)$ of the four models in the left panel (looping over a dictionary gives its keys, here in the order M2, M3, M4, M5).

```
left.plot(a_plot, -0.861 - 0.60 * (1 - a_plot), "k--", label="Unite CPL line")
left.axhline(-1.0, color="black", linestyle=":", linewidth=0.8)
left.set_xlabel("observer scale factor $a$")
left.set_ylabel("$w_{eff}$ under definition C")
left.legend(fontsize=7)
```

The observed CPL line (dashed), the value -1 (dotted), the labels and the legend of the left panel.

```
PARTS = [("condensate", MODELS["M5"][0]), ("extra-time mode", MODELS["M5"][1]),
         ("ghost-like part", MODELS["M5"][2])]
for colour, (label, component) in zip(PALETTE[4:], PARTS):
    right.plot(a_plot, model(a_plot, [component])[0], color=colour, label=label)
right.plot(a_plot, model(a_plot, MODELS["M5"])[0], "k-", label="total")
right.axhline(0.0, color="black", linewidth=0.6)
```

The right panel shows the **populations** of M5: the energy density of each of its three parts, computed by calling `model` with a list that holds only that part (`[0]` takes the first of the two returned sums, the energy density), in the colours from the fifth on (`PALETTE[4:]`), and their total in black, with the zero line.

```
right.set_xlabel("observer scale factor $a$")
right.set_ylabel("energy density, M5")
right.legend(fontsize=7)
fig.subplots_adjust(wspace=0.3)  # room between the two panels
save_figure(fig, "models_against_unite",
            "The models of dirac16complex00 under definition C against the "
...)
```

Labels and legend of the right panel; `subplots_adjust(wspace=0.3)` widens the gap between the panels so that the labels do not overlap; Figure 22b.5. **What to see:** on the left, M2, M3 and M4 pass through $w = -0.861$ at $a = 1$, because their parameters were CHOSEN to give that value

today. M5 ends a little higher, at $w = -0.8396$ (the record `eos-theory.json`, model M5, key `w(a=1)`: -0.839622680899), because its two parameters were CHOSEN so that its least-squares fit over a from 1/2 to 1, not its value today, equals the Unite pair $(-0.861, -0.60)$. Read the curves from left to right, in the direction in which a grows. M2 falls toward -1: it slopes the wrong way (freezing, $w_a > 0$), while the dashed Unite line rises. M3 and M4 rise away from -1: they slope the right way (thawing, $w_a < 0$), but toward the past they flatten above the dotted line -1: with positive energies and real frequencies they cannot go below it, and the whole plotted range lies before the turning points of their extra-time modes ($a_{\rm turn} = 1.8434$ for M3, 1.2355 for M4); past those points the bound is not established. M4 even has the right slope at $a = 1$, by construction. Only M5 follows the dashed line through -1, and it does so only because its ghost-like part, the violet curve on the right, carries a negative energy that grows like $1/a$ toward the past. Nothing in the field equations selects any of these populations.

In [9], the comparison with the observed values.

```
unite = theory00["models"]["unite"]
w0_u, wa_u = Fraction(unite["w0"]), Fraction(unite["wa"])
crossing_u = 1 + (1 + w0_u) / wa_u  # w0 + wa (1 - a) = -1 solved for a
```

The record stores the observed values as exact fractions in text form (`"-861/1000"`, `"-3/5"`), which `Fraction` reads. The crossing of the CPL line with -1 is solved as in Section 22.16: $a = 1 + (1 + w_0)/w_a$.

```
TABLE = [("w = -0.764", "condensate ratio, u = -382/441", "1 for 1"),
         ("w0 = -0.861", "M2; M3; gas plus condensate", "1 for 1"),
         ("(w0, wa) = (-0.861, -0.60)", "M4 tangent; M5 fit", "2 for 2"),
         ("crossing of -1, a = 0.7683", "only M5", "ghost-like part")]
say("Unite value | reproduced by | CHOSEN parameters")
for row in TABLE:
    say(" | ".join(row))
report("the Unite CPL line crosses w = -1 at a", f"{crossing_u}")
```

A short form of the comparison table of Section 22.19: each observed value, what reproduces it, and how many parameters were CHOSEN for it. `" | ".join(row)` writes the three texts of a row with a vertical bar between them. The crossing is printed as the fraction 461/600.

```
check(w0_u == Fraction(-861, 1000) and wa_u == Fraction(-3, 5)
      and crossing_u == Fraction(unite["crossing_of_minus_1"]["a"])
      and crossing_u == Fraction(461, 600),
      "the Unite values and their crossing a = 461/600",
      record=f"{D00}/reports/python-derive-eos.json, check unite_crossing_point")
files = [f"{FIGURE_FOLDER}/{NOTEBOOK_ID}_{number}_{name}.png"
         for name, number in FIGURE_NUMBERS.items()]
check(len(files) == 5 and all(output_file(path).is_file() for path in files),
      "every figure file of this notebook exists")
all_checks_passed()
```

The observed values are the ones `Revision/README.md` quotes, and their crossing is exactly the record's 461/600. `files` rebuilds the names of the saved figures from the dictionary `FIGURE_NUMBERS` of the set-up cell, and the last check requires five of them, all present. The last line prints ALL 28 CHECKS PASSED (notebook 22b).

22.24 What Notebook 22b found, and what remains open for the dark sector

The results. Every number below is printed by the notebook in the cell named, and every one reproduces the Revision record named in the same cell.

result	value	status	where
energy balance $dE/da_4 = -3X$ on the history	relative violation 1.235×10^{-7}	PROVED exactly in the record; COMPUTED here	Out [3]
$w_{\text{eff}}(A,B) = X/E$, $w_{\text{eff}}(C) = X/E - 1$ from the dilution	to 1.7×10^{-8}	PROVED in the record; COMPUTED here	Out [3]
X/E of the gas, all series	0.292893 to 0.328105, rising	COMPUTED (record)	Out [3]
$w_{\text{eff}}(C)$ of the gas	-0.707107 to -0.671895	COMPUTED; rests on the ASSUMED definition C	Out [3]
tangent w_a of the gas	-0.020523 to -0.008894	COMPUTED (record)	Out [4]
bulk-band level, $w_{\text{eff}}(A)$	0.239626 to 2.268×10^{-3}	COMPUTED (record)	Out [5]
condensate ratio at $u = -382/441$	-0.764 exactly	PROVED; u CHOSEN	Out [6]
gas plus condensate, $w_0(C) = -0.861$	share 0.436703, $w_a = 0.067014$	COMPUTED; share CHOSEN	Out [7]
M2, M3, M4 tangents	$w_a = 0.162074$, -0.393926, -0.600	PROVED (record); parameters CHOSEN	Out [8]
M5 fit over $1/2 \le a \le 1$	$(-0.861, -0.600)$	by construction	Out [8]
M5 crossing of -1	$a = 0.77909966367$ (B: 0.77905405)	COMPUTED; needs the ghost-like part	Out [8]

What the results mean. The equations of state that the record finds follow from two things: which quanta are present, and which definition of ρ_4 the observer uses. Neither is fixed by the field equations of the record. Under A and B the theory contains radiation-like content (the computed gas) and dark-matter-like content (the bulk band of dirac16complex, the good-sector gas of dirac16complex00), but the computed states of dirac16complex are only of the first kind. Under C the same content reads like dark energy: the gas between -0.71 and -0.67, a condensate at -1. The observed values are reached only by tuning as many parameters as numbers, and the crossing of -1 only with a component of negative energy. Neither hypothesis is established, and neither is refuted: what the record rules out, under its stated assumptions, is that the computed states of dirac16complex give the observed pair, and that any positive-energy content of dirac16complex00 with real frequencies crosses -1 (within the adiabatic model; for an extra-time mode only before its turning point, past which this is not established).

Why it is hard. The observer's ρ_4 needs a physical argument, not a choice: how a 4-dimensional observer measures energy when three time-like directions shrink. The populations need a dynamical origin: which quanta the early universe made, which is the time-dependent problem (Problem 2) and, beyond it, the creation question (Problem 1). The equation of state must come from the coupled equations, which brings back the back-reaction (Problem 3): no computed Kohn-Sham

state is an admissible source of the author's metric. And the ghost-like and growing modes of dirac16complex00 make its classical energy unbounded below and its initial-value problem ill-posed (Chapter 8).

What remains OPEN (the record's own list, `Revision/docs/DARK_SECTOR_HYPOTHESES.md`, section 10):

1. a self-consistent history $a_4(x_4)$ with an admissible source (no recorded Kohn-Sham state is one; the condensate is an exact source only on the linear member);
2. populated bulk-band or thermal states along the history; only $T = 0$ ground states and $0 \leq a_4 \leq 2$ are computed;
3. modes of dirac16complex with extra-time momentum (outside the good sector), and the non-adiabatic Kohn-Sham problem;
4. for dirac16complex00: sources that depend on x_0, the frozen warp of the adiabatic model, the growing modes, a quantum treatment;
5. which normalisation of ρ_4, if any, describes a physical 3-space observer, and the value of $a_{4,\mathrm{today}}$;
6. what would select the populations of M2 to M5, the mixture shares or the condensate's u;
7. a supernova likelihood (distances, covariances): no fit to data is part of the record.

A first step. (a) Redo the derivations of Sections 22.17 to 22.19 by hand, then change one assumption at a time in Notebook 22b: take today at $a_{4,\mathrm{today}} = 1$ instead of 2 in In [7], or remove the ghost-like part of M5 in In [8] and watch its crossing of -1 disappear (Exercise 14 shows why). (b) Write down a physical model of the observer: for example a 4-dimensional brane-world observer whose energy is the integral over the extra times with a weight derived from the metric, and find which s of Section 22.17 it gives. (c) Populate the bulk band thermally along the history (fixed entropy) with the Kohn-Sham solver of Chapter 15 and compute X/E; this is the record's open item 2.

Where to start. These files of the repository:

- the folder `Revision/dark_sector/dirac16complex` with its README, its four scripts in the subfolders `derive`, `compute` and `independent`, and its outputs and reports;
- the folder `Revision/dark_sector/dirac16complex00` with its README, its two implementations in the subfolder `python`, the model record `eos-theory.json`, and its results and reports;
- the document `Revision/docs/DARK_SECTOR_HYPOTHESES.md`, which states every result with its record;
- the builder of Notebook 22b, `Revision/textbook/notebooks/src/22b_dark_sector.py`.

22.25 Problem 6: matter and antimatter

The question. The universe we observe contains matter and almost no antimatter (Chapter 21 teaches the observations and the measured baryon-to-photon ratio from zero). The author asked that this theory solve the matter-antimatter mysteries. The open problem is whether an extension of the theory could produce the observed excess of matter from a start without excess, and with the measured size.

What is known.

- PROVED: the LOCAL conservation law $\partial_\mu(\cos z\, J^\mu) = 0$ of the U(1) current holds on every solution in the author's metric, for every history $a_4(x_4)$ (`Revision/lead_checks/reports/charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity`). It says that charge is neither made nor destroyed at any point: the charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, d^7x$ of a slice changes only by the flux of $\cos z\, J^\mu$ through the boundary of the slice. NOT proved: that the total charge of one universe is constant. That needs no flux through the brane $z = \pi/2$, a boundary condition that the record does not impose: wherever it is used it is ASSUMED, and whether it holds is OPEN, part of the junction conditions of Problem 4 (Sections 10.2, 18.21 and 21.18 show exact solutions whose charge changes by exactly this flux). Hence no net charge can be generated at any point inside one universe, and the total charge of one universe is constant if no charge flows through the brane.
- PROVED: the charge conjugations are matrices: $\mathcal{C}_+ = C$ (same mass) and $\mathcal{C}_- = \Gamma C$ (mass reversed) (checks `charge_conjugation_matrix_plus` and `charge_conjugation_matrix_minus` of the same report); for a real commuting field the current vanishes identically and $\mathcal{C}_+$ acts as the identity, so the nontrivial real map between matter and antimatter is the matrix Γ with the mass reversed, which is T1 (check `real_fields_charge_conjugation`); for the quantised Grassmann field the conjugation that keeps the canonical anticommutator is $\Psi \to \Gamma \Psi^{\dagger T}$, which reverses the mass (check `quantum_charge_conjugation_unitary_type`). Chapters 5 and 21 derive all of this.
- PROVED: a T1 partner carries the opposite charge, so a T1 pair $\{+m, -m\}$ has total charge zero as classical bilinears (T1d, Chapter 18); for two universes that are quantised independently of each other there is no such cancellation (Q). The idea that our universe has a partner of opposite charge, an anti-universe, belongs to a class of ideas of which one published example is L. Boyle, K. Finn and N. Turok, Phys. Rev. Lett. 121, 251301 (2018). That our universe has such a partner is a HYPOTHESIS.
- The theory as built does NOT solve the matter-antimatter problem: it has no baryons, no process that violates baryon number, no violation of CP, and no computation of a departure from thermal equilibrium.

What would be needed. Sakharov's three conditions (Chapter 21) in an extended theory: processes that violate baryon number; violation of C and of CP; and a departure from thermal equilibrium; and then a computation of the excess that agrees with the measured baryon-to-photon ratio. Every scenario that adds these is a HYPOTHESIS until it is computed and checked.

Why it is hard. The U(1) symmetry of the theory is exact, so inside the patch $0 < z < \pi/2$ no process of the Lagrangian of the record makes a net charge (the local law above); an asymmetry

therefore needs either new terms in the Lagrangian, and with every new term the pairing theorems must be derived again (they hold for the Lagrangian of the record, not for an arbitrary extension), or a flow of charge through the brane $z = \pi/2$, which the record neither excludes nor describes (OPEN; Sections 18.21 and 21.18). For the commuting field dirac16complex00 even such a flow could not produce an average asymmetry from a C-symmetric start unless the condition at the brane itself broke the symmetry $\mathcal{C}_+$ (Proposition 2 of Section 21.5): no such condition is derived. The field dirac16complex is not the field of the baryons of the Standard Model, so even a charge asymmetry of this field would still have to be connected to baryons. A departure from equilibrium needs the time-dependent dynamics of Problem 2, and a quantum computation of rates needs the Krein quantisation of Chapter 10 beyond the good sector.

A first step. (a) List the simplest terms that could be added to the Lagrangian and decide, with the exact matrix methods of the record (the solution of $M(\gamma^a)^* = \pm\gamma^a M$ in `Revision/lead_checks/charge_conjugation_and_u1.py` is the model), which of them break the U(1) and which of the discrete maps ($\mathcal{C}_+$, $\mathcal{C}_-$, Γ, the reflections) they respect. (b) For each such term, derive T1 again and state exactly how it changes. (c) Only then add a departure from equilibrium, with the time-dependent tools of Problem 2, and compute the charge produced from a symmetric start. Each of these steps is labelled HYPOTHESIS until it is done and checked.

Where to start. `Revision/lead_checks/charge_conjugation_and_u1.py` and its report; Chapters 5 and 21 and their notebooks; the pairing record `Revision/pairing/pairing-theory.json`.

22.26 Smaller open items

The table lists further open items that earlier chapters met, with their status and the record that states them.

22.27 What we proved, what we computed, what we assumed

PROVED (exact; each derivation is written out line by line in this chapter; the record checks are named where the Revision record verifies the statement):

statement	where it is verified
a T1 pair as the complete source leaves no real history a_4 in Einstein gravity for $H > 0$ (corollary C1): $(a_4')^2 = -H^2$	`wolfram-a4-report.json`, `einstein_no_vacuum_solution`; `python-a4-report.json`, `einstein_no_vacuum`; lead's report `einstein-gauss-bonnet-a4.json`, `no_vacuum_for_H_positive`; Section 22.4
the Ricci scalar of the author's metric is $R = 6(a_4')^2 - 42H^2$	derived in Section 22.4 from the record's Einstein components; the same R in `python-field-theory.json` (detail of `curvature_nonzero_flat_only_formally`; Wolfram comparison `ricci_scalar`: agree)
the total probability $\langle\chi\|\chi\rangle$ is conserved	`ks-theory-python.json` and `ks-theory-wolfram.json`, `hamiltonian_16_hermitian`; Section 22.6
$K_{mn} = \langle m\|\partial_a h\|n\rangle/(\varepsilon_n - \varepsilon_m)$ for $m \neq n$	`ks-theory-python.json`, `adiabatic_offdiagonal_identity`; Section 22.6, line 6
$\partial_a h = -j\kappa k\sigma_3$ in the free field	`ks-theory-python.json`, `adiabatic_hellmann_feynman`; Section 22.6, line 8
the amplitude equations (lines 1 to 5) and $K_{nn} = 0$ (line 7)	derivations of this book, Section 22.6; no Revision check covers them
the dressing amplitude $\|\alpha_m\| = Q_{0m}$; $Q(A) = A\,Q(1)$	derivations of this book, Section 22.7 ($Q(A) = A\,Q(1)$ read off the record's formula, `ks-theory.json`, key `adiabaticity.measure`); the dressing tested numerically in Notebook 22a, In [14]

statement	where it is verified
in the free field $Q/A = G(q)$ with $q = ke^{-a_{4,0}}$	ks-theory-python.json, rescaling_identity; Section 22.7
the sudden limit $P_{sudden} = 1 - \|\langle\varphi_0(s_2)\|\varphi_0(s_1)\rangle\|^2$, the rate of the smooth passage, the first-order formula for $P^{(1)}$	derivations of this book, Section 22.8; tested numerically in Notebook 22a, In [12] and In [14]
in Einstein gravity every source has $\kappa(\rho + p_0) = -6((a_4')^2 + H^2)$	both a4 reports, einstein_null_energy_x0; lead's report, einstein_null_energy; Section 22.14
the line element in the coordinate y is regular at $y = 0$; the mirror warp $e^{-H\|y\|}$ has a kink, and $\int_{-\epsilon}^{\epsilon} W''\,dy \to -2H$	derived in Section 22.15 from the record's statements (ks-theory-python.json, geometry_warped_form)
$w(1) = w_0$, $w(0) = w_0 + w_a$; the CPL line crosses -1 at $a = 461/600$; $w < -1$ with $\rho > 0$ if and only if $\rho + p < 0$	algebra, Section 22.16; python-derive-eos.json, unite_crossing_point
the proper 7-volume element is $\cos z$, independent of a_4; $dE/da_4 = -3X$	derivation-checks.json, proper_7_volume_element_independent_of_a4, integrated_identity_dE_da4; Section 22.17
$w_{\text{eff}}(A) = w_{\text{eff}}(B) = X/E$ and $w_{\text{eff}}(C) = X/E - 1$ (in general $X/E - s$), for each stated definition of ρ_4	derivation-checks.json, w_eff_A_equals_X_over_E, w_eff_B_equals_w_eff_A, w_eff_C_equals_X_over_E_minus_1, w_eff_general_normaliser; Section 22.17
on the linear member $w_{\text{exp}} = -1$; $w_{\text{eff}}(C) < -1$ if and only if $X/E < 0$	derivation-checks.json, expansion_inferred_w, phantom_condition; Section 22.17
the flat-limit law $w_{\text{eff}} = k^2/(3(M^2a^2 + k^2))$ of a massive quantum	derivation-checks.json, massive_mode_w_eff_law; Section 22.18
the condensate: $X = 0$, $w_{\text{eff}} = 0$ (A, B) and -1 (C); ratio $u/(2 + u)$, equal to -0.764 at $u = -382/441$, phantom exactly for $-2 < u < -1$	derivation-checks.json, condensate_w_eff, condensate_ratio_equal_unite_constant_w; python-derive-eos.json, condensate_phantom_interval; Section 22.18
radiation plus condensate: $w_a = r_0/(3(1 + r_0)^2) > 0$ (freezing)	derivation-checks.json, mixture_radiation_condensate_cpl, mixture_C_matching_w0_unite; Section 22.18
dirac16complex00: modes of both energy signs at every real frequency; in the adiabatic model $\varepsilon_i \geq 0$, and with positive energies of real frequency $w_{\text{eff}}(C) \geq -1$ (for an extra-time mode only before its turning point); the tangents of M2, M3, M4	wolfram-pairing.json, Q_one_particle_Krein_inertia_real_frequencies, and python-pairing.json, Q.one_particle_Krein_inertia_proof (Theorem 10.1, the general statement); python-derive-eos.json, mode_krein_inertia_* (the three test cases), wkb_epsilon_sign_free, M2_tangent_exact, M3_tangent_exact, M4_tangent_equals_unite; Section 22.19
the LOCAL U(1) law $\partial_\mu(\cos z\, J^\mu) = 0$ (a constant total charge needs no flux through the brane: ASSUMED where used, OPEN), the charge-conjugation matrices, T1, T2, Q, T3	Chapters 5, 10 and 18 to 21; charge-conjugation-and-u1.json, pairing and T3 reports; Section 22.25

COMPUTED (numerical, with measured accuracy): from the Revision record, $Q_{max} \leq 0.0935$ for the 75 ground states at $A = 1$, the adiabatically continued state of $N = 696$ above the instantaneous ground state by up to 8.623, the violations of the source conditions (ratios 2.09 to 3.99, closest integrated ratio 0.414), and the agreement of dE/da_4 from finite differences and from the energy-momentum integral (for N688_lam0_a00, -597.9157012757526 against -597.9157012806555). In Notebook 22a (free field, the Fermi-shell sector of $N = 688$): the record's levels and Q reproduced to 10^{-13}; $G^* = 0.09979$ at $q^* = 2.128$; the strongest jump across the gap 0.0489 per unit rate; $P = 0.0138$ at the peak rate 1; $A_{1/2} = 1.508$; the sudden limit 0.0749 (span 0 to 2) and 0.1051 (0 to 6); the breakdown estimates 10.701, 10.021, 2.929 and 1.508; with the errors of Section 22.13. From the dark-sector record (reproduced in Notebook 22b): the Kohn-Sham gas along the prescribed history, X/E from 0.292893 to 0.328105 rising toward 1/3, $w_{\text{eff}}(C)$ from -0.707107 to -0.671895, tangent w_a from -0.020523 to -0.008894, the energy balance on the data to 1.235×10^{-7}; the bulk-band level from 0.239626 to 2.268×10^{-3}; the computed mixture with $w_a = 0.067014$; the M5 fit, its crossing at $a = 0.7791$ and the field-equation implementation B (crossing 0.77905405, agreement with A within 0.00083082726).

ASSUMED: the Z2 brane and the parities it gives; the good sector; the tip (CHOSEN); which levels count as particles (CONVENTION); the history $a_4 = AHx_4$ (PRESCRIBED BACKGROUND); in Notebook 22a the free field ($\lambda = 0$) and one sector; the observer's density ρ_4 (definitions A, B, C) and the value of $a_{4,\text{today}}$; the adiabatic (WKB) model of dirac16complex00, an APPROXIMATION measured by implementation B; every parameter labelled CHOSEN in Sections 22.18 and 22.19 (several of them chosen to reproduce the observed values, so that those matches are NOT predictions); the no-flux condition at the brane wherever a constant total U(1) charge is used; the expansion in instantaneous orbitals, truncated to 20 levels with its convergence measured; the first-order approximations of Sections 22.7 and 22.8, whose range of validity the notebook measures.

HYPOTHESIS: the author's dark-sector hypotheses (investigated by the record, established in neither form; the ghost-like component of M5 is not an established physical state); that our universe has a partner of opposite charge; every scenario of creation or of matter-antimatter asymmetry; the generalised metric of Section 22.14 and the reduced quantum model of Section 22.4 as useful next steps.

OPEN: whether any universe is created, in pairs or otherwise (no creation process, rate, amplitude or big-bang dynamics follows from the equations); the time-dependent Kohn-Sham problem with interaction; the reading of jumps into the negative branch; relaxation through Fermi-level crossings; the back-reaction of the gas on a_4; the junction conditions of the brane; which definition of ρ_4 describes a physical 3-space observer; populated bulk-band or thermal states; what selects the populations of the dark-sector models; a fit to supernova data; whether the total U(1) charge of one universe is constant (no flux through the brane); an asymmetry between matter and antimatter in an extended theory; the extra-time modes beyond the good sector.

22.28 Exercises

Exercise 1. The record's largest Q of the free state N136_lam0_a00 is 0.0851488 at $A = 1$ (Out [5]). (a) What is its naive breakdown rate? (b) What is Q at $A = 5$, and the first-order dressing probability Q^2 there? (c) Can the first-order estimate be trusted at $A = 5$?

Answer. (a) By exact rule 1, $Q(A) = 0.0851488\,A$ reaches 1 at $A = 1/0.0851488 = 11.744$. (b) $Q(5) = 5 \cdot 0.0851488 = 0.425744$ and $Q^2 = 0.181258$. (c) No: first order needs $Q \ll 1$, and 0.43 is

not small. Notebook 22a shows for the free Fermi shell of $N = 688$ what happens at such rates: the exact probability levels off at the sudden limit of about 0.075 over the record's span, while the first-order estimate overshoots (Figure 22a.5). A first-order number of 0.18 is therefore not to be trusted.

Exercise 2. From the row of Out [5] for $N = 688$ at the slice 0 ($\varepsilon_0 = 1.247113$, $\varepsilon_1 = 3.500518$, $Q = 0.0934506$) compute the energy difference, the matrix element $|\langle 0|\partial_a h|1\rangle|$ and $|K_{10}|$. Compare with the record's column `Q_max_matrix_element` (0.4745266881) and with the right panel of Figure 22a.4.

Answer. $\varepsilon_1 - \varepsilon_0 = 2.253405$. From $Q = |\langle 0|\partial_a h|1\rangle|/(\varepsilon_1 - \varepsilon_0)^2$ (Section 22.7, with $A = H = 1$): $|\langle 0|\partial_a h|1\rangle| = Q(\varepsilon_1 - \varepsilon_0)^2 = 0.0934506 \cdot 5.077834 = 0.474527$, which agrees with the record to the seven digits of the inputs. By line 6 of Section 22.6, $|K_{10}| = |\langle 1|\partial_a h|0\rangle|/|\varepsilon_0 - \varepsilon_1| = Q(\varepsilon_1 - \varepsilon_0) = 0.0934506 \cdot 2.253405 = 0.210582$, the starting value of the blue curve on the right of Figure 22a.4.

Exercise 3. Show that the cubic polynomial $p(t)$ with $p(0) = f_0$, $p(h) = f_1$, $p'(0) = f'_0$, $p'(h) = f'_1$ has the value $p(h/2) = (f_0 + f_1)/2 + h(f'_0 - f'_1)/8$ in the middle (the rule of the function `orbitals` in In [4]). Test it on $f(t) = t^3$ with $h = 1$.

Answer. Write $p(t) = f_0 + f'_0 t + ct^2 + dt^3$; this already gives $p(0) = f_0$ and $p'(0) = f'_0$. Put $\Delta = f_1 - f_0 - f'_0 h$ and $\delta = f'_1 - f'_0$. The two conditions at $t = h$ read $ch^2 + dh^3 = \Delta$ and $2ch + 3dh^2 = \delta$. Multiply the first by $3/h$ and subtract the second: $ch = 3\Delta/h - \delta$, so $ch^2 = 3\Delta - \delta h$, and from the first condition $dh^3 = \Delta - ch^2$. Then $p(h/2) = f_0 + f'_0 h/2 + ch^2/4 + dh^3/8 = f_0 + f'_0 h/2 + ch^2/4 + (\Delta - ch^2)/8 = f_0 + f'_0 h/2 + ch^2/8 + \Delta/8$. Insert $ch^2 = 3\Delta - \delta h$: $ch^2/8 + \Delta/8 = \Delta/2 - \delta h/8$. Hence $p(h/2) = f_0 + f'_0 h/2 + (f_1 - f_0 - f'_0 h)/2 - (f'_1 - f'_0)h/8 = (f_0 + f_1)/2 + h(f'_0 - f'_1)/8$. Test: $f_0 = 0$, $f_1 = 1$, $f'_0 = 0$, $f'_1 = 3$: $(0 + 1)/2 + (0 - 3)/8 = 0.5 - 0.375 = 0.125 = (1/2)^3$. Exact, as it must be, because t^3 is itself a cubic.

Exercise 4. Compute the redshifted momenta of the Fermi shell of $N = 136$ at the slice 1.5 and of the Fermi shell of $N = 688$ at the slice 2. Why are their Q in Out [5] (0.0527487 and 0.0528933) nearly equal, and why is the second slightly larger?

Answer. $q = 0.5\, e^{-1.5} = 0.5 \cdot 0.223130 = 0.111565$ and $q = 0.829156\, e^{-2} = 0.829156 \cdot 0.135335 = 0.112214$ (Out [5] prints 0.1116 and 0.1122). By exact rule 2 the free Q/A depends only on q, and the two values of q differ by only 0.6 percent, so the two Q are nearly equal although the shells and the slices are different. In this range $G(q)$ rises with q (the whole recorded range lies left of the top in Figure 22a.2), so the larger q has the slightly larger Q. The band levels behave the same way: 0.204636 and 0.205760.

Exercise 5. The sudden limit of the span $a_{4,0} = 0$ to 2 is $P_{sudden} = 0.074906$ (Out [12]). Compute the overlap $|\langle\varphi_0(2)|\varphi_0(0)\rangle|$ and the angle θ with $\cos\theta$ equal to it. Show that for a particle whose orbital is turned by the angle θ in the plane of two orthonormal orbitals, $P_{sudden} = \sin^2\theta$.

Answer. $|\langle\varphi_0(2)|\varphi_0(0)\rangle| = \sqrt{1 - 0.074906} = \sqrt{0.925094} = 0.961818$, and $\theta = \arccos 0.961818 = 0.27723$ radian, about 15.9 degrees. If the new band orbital is $\varphi_0(2) = \cos\theta\, \varphi_0(0) + \sin\theta\, \varphi_1$ with φ_1 orthonormal to $\varphi_0(0)$, the overlap is $\cos\theta$ and $P_{sudden} = 1 - \cos^2\theta = \sin^2\theta$; here $\sin^2(0.27723) = 0.074906$. The band orbital turns by only about 16 degrees over two e-folds of the extra times.

Exercise 6. Show that $a'_4 = iH$ with $\Lambda = -18H^2$ solves both vacuum equations of Einstein gravity of Section 22.4. Why is it not a history of the author's universe?

Answer. $(iH)^2 = -H^2$. The x_4 equation: $3(-H^2) + 21H^2 - 18H^2 = 0$. The x_0 equation:

$-3(-H^2) + 15H^2 - 18H^2 = 3H^2 + 15H^2 - 18H^2 = 0$. Both hold. But $a_4 = iHx_4 + a_0$ is complex, so the metric components $e^{2a_4}\sin^{1/3} z$ would be complex numbers, and a metric must be real. So there is no real history: this is corollary C1 again.

Exercise 7. The source-condition report gives for N136_lam0_a00 the integrals $\int \rho = 80.2822$, $\int p_3 = 23.8133$, $\int p_t = 0$ (each $2\mathrm{Vol}_7 \int e^{6Hy}(\dots)\,dy$). Use the energy-exchange identity of Section 22.14 to compute dE/da_4, and compare with the record's columns `dE_da4_emt` (-71.43975618) and `dE_da4_finite_difference` (-71.43975618). Do the same for N688_lam0_a00 ($\int p_3 = 199.305$, $\int p_t = 0$). What does the sign mean?

Answer. $dE/da_4 = -3(\int p_3 - \int p_t) = -3 \cdot 23.8133 = -71.4399$, in agreement with both columns to the six digits that the source-condition report prints. For $N = 688$: $-3 \cdot 199.305 = -597.915$, against -597.9157 in the record. The sign: as a_4 grows (the extra times deflate and 3-space inflates), the energy of the gas falls, because its 3-momenta redshift; $p_t = 0$ here because the gas has no kinetic pressure along the extra times. In a coupled solution this energy would have to go into the geometry, which is why the history cannot be the linear member with a constant ρ (Section 22.14).

Exercise 8. For the mirror warp $W(y) = e^{-H|y|}$ with $H = 1$: compute $W(0)$, the slopes $W'(0^-)$ and $W'(0^+)$, and $\int_{-0.01}^{0.01} W''\,dy$. Then show that $\sqrt{|g|} = e^{6Hy}$ in the coordinate y becomes $\cos z$ in the coordinate x_0.

Answer. $W(0) = 1$; $W'(0^-) = 1$, $W'(0^+) = -1$. $\int_{-0.01}^{0.01} W''\,dy = W'(0.01) - W'(-0.01) = -e^{-0.01} - e^{-0.01} = -2e^{-0.01} = -1.980100$, close to $-2H = -2$, and closer still for a shorter interval. For the volume: $\sqrt{|g|}\,dy$ must equal $\sqrt{|g|_{x_0}}\,dx_0$, and $dy = \cot z\,dx_0$, so $\sqrt{|g|_{x_0}} = e^{6Hy}\cot z = \sin z \cot z = \cos z$, using $\sin z = e^{6Hy}$.

Exercise 9. For the CPL values $(w_0, w_a) = (-0.861, -0.60)$ compute w at $a = 1$, $a = 1/2$ and $a \to 0$, and the scale factor at which $w = -1$. Is this thawing or freezing in the convention of Section 22.16? What does $w < -1$ require of a fluid with $\rho > 0$?

Answer. $w(1) = -0.861$; $w(1/2) = -0.861 - 0.60 \cdot 0.5 = -1.161$; $w(0) = -0.861 - 0.60 = -1.461$. $w = -1$ when $0.60(1 - a) = 0.139$, that is $1 - a = 0.231667$ and $a = 0.768$. Since $w_a < 0$ it is thawing in this convention (w rises towards today from below). For $\rho > 0$, $w < -1$ means $\rho + p < 0$ (Section 22.16): the fluid violates the null energy condition. These are statements about the quoted fit; this book claims nothing about whether either field can produce them.

Exercise 10. From Out [17] check the first-order estimate 2.929 of the breakdown rate, and compute how much larger the naive estimate is than the exact $A_{1/2}$ and than the first-order estimate.

Answer. The first-order estimate is the rate at which $(AQ_0)^2 = P_{sudden}$ with $Q_0 = 0.0934506$ and $P_{sudden} = 0.074906$: $A = \sqrt{0.074906}/0.0934506 = 0.273690/0.0934506 = 2.929$. The naive estimate 10.701 is $10.701/1.508 = 7.10$ times the exact $A_{1/2}$ and $10.701/2.929 = 3.65$ times the first-order estimate. Comparing the dressing probability with the largest probability that can leave the level at all is what brings the estimate within a factor of two of the exact evolution.

Exercise 11. (a) The gas N688_lam0 has $X/E = 0.3183$ at $a_4 = 2$ (Out [3]). Give its w_{eff} under the definitions A, B and C, and under the general normalisation of Section 22.17 with $s = 1/2$. (b) Show from $dE/da_4 = -3X$ that a state with $X = E/3$ at every time has $E \propto e^{-a_4}$, and that under A its density thins out like a^{-4}. (c) What does a condensate give under C, and why?

Answer. (a) Under A and B, $w_{\text{eff}} = X/E = 0.3183$; under C, $0.3183 - 1 = -0.6817$; with $s = 1/2$, $0.3183 - 0.5 = -0.1817$. The same state gives three different readings: only the ASSUMED

normalisation changed. (b) With $X = E/3$ the balance reads $dE/da_4 = -E$; the function whose derivative is minus itself is $E = E_0 e^{-a_4}$ (check: $d(E_0 e^{-a_4})/da_4 = -E_0 e^{-a_4}$). Under A, $\rho_4 \propto E\, e^{-3a_4} = E_0 e^{-4a_4}$, and since $a = e^{a_4 - a_{4,\text{today}}}$, $e^{-4a_4} \propto a^{-4}$: radiation, $w = 1/3$. (c) A condensate has $X = 0$, so $dE/da_4 = 0$ and E is constant; under C, $\rho_4 \propto E$ is constant, and $w_{\text{eff}} = -1 - \frac{1}{3} \cdot 0 = -1$: it reads like a cosmological constant (under A and B, $\rho_4 \propto e^{-3a_4} \propto a^{-3}$, like dust).

Exercise 12. For a massive quantum in the flat limit with $M = 1$ and $k = 1$, compute $w_{\text{eff}}(A) = k^2/(3(M^2a^2 + k^2))$ at $a = 0.1$, 1 and 10, the same values under C, and the CPL tangent at $a = 1$ under C. Is it thawing or freezing?

Answer. $w_{\text{eff}}(A) = 1/(3(a^2 + 1))$: at $a = 0.1$, $1/(3 \cdot 1.01) = 0.330033$; at $a = 1$, $1/6 = 0.166667$; at $a = 10$, $1/(3 \cdot 101) = 0.003300$. It falls from radiation toward dust: the dark-matter-like law. Under C: -0.669967, -0.833333, -0.996700. The derivative is $dw/da = -2a/(3(a^2 + 1)^2)$, at $a = 1$ equal to $-2/12 = -1/6$, so $w_0 = -0.833333$ under C and $w_a = -dw/da = +0.166667$ in every definition: freezing (it moves toward -1 as a grows). This is why the bulk band, even if it were populated, would not give the observed thawing slope under C.

Exercise 13. The record mixes the computed gas ($X/E = 0.3182941676741$ at $a_4 = 2$) with a condensate so that $w_{\text{eff}}(C) = -0.861$ today. (a) Compute the gas share of the energy today. (b) For an exactly radiation-like gas ($X/E = 1/3$) the same condition gives $r_0 = 417/583$; what is the gas share then? (c) Why does the computed gas need the larger share?

Answer. (a) The condensate adds energy but no X, so $w_{\text{eff}}(C) = \text{share} \cdot X/E - 1$; setting this to -0.861 gives share $= 0.139/0.3182941676741 = 0.436703$ (Out [7]). (b) With $X/E = 1/3$: share $= 3 \cdot 0.139 = 0.417$, and indeed $r_0/(1 + r_0) = (417/583)/(1000/583) = 417/1000$. (c) The computed gas has $X/E = 0.3183$, a little below $1/3$, so it contributes less X per unit energy, and a larger share of it is needed to reach the same 0.139. In both cases the share is CHOSEN, and the slope comes out positive (0.067014 and 0.081037): freezing, not the observed -0.60.

Exercise 14. Two components of an adiabatic gas of dirac16complex00 have the energy densities $\rho_1 = 0.7$, $\rho_2 = 0.3$ and the values $\varepsilon_1 = 0$ (a condensate), $\varepsilon_2 = 0.5$ (an extra-time mode). (a) Compute $w_{\text{eff}}(C) = \sum_i \varepsilon_i \rho_i / \sum_i \rho_i - 1$. (b) Replace them by $\rho_1 = 1.3$, $\varepsilon_1 = 0$ and a ghost-like component $\rho_2 = -0.3$, $\varepsilon_2 = 1/3$ (the total is again 1); compute $w_{\text{eff}}(C)$. (c) Explain with these numbers why a crossing of -1 needs a component of negative energy.

Answer. (a) $(0 \cdot 0.7 + 0.5 \cdot 0.3)/(0.7 + 0.3) - 1 = 0.15 - 1 = -0.85$. (b) $(0 \cdot 1.3 + \frac{1}{3} \cdot (-0.3))/(1.3 - 0.3) - 1 = -0.1 - 1 = -1.1$: below -1, phantom. (c) With positive weights ρ_i the fraction is an average of the numbers $\varepsilon_i \geq 0$, so it lies between their smallest and largest value and cannot be negative: $w_{\text{eff}}(C) \geq -1$. A negative weight breaks this rule: the "average" -0.1 lies outside the range of the ε_i (0 to 1/3). This is the theorem of Section 22.19 (for components of real frequency), and it is why M5 crosses -1 only because of its ghost-like part, and why the record's M5 without that part does not cross on $1/3 \leq a \leq 1$ (Out [8]). The size of the ghost share is a choice: the record notes that $G = 0.28$ would need $s = 0.726$ and $G = 0.24$ would need $s = 0.921$ (an exploration of the record, not a check), so nothing fixes it.

23 Reproducing everything

23.1 What this chapter does

Every result of this book comes from a file that a program wrote, and every one of those programs can be run again. This chapter gives every command that reproduces the book and the Revision record behind it, in the order in which they depend on each other, for Windows 11 (PowerShell), macOS (zsh) and Linux (bash). For each command it says what the command runs, what it prints when it works, how long it took on the development machine (Windows 11, 24 processor threads), and what to do when it fails. Every time quoted here is a MEASURED time read from a provenance file, from the step table of the Revision gate, or from a run made for this chapter on 2026-10-08, and it is labelled as measured or expected; on another computer the times differ, the results do not.

The chapter's example, Notebook 23a, is the bookkeeping of the whole book. By default it READS the recorded checks of the other 90 notebooks from their provenance files; it does NOT re-run them. It prints a table of every notebook, draws the run times, reads the step table of the Revision gate, and builds the index of every check of every report of the Revision record together with the chapters that cite it. With the environment variable `BOOK_RERUN_ALL` set to `1` it also re-runs every other notebook (Section 23.9 gives its measured time and the commands). The chapter ends with the two indexes of the book (Sections 23.13 and 23.14) and with the glossary.

23.2 The words of this chapter

- **Command**: one line typed into a terminal and run by pressing Enter. A **terminal** is the window in which commands are typed: on Windows the app Windows PowerShell or Terminal, on macOS the app Terminal (its shell is zsh), on Linux any terminal (its shell is bash).
- **Repository**: the folder Dirac_claude with every file of this project, downloaded with the program Git. The **repository root** is that folder itself; every command of this chapter is typed there.
- **Verifier** and **checker**: a program of the Revision record that recomputes a result (exactly, with Wolfram or with sympy, or numerically, with Rust or Python) and writes a **report**: a JSON file that lists named **checks**, each with a **verdict** such as PASS.
- **Gate**: the script `Revision/verify_revision.sh` (for bash) and its twin `Revision/verify_revision.ps1` (for PowerShell 7). It re-runs every verifier and checker in **dependency order** (a program that reads the output of another runs after it), then demands that every committed output is unchanged byte for byte and that every report passes.
- **Step**: one command of the gate, with a name such as `algebra-wolfram`. A **long step** is one documented as longer than 5 minutes, or one that needs such a step (`ks-rust-determinism`, 30 s, needs the refined run).
- **Builder**: the Python file `Revision/textbook/notebooks/src/NNx_name.py` from which the tool `nbkit` builds Notebook NNx.
- **nbkit check**: re-executing a notebook into a scratch folder and comparing the result byte for byte with the stored notebook, its files and its provenance file. A **scratch folder** is a folder for throw-away files.

- **Provenance file**: `NNx_name.PROVENANCE.md`, next to each notebook. Its last line records the measured facts of the notebook's last verified run, among them the date, result and seconds of its last nbkit check.
- **Assembly**: joining the 24 chapter files, with every notebook expanded, into the one file `Revision/textbook/UNIVERSES_IN_PAIRS_TEXTBOOK.md`.
- **Wall time**: the time a clock on the wall shows between the start and the end of a command.
- **Environment variable**: a named piece of text that a terminal hands to every program it starts.

23.3 What you need, and the set-up in every new terminal

The notebooks need Git and Python 3.12 or newer with the nine pinned packages; the run-instruction section before every notebook of this book gives the complete installation for the three systems, and the installation commands are repeated here so that this chapter can be followed on its own. Install Git and Python as described there, then download the repository, create the private environment `dirac-book-env` and install the packages:

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

macOS (zsh) and Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

In every new terminal, activate the environment and go to the repository root before any command of this chapter:

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

The Revision gate needs four more programs, which the notebooks do not need.

- **Rust** (the command `cargo`), for the Rust programs of the GKD and Kohn-Sham records and for the notebooks that run them: install it from https://rustup.rs and open a new terminal.
- **WolframScript** (the command `wolframscript`), for the exact Wolfram verifiers. It must be installed AND activated by you, with your own Wolfram licence; the gate never activates it.
- **pdflatex**, for the six documents of the Revision record and for the book's PDF: on Windows MiKTeX (https://miktex.org), on macOS MacTeX (https://tug.org/mactex), on Linux the TeX Live packages of your distribution.
- On Windows, **PowerShell 7** (the command `pwsh`), from https://aka.ms/powershell, for the PowerShell twin of the gate; Git for Windows also brings bash, so the bash form of the gate works there too.

23.4 The order of everything

The five stages below must be run in this order, because each reads what the stages before it wrote and checked.

1. The Revision record: the gate re-runs every verifier and checker (Section 23.5).
2. The notebooks of the book: each nbkit check re-executes one notebook (Section 23.6). The notebooks read the committed Revision record, so they come after it.
3. Notebook 23a: it reads the provenance files of all other notebooks and the reports of the Revision record, so it comes after both (Sections 23.9 to 23.12).
4. The assembly of the book from its chapters and notebooks (Section 23.7).
5. The PDF of the book, built from the assembled file (Section 23.7).

Stages 1 and 2 only VERIFY: they change no committed file when everything agrees. Stages 4 and 5 rewrite the book's files; run them only when you have changed a chapter or a notebook.

23.5 Stage 1: the Revision gate, step by step

First look at what the gate would do, without running anything. The option dry-run prints every selected step with its expected wall time and its command, and the last line `revision_verific ation=NOT-RUN`:

Windows (PowerShell 7):

```
pwsh -NoProfile -File Revision/verify_revision.ps1 --dry-run
```

macOS (zsh), Linux (bash), and Git Bash on Windows:

```
bash Revision/verify_revision.sh --dry-run
```

The full gate is the same command without any option; the fast option skips the long steps; the option steps runs only the named steps (the two audits `committed-unchanged` and `reports-pass` always run):

```
bash Revision/verify_revision.sh
bash Revision/verify_revision.sh --fast
bash Revision/verify_revision.sh --steps algebra-wolfram,algebra-sympy
pwsh -NoProfile -File Revision/verify_revision.ps1
pwsh -NoProfile -File Revision/verify_revision.ps1 --fast
pwsh -NoProfile -File Revision/verify_revision.ps1 --steps algebra-wolfram,algebra-sympy
```

What it runs. Notebook 23a writes the gate's complete step table to the data file `Revision/textbook/data/23a_gate_steps.csv`, one line per step with its expected wall time and the program it runs, prints its long steps and audits in Out [9] of Section 23.11, and draws the whole table as Figure 23a.6. In order, the 85 steps are these groups.

- **The algebra** (2 steps, expected 10 s and 5 s): the author's gamma matrices, C, Gamma and B, exactly with Wolfram (`verify_algebra.wls`) and with sympy (`check_algebra.py`); Chapters 4 and 5.
- **GKD and the Lovelock tensors** (10 steps): the Rust program `lovelock_gkd` is built (60 s), computes the curvature and the three Lovelock tensors of the metric with b_4 (15 s) and runs its exhaustive self-test (900 s, long, the longest step); Wolfram (110 s) and sympy (30 s) verify the result; four steps read the author's notebook and one compares it with the record (10 s, 5 s, 10 s, 120 s, 60 s); Chapter 11.
- **The metric with b_4** (5 steps): the author's notebook `Dirac_Einstein-Lovelock_4+4_Nash.nb` must be the pinned version (5 s); its stored outputs for the metric with b_4 are extracted (10 s); Wolfram (90 s) and sympy (40 s) recompute the curvature and the Lovelock tensors with b_4 and compare them with those outputs; and the vacuum theorem for the author's weights is proved (10 s); Chapters 3 and 12.
- **The field theory** (10 steps): the Lagrangians, field equations, energy-momentum tensor and quantisation with Wolfram (310 s, long) and sympy (240 s), the scope checks with Wolfram (60 s) and sympy (5 s), a comparison of the two (2 s), and the energy-momentum tensor operator for $\lambda \neq 0$ in a finite Fock model (10 s); then the field theory in the metric with b_4 with Wolfram (15 s), its energy-momentum tensor for the commuting and the Grassmann field (190 s and 110 s) and sympy (5 s); Chapters 6 to 10.
- **The pairing theorems** (2 steps): Wolfram (280 s) and sympy (240 s); Chapter 18.
- **The a4 equations** (6 steps): Wolfram (70 s) and sympy (30 s), the block of the equations with b_4 (35 s), the Kohn-Sham source conditions (5 s), the a4 equations with the Kohn-Sham source (20 s) and its unit tests (30 s); Chapters 12 and 17.

- **The Kohn-Sham record** (24 steps): the theory with Wolfram and sympy (60 s each), its statements for the metric with b_4 (5 s) and the consequences of b_4 (5 s); the Rust solver built and tested (60 s each); the canonical matrix (250 s), the Mermin roots (30 s), a repeat run (250 s) and its byte comparison (5 s), a refined run (330 s, long) and the determinism report (30 s, long because it needs the refined run); the Python reference solver in four parts (240 s, 235 s, 265 s, 270 s) and the step that joins them (5 s), the refinement measurement (90 s), the repeat run of the reference solver for the cross-check, again in four parts (240 s, 235 s, 265 s, 270 s), the cross-check (25 s) and the study of the tip cutoff L (200 s); Chapters 14 to 16.
- **T3 and its completion** (6 steps): Wolfram (15 s, 20 s) and sympy (10 s, 10 s), and the two numerical demonstrations with the Rust solver (285 s) and the reference solver (170 s); Chapter 19.
- **The dark sector** (7 steps): four for dirac16complex (10 s, 150 s, 5 s, 180 s) and three for dirac16complex00 (30 s each); Chapter 22.
- **The lead's checks** (3 steps): the energy-momentum divergence (10 s), Einstein-Gauss-Bonnet (20 s) and the charge-conjugation matrices with the local U(1) law (15 s); Chapters 9, 12 and 21.
- **The Revision notebooks** (1 step, 90 s): every notebook of `Revision/notebooks` is audited and checked.
- **The six documents** (6 steps, 30 s each): each PDF is rebuilt in verify mode.
- **The audits** (3 steps): `committed-unchanged` (10 s) demands that no committed output changed; `reports-pass` (5 s) reads every report of the step table and demands that every check passes; `unit-tests` (150 s) runs the Revision unit tests, except the textbook test, which has its own build.

How long it takes. Out [9] adds up the step table: the expected wall time of the full gate is 8057 s, that is 2.24 hours, of which the 4 long steps take the difference to the time of the fast option, which skips them (Figure 23a.6); with the fast option the expected times add up to 6487 s (108.1 minutes). The README of the Revision record states the MEASURED time of the fast option on 2026-10-08, when it had 55 steps, as about 20 minutes (most steps ran faster than the expected times of the table) and expects about 3.1 hours for the full gate.

What it prints when it works. First the tools it found (`revision_tool_python=...` and, when needed, cargo, wolframscript, git and pdflatex), then `revision_selected_steps=85 expected_seconds=8057 skipped_steps=0` (with the fast option: 81 steps, 6487 s, 4 skipped, each skipped step named on a line `revision_skipped_step=...`), then the precheck line `revision_output_paths=... preexisting_changes=0`. For every step it prints `revision_step=NAME expected_seconds=N`, the step's own output, `revision_step_seconds=NAME n (expected N)` and `revision_step_ok=NAME`. The step `reports-pass` prints one line `revision_report=PATH checks=k/k passed` per report. The last two lines are `revision_gate_seconds=...` and

```
revision_verification=OK
```

Every step's complete output is also written to a log file `build/logs/revision/STEP-bash.log` (or `STEP-pwsh.log`); the folder `build/` is ignored by Git.

When it fails. The gate stops at the first failing step and prints `revision_failed_step=NAME`, `revision_failed_log=PATH` and `revision_verification=FAILED`. Open the log file it names and read its last lines. The most likely causes:

- `revision_failed_step=tools` with "wolframscript was not found", "cargo was not found" or "pdflatex was not found": install the program (Section 23.3), open a new terminal and run the gate again; for WolframScript, also activate it with your licence.
- A Wolfram step whose log shows a licence or kernel-limit message: the gate retries it after 30 s, at most 3 times; if it still fails, close other Wolfram sessions and run that step alone with the option steps.
- `revision_failed_step=precheck`: an output file of a selected step already differs from the committed version, and the gate refuses to overwrite your work. Run it in a fresh clone of the repository, or leave those steps out with the option steps.
- `revision_failed_step=committed-unchanged`: a verifier wrote an output that differs from the committed one; the lines `revision_changed_output=PATH` name the files. Run `git diff` on them to see the difference; this is a real disagreement with the record and must be reported, not hidden.

23.6 Stage 2: every notebook of the book

One command checks all notebooks of one chapter. The first line of each pair below names the folder of the builders; the second runs nbkit check on the builders of chapter 00 into the scratch folder `book-check` in your home folder. For another chapter, replace `00` by its two-digit number, `01` to `23`.

Windows (PowerShell):

```
$builders = (Get-ChildItem Revision/textbook/notebooks/src/00*.py).FullName
python Revision/textbook/tools/nbkit.py check $builders --scratch "$HOME\book-check"
```

macOS (zsh) and Linux (bash):

```
src=Revision/textbook/notebooks/src
python Revision/textbook/tools/nbkit.py check $src/00*.py --scratch ~/book-check
```

To check every notebook of the book, one after the other, give the folder itself:

Windows (PowerShell):

```
$src = "Revision/textbook/notebooks/src"
python Revision/textbook/tools/nbkit.py check $src --scratch "$HOME\book-check"
```

macOS (zsh) and Linux (bash):

```
src=Revision/textbook/notebooks/src
python Revision/textbook/tools/nbkit.py check $src --scratch ~/book-check
```

What it prints when it works. For each notebook NNx four lines, for example for the first notebook

```
check_00a_compared_files=4
check_00a_seconds=3.6
check_00a_peak_mb=174.0
check_00a=PASSED
```

(the seconds and megabytes differ from run to run), and at the end `nbkit_seconds=...` and `nbkit=OK`. The number of compared files counts the notebook itself together with the files it writes: Notebook 00a writes three files, so nbkit compares $3 + 1 = 4$ files with the stored ones. A check changes no file of the repository.

How long it takes. The recorded check times of the notebooks of each chapter, added up, are printed by Notebook 23a in Out [6] of Section 23.11 and drawn in Figure 23a.5. On the development machine the Kohn-Sham chapters 14, 15 and 16 take the most, 88.1 s, 240.4 s and 121.2 s; chapter 11 takes 48.0 s (Notebook 11a only 7.6 s: it reads the record of the Rust GKD self-test, whose run takes 7 to 13 minutes, instead of running it); every other chapter takes between 9.8 s (chapter 17) and 87.2 s (chapter 6). All 90 notebooks of chapters 0 to 22 take 1097.9 s, about 18 minutes, one after the other (Out [6]); Notebook 23a adds about 6.5 s (its recorded check). The seven notebooks that run a Rust program (11a, 11b, 15a, 15b, 15d, 16a and 19a) build it with cargo the first time, which takes a few minutes more.

When it fails. A failed check prints `check_NNx=FAILED` and, before it, lines that start with `problem=`. The most likely causes:

- A problem line saying that the notebook differs from the stored one: the new execution printed something else than the stored one. The new notebook is in the scratch folder, in the subfolder named after the notebook; compare it with the stored one (the line after the problem shows the first difference). A different package version is the usual cause: install exactly the pinned versions (Section 23.3).
- `cargo was not found`: install Rust (Section 23.3) and open a new terminal.
- A problem line saying that the provenance file differs from the provenance regenerated from its own record: someone edited the provenance file by hand or rebuilt the notebook without its provenance; rebuild the notebook with `nbkit.py build` and the date of the verified execution.

23.7 Stages 4 and 5: assembling the book and building its PDF

The assembler checks the whole book and compares it with the stored file, without writing anything, with the first command below; the second command writes the book's Markdown file `Revision/textbook/UNIVERSES_IN_PAIRS_TEXTBOOK.md`. The commands are the same in PowerShell, zsh and bash:

```
python Revision/textbook/tools/assemble_textbook.py --check
python Revision/textbook/tools/assemble_textbook.py
```

It checks every rule of the book's format: every reference "Chapter N" and "Section N.M" resolves, no section number repeats, every notebook marker resolves to an executed notebook and is preceded by its run instructions, every figure file exists, every code line fits. It prints one line `check_NAME=true` per check, then the measurements (`measurement_chapters=24`, the numbers of sections, notebooks, figures and lines, `measurement_pages=...`), `failed_check_count=0`, `output=...` and finally `textbook_assembly=OK`. A failed check prints `problem=...` lines that name the chapter, the reference or the file, and the last line `textbook_assembly=FAILED`. On the development machine the check took about 4 seconds (measured 2026-10-08).

The PDF is built from the assembled file with one command. In PowerShell, the first three lines put the parts of the command into variables (a list of texts after `=` is passed to the program as separate words), and the fourth runs it; in zsh and bash, the backslash at the end of a line continues the command on the next line:

Windows (PowerShell):

```
$book = "Revision/textbook/UNIVERSES_IN_PAIRS_TEXTBOOK.md"
$layout = "--developer-layout", "--number-sections-from-zero", "--wide-page-numbers"
$more = "--specifications", "Revision/pdf-specifications.json", "--date", "October 2026"
python scripts/build_provenance_pdf.py $book $layout $more
```

macOS (zsh) and Linux (bash):

```
python scripts/build_provenance_pdf.py Revision/textbook/UNIVERSES_IN_PAIRS_TEXTBOOK.md \
    --developer-layout --number-sections-from-zero --wide-page-numbers \
    --specifications Revision/pdf-specifications.json --date "October 2026"
```

Without further options it builds in VERIFY mode: it builds the PDF twice, demands that the two builds are byte for byte identical and that pdflatex printed no warning, and compares the result with the edition `universes-in-pairs-textbook` registered in `Revision/pdf-specifications.json` (the registry entry holds the page count of the PDF and its sha256, a fingerprint of its bytes). The option date sets the date printed under the title, so it is part of the PDF: the comparison succeeds only with the date with which the registered edition was built. The book's edition is built with the date "October 2026", as in the commands above; without the option the builder prints its default date, "September 2026", and the PDF then differs from the edition built with October. With the option register added at the end it records a changed book as the new edition. It needs pdflatex. When it works it prints one line `check_NAME=true` per check, the measurements (among them the page count), `failed_check_count=0` and the last line `provenance_pdf=OK`; any LaTeX warning (an overfull line, a figure too large for a page) is printed and fails the build, and the message names the line of the `.tex` file, which belongs to the chapter text at the same place.

To try the PDF build without touching the registered book, `check_chapter.py` builds one chapter, or with the option book all chapters, into a scratch folder with a throw-away copy of the registry:

Windows (PowerShell):

```
$chapter = "Revision/textbook/chapters/23-reproducing-everything.md"
python Revision/textbook/tools/check_chapter.py $chapter --scratch "$HOME\book-pdf"
python Revision/textbook/tools/check_chapter.py --book --scratch "$HOME\book-pdf"
```

macOS (zsh) and Linux (bash):

```
chapter=Revision/textbook/chapters/23-reproducing-everything.md
python Revision/textbook/tools/check_chapter.py $chapter --scratch ~/book-pdf
python Revision/textbook/tools/check_chapter.py --book --scratch ~/book-pdf
```

It prints `chapter_check=OK` when the chapter builds without any problem and warning. A test build of the whole book made in this way on 2026-10-08, with the chapters as they stood that day, took 287 s for its first pass (two complete pdflatex builds of a book of 6289 pages, compared byte for byte), and that pass ended FAILED: pdflatex printed warnings for the text of other chapters as it stood then, so the second, verify pass, which repeats the builds, did not run. A warning-free build of the whole book had not yet been measured when this chapter was written.

23.8 What to do when something fails: the general rules

1. Read the LAST lines first: every tool of this chapter ends with one line that says OK or FAILED, and the lines just before it say why.
2. Make sure the environment is active (the prompt starts with `(dirac-book-env)`) and that you are in the repository root; most "file not found" messages come from a terminal in another folder.
3. Install exactly the pinned versions; a newer matplotlib draws a figure with different bytes, and a byte comparison then fails although the physics is the same.
4. Run the failing piece alone: one gate step with the option steps, one notebook with one nbkit check.
5. Never "fix" a failure by editing a report, a provenance file or a stored notebook by hand. A difference between a fresh run and the record is a finding; report it.

23.9 Example: the bookkeeping of the whole book (Notebook 23a)

Notebook 23a collects in one place what the other notebooks and the Revision record have recorded. By default it re-runs nothing: every table and figure it shows is read from files. It reads the provenance file of every other notebook and prints a table of all 90 with their checks, figures, last recorded check and section of the book; it adds them up per chapter and draws five figures of the counts and times; it reads the step table of the gate and draws its expected times; and it builds the index of the 1357 checks of the 51 reports of the Revision record, with the chapters that cite each, and writes it to a data file. With `BOOK_RERUN_ALL=1` its thirteenth part, "Re-running every notebook", re-runs the nbkit check of every other notebook, at most 8 at a time and the slowest first, into a scratch folder in the system's temporary folder, and prints the fresh results per chapter. On the development machine (24 threads, so 8 notebooks at a time) that re-run took 406 s of wall

time on 2026-10-08 (the whole notebook, run headless, 414 s), and all 90 notebooks passed. To run it, set the variable in the terminal and run the notebook headless, writing the executed copy into the folder `book-rerun` of your home folder (so that the stored notebook is not overwritten); afterwards remove the variable again:

Windows (PowerShell):

```
$nb = "Revision/textbook/notebooks/23a_reproduce_everything.ipynb"
$options = "--to", "notebook", "--execute", "--ExecutePreprocessor.timeout=3600"
$env:BOOK_RERUN_ALL = "1"
python -m nbconvert $options --output-dir "$HOME\book-rerun" $nb
Remove-Item Env:BOOK_RERUN_ALL
```

macOS (zsh) and Linux (bash):

```
nb=Revision/textbook/notebooks/23a_reproduce_everything.ipynb
BOOK_RERUN_ALL=1 python -m nbconvert --to notebook --execute \
    --ExecutePreprocessor.timeout=3600 --output-dir ~/book-rerun $nb
```

(In zsh and bash, a variable written before a command on the same line holds only for that command.) It prints `[NbConvertApp] Writing ... bytes to ...`; the fresh table is in the executed copy, which you open in JupyterLab, and in the file `fresh_results.csv` whose path the notebook prints. To use JupyterLab directly instead, set the variable in the terminal first and then start JupyterLab from that same terminal.

23.10 How to run Notebook 23a

Step 1. What this notebook does and what it needs.

Notebook 23a (Reproducing everything: every notebook, every check, the gate) is the file `Revision/textbook/notebooks/23a_reproduce_everything.ipynb` of the repository Dirac_claude. It reads the recorded nbkit check of every other notebook of the book from its provenance file (by default it does NOT re-run the other notebooks), prints a table of every notebook with its title, number of checks, number of figures, the date, result and seconds of its last recorded check and the section of the book where it is printed, and draws the run times; it reads the step table of the Revision gate with the expected wall time of every step; and it builds the index of every check of every report of the Revision record, with its verdict and the chapters that cite it, written to a data file. With the environment variable BOOK_RERUN_ALL set to 1 it also runs the nbkit check of every other notebook, several at a time, into a scratch folder in the system temporary folder, and tabulates the fresh results. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private

Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 23a_reproduce_everything.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 23a_reproduce_everything.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 23a_reproduce_everything.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- Revision/textbook/figures/23a.captions.json
- Revision/textbook/figures/23a_1_check_time_per_notebook.png
- Revision/textbook/figures/23a_2_cumulative_check_time.png
- Revision/textbook/figures/23a_3_checks_per_chapter.png
- Revision/textbook/figures/23a_4_figures_per_chapter.png
- Revision/textbook/figures/23a_5_check_time_per_chapter.png
- Revision/textbook/figures/23a_6_gate_step_times.png
- Revision/textbook/data/23a_notebooks.csv
- Revision/textbook/data/23a_check_index.csv
- Revision/textbook/data/23a_gate_steps.csv

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every file this notebook writes exists
ALL 10 CHECKS PASSED (notebook 23a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file Revision/textbook/notebooks/23a_reproduce_everything.ipynb inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 23a_reproduce_everything.ipynb
python -m nbconvert --execute --inplace 23a_reproduce_everything.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The last section prints that no other notebook was re-run: that is the default. To re-run every other notebook, set the environment variable BOOK_RERUN_ALL to 1 in the terminal, start JupyterLab or the headless run from that same terminal, and run the notebook again. Unset it afterwards.

```
$env:BOOK_RERUN_ALL = "1"      (Windows PowerShell)
export BOOK_RERUN_ALL=1          (macOS zsh, Linux bash)
```

- With BOOK_RERUN_ALL set to 1, the notebooks that run a Rust program fail: install Rust from https://rustup.rs, open a new terminal, activate the environment and run the notebook again; the first build of each Rust program takes a few minutes. On the development machine the re-run of all other notebooks took 406 seconds of wall time, 8 notebooks at a time.

23.11 Notebook 23a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/23a_reproduce_everything.ipynb`: every cell in order, with the output that the stored, executed

notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This book has one executed notebook for every worked example. Each notebook has a
provenance file next to it, and the last line of that file records the most recent
verified check of the notebook: the tool ‘nbkit‘ executed the notebook a second time
into a scratch folder and compared everything it produced, byte for byte, with the
stored copy. This notebook collects those records and the check reports of the
Revision record into the tables of the last chapter:

- a table of every other notebook of the book: its id, title, number of checks,
  number of figures, the date, result and seconds of its last RECORDED check, and
  the section of the book where its run instructions are printed;
- the totals per chapter, and five figures of the counts and the run times;
- the step table of the Revision gate ‘Revision/verify_revision.sh‘ (the script that
  re-runs every verifier of the Revision record), with the expected wall time of
  every step, and a sixth figure;
- the index of the checks: every check of every report of the Revision record, its
  verdict and the chapters that cite it, written to a data file.

By DEFAULT this notebook does NOT re-run the other notebooks: it reads what their
provenance files record. Only when the environment variable ‘BOOK_RERUN_ALL‘ is set
to ‘1‘ does its last computing section run the check of every other notebook
again, several at a time, and print the fresh results. Notebook 23a does not list
itself: its own record changes every time it is built.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 23a (Reproducing everything: every notebook, every check, the gate) is the file
‘Revision/textbook/notebooks/23a_reproduce_everything.ipynb‘ of the repository
Dirac_claude. It reads the recorded nbkit check of every other notebook of the book from
its provenance file (by default it does NOT re-run the other notebooks), prints a table
of every notebook with its title, number of checks, number of figures, the date, result
and seconds of its last recorded check and the section of the book where it is printed,
and draws the run times; it reads the step table of the Revision gate with the expected
wall time of every step; and it builds the index of every check of every report of the
Revision record, with its verdict and the chapters that cite it, written to a data file.
With the environment variable BOOK_RERUN_ALL set to 1 it also runs the nbkit check of
every other notebook, several at a time, into a scratch folder in the system temporary
folder, and tabulates the fresh results. It needs a computer with Windows 11, macOS or
Linux, an internet connection for the installation, the program Git, and Python 3.12 or
newer (the notebooks were built with Python 3.14.5) with these packages at exactly these
```

versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 23a_reproduce_everything.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 23a_reproduce_everything.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 23a_reproduce_everything.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/23a.captions.json‘
- ‘Revision/textbook/figures/23a_1_check_time_per_notebook.png‘
- ‘Revision/textbook/figures/23a_2_cumulative_check_time.png‘
- ‘Revision/textbook/figures/23a_3_checks_per_chapter.png‘
- ‘Revision/textbook/figures/23a_4_figures_per_chapter.png‘
- ‘Revision/textbook/figures/23a_5_check_time_per_chapter.png‘
- ‘Revision/textbook/figures/23a_6_gate_step_times.png‘
- ‘Revision/textbook/data/23a_notebooks.csv‘
- ‘Revision/textbook/data/23a_check_index.csv‘
- ‘Revision/textbook/data/23a_gate_steps.csv‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every file this notebook writes exists
ALL 10 CHECKS PASSED (notebook 23a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/23a_reproduce_everything.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 23a_reproduce_everything.ipynb
      python -m nbconvert --execute --inplace 23a_reproduce_everything.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- The last section prints that no other notebook was re-run: that is the default. To re-run every other notebook, set the environment variable BOOK_RERUN_ALL to 1 in the terminal, start JupyterLab or the headless run from that same terminal, and run the notebook again. Unset it afterwards.

      $env:BOOK_RERUN_ALL = "1"   (Windows PowerShell)
      export BOOK_RERUN_ALL=1   (macOS zsh, Linux bash)

- With BOOK_RERUN_ALL set to 1, the notebooks that run a Rust program fail: install Rust from https://rustup.rs, open a new terminal, activate the environment and run the notebook again; the first build of each Rust program takes a few minutes. On the development machine the re-run of all other notebooks took 406 seconds of wall time, 8 notebooks at a time.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 23a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 23a (Reproducing everything: every notebook, every check, the gate) is the
# file Revision/textbook/notebooks/23a_reproduce_everything.ipynb of the repository
# Dirac_claude. It reads the recorded nbkit check of every other notebook of the book
# from its provenance file (by default it does NOT re-run the other notebooks), prints a
# table of every notebook with its title, number of checks, number of figures, the date,
# result and seconds of its last recorded check and the section of the book where it is
# printed, and draws the run times; it reads the step table of the Revision gate with the
# expected wall time of every step; and it builds the index of every check of every
```

```
# report of the Revision record, with its verdict and the chapters that cite it, written
# to a data file. With the environment variable BOOK_RERUN_ALL set to 1 it also runs the
# nbkit check of every other notebook, several at a time, into a scratch folder in the
# system temporary folder, and tabulates the fresh results. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
```

```
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
```

```
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 23a_reproduce_everything.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 23a_reproduce_everything.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 23a_reproduce_everything.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/23a.captions.json
# - Revision/textbook/figures/23a_1_check_time_per_notebook.png
# - Revision/textbook/figures/23a_2_cumulative_check_time.png
```

```
# - Revision/textbook/figures/23a_3_checks_per_chapter.png
# - Revision/textbook/figures/23a_4_figures_per_chapter.png
# - Revision/textbook/figures/23a_5_check_time_per_chapter.png
# - Revision/textbook/figures/23a_6_gate_step_times.png
# - Revision/textbook/data/23a_notebooks.csv
# - Revision/textbook/data/23a_check_index.csv
# - Revision/textbook/data/23a_gate_steps.csv
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every file this notebook writes exists
#     ALL 10 CHECKS PASSED (notebook 23a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/23a_reproduce_everything.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 23a_reproduce_everything.ipynb
#     python -m nbconvert --execute --inplace 23a_reproduce_everything.ipynb
```

```
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - The last section prints that no other notebook was re-run: that is the default. To
#   re-run every other notebook, set the environment variable BOOK_RERUN_ALL to 1 in the
#   terminal, start JupyterLab or the headless run from that same terminal, and run the
#   notebook again. Unset it afterwards.
#     $env:BOOK_RERUN_ALL = "1"      (Windows PowerShell)
#     export BOOK_RERUN_ALL=1          (macOS zsh, Linux bash)
# - With BOOK_RERUN_ALL set to 1, the notebooks that run a Rust program fail: install
#   Rust from https://rustup.rs, open a new terminal, activate the environment and run
#   the notebook again; the first build of each Rust program takes a few minutes. On the
#   development machine the re-run of all other notebooks took 406 seconds of wall time,
#   8 notebooks at a time.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)

Text cell:

```
## 3. The words used in this notebook

- **Builder**: the Python file ‘Revision/textbook/notebooks/src/NNx_name.py‘ that
  defines the cells of notebook NNx; the tool ‘nbkit‘ builds the notebook from it.
- **nbkit check**: the command ‘python Revision/textbook/tools/nbkit.py check
  BUILDER‘. It executes the notebook again into a scratch folder and compares the
  notebook, every file it writes and its provenance file byte for byte with the
  stored ones; it prints ‘check_NNx=PASSED‘ or ‘check_NNx=FAILED‘.
- **Provenance file**: ‘NNx_name.PROVENANCE.md‘, next to each notebook; its last line,
  an HTML comment that starts with the word ‘nbkit-record‘, holds the measured facts
  of the last verified run, written in JSON.
```

- **JSON**: a text format for numbers, strings, lists and tables of named values.
- **CSV**: a text table, one row per line, the cells separated by commas.
- **Wall time**: the time on a clock on the wall, from start to finish, in seconds.
- **Report**: a JSON file of the Revision record that holds a list (or table) of named checks, each with a verdict such as PASS.
- **Gate**: the script `Revision/verify_revision.sh` (and its twin `Revision/verify_revision.ps1`) that re-runs every verifier and checker of the Revision record in dependency order.
- **Cite**: a chapter cites a check when one paragraph of the chapter, or the output of one code cell of one of the chapter's notebooks, names both the check and the file name of its report.
- **Environment variable**: a named text value that a terminal hands to every program it starts; `BOOK_RERUN_ALL` is one.

Text cell:

```
## 4. The physical and mathematical situation

Nothing in this notebook is physics: it is bookkeeping, and every number it prints is
COUNTED from files of the repository. The seconds are those MEASURED by nbkit on the
development machine (Windows 11, 24 threads) and recorded in the provenance files;
the gate's times are the EXPECTED wall times written in its step table. On another
computer the times differ, but the counts, the verdicts and the results do not.
```

Text cell:

```
## 5. The provenance record of every notebook

The next cell reads every provenance file of the folder of notebooks, except the
one of this notebook. From each it takes the title, the number of checks (from the
line `ALL n CHECKS PASSED`) and the recorded check; from the notebook's caption file
it counts the figures. It then checks that builders and provenance files match one
to one, that every recorded check passed, and that every figure file exists.
```

In [2]:

```
import csv  # reads and writes comma-separated tables
import re  # regular expressions: patterns that find pieces of text

NOTEBOOKS = repository_file("Revision/textbook/notebooks")  # notebooks and records
RECORD = re.compile(r"nbkit-record (\{.*\}) -->")  # the record line

PASS every figure named in a caption file exists
```

Text cell:

```
## 6. Where each notebook is printed in the book

A notebook is placed in its chapter by a marker line: an HTML comment that holds the
word ‘NOTEBOOK‘ and the notebook's id, such as ‘NOTEBOOK 03b‘. The book's assembler
replaces the marker by two new sections: the run instructions,
numbered one more than the last section heading ‘### N.M‘ before the marker, and
then the complete text of the notebook. The next cell reads chapters 0 to 22 (this
chapter 23 is left out, so that its own text cannot change the results), finds
every marker and the heading before it, and checks that every notebook is placed
exactly once, in the chapter of its own number.
```

In [3]:

```
CHAPTERS = [path for path in by_name(repository_file("Revision/textbook/chapters")

## 7. The table of every notebook

The next cell defines a function that prints the rows of a range of chapters as a
table, and prints chapters 0 to 10. The columns: the id; the title (cut to 34
characters, with ‘...‘ when it is longer); the number of checks; the number of
figures; the date of the last recorded check; its result; its wall time in seconds;
and the section of the book that holds the notebook’s run instructions (the
notebook’s complete text is the section after it).
```

In [4]:

```
def show_table(first, last):
    """Print the notebooks of the chapters first to last as a table."""
    print("id  title                              checks figs checked    result "
          "   sec section")
    for row in ROWS:

```
## 12. The index of the checks of the Revision record

A report is any JSON file of the Revision record (outside the textbook folder and
the Rust build folders) whose top level holds a list ‘checks‘ of named checks with
verdicts, a table ‘checks‘ of named checks (each ‘true‘ or a table with ‘passed‘ or
a verdict), or, for the GKD self-test, a list ‘results‘ of cases each with a number
of ‘mismatches‘. This is the rule of the gate’s step ‘reports-pass‘. The next cell
defines a function that turns one such file into a list of (check name, verdict),
reads every JSON file of the record, and keeps the reports.
```

## 13. Re-running every notebook (only with BOOK_RERUN_ALL=1)

The next cell does nothing but print one sentence, unless the environment variable
‘BOOK_RERUN_ALL‘ is ‘1‘. Then it runs ‘nbkit check‘ on the builder of every other
notebook, at most 8 at a time (half the processor threads, when that is fewer),
the slowest first, into a new scratch folder in the system’s temporary folder. It
never changes a file of the repository. It prints, per chapter, how many notebooks
passed and their fresh and recorded seconds, every notebook that failed, the wall
time of the whole re-run, and writes the fresh results to ‘fresh_results.csv‘ in the
scratch folder; it stops with an error if any notebook failed. The figures above
keep showing the RECORDED times. On the development machine (24 threads, so 8 at a
time) this re-run of the 90 notebooks took 406 s of wall time on 2026-10-08, and
all 90 passed; each notebook took longer than its recorded time, because 8 ran at
once and shared the processor.
```

In [15]:

```
RERUN = os.environ.get("BOOK_RERUN_ALL") == "1"  # the switch of this section
if not RERUN:

```
## 14. The last check

The last cell checks that every file this notebook writes exists and prints the
number of checks that passed.
```

In [16]:

```
check(all(output_file(path).is_file() for path in
          [f"{FIGURE_FOLDER}/{name}" for name in CAPTIONS]
          + [NOTEBOOK_TABLE, CHECK_INDEX, GATE_TABLE, CAPTION_FILE]),
      "every file this notebook writes exists")
all_checks_passed()
```

Out [16]:

```
PASS every file this notebook writes exists
ALL 10 CHECKS PASSED (notebook 23a)
```

Text cell:

```
## 15. What this notebook showed

- Every other notebook of the book has a builder and a provenance file, is placed
  exactly once in its own chapter, and its last RECORDED nbkit check passed; the
  table gives, for each, its checks, figures, check date, result, seconds and
  section, and the data file ‘Revision/textbook/data/23a_notebooks.csv‘ holds it.
- The totals per chapter and the six figures show where the checks, the figures
  and the run time of the book are.
- The gate of the Revision record has the steps printed in Section 11, with their
  expected wall times; the full gate and the option ‘--fast‘ are added up.
- Every check of every report of the Revision record is PASS or NOT-AVAILABLE; the
  index of all of them, with the chapters that cite each, is in
  ‘Revision/textbook/data/23a_check_index.csv‘.
- By default nothing was re-run: the results are the RECORDED ones. With
  ‘BOOK_RERUN_ALL=1‘ the last computing section re-runs every other notebook.
```

23.12 Line-by-line walk-through of Notebook 23a

In [1], the set-up cell. It is the set-up cell of every notebook of this book, with the name `"23a"`. Its comment lines repeat the run instructions of Section 23.10. Its code finds the repository folder (`REPO`), decides where files are written (`OUTPUT_ROOT`: the repository, or a scratch folder during an nbkit check), and defines the helpers the later cells use: `repository_file(relative)` gives the path of a repository file for reading; `output_file(relative)` the path at which to write one; `say(text)` prints in lines of at most 89 characters; `save_figure(fig, name, caption)` saves a figure as `Revision/textbook/figures/23a_<k>_<name>.png`, records its caption in the dictionary `CAPTIONS` and the file `CAPTION_FILE`, shows it and prints where it was saved; `check(condition, name, record)` stops the notebook if the condition is false and otherwise prints PASS with the name (and a second line naming the Revision record when `record` is given); `report(label, value, unit)` prints a line RESULT label = value unit; `all_checks_passed()` prints the last line. `FIGURE_FOLDER` is `"Revision/textbook/figures"` and `NOTEBOOK_ID` is `"23a"`. The modules `json`, `os` and `Path` and the plotting module `plt` are imported there.

In [2], the provenance records.

```
import csv  # reads and writes comma-separated tables
import re  # regular expressions: patterns that find pieces of text
```

Two modules of Python's standard library: `csv` reads and writes tables in which each line is a row and the cells are separated by commas; `re` provides **regular expressions**, patterns that describe pieces of text to be found.

```
NOTEBOOKS = repository_file("Revision/textbook/notebooks")  # notebooks and records
RECORD = re.compile(r"nbkit-record (\{.*\}) -->")  # the record line
ALL_LINE = re.compile(r"ALL (\d+) CHECKS PASSED")  # the last line of a notebook
TITLE = re.compile(r"^# Provenance of Notebook \w+: (.+)$", re.MULTILINE)
```

`NOTEBOOKS` is the folder of the notebooks and their provenance files. `re.compile` turns a pattern into an object that can search text. In a pattern, `\{` and `\}` are the braces themselves, `.*` means "any characters", and the round brackets mark the piece to be returned: `RECORD` finds the record line and returns its JSON text; `\d+` means "one or more digits", so `ALL_LINE` finds the line `ALL n CHECKS PASSED` and returns n; `\w+` means "one or more letters or digits", `^` and `$` mean the start and the end of a line (with `re.MULTILINE`, of any line), so `TITLE` returns the title from the first line of a provenance file. The `r` before a string makes Python keep every backslash as it is.

```
def by_name(paths):
    """Sort paths by their repository-relative name, the same on every system."""
    return sorted(paths, key=lambda path: path.relative_to(REPO).as_posix())
```

`by_name` sorts a list of paths by their names relative to the repository, written with forward slashes. `lambda path: ...` is a small function without a name that gives each path its sorting key. Sorting by this text gives the same order on Windows, macOS and Linux, so that the printed tables never depend on the computer.

```
ROWS = []  # one dictionary per notebook
for path in by_name(NOTEBOOKS.glob("*.PROVENANCE.md")):
    name = path.name.removesuffix(".PROVENANCE.md")  # e.g. 00a_check_installation
    if name.startswith(NOTEBOOK_ID):
        continue  # this notebook's own record changes whenever it is built
```

`ROWS` starts as an empty list. The loop visits every file whose name ends in `.PROVENANCE.md`, in name order. `removesuffix` cuts the ending off the name, leaving for example `00a_check_installation`. `continue` jumps to the next file when the name starts with `"23a"`: this notebook's own record changes every time it is built, so it cannot list itself.

```
    text = path.read_text(encoding="utf-8")
    record = json.loads(RECORD.search(text).group(1))
    captions = json.loads(repository_file(
        f"{FIGURE_FOLDER}/{name[:3]}.captions.json").read_text(encoding="utf-8"))
    ROWS.append({"id": name[:3], "chapter": int(name[:2]), "name": name,
                 "title": TITLE.search(text).group(1),
                 "checks": int(ALL_LINE.search(text).group(1)),
                 "figures": len(captions), "figure_files": sorted(captions),
                 "date": record["check"]["date"],
                 "result": record["check"]["result"],
                 "seconds": record["check"]["seconds"],
                 "builder": f"Revision/textbook/notebooks/src/{name}.py"})
```

The file is read as text; `RECORD.search(text).group(1)` is the JSON text of the record line, and `json.loads` turns it into a dictionary. The caption file of the notebook, `Revision/textboo`

k/figures/NNx.captions.json, holds one entry per figure; name[:3] is the id (the first three characters). ROWS.append adds one dictionary per notebook: the id, the chapter number (int turns the text "05" into the number 5), the name, the title, the number of checks, the number of figures and the sorted list of figure files, the date, result and seconds of the last recorded check (record["check"]), and the path of the builder.

```
builders = [path.stem for path in by_name(NOTEBOOKS.glob("src/*.py"))
            if not path.stem.startswith(NOTEBOOK_ID)]
say(f"{len(ROWS)} provenance files read, {len(builders)} builders found.")
```

builders lists the names of the builder files (path.stem is a file name without its ending .py), again without this notebook. The line printed by say is the first line of Out [2]: 90 provenance files and 90 builders.

```
check([row["name"] for row in ROWS] == builders,
      "every builder has a provenance file and every provenance file a builder")
check(all(row["result"] == "passed" for row in ROWS),
      "the last recorded nbkit check of every notebook passed")
check(all(repository_file(f"{FIGURE_FOLDER}/{figure}").is_file()
          for row in ROWS for figure in row["figure_files"]),
      "every figure named in a caption file exists")
```

Three checks. The first compares the two lists of names: every builder has a provenance file and every provenance file a builder, in the same order. The second demands that every recorded check passed (all is true when the condition holds for every row). The third demands that every figure named in a caption file exists. Each prints a PASS line in Out [2].

In [3], where each notebook is printed.

```
CHAPTERS = [path for path in by_name(repository_file("Revision/textbook/chapters")
                                     .glob("[0-9][0-9]-*.md"))
            if int(path.name[:2]) <= 22]  # the chapter files 00 to 22
HEADING = re.compile(r"^### (\d+)\.(\d+) ")  # a section heading such as ### 3.4
MARKER = re.compile(r"^<!-{2} NOTEBOOK (\w+) -->$")  # a notebook marker line
PLACED = {}  # notebook id -> list of (chapter file name, section of its instructions)
```

CHAPTERS is the list of the chapter files of chapters 0 to 22 ([0-9][0-9]-*.md matches every file name that starts with two digits and a hyphen and ends in .md; the condition int(path.name[:2]) <= 22 leaves out this chapter 23, so that its own text cannot change the results). HEADING finds a section heading such as ### 3.4 and returns its two numbers. MARKER finds a notebook marker line and returns the id; -{2} means "the character - two times", which lets the cell describe the marker without containing one. PLACED will hold, for each notebook id, the list of places where it is placed.

```
for chapter in CHAPTERS:
    section = None
    for line in chapter.read_text(encoding="utf-8").splitlines():
        if HEADING.match(line):
            section = HEADING.match(line).groups()  # e.g. ("3", "4")
```

```
        elif MARKER.match(line):
            number = f"{section[0]}.{int(section[1]) + 1}"  # the next section
            PLACED.setdefault(MARKER.match(line).group(1), []).append(
                (chapter.name, number))
```

For each chapter, `section` remembers the last heading seen. Each line is tested: a heading updates `section` (`.groups()` returns the two numbers as texts); a marker records the chapter's file name and the section number one higher than the last heading, `N.(M+1)`, which is the number the assembler gives the notebook's run-instruction section. `setdefault` creates an empty list for an id seen for the first time.

```
for row in ROWS:
    places = PLACED.get(row["id"], [])
    row["section"] = places[0][1] if len(places) == 1 else "?"
say(f"{len(CHAPTERS)} chapter files read, {len(PLACED)} notebook markers found.")
check(all(len(PLACED.get(row["id"], [])) == 1
          and PLACED[row["id"]][0][0].startswith(row["id"][:2] + "-")
          for row in ROWS),
      "every notebook is placed exactly once, in the chapter of its number")
```

Each row receives its section, or `"?"` when the notebook is not placed exactly once. The printed line is Out [3]: 23 chapter files and 90 markers. The check demands that each notebook has exactly one marker and that the marker is in the chapter file whose name starts with the notebook's own two digits.

In [4], the table, chapters 0 to 10.

```
def show_table(first, last):
    print("id  title                                checks figs checked    result "
          "   sec section")
    for row in ROWS:
        if first <= row["chapter"] <= last:
            title = row["title"]
            if len(title) > 34:
                title = title[:31] + "..."
            print(f"{row["id"]:3} {title:34} {row["checks"]:6d} {row["figures"]:4d} "
                  f"{row["date"]:10} {row["result"]:6} {row["seconds"]:6.1f} "
                  f"{row["section"]:>7}")
```

`show_table(first, last)` prints a header line and then one line per notebook of the chapters `first` to `last`. A title longer than 34 characters is cut to 31 characters and three dots. In an **f-string** (a string with `f` before it) every `{...}` is replaced by the value inside; after the colon, `:3` and `:34` fill the value to that width, `:6d` writes a whole number in 6 places, `:6.1f` a number with one decimal in 6 places, and `:>7` puts the text at the right end of 7 places.

```
show_table(0, 10)
```

prints the first part of the table, Out [4]: the 50 notebooks of chapters 0 to 10. The last column is the section of the run instructions; for example Notebook 05c is placed in Section 5.31, and its complete text is Section 5.32.

In [5], the table, chapters 11 to 22, and the data file.

```
show_table(11, 22)
COLUMNS = ["id", "chapter", "title", "checks", "figures", "date", "result",
           "seconds", "section", "builder"]
NOTEBOOK_TABLE = "Revision/textbook/data/23a_notebooks.csv"
```

The second part of the table is printed (Out [5], 40 notebooks). `COLUMNS` names the columns of the data file, and `NOTEBOOK_TABLE` its path.

```
with output_file(NOTEBOOK_TABLE).open("w", encoding="utf-8", newline="") as handle:
    writer = csv.writer(handle, lineterminator="\n")
    writer.writerow(COLUMNS)
    writer.writerows([row[column] for column in COLUMNS] for row in ROWS)
say(f"The table of {len(ROWS)} notebooks was written to {NOTEBOOK_TABLE}.")
```

`with ... as handle` opens the file for writing (`"w"`) and closes it at the end of the indented block; `newline=""` and `lineterminator="\n"` make every line end with a single line-feed character on every system. `writer.writerow` writes the header and `writer.writerows` one row per notebook, each the list of the values of the columns. The last line prints where the table was written.

In [6], the totals per chapter.

```
PER_CHAPTER = {}  # chapter number -> its totals
for row in ROWS:
    total = PER_CHAPTER.setdefault(row["chapter"], {"notebooks": 0, "checks": 0,
                                                    "figures": 0, "seconds": 0.0})
    total["notebooks"] += 1
    total["checks"] += row["checks"]
    total["figures"] += row["figures"]
    total["seconds"] += row["seconds"]
```

`PER_CHAPTER` gets, for each chapter, a dictionary of four totals, created with zeros the first time the chapter appears (`setdefault`). `+=` adds the row's value to the total.

```
print("chapter notebooks checks figures  seconds")
for chapter, total in sorted(PER_CHAPTER.items()):
    print(f"{chapter:7d} {total["notebooks"]:9d} {total["checks"]:6d} "
          f"{total["figures"]:7d} {total["seconds"]:8.1f}")
```

The header and one line per chapter, in chapter order (`sorted` sorts the pairs of the dictionary by the chapter number). This is the table of Out [6].

```
ALL_SECONDS = sum(row["seconds"] for row in ROWS)
report("notebooks (without 23a)", len(ROWS))
report("checks in these notebooks", sum(row["checks"] for row in ROWS))
report("figures of these notebooks", sum(row["figures"] for row in ROWS))
report("recorded check time, one after the other", f"{ALL_SECONDS:.1f}", "s")
check(sorted(PER_CHAPTER) == list(range(23)),
      "every chapter 0 to 22 has at least one notebook")
```

`ALL_SECONDS` is the sum of all recorded check times. The four RESULT lines of Out [6]: 90 notebooks, 2244 checks, 563 figures and 1097.9 s, the time of all checks one after the other. The check demands that the chapter numbers are exactly 0 to 22 (`list(range(23))` is the list 0, 1, ..., 22).

In [7], two figures of the run times.

```
ids = [row["id"] for row in ROWS]
seconds = [row["seconds"] for row in ROWS]
fig, ax = plt.subplots(figsize=(12, 4.5))
ax.bar(range(len(ROWS)), seconds, color="#2a78d6")
ax.set_yscale("log")  # equal steps on the axis are equal factors
ax.set_xticks(range(len(ROWS)), ids, rotation=90, fontsize=6)
ax.set_xlim(-1, len(ROWS))
ax.set_xlabel("notebook")
ax.set_ylabel("recorded nbkit check time (s)")
ax.grid(axis="y", which="both", alpha=0.3)
```

`ids` and `seconds` are the ids and recorded times in book order. `plt.subplots(figsize=(12, 4.5))` makes a figure 12 inches wide and 4.5 inches high with one drawing area `ax`. `ax.bar` draws one bar per notebook at the positions 0, 1, 2, ...; `set_yscale("log")` makes the vertical axis logarithmic, so that 1 s, 10 s and 100 s are equally far apart; `set_xticks` writes the ids under the bars, turned by 90 degrees; `set_xlim` leaves half a bar of space at both ends; the two labels name the axes, and `grid` draws light horizontal lines.

```
save_figure(fig, "check_time_per_notebook",
            "The wall time in seconds of the last recorded nbkit check of every "
            "notebook of chapters 0 to 22 (one bar each, in book order), on a "
            "logarithmic vertical axis. Most notebooks take a few seconds; a few, "
            "which run the Rust programs or long numerical scans, take minutes.")
```

`save_figure` saves the figure as Figure 23a.1 with the caption given. It shows that most notebooks take a few seconds and a few take minutes; the tallest bar is Notebook 11a.

```
slowest = sorted(seconds, reverse=True)
shares = [100 * sum(slowest[:k]) / ALL_SECONDS for k in range(len(slowest) + 1)]
fig, ax = plt.subplots(figsize=(7, 4.5))
ax.plot(range(len(shares)), shares, color="#eb6834", marker="o", markersize=3)
ax.set_xlabel("number of notebooks, slowest first")
ax.set_ylabel("share of the total check time (%)")
ax.grid(alpha=0.3)
```

`slowest` is the list of times sorted from the largest down (`reverse=True`). `shares[k]` is the percentage of the total time taken by the k slowest notebooks: `slowest[:k]` is the list of the first k entries, `sum` adds them, and the result is divided by `ALL_SECONDS` and multiplied by 100; `k` runs from 0 to 90, so `shares[0]` is 0 and `shares[90]` is 100. `ax.plot` draws the points joined by lines, with small circles (`marker="o"`).

```
save_figure(fig, "cumulative_check_time",
...)
report("share of the three slowest notebooks", f"{shares[3]:.1f}", "%")
```

The figure is saved as Figure 23a.2, and the RESULT line of Out [7] gives `shares[3]`: the three slowest notebooks take 22.2 % of the whole time.

In [8], checks, figures and time per chapter.

```
chapters = sorted(PER_CHAPTER)
for key, name, label, colour, caption in [
        ("checks", "checks_per_chapter", "checks", "#1baf7a",
...),
        ("figures", "figures_per_chapter", "figures", "#eda100",
...),
        ("seconds", "check_time_per_chapter", "recorded check time (s)", "#4a3aa7",
...)
    fig, ax = plt.subplots(figsize=(8, 3.6))
    ax.bar(chapters, [PER_CHAPTER[chapter][key] for chapter in chapters],
           color=colour)
    ax.set_xticks(chapters)
    ax.set_xlabel("chapter")
    ax.set_ylabel(label)
    ax.grid(axis="y", alpha=0.3)
    save_figure(fig, name, caption)
```

`chapters` is the sorted list of chapter numbers. The loop goes through a list of three groups of five values; in each pass `key` is the total to draw (`"checks"`, `"figures"` or `"seconds"`), `name` the figure's file name, `label` the text of the vertical axis, `colour` the colour of the bars and `caption` the caption (the three captions are printed with the figures). Each pass draws one bar per chapter of the chosen total, writes every chapter number under the axis, labels the axes and saves the figure: Figures 23a.3, 23a.4 and 23a.5.

In [9], the steps of the gate.

```
gate = repository_file("Revision/verify_revision.sh").read_text(encoding="utf-8")
table = gate.split("REVISION_GATE_STEPS")[1]  # the text between the two marks
STEPS = [line.split("|") for line in table.splitlines() if line.count("|") == 6]
```

The gate script is read as text. `gate.split("REVISION_GATE_STEPS")` cuts it at every appearance of that word; the piece with index 1 is the text between the first and the second appearance, which is the step table. `STEPS` keeps every line of it that has exactly six `|` characters, that is seven fields, split into a list of the seven fields.

```
def short_command(command):
    """What a step runs: the script file for python and wolframscript, else the
    first two words of the command that are not options."""
    words = [word.strip("{}").rsplit("/", 1)[-1] for word in command.split()
             if not word.startswith("-")]
    if words[0] in ("python", "wolframscript"):
        return next(word for word in words[1:] if "." in word)
    return " ".join(words[:2])
```

`short_command` makes a short form of a step's command for the table. It splits the command into words (`split()`), leaves out the options (words that start with `-`), removes the braces of

the placeholders such as {python}, and keeps of every path only the part after the last /. For a command run by python or wolframscript it returns the first later word with a . in it, the script file; next returns the first item of such a sequence. For any other command it returns the first two words, such as cargo build.

```
GATE_TABLE = "Revision/textbook/data/23a_gate_steps.csv"
with output_file(GATE_TABLE).open("w", encoding="utf-8", newline="") as handle:
    writer = csv.writer(handle, lineterminator="\n")
    writer.writerow(["step", "expected_seconds", "kind", "program"])
    for name, expected, kind, _, _, _, command in STEPS:
        mark = {"1": "long", "A": "all"}.get(kind, "")
        writer.writerow([name, int(expected), mark, short_command(command)])
```

The complete step table is written to the data file Revision/textbook/data/23a_gate_steps.csv, one row per step, with the header step, expected_seconds, kind, program: the seven fields are unpacked into seven names (_ marks fields not used here); mark is long for kind 1, all for kind A (the audits that always run) and empty otherwise. csv.writer writes the rows, as in In [5].

```
say(f"all {len(STEPS)} steps: {GATE_TABLE}; the long steps and the audits:")
print(f"{"step":33} {"sec":>5} {"kind":4} command")
for name, expected, kind, _, _, _, command in STEPS:
    if kind in ("1", "A"):  # the long steps and the audits that always run
        mark = {"1": "long", "A": "all"}.get(kind, "")
        print(f"{name:33} {int(expected):5d} {mark:4} {short_command(command)}")
```

One printed line names the data file. Then the header and one line for each long step and each audit: printing all 85 steps would make the output of the cell longer than the 80 lines a cell of this book may print. This is the table of Out [9].

```
FULL = sum(int(step[1]) for step in STEPS)
FAST = sum(int(step[1]) for step in STEPS if step[2] != "1")
report("gate steps", len(STEPS))
report("long steps (skipped by --fast)", sum(step[2] == "1" for step in STEPS))
report("expected wall time of the full gate", f"{FULL} s = {FULL / 3600:.2f} h")
report("expected wall time with --fast", f"{FAST} s = {FAST / 60:.1f} min")
```

FULL adds up the expected seconds of all steps, FAST those of the steps that are not long. The RESULT lines of Out [9]: 85 steps, 4 of them long, 8057 s (2.24 h) for the full gate and 6487 s (108.1 min) with the fast option.

In [10], the figure of the gate.

```
fig, ax = plt.subplots(figsize=(12, 5))
colours = ["#e34948" if step[2] == "1" else "#2a78d6" for step in STEPS]
ax.bar(range(len(STEPS)), [int(step[1]) for step in STEPS], color=colours)
ax.set_yscale("log")
ax.set_xticks(range(len(STEPS)), [step[0] for step in STEPS], rotation=90,
              fontsize=6)
ax.set_xlim(-1, len(STEPS))
ax.set_ylabel("expected wall time (s)")
ax.grid(axis="y", which="both", alpha=0.3)
```

`colours` gives each bar a colour: red (`"#e34948"`) for a long step, blue otherwise; the expression `A if condition else B` chooses between two values. The bars are the expected seconds on a logarithmic axis, with the step names written under them.

```
save_figure(fig, "gate_step_times",
...)
```

saves Figure 23a.6.

In [11], the reports of the Revision record.

```
def check_list(document):
    """The (name, verdict) pairs of a report, or [] if it is not a report."""
    if not isinstance(document, dict):
        return []
    checks, results = document.get("checks"), document.get("results")
    if isinstance(checks, list):
        return [(item["name"], str(item["verdict"]).upper()) for item in checks]
```

`check_list` turns a JSON document into a list of pairs (check name, verdict). `isinstance(document, dict)` asks whether the document is a dictionary; if not, it is not a report and the empty list is returned. `document.get("checks")` is the value stored under `checks`, or `None` if there is none. When `checks` is a list, each item is a dictionary with a `name` and a `verdict`; `str(...).upper()` writes the verdict in capital letters, so that `pass` and `PASS` count alike.

```
    if isinstance(checks, dict) and all(isinstance(item, (bool, dict))
                                        for item in checks.values()):
        return [(name, "PASS" if item is True or (isinstance(item, dict) and (
            item.get("passed") is True or
            str(item.get("verdict", "")).upper() == "PASS")) else "FAIL")
            for name, item in checks.items()]
```

When `checks` is a dictionary whose values are all `True`/`False` or dictionaries, each entry is a named check: it is PASS when its value is `True`, or a dictionary with `passed` equal to `True` or with the verdict PASS; otherwise FAIL. (A dictionary of plain numbers, such as a summary `{"total": 13, "pass": 13}`, is not a list of checks and is skipped.)

```
    if isinstance(results, list) and results and all(
            isinstance(item, dict) and "mismatches" in item for item in results):
        return [(", ".join(f"{key}={value}" for key, value in item.items()
                           if key != "mismatches"),
                 "PASS" if item["mismatches"] == 0 else "FAIL") for item in results]
    return []
```

The GKD self-test stores a list `results` of cases, each with a number of `mismatches`. Each case becomes a check named by its other entries (for example `p=1, mode=exhaustive, pairs=64`), PASS when it has no mismatch. Any other document gives the empty list.

```
REPORTS = {}  # report path -> list of (check name, verdict)
for path in by_name(repository_file("Revision").rglob("*.json")):
    relative = path.relative_to(REPO).as_posix()
    if relative.startswith("Revision/textbook/") or "/target/" in relative:
        continue
    pairs = check_list(json.loads(path.read_text(encoding="utf-8")))
    if pairs:
        REPORTS[relative] = pairs
```

`rglob("*.json")` finds every JSON file in the folder `Revision` and all folders below it. Files of the textbook and of the Rust build folders (`target`) are skipped. Each file is read and turned into its list of checks; a file with at least one check is kept in `REPORTS`, under its repository path.

```
gate_reports = {path for step in STEPS for path in step[5].split(",") if path != "-"}
say(f"{len(REPORTS)} reports found with {sum(map(len, REPORTS.values()))} checks; "
    f"the gate's step table names {len(gate_reports)} reports.")
check(gate_reports <= set(REPORTS),
      "every report named in the gate's step table is in the index")
check(all(verdict in ("PASS", "NOT-AVAILABLE")
          for pairs in REPORTS.values() for _, verdict in pairs),
      "every check of every report is PASS or NOT-AVAILABLE")
```

`gate_reports` is the set of the report paths named in the sixth field of the gate's steps (`"-"` means none). The printed line of Out [11]: 51 reports with 1357 checks, and the gate names 51 reports. The first check demands that every report of the gate is in the index (`<=` between two sets means "is contained in"); the second, that every verdict is PASS or NOT-AVAILABLE. NOT-AVAILABLE occurs only in the comparison with the author's notebook, for 5 outputs that the author's notebook does not store; this is the same rule as the gate's step `reports-pass`.

In [12], the chapters that cite each check.

```
BLOCKS = {}  # chapter number -> its paragraphs and the outputs of its notebooks
for chapter in CHAPTERS:
    number = int(chapter.name[:2])  # the chapter number, e.g. 5
    text = chapter.read_text(encoding="utf-8")
    blocks = [block for block in re.split(r"\n\s*\n", text) if block.strip()]
```

For each chapter of 0 to 22, `BLOCKS` will hold a list of text blocks. `re.split(r"\n\s*\n", text)` cuts the chapter at every empty line (a line break, possibly blanks, another line break), giving its paragraphs; empty pieces are dropped.

```
    for row in ROWS:
        if row["chapter"] == number:
            notebook = json.loads((NOTEBOOKS / f"{row["name"]}.ipynb").read_text(
                encoding="utf-8"))
            for cell in notebook["cells"]:
                outputs = [output.get("text", "") for output in cell.get("outputs", [])]
                blocks.append("".join("".join(item) for item in outputs))
    BLOCKS[number] = blocks
```

For each notebook of the chapter, the stored notebook file is read as JSON. A notebook is a dictionary whose entry `cells` is the list of its cells; a code cell has a list `outputs`, and a printed output has its text under `text` (a list of lines). The printed text of all outputs of one cell is joined into one block and added. `BLOCKS[number]` stores the chapter's blocks.

```
CITED = {}  # (report, check name) -> set of chapter numbers
for number, blocks in BLOCKS.items():
    for block in blocks:
        for report_path, pairs in REPORTS.items():
            if report_path.rsplit("/", 1)[1] not in block:
                continue
            for check_name, _ in pairs:
                word = r"(?<![\w.-])" + re.escape(check_name) + r"(?![\w-])"
                if re.search(word, block):
                    CITED.setdefault((report_path, check_name), set()).add(number)
say(f"{len(CITED)} (report, check) pairs are cited by at least one chapter.")
```

For every block, every report whose file name (the part of its path after the last `/`) occurs in the block is examined, and each of its check names is searched for as a whole word: `re.escape` makes any special character of the name an ordinary character, and the two conditions `(?<![\w.-])` and `(?![\w-])` demand that the name is not part of a longer word (no letter, digit, `_`, `.` or `-` just before it, no letter, digit, `_` or `-` just after it). Each hit adds the chapter number to the set of the pair (report, check) in `CITED`. Out [12]: 760 pairs are cited at least once.

In [13], the index of the checks.

```
print(f"{"report (under Revision/, without .json)":63} {"checks":>6} {"PASS":>4} "
      f"{"N/A":>3} {"cited":>5}")
INDEX = []  # one row per check: report, check, verdict, citing chapters
for report_path, pairs in REPORTS.items():
    for check_name, verdict in pairs:
        chapters = sorted(CITED.get((report_path, check_name), set()))
        INDEX.append([report_path, check_name, verdict,
                      " ".join(str(chapter) for chapter in chapters)])
    short = report_path.removeprefix("Revision/").removesuffix(".json")
    print(f"{short:63} {len(pairs):6d} "
          f"{sum(verdict == "PASS" for _, verdict in pairs):4d} "
          f"{sum(verdict == "NOT-AVAILABLE" for _, verdict in pairs):3d} "
          f"{sum((report_path, name) in CITED for name, _ in pairs):5d}")
```

The header, then for each report: one row per check is added to `INDEX`, with the citing chapters written as numbers separated by blanks; `short` is the report path without `Revision/` at the start (`removeprefix`) and without `.json` at the end; the printed line gives the numbers of checks, of PASS, of NOT-AVAILABLE and of cited checks (`sum` of true conditions counts them). This is the table of Out [13].

```
CHECK_INDEX = "Revision/textbook/data/23a_check_index.csv"
with output_file(CHECK_INDEX).open("w", encoding="utf-8", newline="") as handle:
    writer = csv.writer(handle, lineterminator="\n")
    writer.writerow(["report", "check", "verdict", "cited_by_chapters"])
```

```
    writer.writerows(INDEX)
with output_file(CHECK_INDEX).open(encoding="utf-8", newline="") as handle:
    read_back = list(csv.reader(handle))
report("reports", len(REPORTS))
report("checks in the index", len(INDEX))
report("checks cited by at least one chapter", sum(bool(row[3]) for row in INDEX))
check(read_back[1:] == INDEX, "the index file holds exactly one row per check")
```

The index is written to the data file `Revision/textbook/data/23a_check_index.csv` with the header `report, check, verdict, cited_by_chapters`, then read back with `csv.reader`. The RESULT lines of Out [13]: 51 reports, 1357 checks, 760 of them cited by at least one chapter. The check demands that the rows read back, after the header (`read_back[1:]`), are exactly the rows written.

In [14], one report as an example.

```
EXAMPLE = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
print(f"{"check":44} {"verdict":7} cited by chapters")
for report_path, check_name, verdict, chapters in INDEX:
    if report_path == EXAMPLE:
        print(f"{check_name:44} {verdict:7} {chapters or "-"}")
check(sum(row[0] == EXAMPLE for row in INDEX) == 12,
      "the example report holds 12 checks",
      record=f"{EXAMPLE}, all checks")
```

The rows of the report of the charge-conjugation matrices and the local U(1) law are printed with their citing chapters (`chapters or "-"` prints a dash when no chapter cites the check). Out [14] shows its 12 checks, all PASS, each cited by at least four chapters; the check `u1_noether_matrix_identity`, the exact local conservation law of Chapter 21, is cited by chapters 0, 5, 10, 18, 20, 21 and 22. The check demands that the report holds 12 checks, and its second line names the record it reproduces.

In [15], the re-run of every notebook.

```
RERUN = os.environ.get("BOOK_RERUN_ALL") == "1"  # the switch of this section
if not RERUN:
    say("BOOK_RERUN_ALL is not set to 1, so no other notebook was re-run: every "
        "table and figure above shows the RECORDED results of the provenance files.")
```

`os.environ.get("BOOK_RERUN_ALL")` is the value of the environment variable, or `None` when it is not set; `RERUN` is true only when the value is the text `"1"`. When it is not, the cell prints the sentence of Out [15] and does nothing else; this is what happened when the stored notebook was built.

```
else:
    import subprocess  # starts other programs
    import sys  # sys.executable is the Python program of this notebook
    import tempfile  # makes a new folder in the system's temporary folder
    import time  # a clock, for the wall time of the re-run
```

```
from concurrent.futures import ThreadPoolExecutor  # several at a time

scratch = Path(tempfile.mkdtemp(prefix="book_rerun_"))
environment = {key: value for key, value in os.environ.items()
               if key not in ("BOOK_RERUN_ALL", "TEXTBOOK_OUTPUT_ROOT")}
nbkit = str(repository_file("Revision/textbook/tools/nbkit.py"))
```

With `BOOK_RERUN_ALL=1` the cell imports four more modules: `subprocess` starts other programs, `sys.executable` is the Python program that runs this notebook, `tempfile.mkdtemp` makes a new, empty folder in the system's temporary folder (its name starts with `book_rerun_`), `time.perf_counter` is a clock. `ThreadPoolExecutor` runs a function on several items at the same time. `environment` is a copy of the environment variables without `BOOK_RERUN_ALL` (so that the notebooks started now do not start the re-run themselves) and without the output folder of an nbkit check. `nbkit` is the path of the tool.

```
def rerun(row):
    done = subprocess.run(
        [sys.executable, nbkit, "check", str(repository_file(row["builder"])),
         "--scratch", str(scratch)], capture_output=True, text=True,
        encoding="utf-8", errors="replace", cwd=REPO, env=environment)
    values = dict(line.split("=", 1) for line in done.stdout.splitlines()
                  if "=" in line)
    fresh = values.get(f"check_{row["id"]}_seconds", "")
    return {"id": row["id"], "chapter": row["chapter"],
            "result": values.get(f"check_{row["id"]}", "FAILED"),
            "seconds": float(fresh) if fresh[:1].isdigit() else 0.0,
            "recorded": row["seconds"]}
```

`rerun(row)` runs the nbkit check of one notebook's builder, with the new scratch folder as its scratch folder (the command of Section 23.6), from the repository root (`cwd=REPO`), keeping its printed output (`capture_output=True`, as text). Every printed line of nbkit has the form `key=value`; `line.split("=", 1)` cuts it at the first `=`, and `dict(...)` collects the pairs. The function returns the id, the chapter, the result (`FAILED` if nbkit printed none), the fresh seconds (0 when nbkit printed no number) and the recorded seconds.

```
workers = max(1, min(8, (os.cpu_count() or 2) // 2))
start = time.perf_counter()
with ThreadPoolExecutor(max_workers=workers) as pool:
    FRESH = list(pool.map(rerun, sorted(ROWS, key=lambda row: -row["seconds"])))
wall = time.perf_counter() - start
FRESH.sort(key=lambda item: item["id"])
```

`workers` is half the number of processor threads, at least 1 and at most 8. The notebooks are handed to the pool slowest first (sorted by minus their recorded time), so that the longest ones start at once and the short ones fill the gaps. `pool.map` returns the results in the order of the input; afterwards they are sorted by id. `wall` is the wall time of the whole re-run.

```
print("chapter notebooks passed  fresh s recorded s")
for chapter in sorted(PER_CHAPTER):
```

```
        items = [item for item in FRESH if item["chapter"] == chapter]
        print(f"{chapter:7d} {len(items):9d} "
              f"{sum(item["result"] == "PASSED" for item in items):6d} "
              f"{sum(item["seconds"] for item in items):8.1f} "
              f"{sum(item["recorded"] for item in items):10.1f}")
```

One line per chapter: the number of notebooks, how many passed, and their fresh and recorded seconds added up.

```
    failed = [item["id"] for item in FRESH if item["result"] != "PASSED"]
    for item_id in failed:
        say(f"FAILED {item_id}: run its nbkit check alone to see the problem lines")
    with (scratch / "fresh_results.csv").open("w", encoding="utf-8",
                                              newline="") as handle:
        writer = csv.writer(handle, lineterminator="\n")
        writer.writerow(["id", "chapter", "result", "seconds", "recorded"])
        writer.writerows([item[key] for key in ("id", "chapter", "result",
                                                "seconds", "recorded")]
                         for item in FRESH)
    say(f"Re-run of {len(FRESH)} notebooks, {workers} at a time: {wall:.0f} s.")
    print(f"Fresh results: {scratch / "fresh_results.csv"}")
    assert not failed, f"nbkit check failed for {failed}"
    say(f"RERUN all {len(FRESH)} other notebooks passed their nbkit check.")
```

`failed` lists the ids of the notebooks that did not pass; each is named on a line. The fresh results are written to `fresh_results.csv` in the scratch folder (never into the repository). The cell prints the number of notebooks, the number run at a time and the wall time, and on a line of its own (with `print`, so that the path is never broken) where the CSV file is; then it stops with an error message (`assert`) if any notebook failed; otherwise it prints that all passed. The figures of the notebook keep showing the RECORDED times. On the development machine this cell, run once with `BOOK_RERUN_ALL=1` on 2026-10-08, printed all 90 notebooks as passed and a wall time of 406 s.

In [16], the last check.

```
check(all(output_file(path).is_file() for path in
          [f"{FIGURE_FOLDER}/{name}" for name in CAPTIONS]
          + [NOTEBOOK_TABLE, CHECK_INDEX, GATE_TABLE, CAPTION_FILE]),
      "every file this notebook writes exists")
all_checks_passed()
```

The check demands that every file this notebook writes exists: the six figures (`CAPTIONS` holds their names), the two data files and the caption file. `all_checks_passed()` prints the last line, `ALL 10 CHECKS PASSED (notebook 23a)`.

23.13 The index of the checks of the Revision record

The index of the checks is the file `Revision/textbook/data/23a_check_index.csv`, written by In [13] of Notebook 23a: one row for each of the 1357 checks of the 51 reports of the Revision record, with the report's path, the check's name, its verdict and the chapters (of 0 to 22) that cite it. Out

[13] in Section 23.11 is its summary, one line per report, and Out [14] shows the rows of one report in full. To find a check by name, open the file in any spreadsheet program, or search it in the terminal:

Windows (PowerShell):

```
Select-String -Path Revision/textbook/data/23a_check_index.csv -Pattern u1_noether
```

macOS (zsh) and Linux (bash):

```
grep u1_noether Revision/textbook/data/23a_check_index.csv
```

Both find the row `Revision/lead_checks/reports/charge-conjugation-and-u1.json,u1_noether_matrix_identity,PASS,0 5 10 18 20 21 22`. grep prints the row alone; Select-String prints in front of it the path of the file and the number of the line in the file, each followed by a colon. A check that no chapter cites (597 of the 1357) is still part of the record and still verified by the gate; the book teaches the results it needs and cites the checks that establish them, and the other checks guard the computations from which those results come (inputs read correctly, intermediate identities, the Rust programs' own tests).

23.14 The index of the notebooks

The index of the notebooks is the table of Out [4] and Out [5] in Section 23.11, also written to `Revision/textbook/data/23a_notebooks.csv`: for each notebook its id, title, number of checks, number of figures, last recorded check, and in the last column the section that holds its run instructions; its complete text is the section after it, and its line-by-line walk-through the section after that. Notebook 23a itself is printed in Sections 23.10 and 23.11 and explained in Section 23.12. All 90 recorded checks of the other notebooks are dated 2026-10-08 and passed.

23.15 What we proved, what we computed, what we assumed

- PROVED: nothing new about physics; this chapter is bookkeeping. Notebook 23a checks facts about files: every builder has a provenance file, every notebook is placed exactly once in its own chapter, every recorded nbkit check passed, every report named by the gate is in the index, and every one of the 1357 checks of the 51 reports is PASS or NOT-AVAILABLE (the 5 NOT-AVAILABLE checks are outputs that the author's notebook does not store).
- COMPUTED (counted from files on 2026-10-15): 90 notebooks in chapters 0 to 22 with 2244 checks and 563 figures; their recorded checks take 1097.9 s one after the other, and the three slowest take 22.2 % of it; the gate has 85 steps, 4 of them long, with expected wall times of 8057 s in full and 6487 s with the fast option; 760 checks of the record are cited by at least one chapter. MEASURED once with `BOOK_RERUN_ALL=1` on 2026-10-08: all 90 other notebooks passed a fresh nbkit check, 8 at a time, in 406 s of wall time; the fresh time of each chapter was between 0.89 and 1.50 times its recorded time (chapter 8: 129.9 s against 86.5 s), because 8 notebooks shared the processor.

- MEASURED elsewhere and quoted: the recorded check times (provenance files), the gate's expected times (its step table, from the folder READMEs and provenance files), the fast option's measured 20 minutes (Revision README), the assembler's 4 seconds and the 287 s of the first pass of the whole-book test build, a pass that ended FAILED on LaTeX warnings in the text of other chapters as it stood then (runs made for this chapter on 2026-10-08).
- ASSUMED: that the files read are the committed ones. The notebook reads whatever is in the working folder; after any other notebook is rebuilt or any chapter changes a citation, Notebook 23a must be rebuilt, or its nbkit check fails because its outputs changed.
- What "cited" means is a DEFINITION of this chapter (one paragraph, or one cell's output, names both the report's file name and the check), not a reading of the author's intention; a chapter may discuss a check in other words without being counted.

23.16 Exercises with worked answers

Exercise 1. You have a fresh clone and want to know, before waiting hours, how long the gate will take on the development machine with and without the fast option. Which command answers this without running anything, and what numbers do you expect?

Answer. The dry run, which runs nothing:

```
bash Revision/verify_revision.sh --dry-run
bash Revision/verify_revision.sh --dry-run --fast
```

(or the PowerShell twin with the same options). The first prints every step with its expected wall time and the line `revision_selected_steps=85 expected_seconds=8057 skipped_steps=0`; the second prints `revision_selected_steps=81 expected_seconds=6487 skipped_steps=4`. These are the sums of the step table that Notebook 23a prints in Out [9]: 8057 s = 2.24 h and 6487 s = 108.1 min. The measured time of the fast option was about 20 minutes, less than the expected sum, because the table's times are generous upper estimates.

Exercise 2. Using Out [6], how long does the nbkit check of all notebooks of chapters 14, 15 and 16 take, one after the other, and what fraction of the whole book's check time is that?

Answer. The three chapter totals are 88.1 s, 240.4 s and 121.2 s; their sum is $88.1 + 240.4 + 121.2 = 449.7$ s. The whole book takes 1097.9 s, so the fraction is $449.7/1097.9 = 0.4096$, about 41 %: three chapters of the Kohn-Sham part take almost a third of the time, because their notebooks run the Rust solver and the reference solver.

Exercise 3. Why does Notebook 23a leave itself out of its table, and why does it leave chapter 23 out of the citation search? What would go wrong otherwise?

Answer. Its own provenance file is rewritten every time it is built, with the new check result and seconds; if the notebook printed its own record, the printed table would differ from the record it was built from, and the second (check) execution would print yet another time, so the byte comparison of nbkit check would fail. Chapter 23 quotes the notebook's own outputs and check names; if the notebook counted citations in chapter 23, every edit of this chapter would change the notebook's output, which the chapter quotes again: a loop with no fixed point. Leaving both out breaks the loop.

Exercise 4. In In [12] a check is cited by a block only when the block contains both the report's file name and the check name as a whole word. Give an example of why the file name is required, and one of why "whole word" is required.

Answer. The same check name can occur in two reports: `fixture_input` is a check of both `ks-theory-python.json` and `ks-theory-wolfram.json`; without the file name, a paragraph about the Wolfram report would also count as citing the Python one. Whole words: a check named `T3` (if one existed) would otherwise be "found" inside `T3C`, inside the word `T3_block_hamiltonian_map` or inside a path; the conditions `(?<![\w.-])` and `(?![\w-])` refuse a name that is part of a longer word.

Exercise 5. You run Notebook 23a with `BOOK_RERUN_ALL=1` on a computer with 4 processor threads. How many notebooks run at the same time, and can the re-run take less time than the slowest notebook, 11a, alone?

Answer. `workers = max(1, min(8, 4 // 2)) = max(1, min(8, 2)) = 2`: two at a time (`//` divides and drops the remainder). No: every notebook runs on one worker from start to end, so the re-run lasts at least as long as the slowest notebook, 7.6 s on the development machine. That is why the slowest are started first: with two workers, 11a runs on one while the other works through the rest, and the total is close to the larger of 7.6 s and half of the total time, $1097.9/2 \approx 549$ s, plus the time the two workers slow each other down.

Exercise 6. The gate prints `revision_failed_step=precheck`. What happened, what must you NOT do, and what are two correct ways forward?

Answer. An output file of a selected step already differs from the committed version: the gate verifies the committed record and refuses to overwrite uncommitted work. Do not delete or reset the changed files without knowing what they are; they may be your own work. Either run the gate in a fresh clone of the repository (`git clone` into a new folder), or leave the steps whose outputs differ out with the option steps; after you have committed or set aside your changes, the full gate runs.

23.17 Glossary

This glossary lists, in alphabetical order, the technical words that the book defines: the words printed in bold where a chapter first explains them, the words of section 3, "The words used in this notebook", of every notebook, the words of the lists "The words of this chapter", and a few words that a notebook defines elsewhere, such as Sakharov's three conditions. Each entry gives the meaning in plain words, taken from a place that defines the word, and then, in brackets, every section where the word is defined or explained. A section titled "Notebook NNx: complete text" means section 3 of that notebook; "the opening of Chapter N" means the paragraphs before its first section. Where a word is defined in several places, the entry quotes the first of them that has the form of a definition (a list entry "word: meaning", or a sentence such as "a word is ..."); the other sections listed explain the same word again, often for a particular case. For a few central words (among them the five status labels, the extra times, the U(1) charge and the word universe) the entry is written from all its defining sections. A word that is defined together with others in one bold phrase (for example "Eigenvalue, eigenvector") is listed under that phrase when it has no entry of its own. The words in capitals PROVED, COMPUTED, ASSUMED, HYPOTHESIS and OPEN are the five status labels of the book; each has its own entry.

0-9

- **0/1 matrix**: A 0/1 matrix has only the entries 0 and 1. (Section 11.8.)
- **2 × 2 matrix**: A 2 × 2 matrix is a table of four numbers in two rows and two columns. (Section 1.12.)
- **3-momentum** k: the momentum along ordinary 3-space; on the coordinate torus of size ℓ the allowed vectors are $\Delta k\,(n_1, n_2, n_3)$ with integers n_i and $\Delta k = 2\pi/\ell = 0.25$ (in units of H). (Section 14.24.)
- **3-space**: x_1, x_2, x_3 are ordinary 3-space; it inflates, with the scale factor $e^{a_4} \sin^{1/6} z$. (Section 3.1.)
- **A 3-space direction**: A 3-space direction, $\mu = x1$ (the same for $x2$ and $x3$). (Section 6.8.)
- **40 digits**: Double precision: the computer's usual numbers, with about 16 significant digits; 40 digits: mpmath's numbers with as many digits as asked for. (Section 15.29.)
- **40-digit arithmetic**: numbers with 40 significant decimal digits, computed by the package mpmath (slow, but exact far beyond what is needed here). (Section 16.23.)

A

- **Absolute value** $|x|$: x without its sign; $\sqrt{x^2} = |x|$. (Sections 1.5 and 1.8.)
- **Acceleration**: Its velocity is $\dot{q} = dq/dt$ and its acceleration $\ddot{q} = d^2q/dt^2$ (a dot over a letter is the derivative with respect to the time t). (Sections 7.2 and 7.8.)
- **Action** $S[q] = \int_0^T L(q(t), \dot{q}(t))\,dt$: one number for a whole path. (Sections 7.2, 7.8 and 9.4.)
- **Activated regime**: When a gap is many times T the state is in the activated regime: only very few quanta are thermally lifted across it. (Sections 16.20 and 16.23.)
- **Adiabatic**: a change of the Hamiltonian slow enough that a system in an eigenstate stays in the eigenstate that continues it (the adiabatic theorem). (Sections 14.3, 15.24, 22.2 and 22.11.)
- **Adiabatic limit**: At a very small rate the particle stays in its instantaneous level, up to the dressing (the adiabatic limit). (Section 22.8.)
- **Adiabatic theorem**: A system whose Hamiltonian changes slowly enough stays in the eigenstate that continues its initial one (the adiabatic theorem of quantum mechanics; Chapter 14 introduced this adiabatic picture); a system whose Hamiltonian changes too fast is kicked into higher levels. (Section 15.21.)
- **Adiabatically continued state**: Adiabatically continued state: the state that keeps the occupations of the first slice. (Section 15.24.)
- **Adiabaticity**: how well an evolution is adiabatic, that is so slow that every particle stays in its instantaneous level. It is measured by the adiabaticity measure Q_{max} (see that entry): a small Q_{max} means that the slow-change approximation holds. (Sections 16.11 and 22.2.)

- **Adiabaticity measure** $Q_{nm} = AH|\langle n|\partial_a h|m\rangle|/(\varepsilon_n - \varepsilon_m)^2$: the first-order amplitude of the jump $n \to m$; Q_{max} is the largest over all allowed pairs. (Sections 15.21, 15.24, 22.2 and 22.11.)

- **Adjoint**: Adjoint $\bar{\Phi} = \Phi^\dagger C$ with $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$; $\Phi^\dagger$ is the row of complex conjugates. (Section 12.29.)

- **Admissible source**: a source for which the field equations of the author's metric can hold. (Sections 17.2, 17.10 and 17.20.)

- **Algebraic condition**: The evolution equation is the 3-space equation minus the extra-time equation; the algebraic condition is $p_3 + p_t = 2p_0$. (Sections 12.2 and 12.9.)

- **Amplification factor** $R(z)$: for the test equation $y' = \lambda y$, one step of a method multiplies y by a number $R(z)$ that depends only on $z = \lambda h$. (Sections 2.5 and 2.10.)

- **Amplitude** and **probability**: when an orbital is written as a sum $\sum_n c_n\varphi_n$ of instantaneous orbitals, the complex number c_n is the amplitude of level n and $|c_n|^2$ the probability to find the particle in level n. (Sections 15.24, 20.2, 20.20, 21.30, 22.2 and 22.11.)

- **Anderson mixing**: a mixing that uses several earlier steps to estimate the slope of G (for one variable it is close to the secant method). (Sections 13.21, 13.24, 15.5, 15.8 and 15.13.)

- **Angle**: The number θ is called the angle of a rotation and the rapidity of a boost. (Section 5.18.)

- **Angular frequency**: where $\omega > 0$ is a fixed number, the angular frequency of the spring. (Section 7.2.)

- **Anisotropic stress**: the difference $p_3 - p_t$ between the 3-space pressure and the extra-time pressure. (Sections 12.2 and 12.24.)

- **Annihilates**: give $bb^* = \mathrm{diag}(1, 0)$ and $b^*b = \mathrm{diag}(0, 1)$, whose sum is the identity; $b|1\rangle = |0\rangle$ (it annihilates the fermion), $b^*|0\rangle = |1\rangle$ (it creates one), and $b^*|1\rangle = 0$: a second fermion cannot be created. (Section 10.11.)

- **Annihilation and creation operators** f_p, f_p^*: f_p empties mode p (and gives zero if it is empty), f_p^* fills it (zero if it is full), each with a sign $(-1)^{(\text{number of occupied modes below } p)}$. (Section 5.37.)

- **Annihilation operator**: Creation operator $a_p^\dagger$, annihilation operator a_p: add or remove a fermion in orbital p, with the sign $(-1)^{\nu_p}$, where ν_p is the number of occupied orbitals before p; on the 16 occupation-number states they are 16×16 matrices. (Sections 5.34, 13.4, 13.13, 21.26 and 21.29.)

- **Annotation**: Tick marks, labels, the vertical range, and an annotation: a text in a white box with an arrow pointing at the place $(2.5\pi, 0)$, where two curves lie on the axis and would otherwise be hard to see. (Section 5.33.)

- **Ansatz**: An ansatz is a guessed form of the solution with unknown parts to be determined. (Section 14.3.)

- **Anti-Hermitian**: A matrix is Hermitian if it equals its conjugate transpose, $M^\dagger = M$, and anti-Hermitian if $M^\dagger = -M$. (Sections 8.17, 8.35 and 10.4.)
- **Anticommutator**: $\{M, N\} = MN + NM$. (Sections 1.28, 1.32, 4.7, 5.9, 5.34, 5.37, 6.13, 8.3, 8.14, 10.11, 10.18, 13.4, 13.13, 17.21, 18.4, 21.25 and 21.29.)
- **Anticommutator matrix**: for two lists of operators $X_1, \ldots, X_n$ and $Y_1, \ldots, Y_n$ whose anticommutators are numbers, the matrix with entries $\{X_i, Y_j\}$. (Section 10.48.)
- **Anticommute**: $AB = -BA$, that is $\{A, B\} = AB + BA = 0$. (Sections 1.28, 4.1, 4.2, 4.9, 4.11, 4.19, 5.2, 5.9, 5.34, 7.1, 7.10, 7.16, 7.32, 8.2, 14.10, 18.8 and 21.7.)
- **Anticommuting**: The components of dirac16complex are anticommuting numbers, also called Grassmann numbers after the mathematician who introduced them: exchanging two of them in a product costs a sign, $\Psi_r \Psi_c = -\Psi_c \Psi_r$, and in particular $\Psi_r \Psi_r = -\Psi_r \Psi_r$, so $\Psi_r \Psi_r = 0$. (Sections 1.10, 5.29, 8.2, 21.2 and 21.7.)
- **Antimatter**: matter made of antiparticles; the antiparticle of a particle has the same mass and the opposite charge, as the positron has for the electron (Chapter 21). (Sections 0.2, 20.23 and 21.2.)
- **Antiparticle**: A particle $b_s^*|0\rangle$ and an antiparticle $d_s^*|0\rangle$ (a hole in the filled sea) both have the energy $+E > 0$. (Sections 5.28, 9.13, 10.20, 10.25, 20.17 and 20.23.)
- **Antiquark**: An antiquark ($\bar{u}$, $\bar{d}$) has the opposite numbers. (Section 21.35.)
- **Antisymmetric**: changing sign when two particles are exchanged. (Sections 1.28, 1.32, 4.2, 4.7, 5.2, 5.9, 6.7, 6.13, 6.27, 7.16, 13.13, 18.8, 21.2, 21.7 and 21.14.)
- **Antisymmetric part**: Write M as the sum of its symmetric part $\frac{1}{2}(M + M^T)$ and its antisymmetric part $\frac{1}{2}(M - M^T)$. (Section 7.12.)
- **Antisymmetry**: (i) Antisymmetry: exchanging the particles i and j exchanges the rows i and j of the table, which changes the sign of the determinant (rule 3). (Section 13.3.)
- **Argument** (or **phase angle**): the angle between the arrow and the positive real axis, measured counterclockwise in radians (π radians = 180 degrees). (Sections 1.11, 1.16 and 2.11.)
- **Array**: `np.linspace(-1.0, 3.0, 401)` makes an array (numpy's list of numbers) of 401 numbers from -1 to 3 with equal steps of $4/400 = 0.01$. (Sections 0.13, 1.9, 2.11, 3.13, 13.14, 15.9, 17.11, 21.15, 22.12 and 22.23.)
- **Assembly**: joining the 24 chapter files, with every notebook expanded, into the one file `Revision/textbook/UNIVERSES_IN_PAIRS_TEXTBOOK.md`. (Section 23.2.)
- **Associative**: Products are associative, $(AB)D = A(BD)$ (both sides are $\sum_{k,l} A_{ik} B_{kl} D_{lj}$), so brackets may be left out. (Sections 1.18 and 4.2.)
- **ASSUMED**: a status label: the statement is used but not derived; it is a starting point of the book (a convention, a physical input or an approximation), and everything that depends on it says so. Example: the Z2 mirror at the edge of the hidden direction. (Sections 0.3, 0.20, 0.26, 1.55, 2.29, 3.1, 3.36, 4.21, 5.40, 6.1, 6.30, 7.34, 8.1, 11.28, 12.31, 14.32, 15.31 and 22.27.)

- **Asymptotic regime**: A ratio close to 4 shows that the grids are fine enough for the h^2 term to dominate (the asymptotic regime), which is what Richardson extrapolation needs. (Section 16.4.)
- **Atan2(b, a)**: the angle of the point (a, b) between $-\pi$ and π. (Section 2.27.)
- **Aufbau**: filling the lowest levels with the N particles. (Sections 13.6, 14.21, 14.24 and 15.24.)
- **The author's second route** (Section 11.5): a determinant identity for the Levi-Civita symbol; raising all labels of the Levi-Civita tensor of a metric gives the factor $\sqrt{|\det g|}/\det g$, so the product of two Levi-Civita tensors is the sign of $\det g$ times the product of two symbols; for the author's metric $\det g = \cos^2 z > 0$ (record `python-lovelock-report.json`, check `sqrt_abs_det_g`), the sign is $+1$, and the author's second route gives the generalized delta without an extra sign. (Section 11.28.)
- **Average**: The ratio $\int E\xi\, dt / \int \xi\, dt$ is an average of E over the bump. (Section 7.3.)
- **Axes**: `plt.subplots(1, 3, ...)` makes a figure `fig` with one row of three panels, the axes (drawing areas) `axes[0]`, `axes[1]`, `axes[2]`, 10.5 by 3.9 inches in all. (Sections 5.10, 11.9, 14.11, 17.11, 19.16 and 20.11.)

B

- **Back-reaction**: Back-reaction: the effect of the matter's own gravity on the metric; a test field has none. (Sections 17.2, 17.10, 17.20, 17.22 and 22.2.)
- **Band level**: The label n is the integer that numbers the levels of one sector in order: $n = 0$ is the band level (bound to the brane; the occupied level of the Fermi shell), $n = 1, 2, \ldots$ are the bulk levels above it, and $n = -1, -2, \ldots$ are the levels of negative energy, the negative branch, which the record's filling convention treats as the normal-ordered sea that holds no particles. (Sections 22.2 and 22.11.)
- **Bare mass** m: the mass in the Lagrangian; effective mass $M_{eff}(y)$: the mass seen by an orbital, m plus the mean-field term. (Section 19.20.)
- **Barrier**: a region that the classical equations forbid, for example a region of too high energy; tunnelling is a quantum transition through it, with a small but nonzero probability. (Section 20.2.)
- **Baryogenesis**: Explaining how is the matter-antimatter problem, also called baryogenesis. (Section 21.4.)
- **Baryon**: a particle made of three quarks, such as the proton $p = uud$ and the neutron $n = udd$ ($B = 1$); a meson (pion π) is a quark and an antiquark ($B = 0$). (Sections 21.2 and 21.35.)
- **Baryon number**: The baryon number counts protons and neutrons minus antiprotons and antineutrons. (Sections 20.23, 21.2 and 21.35.)
- **Baryon-to-photon ratio** η_B: the number of baryons minus antibaryons per photon of the microwave background (Section 21.4). The letter η with two indices, η_{ab} or η^{ab}, is the frame metric; $\eta(K)$ without a subscript is the efficiency of the rate model of Section 21.6. (Sections 21.2 and 21.4.)

- **Basic operators**: Every operator used here is a combination of 32 basic operators O_i: $O_p = F_p$ and $O_{16+p} = F_p^*$ for $p = 0, \dots, 15$, where $F_p = b_{p+1} = f_p$ for $p < 8$ (particles) and $F_p = d_{p-7}^* = f_p^*$ for $p \geq 8$ (antiparticles appear in Ψ through their creation operators), and F_p^* is the Hilbert adjoint of F_p. (Section 5.38.)

- **Basis**: a set of orbitals in which every orbital is written as a sum. (Sections 4.13, 4.15, 5.16, 5.23, 7.29, 22.2 and 22.11.)

- **Bianchi identities**: $R^a{}_{bcd} + R^a{}_{cdb} + R^a{}_{dbc} = 0$ (first) and $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$ (contracted): identities that every metric satisfies; checking them checks the computation. (Sections 3.29, 11.26, 12.2, 12.15, 17.2 and 17.20.)

- **Bilinear**: an expression $\Psi^\dagger K \Psi = \sum_{r,c} \Psi_r^* K_{rc} \Psi_c$ with a fixed matrix K. (Sections 5.1, 5.29, 5.32, 8.35, 9.2, 12.29, 18.2, 18.4, 18.8, 21.2 and 21.14.)

- **Bilinear form**: an expression $\sum_{A,B} x_A M_{AB} y_B$ that contains one factor from the column x and one from the column y in every term. (Sections 7.12, 7.16, 10.33 and 10.37.)

- **Bilinear operator**: $\Psi^\dagger K \Psi = \sum_{A,C} \Psi_A^\dagger K_{AC} \Psi_C$ for a fixed 16×16 matrix K. (Section 5.37.)

- **Binary**: the way of writing numbers with the two digits 0 and 1, in powers of 2 instead of powers of 10: binary 101 is $4 + 0 + 1 = 5$, and binary 0.11 is $1/2 + 1/4 = 3/4$. (Sections 0.22, 0.24, 1.49 and 1.53.)

- **Binary digits**: The computer stores a pattern of occupations as a whole number n whose binary digits are the occupations: digit q (counted from 0, from the right) is the occupation of mode q. (Section 5.38.)

- **Binomial coefficient** $\binom{n}{k}$ ("n choose k"): the number of subsets with k elements of a set with n elements; $\binom{n}{k} = \frac{n!}{k!(n-k)!}$ with $n! = 1 \cdot 2 \cdots n$ and $0! = 1$. For example $\binom{8}{2} = 28$. (Sections 4.13, 4.15, 7.10 and 10.20.)

- **Birthday problem**: This is the birthday problem: the chance that p people have p different birthdays, with 8 "days" instead of 365. (Sections 1.50 and 11.4.)

- **Bisection**: halving an interval that contains the number again and again, keeping the half that still contains it. (Sections 1.3, 1.8, 2.16, 10.43, 13.14, 13.24, 13.26, 13.30, 14.14, 14.17, 14.18, 15.3, 15.8, 15.9, 16.3, 16.18, 16.23, 17.21, 19.16, 22.11, 22.12 and 22.23.)

- **Bisection method**: `bisection` finds the same time independently, by the bisection method: start with an interval $[-30, 30]$ in which E^2 changes sign; look at the middle; if E^2 is still positive there, the onset is later and the middle becomes the new left end, otherwise the new right end; after 200 halvings the interval is far smaller than the rounding of the numbers, and its middle is returned. (Section 8.29.)

- **Bit mask**: To test this quickly it stores a set of labels as a bit mask, the whole number $\sum 2^{\text{label}}$: the set $\{x_1, x_3\}$ (numbers 0 and 2) is $2^0 + 2^2 = 5$. (Section 11.12.)

- **Bits**: the 16 components are numbered $j = 8b_1 + 4b_2 + 2b_3 + b_4$ with four binary digits (bits) b_1, b_2, b_3, b_4, each 0 or 1, one per slot; for example $j = 5$ has the bits 0101. (Sections 0.22, 0.24, 1.4, 1.49, 1.53, 4.17, 4.19 and 21.30.)

- **Block**: a 16×16 matrix cut into four 8×8 pieces; rows and columns 1 to 8 form the first half, 9 to 16 the second half. $\mathrm{diag}(X, Y)$ is the matrix with the blocks X (top left) and Y (bottom right) and zeros elsewhere. (Sections 4.2, 5.9, 14.10, 19.2 and 19.15.)

- **Block diagonal**: a 16×16 matrix whose upper-right and lower-left 8×8 blocks are zero; block off-diagonal: one whose upper-left and lower-right blocks are zero. (Sections 4.2, 4.15 and 5.5.)

- **Block equation**: in each of eight 2×2 blocks the Kohn-Sham equation is $h_j \chi = \varepsilon \chi$ with $h_j = j[-i\sigma_1 \, d/dy + M\sigma_2 + \kappa k \, \sigma_3] + v$, where $j = \pm 1$ is the block type, M the (effective) mass, κk the weighted 3-momentum and v the vector potential. (Section 14.17.)

- **Block equation in real form**: Its level ε and the two functions obey the block equation in real form (`Revision/kohn_sham/ks-theory.json`, blockEquation.realForm; checks block_hamiltonian and block_ode_equivalent): $a' = Ma - \big(\kappa k + j(\varepsilon - v)\big)\, b, \qquad b' = \big(j(\varepsilon - v) - \kappa k\big)\, a - Mb$. (Section 15.2.)

- **Block matrix**: a big matrix cut into smaller matrices (blocks). For example $\begin{pmatrix} 0 & B \\ D & 0 \end{pmatrix}$ has the zero matrix as its upper-left and lower-right blocks. (Section 4.7.)

- **Block off-diagonal**: A matrix whose two off-diagonal blocks are zero is block diagonal; one whose two diagonal blocks are zero is block off-diagonal. (Sections 4.2, 4.15 and 5.5.)

- **Block type** $j = \pm 1$ and **brane parity** (even or odd): labels of the orbitals (explained in section 4 of Notebook 19a). (Sections 16.18, 19.2 and 19.20.)

- **Blueshifted**: The frame velocity along an extra time grows like e^{a_4}: motion along the extra times is blueshifted, because they deflate (in general it grows like $1/h_j$, that is like $e^{-\int \alpha_t \, dx_4}$). (Section 3.31.)

- **Bogoliubov coefficient**: in a quantum field on a gravitational field that changes in time, a number that says how much of a wave that oscillates with positive frequency at early times has turned into a wave of negative frequency at late times; its squared modulus is the mean number of particles created in that wave. It is the standard measure of particle creation by a changing background. (Sections 10.45, 18.2 and 20.2.)

- **Bogoliubov method**: a way to count the quanta of a field that a changing background creates: one compares the modes of the field before and after the change, and the part of a positive-energy mode of the start that has turned into negative-energy modes of the end measures the creation. It is quoted in Chapter 22, not derived or applied. (Section 22.2.)

- **Bonding**: For $\epsilon = -t$ the first row of $(h + t)\phi = 0$ reads $t\phi_L - t\phi_R = 0$, so $\phi_L = \phi_R$, and normalised $\phi = (1, 1)/\sqrt{2}$ (the bonding orbital, lower energy); for $\epsilon = +t$ we get $(1, -1)/\sqrt{2}$ (antibonding). (Section 13.2.)

- **Boolean mask**: `energies[dirac_svals < 1e-9]` keeps the energies at which it is below 10^{-9} (zero up to rounding): a boolean mask, an array of True/False that selects entries. (Section 4.12.)

- **Boost**: the matrix with rows $(\cosh\varphi, \sinh\varphi)$ and $(\sinh\varphi, \cosh\varphi)$ acting on a pair (t, x) of a time-like and a space-like coordinate; it keeps $x^2 - t^2$. (Sections 1.13, 1.16, 4.13, 5.12, 5.18, 5.21, 5.26, 6.21, 8.3, 8.14, 10.34 and 10.37.)

- **Boost pair**: Kinds of pairs $\{a, b\}$ of two different frame directions: space-space (both space-like), time-time (both time-like) and boost pair (one space-like and one time-like). (Section 6.27.)

- **Bosons**: Nature realises this in two ways: for bosons Ψ itself is unchanged, for fermions it changes sign: $\Psi(\dots, x_i\sigma_i, \dots, x_j\sigma_j, \dots) = -\Psi(\dots, x_j\sigma_j, \dots, x_i\sigma_i, \dots)$ (fermions). (Section 13.3.)

- **Bound**: If all of them had their largest size and the same sign, their total would be about $N\epsilon = \epsilon/h$ times the size of the solution; this is a pessimistic bound, the scale of the worst case. (Section 2.6.)

- **Bound state**: A bound state is a solution with $-V_0 < E < 0$ that decays to zero far away on both sides; its energy is an eigenvalue. (Section 2.13.)

- **Boundary conditions**: at the tip $b(-L) = 0$ (the *regular tip*, a choice of the model); at the brane $b(0) = 0$ (*even* orbitals) or $a(0) = 0$ (*odd* orbitals), which follow from the ASSUMED mirror symmetry of the model (the record labels it ASSUMED). (Sections 0.2, 2.27, 10.27, 10.31 and 14.17.)

- **Boundary terms**: An operator A is called antisymmetric for the weight $w(x_0)$ when $\int w\, p\, (Aq)\, dx_0 = -\int w\, (Ap)\, q\, dx_0$ for all functions p, q, up to boundary terms (values at the ends of the interval). (Sections 6.24, 7.3, 7.8, 8.32, 8.35, 10.27 and 20.22.)

- **Boundary value**: We call the numerator, divided by $1 - e^{-6HL}$, the boundary value of p_0. (Section 17.15.)

- **Boundary-value problem**: a differential equation with conditions at two different points (here at both ends of an interval), instead of all conditions at the start. (Sections 2.12 and 2.16.)

- **Bracket**: two guesses at which F has opposite signs; a continuous F has a zero between them. (Sections 2.12, 2.16, 2.27, 15.3, 15.8 and 19.16.)

- **Branch point**: Branch point: a value of a_4' where $F(a_4') = 0$, so that the evolution equation cannot be solved for a_4''. (Sections 17.2 and 17.17.)

- **Branching probability**: the probability that a decaying particle decays in one particular way (one channel). (Section 21.35.)

- **Brane**: a boundary surface of spacetime; in this book the end $z = \pi/2$ of the hidden direction (in the hidden coordinate $y = \ln(\sin z)/(6H)$ the end $y = 0$), where the author's coordinate patch ends and $g_{00} = \cot^2 z = 0$. In the ASSUMED Z2 construction the patch $0 < z < \pi/2$ is glued there to its mirror patch $\pi/2 < z < \pi$. (Sections 2.24, 5.6, 8.31, 8.35, 14.2, 15.1, 15.13, 16.1, 17.2, 17.10, 17.20, 18.2, 18.19, 18.26, 19.2, 19.15, 19.20, 20.2, 20.10, 20.15, 21.2, 21.22, 22.1 and 22.2.)

- **Brane band**: the even-parity level of label 0 in the blocks $j = +1$, which is the zero mode at $k = 0$ and rises with k. (Sections 14.19, 14.24, 15.2, 15.4, 16.15, 16.18, 19.2 and 19.12.)

- **Brane parity**: even means $\chi_2(0) = 0$, odd means $\chi_1(0) = 0$; both kinds of orbitals belong to every state. (Sections 19.2, 19.15 and 19.20.)

- **Brane tension**: Brane tension: an energy per unit area carried by such a surface itself (for the brane, per unit of its seven-dimensional area). (Section 18.2.)

- **Brane value**: A level is a value of ε at which this brane value is zero. (Sections 16.11 and 19.16.)

- **Brane zero mode**: So $\chi = (Ae^{My}, 0)$ is an orbital with $\varepsilon = 0$, for every L: the brane zero mode, largest at the brane. (Section 14.13.)

- **Breakdown**: a point where $F(a_4') = 0$, so that the evolution equation can no longer be solved for a_4''. (Sections 12.24 and 22.2.)

- **Breakdown rate**: a rate at which the probability that a particle is NOT in its instantaneous level stops being small. (Section 22.11.)

- **Broadcasting**: `lowers[:, :, None] == uppers[:, None, :]` compares every lower label with every upper label of the same pair at once (numpy broadcasting: the inserted axes of length 1 are stretched to match), giving one matrix `Outer` of True and False per pair. (Sections 1.48, 5.33, 18.27 and 22.12.)

- **Brute force**, **literal sum**: a computation that tries every case without any shortcut. (Section 11.18.)

- **Bubble sort**: `sort_with_sign(generators)` sorts a list of generator numbers by the method called bubble sort and counts the exchanges. (Section 7.17.)

- **Builder**: the Python file `Revision/textbook/notebooks/src/NNx_name.py` from which the tool `nbkit` builds Notebook NNx. (Sections 0.9, 23.2 and 23.11.)

- **Bulk band**: In the author's metric the record finds this law for the massive bulk band (odd brane parity; its edge at zero momentum is $\varepsilon(0) = 1.292292828069$): the lowest odd-parity level of the shell $n_2 = 1$ has $w_{\text{eff}}(A)$ falling monotonically from 0.239626 at $a_4 = -3$ to 2.268×10^{-3} at $a_4 = 4$, while the brane-band level of the same shell stays between 0.291594 and 0.333275, tending to 1/3 (`Revision/dark_sector/dirac16complex/reports/independent-checks.json`, checks `bulk_band_dark_matter_law` and `brane_band_radiation_law`; Notebook 22b, In [5] and Figure 22b.2). (Section 22.18.)

- **Bulk edge**: the lowest level that is not on the brane band (here a $k = 0$ level of the odd parity). (Sections 14.19, 14.24, 15.2 and 16.13.)

- **Bulk levels**: The label n is the integer that numbers the levels of one sector in order: $n = 0$ is the band level (bound to the brane; the occupied level of the Fermi shell), $n = 1, 2, \ldots$ are the bulk levels above it, and $n = -1, -2, \ldots$ are the levels of negative energy, the negative branch, which the record's filling convention treats as the normal-ordered sea that holds no particles. (Sections 22.2 and 22.11.)

- **Bump**: a smooth shape that is positive on a small interval and zero outside. (Sections 7.3 and 7.8.)

- **Byte**: 8 bits, a whole number from 0 to 255. (Sections 0.24, 0.25, 1.49 and 1.53.)

- **Byte for byte**: Byte for byte: two files equal in every byte. (Sections 11.2, 11.8 and 11.18.)
- **Byte for byte identical**: Byte for byte identical: two files that agree in every character. (Section 16.11.)
- **Byte-identical**: two files with exactly the same bytes. (Section 0.24.)

C

- **C** (charge conjugation): the exchange of particles and antiparticles; CP: C combined with a mirror reflection of space. (Sections 21.35 and 22.17.)
- **C1** (a consequence of T1): a T1 pair taken as the complete classical source of the author's metric is a zero source, and Einstein's equations then have no solution for $H > 0$. (Sections 0.2 and 17.20.)
- **C2**: Source conditions (from the a_4 equations): C1 no component of the source depends on x_0 and $q_{40} = q_{04} = 0$; C2 $p_3 + p_t = 2p_0$; C3 for the linear member $a_4 = AHx_4 + a_0$: $p_3 = p_t = p_0$ and a constant ρ. (Section 17.20.)
- **C3**: Source conditions (from the a_4 equations): C1 no component of the source depends on x_0 and $q_{40} = q_{04} = 0$; C2 $p_3 + p_t = 2p_0$; C3 for the linear member $a_4 = AHx_4 + a_0$: $p_3 = p_t = p_0$ and a constant ρ. (Section 17.20.)
- **Cancellation**: the loss of digits when two nearly equal numbers are subtracted. (Sections 1.4 and 1.8.)
- **Canonical**: The canonical one is fixed by the vielbein postulate (below). (Section 6.13.)
- **Canonical anticommutation relations**: Because of this sign, operators of different modes anticommute; together these rules give the canonical anticommutation relations. (Sections 5.34 and 5.37.)
- **Canonical anticommutator**: the rule $\{\Psi_A, \Psi_C^\dagger\} = B_{AC}$ (times the delta function) that canonical quantisation of the Lagrangian gives. (Sections 10.12, 21.25 and 21.29.)
- **Canonical conjugate**: the operator $\Psi_A^\dagger$ that the Lagrangian pairs with Ψ_A; the question of the notebook is whether it equals the Hilbert adjoint Ψ_A^*. (Sections 5.37 and 10.18.)
- **Canonical Hartree-Fock equations**: It depends on the occupied orbitals only through ρ, which does not change when the occupied orbitals are mixed among themselves by a unitary matrix; such a mixing can make the Hermitian matrix Λ diagonal, which gives the canonical Hartree-Fock equations $\hat{F}\phi_a = \epsilon_a \phi_a$. (Section 13.6.)
- **Canonical history**: the author's metric leaves the function $a_4(x_4)$ free; the author requires only that the extra times deflate ($a_4' > 0$). The linear member with the constant rate $a_4' = AH$ and $A = 1$ is the canonical history of the Revision record (ASSUMED, a prescribed choice); Notebook 12c also uses the faster member $A = 2$. (Sections 12.2, 12.12 and 12.24.)
- **Canonical matrix**: the fixed list of states the solver computes: particle numbers $N = 8, 136, 688$; couplings $\lambda = 0, \pm\lambda_1, \pm\lambda_2$; slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$; and temperatures $T = 0.01, 0.02, 0.05$ (in units of the mass m) for $\lambda = 0, \pm\lambda_1$. (Sections 15.1, 15.13 and 16.3.)

- **Canonical numerics** of the Rust solver: $G = 900$ RK4 steps and its standard tolerances. (Sections 16.6 and 16.11.)
- **Canonical quantisation**: After canonical quantisation (Chapter 10) the 16 components of the field dirac16complex are no longer numbers but operators Ψ_A, $A = 1, \ldots, 16$: rules that turn one state of the quantum system into another. (Section 21.25.)
- **Canonical spin connection** $\omega_{\mu ab}$: the connection that makes the gammas $\gamma^\mu = e^\mu{}_a \gamma^{(a)}$ covariantly constant (the *vielbein postulate*); it is antisymmetric in a, b. $\Omega_\mu = \frac{1}{2}\sum_{a,b} \omega_{\mu ab} S^{ab}$ enters the covariant derivative $D_\mu \Psi = \partial_\mu \Psi + \Omega_\mu \Psi$. (Sections 6.4, 7.18, 7.26, 8.4, 8.14 and 18.19.)
- **Capture**: `re.search` looks for a pattern in that text: `\d+` matches one or more digits, round brackets around a part of the pattern capture what that part matches, `.*?` matches any text up to the next part of the pattern, and `\(` matches a round bracket itself. (Section 12.25.)
- **cargo**: cargo is Rust's program that turns the Rust code of a program into a program that the computer can run (it builds it). (Sections 0.8 and 0.12.)
- **Carry a representation**: One says that the 16 components carry a representation of the group. (Section 5.11.)
- **Cauchy problem**: This is the initial-value problem, also called the Cauchy problem. (Section 8.16.)
- **Cells**: Every worked example of the book is a Jupyter notebook: a file (with the ending `.ipynb`) that holds text and Python code in cells, together with everything the code printed and drew when it ran. (Sections 0.7, 16.14 and 16.18.)
- **Central difference**: The central difference: $\frac{f(x+h)-f(x-h)}{2h} = f'(x) + \frac{h^2}{6} f'''(x) + \ldots$. (Sections 2.18, 3.30, 6.14, 7.9 and 21.23.)
- **Central finite differences**: They are replaced by central finite differences, $\partial F \approx (F(x + h) - F(x - h))/(2h)$, whose error falls like h^2 as the step h shrinks (the Taylor series: the terms of first and third order of $F(x + h)$ and $F(x - h)$ cancel in the difference, up to the error term $\frac{h^2}{6} F'''$). (Section 9.30.)
- **Centred average**: So the centred difference and the centred average of the two neighbours half a cell away are second-order approximations of f' and f at the midpoint, and their errors contain only even powers of h (the next terms are h^4, h^6, ...). (Section 16.14.)
- **Centred difference**: The growth rate at the end of the run is computed by a centred difference, the change of $\ln(u^\dagger u)$ over the last two steps divided by their length, which approximates the derivative at the middle point; the first-order prediction is evaluated at that middle point. (Sections 8.29 and 16.14.)
- **Chain matrix**: The 3×3 chain matrix T_3 has 2 on the diagonal, -1 just above and just below it, and 0 elsewhere. (Section 1.34.)
- **Chain rule**: if f depends on z and z on x_0, then $\partial f/\partial x_0 = (df/dz)(\partial z/\partial x_0)$. (Sections 2.22 and 3.2.)

- **Change of basis**: two sets of matrices are related by a change of basis when an invertible matrix Q gives $\gamma^a = Q\,\hat{\gamma}^a Q^{-1}$ for every a. Writing the column $\Psi = Q\chi$ then turns every equation written with one set into the same equation written with the other. (Section 4.19.)

- **Channel**: Branching probability: the probability that a decaying particle decays in one particular way (one channel). (Section 21.35.)

- **Character** of a map M: the sign χ in $M^\dagger C M = \chi C$. It says whether S keeps ($\chi = +1$) or reverses ($\chi = -1$) its sign under $\Psi \to M\Psi$. (Sections 18.2 and 18.8.)

- **Characteristic function**: a function of ε whose zeros are exactly the levels. (Sections 19.2, 19.12 and 19.15.)

- **Characteristic polynomial**: $p(\lambda) = \det(M - \lambda I)$, a polynomial in λ whose roots are the eigenvalues. (Sections 1.34, 1.40 and 4.9.)

- **Charge** Q and **charge current** J: a number carried by a field whose density obeys an exact local conservation law, so that the charge of a region changes only by what flows through the boundary of the region (the law is proved at every point with $0 < z < \pi/2$; at the edge $z = \pi/2$ the no-flux condition, that no charge flows through the edge, is ASSUMED, not derived, and only under it is the total charge of a universe constant), and the flow of this number through space (Chapters 10, 18 and 21). (Sections 0.2, 10.25, 20.2, 21.2 and 21.22.)

- **Charge balance**: Flux: the amount of charge that flows through a surface per unit time; charge balance: the charge inside a region changes exactly by the flux through its boundary. (Sections 21.18 and 21.22.)

- **Charge conjugation**: a map that turns a field into a field of the opposite charge. (Sections 5.28, 7.29, 7.32 and 21.8.)

- **Charge current**: charge Q and charge current J: a number carried by a field whose density obeys an exact local conservation law, so that the charge of a region changes only by what flows through the boundary of the region (the law is proved at every point with $0 < z < \pi/2$; at the edge $z = \pi/2$ the no-flux condition, that no charge flows through the edge, is ASSUMED, not derived, and only under it is the total charge of a universe constant), and the flow of this number through space (Chapters 10, 18 and 21). (Section 0.2.)

- **Charge density**: What is the charge density of a spinor field, the quantity whose total stays constant in time when no charge flows in or out through the edges of space? (Sections 5.1, 5.6, 5.32, 7.28, 18.26, 20.2, 20.10, 20.12, 20.15, 21.2 and 21.22.)

- **Charge matrix**: The charge matrix is the product of the four space-like gammas. (Sections 5.4, 20.2, 21.2, 21.7 and 21.14.)

- **The charge of the conjugated field**: The charge of the conjugated field, line by line, for $\Psi' = \Gamma \Psi^{\dagger T}$. (Section 21.26.)

- **Charge operator**: Charge operator $Q = \sum_{A,C} \Psi^\dagger_A B_{AC} \Psi_C$ (the integral of the charge density $\Psi^\dagger B \Psi$ for one point). (Section 21.29.)

- **Charge sloshing**: the loop moves the charge back and forth between regions instead of settling. (Sections 13.21 and 13.24.)

- **Charge-conjugation matrix** $\mathcal{C}$: a constant matrix for which $M = \mathcal{C}C$ obeys the intertwiner condition (the definition of the Revision record); same mass for $s = +1$, mass reversed for $s = -1$. In Notebook 05c, section 4 shows that then $\Psi^c = \mathcal{C}\bar{\Psi}^T$ solves the field equation with V (same mass) or with $-V$ (mass reversed) whenever Ψ solves it. (Sections 5.1, 5.28, 5.32, 7.29, 7.32, 21.2, 21.8 and 21.14.)

- **Chart**: A chart is a choice of coordinates. (Section 17.20.)

- **Chebyshev interpolation**: the polynomial through the values of a function at the Chebyshev nodes $s_j = 1 + \cos\theta_j$, $\theta_j = \pi(j + 1/2)/N$; for smooth functions it is accurate to many digits. (Section 22.11.)

- **Chebyshev nodes**: The Chebyshev nodes are the slices $s_j = 1 + \cos\theta_j$ with $\theta_j = \pi(j + \frac{1}{2})/56$, $j = 0, \ldots, 55$ (`0.5 * END` is 1). (Section 22.12.)

- **Check**: a statement that must be true. The helper `check(condition, name)` of the set-up cell stops the notebook with an *AssertionError* when the condition is false, and prints `PASS name` when it is true. (Sections 0.4, 0.7, 0.12, 0.20, 5.9 and 23.2.)

- **Checker**: Verifier and checker: a program of the Revision record that recomputes a result (exactly, with Wolfram or with sympy, or numerically, with Rust or Python) and writes a report: a JSON file that lists named checks, each with a verdict such as PASS. (Section 23.2.)

- **Chemical potential** μ: the energy that fixes the average particle number. (Sections 13.9, 13.26, 13.30, 15.26, 15.29, 16.23, 21.2, 21.5 and 21.35.)

- **Chiral halves**: the components 1 to 8 (chirality $\Gamma = -1$) and 9 to 16 ($\Gamma = +1$); $P_- = \mathrm{diag}(1_8, 0)$ and $P_+ = \mathrm{diag}(0, 1_8)$. (Sections 5.1, 5.5, 5.16, 18.2 and 18.8.)

- **Chiral projectors**: $P_\mp = \frac{1}{2}(I \mp \Gamma)$ with the chirality $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$; P_- keeps components 1 to 8, P_+ components 9 to 16. (Sections 10.37 and 18.2.)

- **Chirality** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$: the product of all eight gammas in the author's order. (Sections 0.2, 4.5, 5.5, 10.9, 18.2, 18.8, 19.15, 19.20, 20.2, 20.10, 20.15, 21.2, 21.7 and 21.14.)

- **Chirality image**: for a field Ψ, the field $\chi = \Gamma\Psi$. Because $\Gamma^2 = I_{16}$, also $\Psi = \Gamma\chi$: the image carries exactly the same information, written in other variables. (Section 10.48.)

- **Chirality matrix** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$: the product of all eight gammas; it anticommutes with every $\gamma^{(a)}$ and $\Gamma^2 = 1$. (Sections 7.32 and 14.10.)

- **Chirality partner**: $\Gamma\Psi$. (Sections 21.2 and 21.22.)

- **Chirality product**: the product $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\cdots\gamma^{(x_7)}$ of all eight gammas, in this order (the author's order); the Revision record calls it the chirality. Here it is only a product of eight matrices. (Section 4.19.)

- **Christoffel symbols** $\Gamma^a{}_{bc}$: numbers built from first partial derivatives of the metric; the geometry of the book explains their meaning. Here they are only an exercise in partial derivatives. (Sections 2.19, 2.22, 3.15, 3.21, 3.29, 6.3, 6.13, 7.18, 7.26, 8.4, 8.14, 9.9, 9.16, 11.2, 11.18, 12.2, 12.15, 17.2, 17.20 and 18.19.)

- **Circle of latitude**: A circle of latitude $\theta = \theta_0$ with $0 < \theta_0 < \pi/2$, run through at unit speed, is NOT a geodesic: along it $d^2\theta/ds^2 = 0$, while the right side is $\sin\theta_0 \cos\theta_0 \, (d\varphi/ds)^2 = \sin\theta_0 \cos\theta_0/(a^2 \sin^2\theta_0) = \cot\theta_0/a^2 \neq 0$ (unit speed means $a \sin\theta_0 \, d\varphi/ds = 1$). (Section 3.16.)

- **Class**: A class is a recipe for objects that carry their own data: `XorShift64Star(seed)` makes a generator object, and the function `__init__` (run when the object is made) stores the seed as its state `self.state`. (Sections 1.54, 7.17, 15.9 and 18.20.)

- **Classical bilinears**: A pair made of a solution Ψ with (m, λ) and its partner $\Gamma\Psi$ with $(-m, -\lambda)$, both in the same gravitational field, has total current zero and total charge zero, as classical bilinears (ordinary numbers for dirac16complex00, elements of the Grassmann algebra for dirac16complex). (Sections 19.11 and 21.19.)

- **Classical field**: a field whose values are numbers, as everywhere in Chapter 0, and not the operators of quantum theory (Chapter 7). (Section 0.2.)

- **Classical fourth-order Runge-Kutta method (RK4)**: The Rust program of the Revision record solves them by the shooting method: it guesses an energy, integrates the equations from one end to the other with the classical fourth-order Runge-Kutta method (RK4) in 900 steps, measures by how much the condition at the far end fails, and corrects the energy with Newton's method. (Section 2.1.)

- **Classical Runge-Kutta method of fourth order**: `rk4` is the classical Runge-Kutta method of fourth order (Chapter 2). (Section 18.27.)

- **Clifford algebra** Cl(4,4): the set of all real combinations of products of eight matrices that satisfy the Clifford relation with four signs $+1$ and four signs -1. (Sections 4.3 and 4.15; the opening of Chapter 4.)

- **Clifford product**: a product $\gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ of k *different* gammas, taken in the order $x0, \ldots, x7$; k is its degree; it is even or odd with k. The degree-0 product is 1. (Section 5.16.)

- **Clifford relation**: $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab} I_{16}$ for all a, b: each gamma matrix squares to $+I_{16}$ (space-like direction) or $-I_{16}$ (time-like direction), and two different gamma matrices anticommute. (Sections 1.28, 1.32, 4.1, 4.3, 4.7, 4.11, 4.19, 5.2, 6.13, 8.2, 17.20, 21.7 and 21.14.)

- **Closed shell**: A particle number N is a closed shell when the filling ends exactly at the end of a group of degenerate levels (levels equal within 10^{-9}), so that the state is unique. (Sections 14.21, 14.24, 15.2 and 17.2.)

- **Closed-shell slab**: the Kohn-Sham states of the model, uniform along 3-space but not along the hidden coordinate y, with complete lattice shells filled. (Section 14.30.)

- **Cobweb diagram**: a picture of an iteration: go vertically to the curve G, horizontally to the diagonal, vertically again, and so on. (Sections 13.24 and 13.25.)

- **Code**: We describe such a matrix by the code of each row: the code $+5$ in row 2 means that the only nonzero entry of row 2 is $+1$ in column 5, so $(Mu)_2 = +u_5$; the code -0 means $-u_0$. (Section 4.2.)

- **Code cell**: A markdown cell holds text; a code cell holds Python code. (Section 0.7.)

- **Coefficient**: A linear expression in some variables $p, q, \ldots$ is a sum of the variables, each multiplied by a fixed number (or, below, a fixed matrix), its coefficient: $\alpha p + \beta q$ is linear, while p^2, pq and $\sqrt{p^2+q^2}$ are not. (Sections 4.1, 7.10 and 7.16.)

- **Coefficient functions**: This form shows the structure that every proof below uses: K is a sum of coefficient functions of the gravitational field ($e^{\mu}{}_{a}$, $\omega_{\mu bc}$; and $\sqrt{|g|}$ in front of $\mathcal{L}$) times bilinears whose kernels are $C\gamma^{(a)}$ and $C\gamma^{(a)}S^{bc}$, $CS^{bc}\gamma^{(a)}$, products of one or three gammas after C. (Section 18.4.)

- **Coefficient matrix**: A *system* is a list of such equations; its coefficients form the coefficient matrix A (one row per equation), and the system reads $Ay = 0$. (Section 5.16.)

- **Coefficient ring**: the symbols $E = e^{a_4}$, $s = \sin^{1/6} z$, $c = \cos z$, $A_1 = a_4'$ and the second and third derivatives $A_2 = a_4''$, $A_3 = a_4'''$, together with H, m, λ, in which every coefficient is written; with the rule $c^2 = 1 - s^{12}$ it allows an exact test whether an expression is zero. (Sections 7.26 and 7.32.)

- **Cofactor**: C_{rc}, the cofactor, contains no entry of row r. (Section 11.13.)

- **Cofactor expansion**: (The record's sympy verifier ran a different exhaustive comparison on the same 266,304 pairs: the literal determinant against a determinant computed by an independent method, the cofactor expansion, which writes a determinant as a sum over the entries of its first row, each entry times the determinant of the smaller matrix left when its row and column are removed, with the signs $+, -, +, \ldots$ in turn; its check is `gkd_literal_equals_cofactor_expansion` in `python-lovelock-report.json`. (Section 1.48.)

- **Colour bar**: The tick labels are the names $x0$ to $x7$, the axes are the frame indices a (rows) and b (columns), and each panel gets its own colour bar (`fig.colorbar`), the scale that translates colours into numbers. (Sections 6.14 and 17.11.)

- **Colour map**: Two tools of matplotlib: a colour map made of a short list of colours, and a coloured square for a legend. (Sections 0.17, 1.25, 5.10 and 21.15.)

- **Colour scale**: A colour scale turns a number into a colour: `DIVERGING` runs from dark blue for -1 through light grey for 0 to red for $+1$, and `SEQUENTIAL` from almost white for 0 to dark blue for large values. (Sections 10.10 and 18.9.)

- **Column**: A column u is a list of n numbers $u_0, \ldots, u_{n-1}$ written one below the other; the matrix acts on it by $(Mu)_i = \sum_j M_{ij} u_j$. (Section 4.2.)

- **Combination**: A combination of matrices $M_1, \ldots, M_N$ is $c_1 M_1 + \cdots + c_N M_N$ with numbers c_j; the span is the set of all combinations. (Section 5.11.)

- **Command**: one line typed into a terminal and run by pressing Enter. (Section 23.2.)

- **Comment**: A line that starts with `#` is a comment: Python skips it; it is there for the reader. (Sections 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 14.11, 15.9, 17.11, 20.11 and 21.15.)

- **Comment lines**: Its first part repeats the complete run instructions of Section 0.11 as comment lines: every line that starts with `#` is a comment, which Python skips. (Sections 0.13, 4.8, 13.14, 16.12, 18.9, 19.16 and 22.12.)

- **Commutant**: all matrices X that commute with every matrix of a list. (Sections 5.11, 5.16 and 14.30.)
- **Commutative**: They are not commutative: in general $AB \neq BA$. (Section 4.2.)
- **Commutator**: where $[A, B] = AB - BA$ is the commutator. (Sections 1.28, 1.32, 4.7, 5.18, 5.21, 5.26, 6.7, 6.13, 7.28, 8.4, 10.11 and 14.11.)
- **Commute**: The components of the field dirac16complex00 are ordinary (complex) numbers, which commute: $\Psi_r \Psi_c = \Psi_c \Psi_r$. (Sections 1.10, 1.28, 4.2, 4.9, 5.9, 5.29, 7.32, 14.10 and 18.8.)
- **Commute with all gammas**: $X\gamma^a = \gamma^a X$ for all eight a. (Section 4.19.)
- **Commuting** and **complex conjugation**: ordinary numbers are commuting, the order of a product does not matter ($ab = ba$), while the anticommuting numbers of Chapter 7 have $ab = -ba$; complex conjugation changes the sign of the imaginary part of every complex number, $a + ib \to a - ib$ (Chapter 1). (Sections 0.2, 1.28, 21.2 and 21.7.)
- **Commuting, anticommuting components**: the components of dirac16complex00 are ordinary numbers ($\Psi_r \Psi_c = \Psi_c \Psi_r$); those of dirac16complex are *anticommuting* (Grassmann) numbers, $\Psi_r \Psi_c = -\Psi_c \Psi_r$, so that exchanging two factors in a product costs a sign. We write $\epsilon = +1$ for commuting and $\epsilon = -1$ for anticommuting components. (Sections 5.32 and 21.14.)
- **Completeness**: Then W is invertible with $W^{-1} = W^\dagger$, and so also $WW^\dagger = I_{16}$, which written out is the completeness relation $\sum_s u_s u_s^\dagger + \sum_s v_s v_s^\dagger = I_{16}$. (Sections 10.20 and 10.25.)
- **Completion** (of theorem T3): the completion record of T3 (2026-10-08). An adversarial verification found no error in the statement or the proof of T3, but gaps in its verification; the completion record closes the three exact ones: the Kohn-Sham coefficients read from the record in both engines (Section 19.8), the filling convention carried onto the partner (Section 19.9), and statement S6, the 16-component expectation rule (Section 19.10). Its Wolfram report passes 3 of 3 checks and its Python report 7 of 7. (Section 19.1.)
- **Complex conjugate**: for a complex number $z = a + ib$ (a, b real) it is $z^* = a - ib$. (Sections 1.10, 1.40, 2.7, 4.9, 5.9, 5.32, 7.4, 10.9, 21.2 and 21.14.)
- **Complex conjugation**: replacing every number by its complex conjugate ($i \to -i$). On a real column it changes nothing: it is the identity. (Sections 0.2 and 7.32.)
- **Complex number**: $z = a + ib$ with real numbers a (the real part, $\mathrm{Re}\, z$) and b (the imaginary part, $\mathrm{Im}\, z$). (Sections 1.10, 1.16, 2.7, 4.9 and 4.11.)
- **Complex plane**: the plane in which $z = a + ib$ is the point (or the arrow from the origin to the point) (a, b); horizontal axis Re, vertical axis Im. (Section 1.16.)
- **Component**: one number of a tensor, such as $E^{x_1}{}_{x_1}$; a diagonal component has $h = j$. (Sections 1.18, 1.24, 11.2, 11.26 and 21.2.)
- **The components along the deflating history**: The components along the deflating history (Sections 11.20 to 11.27). (Section 11.1.)
- **COMPUTED**: a status label: the statement is a number from a numerical (floating-point) computation, given with its measured uncertainty and the file that holds it. (Sections 0.3, 0.20, 3.1, 4.21, 5.40, 6.1, 6.30, 8.1, 11.28, 12.31, 13.38, 14.32, 15.31, 16.26, 17.23 and 22.27.)

- **Condensate**: a configuration that depends only on the time x_4. (Sections 9.18, 9.24, 9.29, 12.2, 12.19, 12.29, 20.12 and 20.15.)
- **The condition**: The condition, line by line. (Sections 21.25 and 21.32.)
- **Conditional expression**: `tiny == 1` is True when exactly one is that small; `x if condition else y` is a conditional expression, which gives `x` when the condition is True and `y` otherwise. (Sections 0.17 and 1.41.)
- **Conditioning**: how strongly a result reacts to small errors of the input. (Sections 15.29 and 16.23.)
- **Configuration**: any field Ψ, that is, 16 components $\Psi_1(x), \ldots, \Psi_{16}(x)$ given at every point x, whether or not it obeys the field equations. (Sections 18.2, 20.2 and 20.10.)
- **Conjugate** $z^* = a - ib$: the mirror image of z in the real axis. (Sections 1.16 and 7.11.)
- **Conjugate transpose** $M^\dagger$: transpose M and replace every entry $x + iy$ by $x - iy$. (Sections 1.36, 1.40, 4.9, 4.11, 5.9, 5.32, 8.22, 20.16, 21.2 and 21.14.)
- **Conjugation**: the rule that turns an element F into F^*. For complex Grassmann numbers the generators come in pairs θ and $\bar{\theta} = \theta^*$; the conjugation exchanges the two members of every pair, replaces every coefficient by its complex conjugate and REVERSES the order of every product: $(FG)^* = G^*F^*$. (Sections 7.11 and 7.16.)
- **Connection coefficients**: The n^3 numbers $\Gamma^a{}_{bc}$ at each point are the connection coefficients; they are chosen so that $\nabla_b V^a$ is a tensor, which fixes how they change between systems of coordinates (we do not need that rule). (Section 3.15.)
- **Conservation**: Conservation means $\nabla_\mu T^\mu{}_\nu = 0$ for all eight. (Sections 9.9, 9.16, 11.2, 12.2, 12.15, 12.24 and 17.2.)
- **Conservation law**: the statement $\nabla_\mu T^\mu{}_\nu = 0$ (the covariant divergence vanishes). In flat spacetime it says that energy and momentum are neither created nor destroyed, they only flow. In the author's metric, which depends on the time x_4 through a_4, it is a local balance law: the energy is not conserved, it changes along the history (sections 4 of Notebook 15b and 9). The momenta along $x_1, x_2, x_3, x_5, x_6, x_7$, coordinates on which the metric does not depend, have totals that are constant, but only under ASSUMED boundary conditions (Section 20.22 of the book). (Sections 9.9, 15.19, 17.20 and 20.20.)
- **Conservation law along** y: This is the conservation law along y (ks-theory.json, emt.conservationY). (Section 15.16.)
- **Conserved**: Conserved: the same number at every point of the path. (Section 3.34.)
- **Conserved number**: a number whose total before a process equals its total after it, in every process that happens. (Section 21.35.)
- **Conserved quantity**: a number whose value does not change in time for every solution. (Sections 20.2 and 20.22.)
- **Consistent**: If $MM^* = 1$ this is automatically true, and the condition is called consistent; otherwise it forces further conditions on Ψ (possibly $\Psi = 0$). (Sections 5.29 and 21.10.)

- **Constant**: They are constant: the same matrices at every point and at every time. (Sections 4.4 and 21.18.)
- **Constraint**: an equation with no second derivative a_4''. (Sections 11.21, 12.2, 12.15, 12.24, 17.2 and 17.20.)
- **Constraint propagation**: The derivative of the constraint is $3a_4'$ times the evolution factor: this is the constraint propagation of the record (`a4-equations.json`, key `generalSource`, entry `constraint_propagation`; `python-a4-report.json`, check `bianchi_x4`). (Section 11.22.)
- **Contact interaction**: $w(\mathbf{r}, \mathbf{r}') = g_c\,\delta(\mathbf{r} - \mathbf{r}')$; it acts only when two particles are at the same point. (Sections 13.19, 13.35 and 14.30.)
- **Contour map**: `ax.contourf(A, B, E_map, levels=30, ...)` colours the plane of the angles (α, β) in 30 bands of equal energy (a contour map: each band joins the points with nearly the same value), and the colour scale is labelled with the energy and its unit t. (Section 13.14.)
- **Contracted Bianchi identity**: For every metric the Einstein tensor has zero divergence, $\sum_\mu \nabla_\mu G^\mu{}_\nu = 0$ for each ν (the divergence is the covariant derivative with its index μ set equal to the upper index of G and summed; a standard theorem, the contracted Bianchi identity; quoted, ASSUMED in general). (Section 3.25.)
- **Contraction**: setting an upper and a lower index equal and summing over it, as in δ^a_a or $v^a w_a$. (Sections 1.26, 1.32, 1.47 and 3.14.)
- **Control**: a comparison case computed with the same method as the case under test; a negative control (see that entry) is one in which the effect must NOT occur. In Chapter 19 the control C is the universe of mass $-M$ with the UNtransformed tip, and the wrong partner D the one with the reversed coupling. (Sections 19.2, 19.10 and 19.12.)
- **Control metric**: Suppose instead the extra times also inflated, with the scale factor $e^{+a_4}\sin^{1/6} z$ (a control metric, not the author's). (Section 21.17.)
- **The conventions of the book**: The conventions of the book (Revision record, `Revision/SPEC.md` section 4; record formula `equation_of_state_definitions`): the energy density and the pressures are (the formula is displayed in that section). (Section 9.4.)
- **Convergence**: Basis: the set of instantaneous levels in which the evolving orbital is expanded; a truncated basis keeps only some of them, and convergence means the result stops changing when more are kept. (Section 22.11.)
- **Convergence factor**: Error: the distance $x - x^*$ from the fixed point; convergence factor: the number by which one step multiplies the error near the fixed point. (Sections 13.21 and 13.24.)
- **Convergence order**: the power q in "error $\approx$ constant $\times h^q$"; halving h divides the error by 2^q. (Section 12.24.)
- **Convergence ratio**: So the convergence ratio $(x(h) - x(h/2))/(x(h/2) - x(h/4))$ is 4 up to a correction of order h^2. (Section 16.4.)

- **Coordinate**: a number that says where a point is along one direction. The author's universe has eight coordinates, named $x_0, x_1, \ldots, x_7$ (the author's own names, in the author's order; the hidden direction x_0 comes first). (Sections 0.16, 3.2, 3.12, 3.21, 3.34, 4.9, 6.13, 6.27, 7.26, 8.14, 8.22, 8.28, 8.35, 9.16, 11.2, 11.18, 11.26, 12.2, 12.15, 12.29, 14.10, 17.2, 17.10, 17.20, 19.15, 19.20, 20.10, 20.15 and 21.2.)

- **Coordinate covariant derivative**: They enter the coordinate covariant derivative of a vector field, $\nabla_\mu V^\nu = \partial_\mu V^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda} V^\lambda$, the derivative that compares the vector at two points correctly although the coordinate directions change between them. (Section 6.3.)

- **Coordinate density**: Coordinate density: the same per unit of the coordinate y (it contains the volume factor e^{6Hy}). (Sections 15.13, 15.19 and 19.20.)

- **Coordinate gammas**: The coordinate gammas are $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (the frame gamma of the same direction divided by its frame factor); they obey $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}$ with the inverse metric $g^{\mu\mu} = \eta_{\mu\mu}/f_\mu^2$. (Sections 7.18, 7.26, 8.2 and 9.2.)

- **Coordinate index**: The lower index μ is a coordinate index: it numbers the coordinates. (Sections 6.2 and 6.13.)

- **Coordinate label**: the name of one of the eight coordinates $x_0, \ldots, x_7$ of the author's metric (x_1, x_2, x_3 ordinary space, x_4 the time, x_5, x_6, x_7 the three extra times, which deflate exponentially, x_0 the hidden direction). Programs number them $0, 1, \ldots, 7$: the number 0 stands for x_1, the number 7 for x_0. (Section 11.8.)

- **Coordinate momenta**: Take a wave $\Psi = u(x_4)\, e^{i(q_1 x_1 + q_5 x_5)}$ with the coordinate momenta q_1 (along 3-space) and q_5 (along an extra time). (Section 10.39.)

- **Coordinate momentum** q_a and **frame momentum** k_a: a wave $e^{iq_a x_a}$ has the coordinate momentum q_a; measured with proper lengths its momentum is $k_a = q_a/f_a$, the frame momentum. (Sections 10.3 and 10.42.)

- **Coordinate plane**: With a before b in the order $x0, \ldots, x7$ there are $8 \cdot 7/2 = 28$ generators, one for each coordinate plane (a, b). (Section 5.12.)

- **Coordinate wave number** q_a and **frame momentum** $k_{(a)} = q_a/f_a$, where f_a is the scale factor: the wave $e^{iq_a x_a}$ has q_a radians of phase per unit of coordinate length and $k_{(a)}$ radians per unit of proper length. (Sections 8.24 and 8.28.)

- **Coordinates on the sphere** of radius a: θ (from 0 at the north pole to π at the south pole) and φ (around the axis); the point is $(a\sin\theta\cos\varphi,\ a\sin\theta\sin\varphi,\ a\cos\theta)$. (Section 3.21.)

- **Corollary**: a statement that follows from a theorem in a few lines; corollary C1 of Chapter 20 is an example. (Sections 20.2 and 20.10.)

- **Correlation energy**: the exact ground-state energy minus the Hartree-Fock energy (never positive). (Sections 13.7 and 13.13.)

- **Cosmic microwave background**: The universe is filled with the photons of the cosmic microwave background, the thermal radiation left over from the hot early universe, today at the temperature 2.7255 K (D. J. Fixsen, Astrophys. (Section 21.4.)

- **Cosmological constant**: Couplings: $\alpha_1, \alpha_2, \alpha_3$ weigh the three Lovelock tensors; Λ is the cosmological constant; $\kappa > 0$ measures the strength of gravity. (Sections 3.26, 3.29, 12.2, 17.2, 20.2 and 20.10.)

- **Cosmological-constant-like**: Radiation-like: $w_{\text{eff}} = 1/3$; dust-like (dark-matter-like): $w_{\text{eff}} = 0$; cosmological-constant-like: $w = -1$; phantom: $w < -1$. (Section 22.22.)

- **Coulomb interaction**: $w = 1/|\mathbf{r} - \mathbf{r}'|$, the repulsion of two electrons (atomic units). (Section 13.19.)

- **Counting**: Counting: for each of the six directions $i \in \{x_1, x_2, x_3, x_5, x_6, x_7\}$ there are ${\Gamma^i}_{ix_4}$, ${\Gamma^i}_{x_4 i}$, ${\Gamma^i}_{ix_0}$, ${\Gamma^i}_{x_0 i}$, ${\Gamma^{x_4}}_{ii}$ and ${\Gamma^{x_0}}_{ii}$: $6 \times 6 = 36$ symbols, plus ${\Gamma^{x_0}}_{x_0 x_0}$: 37 nonzero symbols of the 512, of which 25 are different. (Section 12.4.)

- **Couplings**: $\alpha_1, \alpha_2, \alpha_3$ weigh the three Lovelock tensors; Λ is the cosmological constant; $\kappa > 0$ measures the strength of gravity. (Sections 12.2, 12.15, 12.19, 17.2, 19.20 and 20.15.)

- **Covariant constancy**: Defining property of a spinor connection: $[\Omega_\mu, \gamma^a] = -\sum_b {\omega_\mu}^a{}_b \gamma^b$; covariant constancy of the curved gammas $\gamma^\mu = \sum_a {e_a}^\mu \gamma^a$: $D_\mu \gamma^\nu = \partial_\mu \gamma^\nu + \sum_\lambda {\Gamma^\nu}_{\mu\lambda} \gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0$. (Section 6.27.)

- **Covariant derivative along the curve**: The right side needs V only on the curve, so it defines the covariant derivative along the curve for any $V(\lambda)$. (Section 3.16.)

- **Covariant derivative** of a spinor: $D_\mu \Psi = \partial_\mu \Psi + \Omega_\mu \Psi$ (∂_μ is the partial derivative with respect to x^μ). (Sections 3.21, 5.28, 6.1, 6.13, 6.21, 7.18, 7.26 and 8.35.)

- **Covariant divergence** $\nabla_\mu {T^\mu}_\nu$: the derivative of the tensor summed over its upper index, corrected by the Christoffel symbols. (Sections 9.9, 9.16, 9.29, 11.26, 17.2 and 17.20.)

- **Covariantly constant**: It makes the gammas covariantly constant: $\partial_\mu \gamma^\nu + \sum_\lambda {\Gamma^\nu}_{\mu\lambda} \gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0$ for all 64 pairs (μ, ν) (PROVED; `python-field-theory.json`, check `covariant_constancy_D_mu_gamma_nu`). (Sections 8.4 and 14.11.)

- **Covector**: A covector is a set of n numbers W_a for every system of coordinates that changes by this rule. (Section 3.14.)

- **CP**: C (charge conjugation): the exchange of particles and antiparticles; CP: C combined with a mirror reflection of space. (Section 21.35.)

- **CPL**: $w(a) = w_0 + w_a(1 - a)$. (Section 22.22.)

- **CPL parametrisation**: CPL parametrisation: the formula $w(a) = w_0 + w_a(1 - a)$ for an equation of state that changes with the scale factor a of the observed universe. (Section 22.2.)

- **Crate**: Rust, cargo, program: Rust is a programming language; cargo builds a Rust crate (a folder with a file `Cargo.toml` and source files) into a program file that the computer runs. (Sections 11.8, 15.14 and 19.21.)

- **Creation**: Creation of a universe: a process whose initial state has fewer universes than its final state. (Section 20.2.)

- **Creation operator** $a_p^\dagger$, **annihilation operator** a_p: add or remove a fermion in orbital p, with the sign $(-1)^{\nu_p}$, where ν_p is the number of occupied orbitals before p; on the 16 occupation-number states they are 16×16 matrices. (Sections 5.34, 13.4, 13.13, 21.26 and 21.29.)

- **Critical rate**: The right-hand side grows without limit, but G has a largest value at the critical rate $v_c = \sqrt{(2 - 80\alpha_2)/(48\alpha_2)}$, where $G' = F = 0$. (Section 12.21.)

- **Cross-check**: The Revision record answers it with a second program that shares no code with the first and solves the same equations by a different method (the reference solver), and with a third program that compares the two, number by number, with a rule for the allowed difference that was written down before any comparison was made (the cross-check). (the opening of Chapter 16.)

- **Cross-section**: a number, with the units of an area, that measures how likely a collision or a reaction is. No cross-section for the creation of universes is computed or implied in this book. (Sections 18.2, 20.2 and 20.20.)

- **CSV**: a text table, one row per line, the cells separated by commas. (Sections 16.11 and 23.11.)

- **CSV file**: The Rust solver's record of the partner problems, a CSV file (comma-separated values: a table as text, one row per line, the cells separated by commas, the first line the column names). (Section 14.11.)

- **Cubic Hermite interpolation**: the value in the middle of a step from the values and the derivatives at its two ends. (Sections 2.24, 14.18, 15.8, 17.2, 17.20 and 22.12.)

- **Cubic Lovelock density** $L_{(3)}$: the third Lovelock scalar, of third order in the curvature: $L_{(3)} = 8(2T_1 + 8T_2 + 24T_3 + 3T_4 + 24T_5 + 16T_6 - 12T_7 + T_8)$, where $T_1, \ldots, T_8$ are the eight cubic invariants made of three factors of the Riemann tensor, the Ricci tensor and the Ricci scalar (each written out in that section). (Section 11.15.)

- **Current** $J^a = -i\bar{\Psi}\gamma^{(a)}\Psi$: the conserved current of the phase symmetry $\Psi \to e^{i\alpha}\Psi$; its time component gives the charge. (Sections 5.4, 5.32, 7.23, 7.28, 7.32, 14.12, 14.17, 18.26, 19.3, 20.2, 20.10, 21.2, 21.14 and 21.22.)

- **The current part**: The current part, line by line. (Section 21.19.)

- **Curvature**: What does not depend on the frame is curvature. (Sections 1.43, 6.17 and 8.4.)

- **Curvature of a plane** $K(a, b) = R^{ab}{}_{ab}$ (no sum): the curvature of the surface spanned by the directions x_a and x_b. (Section 11.18.)

- **Curvature of that plane**: For the coordinate plane of x_a and x_b, $\sigma(a, b) = R^{ab}{}_{ab}$ (no sum) is the curvature of that plane (the sectional curvature). (Section 3.29.)

- **Curvature of the coordinate plane**: is the curvature of the coordinate plane of x_a and x_b (its sectional curvature; "plane" means here the plane of the two directions x_a and x_b at one point). (Section 3.17.)

- **Curvature of the spinor connection** $F_{\mu\nu} = \partial_\mu\Omega_\nu - \partial_\nu\Omega_\mu + [\Omega_\mu, \Omega_\nu]$: the 16 x 16 matrix with $D_\mu D_\nu\Psi - D_\nu D_\mu\Psi = F_{\mu\nu}\Psi$. (Sections 6.5 and 6.21.)

- **The curvature that the sums use** (Section 11.10): the mixed components $R^{x_4 k}{}_{x_0 k} = \sigma_k H a_4' \cot z$ carry the sign $\sigma_k = \pm 1$ of inflation or deflation, not of the space-like or time-like character, and $R^{x_4}{}_{x_0} = 0$ because three inflating and three deflating directions cancel, on the background $b_4 = 1$ (with a changing b_4, $R^{x_4}{}_{x_0} = \frac{3}{2} H \cot z \, b_4'/b_4$, record `curvature.json`); every nonzero $R^{ab}{}_{cd}$ has the weight 2. (Section 11.28.)

- **Curve**: A curve is a point that moves with a parameter λ (a time, or a length along the curve): $x^a(\lambda)$. (Section 3.14.)

- **Curved Clifford relation**: They obey the curved Clifford relation. (Section 6.2.)

- **Curved gamma**: The constant gamma matrix of a direction carries the direction in parentheses, $\gamma^{(x4)}$; a gamma without parentheses, γ^{x4} or γ^{μ}, is a curved gamma (Section 6.2). (Sections 6.1, 6.13, 6.21 and 14.11.)

- **Cyclic property**: It has the cyclic property $\mathrm{tr}(AB) = \mathrm{tr}(BA)$. (Section 4.2.)

D

- **Dagger**: Take a column Ψ of n complex Grassmann components with generators $\psi_A = \Psi_A$ and the conjugate row $\Psi^\dagger$ with generators $\chi_A = \psi_A^*$ (the dagger $\dagger$ means transpose and conjugate). (Sections 7.12, 10.9 and 18.8.)

- **Dark energy**: Dark energy is the name for the unknown cause of the observed speeding-up of the expansion of the universe, and dark matter for the unseen matter that is detected only through its gravity. (Section 9.1.)

- **Dark matter**: Dark energy is the name for the unknown cause of the observed speeding-up of the expansion of the universe, and dark matter for the unseen matter that is detected only through its gravity. (Section 9.1.)

- **Data**: A field equation that contains the time derivative $\partial_4 \Psi$ is used like this: one gives the field on the slice $x_4 = 0$ (a seven-dimensional set with the coordinates $x_1, x_2, x_3, x_5, x_6, x_7, x_0$), the data, and asks for the field at later times. (Section 8.16.)

- **Decorator**: The line `@lru_cache(maxsize=None)` above the function is a decorator: it wraps the function so that a result, once computed for some n_2, is remembered and returned at once the next time. (Section 16.24.)

- **Deep dive**: the way this book is written: every notion is defined, in plain words, before it is used; every derivation is written out line by line, each line followed by the rule that produced it from the line before; every worked example is a complete Jupyter notebook, printed in full, with the complete instructions for running it just before it and the explanation of every line of its code just after it; every number in the text names the notebook cell that computes it and, where it reproduces the Revision record, the record file and the check. (Section 0.1.)

- **Default value**: `diagonal_values` evaluates the eight functions at an array of values of z for one value of a_4 and one of b_4 (`b4_value=1.0` is a default value: a call that leaves out the third argument gets $b_4 = 1$) and returns a table with eight rows, row k for g_{kk}. (Sections 3.13, 5.33, 6.14, 9.30, 10.43, 13.25, 14.18 and 15.9.)

- **Defining property** of a spinor connection: $[\Omega_\mu, \gamma^a] = -\sum_b \omega_\mu{}^a{}_b \gamma^b$; covariant constancy of the curved gammas $\gamma^\mu = \sum_a e_a{}^\mu \gamma^a$: $D_\mu \gamma^\nu = \partial_\mu \gamma^\nu + \sum_\lambda \Gamma^\nu{}_{\mu\lambda} \gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0$. (Sections 6.7 and 6.27.)

- **Deflate**: The author's metric (the rule that gives the length of a small step in each direction; Section 0.14 introduces it from zero) makes ordinary space grow (inflate) and the three extra times shrink (deflate) exponentially as the time x_4 runs. (Sections 0.1, 0.14, 0.16, 3.12, 4.4, 8.2, 11.26 and 14.2.)

- **Deflate exponentially**: A step dx_5 along an extra time has the proper duration $b_4^{1/2} e^{-a_4} \sin^{1/6} z \, dx_5$: when a_4 grows and b_4 stays constant, the three extra times deflate exponentially (in general their rate of change is $-a_4' + b_4'/(2b_4)$, Section 3.7). (Sections 1.1, 2.1, 3.1, 3.5, 7.1, 11.2, 12.1, 17.2, 17.10, 17.20, 19.15, 19.20 and 21.2.)

- **Deflating**: shrinking. When a_4 grows, e^{-a_4} shrinks: the extra times deflate exponentially while 3-space inflates. (Sections 8.28, 12.15 and 14.10.)

- **Deflating history**: the time dependence $a_4 = AHx_4$ with $A = 1$; as x_4 grows, 3-space inflates and the extra times deflate, both exponentially. (Sections 10.42, 18.26 and 20.1.)

- **Deflation rate**: the rate a_4'. While $a_4' > 0$ the scale factor e^{-a_4} of the extra times shrinks exponentially, at the momentary rate a_4'. (Section 12.24.)

- **Degeneracy** g: the number of different orbitals that share one level. (Sections 15.2, 15.13, 16.20, 16.23, 19.2 and 19.20.)

- **Degree**: The number k of factors is the degree of γ_A; the product is even if k is even and odd if k is odd. (Sections 4.13, 4.15, 5.3, 5.16, 7.10, 7.16 and 21.10.)

- **Delta function** $\delta^7(x - y)$: an idealised object that is zero whenever the point x differs from y and whose integral over the seven coordinates other than the time is 1. (Sections 5.34, 5.37 and 10.12.)

- **Delta-SCF**: the excitation energy as the difference of two self-consistent energies, with one particle moved from the highest occupied orbital (H) to the lowest empty one (L). (Sections 13.27, 13.30, 13.35, 15.13 and 16.11.)

- **Density** $S = \bar{\Phi}\Phi$, a real number. **Bilinear**: a number $\bar{\Phi} X \Phi$ with a 16 by 16 matrix X; a three-gamma bilinear has $X = \gamma^{(a)}\gamma^{(b)}\gamma^{(c)}$ with three different directions. (Sections 11.2, 11.11, 12.29, 13.1, 13.24, 13.35, 14.30, 19.20 and 20.15.)

- **Density functional theory**: This chapter builds, from zero, the tool with which Chapters 14 to 16 compute the states of many quanta of the field dirac16complex in the author's primordial field: density functional theory, DFT for short, in the form of Kohn and Sham. (the opening of Chapter 13.)

- **Density matrix** $\rho(x, x')$: $\sum_a \phi_a(x) \, \phi_a^*(x')$ over the occupied orbitals; its diagonal $\rho(x, x)$ is the density. (Sections 13.13 and 13.19.)

- **Density operator** $\hat{\rho}$: a Hermitian matrix with eigenvalues between 0 and 1 that add up to 1; it describes a mixture of states with these probabilities. (Sections 13.26 and 13.30.)

- **Dependency order**: It re-runs every verifier and checker in dependency order (a program that reads the output of another runs after it), then demands that every committed output is unchanged byte for byte and that every report passes. (Section 23.2.)
- **Derivative**: $y'(t) = dy/dt$ is the rate of change of y at time t, the slope of the graph of y. (Section 2.10.)
- **Determinant**: one number computed from a square matrix. For a diagonal matrix it is the product of the diagonal entries. (Sections 0.14, 0.16, 1.12, 1.20, 1.24, 1.40, 2.19, 3.6, 3.12, 5.3, 11.2, 11.8 and 12.3.)
- **Determinant of a diagonal matrix**: the product of its diagonal entries. (Section 2.22.)
- **Diagonal**: The rules of this book are diagonal: each squared step is multiplied by its own number g_{ii}, called the entry of the metric for the direction x_i, and the results are added: $ds^2 = g_{00}\,dx_0^2 + g_{11}\,dx_1^2 + \cdots + g_{77}\,dx_7^2$. (Sections 0.14, 1.5, 1.20, 2.19, 3.3, 11.2, 12.2 and 12.15.)
- **Diagonal / off-diagonal entry**: the entry $T^{\nu}{}_{\mu}$ with $\nu = \mu$ / with $\nu \neq \mu$. Off-diagonal entries describe flows of energy and momentum (for example $T^{x_4}{}_{x_1}$ is a flow of momentum along x_1) and stresses that shear. (Section 9.29.)
- **Diagonal frame**, scale factors f_a: $f_{1,2,3} = e^{a_4}\sin^{1/6} z$, $f_4 = 1$, $f_{5,6,7} = e^{-a_4}\sin^{1/6} z$, $f_0 = \cot z$; $\gamma^{\mu} = \gamma^{(\mu)}/f_{\mu}$. (Sections 7.18, 8.2 and 8.35.)
- **Diagonal matrix**: a square table of numbers that is zero everywhere except on the line from the top left to the bottom right (the *diagonal*). The author's metric is an 8×8 diagonal matrix with the entries $g_{00}, \ldots, g_{77}$. (Sections 0.16 and 4.19.)
- **Diagonal metric**: $g_{\mu\nu} = 0$ whenever $\mu \neq \nu$; then $ds^2 = \sum_{\mu} g_{\mu\mu}(dx^{\mu})^2$. (Section 3.12.)
- **Diagonal vielbein**: The diagonal vielbein is $e^{a}{}_{\mu} = f_{\mu}\delta^{a}_{\mu}$, its inverse $e^{\mu}{}_{a} = \delta^{\mu}_{a}/f_a$, and the curved gammas are $\gamma^{\mu} = e^{\mu}{}_{a}\gamma^{(a)} = \gamma^{(\mu)}/f_{\mu}$ (no sum) and $\gamma_{\mu} = g_{\mu\mu}\gamma^{\mu} = \eta_{\mu\mu}f_{\mu}\gamma^{(\mu)}$. (Section 18.3.)
- **Dictionary**: The braces `{...}` make a dictionary: pairs of a key and a value, written `key: value`. (Sections 0.13, 0.20, 1.9, 2.11, 3.13, 3.22, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15, 22.12 and 22.23.)
- **Dictionary comprehension**: A dictionary comprehension (a dictionary written with a `for` inside its braces) stores the volume factor at $b_4 = 1$ under each of $a_4 = 0$, 1 and 2; `volume_b4_2` is the volume factor at $a_4 = 1$, $b_4 = 2$. (Sections 0.17, 0.21, 0.25, 1.9, 2.11, 3.22, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 12.25, 13.14, 14.18, 15.9, 16.12, 17.11, 18.9, 20.11, 21.15 and 22.12.)
- **Difference formula**: On the grid the second derivative is replaced by the difference formula $(\phi_{k+1} - 2\phi_k + \phi_{k-1})/h^2$, which follows from the Taylor expansions $\phi_{k\pm1} = \phi_k \pm h\,\phi'_k + \frac{1}{2}h^2\phi''_k \pm \frac{1}{6}h^3\phi'''_k + O(h^4)$: adding them, the odd powers cancel, and the error is of order h^2. (Section 13.2.)
- **Difference quotient**: The heat capacity is also computed as dE/dT, a difference quotient: energies at the temperatures $T \pm dT$ (and $T \pm 2dT$) are subtracted and divided by multiples of $dT = 0.01\,T$. (Section 16.7.)

- **Dimension**: The span of a list of matrices is the set of all their combinations; a basis of a space is an independent list that spans it, and the number of its elements is the dimension of the space. (Sections 4.13, 4.15, 4.19, 5.11, 5.16, 7.10, 8.17 and 21.14.)
- **Dirac adjoint** $\bar{\Psi} = \Psi^\dagger C$: a row of 16 numbers. (Sections 5.4, 5.32, 7.19, 8.2, 9.2, 18.2, 21.2 and 21.14.)
- **Dirac conjugate**: It is not a new equation: it is the Dirac conjugate of the field equation. (Section 7.21.)
- **Dirac operator**: Dirac operator: $\gamma^\mu D_\mu = \sum_\mu \gamma^\mu D_\mu$. (Section 6.13.)
- **Dirac sea**: the picture in which every negative-energy level is filled in the vacuum. Its energy, $-E$ for each of the 8 negative levels, is $-8E$. (Sections 10.20 and 10.25.)
- **Dirac's exchange energy**: With $n_\sigma = n/2$ and $k_F = (3\pi^2 n)^{1/3}$ this is Dirac's exchange energy (1930). (Section 13.15.)
- **dirac16complex** has components that **anticommute**: for two of its components $\Psi_A \Psi_B = -\Psi_B \Psi_A$. (Sections 0.1 and 7.1.)
- **dirac16complex00**: the second field of the theory, with 16 COMMUTING complex components; it is a classical field (it is not quantised). (Sections 0.1, 7.1 and 10.25.)
- **Discrete symmetry**: a symmetry that is a single operation, such as a reflection, and not a continuous family of operations such as the multiplications of the U(1) symmetry (Chapter 21). (Section 0.2.)
- **Discretisation error**: The discretisation error: the program replaces the continuous interval $-L \le y \le 0$ by finitely many points, so it solves a nearby problem, not the exact one. (Section 16.2.)
- **Dispersion relation**: the dispersion relation: the wave oscillates in time for every k (PROVED; Notebook 07d, In [14]). (Sections 7.5 and 7.8.)
- **Distributive**: The product is, however, associative, $(AB)C = A(BC)$, because both sides have the entries $\sum_j \sum_k A_{ij} B_{jk} C_{kl}$, and distributive, $A(B + C) = AB + AC$ (multiply out inside the sum). (Section 1.18.)
- **Divergence** $\nabla_h P^h{}_j$: the curved-space form of "change plus outflow"; zero divergence means conservation. (Sections 3.25, 11.1, 11.2, 12.2 and 21.22.)
- **Divergence form**: the theory record writes the term $\gamma^\mu \Omega_\mu$ as a sum of derivatives: it equals $1/(2\sqrt{|g|})$ times the sum over μ of $\partial_\mu(\sqrt{|g|}\,\gamma^{(\mu)}/f_\mu)$, computed on both patches; the coefficient of $\gamma^{(\mu)}$ is $\partial_\mu(\sqrt{|g|}/f_\mu)/(2\sqrt{|g|})$. (Section 18.27.)
- **Docstring**: Two kinds of lines are text for the reader and are not executed: a comment is everything after a `#` sign on a line, and a docstring is a text in triple quotes `"""..."""` directly below a `def` line, which says in words what the function does (Python stores it with the function and skips it when the function runs). (Sections 0.13, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15 and 22.12.)
- **Domain**: A `DomainMatrix` is sympy's fast matrix of exact numbers from a chosen domain: the rational numbers `QQ` (fractions) or the integers `ZZ`. (Section 21.15.)

- **Dot product**: The dot product of two vectors with n components is the number. (Sections 1.18, 2.18 and 20.17.)
- **Double**: the ordinary number of a computer, with 53 binary digits (about 16 decimal digits). (Sections 16.20 and 16.23.)
- **Double cover**: two spinor matrices, R and $-R$, move the vectors in the same way. (Sections 5.12, 5.18 and 5.21.)
- **Double occupancy**: the probability that both electrons sit on the same site. (Sections 13.7 and 13.13.)
- **Double precision**: the computer's usual numbers, with about 16 significant digits; 40 digits: mpmath's numbers with as many digits as asked for. (Section 15.29.)
- **Double-counting formula**: This double-counting formula gives the same energy as the direct sum of the four parts, which the notebook checks. (Section 13.32.)
- **Doubled system**: The weight $w = \frac{1}{2}$ belongs to the doubled system: the Z2 mirror makes a copy of the patch, every orbital is normalised on the patch, $\int_{-L}^{0}(a^2 + b^2)\,dy = 1$, and the particle number $N = \sum gf$ counts the quanta of the patch and of its mirror copy together; one patch holds $N/2$. (Section 15.2.)
- **Dressing**: the small admixture of other levels that a particle carries while the background keeps moving. (Sections 22.2 and 22.11.)
- **Drift**: The drift is the largest change of the Krein form, divided by $\max(u^\dagger u, 1)$: rounding errors grow with the size of the numbers, so the change is measured relative to it. (Section 8.23.)
- **Dual**: The dual of an antisymmetric 4×4 matrix M is $(\star M)_{pq} = \frac{1}{2}\sum_{r,s}\epsilon_{pqrs}M_{rs}$, where the Levi-Civita symbol ϵ_{pqrs} is the permutation sign of (p, q, r, s). (Section 4.5.)
- **Dummy**: A summed index is called a dummy index (its name does not matter: $A_{ij}B_{jk} = A_{il}B_{lk}$), an index that is not summed a free index (the formula holds for each of its values). numpy's function `einsum` reads this convention literally: `np.einsum("ij,jk->ik", A, B)` says "the first factor has the indices i, j, the second j, k; j appears twice and is summed; the result has the indices i, k". (Sections 1.18, 1.24 and 1.26.)
- **Dummy index**: an index that appears twice in one term, once up and once down; it is summed over all its values. Its name does not matter. (Section 1.32.)
- **Duration**: A step dt alone has $ds^2 = -dt^2 < 0$: it is not a length but a duration, and the time that a clock carried along the step shows, its proper time, is $d\tau = \sqrt{-ds^2} = dt$. (Section 3.4.)
- **Dust-like**: Radiation-like: $w_{\text{eff}} = 1/3$; dust-like (dark-matter-like): $w_{\text{eff}} = 0$; cosmological-constant-like: $w = -1$; phantom: $w < -1$. (Section 22.22.)

E

- **E-fold**: a growth by the factor e; a growth of a_4 by $\ln 2 \approx 0.693$ doubles e^{a_4} and halves e^{-a_4}. (Sections 1.5, 1.8, 22.2 and 22.11.)
- **Effective mass** $V = m + U'(S) = m + \lambda S$: the number that multiplies Φ on the right side of the field equation. (Sections 7.19, 9.2, 9.24, 12.26, 12.29, 14.3, 15.2, 19.20, 20.12 and 20.15.)
- **Effective potential**: Kohn-Sham state: an approximate state of N identical fermions built from one-particle wave functions (orbitals) that each solve a one-particle equation in a common effective potential; the potential depends on the densities of the occupied orbitals, so the equations are solved self-consistently (repeat until nothing changes). (Section 19.20.)
- **Efficiency**: The final asymmetry is $a(\infty) = \epsilon\,\eta(K)$ with the efficiency. (Section 21.6.)
- **Eigen-orbital**: Words of the Kohn-Sham method used again here (Chapters 13 to 15 define them in full): an orbital is the wave of one quantum, and an eigen-orbital one that solves the Kohn-Sham equation with a definite energy; the Fermi level is the energy that separates the occupied orbitals from the empty ones; a state is self-consistent when the potentials computed from its own density are the potentials its orbitals were computed with; the good sector is the set of orbitals that do not depend on the extra times x_5, x_6, x_7; the Z2 mirror is the ASSUMED rule that the hidden direction continues beyond the brane as a mirror image of the computed patch, with the field there fixed by the field on the computed side (Chapter 14 states the rule; record `Revision/kohn_sham/ks-theory.json`, key `boundaryConditions.brane`). (Section 17.2.)
- **Eigenfunctions**: Often it contains a number that is not known in advance, and it has a solution that is not zero everywhere only for special values of that number: these values are the eigenvalues and the solutions the eigenfunctions. (Section 2.12.)
- **Eigenspace**: The set of all eigenvectors of one eigenvalue (with the zero column) is its eigenspace, and the number of independent ones is its dimension. (Sections 8.17, 10.5 and 10.9.)
- **Eigenstate**: A state with $h\phi = \epsilon\,\phi$ is an eigenstate (a stationary state) with the energy ϵ, an eigenvalue of h. (Section 13.2.)
- **Eigenvalue and eigenvector**: a number λ and a nonzero column u with $Mu = \lambda u$. (Section 4.11.)
- **Eigenvalue** and **eigenvector**: a number ε and a column $z \neq 0$ with $Tz = \varepsilon z$. A symmetric matrix of size n has n real eigenvalues. (Sections 1.34, 1.40, 2.12, 4.9, 4.19, 5.3, 5.9, 8.17, 8.22, 9.25, 10.9, 13.2, 13.35, 16.18 and 18.26.)
- **Eigenvalue, eigenfunction**: a value of the number λ (or the energy E) for which the boundary-value problem has a solution that is not zero everywhere; that solution is an eigenfunction. (Section 2.16.)
- **Eigenvector, joint eigenvector**: a column v with $Mv = \mu v$ for a number μ (the eigenvalue); a joint eigenvector of several matrices is an eigenvector of each of them. (Section 9.29.)
- **Eigenvectors**: So the energies of the fields of one momentum k are the eigenvalues of the 16×16 matrix h, and the columns u are its eigenvectors (the columns $v \neq 0$ with $hv = Ev$, Rule 6 of Section 5.3). (Sections 1.34, 1.40, 4.9, 4.19, 5.9, 5.34, 8.17, 8.22, 9.25, 10.9, 13.35, 16.18 and 18.26.)

- **Einstein equations** with cosmological constant Λ and coupling κ: $G^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu$. (Sections 12.29 and 20.15.)
- **Einstein gravity**: Einstein gravity: $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$. (Sections 12.2, 12.15, 12.19, 17.2 and 20.2.)
- **Einstein tensor**: Ricci tensor $R^a{}_b = \sum_c R^{ac}{}_{bc}$, Ricci scalar $R = \sum_a R^a{}_a$, Einstein tensor $G^a{}_b = R^a{}_b - \frac{1}{2}\delta^a{}_b R$: the averages of the curvature that enter Einstein's field equations. (Sections 3.17, 3.29, 11.2, 11.18, 12.2, 12.15 and 20.10.)
- **Einstein's equations**: the field equations of gravity, which say how the source shapes the metric (Chapter 12). (Section 0.2.)
- **Einstein's field equations** $G^\mu{}_\nu + \Lambda\,\delta^\mu{}_\nu = \kappa\,T^\mu{}_\nu$: the Einstein tensor plus a constant Λ (the cosmological constant) times $\delta^\mu{}_\nu$ equals a positive constant κ times the energy-momentum tensor $T^\mu{}_\nu$ of the matter. (Section 3.29.)
- **Einstein-Gauss-Bonnet gravity**: Einstein-Gauss-Bonnet gravity: $\alpha_1 = 1$, $\alpha_3 = 0$. (Sections 12.2 and 20.2.)
- **Einstein-Hilbert Lagrangian**: the Lagrangian density $\sqrt{|g|}R$ of the geometry, with R the Ricci scalar; varying its action with respect to the metric gives Einstein's equations without a source. (Sections 22.2 and 22.4.)
- **Einstein-Lovelock equations**: $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu$, with the three Lovelock tensors $E_{(k)}$ (Chapter 12), couplings α_k, the cosmological constant Λ and the gravitational coupling κ. (Section 20.2.)
- **Einstein-Lovelock gravity**: We use the most general gravity theory that keeps the field equations of second order in eight dimensions, Einstein-Lovelock gravity, and its special case, Einstein gravity. (Section 12.1.)
- **einsum**: numpy's function that evaluates a product written with the summation convention, for example `np.einsum("ij,jk->ik", A, B)`. (Sections 1.24 and 1.32.)
- **Electric charge**: Electric charge Q_{el}, in units of the proton charge. (Section 21.2.)
- **Electron, positron**: two particles of the same mass m and opposite electric charge -1 and $+1$. (Section 20.20.)
- **Elimination**: Computers therefore use elimination: by rule 6 one may subtract multiples of rows from other rows without changing the determinant, and doing so step by step makes every entry below the diagonal zero, which needs about $n^3/3$ multiplications. (Section 1.21.)
- **Ellipse**: So the unit circle becomes an ellipse whose longest and shortest half-axes have the lengths $\sqrt{9} = 3$ and $\sqrt{1} = 1$, the two eigenvalues, and lie along the two eigenvectors (Figure 01g.1). (Section 1.34.)
- **Empty set**: A set is a collection of different objects, written in braces, for example $A = \{x_2, x_5\}$; the empty set $\{\}$ has no element. (Section 4.13.)

- **Empty state**: A system may have several conserved quantities, and each forbids on its own: the conservation laws allow a transition only when EVERY conserved quantity has the same value in A and in B. The empty state of the classical theory is the configuration in which every field is zero everywhere; all its bilinears, and hence all its conserved quantities, are zero. (Section 20.22.)

- **End angle** $\Phi(\varepsilon) = \theta(0)$: the angle reached at the brane when we shoot with the energy ε. (Section 2.27.)

- **Energy**: a column that depends on the time as $e^{-iE\,x4}$ (E real) has the energy E. (Sections 2.2, 4.9, 5.34, 5.37, 7.4, 7.8 and 20.20.)

- **Energy density** $\rho = -T^{x_4}{}_{x_4}$: energy per unit (proper) volume. (Sections 3.26, 3.29, 5.34, 5.37, 9.1, 9.16, 9.24, 10.25, 12.2, 15.16, 15.19, 17.2, 17.10, 20.2 and 20.10.)

- **Energy exchange**: the change of the energy density in time caused by work done by the inflating 3-space and the deflating extra times. (Section 9.24.)

- **Energy kernel**: at the one-particle level the energy of a plane wave is $\Psi^\dagger \mathcal{E}_m(k)\Psi$ with the energy kernel $\mathcal{E}_m(k) = Bh_m(k)$; the evolution is $i\partial_4\Psi =$ (anticommutator matrix) times (energy kernel) times Ψ, that is $i\partial_4\Psi = B\mathcal{E}_m\Psi = h_m\Psi$. (Section 18.23.)

- **Energy level** ε: a value of the energy for which the equations have a solution with all boundary conditions; an eigenvalue. Unit: the mass m (in units with $m = H = 1$). (Sections 2.1 and 2.27.)

- **Energy-change law**: This is the energy-change law (ks-theory.json, emt.energyChange; PROVED, check emt_x4_component; COMPUTED for all 75 states against differences of the self-consistent energies at neighbouring slices with fixed occupations, check emt_energy_change_dE_da4, worst 1.5×10^{-10}). (Section 15.16.)

- **Energy-momentum profiles**: the energy density $\rho(y)$ and the pressures $p_3(y)$ (3-space), $p_t(y)$ (extra times), $p_0(y)$ (hidden direction). (Section 19.20.)

- **Energy-momentum tensor** T: the table of the energy and the momentum that a field carries and of the pressures it exerts (Chapter 9). (Sections 0.2, 3.26, 3.29, 9.16, 12.2, 12.15, 12.29, 15.16, 15.19, 17.2, 17.10, 17.20, 18.26, 20.2, 20.10 and 20.15.)

- **Engine**: the program that did the computation: Wolfram Language (the language of Mathematica, run with wolframscript), Python (with the packages sympy, numpy and mpmath), or Rust (a fast compiled language). The *lead's independent checks* are short Python programs that share no code with the other verifiers. (Sections 0.20 and 0.21.)

- **Ensemble**: The Revision solver uses an ensemble form: one particle is moved from the highest occupied group of equal levels to the lowest empty group, spread evenly over each group, which keeps the symmetries of its reduction (`Revision/kohn_sham/results/parameters.json`, conventions deltaScf). (Sections 13.27 and 15.5.)

- **Entropy** $S = -\sum g[f \ln f + (1-f)\ln(1-f)]$: a measure of how many microscopic arrangements the gas can take. (Sections 13.26, 13.30, 15.26 and 15.29.)

- **Entry**: A_{ij} is the entry in row i and column j. (Sections 1.24, 4.2, 10.9 and 18.8.)

- **Envelope theorem**: (i) $dF/dT = -S_s$ (the envelope theorem). (Section 13.26.)
- **Environment variable**: a named setting that a program receives from the computer when it starts. (Sections 0.13, 0.22, 0.24, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15, 22.12, 23.2 and 23.11.)
- **Equation of state** $w = p/\rho$: pressure divided by energy density. With different pressures along different directions there is one such ratio for each: $w_3 = p_3/\rho$ (3-space), $w_t = p_t/\rho$ (the extra times) and $w_0 = p_0/\rho$ (the hidden direction); these are the equations of state of Section 9.4. (Sections 9.1, 9.4, 9.16, 9.24, 12.2, 12.19, 22.2 and 22.22.)
- **Equator**: The equator $\theta = \pi/2$, $\varphi = s/a$ is a geodesic: $d^2\theta/ds^2 = 0$ and $\sin(\pi/2)\cos(\pi/2) = 0$, and $d^2\varphi/ds^2 = 0$ with $d\theta/ds = 0$. (Section 3.16.)
- **Equilibrium density**: For an external potential v write $\hat{H}_v = \hat{T} + \hat{W} + \hat{V}$, its grand potential $\Omega_v[\hat{\rho}] = \mathrm{Tr}[\hat{\rho}\,(\hat{H}_v - \mu\hat{N})] - T\,S[\hat{\rho}]$, its Gibbs state $\hat{\rho}_v$, and n_v for the density of $\hat{\rho}_v$, the equilibrium density. (Section 13.26.)
- **Error**: the computed value minus the exact value (we print its size, the *absolute value*). (Sections 2.6, 2.10, 13.24 and 16.2.)
- **Error function**: (the error function $\mathrm{erf}(u) = \frac{2}{\sqrt{\pi}}\int_0^u e^{-t^2}dt$ gives $\int_{u_0}^{u_1} e^{-t^2}dt = \frac{\sqrt{\pi}}{2}(\mathrm{erf}\,u_1 - \mathrm{erf}\,u_0)$, and erf is odd, $\mathrm{erf}(-u) = -\,\mathrm{erf}\,u$). (Section 12.21.)
- **Euler characteristic**: The name comes from a classical theorem that this book quotes and does not prove (ASSUMED): in a space of even dimension $n = 2m$ the Lovelock scalar of order m is called the Euler density, because for a closed space (finite and without an edge, like the surface of a ball) with a positive-definite metric (every squared length positive, unlike the author's metric) its integral over the whole space, with the volume factor $\sqrt{|\det g|}$, is a constant times the Euler characteristic: a whole number that depends only on the shape of the space (2 for the surface of a ball, 0 for the surface of a ring) and does not change when the metric is deformed (the Chern-Gauss-Bonnet theorem). (Sections 11.2 and 11.11.)
- **Euler density**: in a space of even dimension $n = 2m$, the Lovelock scalar of order m (in eight dimensions $L_{(4)}$). (Sections 11.2 and 11.11.)
- **Euler's formula**: $e^{i\theta} = \cos\theta + i\sin\theta$ for real θ. (Sections 1.11 and 1.16.)
- **Euler, midpoint, RK4**: three rules that compute the value after one step from the value before it (the formulas are in section 4 of Notebook 02a). (Section 2.10.)
- **Euler-Lagrange equation**: the field equation obtained from a Lagrangian L by requiring that the action does not change, to first order, when the field is changed a little. (Sections 7.8, 7.16 and 7.26; the opening of Chapter 7.)
- **Euler-Lagrange expression**: $\partial\mathcal{L}/\partial\Psi_A^* - \sum_\mu \partial_\mu(\partial\mathcal{L}/\partial(\partial_\mu\Psi_A^*))$; the field equations say it is zero. (Sections 7.3, 7.8 and 18.19.)
- **Even**: So $u(-x) = c\,u(x)$, and applying this twice gives $c^2 = 1$: every bound state is even, $u(-x) = u(x)$, or odd, $u(-x) = -u(x)$. (Sections 1.19, 1.24, 2.13, 2.16, 3.30, 4.13, 4.15, 5.5, 5.12, 5.16, 7.11, 7.16, 11.2, 11.8 and 16.18.)
- **Even function**: $f(-u) = f(u)$. (Section 11.26.)

- **Evolution equation**: This difference is the only combination in which a_4'' survives; in the field equations it is the evolution equation, which decides how a_4 changes (Chapter 12). (Sections 3.26, 11.21, 12.2, 12.9, 12.15, 17.2, 17.3 and 17.20.)
- **Evolution form**: and because $(\gamma^{(4)})^2 = -1$ and $f_4 = 1$ it can be solved for the time derivative (the evolution form; multiply by $-\gamma^{(4)}$): $\partial_4\Phi = -\gamma^{(4)}\Big[V\Phi - \sum_{a\neq 4}\frac{1}{f_a}\gamma^{(a)}\partial_a\Phi - 3H\gamma^{(0)}\Phi\Big]$. (Section 9.2.)
- **Exact arithmetic**: computing with fractions, never rounding. The package sympy does this (`DomainMatrix` over `QQ`, the rational numbers). (Section 5.16.)
- **Exact** computation: with symbols and fractions (sympy), not with rounded decimal numbers; an exact check that an expression is zero proves it for ALL values of the symbols. (Sections 1.24, 6.13, 6.21, 6.27, 11.2, 11.18, 16.18 and 18.8.)
- **Exact local conservation law**: It obeys an exact local conservation law: in the author's metric, for every history $a_4(x_4)$, in particular the one in which ordinary space inflates and the three extra times x_5, x_6, x_7 deflate exponentially, the charge of a region changes only by what flows through its boundary (PROVED, Sections 21.16 and 21.17). (Section 21.1; the opening of Chapter 21.)
- **Exactly rounded**: The module `math` of Python provides `math.fsum`, which adds stored numbers exactly and rounds only once, at the end (the exactly rounded sum), and π. (Section 0.25.)
- **Exchange**: (The index C' carries a prime so that it is not confused with the matrix C.) The first product is the direct (Hartree) term, the second the exchange (Fock) term. (Sections 13.4 and 14.26.)
- **Exchange energy**: E_x is the exchange energy (the Fock term); it has no classical analogue, it comes from the antisymmetry of Φ, and for a repulsive w it lowers the energy. (Sections 13.5 and 13.19.)
- **Exchange hole**: the dip in the probability of finding a second fermion near a first one, caused by the Pauli principle. (Sections 13.15 and 13.19.)
- **Exchange potential**: Hartree potential: the potential that one particle feels from the average density of all particles; exchange potential: the correction that comes from the Pauli principle (equal-label particles avoid each other). (Section 13.35.)
- **Exchange-correlation energy**: The price is one quantity, the exchange-correlation energy, that is not known exactly and must be approximated. (Sections 13.1 and 13.10.)
- **Exchange-only**: So this is an exchange-only Kohn-Sham scheme, which for a contact interaction is the same as the Hartree-Fock approximation: an approximation to the true ground state, whose error is the correlation energy (Section 13.7 showed how large it can be on two sites). (Section 13.32.)
- **Exclusive or** (XOR, `x ^ y`): the two numbers are compared bit by bit, and a result bit is 1 when exactly one of the two bits is 1. Applying the same exclusive or twice gives back the number: for single bits, $(a \oplus b) \oplus b = a$ in all four cases ($b = 0$ changes nothing twice; $b = 1$ flips the bit twice), so it holds bit by bit. That is why an XOR step loses nothing. (Sections 1.49 and 1.53.)

- **Exhaustive check**: a check of *every* possible case, not of examples. (Section 1.47.)
- **Exhaustive test**: a test of every possible case. (Section 11.8.)
- **Expansion rate** (Hubble rate) of a direction: $\partial_{x_4} \ln h_\mu$, the fraction by which its lengths grow per unit of time x_4. (Section 3.12.)
- **Expansion rate of the extra times**: We call α_t the expansion rate of the extra times. (Section 3.7.)
- **Expectation value**: $\langle\phi|X|\phi\rangle$ in a normalised state ϕ. (Sections 5.37, 9.13, 10.25, 13.2 and 19.11.)
- **Expectation-value rule**: for one quantum in the mode u, $\langle\Psi^\dagger X\Psi\rangle = u^\dagger BXu$; for many, $\langle\Psi^\dagger X\Psi\rangle = \mathrm{Tr}(X\rho)$ with the one-body matrix $\rho = \sum_{\text{occupied}} f\, uu^\dagger B$ (f the occupation). (Sections 10.21 and 14.30.)
- **Expected number**: The expected number of events in a list is the average number of them that happen, taken over very many repetitions; it equals the sum of the probabilities of the single events, whether or not they are independent (a rule of the theory of chance that we use without proof). (Section 0.18.)
- **Expected value**: For N tries that each succeed with probability q, the number of successes is about Nq, its expected value, typically within one standard deviation $\sqrt{Nq(1-q)}$ of it (ASSUMED from probability theory). (Sections 1.50 and 1.53.)
- **Exponent**: The caption quotes the count for $n = 16$ as computed, not typed: `f"{x:.1e}"` writes 16! as the text 2.1e+13, and `.split("e")` cuts it at the letter e into the mantissa 2.1 and the exponent +13 (both are still texts). (Section 1.25.)
- **Exponential**: the function e^t; $e^{-t} = 1/e^t$. (Sections 0.16, 5.18 and 5.26.)
- **Exponential function** e^x and **natural logarithm** $\ln x$, which undoes it: $\ln(e^x) = x$. The number $e = 2.71828\ldots$. (Sections 1.5 and 1.8.)
- **Exponential of a matrix**: $\exp(M) = 1 + M + \frac{1}{2}M^2 + \frac{1}{6}M^3 + \cdots = \sum_{k\geq 0} M^k/k!$, the same power series as for e^x. (Sections 5.21 and 10.31.)
- **Exponential wall**: This growth is called the exponential wall of the many-body problem. (Section 13.1.)
- **Exponentially**: A quantity whose rate of change is a fixed negative multiple of itself decreases exponentially: in every interval of time of length $1/(AH)$ it is multiplied by the same factor $e^{-1} = 0.3679$. (Section 0.14.)
- **Exporter**: the small Rust program, held as text inside the Wolfram check Revision/gkd_lovelock/verification/verify_lovelock_gkd.wls, that wrote the GKD values into a file for the Wolfram check. (Sections 1.49 and 1.53.)
- **Extra times** x_5, x_6, x_7: the three time-like directions of the author's space-time besides the time x_4. They are time-like like x_4, and they deflate exponentially: lengths along them carry the scale factor $e^{-a_4}\sin^{1/6} z$, which shrinks while a_4 grows, whereas ordinary space, with the scale factor $e^{a_4}\sin^{1/6} z$, inflates. (Sections 0.1, 1.1, 2.1, 3.1, 3.12, 3.34, 4.1, 6.8, 6.13, 6.27, 7.1, 7.26, 8.2, 9.2, 11.2, 12.1, 12.15, 17.2, 17.10, 17.20, 19.15, 19.20 and 21.2.)

- **Extra-time momentum** k_5, k_6, k_7: the momentum along the extra times; the good sector has $k_5 = k_6 = k_7 = 0$. (Section 21.29.)

F

- **F-string**: A string that starts with `f` is an f-string: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/00a.captions.json"`. (Sections 0.13, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15, 22.12, 22.23 and 23.12.)
- **Factorial**: Here $n! = 1 \cdot 2 \cdot 3 \cdots n$ (with $0! = 1$) is the factorial. (Sections 1.16, 2.3, 4.13 and 7.10.)
- **Falling factorial** $n!/(n-p)! = n(n-1)\cdots(n-p+1)$: the number of ways to choose p different labels from n in order (`math.perm(n, p)`). (Sections 1.43 and 1.47.)
- **False vacuum**: a state that has the lowest energy only among its neighbouring states; vacuum decay is its quantum transition into a state of still lower energy. (Section 20.2.)
- **Fermi level**: Words of the Kohn-Sham method used again here (Chapters 13 to 15 define them in full): an orbital is the wave of one quantum, and an eigen-orbital one that solves the Kohn-Sham equation with a definite energy; the Fermi level is the energy that separates the occupied orbitals from the empty ones; a state is self-consistent when the potentials computed from its own density are the potentials its orbitals were computed with; the good sector is the set of orbitals that do not depend on the extra times x_5, x_6, x_7; the Z2 mirror is the ASSUMED rule that the hidden direction continues beyond the brane as a mirror image of the computed patch, with the field there fixed by the field on the computed side (Chapter 14 states the rule; record `Revision/kohn_sham/ks-theory.json`, key `boundaryConditions.brane`). (Section 17.2.)
- **Fermi shell**: Fermi shell: the highest occupied shell of a state. (Sections 22.2 and 22.11.)
- **Fermi sphere, Fermi wave number** k_F: the ground state of the free gas fills every plane wave with $|\mathbf{k}| < k_F$, once per label. (Section 13.19.)
- **Fermi wave number**: The non-interacting ground state fills all $\mathbf{k}$ with $|\mathbf{k}| < k_F$ (the Fermi wave number), once for each of the g labels. (Section 13.15.)
- **Fermi-Dirac**: each orbital is an independent two-state system, occupied with the Fermi-Dirac probability f_a (the second step multiplies numerator and denominator by $e^{(\epsilon_a-\mu)/T}$). (Sections 13.26, 15.26 and 21.5.)
- **Fermi-Dirac occupation** $f(\epsilon) = 1/(e^{(\epsilon-\mu)/T}+1)$: the probability that an orbital of energy ϵ is occupied. (Sections 13.30, 15.29, 16.23, 21.2 and 21.35.)
- **Fermi-level crossing**: Fermi-level crossing: an empty level comes down below an occupied one along the history, so the aufbau filling changes. (Sections 15.21 and 15.24.)
- **Fermion**: a particle of a kind that obeys the Pauli principle: two identical fermions with the same label never occupy the same one-particle state. (Sections 7.10, 13.3 and 13.35.)

- **Fermion mode**: A fermion mode is a place that holds zero or one particle. (Sections 5.34, 10.18 and 21.26.)
- **Fermion modes, occupation**: a fermion mode is either empty (0) or occupied (1); 16 modes have $2^{16} = 65536$ states, each a list of 16 zeros and ones. (Section 21.29.)
- **Field**: a function of several coordinates, here $\phi(x_1, x_4)$ or $\phi(x_5, x_4)$, with the author's names: x_1 a direction of 3-space, x_4 the time, x_5 one of the three extra times. (Sections 0.1, 7.5 and 7.8.)
- **Field equation** (the Euler-Lagrange equation of the Revision record): $(\gamma^\mu D_\mu - V)\Psi = 0$ with $V = m + U'(S)$ a real function, m the mass, $D_\mu = \partial_\mu + \Omega_\mu$ the covariant derivative with the spin connection Ω_μ. (Sections 5.32, 7.21, 9.2, 12.2, 21.7 and 21.14.)
- **The field equations of Einstein-Lovelock gravity**: The field equations of Einstein-Lovelock gravity are $\sum_{k=1}^{3} \alpha_k \, E_{(k)}{}^\mu{}_\nu + \Lambda \, \delta^\mu_\nu = \kappa \, T^\mu{}_\nu$. (Section 12.8.)
- **Field equations of gravity**: $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda \, \delta^\mu_\nu = \kappa \, T^\mu{}_\nu$. (Sections 12.1 and 17.2.)
- **Field operators**: $\Psi_A = \sum_s \left((u_s)_A b_s + (v_s)_A d_s^* \right)$ for $A = 1, \ldots, 16$, with χ_A its Hilbert adjoint and the canonical conjugate $\Psi_A^\dagger = \sum_C \chi_C B_{CA}$. (Section 5.37.)
- **Field-equation expression**: Define the field-equation expression $E = \gamma^\mu D_\mu \Phi - V\Phi$ and its adjoint $\bar{E} = (D_\mu \bar{\Phi})\gamma^\mu + V\bar{\Phi}$ (sums over μ); a configuration is on shell exactly when $E = 0$, and then $\bar{E} = 0$ too. (Section 9.8.)
- **Figure, plot, axis**: a figure is a picture; a plot draws numbers as points or lines; the horizontal axis and the vertical axis are the two number lines of the plot. (Section 0.12.)
- **Fine grid**: One RK4 step needs the coefficients M, v and κ at the start, the middle and the end of the step, so the potentials are stored on the fine grid of the $2G + 1 = 1801$ step ends and midpoints, $y_i = -L + i\,h/2$. (Sections 15.3 and 22.12.)
- **Fingerprint**: To tie the two together, a report writes down a fingerprint of each file it read. (Sections 0.18, 0.20 and 0.24.)
- **Finite difference**: an approximation of a derivative from values of the function at nearby points, with a small spacing h. (Sections 2.22, 3.29, 9.17, 9.29, 11.26, 15.19, 17.2 and 17.20.)
- **First Bianchi identity**: (S2) The first Bianchi identity $R^a{}_{bcd} + R^a{}_{cdb} + R^a{}_{dbc} = 0$. (Section 3.17.)
- **First integral**: an equation with only first derivatives that every solution of a second-order equation obeys; here $a_4'^2$ as a function of a_4. (Sections 17.2 and 17.20.)
- **First jet**: At one point x, every quantity of the theory (the Lagrangian, the 16 components of the field operator, the 36 components of $T_{\mu\nu}$, the 8 of J^μ) is a polynomial in the 288 numbers of the first jet: the 16 values Ψ_A, the 16 values Ψ_A^* and the $2 \times 8 \times 16 = 256$ first derivatives $\partial_\mu \Psi_A$, $\partial_\mu \Psi_A^*$. (Section 18.20.)
- **First order**: an approximation that keeps only terms linear in the small amplitudes. (Section 22.11.)

- **First variation**: The first variation is its slope at $\epsilon = 0$: $S_1 = \frac{d}{d\epsilon} S[q + \epsilon\xi]\Big|_{\epsilon=0}$. (Sections 7.2 and 7.8.)
- **First-order Lagrangian**: a Lagrangian that contains the velocities only to the first power, like the Lagrangians of the fields of this book. (Section 7.8.)
- **First-order mean-field potential**: More words of the Kohn-Sham computations: a shell is a group of orbitals with the same energy, and a closed shell is a particle number N that fills every orbital up to some energy completely and none above it (so the ground state is unique); the first-order mean-field potential is the potential that one quantum feels from the others when the interaction is counted once, to first order in the coupling λ, with the density of the free gas; fixed occupations means that the same orbitals stay filled when a_4 is changed a little, even if their energies move. (Section 17.2.)
- **First-order system**: the second-order equation written as two first-order ones, $\frac{d}{dx_4} a_4 = v$ and $\frac{d}{dx_4} v = \kappa(p_3 - p_t)/F(v)$, with $v = a_4'$. (Section 12.24.)
- **Fisher-Yates shuffle**: a way to put a list into a random order by swapping entries one after the other. (Sections 1.49 and 1.53.)
- **Fit**: Fit: the least-squares straight line in $1 - a$ over a range of a. (Section 22.22.)
- **The five labels**: PROVED (exact; the book gives the complete proof and, where the Revision record contains an exact computer check of the statement, names the report file and the check), COMPUTED (a number from a numerical computation, with its measured uncertainty and the file that holds it), ASSUMED (a starting point that the book does not derive: a convention, a physical input or an approximation), HYPOTHESIS (an idea that is stated and examined but not established), OPEN (a question that neither the Revision record nor the book answers). (Section 0.20.)
- **Fixed occupations**: More words of the Kohn-Sham computations: a shell is a group of orbitals with the same energy, and a closed shell is a particle number N that fills every orbital up to some energy completely and none above it (so the ground state is unique); the first-order mean-field potential is the potential that one quantum feels from the others when the interaction is counted once, to first order in the coupling λ, with the density of the free gas; fixed occupations means that the same orbitals stay filled when a_4 is changed a little, even if their energies move. (Section 17.2.)
- **Fixed point** of a map G: a number x^* with $G(x^*) = x^*$. (Sections 13.21, 13.24 and 19.4.)
- **Flat**: A space whose Riemann tensor is zero everywhere is flat; conversely, near each point of a space with zero Riemann tensor there are coordinates in which the metric is constant (a standard theorem, quoted, ASSUMED). (Section 3.17.)
- **Flat 4+4 space**: space-time with the constant metric η, whose diagonal entries are $+1$, $+1$, $+1$, $+1$, -1, -1, -1, -1 in the order $x_0, \ldots, x_7$: no gravity, no inflation, no deflation. (Sections 4.9 and 4.11.)
- **Floating-point number**: the way the computer stores a number with a fraction part: a whole number of at most 53 binary digits times a power of 2. Python's `float` and numpy's `float64` are such numbers. They have about 16 significant decimal digits. (Sections 0.22, 0.24, 1.4, 1.8, 1.24, 4.11, 14.11 and 18.27.)

- **Floor**: The second term, $2 \cdot 10^{-12}$ times the size of R (at least 1), is a floor for the rounding errors of the computer, which do not shrink with h. (Section 16.5.)

- **Flux**: the value of the bracket at an end; a nonzero flux at $z = \pi/2$ means that something flows through the patch end (in or out). (Sections 5.6, 8.32, 10.2, 10.27, 10.31, 21.17 and 21.22.)

- **Fock operator**: $\hat{F}$ is the Fock operator. (Section 13.6.)

- **Fock space**: all combinations of the 65536 basis states. (Sections 5.34, 5.37, 9.13, 10.11, 10.18 and 10.25.)

- **Format string**: The three curves are W, W^2 and W^6 with $H = 1$; the third argument of `semilogy`, a short text called a format string, sets the line style: two hyphens draw a dashed line and a colon a dotted one (the plain `plot` lines of this book use the same format strings); `legend` shows the `label` texts in a box. (Section 14.11.)

- **Former measure**: `\w+` is one or more letters, digits or underscores (the name of a state, such as N8_lam0_a00_T10), `\S+` a number, and `\(` and `\)` are round brackets themselves; the four bracketed parts are the name of the state, the error of the old method, the former measure (the difference between the two runs when both used the old method) and the present measure (the difference seen by the present refined run). (Section 0.25.)

- **Forward difference**: The forward difference: $\frac{f(x+h)-f(x)}{h} = f'(x) + \frac{h}{2} f''(x) + \dots$. (Section 2.18.)

- **Fourth-order central difference**: `slope` estimates the derivative of a tabulated function with the fourth-order central difference of step $\delta = sh$: $f'(y) \approx \frac{-f(y+2\delta)+8f(y+\delta)-8f(y-\delta)+f(y-2\delta)}{12\,\delta}$. (Sections 17.21 and 22.23.)

- **Fraction** (rational number): p/q with whole numbers p and $q \neq 0$. (Sections 1.2 and 1.8.)

- **Frame**: Such a set is a frame, and the matrix $e^a{}_\mu$ that converts coordinate steps into frame components is the vielbein (German for "many legs"): the metric is $g_{\mu\nu} = \sum_{a,b} e^a{}_\mu \, \eta_{ab} \, e^b{}_\nu$. (Sections 3.7, 4.4, 4.9, 6.1, 8.2 and 8.14.)

- **Frame current** q_8: for a homogeneous field, the number $q_0 = -i\bar{\Psi}\gamma^{(x_0)}\Psi$, which depends on x_4 only; the hidden-direction charge current is $J^{x_0} = \tan z \, q_0$, so the flux through the brane is $\sqrt{|g|}J^{x_0} = \sin z \, q_0$. It is NOT the charge Q. (Section 18.21.)

- **Frame factors**: These factors are the frame factors: they carry the metric into every derivative term. (Sections 4.4, 7.18 and 8.2.)

- **Frame gamma matrices** $\gamma^{(a)}$: the author's eight real 16×16 matrices with $\gamma^{(a)}\gamma^{(b)}+\gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}$, $\eta = \mathrm{diag}(1,1,1,1,-1,-1,-1,-1)$ (in the order $x_0, \dots, x_7$). (Section 7.26.)

- **Frame index**: The upper index a is a frame index: it numbers the eight frame directions. (Sections 6.2 and 6.13.)

- **Frame metric** η_{ab}: the diagonal table $\mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order $x_0, \dots, x_7$; η^{ab} (upper indices) is its inverse. (Sections 1.9, 1.13, 1.27, 1.32, 4.7, 6.13, 6.27 and 8.2.)

- **Frame momenta**: What carries over is the algebra of the frame: in a region so small that the metric functions change little across it, waves with frame momenta k_a obey the same matrix algebra; the Revision record uses this local plane-wave reading with the coefficients of the equation held fixed. (Sections 4.9 and 8.17.)

- **Frame momentum**: Coordinate momentum q_a and frame momentum k_a: a wave $e^{iq_a x_a}$ has the coordinate momentum q_a; measured with proper lengths its momentum is $k_a = q_a/f_a$, the frame momentum. (Sections 8.28, 10.3, 10.39 and 10.42.)

- **Frame rotation** (local Lorentz transformation): a new vielbein $e'^a{}_\mu = \sum_b \Lambda^a{}_b(x)\, e^b{}_\mu$ with a matrix $\Lambda(x)$ that keeps η: $\Lambda^T \eta \Lambda = \eta$. It describes the same metric. (Section 6.21.)

- **Frame velocity**: Scale factor $h_a = \sqrt{|g_{aa}|}$ and frame velocity $\hat{u}^a = h_a u^a$: the proper length (along an extra time: the proper duration) that the body covers along x_a per unit of its own proper time, measured with the rulers and clocks of an observer at rest at its place; divided by u^4 it is the velocity that this observer measures. (Sections 3.31 and 3.34.)

- **Frame-dependent**: a quantity whose value changes when the vielbein is changed (such as $\gamma^\mu \Omega_\mu$). (Sections 6.15 and 6.21.)

- **Frame-independent**: Frame-independent: a statement that holds in every vielbein (such as "$F_{\mu\nu}$ is not zero"). (Section 6.21.)

- **Free**: A summed index is a dummy index (its name does not matter); an index that is not summed is a free index. (Sections 1.18, 1.24 and 1.26.)

- **Free energy**: Free energy $F = E - TS$; heat capacity $C_V = dE/dT$ at a fixed particle number. (Sections 13.30, 15.26 and 15.29.)

- **Free fall**: motion under no force other than the geometry. (Sections 3.16 and 3.34.)

- **Free index**: an index that appears once in every term of a formula; the formula holds for each of its values, so a formula with k free indices over 8 coordinates stands for 8^k equations. (Section 1.32.)

- **Freezing**: The mixture is freezing: as the gas redshifts, w moves toward the condensate's value (check `mixture_radiation_condensate_cpl`). (Sections 22.18 and 22.22.)

- **Frequency**: the number ε in $e^{-i\varepsilon t}$; for real ε the real and imaginary parts oscillate like cos and sin. (Sections 1.13, 1.16, 8.17, 9.29, 10.3, 10.9, 12.29, 20.12, 20.15 and 21.29.)

- **Frozen coefficients**: in a curved space the factors in front of the derivatives change from point to point and in time; near one point and for a short time one replaces them by their values at that point. The momenta measured with these factors are the *frame momenta* k_a. This is a device of the analysis near one point (labelled MODEL); it does NOT say that the extra times stop deflating: in the author's metric they always deflate exponentially, and Notebook 08b follows a wave along the deflating history. (Sections 8.17 and 8.22.)

- **Frozen-coefficient model**: The end of this section defines the frozen-coefficient model of the author's universe, which has the same equation with the derivatives divided by scale factors; it is an ASSUMPTION, because it also leaves out two terms of the author's field equation. (Section 10.3.)

- **Function**: `def` defines a function: a named piece of code that runs when it is called. (Sections 0.13, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15 and 22.12.)
- **Function of a Hermitian matrix**: A function of a Hermitian matrix $A = \sum_i a_i\, u_i u_i^\dagger$ (eigenvalues a_i, orthonormal eigenvectors u_i) is defined through its eigenvalues, $f(A) = \sum_i f(a_i)\, u_i u_i^\dagger$; for $f = \exp$ this agrees with the power series, because $A^m = \sum_i a_i^m u_i u_i^\dagger$. (Section 13.26.)
- **Function of several variables**: a rule $f(x, y)$ that gives a number for every pair of numbers (x, y) (or for every list $x_0, \ldots, x_7$). (Section 2.22.)
- **Functional**: The square brackets in $S[q]$ say that S depends on the whole function q, not on one number; a rule that takes a function and gives a number is called a functional. (Sections 7.2, 7.8 and 13.9.)
- **Functional derivative**: for every η, the function $\delta F/\delta n(x)$ is the functional derivative of F at n. (Sections 13.6 and 13.9.)
- **Fundamental symmetry**: A Krein space is a space with a Hermitian form $[u, v]$ that is *nondegenerate* (no nonzero u has $[u, v] = 0$ for all v) but *indefinite* (it takes both signs), together with a matrix J, the fundamental symmetry, with $J^\dagger = J = J^{-1}$, such that $[u, Jv]$ is a positive inner product. (Sections 10.13 and 10.18.)
- **Fundamental theorem of algebra**: The fundamental theorem of algebra (ASSUMED) says that a polynomial of degree n has exactly n roots $\lambda_1, \ldots, \lambda_n$ when complex numbers are allowed and a repeated root is counted as often as it appears, its multiplicity. (Section 1.34.)

G

- **Gamma matrices**: eight fixed 16×16 matrices of the author, one for each direction, from which the equations of both fields are built (Chapter 4). (Sections 0.2, 1.1, 1.32, 6.13, 8.22, 12.29, 14.10, 17.20, 18.8, 19.15, 19.20, 20.10, 20.15, 21.2 and 21.14; the opening of Chapter 4.)
- **Gap**: an energy interval without levels. (Sections 14.20, 16.20 and 16.23.)
- **Gate**: the script `Revision/verify_revision.sh` (for bash) and its twin `Revision/verify_revision.ps1` (for PowerShell 7). (Sections 23.2 and 23.11.)
- **Gauss-Bonnet**: Lovelock tensors $E_{(1)}, E_{(2)}, E_{(3)}$: the three curvature tensors built with the GKD; $E_{(1)}$ is the Einstein tensor and $E_{(2)}$ the Gauss-Bonnet tensor. (Section 12.2.)
- **Gauss-Bonnet scalar**: GB $= R^2 - 4R^a{}_b R^b{}_a + R^{ab}{}_{cd} R^{cd}{}_{ab}$ is the classical Gauss-Bonnet scalar. (Section 11.15.)
- **Gauss-Bonnet tensor**: Gauss-Bonnet tensor: the classical name of the order-2 Lovelock tensor. (Sections 11.2 and 11.18.)
- **Gaussian curvature**: A space of two dimensions has a single coordinate plane, and its curvature $\sigma(1, 2)$ is the Gaussian curvature. (Sections 3.17 and 3.21.)

- **Gaussian integers**: `random_matrix` is a 4×4 sympy matrix with random Gaussian integers (whole numbers $a + bi$ with a, b from -3 to 3; the `lambda i, j: ...` is a small unnamed function that gives the entry in row `i` and column `j`). (Sections 4.16 and 7.17.)

- **Generalized Kronecker delta**: $\delta^{u_1 \dots u_p}_{l_1 \dots l_p} = \det[\delta(l_i, u_j)]$, the author's `kδ[lower, upper]`. (Sections 1.1, 1.42, 1.47, 11.1, 11.2, 11.8, 11.18, 11.28, 12.2 and 12.15; the opening of Chapter 11.)

- **Generator expression**: The generator expression counts 1 for every nonzero symbol with $\mu \leq \nu$ (the symbols are symmetric in the two lower indices, so the pairs with $\nu < \mu$ are not new); the count is printed as a RESULT line: 25. (Sections 7.9, 8.15 and 18.9.)

- **Generator, Spin(4,4)**: the 28 matrices S^{ab} $(a < b)$ generate the spin transformations $R = \exp(\theta S^{ab})$, which turn the frame of the eight directions; their products form Spin(4,4). Spin(4,3) is the part generated by the 21 S^{ab} with $a, b \neq x_4$ (the transformations that leave the time x_4 alone). (Section 10.37.)

- **Generators** $S^{ab} = \frac{1}{4}[\gamma^a, \gamma^b] = \frac{1}{4}(\gamma^a \gamma^b - \gamma^b \gamma^a)$: the 28 matrices $(a < b)$ from which every element of the part of Spin(4,4) connected to 1 is built as a product of exponentials $\exp(\theta S^{ab})$. (Sections 4.13, 5.12, 5.16, 5.21, 7.10, 7.16, 8.4, 10.33, 10.48, 16.24, 17.11, 17.21, 18.8, 18.19, 21.2, 21.7 and 22.12.)

- **Geodesic**: a curve whose velocity is parallel transported along itself: the straightest possible curve. Its equation is $d^2x^a/ds^2 + \sum_{b,c} \Gamma^a{}_{bc}\,(dx^b/ds)(dx^c/ds) = 0$. (Sections 3.16, 3.21 and 3.29.)

- **Geodesic deviation equation**: In general the distance $\xi(s)$ between two neighbouring geodesics of a surface obeys the geodesic deviation equation $d^2\xi/ds^2 = -\sigma\,\xi$ with the Gaussian curvature $\sigma = \sigma(1,2)$ of Section 3.17 (a standard theorem, quoted, ASSUMED; on the sphere we have just verified it, with $\sigma = 1/a^2$). (Section 3.18.)

- **Geodesic equation**: $du^a/d\tau = -\sum_{b,c} \Gamma^a{}_{bc}\,u^b u^c$, with the Christoffel symbols $\Gamma^a{}_{bc}$ of the metric; its solutions are the paths of free fall. (Section 3.34.)

- **Geometric-tail rule**: If the last two ratios both lie between 0 and 0.5, the study takes the differences to go on shrinking like a geometric series, each one the fraction r (the last ratio) of the one before; this is the geometric-tail rule, and the limit, which the record calls the extrapolated value and Chapter 15 also the large-L value, adds the differences still missing: $x_\infty = x(L_{max}) + d_{last}\,(r + r^2 + r^3 + \dots) = x(L_{max}) + d_{last}\,\frac{r}{1-r}$. (Section 15.2.)

- **Ghost-like**: A component of negative classical energy is called ghost-like; it is not an established physical state. (Section 22.19.)

- **Ghost-like component**: a component of negative classical energy. (Section 22.22.)

- **Gibbs state**: In a finite-dimensional state space Ω has exactly one minimiser, the Gibbs state $\hat{\rho}_0 = e^{-(\hat{H}-\mu\hat{N})/T}/Z$ with $Z = \mathrm{Tr}\, e^{-(\hat{H}-\mu\hat{N})/T}$, and $\Omega[\hat{\rho}_0] = -T \ln Z$. (Sections 13.26 and 13.30.)

- **Git**: Git is the program that downloads the repository and keeps track of the versions of its files. (Section 0.8.)

- **GKD**: the Revision record's program (written in the language Rust) that computes the generalized delta without a determinant. (Sections 1.47, 11.2, 11.8 and 11.18; the opening of Chapter 11.)
- **Global U(1) transformation**: Multiplying every component of Ψ by the same $e^{i\alpha}$ is a global U(1) transformation (U(1) is the name of the group of these phases). (Section 21.22.)
- **Good sector**: the fields that do not depend on x_5, x_6, x_7 ($k_5 = k_6 = k_7 = 0$). (Sections 4.9, 5.34, 5.37, 8.17, 8.22, 8.35, 9.13, 10.4, 10.9, 10.20, 10.25, 10.42, 15.16, 17.2 and 21.29.)
- **Gradient**: the arrow $(\partial f/\partial x, \partial f/\partial y)$. It points in the direction in which f grows fastest and is perpendicular to the level curve through its point. (Sections 2.18, 2.22 and 3.14.)
- **Gram matrix**: The 256 numbers $\mathrm{tr}(\gamma_A^T \gamma_B)$ therefore form the table $16\,\delta_{AB}$; this table is called the Gram matrix. (Sections 4.13, 10.5, 14.31 and 15.5.)
- **Gram-Schmidt method**: This is the Gram-Schmidt method. (Section 10.10.)
- **Gram-Schmidt procedure**: The Gram-Schmidt procedure: it goes through the columns of a matrix P (the rows of `P.T`), subtracts from each column its parts along the columns already kept ($e^\dagger v$ is the size of the part of v along the unit column e), and keeps it, divided by its length, when the length that remains is not zero. (Section 5.38.)
- **Grand potential**: When the particle number is fixed only on average by a chemical potential μ, the equilibrium state at the temperature T minimises the grand potential. (Sections 13.26, 13.30, 15.26 and 15.29.)
- **Grassmann**: Statistics: dirac16complex has complex ANTICOMMUTING components, called Grassmann numbers ($\theta_1\theta_2 = -\theta_2\theta_1$, so $\theta\theta = 0$); dirac16complex00 has complex COMMUTING components (ordinary complex numbers). (Section 18.2.)
- **Grassmann algebra**: all sums of ordinary numbers times monomials, with the rules above. (Sections 7.10 and 7.16.)
- **Grassmann generators**: symbols that anticommute, $\theta_1\theta_2 = -\theta_2\theta_1$, so $\theta_1\theta_1 = 0$. They model the anticommuting components of dirac16complex. (Section 18.19.)
- **Grassmann numbers**: The components of dirac16complex are anticommuting numbers, also called Grassmann numbers after the mathematician who introduced them: exchanging two of them in a product costs a sign, $\Psi_r\Psi_c = -\Psi_c\Psi_r$, and in particular $\Psi_r\Psi_r = -\Psi_r\Psi_r$, so $\Psi_r\Psi_r = 0$. (Sections 5.29, 7.1, 7.10 and 7.16.)
- **Gravitational field**: in this book, the author's metric of Section 0.1, the rule for the lengths of small steps; since Einstein, gravity is described by such a rule (Chapter 3). (Section 0.2.)
- **Gravitational term**: We call $M = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ the gravitational term. (Section 7.18.)
- **Great circle**: Great circle: a circle on the sphere whose centre is the centre of the sphere (the equator, the meridians, and all their rotations). (Sections 3.16 and 3.21.)
- **Greatest common divisor** $\gcd(p, q)$: the largest whole number that divides both p and q (`math.gcd`). (Sections 1.2 and 1.8.)

- **Grid**: the equally spaced times $t_n = nh$, $n = 0, 1, \ldots, N$, with step $h = T/N$. (Sections 7.3, 7.8, 16.11 and 16.18.)
- **Grid error**: the difference between a number computed on a grid and the exact number. For the reference it shrinks like h^2. (Section 16.11.)
- **Grid, finite differences**: the line is replaced by equally spaced points; the second derivative is replaced by the difference formula $(f_{k+1} - 2f_k + f_{k-1})/h^2$. (Section 13.35.)
- **Ground states**: Ground states ($T = 0$): three particle numbers $N = 8, 136, 688$, five couplings and five slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$, that is $3 \cdot 5 \cdot 5 = 75$ states. (Sections 13.1 and 15.2.)
- **The ground states without interaction** (Notebook 15a, Out [7]; `Revision/kohn_sham/results/ground/summary.csv`): (Section 15.15.)
- **Group**: a set of invertible matrices that contains the products and the inverses of its members. (Sections 5.11, 5.16 and 19.21.)
- **Group, Pin(4,4)**: a group is a collection of transformations that can be combined and undone; Pin(4,4) is the group of the transformations of the sixteen components of a field that go with the rotations and reflections of the eight directions, rotations in a wide sense that includes the mixing of space-like and time-like directions (Chapter 5). (Section 0.2.)
- **Growth rate**: κ is the growth rate. (Sections 7.5, 8.18 and 8.22.)
- **Guide line**: For each ground state (`zip` pairs the colours with the ids) the left axes draw the distances $|E_{KS}(G) - R|$ against h with logarithmic axes (`loglog`: equal distances on the axis are equal factors), as circles joined by lines (`"o-"`, line width 1.5, marker size 6), and a dashed guide line proportional to h^2 that starts a factor 3 below the first point. (Section 16.12.)

H

- **Half nodes**: The cell ends, the nodes, are $y_i = -L + i\,h$ for $i = 0, \ldots, G$; the cell centres, the half nodes, are $y_{p+1/2} = -L + (p + \frac{1}{2})\,h$ for $p = 0, \ldots, G - 1$. (Sections 16.14 and 16.18.)
- **Half-density term**: The record calls it the half-density term (volume and vielbein divergence). (Sections 6.29 and 8.5.)
- **Hamiltonian**: The energy operator of one particle in an external potential $v(x)$ is the Hamiltonian. (Sections 10.11 and 13.2.)
- **Hamiltonian density**: The rest of the Lagrangian has no x_4-derivative; the Revision record writes it as $-\mathcal{H}$ with the Hamiltonian density $\mathcal{H} = \cos z\,[\Psi^\dagger(mC - \sum_{\mu \neq x_4} C\gamma^\mu D_\mu)\Psi + U(S)]$, so that $\mathcal{L} = \Psi^\dagger K \partial_4 \Psi - \mathcal{H}$ exactly, up to the total derivative (`python-field-theory.json`, check `hamiltonian_form_and_heisenberg_equation`). (Section 10.12.)
- **Harmonic trap**: the external potential $v(x) = x^2/2$, a parabola; a particle in it has the levels $1/2, 3/2, 5/2, \ldots$ (in the units below). (Sections 13.32 and 13.35.)
- **Hartree**: The first term is a Hartree (direct) term, the second an exchange term. (Sections 13.4 and 14.26.)

- **Hartree approximation**: The older Hartree approximation keeps v_H and drops the exchange integral, and with it the cancellation of the self-interaction. (Section 13.6.)
- **Hartree energy**: E_H is the Hartree energy: the classical energy of the cloud n with itself. (Sections 13.5 and 13.19.)
- **Hartree only**: (b) Hartree only: drop the exchange, $v_s = v + g_c n$; every fermion is then also repelled by its own density (the self-interaction of Section 13.5). (Section 13.32.)
- **Hartree potential**: the potential that one particle feels from the average density of all particles; exchange potential: the correction that comes from the Pauli principle (equal-label particles avoid each other). (Sections 13.6 and 13.35.)
- **Hartree term, exchange term**: the direct and the exchange part of the interaction energy. (Section 14.30.)
- **Hartree-Fock**: Hartree-Fock: keeping both, for a quasi-free state. (Sections 13.13 and 14.30.)
- **Hartree-Fock approximation**: The Hartree-Fock approximation takes the best single determinant: it minimises $\langle\Phi|\hat{H}|\Phi\rangle$ over all choices of N orthonormal orbitals. (Section 13.6.)
- **Hash values**: When Python prints a set, the order of its members depends on their hash values, numbers computed from the names with a secret key that Python chooses anew every time it starts, unless the environment variable `PYTHONHASHSEED` (a named setting that a program receives when it starts) fixes the key. (Section 0.22.)
- **Headless**: A notebook can also be run without a browser (headless) with `jupyter nbconver t`; the run instructions print the exact command. (Section 0.8.)
- **Heat capacity** $C_V = dE/dT = T\,dS/dT$ at fixed N: how much energy one unit of temperature costs. (Sections 13.26, 13.30, 15.26 and 15.29.)
- **Heat map**: a picture of a matrix in which every entry is a coloured square. (Sections 0.16, 1.18, 1.24, 4.7, 5.9, 6.13, 6.21, 6.27, 7.17, 9.16, 9.17, 10.10, 13.14, 14.11, 15.24, 16.19, 17.2, 18.9, 19.15 and 20.11.)
- **Heisenberg equation**: Differentiating with the product rule, and using that H commutes with $e^{\pm iHx_4}$ (both are power series in H), gives the Heisenberg equation. (Section 10.11.)
- **Hellmann-Feynman rule**: for a normalised eigenvector, the derivative of the level is the expectation value of the derivative of the Hamiltonian: $d\varepsilon/dk = \langle\chi|\,\partial h/\partial k\,|\chi\rangle$. (Sections 14.24 and 19.2.)
- **Hellmann-Feynman theorem**: the derivative of a level with respect to a parameter equals the matrix element of the derivative of the Hamiltonian. (Sections 15.21, 15.24 and 16.15.)
- **Hermitian**: $M^\dagger = M$. A Hermitian matrix has real eigenvalues. (Sections 1.36, 4.9, 4.11, 5.4, 5.9, 7.12, 7.16, 8.17, 8.22, 8.35, 9.25, 10.4, 10.9, 10.11, 13.2, 13.6, 14.4, 21.2, 21.14 and 22.6.)
- **Hermitian form, charge density**: a form $\Psi^\dagger X \Psi$ with a Hermitian matrix X; it is real for every Ψ. A charge density is the time component of a current. (Section 10.37.)
- **Hermitian matrix**: $H^\dagger = H$; a real Hermitian matrix is a symmetric matrix. (Sections 1.40 and 14.10.)

- **Hermitian part, anti-Hermitian part**: every matrix is $h = h_H + h_A$ with $h_H = \frac{1}{2}(h + h^\dagger)$ Hermitian and $h_A = \frac{1}{2}(h - h^\dagger)$ anti-Hermitian ($h_A^\dagger = -h_A$). (Section 10.42.)
- **Hex code**: Each colour is written as a hex code: `#` and three pairs of hexadecimal digits for the amounts of red, green and blue. (Section 3.13.)
- **Hexadecimal**: writing a number with the 16 digits `0-9` and `A-F` (worth 10 to 15); Python writes such a number with the prefix `0x`. One hexadecimal digit is exactly 4 bits. (Sections 0.18, 0.20, 0.24, 1.49 and 1.53.)
- **Hexadecimal colour codes**: The colours are written as hexadecimal colour codes: after `#`, three pairs of hexadecimal digits give the amounts of red, green and blue (from 00, none, to ff, 255). (Sections 0.17 and 17.11.)
- **Hidden**: The first, x_0, is a hidden direction of space. (Sections 0.1, 3.1, 3.12, 3.34, 7.26, 8.2, 9.2, 12.1, 12.15 and 21.2.)
- **Hidden angle** $z = 6Hx_0$: the metric depends on x_0 only through z, which runs from 0 to $\pi/2$ (the patch). $H > 0$ is a constant of the author's metric with the unit of an inverse length. (Section 12.2.)
- **Hidden coordinate** y: the book's coordinate along the hidden direction x_0, $y = \ln(\sin z)/(6H)$ with $z = 6Hx_0$; $y = 0$ is the end of the patch $z = \pi/2$ (the *brane*), and the interval is cut off at $y = -L$ (the *tip*). (Sections 2.24, 2.27, 3.12, 3.34, 8.28, 8.35, 14.10, 14.17, 17.2, 17.10, 17.20, 19.2, 19.15 and 19.20.)
- **Hidden direction**: Coordinates $x0, \ldots, x7$: the eight numbers that name a point, with the author's names: $x0$ the hidden direction; $x1, x2, x3$ ordinary 3-space; $x4$ the time; $x5, x6, x7$ the three extra times. (Sections 6.13, 6.27 and 10.31.)
- **Hidden equation**: Their four independent parts are the constraint (time, x_4), the 3-space equation, the extra-time equation and the hidden equation (x_0). (Section 12.2.)
- **Hidden position** y: the coordinate $y = \ln(\sin z)/(6H)$ by which the Kohn-Sham record measures the hidden direction, so that $\sin^{1/6} z = e^{Hy}$. The patch end $z = \pi/2$ is $y = 0$, and $y < 0$ lies towards the tip. (Section 10.42.)
- **Hilbert adjoint** X^* of an operator: the conjugate transpose of its matrix (with the ordinary, positive inner product of the Fock space). (Sections 5.34, 5.37, 10.11, 10.18 and 21.29.)
- **Hilbert norm**: The ordinary size of a column u is the Hilbert norm $u^\dagger u = |u_1|^2 + \cdots + |u_{16}|^2$. (Sections 8.19, 8.22 and 8.28.)
- **Hilbert space**: A space of states with a positive inner product is a Hilbert space. (Sections 10.11 and 10.18.)
- **Histogram**: bars that show how many numbers fall into each interval. (Sections 0.21, 1.32, 9.24, 9.25, 10.19 and 21.23.)
- **History** $a_4 = AHx_4$, $b_4 = 1$: the time dependence of the metric used for the numbers, the one of the Revision Kohn-Sham work ($A = 1$, $H = 1$); with $A > 0$ the extra times deflate. (Sections 3.34, 8.28, 11.2, 11.26, 14.24, 15.13, 17.10, 17.20 and 22.11.)

- **Hohenberg-Kohn theorem**: the ground-state density determines the external potential (up to a constant); Kohn-Sham inversion: finding the potential of NON-interacting electrons that gives the same density. (Section 13.13.)
- **Hole**: an empty place in a level that is normally occupied. (Sections 13.27 and 15.29.)
- **Holonomy** (turning angle): the angle by which a parallel-transported vector is turned after going once around a closed curve. (Section 3.21.)
- **HOMO**: `homo_lumo` returns the highest occupied level (HOMO: occupation above one half) and the lowest empty one (LUMO). (Sections 13.35, 15.13, 16.11, 19.20 and 19.21.)
- **Homogeneous**: Take a homogeneous configuration: one that depends on the time x_4 only, so that $\partial_\mu \Phi = 0$ for every $\mu \neq x_4$. (Sections 9.12 and 18.21.)
- **Homogeneous configuration**: A condensate (also called a homogeneous configuration) is a field that is the same at every place: it depends on the time x_4 only, not on $x_1, x_2, x_3, x_5, x_6, x_7, x_0$. (Section 9.18.)
- **Homogeneous field**: a field that does not depend on $x_1, x_2, x_3, x_5, x_6, x_7, x_0$, only on the time x_4. (Section 18.26.)
- **Homogeneous of degree 2**: e_{int} is homogeneous of degree 2: doubling both densities multiplies it by 4. (Section 14.27.)
- **Honesty ledger**: The honesty ledger is the table of the main statements of the book, each with its label (Section 0.3), a short note where one is needed, and the reports of the Revision record that verify it. (Section 0.18.)
- **Honesty rule**: The book therefore follows one rule above every other, the honesty rule: it teaches exactly what the Revision record proves and computes, with every assumption, and it never writes "proved" for a statement that is not proved. (Section 0.2.)
- **Hyperbola**: Since $\cosh^2 t - \sinh^2 t = 1$, the points $(\pm\cosh t, \sinh t)$ lie on the hyperbola $a^2 - b^2 = 1$ (blue, the columns of Krein norm $+1$) and the points $(\sinh t, \pm\cosh t)$ on $a^2 - b^2 = -1$ (orange). (Sections 1.13, 6.16 and 10.19.)
- **Hyperbolic cosine**: the function $\cosh\varphi = (e^\varphi + e^{-\varphi})/2$. (Section 1.13.)
- **Hyperbolic functions**: $\cosh\varphi = (e^\varphi + e^{-\varphi})/2$ and $\sinh\varphi = (e^\varphi - e^{-\varphi})/2$; they satisfy $\cosh^2\varphi - \sinh^2\varphi = 1$. (Sections 1.16, 5.21, 6.21 and 8.3.)
- **Hyperbolic sine**: the function $\sinh\varphi = (e^\varphi - e^{-\varphi})/2$. (Section 1.13.)
- **Hyperbolic sine and cosine**: We use the hyperbolic sine and cosine, $\sinh t = (e^t - e^{-t})/2$ and $\cosh t = (e^t + e^{-t})/2$: each is the derivative of the other, $\sinh 0 = 0$, and both are positive for $t > 0$. (Section 16.13.)
- **Hypotheses** (`Revision/pairing/kohn_sham/t3-theory.json`, hypotheses H1 to H6, in words): (Sections 19.10, 20.5 and 20.7.)
- **HYPOTHESIS**: a status label: an idea, such as a proposed mechanism or scenario, that is stated and examined but that this book does not establish. Example: the author's Hypothesis P, that the big bang creates universes of masses $+M$ and $-M$ in pairs (Section 20.3). (Sections 0.3, 0.20, 5.39, 12.31, 15.31, 20.3, 21.19, 21.37, 22.2 and 22.27.)

- **Hypothesis P**: Hypothesis P ("the big bang creates universes of masses $+M$ and $-M$ in pairs") therefore remains what it was: a HYPOTHESIS. (Section 20.26.)

I

- **Identity**: The identity 1 has ones on the diagonal and zeros elsewhere: $1A = A1 = A$. (Sections 4.19, 10.9 and 21.14.)
- **Identity in the jets**: a polynomial whose every coefficient is zero. It is zero for EVERY value of the jet, that is, for every field at every point, whether the field solves the field equations or not (*off shell*). An identity off shell holds in particular for solutions (*on shell*). (Section 18.19.)
- **Identity matrix** I: the square matrix with 1 on the diagonal and 0 elsewhere. (Sections 1.12, 1.18, 1.24, 4.2, 4.7 and 5.9.)
- **If**: Hence the total charge $Q = \int \cos z \, \Psi^\dagger B \Psi \, d^7x$ of one solution (at $b_4 = 1$; for a general b_4 it carries the factor $b_4^{3/2}$) is constant in time if its current flux through the boundary of the seven other directions vanishes (Section 5.6); this is a conditional statement, and its condition is not established (next list). (Section 5.39.)
- **Ill-conditioned**: The problem is ill-conditioned: its answer reacts strongly to small errors of its input. (Section 16.20.)
- **Illinois method**: All brackets are refined together, 16 rounds, by the Illinois method. (Section 19.16.)
- **Image**: the orbital, state or problem obtained by applying the map of T3. (Sections 5.11, 19.2 and 19.10.)
- **Imaginary part**: The number $a = \operatorname{Re} z$ is its real part and $b = \operatorname{Im} z$ its imaginary part. (Sections 1.10 and 1.16.)
- **Imaginary unit** i: a new number with $i^2 = -1$. Python writes it `1j`, sympy writes it `I`. (Sections 1.10 and 1.16.)
- **Indefinite**: a quadratic expression that can take both signs. (Sections 1.37, 5.34 and 21.22.)
- **Indefinite (Krein) metric**: a rule for the squared length of a quantum state that can also give negative numbers (Chapter 10). (Section 0.2.)
- **Independent universes**: two quantum fields Ψ_1, Ψ_2 on one state space with $\{\Psi_{1A}, \Psi_{2C}^\dagger\} = 0$ and $\{\Psi_{1A}, \Psi_{2C}\} = 0$: nothing done to one changes the anticommutation rules of the other. (Section 10.48.)
- **Index**: a letter such as i, j or k that numbers the components of a vector or the rows and columns of a matrix. In mathematics rows and columns are numbered $1, 2, 3, \ldots$; Python numbers them $0, 1, 2, \ldots$, so the entry A_{11} (row 1, column 1) is `A[0, 0]` in Python. (Sections 1.18, 1.24, 1.26, 1.32 and 3.2.)
- **Index list**: an ordered list of labels, such as (x_1, x_3, x_3); its length is the number of entries (here 3). (Sections 1.42, 1.47, 11.2 and 11.8.)

- **Index notation**: $a, b, c, \ldots$ each run over the eight coordinates $x_0, \ldots, x_7$; an upper and a lower index are positions in a table of numbers; ∂_c means the partial derivative $\partial/\partial x_c$. (Sections 1.26 and 3.29.)
- **Index up, index down**: a tensor component carries upper and lower coordinate labels, such as $R^{ab}{}_{cd}$; a label is raised with the inverse metric. (Sections 11.18 and 12.2.)
- **Inertia**: On an eigenspace of a real frequency $E \neq 0$, by contrast, the Krein form has four positive and four negative directions: its inertia is (4,4) (PROVED in the pairing record for every real frequency; `python-pairing.json`, checks `Q.one_particle_Krein_inertia_proof` and, for an exact sample, `Q.one_particle_Krein_inertia`). (Sections 8.19 and 10.9.)
- **Inflate**: The author's metric (the rule that gives the length of a small step in each direction; Section 0.14 introduces it from zero) makes ordinary space grow (inflate) and the three extra times shrink (deflate) exponentially as the time x_4 runs. (Sections 0.1, 0.14, 0.16, 3.5, 3.12, 4.4, 8.2, 11.26 and 14.2.)
- **Inflating**: Inflating means growing, deflating shrinking. (Sections 8.28 and 14.10.)
- **Initial values**: Given the values at one point (the initial values) it fixes the functions everywhere. (Section 15.8.)
- **Initial-value (Cauchy) problem**: find the field at later times x_4 from its values at $x_4 = 0$ (the *data*). (Section 8.22.)
- **Initial-value problem**: an ODE together with the starting value $y(0)$. Exactly one solution belongs to it (for the smooth f of Notebook 02a). (Sections 2.2, 2.10, 8.16 and 12.24.)
- **Inner product**: The inner product of two states ϕ and ψ is the complex number. (Sections 10.11, 10.18 and 13.2.)
- **Instability**: An imaginary part of a frequency is the mathematical sign of an instability; Chapter 8 meets it in the waves along the extra times. (Section 1.13.)
- **Instantaneous**: computed with the coefficients of one instant, as if they did not change. (Sections 10.39, 10.42, 15.21, 19.2 and 22.2.)
- **Instantaneous (adiabatic) state**: the ground state of the Hamiltonian $h(a_{4,0})$ of one instant of the history (one slice $a_{4,0}$); the history itself keeps moving, with 3-space inflating and the extra times deflating. (Section 15.24.)
- **Instantaneous level and orbital**: a solution $h\varphi = \varepsilon\varphi$ of the Hamiltonian h of one slice. (Section 22.11.)
- **Integers**: The whole numbers (or integers) are $\ldots, -2, -1, 0, 1, 2, \ldots$. (Section 1.2.)
- **Integral over the patch** $\int X$: the total amount of a density X in the computed region, $2\,\mathrm{Vol}_7 \int_{-3}^{0} e^{6Hy} X \, dy$ (Section 17.7). (Sections 17.2 and 17.10.)
- **Integration by parts**: the product rule $\frac{d}{dt}(fg) = \dot{f}g + f\dot{g}$ integrated from 0 to T: $\int_0^T f\dot{g}\,dt = [fg]_0^T - \int_0^T \dot{f}g\,dt$, where $[fg]_0^T = f(T)g(T) - f(0)g(0)$ is the boundary term. (Sections 7.2 and 7.8.)

- **Interaction**: The interaction $-U(S) = -\frac{\lambda}{2}S^2$ with a real coupling λ is quartic in the field. (Section 7.19.)
- **Interaction energy density** $e_{int} = \lambda(\frac{15}{32}S^2 - \frac{1}{32}n^2)$: the energy of the contact interaction per proper 7-volume. (Sections 15.19 and 19.4.)
- **Intermediate value theorem**: If F is continuous, it has a zero between them: this is the intermediate value theorem of calculus (ASSUMED: quoted without proof). (Section 2.12.)
- **Intertwiner**: a matrix X with $\gamma^a X = X\hat{\gamma}^a$ for every a. (Sections 4.17, 4.19, 5.11 and 5.16.)
- **Intertwiner condition**: A charge-conjugation matrix is a constant 16×16 matrix $\mathcal{C}$ for which the matrix $M = \mathcal{C}C$ obeys the intertwiner condition. (Sections 5.28, 5.32, 21.2, 21.8 and 21.14.)
- **Invariant**: Three facts follow from the definition, by the computation just made: a contraction of one upper with one lower index of a tensor is again a tensor (with two fewer indices); a product of tensors is a tensor; and a quantity in which every index is contracted, an invariant (or scalar), has the same value in every system of coordinates. (Sections 3.14, 3.29, 5.11, 10.33 and 10.37.)
- **Invariant mass** μ of a collection of bodies: $\mu^2 = E_{\text{tot}}^2 - |\vec{p}_{\text{tot}}|^2$, computed from the totals. Because the totals are conserved, so is μ. For one body μ is its mass. (Sections 20.17 and 20.20.)
- **Inverse** M^{-1}: the matrix with $MM^{-1} = M^{-1}M = 1$. When $MM = 1$, the matrix is its own inverse. (Sections 1.19, 4.2, 5.9 and 6.13.)
- **Inverse metric**: Metric $g_{\mu\nu}$, inverse metric $g^{\mu\nu}$ (the inverse matrix: $\sum_\lambda g^{\mu\lambda}g_{\lambda\nu} = \delta^\mu{}_\nu$, which is 1 when $\mu = \nu$ and 0 otherwise). (Sections 3.29, 11.2 and 11.18.)
- **Inverse vielbein**: The inverse vielbein $e_a{}^\mu$ is the inverse matrix, $\sum_\mu e^a{}_\mu e_b{}^\mu = \delta^a_b$ (1 when $a = b$, 0 otherwise). (Section 6.2.)
- **Inversion**: a pair of places in a permutation whose two entries stand in the wrong order (the larger one first). (Sections 1.19, 1.24, 1.47, 4.2, 11.2, 11.8 and 18.9.)
- **Invertible**: A square matrix M is invertible if there is a matrix M^{-1} with $MM^{-1} = M^{-1}M = I$; then the equation $Mv = w$ can be undone, $v = M^{-1}w$. (Section 1.20.)
- **Involution**: A map is an involution when applying it twice gives back the start. (Sections 19.2 and 19.9.)
- **Irrational**: A number that is not a fraction is called irrational; its decimal digits never end and never repeat (by the formula of Section 1.2, a number whose digits end or repeat is a fraction). (Sections 1.3 and 1.8.)
- **Irreducible**: The representation is irreducible when there is no other invariant subspace: the 16 components cannot be cut into smaller pieces that the group keeps apart. (Sections 5.11, 5.16 and 21.9.)
- **Isometry**: a change of coordinates that does not change the metric. (Sections 18.2, 18.19 and 20.22.)

- **Isotropic**: For a configuration that looks the same in the three directions of 3-space (such a configuration is called isotropic in 3-space), $T^{x_1}{}_{x_1} = T^{x_2}{}_{x_2} = T^{x_3}{}_{x_3} = p_3$, and likewise p_t for a configuration isotropic in the extra times. (Section 9.4.)

- **Iteration**: One iteration: (1) from the input x, solve every level of the label set (Section 15.3); (2) fill them (aufbau at $T = 0$, Fermi-Dirac at $T > 0$); (3) build the densities n and S and from them the output potentials $x_{out} = (\frac{15}{16}\lambda S,\ -\frac{1}{16}\lambda n)$; (4) the residual is $r = x_{out} - x$, and its size is its largest entry in absolute value. (Sections 13.35 and 15.5.)

J

- **Jacobi identity**: Multiplying out shows the Jacobi identity $[[X, Y], Z] = [X, [Y, Z]] - [Y, [X, Z]]$ for any three matrices (both sides are $XYZ - YXZ - ZXY + ZYX$). (Section 5.23.)

- **Jacobi's formula** for the derivative of the volume factor of a diagonal metric: (Section 2.19.)

- **Jacobian matrix**: The $n \times n$ table of partial derivatives $\partial x'^a/\partial x^b$ is the Jacobian matrix of the change. (Section 3.14.)

- **Janak's theorem**: the derivative of the self-consistent energy with respect to the occupation f_a of an orbital is its level ϵ_a. (Section 13.30.)

- **Jet**: the value of a field component and its derivatives at one point, treated as independent symbols (ψ_A, $\partial_\mu \psi_A$, ...). (Sections 7.13, 7.26, 7.32, 9.17, 18.2, 18.19 and 20.10.)

- **Jet at a point**: the values of the field and of its eight first derivatives at one point. The energy-momentum tensor needs nothing else. (Section 9.16.)

- **Jitter**: `rng.uniform(-0.28, 0.28, size=...)` gives one random number between -0.28 and 0.28 per ratio; adding it to the class's position spreads the dots a little sideways so that they do not hide one another (jitter). (Section 16.12.)

- **Job**: A ground-state job (one unit of work of the program) solves the state, its Delta-SCF excited state (one quantum moved from the highest occupied to the lowest empty group of levels), four neighbouring slices $a_{4,0} \pm 0.002$ and $a_{4,0} \pm 0.004$ at fixed occupations (for the derivative dE/da_4 and the adiabaticity measure of Chapter 15), and the list of the lowest particle-hole excitations, each on the three grids. (Section 16.3.)

- **Jordan-Wigner**: The sign rule that makes them anticommute is the Jordan-Wigner rule: acting on mode j gives the factor (-1) to the power of the number of occupied modes before j. (Sections 21.26 and 21.29.)

- **JSON** and **CSV**: two text formats for stored numbers (JSON: named entries in braces; CSV: a table, one line per row, entries separated by commas). (Sections 0.16, 16.11 and 23.11.)

- **Junction condition**: an equation that says how the fields and the geometry must match across a surface, here across the brane $z = \pi/2$. The junction conditions at the brane are not derived in this book: the Z2 mirror continuation is ASSUMED, and deriving the conditions is an open problem (OPEN, Section 22.15). (Sections 18.2, 22.2 and 22.15.)

- **Jupyter notebook**: Every worked example of the book is a Jupyter notebook: a file (with the ending `.ipynb`) that holds text and Python code in cells, together with everything the code printed and drew when it ran. (Section 0.7.)
- **JupyterLab** shows a notebook in your web browser and runs it: with the environment active, in the folder `Revision/textbook/notebooks`, the command `jupyter lab` followed by the name of the notebook file opens it, and the menu Run > Run All Cells runs every cell from the top. (Section 0.8.)

K

- **Kernel**: The kernel is the running Python program that executes the code cells one after the other. (Sections 0.7, 5.11 and 18.2.)
- **Key**: `read_levels` reads the level table of one state and returns a dictionary whose key is the key of a level, the four numbers (shell n_2, block type j, parity, Pruefer label l), and whose value is the pair (level, occupation). (Section 15.14.)
- **Key rule**: With line 10 this gives the key rule for all 64 pairs $A, B = 0, \ldots, 7$: $\tau_A \bar{\tau}_B + \tau_B \bar{\tau}_A = \bar{\tau}_A \tau_B + \bar{\tau}_B \tau_A = 2\,\mathrm{eta4488}_{AB}\, I_8$. (Section 4.5.)
- **Kinetic numbers**: The eight kinetic numbers $\Psi^T C \gamma^a \Psi$ are computed before and after the map Γ, and so is the scalar: $S = \Psi^T C \Psi$ before and $(\Gamma\Psi)^T C (\Gamma\Psi)$ after. (Section 21.15.)
- **Kinetic part**: The terms with derivatives (the K's) form the kinetic part; the terms without derivatives, $mS + U(S)$, form the potential part. (Section 9.7.)
- **Kinetic term** K_μ: the part of the Lagrangian that holds the derivative along the direction μ; potential energy: $mS + U(S)$, the part without derivatives. (Sections 7.19, 9.16 and 18.4.)
- **Kinetic term of the direction**: The number K_μ (no sum) is called the kinetic term of the direction x_μ: the part of the Lagrangian that holds the derivative along x_μ. (Section 9.3.)
- **Kinetic-sum identity**: This kinetic-sum identity holds off shell (PROVED; check `kinetic_sum_on_shell_C`). (Section 9.8.)
- **Kink**: Kink: a point where a function is continuous but its slope jumps. (Section 22.2.)
- **Klein's inequality**: $D = \mathrm{Tr}[\hat{\rho}(\ln\hat{\rho} - \ln\hat{\sigma})] \geq 0$ for two density operators, with equality only when they are equal. (Sections 13.26 and 13.30.)
- **Klein-Gordon equation**: So $\partial_4^2\phi = \partial_1^2\phi - m^2\phi$: the wave equation with a mass, called the Klein-Gordon equation. (Section 7.5.)
- **Kohn-Sham**: The spinor fields of Chapters 4 to 10 need its vielbein (the scale factors of Section 3.7); the energy-momentum tensor of Chapter 9 needs its Christoffel symbols (Section 3.23); the field equations of the metric functions a_4 and b_4 in Chapter 12 need its Einstein tensor (Section 3.25); the Kohn-Sham model of Chapters 14 to 17 (Kohn-Sham: an approximation of density functional theory that replaces many interacting particles by independent particles, each moving in one common effective potential; Chapter 13 teaches it from zero) is written in the hidden coordinate y of Section 3.9. (Section 3.1.)

- **Kohn-Sham approximation**: Rows 8, 9, 12 and 13 rest on the Kohn-Sham approximation, which is ASSUMED, not derived. (Section 0.18.)
- **Kohn-Sham energy**: and the Kohn-Sham energy of the doubled system is $E_{KS} = \sum g\, f\, \varepsilon - 2\,\mathrm{Vol}_7 \int_{-L}^{0} e^{6Hy} e_{int}\, dy$. (Section 15.2.)
- **Kohn-Sham equations**: one-particle Schroedinger equations in an effective potential $v_s(x)$ chosen so that their orbitals give the density of the interacting system. (Sections 13.10 and 13.35.)
- **Kohn-Sham gap** Δ_{KS}: the smallest cost of moving one particle from an occupied Kohn-Sham orbital to an empty one, $\Delta_{KS} = \epsilon_{LUMO} - \epsilon_{HOMO}$ (lowest unoccupied minus highest occupied level). In an interacting system the levels move when the occupations change, so Δ_{KS} is only a first estimate of the lowest excitation energy. (Sections 13.27, 15.13 and 19.20.)
- **Kohn-Sham inversion**: Hohenberg-Kohn theorem: the ground-state density determines the external potential (up to a constant); Kohn-Sham inversion: finding the potential of NON-interacting electrons that gives the same density. (Section 13.13.)
- **Kohn-Sham potential**: the derivative of the interaction energy density with respect to a density; it enters the one-quantum equation. (Sections 13.10 and 14.30.)
- **Kohn-Sham state**: an approximate state of many identical fermions, built from one-particle wave functions (*orbitals*) that each solve a one-particle equation in a common *effective potential*; the potential depends on the densities of the occupied orbitals, so the equations must be solved *self-consistently*. (Sections 15.13, 17.2, 17.10, 17.20, 19.2 and 19.20; the opening of Chapter 19.)
- **Kohn-Sham universe**: a solution of the equations of the density-functional approximation, in which the field moves in a potential computed from its own density; self-consistent means that this potential and this density fit each other; the mass of the field in this model is written M (Chapters 13 to 15). (Section 0.2.)
- **Krein**: Because B has eight eigenvalues $+1$ and eight -1, the state space carries an indefinite Krein form when $\Psi^\dagger$ is read as the ordinary adjoint (Chapter 10). (Section 18.22.)
- **Krein (indefinite) form**: the form $\Phi^\dagger B \Phi$ built with the matrix B, which has eight eigenvalues $+1$ and eight eigenvalues -1; it can be positive or negative. (Section 9.24.)
- **Krein boost**: A Krein boost of a pair, $u_1' = \cosh t\, u_1 + \sinh t\, u_9$ and $u_9' = \sinh t\, u_1 + \cosh t\, u_9$ (with $Bu_1 = u_1$, $Bu_9 = -u_9$, both of length 1 and orthogonal), keeps the Krein norms, because $\cosh^2 t - \sinh^2 t = 1$, and keeps the two modes Krein-orthogonal, because $\cosh t \sinh t - \sinh t \cosh t = 0$; but it changes the ordinary squared length to $\cosh^2 t + \sinh^2 t$. (Section 10.14.)
- **Krein form**: the number $u^\dagger B v$ for two columns u, v. Because B is Hermitian, $u^\dagger B u$ is real, but it can be positive, negative or zero. In the theory it is the charge of the wave u. (Sections 8.19, 8.22, 8.28, 10.2, 10.9, 10.18 and 21.29.)
- **Krein form, Krein charge**: $\int \cos z\, u^\dagger B v\, dx_0$; for $u = v = \Psi$ it is the charge of the wave. (Section 10.31.)

- **Krein inertia** of a set of columns: how many independent directions have a positive and how many a negative Krein norm. (Sections 9.21, 10.5, 10.42, 18.26, 21.26 and 21.29.)
- **Krein matrix** $B = -iC\gamma^{(x_4)}$: the charge density is $\Psi^\dagger B\Psi$, and B is the matrix of the canonical anticommutator of the quantised field (Chapter 10). (Sections 18.2, 20.2, 21.2, 21.7, 21.14 and 21.29.)
- **Krein norm** of a column u: the real number $u^\dagger Bu$, which can be positive or negative because B has eight eigenvalues $+1$ and eight -1. (Sections 10.2, 18.2 and 18.26.)
- **Krein self-adjoint**: In words, h is Krein self-adjoint: $Bh = h^\dagger B$. (Section 10.4.)
- **Krein sign** σ of a map M: the sign in $MBM^\dagger = \sigma B$. (Sections 14.5, 18.2, 18.8 and 19.2.)
- **Krein space**: a space with an *indefinite* inner product (some vectors have a negative norm). (Sections 1.37, 5.34, 5.37, 10.13, 10.18 and 21.25.)
- **Krein-neutral**: So the Krein form vanishes identically on the eigenspace of a growing frequency: the eigenspace is Krein-neutral (PROVED by the argument just given; the pairing record proves the same and checks it on exact samples, `Revision/pairing/reports/python-pairing.json`, check `Q.one_particle_complex_frequency_Krein_neutral`). (Sections 8.19, 10.5, 10.42, 18.23, 18.27, 21.26 and 21.29.)
- **Krein-orthonormal modes**: columns u_n with $u_n^\dagger Bu_m = \epsilon_n\delta_{nm}$, $\epsilon_n = +1$ or -1. A *Krein boost* mixes a mode of Krein norm $+1$ with one of -1 by the numbers $\cosh t$ and $\sinh t$; it keeps the Krein form but changes the ordinary length. (Section 10.18.)
- **Krein-unitary**: We call such an R Krein-unitary. (Sections 10.34 and 10.37.)
- **Kretschmann scalar** $K = \sum_{a,b,c,d} R^{ab}{}_{cd}R^{cd}{}_{ab}$: one number per point, the same in every coordinate system (an invariant). (Sections 3.17, 3.21 and 3.29.)
- **Kronecker delta** δ^a_b: 1 if $a = b$ and 0 otherwise; as a table it is the identity matrix I. (Sections 1.18, 1.24, 1.32, 1.42, 1.47, 4.2, 4.7, 11.2 and 11.8.)
- **Kronecker product** `np.kron(L, R)`: the big matrix whose block in block row r and block column k is L_{rk} times the whole matrix R. (Sections 4.17, 4.19, 5.13, 5.16, 10.38 and 21.15.)
- **KS gap**: HOMO, LUMO: the highest occupied and lowest unoccupied level; the KS gap is their difference. (Section 16.11.)

L

- **L1 measure**: The record measures the remaining part in two ways: $\mu_1 = \int e^{6Hy}|X - \bar{X}|\,dy / \int e^{6Hy}|X|\,dy$ (the L1 measure) and $\mu = \sqrt{D(\bar{X})/D(0)}$ (the L2 measure); both are 0 for a flat profile. (Section 17.17.)
- **L2 measure**: The record measures the remaining part in two ways: $\mu_1 = \int e^{6Hy}|X - \bar{X}|\,dy / \int e^{6Hy}|X|\,dy$ (the L1 measure) and $\mu = \sqrt{D(\bar{X})/D(0)}$ (the L2 measure); both are 0 for a flat profile. (Section 17.17.)

- **Label**: a name of a coordinate, here $x_0, \ldots, x_7$. The computer often numbers them $0, \ldots, 7$; only the question "are two labels equal?" matters below, so the names do not change any result. (Sections 1.42, 1.47, 2.24, 2.27, 11.2, 13.19, 13.35, 14.13, 14.14, 14.24, 15.8, 16.11, 19.21, 22.2 and 22.11.)

- **Label set**: For a state of the gas the solver chooses the sectors and labels it will solve, its label set. (Section 15.4.)

- **Lagrange multiplier**: The number λ is a Lagrange multiplier; with several conditions one takes one multiplier for each. (Section 13.6.)

- **Lagrangian**: the function from which the equations of a field follow (Chapter 7). (Sections 0.2, 7.2, 7.8 and 10.48; the opening of Chapter 7.)

- **Lagrangian density** L: the function whose integral (the action) must not change to first order when the field is varied; that requirement is the Euler-Lagrange equation, the field equation. (Sections 7.5, 7.8 and 7.26.)

- **Lambda**: A lambda is a function written in one line without a name: `lambda e: ...` takes an entry `e`, multiplies it out, replaces every w^2 by $m^2 + k_s^2 - k_t^2$ (the expression `w2_sym` of In [6]) and multiplies out again. (Sections 10.10, 16.12 and 16.19.)

- **Laplace's rule**: Laplace's rule for determinants of every size, and the expansion of every Lovelock tensor along the column of its free upper label, $P_{(k)} = \delta\, L_{(k)} - 2k\, Y_{(k)}$ (Section 11.13; Notebook 11b, In [21]). (Section 11.28.)

- **Laurent polynomial**: The program represents every quantity as an exact Laurent polynomial (a sum of monomials that may contain negative powers, such as $\cot^{-1} z$) in H, a_4', a_4'' (and the higher derivatives), e^{a_4}, $\sin^{1/3} z$ and $\cot z$, with coefficients that are exact fractions of whole numbers (the files `poly.rs` and `rational.rs` of the crate; every operation that would overflow stops the program instead of rounding). (Sections 11.12, 11.18 and 12.16.)

- **Laws of powers**: Power a^p and root $a^{1/n}$; the laws of powers $a^p a^q = a^{p+q}$, $(a^p)^q = a^{pq}$, $(ab)^p = a^p b^p$, $a^{-p} = 1/a^p$ for positive a, b. (Section 1.8.)

- **Lax-Mizohata theorem**: a standard theorem of the theory of partial differential equations (P. D. Lax, 1957; S. Mizohata, 1961), quoted in this book without proof and therefore ASSUMED: if the initial-value problem of a linear system of first-order equations with smooth coefficients is well posed near a point, then at that point the frequencies of its principal part are real for every real momentum. (Section 8.18.)

- **Lead checks**: short independent Python programs of the Revision record (folder `Revision/lead_checks`), written from scratch by the coordinator of the Revision work (the "lead") without importing any other Revision code; each writes a report with a list of named checks and their verdicts. (Sections 3.7, 3.12 and 3.29.)

- **Lead report**: The lead report is the file `emt-divergence-and-spin-connection.json` in the folder `Revision/lead_checks/reports`, written by an independent program of the lead of the Revision work for the metric at $b_4 = 1$. (Section 6.1.)

- **Leaf**, **pruning** (skipping): a complete combination of k curvature entries in the computer's search; pruning means leaving out combinations known to give zero. (Sections 11.2 and 11.12.)

- **Least squares**: the straight line through a set of points that makes the sum of the squared vertical distances of the points from the line as small as possible. (Sections 2.6, 13.21, 17.2 and 17.20.)

- **Ledger**: the table of the statements, their labels and the reports that verify them. (Section 0.20.)

- **Left (right) derivative** $\partial_L F/\partial\theta_k$ ($\partial_R F/\partial\theta_k$): move θ_k to the far left (right) of every monomial that contains it, collecting a -1 for every generator it passes, and then delete it. (Section 7.16.)

- **Left derivative**: The left derivative $\partial_L F/\partial\theta_k$: in every monomial that contains θ_k, move θ_k to the far left, collecting a -1 for every generator it passes, and then delete it; monomials without θ_k give nothing. (Sections 7.11 and 18.20.)

- **Left multiplication**: For a fixed quaternion u the right multiplication R_u maps q to $q\,u$ and the left multiplication L_u maps q to $u\,q$. (Section 4.5.)

- **Legend**: `plot` draws a curve through the points; `lw` is the line width, `ls` the line style (two hyphens in quotes mean dashed, a colon `":"` dotted), and `label` the text for the legend (the box that names the curves), which `legend` draws in the upper right corner. (Section 19.16.)

- **Legendre transform**: the rule that turns a Lagrangian into the energy (Hamiltonian) density: for each field, its time derivative times its canonical momentum, summed over the fields, minus the Lagrangian. (Section 18.2.)

- **Leibniz formula**: the sum over all $n!$ permutations σ of $1,\dots,n$ (the Leibniz formula). (Section 1.20.)

- **Lemma**: a proved statement that is a step towards others (Notebook 20c). Compare Proposition and Schur's lemma. (Section 20.20.)

- **Length**: Length (norm) of a vector, $|v| = \sqrt{v_1^2 + \cdots + v_n^2}$; a unit vector has length 1. (Sections 1.36, 1.40, 1.42, 1.47, 2.18, 10.11, 11.2 and 11.8.)

- **Length factor**: the number $f_i = \sqrt{|g_{ii}|}$; a small step dx_i along x_i has the size $f_i\,|dx_i|$. (Sections 0.14, 0.16 and 1.5.)

- **Lepton number** L: $+1$ for the electron and its neutrino ν_e, -1 for the positron and the antineutrino $\bar{\nu}_e$, 0 for quarks and photons. It is not the Lagrangian $\mathcal{L}$. (Sections 21.2 and 21.35.)

- **Level**: an allowed energy ε of the one-particle equation. (Sections 14.3, 14.17, 14.24, 15.13, 16.18, 16.23, 19.2, 19.15, 19.20 and 22.2.)

- **Level curve**: A level curve (contour) is a curve on which f has one fixed value. (Sections 2.18 and 2.22.)

- **Level key** `n2:j:parity:rank`: the shell $n_2 = |\vec{n}|^2$ of the 3-space momentum, the block type $j = \pm 1$, the brane parity (even or odd), and the rank, the position of the level among the particle levels of its sector (0 = the lowest). (Section 16.11.)

- **Level ladder**: For each case a level ladder at the horizontal place $x_0 = 0, 3, 6$: every exact level is a short horizontal line (from $x_0 + \text{shift} - 0.4$ to $x_0 + \text{shift} + 0.4$), even parity at the left and odd parity 1.2 further right, and the numerical level is a marker in its middle. (Section 14.18.)

- **Levi-Civita symbol** $\varepsilon_{i_1 \ldots i_n}$: the sign of the list $(i_1, \ldots, i_n)$ if it is a re-ordering of all n labels, and 0 otherwise. (Sections 1.44, 1.47, 4.5 and 11.2.)

- **Levi-Civita tensors**: The author's notebook builds the generalized delta also in a second way, from two Levi-Civita tensors, in the cell In[32] (record `Revision/gkd_lovelock/results/notebook-input-cells.txt`). (Section 11.5.)

- **Lichnerowicz identity**: The Revision record proves the Lichnerowicz identity for the square of the Dirac operator in the author's metric, for every Ψ, solution or not (the formula is displayed in that section). (Section 7.23.)

- **Lie algebra so(4,4)**: the commutation rules $[S^{ab}, S^{cd}] = \eta^{bc} S^{ad} - \eta^{ac} S^{bd} - \eta^{bd} S^{ac} + \eta^{ad} S^{bc}$ of the 28 generators. (Sections 5.18 and 5.21.)

- **Light line**: One square panel. 200 rapidities from -1.4 to 1.4 trace the two unit hyperbolas: $(\cosh b, \sinh b)$, where $t^2 - y^2 = 1$ (blue), and $(\sinh b, \cosh b)$, where $y^2 - t^2 = 1$ (orange); the dotted diagonal is the light line $t = y$. (Section 6.22.)

- **Light-like** vector: $v \neq 0$ with $Q(v) = 0$ (notebook 01e). (Sections 1.13, 1.27, 1.32 and 1.40.)

- **Line**: Two wrong paths with the same end values are the line $q = t$ and the parabola $q = t^2$. (Section 7.2.)

- **Line continuation**: The second statement is broken over two lines by a backslash at the end of the first (a line continuation); it tests that $(\Gamma r)^T C (\Gamma r) - r^T C r$ is exactly zero, so Γ keeps S. (Section 21.15.)

- **Line element**: the formula for ds^2. (Sections 1.29, 1.32, 3.3 and 3.12.)

- **Linear**: The map $v \mapsto Av$ is linear: $A(v + w) = Av + Aw$ and $A(cv) = c\,Av$, because $\sum_j A_{ij}(v_j + w_j) = \sum_j A_{ij} v_j + \sum_j A_{ij} w_j$ and $\sum_j A_{ij}(c v_j) = c \sum_j A_{ij} v_j$ (multiply out inside the sum; a common factor comes out of a sum). (Sections 1.18 and 4.2.)

- **Linear combination**: $c_1 M_1 + c_2 M_2 + \ldots$ with numbers c_j. (Sections 4.2 and 4.15.)

- **Linear equation, system**: an equation of the form $c_1 y_1 + c_2 y_2 + \cdots + c_n y_n = 0$ for unknown numbers $y_1, \ldots, y_n$ with given coefficients c_j. (Section 5.16.)

- **Linear equations**: So $LX - XR = 0$ is a list of nm linear equations for the nm entries of X: in the equation (r, c) the unknown X_{kc} has the coefficient L_{rk} and the unknown X_{rk} the coefficient $-R_{kc}$. (Section 5.13.)

- **Linear expression**: A linear expression in some variables $p, q, \ldots$ is a sum of the variables, each multiplied by a fixed number (or, below, a fixed matrix), its coefficient: $\alpha p + \beta q$ is linear, while p^2, pq and $\sqrt{p^2 + q^2}$ are not. (Section 4.1.)

- **Linear history** $a_4 = AHx_4$ with a constant number A: then $a_4' = AH$ and $a_4'' = 0$, and the extra times shrink like e^{-AHx_4}: exponential deflation for $A > 0$. (Sections 3.8, 11.2 and 11.26.)

- **Linear member**: the history $a_4 = AHx_4 + a_0$ with a constant slope A. For $A > 0$ the extra times deflate as e^{-AHx_4}. (Sections 12.2, 12.19, 12.29, 17.2, 17.10, 20.10 and 20.15.)

- **Linear mixing**: Plain iteration: $x \leftarrow G(x)$; linear mixing: $x \leftarrow (1-\beta)\,x + \beta\,G(x)$ with the mixing parameter β. (Sections 13.21, 13.24, 15.5 and 15.8.)

- **Linearly dependent**: We use one fact of linear algebra without proof (ASSUMED): more than n vectors with n components are linearly dependent, that is, some combination $c_1u_1+c_2u_2+\cdots$ with numbers c_i not all 0 gives the zero vector. (Section 1.36.)

- **Linearly independent**: Multiplying from the left by γ_A^T and taking the trace gives $\sum_B c_B \,\mathrm{tr}(\gamma_A^T\gamma_B) = 16\,c_A = 0$, so every coefficient is 0: the 256 products are linearly independent (no combination of them with coefficients not all zero gives the zero matrix). (Sections 4.13, 4.15, 5.11 and 8.6.)

- **Linearly independent matrices**: no one of them is a combination of the others. Writing each 16×16 matrix as one row of 256 numbers, N matrices are independent when these N rows have rank N. (Section 5.16.)

- **List**: `here.parents` lists the parent folder, its parent, and so on up to the top of the disk; `[here, *here.parents]` is the list (an ordered collection, written in square brackets) that starts with `here` and continues with all of them. (Sections 0.13, 0.20, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15, 21.23 and 22.12.)

- **List comprehension**: The line `different = [...]` is a list comprehension: it collects every package `p` whose installed version differs from its pinned version `v` (`!=` means "is not equal to"). (Sections 0.13, 1.9, 3.13, 4.8, 4.12, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 19.16, 20.11 and 22.23.)

- **Literal sum**: Brute force, literal sum: a computation that tries every case without any shortcut. (Section 11.18.)

- **Local**: What this theory proves is: the charge of each field obeys an exact local conservation law (it follows from an exact U(1) symmetry), so no process creates or destroys charge at any point inside a universe off its edge (at every point with $0 < z < \pi/2$, where the law is proved): charge can only flow from one place to another; the total charge Q of a universe is constant only if no charge flows out through the edge $z = \pi/2$ of the hidden direction, and this no-flux condition is ASSUMED, not derived (whether a boundary condition at the edge supplies it is OPEN; Chapters 10, 18 and 21 show exact solutions through whose edge charge does flow, so that their total charge changes); the discrete symmetries of the theory are derived exactly (Chapter 21), among them its two charge conjugations, which are matrices, $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$; and a T1 partner (mass $-m$, self-coupling $-\lambda$) carries the opposite charge, so a T1 pair $\{+m, -m\}$ has total charge zero as classical fields (for two universes that are quantised independently of each other there is no such cancellation; this is part of Q). (Sections 0.2, 14.26, 21.16 and 21.22.)

- **Local conservation law**: The Revision record proves a local conservation law: for every solution of the field equation. (Sections 0.2, 5.6 and 10.2.)

- **Local density approximation**: The local density approximation (LDA) treats each small volume as a piece of uniform gas with the local density: $E_{xc}^{LDA}[n] = \int e_{xc}(n(\mathbf{r}))\, d^3r, \qquad v_{xc}^{LDA}(\mathbf{r}) = \frac{de_{xc}}{dn}\Big|_{n(\mathbf{r})}$. (Section 13.15.)

- **Local frame rotation**: Such a point-dependent turning of the frame is a local frame rotation (a rotation, or a boost when it mixes a space-like with a time-like direction; Chapter 5). (Section 6.2.)

- **Local-frame model**: the equation $i\,du/dx_4 = h(x_4)u$ in which the frame momenta change with x_4 as the history prescribes, while the hidden position is held fixed (section 4 of Notebook 08b). (Sections 8.25, 8.28 and 10.42.)

- **Log-log plot**: A log-log plot marks both axes in powers of ten, so the errors of a method of order p lie on a straight line of slope p, and the order can be read off as a slope. (Sections 2.6 and 2.10.)

- **Log-sum-exp**: The solver solves $\ln(P + d_-) - \ln(H_l + d_+) = 0$ with $d_\pm = \max(\pm d, 0)$, adding each sum in the form $\ln \sum e^{t_i} = t_{max} + \ln \sum e^{t_i - t_{max}}$ (the log-sum-exp, which never overflows or underflows), by Newton's method in a bracket and then bisection down to neighbouring double-precision numbers (`Revision/kohn_sham/solver/src/mermin.rs`). (Section 15.26.)

- **Logarithm**: The logarithm $\log_{10} x$ is the power to which 10 must be raised to give x; for example $\log_{10} 1000 = 3$ and $\log_{10} 0.001 = -3$. (Sections 2.6 and 2.10.)

- **Logarithmic**: `ax.set_yscale("log")` makes the vertical axis logarithmic: equal distances on it mean equal factors (0.1, 1, 10, 100). (Sections 0.17, 4.12 and 19.21.)

- **Logarithmic axes**: The right panel draws the size of the errors (`np.abs`) against the width on logarithmic axes (`loglog`), one marker shape per centre, and a grey dashed reference line proportional to w^2, which on these axes is a straight line of slope 2. (Sections 7.9 and 16.12.)

- **Logarithmic axis**: an axis on which equal steps mean equal *factors* (1, 10, 100, ...) instead of equal differences; on it e^t and e^{-t} are straight lines. (Sections 0.16, 1.5, 1.8, 9.17 and 11.9.)

- **Logarithmic derivative** $\partial \ln s/\partial x = (\partial s/\partial x)/s$: the rate of growth of s per unit of x, as a fraction of s itself. (Sections 2.19 and 2.22.)

- **Logarithmic vertical axis**: `semilogy` draws with a logarithmic vertical axis: equal distances mean equal factors (each tick is ten times the one below). (Section 14.11.)

- **Long division**: the school method that produces the decimal digits of p/q one after the other from the remainders. (Section 1.8.)

- **Long step**: A long step is one documented as longer than 5 minutes, or one that needs such a step (`ks-rust-determinism`, 30 s, needs the refined run). (Section 23.2.)

- **Lovelock equations**: In eight dimensions the field equations of gravity that the author's theory uses are the Lovelock equations (Chapters 11 and 12). (Section 1.42.)

- **Lovelock scalar**: $L_{(1)}$ is the first Lovelock scalar: the Revision record builds the field equations from three curvature scalars $L_{(1)}, L_{(2)}, L_{(3)}$, made from products of one, two or three Riemann tensors with the generalized Kronecker delta of Chapter 1, and the first of them is

exactly twice the Ricci scalar, $L_{(1)} = 2R$ (Chapter 11 treats all three). (Sections 3.30, 11.2, 11.11, 11.18 and 11.26.)

- **Lovelock scalars and tensors**: curvature quantities built from products of one, two or three Riemann tensors with the generalized Kronecker delta; the first Lovelock scalar is $L_{(1)} = 2R$ and the first Lovelock tensor is $P_{(1)} = -4G$. A later chapter treats them in full. (Section 3.29.)
- **Lovelock tensors**: combinations of the curvature of spacetime that enter the field equations of gravity in more than four dimensions; the Revision record computes three of them for the author's metric, with GKD as the weight of every term. (Sections 1.43, 1.47, 3.26, 11.2, 11.11, 11.18, 11.26, 12.2, 12.7, 12.15, 17.2 and 20.10; the opening of Chapter 11.)
- **Lower**: A pair of index lists is a lower list $(l_1, \ldots, l_p)$ and an upper list $(u_1, \ldots, u_p)$ of the same length. (Sections 11.2 and 11.8.)
- **Lower incomplete gamma function**: In the second substitute $u = Ky$ ($dy = du/K$, limits 0 and K): $\int_0^1 y^{K-1} e^{-Ky} dy = \int_0^K (u/K)^{K-1} e^{-u} du/K = K^{-K}\gamma(K, K)$, where $\gamma(s, x) = \int_0^x u^{s-1} e^{-u} du$ is the lower incomplete gamma function. (Section 21.6.)
- **Lower index**: A second list of eight numbers that belongs to the same vector, $v_0, \ldots, v_7$, carries a lower index; Section 1.27 says how one list is made from the other. (Section 1.26.)
- **Lowering**: So lowering an index keeps the four space-like components and changes the sign of the four time-like ones: for $v^a = (1, 2, \ldots, 8)$ (that is $v^0 = 1, v^1 = 2, \ldots, v^7 = 8$), $v_a = (1, 2, 3, 4, -5, -6, -7, -8)$. (Sections 1.27 and 6.27.)
- **Lowering and raising**: $v_a = \eta_{ab} v^b$ and $v^a = \eta^{ab} v_b$. (Section 1.32.)
- **Lowest terms**: The spelling is in lowest terms when p and q have no common factor larger than 1. (Sections 1.2 and 1.8.)
- **LUMO**: HOMO, LUMO: the highest occupied and lowest unoccupied level; the KS gap is their difference. (Sections 13.35, 15.13, 16.11, 19.20 and 19.21.)

M

- **Machine epsilon** ϵ: the gap between 1 and the next larger floating-point number, $\epsilon = 2^{-52} \approx 2.22 \times 10^{-16}$. (Sections 0.22, 0.24, 1.4, 1.8, 2.6, 2.10, 16.18, 16.20 and 16.23.)
- **Majorana**: A field equal to its own conjugate obeys $\Psi = M\Psi^*$; such a requirement is called a Majorana or reality condition, after the physicist who first used one. (Section 5.29.)
- **Majorana (reality) condition**: the requirement $\Psi^c = \Psi$. (Sections 5.32, 7.29, 7.32, 21.2 and 21.14.)
- **Majorana-type**: built with the transpose Θ^T instead of the Dirac adjoint (a Lagrangian of this kind is called Majorana-type, after the physicist Ettore Majorana, who studied real spinor fields). (Section 7.28.)
- **Majorana-type Lagrangian** L_g: the Lagrangian of the author's notebook, built with the transpose Θ^T of a real column instead of the Dirac adjoint $\bar{\Psi} = \Psi^\dagger C$. (Section 7.32.)

- **Majorana-type mass terms**: The simplest candidates are Majorana-type mass terms $\Psi^T M \Psi$ with a constant 16×16 matrix M, built from Ψ twice and without $\Psi^\dagger$. (Section 21.32.)

- **Majorana-type term**: a term $\Psi^T M \Psi$ built from Ψ twice, without $\Psi^\dagger$ (Section 21.32). (Sections 21.2 and 21.35.)

- **Manifest**: a file that lists other files with their fingerprints. (Sections 0.22, 0.24 and 15.13.)

- **Mantissa**: The caption quotes the count for $n = 16$ as computed, not typed: `f"{x:.1e}"` writes 16! as the text 2.1e+13, and `.split("e")` cuts it at the letter e into the mantissa 2.1 and the exponent +13 (both are still texts). (Section 1.25.)

- **Map**: a rule that turns a field Ψ into a new field Ψ'. All maps of Chapter 18 are of the form $\Psi'(x) = M\Psi(x)$ with a constant 16×16 matrix M, possibly combined with a change of the coordinate x_0. (Sections 4.2 and 18.2.)

- **Map between solution sets**: a rule that takes EVERY solution of one theory to a solution of another theory (here: multiply the field by a fixed matrix, possibly together with a change of the coordinate x_0). (Section 20.2.)

- **Map between two sets of solutions**: This is a map between two sets of solutions. (Section 21.1.)

- **Maps between sets of solutions**: All of these are exact statements about maps between sets of solutions of the field equations. (Section 5.39.)

- **Maps between solution sets**: They are exact maps between solution sets: if a configuration of the field is a solution of the equations, its image under the map is a solution of the equations with the mapped parameters (for T1, of the equations with $(-m, -\lambda)$ in place of (m, λ)). (Sections 0.2 and 20.1.)

- **Margins**: The eight measured largest differences are below their tolerances by factors (margins) between 4.7 and 7692 (COMPUTED: `Revision/kohn_sham/reports/ks-rust-determinism.json`; the measured values are quoted by `Revision/kohn_sham/reports/ks-crosscheck.json`, key `rust_matrix_wide_uncertainties`). (Sections 0.22, 0.25, 16.12 and 19.17.)

- **Markdown cell**: A markdown cell holds text; a code cell holds Python code. (Section 0.7.)

- **Mask**: The same selection by hand, to draw it: `d1` and `d2` are the two differences of every level (numpy subtracts arrays entry by entry), `keep` is a mask, an array of truth values that is true where both differences exceed the floor (`&` combines two masks with "and"), and `energies` are the Richardson values of the kept levels (`array[keep]` keeps the entries where the mask is true). (Section 16.12.)

- **Mass** m: a number in the equations of a field; for a field that describes particles it is their mass (Chapter 7). (Sections 0.2, 2.27, 12.29, 20.15 and 21.14.)

- **Mass gap**: the energies $-m < \varepsilon < m$, where a free particle of mass m has no level. (Sections 19.2 and 19.15.)

- **Mass reversed**: solves the field equation of the same form, either with the same V (same mass) or with $-V$ (mass reversed). (Sections 5.28, 5.32 and 21.8.)
- **Mass shell** (or *dispersion relation*): the relation between E, the k_a and the mass m that a plane wave must obey. (Sections 4.3, 4.9 and 4.11.)
- **Mass term**: The mass term $-mS = -m\bar{\Psi}\Psi$ is linear in the mass m (a real number) and quadratic in the field: every term contains one component of $\Psi^\dagger$ and one of Ψ. (Sections 7.19 and 18.4.)
- **matplotlib**: sympy: the Python package for exact algebra with symbols; numpy: arrays of numbers; matplotlib: plots. (Section 3.12.)
- **The matrices C, Γ and B**: three fixed 16×16 matrices built from gamma matrices: C is the product of the four space-like ones, Γ (the chirality) the product of all eight, and B the product of C and the gamma matrix of the time x_4, times $-i$; B enters the quantum theory (Chapter 5). (Sections 0.2, 0.14, 1.18, 1.24, 2.19, 4.2, 4.7, 4.19, 5.9, 5.28, 7.16, 10.9, 16.18, 18.8, 19.15, 21.8 and 21.14; the opening of Chapter 21.)
- **Matrix element** $\langle n|X|m\rangle$: for orbitals $\chi_n = (a_n, ib_n)$ the integral $\int \chi_n^\dagger X \chi_m \, dy$; for $X = \sigma_3$ it is $\int (a_n a_m - b_n b_m)\, dy$. (Sections 15.24 and 22.11.)
- **Matrix exponential**: for a square matrix M the matrix $e^{Mx_4} = 1 + Mx_4 + \frac{1}{2}M^2x_4^2 + \ldots$; the column $e^{Mx_4}\chi$ solves $\frac{d}{dx_4}\Phi = M\Phi$ with $\Phi(0) = \chi$. When $M^2 = k^2$ times the unit matrix, the series sums to $\cosh(kx_4) + \frac{\sinh(kx_4)}{k}M$. (Sections 8.18, 9.18 and 9.24.)
- **Matrix identity**: *Line 5 (the matrix identity).* So $\partial_\mu(\cos z\, J^\mu) = -i\cos z\,(\Psi^\dagger C E - E^\dagger C \Psi)$ holds for every field as soon as the first part of line 1 equals line 4, that is (dividing by $-i$) as soon as the 16×16 matrix identity. (Section 21.17.)
- **Matrix product**: $(AB)_{ik} = \sum_j A_{ij}B_{jk}$: entry (i,k) of AB is row i of A times column k of B, entry by entry, added up. (Sections 1.24 and 5.9.)
- **Matrix, entry, row, column**: a matrix is a rectangle of numbers; the number in row i and column j is the entry M_{ij}. (Section 11.8.)
- **Matter**: Matter is what stars, planets and we are made of: protons, neutrons and electrons. (Section 20.23.)
- **The matter-antimatter problem**: The matter-antimatter problem is the question why the universe contains baryons but essentially no antibaryons. (Section 21.3.)
- **Max|T|**: the largest absolute value of ρ, p_3, p_t and p_0 of a state over the whole patch. We divide by it to compare states of very different size. (Sections 17.2 and 17.10.)
- **Mean field**: each electron feels the other one only through its average density; here an electron on a site feels U times the density of the other label on that site, i.e. $Un_L/2$ on L and $Un_R/2$ on R. (Sections 13.24 and 19.2.)
- **Mean value theorem**: (by the mean value theorem of calculus, $g(\phi) - g(\omega) = (\phi - \omega)\, g'(\xi)$ for some ξ between ω and ϕ; applied to $g = \tan$, whose derivative is $1 + \tan^2$, it gives $\tan\phi - \tan\omega = (\phi - \omega)(1 + \tan^2\xi)$, and $1 + \tan^2\xi = 1 + \ldots$ for small angles). (Section 2.24.)

- **Mean-field potential** $w(x)$: here the Hartree plus exchange potential, so that $v_s = v + w$. (Sections 13.32 and 13.35.)

- **Median**: The median is the middle value of the sorted list: `len(ratios) // 2` is the position of the middle (`//` divides and drops the remainder; with 39 ratios it is the 20th value, position 19 counting from 0). (Sections 14.18, 15.9 and 16.12.)

- **Mermin condition**: $N(\mu) = \sum_i g_i\, f(x_i) = N$, the equation that fixes μ. (Sections 16.20 and 16.23.)

- **Meson**: Baryon: a particle made of three quarks, such as the proton $p = uud$ and the neutron $n = udd$ ($B = 1$); a meson (pion π) is a quark and an antiquark ($B = 0$). (Section 21.35.)

- **Metric**: the rule that turns a small step in the coordinates into its size. For the author's metric the rule is $ds^2 = g_{00}dx_0^2 + g_{11}dx_1^2 + \cdots + g_{77}dx_7^2$, where dx_i is the small step along x_i and g_{ii} is the i-th entry of the metric. (Sections 0.1, 0.14, 0.16, 1.1, 1.24, 1.32, 3.3, 3.12, 3.21, 3.29, 6.13, 7.26, 8.14, 11.2, 11.18, 12.2, 12.15, 14.10, 17.2 and 18.19.)

- **Metric functions**: where $z = 6Hx_0$, $H > 0$ is a constant of the author, and a_4 and b_4 are functions of the time x_4 alone, the metric functions (their field equations are the subject of Chapter 12); b_4 is positive. (Sections 0.14, 3.1 and 8.2.)

- **Metric product**: The metric product is $\eta(u, v) = \sum_a \eta_{aa} u_a v_a$; u is a unit vector when $\eta(u, u) = +1$ or -1. (Sections 5.12 and 5.21.)

- **Metric, diagonal entries** g_{aa}: the eight numbers (functions of x_4 and x_0) that turn coordinate distances into true distances in the author's 8-dimensional world; positive for the space directions x_0, x_1, x_2, x_3 and negative for the time directions x_4, x_5, x_6, x_7. (Section 2.22.)

- **Milne wedge**: the part $t > |y|$ of the flat plane with one time t and one space direction y, $ds^2 = -dt^2 + dy^2$, described by $\tau = \sqrt{t^2 - y^2}$ and θ with $t = \tau \cosh\theta$, $y = \tau \sinh\theta$; its metric is $ds^2 = -d\tau^2 + \tau^2 d\theta^2$. (Sections 6.23 and 6.27.)

- **Minimum**: For $T < \pi/\omega$ the bracket is positive, so $S_2 > 0$ and the action of $q + \epsilon\xi_1$ is $S_0 + S_2\epsilon^2$ with a positive S_2: the true path is a minimum along this shape. (Section 7.2.)

- **Minor**: Minor $M^{(rc)}$: the matrix left when row r and column c of M are removed. (Sections 11.2 and 11.18.)

- **Mirror patch**: The map $z \to \pi - z$ takes it to the mirror patch $\pi/2 < z < \pi$. (Sections 18.2, 18.19, 18.26, 20.2 and 20.15.)

- **Mismatch**: 3. see where the "shot" lands at the right end: the mismatch $F(\lambda) = u(1; \lambda)$. (Section 2.12.)

- **Mixed**: $T^{\mu}{}_{\nu}$ has one of each and is called mixed. (Sections 2.18, 12.2 and 17.2.)

- **Mixed components**: Its components $\omega_{\mu}{}^{a}{}_{b}$, with the first frame index up, are called the mixed components. (Sections 6.4, 6.27 and 12.2.)

- **Mixed partial derivative**: $\partial^2 f/\partial x \partial y$, first with respect to y, then x (or the other way round). Schwarz's theorem: for a function with continuous second derivatives the order does not matter. (Section 2.22.)

- **Mixed-product rule**: The mixed-product rule $(A \otimes B)(C \otimes D) = (AC) \otimes (BD)$ holds. (Section 4.17.)

- **Mixing**: feeding only part of the change back (linear mixing) or a combination of several earlier passes (Anderson mixing) to make the loop converge. (Sections 13.35 and 15.8.)

- **Mode Hamiltonian** h: the 16×16 matrix with $E\,u = h\,u$ for the field $u\,e^{i(k\,x1 - E\,x4)}$ of one momentum; its eigenvalues are the energies of the fields of that momentum (section 8 of Notebook 05e derives it). (Sections 5.34, 5.37, 10.3, 10.25 and 10.42.)

- **Mode matrix** h_k: the 16×16 complex matrix with $Eu = h_k u$. (Sections 8.17, 8.22 and 8.28.)

- **Mode operator** h: the field equation written as $i\,\partial_4 \Psi = h\Psi$; for fields that depend only on x_4 and x_0 (and $U = 0$), $h = -im\gamma^{(4)} + i\gamma^{(4)}\gamma^{(0)}(\tan z\,\partial_0 + 3H)$. (Sections 8.32 and 8.35.)

- **Mode, occupation, pattern**: a fermion *mode* is a place that holds zero or one particle. With 16 modes a basis state is a *pattern* of 16 occupations (0 or 1); the computer stores it as a whole number n whose binary digit p is the occupation of mode p ($p = 0, \ldots, 15$). There are $2^{16} = 65536$ patterns. (Section 5.37.)

- **Module**: `import` loads a module (a part of Python or of a package) so that the code can use it; the text after `#` on each line is a comment. (Sections 0.13, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15 and 22.12.)

- **Modulus** $|z| = \sqrt{a^2 + b^2}$: the length of the arrow. (Sections 1.10 and 1.16.)

- **Moment equation**: A moment equation is a field equation multiplied by e^{6Hy} and integrated over the patch. (Section 17.20.)

- **Moment** of a field equation: the equation multiplied by the volume weight e^{6Hy} and integrated over the patch; it involves the source only through its weighted means $\bar{\rho}$, $\bar{p}_3$, $\bar{p}_t$, $\bar{p}_0$. (Sections 17.2, 17.17 and 17.20.)

- **Momenta**: The metric does not depend on the six transverse coordinates, so by Section 3.16 the six momenta $p_k = g_{kk}u^k$ (no sum) do not change during free fall: $p_i = h_i^2\,u^i, \qquad p_j = -h_j^2\,u^j \qquad$ (both constant). (Sections 3.31, 4.9 and 10.3.)

- **Momentum** $p_a = g_{aa}u^a$ (no sum) of a direction x_a. **Conserved**: the same number at every point of the path. (Sections 3.16, 3.34, 5.34, 5.37, 8.17, 10.9, 20.17, 20.20 and 20.22.)

- **Momentum weight**: The factor e^{-Hy-a_4} is exactly the momentum weight $\kappa(y, x_4) = e^{-Hy-a_4(x_4)}$ (the Revision record's name for it; this $\kappa(y, x_4)$, always written in Chapter 3 with its two arguments, is a function and has nothing to do with the constant κ of Einstein's equations in Section 3.26) that the Revision Kohn-Sham record uses to turn a conserved 3-space momentum into the momentum seen at height y and time x_4 (`Revision/kohn_sham/ks-theory.json`, key `geometry.kappa`; PROVED here; Notebook 03d, In [5]). (Sections 3.31, 14.2 and 19.3.)

- **Monomial**: a product of different generators written in increasing order, such as $\theta_0\theta_2\theta_5$; the empty product is the number 1. (Sections 7.10, 7.16, 7.26, 11.18, 12.16, 18.19 and 18.20.)

- **Monotone (increasing)**: a function that grows whenever its argument grows. (Section 2.27.)

- **mpmath**: a Python package that computes with as many decimal digits as requested (here 50). (Sections 1.8 and 1.16.)
- **Multiple of the identity**: A number c times a matrix multiplies every entry by c; cI_n is called a multiple of the identity. (Section 4.2.)
- **Multiplicity**: The fundamental theorem of algebra (ASSUMED) says that a polynomial of degree n has exactly n roots $\lambda_1, \ldots, \lambda_n$ when complex numbers are allowed and a repeated root is counted as often as it appears, its multiplicity. (Sections 1.34, 1.40, 4.9, 4.11, 4.19 and 5.3.)

N

- **Natural logarithm**: The exponential function e^t is defined for every real t, is always positive and grows; its inverse is the natural logarithm $\ln x$, defined for $x > 0$: $\ln(e^t) = t$ and $e^{\ln x} = x$. (Sections 1.5 and 1.8.)
- **nbkit**: The book's tool nbkit (the file `Revision/textbook/tools/nbkit.py`) turns a builder into a notebook in two steps. (Section 0.9.)
- **nbkit check**: re-executing a notebook into a scratch folder and comparing the result byte for byte with the stored notebook, its files and its provenance file. (Sections 23.2 and 23.11.)
- **Negative branch**: Label n: the integer that numbers the levels of a sector: $n = 0$ is the band level (bound to the brane, occupied in the Fermi shell), $n = 1, 2, ...$ the bulk levels above it (empty), $n = -1, -2, ...$ the levels of negative energy, the negative branch (in the record's convention the normal-ordered sea, not populated). (Sections 22.2 and 22.11.)
- **Negative control**: a deliberately changed case in which the effect must NOT occur (or must occur differently); it shows that a check can fail and that the result depends on the feature that was changed. (Sections 0.22, 1.50, 6.1, 6.13, 7.28, 7.32, 9.26, 9.29, 18.2, 18.13, 18.19, 19.2, 19.20, 20.11, 21.15, 21.17 and 22.3.)
- **Neutral subspace**: a subspace on which $u^\dagger B v = 0$ for all u, v in it. (Section 10.9.)
- **Newton's method**: replace a function by its tangent line at the current guess and take the zero of that line as the next guess. (Sections 2.27, 15.8, 16.20 and 16.23.)
- **Nilpotent**: For a light-like $v \neq 0$, $\gamma(v)$ is not the zero matrix, because $\mathrm{tr}(\gamma(v)\gamma^b) = v_a \,\mathrm{tr}(\gamma^a\gamma^b) = 16\, v_a \eta^{ab} = 16\, v^b$ (the third contraction of Section 1.28; raising the index) is not 0 for a component $v^b \neq 0$; but $\gamma(v)^2 = 0$: a matrix with a power equal to 0 is called nilpotent, and all its eigenvalues are 0 ($\lambda^2 v = \gamma(v)^2 v = 0$ gives $\lambda = 0$); its characteristic polynomial is λ^{16}. (Sections 1.37 and 8.10.)
- **Nilpotent matrix**: a matrix $N \neq 0$ with $N^k = 0$ for some power k; all its eigenvalues are 0. (Section 1.40.)
- **No-boundary proposal**: a proposed boundary condition (J. B. Hartle and S. W. Hawking) that picks one solution of the Wheeler-DeWitt equation. It is named in Chapter 22, not used, and is not formulated for this 8-dimensional theory. (Sections 22.2 and 22.4.)

- **No-flux condition**: the condition that no charge flows through the edge $z = \pi/2$ of the hidden direction (the brane). The local conservation law is proved at every point with $0 < z < \pi/2$; the no-flux condition is ASSUMED, not derived, and only under it is the total charge of a universe constant. Exact solutions exist through whose edge charge does flow, so that their total charge changes. (Sections 0.2, 5.6, 5.39, 18.21, 20.22, 21.1 and 21.17.)
- **No-flux condition at the brane**: the condition $\sqrt{|g|}J^{x_0} = 0$ at $z = \pi/2$ (for the homogeneous solutions, $q_0 = 0$): no charge flows out through the brane. Only under it is the total charge of a universe constant. It is ASSUMED wherever it is used, not derived; it holds for some exact solutions and fails for others (Notebook 18c), and whether the junction condition at the brane implies it is OPEN. (Section 18.28.)
- **Node**: a point where the eigenfunction changes sign. (Sections 2.16, 2.17, 2.24, 16.14 and 16.18.)
- **Noether identity**: On every solution of the field equation the tensor is conserved: this is a theorem, proved in the record from the invariance of the action under a change of coordinates (the Noether identity; PROVED, see the table below). (Section 9.9.)
- **Noether's construction**: This is Noether's construction. (Section 21.16.)
- **Noether's theorem**: a continuous symmetry of the Lagrangian gives a current whose divergence vanishes on every solution (Section 21.16). (Sections 21.2 and 21.22.)
- **Non-characteristic**: So the time derivative of every component is fixed by the field and its derivatives along the other seven directions at the same time x_4: the slices $x_4 =$ const are non-characteristic (PROVED; Notebook 07b, In [19]; `wolfram-field-theory-b4.json`, checks `evolution_form_G` and `evolution_form_C`; the part $\frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$ of M gives $-\frac{3}{4}(b_4'/b_4)\Psi$ on the right, formula record key `evolution_form`). (Sections 7.22 and 8.16.)
- **Non-interacting v-representability**: The Kohn-Sham scheme ASSUMES that the density of interest is the ground-state density of some non-interacting system in some potential v_s (non-interacting v-representability). (Section 13.10.)
- **Non-trivial**: The author asked that the Lagrangians of both fields be non-trivial: their Euler-Lagrange equations must always contain nonzero contributions from gravity through the canonical spin connection, unless space-time is flat 4+4 space ([1] for dirac16complex, [2] for dirac16complex00), and must be self-consistent. (Section 7.23.)
- **Nondegenerate**: Such a form is called nondegenerate on the eigenspace: its Gram matrix has no zero eigenvalue. (Section 10.5.)
- **Nonlinear**: They look like one-particle equations, but $\hat{F}$ contains the unknown orbitals: they are nonlinear and are solved by iteration, starting from a guess and repeating until nothing changes any more (self-consistency, Section 13.21). (Section 13.6.)
- **Norm** of a field in the hidden direction: $\int \cos z \, \Psi^\dagger \Psi \, dx_0$ ($\cos z = \sqrt{|g|}$ is the volume factor). It is *finite* when the integral does not diverge at the ends. (Sections 8.16 and 8.35.)
- **Normal ordering**: writing every product with the annihilators to the right, by definition dropping the constant that the reordering produces (here $-8E$ for the energy). The normal-ordered value of an operator X in a state is its value minus the vacuum value. (Sections 5.34, 5.37, 7.29, 10.20, 10.25 and 14.30.)

- **Normal random numbers**: random numbers whose histogram is the bell curve $e^{-x^2/2}/\sqrt{2\pi}$; numpy's `normal` draws them. (Sections 1.25, 1.27 and 1.32.)
- **Normal-ordered**: After canonical quantisation (Chapter 10; the field becomes an operator, a rule that acts on the quantum states) the record defines the tensor as an operator too: every bilinear is replaced by the normal-ordered product of the quantised field (the product rearranged so that the operators that remove a particle stand to the right of those that create one, which gives the empty state the energy zero; Chapter 10 defines it exactly), $\hat{T}^{\nu}{}_{\mu} = :T^{\nu}{}_{\mu}[\hat{\Psi}, \hat{\bar{\Psi}}]:$, normal ordered with respect to the waves of the good sector (the waves that do not depend on the extra times x_5, x_6, x_7), and the numbers are expectation values (the average value that measurements of the operator give in a given quantum state) (record `Revision/docs/DIRAC16COMPLEX_FIELD_THEORY.md`, section 12). (Section 9.13.)
- **Normal-ordered energy**: the energy of a state minus the energy of the vacuum (the filled sea), as in the third notebook of Chapter 10. (Section 10.48.)
- **Normal-ordered square**: Its normal-ordered square puts all creation operators to the left: $:S^2: = \sum V_{pq} V_{rs}\, a_p^\dagger a_r^\dagger a_s a_q$. (Section 13.4.)
- **Normalisation**: multiplying an orbital by a number so that $\int_{-L}^{0} (a^2 + b^2)\, dy = 1$. (Section 15.8.)
- **Normalised**: The function u is the wave function: $u(x)^2$ is the probability density of finding the particle at x, so u is normalised, $\int u^2\, dx = 1$. (Sections 2.13, 10.11, 10.14, 13.2 and 22.12.)
- **Normalised Lovelock tensor**: Normalised Lovelock tensor $E_{(k)} = -P_{(k)}/2^{k+1}$; $E_{(1)}$ is the Einstein tensor. (Sections 11.2 and 11.26.)
- **NOT COMPUTED**: a label used next to the five status labels in Chapters 20 and 21: no computation of the quantity exists in the Revision record or in this book (for example the rate of a process that violates C or CP). (Sections 20.23, 21.1, 21.2, 21.4, 21.31, 21.36 and 21.38.)
- **Nucleus**: A photon of energy E_γ that hits a nucleus (the heavy centre of an atom) of mass M at rest can make an electron-positron pair, the nucleus remaining in the final state, only if $E_\gamma \geq 2m(1 + m/M)$. (Sections 20.17 and 20.20.)
- **Null**: A vector $v \neq 0$ is space-like if $Q(v) > 0$, time-like if $Q(v) < 0$ and light-like (or null) if $Q(v) = 0$. (Sections 1.27, 1.32, 3.4 and 5.12.)
- **Null combination** $\rho + p_0$: the energy density plus the pressure along x_0. (Sections 20.2, 20.10 and 20.15.)
- **Null energy condition** (NEC) along x_0: $\rho + p_0 \geq 0$. Ordinary matter satisfies it; a source with $w < -1$ and $\rho > 0$ (called *phantom*) violates it. (Sections 3.26, 12.2, 12.15, 12.19 and 22.2.)
- **Null lines**: The right picture draws the two hyperbola branches and the two dotted null lines $v_4 = \pm v_1$, on which $v_1^2 - v_4^2 = 0$. (Section 5.22.)
- **Null space**: The columns v with $Av = -i\omega v$ are the solutions of $(A + i\omega)v = 0$, the null space of $A + i\omega$. (Sections 9.30 and 20.16.)

- **Null vector**: a direction of zero length, such as the frame direction $x_4 + x_0$ (time-like plus space-like). (Sections 12.2 and 12.11.)
- **Number density**: (Check gas_densities.) The three densities that matter are the number density (the U(1) charge density, whose integral counts the quanta), the scalar density and a third density Q (the formula is displayed in that section). (Section 19.4.)
- **Number operator**: The number operator $\hat{n}_p = a_p^\dagger a_p$ gives n_p, and $\hat{N} = \sum_p \hat{n}_p$ counts the particles of a state. (Sections 10.11 and 13.4.)
- **The numerical parameters** (parameters.json, numerics): $G = 900$ steps of the Runge-Kutta method on $[-L, 0]$, a root tolerance of $10^{-13}\,m$ for each level, a self-consistency tolerance of $10^{-11}\,m$ with at most 400 iterations, Anderson mixing with depth 6 and $\beta = 0.4$, the step $\delta = 0.002$ in a_4 for derivatives along the history, and levels closer than $10^{-9}\,m$ count as equal (one degenerate group). (Section 15.2.)
- **Numerics**: The cross-check is a test of the numerics: of the discretisation, the rounding and the programming of the Rust solver, against a second program that differs in all three. (Section 16.25.)
- **numpy**: sympy: the Python package for exact algebra with symbols; numpy: arrays of numbers; matplotlib: plots. (Sections 3.12, 10.9 and 20.11.)

O

- **O(4,4)**: the real 8×8 matrices Λ with $\Lambda^T \eta \Lambda = \eta$ (they keep the metric product); SO(4,4): those with determinant $+1$. (Sections 5.12 and 5.26.)
- **O(4,4), SO(4,4)**: the real 8×8 matrices Λ with $\Lambda^T \eta \Lambda = \eta$ (they keep the metric product); SO(4,4): those with determinant $+1$. (Section 5.21.)
- **Observer**: Observer: someone who, like us, measures only the three space directions x_1, x_2, x_3 and the time x_4. (Section 22.22.)
- **Occupation**: Level ε: an allowed energy of the one-particle equation; occupation f: how many particles sit in an orbital of that level (0 to 1); degeneracy g: how many orbitals share the level. (Sections 10.18, 19.2 and 19.20.)
- **Occupation numbers**: A determinant built from some of them is fixed, up to its sign, by the occupation numbers $n_p \in \{0, 1\}$, $n_p = 1$ when ϕ_p is used. (Section 13.4.)
- **Occupation states**: The finite model of limit 2 gives exact values on the occupation states of its one mode set at rest (momentum $k = 0$). (Section 9.13.)
- **Occupation-number state** $|n_0 n_1 n_2 n_3\rangle$: the determinant that uses the orbitals p with $n_p = 1$; there are $2^4 = 16$ of them for four orbitals. (Section 13.13.)
- **Occupied**: A level is occupied if particles sit in it ($f = 1$) and empty if not ($f = 0$). (Section 15.13.)
- **Odd**: The doubled problem is therefore mirror-symmetric only if the mass is odd across the brane. (Sections 1.19, 2.13, 2.16, 4.13, 4.15, 5.5, 5.12, 5.16, 7.11, 7.16, 11.2, 11.8, 14.12, 16.18 and 19.11.)

- **Off shell**: A configuration that satisfies the field equation is said to be on shell; one that need not satisfy it is off shell. (Sections 9.2, 9.16, 18.2, 20.2 and 20.10.)

- **Off-diagonal**: Besides these 27 nonzero diagonal components there are 12 nonzero off-diagonal ones. (Section 12.5.)

- **On shell**: on solutions of the field equation. (Sections 7.26, 9.2, 9.16, 18.2, 20.2 and 20.10.)

- **One momentum**: A field of one momentum k along $x1$ is a field of the form $\Psi = \psi\, e^{ik\,x1}$: a column ψ (which may still depend on the time) times the number $e^{ik\,x1} = \cos(k\,x1) + i\sin(k\,x1)$, which goes once around the circle of complex numbers of size 1 each time $x1$ grows by $2\pi/k$. (Section 5.34.)

- **One-body density matrix**: Both formulas are summarised by the one-body density matrix $\rho = \sum_{a\in O} |\phi_a\rangle\langle\phi_a|$, whose matrix elements are $\rho_{qp} = \langle a_p^\dagger a_q\rangle$: $\langle a_p^\dagger a_q\rangle = \rho_{qp}$, $\qquad \langle a_p^\dagger a_q^\dagger a_s a_r\rangle = \rho_{rp}\,\rho_{sq} - \rho_{sp}\,\rho_{rq}$. (Section 13.4.)

- **One-body matrix**: The 16×16 matrix ρ is the one-body matrix of the state. (Section 14.26.)

- **One-particle Hamiltonian** $h_m(k)$: the 16×16 matrix that gives the time evolution $i\,\partial_4 u = h_m(k)u$ of a plane wave $u\,e^{ik\cdot x}$ in flat 4+4 space; its eigenvalues are the frequencies $\pm w$. (Sections 21.26 and 21.29.)

- **One-particle matrix**: The frequencies w are the eigenvalues of the one-particle matrix $h_m(k)$. (Section 18.22.)

- **One-sided fourth-order difference**: At the last slice there are no neighbours on the right, so the derivative uses the one-sided fourth-order difference $f'(x) \approx [3f(x-4h) - 16f(x-3h) + 36f(x-2h) - 48f(x-h) + 25f(x)]/(12h)$, the same stencil as the record; `w_mix[-5]` is the fifth entry from the end. (Section 22.23.)

- **One-step value**: The one-step value $r(h)$ has no h^2 error left; its error starts with h^4. (Section 16.5.)

- **Onset**: So along the history (where X grows with the time) E^2 crosses zero exactly once and stays negative afterwards; the moment of the crossing is the onset. (Sections 8.24 and 8.28.)

- **Onset time** x_4^*: the time at which w^2 changes from positive (the wave oscillates) to negative (the wave grows). (Sections 10.39 and 10.42.)

- **OPEN**: a status label: a question that neither the Revision record nor this book answers; it is not settled. Example: whether the big bang creates universes in pairs is, as a question of this book, OPEN: it is not proved. (Sections 0.3, 0.20, 3.1, 3.31, 8.1, 12.31, 15.31 and 22.27.)

- **Open problem**: a question that neither the Revision record nor this book answers, put precisely enough that one can recognise an answer. (Section 22.2.)

- **Open shell**: a degenerate group of levels only partly filled. (Sections 15.4 and 15.24.)

- **Operator**: a rule that turns a state into another state, here a big matrix that acts on columns of numbers. Operators are multiplied by doing one after the other; the order matters. (Sections 5.34, 5.37, 9.13, 10.11, 10.18, 13.2, 21.25 and 21.29.)

- **Orbifold**: The Revision theory ASSUMES a Z2 mirror (also called an orbifold): the patch $y \le 0$ is glued at $y = 0$ to a mirror copy of itself, with the warp $e^{-H|y|}$ on both sides, and a field on the doubled interval obeys $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$. (Sections 14.12 and 22.2.)

- **Orbital**: a single-particle state of the Kohn-Sham model. Here it is described by two real functions $a(y)$ and $b(y)$, its *components*. (Sections 2.1, 2.27, 13.3, 13.13, 13.35, 14.1, 14.12, 14.17, 14.24, 15.8, 16.18, 17.2, 19.2, 19.15, 19.20 and 22.2.)

- **Orbital relaxation**: At $\tau = 0$ the integrand is Δ_{KS}; the difference $\Delta_{SCF} - \Delta_{KS}$ measures how much the levels move when the particle is transferred (the orbital relaxation). (Sections 13.27 and 15.5.)

- **Order** p: a method has order p when its error at a fixed end time is close to Ch^p for small h, with a number C that does not depend on h. Halving h then divides the error by 2^p. (Sections 2.6, 2.10, 11.2, 11.11 and 18.27.)

- **Order of accuracy**: Its order of accuracy p: its error falls like h^p when the step h shrinks. (Sections 17.2 and 17.20.)

- **Order of convergence**: the power q in an error $\approx Ch^q$; the reference has $q = 2$. (Sections 7.8, 16.4 and 16.18.)

- **An ordinary differential equation**: An ordinary differential equation (ODE) is an equation of the form. (Sections 2.2, 2.10, 12.21, 12.24, 15.8 and 18.26.)

- **Orthogonal**: two functions with $\int u_m u_n \, dx = 0$. (Sections 1.28, 2.13, 2.16, 4.2, 4.19, 7.29 and 13.2.)

- **Orthogonal matrix**: a real matrix O with $O^T O = I$, so $O^T = O^{-1}$. (Sections 1.32, 1.40 and 4.15.)

- **Orthogonal projection**: So the closest flat profile is the weighted mean $\bar{X}$ of Section 17.7; it is called the orthogonal projection of X on the flat functions. (Section 17.17.)

- **Orthonormal basis**: `eigenspace` returns, as columns, all right singular vectors of $h_k - \lambda I$ whose singular value is below 10^{-9}: an orthonormal basis (columns of length 1, perpendicular to each other) of the eigenspace of λ. (Section 8.23.)

- **Orthonormal columns**: columns of length 1 with $u^\dagger v = 0$ for any two different ones. (Section 4.11.)

- **Orthonormal** columns: each has length 1 ($u^\dagger u = 1$) and every two are perpendicular ($u^\dagger w = 0$). (Sections 4.9, 5.34, 5.37, 10.10, 10.25, 13.2 and 22.6.)

- **Oscillation and growth**: e^{-iEx_4} oscillates (its size stays 1) when E is real; when $E = \pm i\kappa$ with $\kappa > 0$ it is $e^{\pm\kappa x_4}$, which grows or decays exponentially. (Section 8.22.)

- **Oscillator**: For the oscillator, a particle of mass 1 on a spring, it is the kinetic energy minus the potential energy: $L(q, \dot{q}) = \frac{1}{2}\dot{q}^2 - \frac{1}{2}\omega^2 q^2$. (Section 7.2.)

- **Out of equilibrium**: An asymmetry can only be made while the universe is out of equilibrium, for example in decays that happen too late for the inverse processes to keep up. (Section 21.5.)

- **Outer**: Mathematica's name for the operation that builds that matrix, `Outer[delta, lower, upper]`. The author's function is called `k\[Delta]` (Mathematica's plain-text spelling of "k" followed by the Greek letter delta). (Section 1.47.)
- **Outer[delta, lower, upper]**: the author's Mathematica name for the $p \times p$ matrix with the entries $M_{ij} = \delta(l_i, u_j)$: row i belongs to the lower label l_i, column j to the upper label u_j. (Section 11.8.)

P

- **Package**: a collection of Python code that someone else wrote and that we *import* (load) to use it: numpy (arrays of numbers and matrices), sympy (exact algebra and calculus with symbols), mpmath (numbers with as many digits as we want), matplotlib (plots). (Section 0.12.)
- **Pair**: a solution together with one partner. (Sections 7.12, 11.2, 11.8, 20.2 and 20.10.)
- **Pair creation of particles**: This is the pair creation of particles, an observed process of ordinary physics, in which the total electric charge stays the same because the two members carry opposite charges. (Section 21.3.)
- **Pair curvature**: Pair curvature $K_{ab} = R^{ab}{}_{ab}$ (no sum): the curvature of the plane spanned by the directions a and b (a name used in Chapter 12). (Sections 12.2 and 12.5.)
- **Paired**: Two universes are paired when an explicit invertible rule takes every solution of the theory with mass m to a solution of the theory with mass $-m$, and takes its Lagrangian, its energy-momentum tensor and its current to stated multiples of those of the partner. (Section 18.1.)
- **Pairwise summation**: `np.sum` adds in pairs, then pairs of pairs, and so on (pairwise summation). (Section 0.25.)
- **Panel**: `draw_signs` draws one matrix into one panel `ax` (a pair of axes) of a figure. (Section 4.8.)
- **Parabola**: Two wrong paths with the same end values are the line $q = t$ and the parabola $q = t^2$. (Section 7.2.)
- **Parallel transport** along a curve $x^a(t)$: carrying a vector so that its covariant derivative along the curve is zero, $dV^a/dt + \sum_{b,c} \Gamma^a{}_{bc}\,(dx^b/dt)\,V^c = 0$ ("not turning"). (Section 3.21.)
- **Parallel transported**: A vector is parallel transported along the curve when $DV^a/d\lambda = 0$: it is carried along without turning. (Section 3.16.)
- **Parameter set** (m, λ): the mass and the coupling of the potential $U(S) = \frac{\lambda}{2}S^2$. The theory with (m, λ) and the theory with $(-m, -\lambda)$ are two DIFFERENT theories: their Lagrangians are different functions of the field. (Section 20.2.)
- **Parameters**: the mass m and the coupling λ of the potential $U(S) = \frac{\lambda}{2}S^2$. The theory with the parameters (m, λ) and the theory with $(-m, -\lambda)$ are two DIFFERENT theories: their Lagrangians are different functions of the field. (Sections 3.13 and 18.2.)

- **Parity**: the condition at the brane $y = 0$: even $b(0) = 0$, odd $a(0) = 0$ (the ASSUMED Z_2 brane). (Sections 14.12, 15.2, 16.18 and 21.24.)
- **Partial derivative** $\partial f/\partial x$: the ordinary derivative with respect to x while all the other variables are held fixed. We also write $\partial_x f$, and for the author's coordinates $\partial_4 = \partial/\partial x_4$ and $\partial_0 = \partial/\partial x_0$. (Sections 2.1, 2.18, 2.22, 3.2 and 7.2.)
- **Partial sum**: A series is an endless sum $t_0 + t_1 + t_2 + \cdots$; its partial sum $S_N = t_0 + \cdots + t_N$ adds the terms up to number N, and the series converges to a number S when the error $|S_N - S|$ becomes as small as we like for large N. (Sections 1.11 and 1.16.)
- **Particle**: A particle $b_s^*|0\rangle$ and an antiparticle $d_s^*|0\rangle$ (a hole in the filled sea) both have the energy $+E > 0$. (Sections 10.20, 10.25, 13.27, 14.21 and 16.13.)
- **Particle and antiparticle operators**: $b_s = f_{s-1}$ for $s = 1, \ldots, 8$ (modes 0 to 7) and $d_s = f_{s+7}$ (modes 8 to 15). (Section 5.37.)
- **Particle branch, sea**: by a CONVENTION of the Revision theory, the levels that are positive in the free problem (and the $k = 0$ zero modes) are particle levels; the negative branch is the filled, normal-ordered sea. (Section 14.24.)
- **Partner**: the image of a state under the map of theorem T3. (Sections 19.2, 19.20 and 20.2.)
- **Partner block**: So Γv lies in the block $(-j, s_2, s_3)$: the partner block, with the opposite type and the same s_2, s_3 (check blocks_relation_to_Gamma). (Section 19.5.)
- **PASS line**: a printed line that says a check passed; "reproduces" names the Revision record (report file and check name) that found the same result. (Section 12.15.)
- **Patch**: the range $0 < z < \pi/2$ on which the metric is used. (Sections 0.14, 3.5, 3.12, 12.2, 17.2, 18.2, 18.19, 18.26, 20.2, 20.15 and 21.2.)
- **Patch and mirror patch**: the author's metric is used on $0 < z < \pi/2$ (the patch). The map $z \to \pi - z$ carries it onto $\pi/2 < z < \pi$ (the mirror patch). (Section 20.10.)
- **Patch end**: Its end $z = \pi/2$ is the patch end; the end $z \to 0$ is the tip. (Sections 3.5, 3.12, 3.34, 8.2, 8.31, 10.27 and 10.31.)
- **Path** (or motion): a function $q(t)$ that gives the position q of a particle on a line at every time t between a start time and an end time. Here the times run from 0 to T. (Sections 7.2 and 7.8.)
- **Path integral**: a way to compute a quantum amplitude by adding one contribution for every possible history of the fields. It is named in the list of what is NOT established (Section 18.28) and not used. (Section 18.2.)
- **Pattern**: With n modes a basic state is a pattern of n occupations, each 0 or 1, so there are 2^n patterns; all combinations of them form the Fock space. (Sections 1.48, 5.34, 10.11, 10.25 and 12.25.)
- **Pattern as a whole number**: the program stores a pattern as one whole number n whose binary digit number p (counted from 0) is the occupation of mode p; the program reads that digit by shifting n to the right by p binary places and keeping the last binary digit. (Section 10.18.)

- **Pauli**: (ii) Pauli: if two orbitals are equal, $\phi_a = \phi_b$ with $a \neq b$, the columns a and b of the table are equal; the transposed table then has two equal rows, so its determinant is 0 (rule 4), and the determinant of the table is the same number (rule 2): $\Phi = 0$. (Section 13.3.)
- **Pauli matrices** $\sigma_1, \sigma_2, \sigma_3$: the three 2×2 matrices $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, $\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$, $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. (Sections 4.3, 14.1, 14.10, 19.15 and 19.20.)
- **Pauli principle**: This is the Pauli principle, and it follows from the anticommutator alone. (Section 10.11.)
- **pdflatex**, for the six documents of the Revision record and for the book's PDF: on Windows MiKTeX (https://miktex.org), on macOS MacTeX (https://tug.org/mactex), on Linux the TeX Live packages of your distribution. (Section 23.3.)
- **Perfect fluid (at rest)**: matter whose energy-momentum tensor is diagonal, with the energy density and the pressures on the diagonal. (Section 9.29.)
- **Perfect fluid at rest**: That does not yet make it a perfect fluid at rest, which has a diagonal energy-momentum tensor: Section 9.12 showed that the spin connection puts entries off the diagonal. (Section 9.26.)
- **Period**: The length of the repeating block is the period; for 1/7 it is 6. (Sections 1.2 and 1.8.)
- **Period-doubling bifurcation**: This splitting of one fixed point into a cycle of period 2 is called a period-doubling bifurcation. (Section 13.25.)
- **Periodic box**: Put the gas in a cube of side ℓ and volume $V = \ell^3$ whose opposite faces are glued together (a periodic box). (Section 13.15.)
- **Permutation**: a re-ordering of the numbers $0, 1, \ldots, n-1$ (or of any n different objects). There are $n! = 1 \cdot 2 \cdots n$ of them. (Sections 1.19, 1.24, 1.47, 11.2 and 11.8.)
- **Permutation matrix**: the matrix with exactly one 1 in every row and every column and 0 elsewhere; row i has its 1 in column $\sigma(i)$ for a permutation σ. (Sections 1.19 and 1.24.)
- **Permutation sign** (Mathematica's *Signature*): for a list of different numbers, $+1$ if the number of *inversions* (pairs of positions in which the larger number stands first) is even, -1 if it is odd; for a list with a repeated number, 0. (Sections 4.2, 4.7 and 18.9.)
- **Perpendicular** (orthogonal) vectors: $u^T w = \sum_i u_i w_i = 0$. (Sections 1.36 and 1.40.)
- **Phantom**: $| -2 < x < -1 \mid w < -1$ (called phantom) $\mid 2 + x > 0$, and $x < -(2 + x)$ means $x < -1 \mid$. (Sections 9.19, 12.2, 22.2, 22.16 and 22.22.)
- **Phase**: a complex number $e^{i\alpha} = \cos\alpha + i \sin\alpha$ of modulus 1. (Section 21.22.)
- **Phase angle**: Every complex number $z \neq 0$ can be written as $z = re^{i\varphi}$ with $r = |z|$ and a real angle φ, its argument (or phase angle): the point $(a/r, b/r)$ lies on the unit circle, so it is $(\cos\varphi, \sin\varphi)$ for some angle φ (school trigonometry, ASSUMED), and then $z = r(\cos\varphi + i \sin\varphi) = re^{i\varphi}$. (Sections 1.11 and 1.16.)

- **Phase factor**: So $\lambda 1$ gives $-|\lambda|^2 B$, which is never B (that would need $(1+|\lambda|^2)B = 0$), and $\lambda\Gamma$ gives $|\lambda|^2 B$, which is B exactly when $|\lambda| = 1$, that is when $\lambda = e^{i\alpha}$ is a phase factor (a complex number of size 1). (Section 5.34.)
- **Phase function** $\Phi(\varepsilon)$: j times the Pruefer angle at the brane. It increases strictly with ε. (Section 15.8.)
- **Phase portrait**: the curve traced by the point (x, v) (position, velocity) as time goes on. (Section 2.10.)
- **Photon**: the particle of light (Chapter 21). (Sections 0.2, 20.17 and 20.20.)
- **Pigeonhole principle**: if more than n objects are put into n boxes, some box gets at least two of them. (Sections 1.43, 1.47, 11.2 and 11.8.)
- **Pin(4,4)**: all products $\gamma(u_1)\cdots\gamma(u_k)$ of unit vectors; Spin(4,4): those with an even number k of factors. (Sections 5.12, 5.21, 5.26, 18.2 and 18.8.)
- **Pinned**: The nine packages are installed with Python's installer pip at fixed (pinned) versions, the versions with which the book was built: numpy 2.4.6 (arrays of numbers, matrices), sympy 1.14.0 (exact algebra and calculus with symbols), mpmath 1.3.0 (numbers with as many digits as we ask for), matplotlib 3.11.0 (plots), and jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6 (the programs that show, store and run notebooks). (Section 0.8.)
- **Pinned version**: the exact version of a package with which the book was built. Another version may print slightly different numbers or pictures. (Section 0.12.)
- **Pivots**: Write $T - x\mathbb{1}$ (where $\mathbb{1}$ is the unit matrix) as a product $\mathcal{L}D\mathcal{L}^T$, with $\mathcal{L}$ (a script letter, because L is the length 3 of the interval) having ones on its diagonal and one band below it, and D diagonal with entries $q_1, \ldots, q_n$, the pivots. (Section 16.15.)
- **Plain iteration**: $x \leftarrow G(x)$; linear mixing: $x \leftarrow (1-\beta)\,x + \beta\,G(x)$ with the mixing parameter β. (Sections 13.21 and 13.24.)
- **Plane curvature**: Christoffel symbol $\Gamma^a{}_{bc}$, Riemann tensor $R^a{}_{bcd}$ and $R^{ab}{}_{cd} = g^{bb}R^a{}_{bcd}$, plane curvature $K(a,b) = R^{ab}{}_{ab}$ (no sum), Ricci tensor $R^h{}_j = \sum_c R^{hc}{}_{jc}$, Ricci scalar $R = \sum_h R^h{}_h$, Einstein tensor $G^h{}_j = R^h{}_j - \frac{1}{2}\delta^h_j R$: Chapter 3 (Sections 3.15 and 3.17) defines them. (Section 11.2.)
- **Plane wave**: a solution of the form $u\,e^{i(k\cdot x - Ex_4)}$, with a constant column u; E is its *energy* (frequency in the time x_4) and the k_a are its *momenta* (wave numbers in the other directions). (Sections 4.9, 4.11, 7.5, 7.8, 8.17, 8.22, 9.21, 10.3, 10.9, 13.15 and 13.19.)
- **PNG**: PNG is the file format in which the figures are saved. (Section 0.12.)
- **Polar coordinates**: Polar coordinates of the plane: the distance r from the origin and the angle φ from the horizontal axis; $x = r\cos\varphi$, $y = r\sin\varphi$. (Section 3.21.)
- **Polar form**: $z = re^{i\varphi}$ with $r = |z|$ and φ the argument. (Section 1.16.)
- **Polarisation**: With the polarisation $\zeta = (n_\uparrow - n_\downarrow)/n$, so $n_\uparrow = \frac{n}{2}(1+\zeta)$ and $n_\downarrow = \frac{n}{2}(1-\zeta)$: one label alone ($g = 1$) has the kinetic energy $\frac{3}{10}(6\pi^2)^{2/3}n_\sigma^{5/3}$ per volume (the formula above with $g = 1$), and the contact interaction gives $g_c\,n_\uparrow n_\downarrow$ (Section 13.5). (Section 13.15.)

- **Polarization** $\zeta = (n_{up} - n_{down})/n$: how unequally two labels are occupied. (Section 13.19.)
- **Polynomial**: By the Leibniz formula every term of $\det(M - \lambda I)$ is a product of n entries, of which at most n (the diagonal ones) contain λ; so p is a polynomial (a sum of powers of λ with number coefficients) of degree n. (Sections 1.34, 2.5, 11.18 and 12.16.)
- **Populations**: The right panel shows the populations of M5: the energy density of each of its three parts, computed by calling `model` with a list that holds only that part (`[0]` takes the first of the two returned sums, the energy density), in the colours from the fifth on (`PALETTE[ 4:]`), and their total in black, with the zero line. (Section 22.23.)
- **Positive branch**: the levels whose value without interaction ($\lambda = 0$) at the same slice is positive. By the filling convention of the Kohn-Sham record, particles occupy the positive branch together with the zero modes at $k = 0$ (the levels $\varepsilon = 0$ of the free problem); the levels of the negative branch form the normal-ordered sea and are never occupied, not even at a temperature. (Section 15.2.)
- **Positive representation**: Because B has eight eigenvalues $+1$ and eight -1, $\Psi^\dagger$ cannot be the Hilbert adjoint of Ψ; the Revision record realises it as $\Psi^\dagger = b^* B$ (the positive representation: $\Psi_A = b_A$, $\Psi^\dagger_C = \sum_D b^*_D B_{DC}$). (Sections 21.25 and 21.29.)
- **Potential**: In quantum mechanics the allowed energies E of a particle in one dimension, moving in a potential $V(x)$ (its potential energy at the position x), are the eigenvalues of the Schrödinger equation; in units in which Planck's constant divided by 2π (written $\hbar$) and the mass m are both 1, it reads $-\frac{1}{2}\,u''(x) + V(x)\,u(x) = E\,u(x)$. (Sections 2.13, 12.29, 15.2 and 18.4.)
- **Potential energy**: Kinetic term K_μ: the part of the Lagrangian that holds the derivative along the direction μ; potential energy: $mS + U(S)$, the part without derivatives. (Section 9.16.)
- **Potential part**: The terms with derivatives (the K's) form the kinetic part; the terms without derivatives, $mS + U(S)$, form the potential part. (Section 9.7.)
- **Potential well, bound state**: a region where V is lower than outside; a bound state is a solution with E below the outside value of V that decays to zero far away. Its energy is an eigenvalue. (Section 2.16.)
- **Power**: Power a^p and root $a^{1/n}$; the laws of powers $a^p a^q = a^{p+q}$, $(a^p)^q = a^{pq}$, $(ab)^p = a^p b^p$, $a^{-p} = 1/a^p$ for positive a, b. (Section 1.8.)
- **Power iteration**: multiply a vector by M again and again and rescale it to length 1; it turns towards the eigenvector of the eigenvalue of largest size. (Sections 1.37 and 1.40.)
- **PowerShell 7**: on Windows, the program PowerShell 7 (the command `pwsh`), downloaded from the address aka.ms/powershell, which runs the PowerShell twin of the gate; Git for Windows also brings bash, so the bash form of the gate works there too. (Section 23.3.)
- **Prescribed background**: a metric that is given and not solved for from field equations. (Sections 0.2, 0.14, 3.12, 3.34, 14.1, 14.32, 15.16, 17.1, 17.2, 17.10, 17.20, 21.31 and 22.2.)
- **Prescribed source**: a source chosen by hand to see what the equations do. It is ASSUMED, not derived from a field. (Sections 12.2 and 12.24.)

- **Present measure**: `\w+` is one or more letters, digits or underscores (the name of a state, such as N8_lam0_a00_T10), `\S+` a number, and `\(` and `\)` are round brackets themselves; the four bracketed parts are the name of the state, the error of the old method, the former measure (the difference between the two runs when both used the old method) and the present measure (the difference seen by the present refined run). (Section 0.25.)

- **Pressure**: Cosmologists describe the matter of the universe, at each moment, by two numbers: the energy density ρ (energy per unit volume) and the pressure p (the push per unit area, which is also energy per unit volume). (Sections 3.26, 3.29, 9.1, 9.16, 9.24, 12.2, 15.16, 15.19, 17.2, 17.10 and 20.2.)

- **Prime**: $a_4' = da_4/dx_4$ and $a_4'' = d^2a_4/dx_4^2$. The code writes them as the symbols `ad1` and `ad2`. (Sections 12.2 and 17.2.)

- **Prime number**: a whole number larger than 1 that only 1 and itself divide. (Sections 1.2 and 1.8.)

- **Principal part**: of a system of first-order partial differential equations at a point: the derivative terms alone, with their coefficients taken at that point. For the field equation with $U = 0$ it is the mode matrix without the mass term, with the frame momenta of that point. (Section 8.18.)

- **The principle of stationary action** (ASSUMED: it is the starting principle of classical mechanics and of classical field theory, not derived from anything simpler). Among all paths with the same end values $q(0) = q_A$ and $q(T) = q_B$, the particle follows one whose action does not change to first order when the path is changed a little. (Sections 7.2 and 7.8; the opening of Chapter 7.)

- **Private environment**: a folder with its own copy of Python and of the packages, so that installing them changes nothing else on the computer. (Section 0.12.)

- **A private Python environment**: A private Python environment is a folder with its own copy of Python and of the packages, so that installing the packages changes nothing else on your computer. (Section 0.8.)

- **Probability**: Amplitude and probability: when an orbital is written as a sum $\sum_n c_n\varphi_n$ of instantaneous orbitals, the complex number c_n is the amplitude of level n and $|c_n|^2$ the probability to find the particle in level n. (Sections 0.18, 20.2 and 22.2.)

- **Probability amplitude**: the number from which quantum theory computes how likely a process is (Chapter 10). (Section 0.2.)

- **Process**: a solution of a dynamical equation that connects an initial state with a different final state. (Section 20.2.)

- **Product** γ_A: for a set A of directions, the product of their gamma matrices in increasing order, for example $\gamma_{\{x_2,x_5\}} = \gamma^{(x_2)}\gamma^{(x_5)}$; for the empty set, $\gamma_{\{\}} = I_{16}$. (Sections 1.12, 1.34, 4.15, 4.19, 18.8 and 21.5.)

- **Product Fock space**: the Fock space of the modes of both universes together, here 16+16 = 32 fermion modes (2^{32} occupation patterns). (Section 10.48.)

- **Product of a set of directions** γ_A: for a set A of directions, the product of their gammas in increasing order, for example $\gamma_{\{x_2,x_5\}} = \gamma^{(x_2)}\gamma^{(x_5)}$; $\gamma_{\{\}} = I_{16}$. There are $2^8 = 256$ sets, so 256 products; they are a *basis* of all real 16×16 matrices when every such matrix is exactly one combination $\sum_A c_A \gamma_A$. (Section 4.19.)

- **Product of different gammas**: a product $P = \gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ of k gammas of k different directions $a_1, \ldots, a_k$; the number k is its degree. (Section 5.3.)

- **Product of matrices**: $(AB)_{ij} = \sum_k A_{ik}B_{kj}$ (row i of A times column j of B, entry by entry, added up). In Python it is written `A @ B`. The order matters: in general $AB \neq BA$. (Section 4.7.)

- **Product rule**: For commutators the product rule $[A, BC] = [A, B]C + B[A, C]$ holds, because both sides are $ABC - BCA$ (on the right, $ABC - BAC + BAC - BCA$). (Sections 5.18 and 7.3.)

- **Profile**: a density as a function of y, stored at the 151 points $y = -3 + 0.02\,i$. (Sections 16.11, 17.2, 17.7 and 17.10.)

- **Projector**: a matrix P with $PP = P$. It maps every column into one subspace, its range, and leaves the columns of that range unchanged; its eigenvalues are 0 or 1, so its trace is the number of eigenvalues 1. (Sections 5.5, 5.9, 8.25, 9.26, 9.29, 9.30, 10.5, 10.9, 14.5, 14.10, 14.26, 18.2, 18.8 and 21.18.)

- **Proper**: Densities: the particle density $n(y)$, the scalar density $S(y)$ and the density $Q(y)$; proper means per unit of proper 7-volume; the coordinate density $e^{6Hy}n(y)$ is the density per unit of y. (Sections 15.2 and 19.20.)

- **Proper density**: a number of particles (or an energy) per unit of proper 7-volume. (Sections 15.13, 15.19, 17.2 and 17.10.)

- **Proper time** τ: the time shown by a clock carried by the body. (Sections 3.4, 3.16 and 3.34.)

- **Proposition**: a proved statement (Notebook 20c); a lemma is a proposition that serves as a step towards others. (Section 20.20.)

- **PROVED**: a status label: the statement is exact. The book gives the complete proof and, where the Revision record contains an exact computer check of the statement, names it: the report file that the verifier wrote and the name of the check in it. A statement is proved by an exact computation of every case, by an exact symbolic computation that holds for every value of its symbols, or by a general derivation in the book (Section 0.3). (Sections 0.3, 0.20, 3.1, 4.21, 5.40, 6.1, 6.30, 8.1, 12.31, 13.38, 14.32, 15.31, 16.26, 17.23 and 22.27.)

- **Provenance file**: `NNx_name.PROVENANCE.md`, next to each notebook. Its last line records the measured facts of the notebook's last verified run, among them the date, result and seconds of its last nbkit check. (Sections 0.7, 23.2 and 23.11.)

- **Pruefer angle** $\theta(y)$: the angle of the point (a, b) seen from the origin, $a = r\cos\theta$, $b = r\sin\theta$ with $r > 0$; we count every full turn, so θ can grow beyond 2π (*winding*). r is the distance of the point from the origin, $r^2 = a^2 + b^2$. (Sections 2.1, 2.24, 2.27, 14.14, 14.17, 15.8 and 22.12.)

- **Pruning**: Leaf, pruning (skipping): a complete combination of k curvature entries in the computer's search; pruning means leaving out combinations known to give zero. (Section 11.2.)
- **Pseudo-random generator**: a formula that turns a number (its state) into a new state and an output, again and again; the outputs look random but are completely fixed by the first state, the seed. (Sections 1.49 and 1.53.)
- **Pseudo-random numbers**: Pseudo-random numbers: numbers made by a fixed recipe that look random; the recipe starts from a number called the seed, and the same seed gives the same numbers on every computer. (Section 11.8.)
- **Purely imaginary**: A real number a is the complex number $a + i0$; a number ib with real part 0 is called purely imaginary. (Section 1.10.)
- **Python**: the programming language of the notebooks. A *version number* such as 3.14.5 names one release of a program: the first number (3) changes rarely, the second (14) for new features, the third (5) for corrections. (Sections 0.8, 0.12 and 0.20.)
- **Python dictionary**: a table that maps keys to values; here monomials (tuples of generator numbers) to coefficients. (Section 7.16.)

Q

- **Q** (dirac16complex): the quantum reading of T1; the image field carries the indefinite (Krein) metric $-B$ and is the same quantum system written in other variables, and there is no cancellation between two universes that are quantised independently of each other. (Section 0.2; the opening of Chapter 18.)
- **QR factorisation**: `rng.normal(size=(M, M))` is a 4×4 table of random numbers, `1j` is the imaginary unit i, so the argument is a random complex matrix; `np.linalg.qr(...)[0]` is the first factor of its QR factorisation, a unitary matrix U (its columns are orthonormal). (Section 13.14.)
- **Quadratic convergence**: The new error is proportional to the square of the old one (quadratic convergence): once the error is small, the number of correct digits roughly doubles at every step. (Section 16.20.)
- **Quadratic form** of a symmetric matrix S: the number $Q(v) = v^T S v = S_{ab} v^a v^b$. (Sections 1.36, 1.40, 4.1, 4.11 and 5.4.)
- **Quantise**: To quantise dirac16complex means to replace its 16 components Ψ_A by operators and to fix their anticommutators. (Section 10.12.)
- **Quantised**: turned into a quantum theory, in which the field becomes an operator, a rule that turns one state of the system into another (Chapter 10). (Sections 0.2 and 5.34; the opening of Chapter 21.)
- **Quantised field, anticommutator**: after quantisation the components are operators with $\{\Psi_r, \Psi_c^\dagger\} = B_{rc}\,\delta$ (δ the delta function of the positions); a conjugation of the quantised field must preserve this rule. (Section 5.32.)

- **Quantum**: An occupation state has each of the 16 modes either empty or holding one quantum (one excitation of the quantised field); Chapter 10 splits the 16 modes into 8 particle modes and 8 antiparticle modes (an antiparticle has the opposite charge of a particle, and both have positive energy). (Section 9.13.)
- **Quantum cosmology**: a quantum theory in which a few numbers that describe the whole geometry, such as a scale factor, are quantum variables; its wave function (the wave function of the universe) is a function of these numbers and obeys the Wheeler-DeWitt equation. It is named in Chapter 22, not used. (Sections 22.2 and 22.4.)
- **Quantum electrodynamics**: That pairs are really made above the threshold, and how often, was computed from quantum electrodynamics, the quantum theory of electrons and light, by Bethe and Heitler (H. Bethe and W. Heitler, Proc. (Section 20.17.)
- **Quantum reading Q**: The Revision pairing record answers with five statements, the quantum reading Q (record `Revision/pairing/pairing-theory.json`, theorem entry `Q`; Revision proof document, section 6). (Section 10.44.)
- **Quantum state**: In the examples of Chapter 10 a quantum state is a column $\psi = (\psi_1, \ldots, \psi_n)$ of n complex numbers. (Section 10.11.)
- **Quark**: a constituent of protons and neutrons. (Section 21.35.)
- **Quasi-free state, Wick's rule**: a Slater determinant or a thermal state of independent quanta; the expectation of four field operators is a sum of products of two-operator expectations (a "direct" and an "exchange" term). (Section 14.30.)
- **Quaternion**: *The blocks are quaternion multiplications.* A quaternion is $q = q_4 + q_1\mathbf{i} + q_2\mathbf{j} + q_3\mathbf{k}$ with four real numbers; we store it as the list (q_1, q_2, q_3, q_4), the real part last, to match the blocks. (Section 4.5.)

R

- **Radians**: with θ in radians (the angle measured as the length of the arc on the circle of radius 1; π radians are 180 degrees). (Section 1.11.)
- **Radiation-like**: $w_{\text{eff}} = 1/3$; dust-like (dark-matter-like): $w_{\text{eff}} = 0$; cosmological-constant-like: $w = -1$; phantom: $w < -1$. (Section 22.22.)
- **Radius**: So every eigenvalue lies within the radius ρ_r of some diagonal entry (Gershgorin's theorem), and the interval from $\min(d - \rho) - 1$ to $\max(d + \rho) + 1$ contains them all. (Section 16.15.)
- **Raising**: Raising with η^{ab} undoes it: $\eta^{ab} v_b = \eta^{ab}\eta_{bc} v^c = \delta^a{}_c v^c = v^a$ (insert the lowered list; the inverse rule; the delta renames). (Section 1.27.)
- **Random numbers with a seed**: Random numbers with a seed: numbers that look random but are the same in every run, because the generator starts from a fixed number. (Section 4.11.)
- **Random walk**: a path that takes a step of $+1$ or -1 at random, again and again. (Sections 0.24 and 0.25.)

- **Random-number generator**: `rng` is a random-number generator with a fixed starting value (the seed 12345), so that the "random" numbers it gives are the same in every run and the figure is the same byte for byte. (Sections 0.24, 1.25, 4.12 and 16.12.)
- **Rank** of a list of matrices: the largest number of independent matrices in it, which is the dimension of its span. sympy computes it exactly with fractions. (Sections 4.13, 4.15, 4.16, 4.19, 5.11, 5.16, 5.26, 8.15, 9.29, 9.30, 10.10, 10.48, 14.5, 16.11, 16.12, 16.13 and 21.15.)
- **Rapidity** b: the "angle" of a boost. (Sections 1.13, 1.16, 5.18, 6.16, 6.21 and 8.3.)
- **Rapidity rate**: The rapidity may change from point to point; we take $b = \beta x_4 + b_0$ with two constants β (the rapidity rate) and b_0, a different boost at every time. (Section 8.3.)
- **Rate** K: a number of events per unit time. (Sections 20.2, 20.20, 21.2, 21.35, 22.2 and 22.11.)
- **Ratio**: The right side is the tolerance, and the left side divided by the right side is the ratio. (Sections 16.2, 16.7, 16.11 and 16.23.)
- **Rational number**: A fraction (or rational number) is a quotient p/q of two whole numbers with $q \neq 0$. (Section 1.2.)
- **Raw string**: A string that starts with `r` is a raw string: its backslashes are kept as they are, which the mathematical titles (typeset by matplotlib between dollar signs) need. (Sections 0.17, 5.10 and 21.15.)
- **Real**: The author's gamma matrices are real: every entry is -1, 0 or $+1$. (Sections 4.1, 5.28, 5.32, 7.11, 7.16, 8.2, 9.2, 19.15, 21.2, 21.8, 21.11 and 21.14.)
- **Real field**: a column Φ whose 16 components are real ($\Phi^* = \Phi$); for Grassmann components, a column of real generators ($\theta^* = \theta$). (Sections 7.28 and 7.32.)
- **Real form**: writing $\chi = (a, ib)$ with real a, b makes all coefficients real. (Sections 14.17, 19.3 and 22.6.)
- **Real matrix**: a matrix whose entries are real numbers (no i). The author's gammas are even simpler: every entry is -1, 0 or $+1$. (Section 18.8.)
- **Real number**: a number on the number line; it may need infinitely many digits that do not repeat, like $\sqrt{2}$ or π. (Sections 1.3 and 1.8.)
- **Real part**: The number $a = \mathrm{Re}\, z$ is its real part and $b = \mathrm{Im}\, z$ its imaginary part. (Sections 1.10 and 1.16.)
- **Reality**: (ii) Reality: every entry of every γ^a is -1, 0 or $+1$, by (i). (Section 4.5.)
- **Reality condition**: A field equal to its own conjugate obeys $\Psi = M\Psi^*$; such a requirement is called a Majorana or reality condition, after the physicist who first used one. (Section 5.29.)
- **Record**: short for the Revision record (see that entry): the committed files of the folder Revision, from which every formula and number of the book comes. A record file is one of them, for example a report whose numbers a notebook reproduces. (Sections 0.16, 5.9 and 16.11.)

- **Recursive**: A function that calls itself is recursive: it goes down into the nested structure until it reaches single values. (Section 16.12.)
- **Redshift**: a 3-momentum k acts like $k\,e^{-a_{4,0}}$ at the slice $a_{4,0}$: momenta shrink as 3-space inflates. (Section 14.24.)
- **Redshift, blueshift**: the decrease, increase of a frame velocity (or momentum) caused by the expansion, contraction of the space it points along. (Section 3.34.)
- **Redshifted**: At a fixed height y, along a deflating history (a_4 increasing, b_4 constant), the frame velocity in 3-space falls like e^{-a_4}: motion in 3-space is redshifted, because 3-space inflates and stretches it out. (Sections 3.31, 14.2 and 15.4.)
- **Redshifted momentum** $q = ke^{-a_{4,0}}$: the 3-momentum as the deflating history sees it (Section 22.7). (Sections 22.2, 22.7 and 22.11.)
- **The reference solver**: The reference solver (`Revision/kohn_sham/reference/run_reference.py` with the module `ks_fd.py` in the same folder). (Sections 16.3 and 16.11; the opening of Chapter 16.)
- **Refined numerics**: Refined numerics: $G = 1800$ steps and ten times smaller tolerances. (Sections 16.6 and 16.11.)
- **Refined run**: `Revision/kohn_sham/reports/ks-rust-determinism.json` (14 checks, all PASS) compares a second run with the canonical one (all 244 files, the 243 result files and the manifest, byte-identical; check repeat_byte_identical) and a refined run with twice the RK4 steps and ten times smaller tolerances, against tolerances fixed before the comparison (10^{-8} for levels, energies and thermodynamics, 10^{-6} for profiles and derived quantities): for example E_{KS} agrees to 1.9×10^{-12} relative (check refined_ground_energies) and 23724 levels agree label by label to $2.1 \times 10^{-9}\,m$ (check refined_eigenvalues). (Section 15.10.)
- **Reflection** R_u along a unit vector u: $R_u v = v - 2\,\eta(u,v)\,u/\eta(u,u)$; it reverses u and keeps every direction orthogonal to u. (Sections 5.12, 5.21, 5.26, 18.2 and 18.8.)
- **Regular**: The decaying branch, $\sigma_2\chi = -\chi$ for $k > 0$, is the regular one. (Section 14.12.)
- **Regular expression**: A regular expression is a pattern that describes a family of texts: in `(\d+)/(\d+)`, `\d` means one digit, `+` means one or more of what stands before it, and the round brackets mark the parts to return. (Sections 0.21, 1.48, 2.28, 7.9, 9.30, 11.9, 14.18, 15.20, 16.12, 19.21 and 23.12.)
- **Regular tip**: the chosen condition $b(-L) = 0$ at the cutoff. (Sections 14.12 and 14.17.)
- **Relative difference**: $|a - b|/\max(|a|, 1)$; numbers that agree to the last digits of a computer have relative differences near 10^{-15}. (Section 19.20.)
- **Relative error**: |computed − exact| divided by |exact|. (Section 1.8.)
- **Remainder**: The last term is the remainder: it shows that the error of keeping only the terms up to h^n is proportional to h^{n+1} when h is small. (Sections 1.2 and 2.3.)
- **Repeating decimal**: a decimal whose digits repeat a block for ever, written with the block in brackets: $1/7 = 0.(142857)$. (Section 1.8.)

- **Report**: a JSON file of the Revision record that holds a list (or table) of named checks, each with a verdict such as PASS. (Sections 0.4, 0.16, 0.20, 3.13, 4.7, 13.20, 23.2 and 23.11.)
- **Repository**: the folder Dirac_claude with every file of this project, downloaded with the program Git. (Sections 0.1, 0.8 and 23.2.)
- **Repository root**: The repository root is that folder itself; every command of Chapter 23 is typed there. (Section 23.2.)
- **Representation, invariant subspace, irreducible**: a group of 16×16 matrices *represents* the group on columns of 16 numbers. A set of columns that every group matrix maps into itself is *invariant*. (Section 5.16.)
- **Required source**: the ρ and p that the field equations demand for a given a_4; we read them off the equations instead of assuming a kind of matter. (Sections 12.1 and 12.19.)
- **Rescaling**: writing the field as a known function times a new field, $\Psi = w(x)\,\chi$, and deriving the equation that χ obeys. (Sections 6.21 and 8.35.)
- **Residual**: in the self-consistent loop, the largest change of the potential from one iteration to the next; the loop stops when it is below 10^{-11}. (Sections 5.33, 9.25, 13.32, 13.35, 15.5, 15.8, 15.13, 16.23 and 20.15.)
- **Rest energies**: For a heavy nucleus the threshold approaches the two rest energies $2m$: for $M = 1000m$ it is $1001m/500 = 2.002m$, and for $M = 1836m$ (about the mass of a proton) $1837m/918 \approx 2.001089m$. (Section 20.17.)
- **Rest state**: A rest state $\Psi = u\,e^{-imx_4}$ with $-i\gamma^{(x4)}u = u$ solves it: $\gamma^{(x4)}\partial_4\Psi = \gamma^{(x4)}(-im)u\,e^{-imx_4} = m(-i\gamma^{(x4)}u)e^{-imx_4} = m\Psi$. (Section 21.18.)
- **Restricted**: Hartree-Fock (HF): the best single determinant; restricted (both labels in the same orbital) or unrestricted (each label its own orbital). (Section 13.13.)
- **Return code**: Every program ends with a return code, 0 for success. (Sections 11.9, 15.14, 16.12 and 19.21.)
- **Revision record**: the computations stored in the folder Revision of the repository, done anew for the author's metric. Every number of the book comes from it or from a notebook of the book. (Sections 0.1, 0.20, 1.1, 1.24, 4.7, 11.8, 11.18 and 14.10.)
- **Ricci scalar**: Riemann tensor $R^a{}_{bcd}$ (the MTW convention of the Revision records), Gaussian curvature $\sigma = R^{\theta\varphi}{}_{\theta\varphi}$ of a surface, Ricci scalar R, Kretschmann scalar K: the measures of curvature. (Sections 3.17, 3.21, 3.29, 6.21, 11.2, 11.18, 12.2 and 12.15.)
- **Ricci tensor** $R^h{}_j$, **Ricci scalar** R, **Einstein tensor** $G^h{}_j$: sums of Riemann components defined in Section 12.6. (Sections 3.17, 3.29, 6.21, 11.2, 11.18, 12.2 and 12.15.)
- **Richardson extrapolation**: combining two finite-difference estimates so that their leading errors cancel. (Sections 14.19, 14.24, 15.9, 16.3, 16.5, 16.11, 16.18 and 19.16.)
- **Richardson's rule**: an estimate of the error made from two computations with the step sizes h and $h/2$. (Section 2.10.)

- **Riemann tensor** $R^{\rho}{}_{\sigma\mu\nu}$: the measure of curvature, built from the Christoffel symbols and their derivatives; it is zero everywhere only for a flat space. (Sections 3.21, 3.29, 6.21, 8.14, 11.2, 11.18, 12.2 and 12.15.)

- **Right derivative**: The right derivative $\partial_R F/\partial\theta_k$ moves θ_k to the far right instead. (Section 7.11.)

- **Right multiplication**: For a fixed quaternion u the right multiplication R_u maps q to $q\,u$ and the left multiplication L_u maps q to $u\,q$. (Section 4.5.)

- **Right-hand side**: for an unknown function $y(t)$, where f is a known rule that produces a number from t and y, the right-hand side. (Section 2.2.)

- **RK4**: the classical Runge-Kutta method of order 4 for solving $dy/dt = f(t, y)$ step by step. (Sections 3.21, 3.34, 8.22, 8.28, 12.24, 14.17, 15.8 and 22.11.)

- **RK4 step count** G: the number of RK4 steps on $-L \le y \le 0$; the step is $h = L/G$. (Section 2.27.)

- **Root** (or zero) of a polynomial: a number where it is 0. (Sections 1.8, 1.34, 1.40, 15.8 and 16.23.)

- **Root of unity**: a complex number z with $z^n = 1$ for a whole number $n \ge 1$. (Section 1.16.)

- **Root-mean-square width**: The root-mean-square width $\sqrt{\int x^2 n\,dx/N}$ measures how far the cloud spreads; `.format(*widths)` puts the three numbers into the three braces of the string. (Section 13.36.)

- **Roots of unity**: They are the roots of unity of order n, the corners of a regular polygon with n sides on the unit circle. (Section 1.12.)

- **Rotation**: turning the plane about the origin by an angle; it keeps every length. (Sections 1.12, 1.16, 4.13, 5.12, 5.18, 5.21, 5.26, 10.34 and 10.37.)

- **Rotation matrix**: The matrix of $e^{i\alpha} = \cos\alpha + i\sin\alpha$ is the rotation matrix. (Sections 1.12 and 1.16.)

- **Round half to even**: If it lies exactly halfway between two neighbours, the rule is to take the neighbour whose m is even (round half to even). (Section 0.22.)

- **Rounding**: replacing a number by the nearest floating-point number. It happens after every addition, multiplication and division. (Sections 0.22 and 0.24.)

- **Rounding bound**: Rounding bound: an upper limit for the error of a computed root. (Section 16.23.)

- **Rounding error**: the difference between the exact result of an operation and the double that the computer stores. (Sections 2.10, 16.2 and 16.23.)

- **Rounding floor**: For RK4 on Problem A this rounding floor is near 10^{-16}, and with more steps the error grows again but stays 524 to 3709 times below the bound $N\epsilon e^{-1}$ (COMPUTED, Notebook 02a, In [10]). (Section 2.6.)

- **Runge-Kutta method**: The classical fourth-order Runge-Kutta method (Chapter 2): from the start $n = 1$, $a = 0$, each step evaluates the slopes at the beginning, twice in the middle and at the end of the step, and advances with their weighted average; the error over a fixed time falls like dt^4. (Sections 9.24, 9.25, 18.26, 19.16 and 21.36.)
- **Runge-Kutta rule of order 4**: Then comes the classical Runge-Kutta rule of order 4 (RK4, Chapter 2): the first slope `p1` from the equation at the start; a half step with it to the midpoint and the second slope `p2` there; a half step with `p2` and the third slope `p3`, again at the midpoint; a full step with `p3` and the fourth slope `p4` at the end; and the new values as the start plus one step times the weighted mean $(p_1 + 2p_2 + 2p_3 + p_4)/6$. (Section 22.12.)
- **Running sum**: Two panels with a shared vertical axis (`sharey=True`); the loop draws in each a bar chart with grey bars for x_0 and x_4, blue for 3-space and red for the extra times, and the running sum (`np.cumsum`, the sum of the first one, two, three, ... values) as black dots joined by lines. (Sections 1.33 and 7.27.)
- **Rust**: Rust is a second programming language. (Sections 0.8, 0.12, 0.20 and 23.3.)
- **The Rust solver**: The Rust solver (Chapter 15). (Sections 15.10, 16.3 and 16.11.)
- **Rust uncertainty**: Rule: multiply by $\frac{16}{15}$; the size of the canonical error is the Rust uncertainty. (Section 16.6.)
- **Rust, cargo, program**: Rust is a programming language; cargo builds a Rust crate (a folder with a file `Cargo.toml` and source files) into a program file that the computer runs. (Section 11.8.)

S

- **Saddle**: For $T > \pi/\omega$ the coefficient is negative: the true path is still stationary ($S_1 = 0$), but along ξ_1 the action is a maximum, while along faster shapes (ξ_n with large n) it is still a minimum; such a point is called a saddle. (Sections 7.2 and 13.32.)
- **Safeguarded Newton-bisection**: The Revision Rust solver finds the root of the same function Φ with fewer evaluations, by the safeguarded Newton-bisection of Section 2.24 (the function find_level of `Revision/kohn_sham/solver/src/shoot.rs`): it widens a bracket around a first guess until $\Phi-$ target changes sign, then takes Newton steps with the derivative $d\Phi/d\varepsilon = \int r^2 dy/r(0)^2$ derived above, takes the midpoint of the bracket instead whenever a Newton step would leave the bracket or the last step has not at least halved the mismatch $|\Phi - \text{target}|$, and stops when the bracket, or its last Newton step, is shorter than the tolerance 10^{-13} (rootTolerance of `Revision/kohn_sham/results/parameters.json`). (Section 14.14.)
- **Sakharov's three conditions**: the three ingredients that, as A. D. Sakharov showed in 1967, any process must contain that makes more matter than antimatter from a start with equal amounts: (1) some process changes the baryon number; (2) C and CP are violated; (3) these processes happen out of thermal equilibrium. In the theory of this book the only number of this kind is the U(1) charge; Section 21.31 applies the three conditions to the theory as built. (Sections 21.5, 21.31 and 21.35.)
- **Same mass**: solves the field equation of the same form, either with the same V (same mass) or with $-V$ (mass reversed). (Sections 5.28, 5.32 and 21.8.)

- **Sample point**: `at_sample(expr)` gives the decimal value of an expression at the sample point $H = 1$, $z = \pi/4$, $a_4 = \frac{1}{2}$, $a'_4 = \frac{1}{2}$, $b_4 = 1$, $b'_4 = \frac{1}{2}$, $a''_4 = b''_4 = 0$. (Section 6.14.)

- **Scalar**: Its Dirac adjoint is the row $\bar{\Phi} = \Phi^\dagger C$ (the dagger means: transpose and take the complex conjugate of every entry), and the scalar is the number $S = \bar{\Phi}\Phi = \Phi^\dagger C \Phi$. (Sections 5.4, 5.32, 9.2, 18.2, 18.26, 21.2 and 21.14.)

- **Scalar density** $S = \bar{\Psi}\Psi = \Psi^\dagger C \Psi$: the bilinear that the mass term and the potential of the Lagrangian contain. (Sections 7.12, 7.16, 7.19 and 19.4.)

- **Scale**: where U_{ref} is the Richardson uncertainty of the reference, U_{Rust} the measured uncertainty of the Rust solver, and the scale s is $\max(1, |x_{ref}|)$ for a single number and the largest value of the profile for a point of a profile. (Section 16.7.)

- **Scale factor** $s_a = \sqrt{|g_{aa}|}$: the factor by which a coordinate length along x_a is multiplied to give a true length. (Sections 2.1, 2.22, 3.7, 3.12, 3.34, 7.26, 8.2, 8.28, 10.42, 12.2, 12.15, 12.24, 14.2, 14.10, 17.2 and 21.7.)

- **Scaled commutator**: For two directions a and b the scaled commutator. (Section 5.12.)

- **Schroedinger equation**: the equation of quantum mechanics that gives the allowed energies E of a particle in a potential $V(x)$; here, for one dimension and in units with $\hbar = m = 1$ ($\hbar$ is Planck's constant divided by 2π, m the mass), $-\frac{1}{2}u''(x) + V(x)u(x) = Eu(x)$. We take it as given. (Sections 2.13 and 2.16.)

- **Schur's lemma** (used here, proved in the text): when the matrices of a representation span all matrices, the representation is irreducible and its commutant is the multiples of 1; an intertwiner between two irreducible representations is zero or invertible. (Section 5.16.)

- **Schwarz's theorem**: This is Schwarz's theorem: for a function whose second partial derivatives are continuous, the order of differentiation does not matter (ASSUMED: a standard theorem of calculus, quoted without proof; Notebook 02c confirms it for this example, and Section 2.24 uses it). (Section 2.18.)

- **Scientific notation**: The `say` line prints the errors in scientific notation (`{e:+.3e}` gives three decimals and a power of ten) and the ratios with four decimals; `", ".join(...)` joins the texts with commas. (Section 7.9.)

- **Scratch folder**: A scratch folder is a folder for throw-away files. (Section 23.2.)

- **Sea**: the levels of the negative branch, which the filling CONVENTION of the record leaves out (normal ordering); sea holes would be thermal antiparticles. (Sections 5.34, 14.21, 15.2 and 15.29.)

- **Sea holes**: Sea: the levels of the negative branch, which the filling CONVENTION of the record leaves out (normal ordering); sea holes would be thermal antiparticles. (Section 15.29.)

- **Secant method**: For one variable and two remembered passes the combined residual can be made exactly zero, and the next input is the point where the straight line through the two last (input, residual) pairs crosses zero: the secant method, which estimates the slope of G from the history. (Section 13.21.)

- **Secant rule**: draw the straight line through the last two points $(\lambda, F(\lambda))$ and take its zero as the next guess. (Section 2.16.)
- **Second difference quotient**: The bracket is $E = -\ddot{q} - \omega^2 q$ with $\ddot{q}$ replaced by the second difference quotient $(q_{n+1} - 2q_n + q_{n-1})/h^2$. (Section 7.3.)
- **Second order**: Such a method is said to be of second order (or to have order of convergence 2), because for small h the first term $c\,h^2$ dominates: halving h divides the error by about $2^2 = 4$. (Section 16.4.)
- **Second quantisation**: Second quantisation labels a determinant only by which orbitals it uses. (Section 13.4.)
- **Sectional curvature**: is the curvature of the coordinate plane of x_a and x_b (its sectional curvature; "plane" means here the plane of the two directions x_a and x_b at one point). (Section 3.17.)
- **Sector** of a Hermitian matrix B with $B^2 = I$: the columns u with $Bu = u$ (the sector $B = +1$), or those with $Bu = -u$ (the sector $B = -1$). (Sections 4.9, 4.11, 9.26, 9.29, 15.2, 15.24, 22.2 and 22.11.)
- **Seed**: It starts from a number called the seed, and the same seed always gives the same sequence. (Sections 0.22, 0.24, 1.25, 1.49, 1.53, 4.12, 5.17, 7.9, 8.23, 9.17, 11.8, 13.14, 14.11, 16.12, 18.9, 20.11 and 21.15.)
- **Self-adjoint**: the Hamiltonian satisfies $\int \varphi^\dagger h\chi\, dy = \int (h\varphi)^\dagger \chi\, dy$; then the levels are real. (Section 14.17.)
- **Self-adjoint for the Krein form**: The mode matrix satisfies $Bh_k = h_k^\dagger B$ for every momentum (PROVED; `python-field-theory.json`, check `mode_hamiltonian_B_selfadjoint_dispersion`; a matrix with this property is called self-adjoint for the Krein form). (Section 8.19.)
- **Self-consistency**: the potential makes the orbitals, the orbitals make the density, the density makes the potential; a solution is self-consistent when the potential that comes out equals the potential that went in. (Sections 13.1, 13.6, 13.35 and 15.8.)
- **Self-consistent**: the orbitals reproduce the mean field that made them. A computer finds such a state by repeating "densities, then mean field, then orbitals, then densities" until nothing changes. (Sections 0.2, 7.23, 17.2 and 19.2.)
- **Self-consistent state**: (v) So the densities that the partner problem computes from its own orbitals and occupations are $(n, -S)$, the densities we started from in (ii): B is a fixed point of the partner's loop, a self-consistent state. (Section 19.9.)
- **Self-consistently**: Kohn-Sham state: an approximate state of N identical fermions built from one-particle wave functions (orbitals) that each solve a one-particle equation in a common effective potential; the potential depends on the densities of the occupied orbitals, so the equations are solved self-consistently (repeat until nothing changes). (Section 19.20.)
- **Self-coupling** λ: the strength with which a field acts on itself (Chapter 7). (Sections 0.2 and 12.29.)

- **Series**: A series is an endless sum $t_0 + t_1 + t_2 + \cdots$; its partial sum $S_N = t_0 + \cdots + t_N$ adds the terms up to number N, and the series converges to a number S when the error $|S_N - S|$ becomes as small as we like for large N. (Sections 1.11 and 1.16.)

- **Set**: an unordered collection of different things, written `{"x1", "x2"}` in Python. Python keeps the names of a set in an order decided by their *hash values*: numbers computed from the names with a secret key that Python chooses anew each time it starts, unless the *environment variable* PYTHONHASHSEED fixes the key. (Sections 0.22, 0.24, 1.41, 2.28, 4.8, 4.13, 4.15, 5.10, 6.14, 8.23, 9.30, 10.43, 11.9, 14.11, 15.14, 17.11, 20.16, 21.15 and 22.23.)

- **Set comprehension**: A set comprehension (braces) keeps each bilinear once, `sorted` puts them in order: 42 components, 15 distinct three-gamma bilinears. (Sections 12.20 and 19.16.)

- **Set-up cell**: The first code cell, the set-up cell, repeats the instructions as comment lines and prepares the helpers that every notebook uses. (Sections 0.7 and 1.1.)

- **sha256**: The fingerprint used here is sha256: a fixed recipe that turns the bytes of a file, however many there are, into a number of 256 binary digits, written as 64 hexadecimal characters. (Sections 0.18 and 15.13.)

- **sha256 fingerprint**: a 64-digit hexadecimal number computed from a file by the method SHA-256; two different files have different fingerprints for all practical purposes, so equal fingerprints mean equal files, byte for byte. (Sections 1.50, 1.53, 17.2 and 17.20.)

- **Shape**: To make "changed a little" precise, take a fixed shape $\xi(t)$ with $\xi(0) = \xi(T) = 0$ (so that the changed path keeps the end values) and a small number ϵ, and form the varied path $q + \epsilon\xi$. (Section 7.2.)

- **Shell**: all lattice vectors with the same $n^2 = n_1^2 + n_2^2 + n_3^2$; $r_3(n^2)$ is their number (for example $r_3(1) = 6$). (Sections 14.21, 14.24, 15.2, 15.13, 17.2 and 19.3.)

- **Shell structure**: Thomas-Fermi uses no orbitals, so it cannot show the four bumps of the Kohn-Sham density (its shell structure). (Section 13.32.)

- **Shift left** by k places (two less-than signs): k zero bits are appended, which multiplies by 2^k (every bit moves to a place worth 2^k times more). (Section 1.49.)

- **Shift right** by k places (Python writes it with the operator made of two greater-than signs): the last k bits are dropped. This is whole-number division by 2^k: writing $x = 2^k q + r$ with $0 \le r < 2^k$, the last k bits of x are the bits of r, and the bits before them are those of q. (Section 1.49.)

- **Shoelace formula**: The signed area of a polygon with the corners $(x_1, y_1), \ldots, (x_K, y_K)$, listed in order, is given by the shoelace formula. (Section 1.21.)

- **Shooting**: solve from one end with the conditions there and a guessed eigenvalue (like aiming a cannon), measure the *mismatch* at the other end (where the shot lands), and change the guess until the mismatch is zero. (Sections 2.16, 14.14, 14.17, 15.8, 19.15 and 19.16.)

- **Shooting function** F: the mismatch as a function of the guess; the eigenvalues are its zeros. (Sections 2.12, 2.16 and 14.14.)

- **Shooting method**: The Rust program of the Revision record solves them by the shooting method: it guesses an energy, integrates the equations from one end to the other with the classical fourth-order Runge-Kutta method (RK4) in 900 steps, measures by how much the condition at the far end fails, and corrects the energy with Newton's method. (Section 2.1.)
- **Sign convention**: Energy-momentum tensor $T^{\mu}{}_{\nu}$: the energy density $\rho = -T^{x_4}{}_{x_4}$, the pressures $p_\mu = T^{\mu}{}_{\mu}$ (no sum), and the mixed components; sign convention $\sigma_T = +1$ of the Revision record. (Section 12.29.)
- **Sign of a permutation**: $\operatorname{sign}(\sigma) = (-1)^N$, where N is the number of inversions: $+1$ for an even permutation (even N), -1 for an odd one. (Section 11.8.)
- **Sign** of a permutation: $+1$ if it has an even number of inversions (an even permutation), -1 if odd. (Sections 1.19, 1.24, 1.47 and 11.2.)
- **Sign of a reordering**: putting the factors of a product into increasing order by exchanging neighbours; every exchange of two generators gives a factor -1. The total factor is $+1$ for an even and -1 for an odd number of exchanges. (Section 7.16.)
- **Sign pattern** of g: the pair $(\operatorname{sign}\det A, \operatorname{sign}\det D)$. (Sections 5.23 and 5.26.)
- **Signature**: the numbers of positive and of negative entries of the metric. Here it is (4,4): four space-like and four time-like directions. (Sections 0.5, 0.14, 0.16, 1.27, 1.32, 1.36, 1.40, 2.19, 3.4, 3.12, 4.4, 5.4, 5.9, 6.13, 7.26, 10.2, 10.9, 12.2 and 21.14.)
- **Signed area**: The signed area of a polygon with the corners $(x_1, y_1), \ldots, (x_K, y_K)$, listed in order, is given by the shoelace formula. (Section 1.21.)
- **Signed byte**: A signed byte uses the same 8 bits for the numbers -128 to 127: a negative number $-m$ is stored as $256 - m$ (the two's complement). (Sections 1.49 and 1.53.)
- **Signed permutation matrix**: a square matrix with exactly one nonzero entry in every row and in every column, that entry being $+1$ or -1. Acting on a column it puts the components into a new order and changes some of their signs. Every gamma matrix of the author, and the matrix C, is one. (Sections 1.19, 1.24, 4.2, 4.5, 4.7, 4.17, 4.19, 5.2, 5.9, 7.12, 17.20, 17.21, 18.2, 18.8, 19.15, 19.16 and 21.7.)
- **The signs of the directions**: the table η whose diagonal entries are $+1$, $+1$, $+1$, $+1$, -1, -1, -1, -1 in the order $x_0, \ldots, x_7$: the directions x_0, x_1, x_2, x_3 are space-like and x_4, x_5, x_6, x_7 time-like; the signature is (4,4). (Section 0.5.)
- **Similar**: Matrices related in this way ($N = SMS^{-1}$) are called similar, and similar matrices have the same eigenvalues. (Sections 10.6, 20.12 and 21.26.)
- **Similar matrices**: $N = PMP^{-1}$; they have the same spectrum. (Section 18.26.)
- **Simpson's rule**: an integration rule with the weights $1, 4, 2, 4, \ldots, 4, 1$ times (step/3). (Sections 13.15, 14.17, 14.18, 15.8, 17.2, 17.20, 17.21 and 22.12.)
- **Singular value decomposition**: The singular value decomposition (`np.linalg.svd`) writes a matrix A as $U\Sigma V^\dagger$ with a list of numbers Σ (the singular values, sorted from large to small) and two matrices U and V whose columns have length 1 and are perpendicular; a column of V whose singular value is zero solves $Au = 0$. numpy returns $V^\dagger$ as `vh`, so the last row of `vh`, conjugated, is the last column of V. (Sections 8.23, 9.30, 18.27 and 21.30.)

- **Singular values**: for a matrix M the square roots of the eigenvalues of $M^T M$. The number of zero singular values of M is the number of independent solutions of $Mx = 0$. (Sections 5.27 and 10.37.)

- **Singularity**: "The big bang." In cosmology the big bang is the hot, dense early phase from which the observed expansion started; in the classical solutions of Einstein's equations that describe it, the scale factor of space goes to zero at a finite time in the past, and the equations break down there (a singularity). (Section 20.3.)

- **Size**: The size of a matrix (the largest factor by which it stretches the length of a column) is therefore exactly k_5 for h_A: $\|h_A u\|^2 = u^\dagger h_A^\dagger h_A u = k_5^2\, u^\dagger u$. (Section 10.39.)

- **Size of a matrix (spectral norm)**: the largest factor by which the matrix stretches the length of a column; in code `np.linalg.norm(M, 2)`. (Section 10.42.)

- **Slater determinant**: the antisymmetric state of N fermions built from N orthonormal orbitals, $\Phi = \det[\phi_a(x_i)]/\sqrt{N!}$. (Sections 13.3 and 13.13.)

- **Slice**: the function of ONE variable obtained by holding the others fixed; the partial derivative is the slope of its graph. (Sections 2.18, 2.22, 3.8, 4.8, 5.10, 14.3, 14.10, 14.24, 15.1, 15.13, 16.1, 17.2, 17.10, 17.20, 18.27, 19.2, 19.16, 19.20, 22.1, 22.11 and 22.23.)

- **Slope** c: $d\varepsilon/dk$ of the brane band at $k = 0$. (Sections 2.6, 3.8, 11.2, 12.2, 12.19, 14.24, 16.18 and 17.2.)

- **Smallest singular value** of a square matrix M: the smallest length of Mu over all columns u of length 1. It is 0 exactly when some nonzero u has $Mu = 0$. numpy computes it with `np.linalg.svd`. (Sections 4.9 and 4.11.)

- **So(4,4)**: the real 8×8 matrices X with $X^T\eta + \eta X = 0$ (the *Lie algebra* of O(4,4)). (Sections 5.12, 5.23 and 5.26.)

- **Sobolev norm of order** s: a way to measure the size of data that also counts how fast they wiggle; for one wave of momentum K and amplitude ϵ it is $\epsilon\,(1 + K^2)^{s/2}$. Larger s punishes wiggly data more. (Sections 8.18 and 8.22.)

- **Solution space**: the set of all solutions X of a list of linear equations without constant terms; its dimension is the number of free parameters. (Sections 4.19, 5.16 and 21.14.)

- **Solution**, **boundary condition**: a solution of a field's equations is a field that satisfies them at every point; a boundary condition is a further condition that a solution must satisfy at the edge of the region in which it is defined (Chapters 2 and 14). (Sections 0.2, 18.1 and 20.2.)

- **Solver**: a program that computes the solution of equations. (Section 16.11.)

- **Source**: the energy-momentum tensor of the fields as it enters the equations of gravity (Chapter 12). (Sections 0.2, 12.2, 12.15, 12.19, 17.2, 17.10 and 17.20.)

- **Source conditions** (from the a_4 equations): C1 no component of the source depends on x_0 and $q_{40} = q_{04} = 0$; C2 $p_3 + p_t = 2p_0$; C3 for the linear member $a_4 = AHx_4 + a_0$: $p_3 = p_t = p_0$ and a constant ρ. (Sections 17.1, 17.2 and 17.20.)

- **Source strength**: In Einstein gravity, with the initial rate $a_4'(0) = H$ (the rate of the history on which the states were computed) and the source strength $\sigma_0 = \kappa\bar{\rho}(0)/H^2$, the constraint at $a_4 = 0$ fixes Λ: $3H^2 + 21H^2 + \Lambda = -\sigma_0 H^2 \quad \Longrightarrow \quad \Lambda = -24H^2 - \sigma_0 H^2$. (Section 17.17.)

- **Space block**: A is the space block and D the time block (the primes distinguish the other two blocks from the matrices B and C). (Sections 5.23 and 5.26.)

- **Space-like and time-like**: two kinds of direction. Along a space-like direction a step is measured like a distance; along a time-like direction it is measured like a duration. In the metric a space-like direction has a positive entry and a time-like direction a negative entry. (Section 0.16.)

- **Space-like** and **time-like**: a direction along which a step is measured like a distance, or like a duration; x_0, x_1, x_2 and x_3 are space-like, x_4 to x_7 time-like (Section 0.14). (Sections 0.2, 0.14, 1.5, 1.13, 1.27, 1.32, 3.4, 3.12, 4.3, 4.4, 5.1, 6.13 and 6.27.)

- **Space-like, time-like direction**: $\eta_{nn} = +1$ (x_1, x_2, x_3 and the hidden direction x_0), respectively $\eta_{nn} = -1$ (the time x_4 and the three EXTRA TIMES x_5, x_6, x_7, which deflate exponentially in the author's metric). (Section 18.8.)

- **Space-space**: The factor $\frac{1}{2}(\eta_{aa} + \eta_{bb})$ is $+1$ for a pair of two space-like directions (space-space), -1 for a pair of two time-like directions (time-time) and 0 for a boost pair. (Sections 6.23 and 6.27.)

- **Span**: all combinations of a list of matrices. (Sections 4.15, 5.11, 5.16 and 5.26.)

- **Spectral theorem**: Symmetry matters: a real symmetric matrix has only real eigenvalues and an orthonormal set of eigenvectors (the spectral theorem, quoted from linear algebra), as the levels of a self-adjoint problem must; and the counting method of Section 16.15 works only for symmetric matrices. (Section 16.14.)

- **Spectrum**: the list of all eigenvalues of a matrix. (Sections 1.34, 1.40 and 5.9.)

- **Spin**: The spin-statistics rule of ordinary four-dimensional quantum field theory says that particles of half-integer spin (the spin is the intrinsic angular momentum of a particle, measured in units of Planck's constant divided by 2π; the electron has spin $\frac{1}{2}$), which are the fermions of Chapter 7, must be described by anticommuting fields; described by commuting fields, as dirac16complex00 is, the energy of a spinor field has no lower bound, and this is exactly what the plane waves above show. (Section 9.21.)

- **Spin connection** $\omega_\mu{}^a{}_b$: the numbers that say how the vielbein turns when one moves along x^μ. (Sections 5.28, 6.1, 6.4, 6.13, 6.21, 8.35, 9.16, 12.29, 14.10, 18.3 and 21.22.)

- **Spin density**: The last term comes from the change of the spin connection; the record calls the bilinear in it the totally antisymmetric spin density (it changes sign when two of its three indices are exchanged). (Section 9.6.)

- **Spin generators**: With the spin generators $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$, which equal $\frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ for $a \neq b$ (the two products differ only in sign) and 0 for $a = b$ (Chapter 5), the spinor connection is $\Omega_\mu = \frac{1}{2}\,\omega_{\mu ab} S^{ab} = \sum_{a<b} \omega_{\mu ab} S^{ab}$. (Section 7.18.)

- **Spin transformation**: A spin transformation is a 16×16 matrix R that acts on the components, $\Psi \to R\Psi$, and at the same time turns the eight directions into each other. (Sections 5.18 and 7.19.)

- **Spin(4,3)**: the spin group of the seven slice directions $x_0, x_1, x_2, x_3, x_5, x_6, x_7$ (every direction except the time x_4: four space-like, three time-like). In Chapter 10 it is generated by the 21 generators S^{ab} whose pair of directions does not contain x_4; exactly these 21 generators are Krein-unitary. (Sections 10.34 and 10.37.)

- **Spin(4,4)**: the subgroup of Pin(4,4) (see that entry) made of the products $\gamma(u_1) \cdots \gamma(u_k)$ of an EVEN number k of unit vectors. Under it the 16 components split into two inequivalent halves of 8 (PROVED, Section 5.13), while under Pin(4,4) they are irreducible. (Sections 5.12, 5.13, 5.21 and 5.26.)

- **Spin-statistics**: This is the classical form of the spin-statistics problem of a commuting field with a first-order Lagrangian. (Section 9.21.)

- **Spin-statistics rule**: The spin-statistics rule of ordinary four-dimensional quantum field theory says that particles of half-integer spin (the spin is the intrinsic angular momentum of a particle, measured in units of Planck's constant divided by 2π; the electron has spin $\frac{1}{2}$), which are the fermions of Chapter 7, must be described by anticommuting fields; described by commuting fields, as dirac16complex00 is, the energy of a spinor field has no lower bound, and this is exactly what the plane waves above show. (Section 9.21.)

- **Spin-statistics theorem**: In ordinary 3+1 dimensional physics this choice is not free: the spin-statistics theorem of quantum field theory shows that, if the energy is to be bounded below and measurements at two points that no signal can connect are not to disturb each other, fields of half-integer spin (such as the electron's) must be quantised with anticommutators and fields of whole-number spin with commutators. (Section 10.12.)

- **Spinor** Φ: a column of 16 complex numbers (here: functions of x_4). dirac16complex00 is a field of such spinors whose components are ordinary (commuting) complex numbers. (Sections 7.1, 12.29 and 20.15.)

- **Spinor boost** $R(x)$: a 16 x 16 matrix that turns spinors when the frame is boosted; it covers Λ when $R^{-1}\gamma^a R = \sum_b \Lambda^a{}_b \gamma^b$ for every a. (Sections 6.21 and 6.27.)

- **Spinor connection** $\Omega_\mu = \frac{1}{2}\sum_{a,b} \omega_{\mu ab} S^{ab}$: a 16 x 16 matrix for every μ. (Sections 6.7, 6.13, 6.21, 6.27, 7.18, 7.26, 8.2 and 8.14.)

- **Spinor curvature**: Spinor curvature $F_{\mu\nu} = \partial_\mu \Omega_\nu - \partial_\nu \Omega_\mu + [\Omega_\mu, \Omega_\nu]$, where $[A, B] = AB - BA$ (the *commutator*); the record proves $F_{\mu\nu} = \frac{1}{4}\sum R_{\rho\sigma\mu\nu}\gamma^\rho\gamma^\sigma$. (Section 8.14.)

- **Spinor field** Ψ: at every point of spacetime a column of 16 numbers $\Psi_1, \ldots, \Psi_{16}$ (its *components*). (Sections 5.32, 21.2 and 21.14.)

- **Spinor norm**: Spinor norm $N(g) = \eta(u_1, u_1) \cdots \eta(u_k, u_k)$ of such a product. (Section 5.21.)

- **Spread**: For a state with a nonzero source the record computes the spread of the energy density. (Section 17.4.)

- **Square**: It is square if $m = n$. (Sections 1.18 and 1.24.)

- **Square root of a quadratic form**: an expression L, linear in the variables, whose square is the quadratic form: $L^2 = p^2 + q^2$ (times the identity matrix when L is a matrix). (Section 4.11.)

- **Squared length**: The squared length of a vector is $Q(v) = \eta_{ab} v^a v^b = v^a v_a = (v^0)^2 + (v^1)^2 + (v^2)^2 + (v^3)^2 - (v^4)^2 - (v^5)^2 - (v^6)^2 - (v^7)^2$. (Sections 1.27, 1.32 and 3.4.)

- **Squared length of the velocity**: $g(u,u) = \sum_a g_{aa}(u^a)^2$ (the metric is diagonal). For a body with mass it equals -1 when τ is its proper time. (Section 3.34.)

- **Stack**: The stack is a list of partial combinations still to be extended, each a tuple of the chosen entry numbers with the two masks; it starts with the empty combination. (Section 11.19.)

- **Stacked bar chart**: A stacked bar chart: for each field the bars of the three types are drawn on top of each other (`bottom=bottoms` starts each new bar where the previous one ended), the counts are written into the bars and the totals above them (`"\n"` in a label is a line break). (Section 7.27.)

- **Staggered**: Such a grid, on which the two components live on alternating points, is called staggered. (Section 16.14.)

- **Staggered grid**: a is stored at the half nodes, b at the nodes. (Sections 16.3 and 16.18.)

- **Standard deviation**: A measured fraction p from N tries is expected to scatter around the true value by about one standard deviation $\sqrt{p(1-p)/N}$ (ASSUMED from probability), here $\sqrt{0.25/200000} \approx 0.0011$ for the first; both measurements lie within 4 standard deviations of $1/2$ and of $1/2 + 1/\pi$ (Figure 01e.2). (Sections 1.27, 1.50, 1.53 and 11.4.)

- **State**: In quantum theory a state is a column of numbers, and an operator is a rule that turns a state into another state; here every operator is a (big) matrix acting on columns. (Sections 1.49, 1.53, 5.34, 5.37, 10.18 and 22.2.)

- **State id**: a name such as `N136_lamp2_a20`: $N = 136$ particles, coupling $+\lambda_2$ (`lam0`: $\lambda = 0$; `lamp1`, `lamm1`: $\pm\lambda_1$; `lamp2`, `lamm2`: $\pm\lambda_2$), slice $a_{4,0} = 2.0$ (the digits are ten times $a_{4,0}$). A thermal state ends with `_T10`, `_T20` or `_T50`: the temperature $T = 0.01$, 0.02 or 0.05 (in units of the mass m). (Sections 16.11 and 16.23.)

- **Stationary**: A path is stationary if $S_1 = 0$ for every shape ξ; the principle says that the true motion is stationary. (Sections 5.6 and 7.2.)

- **Stationary path**: a path whose first variation is zero for every variation. (Section 7.8.)

- **Stationary state**: So $\Psi_0 = \sin z\, e^{iwx_4}\chi_0$ has a single frequency: a stationary state. (Section 21.18.)

- **Statistics**: whether the components of a field commute (the field dirac16complex00) or anticommute (the field dirac16complex, whose components are Grassmann numbers). (Sections 7.26 and 18.2.)

- **Status labels**: PROVED (exact, by a derivation or by exact computation, with the record file and check), COMPUTED (numerical, with its accuracy), ASSUMED, HYPOTHESIS, OPEN. (Sections 11.2, 12.2, 12.19, 17.10, 17.20, 21.2 and 21.35.)

- **Status words**: PROVED (exact, for all values), CHECKED (exact or to rounding, for the values shown), REPRODUCED (agrees with a Revision record), NOT ESTABLISHED (not shown by these equations). (Section 10.48.)
- **Step**: one command of the gate, with a name such as `algebra-wolfram`. (Sections 15.8 and 23.2.)
- **Step rule**: A step rule says how to compute y_{n+1} from y_n. (Section 2.4.)
- **Step size**: It chooses a step size h, the times $t_n = nh$, and computes numbers y_n that approximate $y(t_n)$, one step after the other. (Section 2.4.)
- **Storage rule**: We call this the storage rule: a number between 2^k and 2^{k+1} is stored as $m \cdot 2^{k-52}$ with a 53-digit m. (Section 0.22.)
- **Strictly increasing**: So $\Phi(\varepsilon)$ is strictly increasing: each target value $l\pi$ or $\pi/2 + l\pi$ is reached for exactly one energy. (Section 2.24.)
- **String**: A variable is a name for a value; this line gives the name `NOTEBOOK_ID` to the text `"00a"` (a text in quotes is called a string). (Sections 0.13, 0.21, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 13.14, 14.11, 15.9, 16.12, 17.11, 18.9, 19.16, 20.11, 21.15 and 22.12.)
- **Sturm count** $c(x)$: the number of eigenvalues of T below a number x. (Sections 16.3, 16.15 and 16.18.)
- **Subgroup**: A subgroup is a subset that is itself a group. (Section 5.11.)
- **Subprocess**: a program that another program starts and whose printed output it reads. (Section 0.24.)
- **Subset**: A subset of a set S is a set whose elements all belong to S. (Sections 4.13, 4.15 and 16.9.)
- **Subspace**: A subspace is a set of columns that contains every sum and every multiple of its members (for example all columns whose components 9 to 16 are zero). (Section 5.11.)
- **Successive differences**: For each computed number x, for example E_{KS}, the study forms the successive differences $d = x(L + 0.5) - x(L)$ over the unbroken run $L = 3, 3.5, 4, \ldots$ of values at which the self-consistent iteration converged (the run ends just before the first L at which the iteration fails, and values at larger L after a failure are not used), and the ratio r of each difference to the one before it. (Section 15.2.)
- **Sudden**: Sudden: so fast that the orbital has no time to change at all. (Section 22.11.)
- **Sudden limit**: the limit of an infinitely fast change, in which the orbital has no time to change at all (Section 22.8). (Section 22.2.)
- **Sum**: Comparing the two: the sum of the eigenvalues is the trace. (Section 1.34.)
- **Sum convention**: the summation convention (see that entry). Chapter 12 writes every sum with $\sum$ or in words, except in the definitions of Section 12.7 and in the formulas quoted from the record, where an index that appears once up and once down is summed over its eight values; "no sum" marks the exceptions. (Sections 5.28 and 12.2.)

- **Summation convention**: an index that appears twice in one product is summed over all its values without writing $\sum$; so $A_{ij}B_{jk}$ means $\sum_j A_{ij}B_{jk}$. (Sections 1.24, 1.26 and 1.32.)
- **Summed label**: in Chapter 11 a label that appears once up and once down inside one term is summed over its eight values, unless "no sum" is said; the free labels h and j are never summed. (Section 11.2.)
- **Sylvester's law of inertia**: the matrices S and $P^T S P$ (P invertible) have the same signature. (Sections 1.40, 3.4 and 16.15.)
- **Symbol** (sympy): a letter that stands for any number, so that sympy can compute exactly with formulas instead of with decimal numbers. (Sections 0.16, 4.11, 4.12, 11.5 and 17.11.)
- **Symmetric (Belinfante) energy-momentum tensor**: the symmetric part $\frac{1}{2}(T^{\nu\rho}_{\text{var}} + T^{\rho\nu}_{\text{var}})$ of the variation tensor T_{var} (the energy-momentum tensor obtained by changing the metric in the action), named after the physicist F. J. Belinfante, who showed how to make the energy-momentum tensor of a spinor field symmetric. The record proves its formula for every configuration, solution or not (PROVED; check `T_symmetric_part_Belinfante_C`). (Section 9.6.)
- **Symmetric** array: $S_{ab} = S_{ba}$; antisymmetric array: $A_{ab} = -A_{ba}$ (its diagonal is 0). (Sections 1.28, 1.32, 3.3, 4.2, 4.7, 5.2, 5.9, 6.4, 6.7, 6.23, 7.16, 16.14, 16.18, 18.8, 21.2 and 21.14.)
- **Symmetric difference** $A \triangle B$: the directions that lie in exactly one of the sets A and B. (Sections 4.13 and 4.15.)
- **Symmetric logarithmic**: The vertical axis is symmetric logarithmic (`"symlog"`): linear between -0.001 and 0.001 and logarithmic outside, so that large and small values of both signs fit. (Sections 1.41, 5.27, 8.15 and 15.14.)
- **Symmetric logarithmic axis**: logarithmic for large positive and negative values and linear near zero, so that both signs fit on one axis. (Sections 15.19 and 17.2.)
- **Symmetric matrix**: $S^T = S$. (Section 1.40.)
- **Symmetric operator (formally Hermitian)**: an operator h with $\int \cos z\, u^\dagger (hv)\, dx_0 = \int \cos z\, (hu)^\dagger v\, dx_0$ for all wave functions u, v. A *boundary term* is a part of the integrand that is a derivative, $\partial_0(\ldots)$; its integral is the difference of the bracket at the two ends, so the operator is symmetric when that difference vanishes. (Section 10.31.)
- **Symmetric part**: Write M as the sum of its symmetric part $\frac{1}{2}(M+M^T)$ and its antisymmetric part $\frac{1}{2}(M - M^T)$. (Sections 7.12 and 9.4.)
- **The symmetries C and CP**: C exchanges every particle with its antiparticle, P reflects space as in a mirror, and CP does both (Chapter 21). (Section 0.2.)
- **Symmetrised**: It is symmetrised: the derivative acts once on Ψ and once on $\bar{\Psi}$, with opposite signs (Section 7.20 shows why). (Section 7.19.)
- **Symmetry**: A symmetry maps the solutions of one theory to solutions of the SAME theory. (Sections 18.13 and 21.22.)

- **Symmetry of the dynamics**: A transformation is a symmetry of the dynamics if it turns every possible history of the system into another possible history that runs in the same direction of time. (Section 21.5.)
- **Symmetry of the metric**: Such a change of coordinates that leaves the metric unchanged is a symmetry of the metric (an isometry). (Section 20.22.)
- **Symmetry pattern**: (iii) The symmetry pattern $(\gamma^a)^T = \eta_{aa}\gamma^a$: symmetric for the space-like x_0, x_1, x_2, x_3, antisymmetric for the time-like $x_4, \ldots, x_7$. (Sections 4.5 and 21.7.)
- **sympy**: the Python package for exact algebra with symbols; numpy: arrays of numbers; matplotlib: plots. (Sections 3.12, 4.11, 10.9, 14.10, 18.20, 19.15 and 20.11.)
- **sympy symbol**: a letter that stands for any number; `ad1` and `ad2` stand for $a_4' = da_4/dx_4$ and $a_4'' = d^2a_4/dx_4^2$. (Section 12.15.)
- **Sympy, Rational**: sympy computes with exact fractions such as $-1/32$, so its checks are exact, not rounded. (Section 13.19.)
- **System**: Several unknown functions that change together, say a position $x(t)$ and a velocity $v(t)$, form a system. (Section 2.2.)
- **System of ODEs**: several unknown functions changing together, for example a position x and a velocity v; y is then a list (a *vector*) of numbers. (Section 2.10.)

T

- **T1** (both fields, every gravitational field): a fixed 16×16 matrix Γ, the chirality, turns every solution with (m, λ) into a solution with $(-m, -\lambda)$; the Lagrangian (the function from which the equations follow) changes as $L_{m,\lambda}[\Gamma\Psi] = -L_{-m,-\lambda}[\Psi]$, the energy-momentum tensor T (the table of the energy and momentum that the field carries) changes into $-T$, and the charge current J into $-J$. (Section 0.2; the opening of Chapter 18.)
- **T1 pair**: A T1 pair has opposite energy-momentum tensors; a T2 pair has equal ones. (Section 20.2.)
- **T1 partner**: T1 partner: $\Gamma\Psi$ with $(-m, -\lambda)$ at the same point. (Sections 20.2 and 20.10.)
- **T2** (both fields): Γ combined with the reflection of one space-like direction (an element of the group Pin(4,4)) turns (m, λ) into $(-m, \lambda)$, with the same self-coupling; in the author's universe the reflection is the Z2 mirror across the edge $z = \pi/2$ of the hidden direction (a choice of boundary condition, which is ASSUMED, not derived), and the energy-momentum tensor of the image is equal to that of the original (reflected across the mirror), not opposite to it. (Section 0.2; the opening of Chapter 18.)
- **T2 mirror copy**: T2 mirror copy: $\gamma^{(x_0)}\Psi$ placed at the mirror point $\pi - z$, with $(-m, \lambda)$. (Sections 20.2 and 20.10.)
- **T2 pair**: A T1 pair has opposite energy-momentum tensors; a T2 pair has equal ones. (Section 20.2.)

- **T3** (dirac16complex, the Kohn-Sham level: within the Kohn-Sham approximation, which is ASSUMED (Section 0.18), with the ASSUMED Z2 mirror and the correspondingly transformed boundary conditions): every self-consistent Kohn-Sham universe with (M, λ) has a partner with $(-M, \lambda)$, and the two have equal energies and equal energy-momentum tensors. (Section 0.2; the opening of Chapter 19.)

- **The table of the plane curvatures**: The table of the plane curvatures (PROVED; Notebook 03b computes all 28 and finds these seven formulas, In [16]), with $\alpha = a_4'$ and $\alpha_t = -a_4' + b_4'/(2b_4)$ (the formula is displayed in that section). (Section 3.24.)

- **Tangent**: the straight line that touches a curve at one point; its slope is the derivative there. (Sections 15.19 and 22.22.)

- **Taylor's theorem** (ASSUMED: a standard theorem of one-variable calculus, quoted without proof). If y has $n+1$ continuous derivatives, then for every step h. (Section 2.3.)

- **Temperature** T: measured as an energy (Boltzmann's constant is set to 1). (Sections 13.30, 15.29 and 21.2.)

- **Temporary folder**: `tempfile.mkdtemp` creates a new, empty temporary folder in the place the operating system keeps for temporary files (outside the repository; its name starts with `textbook_16a_` and ends with random characters) and returns its name, which `Path` turns into a path: `RUN_FOLDER`. (Section 16.12.)

- **Tension**: Tension: the energy per unit area of a surface, which acts like a negative pressure along it. (Section 22.2.)

- **Tensor** $T^{\nu}{}_{\mu}$: a table of 8×8 numbers at every point, one for each pair of directions (ν, μ). The upper index ν is the row, the lower index μ the column. Lowering the upper index with the metric gives $T_{\nu\mu} = g_{\nu\nu} T^{\nu}{}_{\mu}$ (the metric here is diagonal). (Sections 1.43, 3.14, 9.16 and 11.5.)

- **A terminal** is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). A command is typed exactly as printed and sent with the Enter key. The commands are printed in framed blocks, one command per line; where they differ between the systems, the block is labelled with the system. (Sections 0.8 and 23.2.)

- **Test equation**: To understand the accuracy of a method we apply it to the simplest equation of all, the test equation. (Section 2.5.)

- **Test field** and **back-reaction**: a field that is computed in a gravitational field given in advance, which the field itself does not change, is a test field. The change of the gravitational field caused by the energy and momentum of the field is its back-reaction. All Kohn-Sham results of the record are test-field results. (Sections 14.3, 15.16, 17.1, 17.2, 17.10, 17.20, 17.22 and 22.2.)

- **Test particle**: A test particle is a body so small that it does not change the metric (ASSUMED: the particles of this section are test particles). (Sections 3.31 and 3.34.)

- **Text buffer**: `io.StringIO()` is a text buffer, a piece of memory that collects printed text. (Section 10.10.)

- **Thawing**: Thawing: $w_a < 0$; freezing: $w_a > 0$. (Section 22.22.)
- **The theorem of the linear history** (PROVED; record entry `theoremLinear`, see the table). Its hypotheses are four: (1) Φ is a homogeneous condensate of the commuting field that solves its field equation; (2) it meets the off-diagonal conditions above; (3) a_4 is twice continuously differentiable (a_4' and a_4'' exist and are continuous functions of x_4); (4) the three Lovelock couplings $\alpha_1, \alpha_2, \alpha_3$ of Chapter 12 are not all zero. Its conclusion: if the author's metric with this a_4 solves the field equations of gravity with the condensate as the source, then $a_4 = AHx_4 + a_0$ with real constants A and a_0. The argument uses, besides (3) and (4), the equality $p_3 = p_t$ of a condensate and one equation of the record (the formula is displayed in that section). (Section 9.26.)
- **Thermal ensemble**: Wick's theorem also holds for a thermal ensemble of non-interacting fermions, the statistical mixture of states that describes them at a temperature $T > 0$ (Section 13.26), with occupations f_a between 0 and 1 in place of 0 and 1. (Section 13.4.)
- **Thermal equilibrium**: a state in which every process runs forwards as often as backwards, so that on average nothing changes (Chapter 21). (Sections 0.2, 21.2, 21.5 and 21.35.)
- **Thermal hole**: If the sea were treated thermally, each of its orbitals would be empty with the probability $1 - f\big((-\varepsilon_{band} - \mu)/T\big) = f\big((\varepsilon_{band} + \mu)/T\big) = 1/(1 + e^{(\mu+\varepsilon_{band})/T})$; such an empty sea orbital is a thermal hole, which a full quantum treatment would count as an antiparticle of the same universe. (Sections 15.26, 16.20 and 16.23.)
- **Thermal particles**: Thermal holes $H_{th} = \sum_{\varepsilon_i<\mu} g_i\,(1 - f(x_i))$ (missing particles below μ) and thermal particles $P = \sum_{\varepsilon_i>\mu} g_i\, f(x_i)$ (particles above μ). (Sections 16.20 and 16.23.)
- **Thermal states**: Thermal states: the same three N, the three couplings $0, \pm\lambda_1$, the five slices and three temperatures $T = 0.01, 0.02, 0.05$, that is $3 \cdot 3 \cdot 5 \cdot 3 = 135$ states. (Section 15.2.)
- **Thomas-Fermi**: (c) Thomas-Fermi: the kinetic energy of each small piece of the line is that of a uniform gas with the local density. (Sections 13.15 and 13.32.)
- **Thomas-Fermi approximation**: the kinetic energy of each small piece of the line is taken from a uniform gas of the same density. (Section 13.35.)
- **The three Lovelock tensors**: The three Lovelock tensors (Sections 11.10 to 11.19). (Section 11.1.)
- **Three rules for moving gammas**: Three rules for moving gammas, each derived from the Clifford relation. (Section 21.7.)
- **Three-gamma bilinear**: the number $\bar{\Phi}\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$ for three different directions a, b, c. (Sections 9.26, 9.29, 12.26, 12.29 and 20.12.)
- **Threshold**: the smallest energy at which a process is allowed. (Sections 20.17 and 20.20.)
- **The time**: x_4 is the time. (Section 3.1.)
- **Time block**: A is the space block and D the time block (the primes distinguish the other two blocks from the matrices B and C). (Sections 5.23 and 5.26.)

- **The time direction contributes only through** b_4: The time direction contributes only through b_4, and nothing when b_4 is constant. (Section 6.9.)

- **Time reversal**: Reflecting a space-like direction (x_0, x_1, x_2 or x_3) is a parity-type operation (P); reflecting the time x_4 is time reversal (T); reflecting an extra time x_5, x_6, x_7 is a time-reversal-type operation of an extra time. (Section 21.24.)

- **Time-dependent Kohn-Sham problem**: the problem in which the orbitals evolve in the time x_4 under the Hamiltonian of each moment, with the potentials recomputed at every moment from the evolving densities. (Section 22.2.)

- **Time-derivative kernel** N: the matrix in the terms of a Lagrangian that contain ∂_4, written as $\frac{i}{2}(\Psi^\dagger N \partial_4 \Psi - \partial_4 \Psi^\dagger N \Psi)$. Canonical quantisation turns it into the anticommutator $\{\Psi_A, \Psi_C^\dagger\} = (N^{-1})_{AC}$ (at one point; derived in the second notebook of Chapter 10). (Section 10.48.)

- **Time-like**: space-like and time-like: a direction along which a step is measured like a distance, or like a duration; x_0, x_1, x_2 and x_3 are space-like, x_4 to x_7 time-like (Section 0.14). (Sections 0.2, 0.14, 1.5, 1.13, 1.27, 1.32, 3.4, 3.12, 4.3, 4.4, 5.1, 6.13 and 6.27.)

- **Time-time**: The factor $\frac{1}{2}(\eta_{aa} + \eta_{bb})$ is $+1$ for a pair of two space-like directions (space-space), -1 for a pair of two time-like directions (time-time) and 0 for a boost pair. (Sections 6.23 and 6.27.)

- **Tip**: Its end $z \to 0$ is the tip and its end $z = \pi/2$ the patch end. (Sections 2.24, 3.5, 3.12, 3.34, 5.6, 8.2, 8.31, 10.27, 10.31, 14.2, 15.1, 15.13, 16.1, 17.2, 17.10, 19.2, 19.15, 19.20 and 22.1.)

- **Tip angle** θ: the angle of the boundary condition at the tip. (Sections 19.2, 19.15 and 19.20.)

- **Tip condition**: the condition $(1 - Q(\theta))\chi(-L) = 0$ at the cutoff $y = -L$; $\theta = 0$ ($b(-L) = 0$) is the canonical choice. (Section 14.24.)

- **Tip cutoff**: The Kohn-Sham computations stop at $y = -L = -3$, the tip cutoff; the region $-3 \leq y \leq 0$ is the patch. (Sections 17.2, 17.10 and 17.20.)

- **Tip value**: Brane value and tip value: its values at $y = 0$ and $y = -3$. (Section 16.11.)

- **Tolerance**: the largest difference between two numbers that a check accepts as agreement. (Sections 0.22, 0.24, 15.13, 16.2, 16.7, 16.11, 16.23 and 18.27.)

- **Torus**: The three directions of 3-space are taken as a torus of coordinate size ℓ: a quantum leaving the box on one side comes back on the other, so the allowed coordinate momenta are $\mathbf{k} = \Delta k\,(n_1, n_2, n_3)$ with whole numbers n_1, n_2, n_3 and $\Delta k = 2\pi/\ell$. (Section 14.3.)

- **Total charge**: The total charge is the integral of the charge density over the seven directions other than the time. (Section 5.6.)

- **Total derivative**: $\frac{d}{dt}F(q(t), t)$ for some function F. (Sections 7.4, 7.8, 7.13, 7.26 and 7.32.)

- **Total derivative on jets**: Jet, total derivative on jets, coefficient ring: as in Notebook 07b: the field components and their derivatives at one point are symbols, and every coefficient is written with $E = e^{a_4}$, $s = \sin^{1/6} z$, $c = \cos z$, $A_1 = a_4'$, A_2, A_3 (higher derivatives of a_4), H, m, λ. (Section 7.32.)

- **Toy fluid (ILLUSTRATION)**: a source with assumed pressures $p_3 = w_3\rho$ and $p_t = w_t\rho$, used only to show what the conservation identity does; it is not a solution of the field equations of this book. (Section 9.24.)

- **Trace** $\operatorname{tr} M$: the sum of the diagonal entries of a matrix; it obeys $\operatorname{tr}(PR) = \operatorname{tr}(RP)$. (Sections 1.18, 1.26, 1.32, 1.40, 1.44, 2.19, 4.11, 4.15, 5.3, 5.9, 6.8, 6.13, 7.27, 8.14, 8.15, 8.17, 9.8, 9.16, 9.26, 9.29, 10.9, 12.32, 14.11, 14.30 and 18.20.)

- **Transcendental equation**: an equation such as $\tan(pL) = -p/M$ that has no solution formula and is solved numerically. (Sections 2.13 and 2.27.)

- **Transition**: a jump of a particle from an occupied level n to an empty level m; its amplitude is a number whose square is the probability of the jump. (Section 15.24.)

- **Transition state**: The midpoint value $\epsilon_{LUMO}(\frac{1}{2}) - \epsilon_{HOMO}(\frac{1}{2})$ (Slater's transition state) is a good estimate of the integral when the integrand is nearly a straight line in τ. (Section 13.27.)

- **Transpose** A^T: the matrix with rows and columns exchanged, $(A^T)_{ij} = A_{ji}$. (Sections 1.12, 1.18, 1.24, 4.7, 4.19, 5.9, 5.32, 7.12, 7.16, 10.9, 18.8, 21.2 and 21.14.)

- **Transposition**: A transposition exchanges two objects. (Section 11.8.)

- **Transverse**: The six transverse scale factors (those of $x_1, x_2, x_3, x_5, x_6, x_7$) multiply to. (Sections 3.7, 3.12 and 3.23.)

- **Trapezoid rule**: the integral over one step approximated by the step length times the average of the two end values. (Sections 2.24, 2.27, 15.3 and 22.12.)

- **Trapezoidal rule**: The flux is added up over time by the trapezoidal rule: on each step the area under the curve is the step times the mean of the two end values, `(fluxes[1:] + fluxes[:-1]) / 2` (`fluxes[1:]` drops the first value and `fluxes[:-1]` the last); `np.cumsum` forms the running sums, and a 0 is put in front for the time 0. (Section 10.32.)

- **Triangle inequality**: Rule: the triangle inequality $|p - q| \le |p| + |q|$ for any two numbers p, q. (Section 16.7.)

- **Triangular**: For a matrix with zeros below the diagonal (a triangular matrix) only the term of the identity survives in the Leibniz formula, because every other permutation σ has some row i with $\sigma(i) < i$ (the numbers $\sigma(i) - i$ add up to 0 and are not all 0, so one of them is negative), and the entry $A_{i\sigma(i)}$ below the diagonal is 0. (Section 1.21.)

- **Tridiagonal**: In the order of the unknowns each row couples only to its two neighbours in the list (a u to the w on either side, a w to the u on either side), so the matrix T of the problem $Tz = \varepsilon z$ is tridiagonal; at $k = 0$ its diagonal is zero. (Sections 16.14 and 16.18.)

- **Tridiagonal matrix**: The differential equations then become the eigenvalue problem of a symmetric tridiagonal matrix with $2G - 1$ rows (a matrix whose only nonzero entries are on the main diagonal and its two neighbours). (Section 16.3.)

- **True path**: The true path is $q(t) = \sin t / \sin 1$: it has $\ddot{q} = -\sin t / \sin 1 = -q$ (the second derivative of $\sin t$ is $-\sin t$), which is Newton's law $\ddot{q} = -\omega^2 q$ for the spring, and $q(0) = 0$, $q(1) = \sin 1 / \sin 1 = 1$. (Section 7.2.)

- **Truncated**: A truncated basis keeps only some of them; a computation converges when its result stops changing as more are kept. (Sections 22.2 and 22.11.)
- **Tunnelling**: a quantum transition through a region that the classical equations forbid (a barrier), with a small but nonzero probability; proposals in which a universe appears by tunnelling are of this kind (Section 20.25). (Sections 18.2 and 20.2.)
- **Tunnelling proposal**: a proposed boundary condition (A. Vilenkin) that picks one solution of the Wheeler-DeWitt equation, in which a universe appears by tunnelling. It is named in Chapter 22, not used, and is not formulated for this 8-dimensional theory. (Sections 22.2 and 22.4.)
- **Tuple**: The loop runs over a tuple (a list in round brackets that cannot be changed) of the two figure names and checks that each file exists. (Sections 0.13, 0.21, 0.25, 2.17, 7.9, 11.9, 12.25, 13.25, 14.11, 14.18, 16.12, 17.11, 19.16, 22.12 and 22.23.)
- **Turning point**: the instant at which the x_4 velocity u^4 passes through zero, so that x_4 stops growing. (Sections 3.31, 3.34, 17.2, 17.20 and 22.19.)
- **Twisted**: For g in Pin(4,4) put $\alpha(g) = g$ if g is even and $\alpha(g) = -g$ if it is odd (the twisted action). (Section 5.12.)
- **The two conservation identities** (Section 11.22), from zero divergence: $\frac{d}{dx_4} E^{x_4}{}_{x_4} = 3a_4'(E^{x_1}{}_{x_1} - E^{x_5}{}_{x_5})$ (I) and $E^{x_0}{}_{x_0} = \frac{1}{2}(E^{x_1}{}_{x_1} + E^{x_5}{}_{x_5})$ (II), and the constraint propagation $\partial E^{x_4}{}_{x_4}/\partial a_4' = 3a_4' F_k$ (record `python-a4-report.json`, check `bianchi_x4`; Notebook 11c, In [4] and In [5]). (Section 11.28.)
- **Two's complement**: A signed byte uses the same 8 bits for the numbers −128 to 127: a negative number $-m$ is stored as $256 - m$ (the two's complement). (Sections 1.49 and 1.53.)
- **Two-site model**: two places L and R, one orbital each, two labels (up, down); hopping t between the sites, repulsion U when both electrons sit on the same site. (Sections 13.13 and 13.24.)

U

- **U(1)**: The group of these phases is called U(1). (Section 21.7.)
- **U(1) charge** Q: the number that belongs to the phase symmetry $\Psi \to e^{i\alpha}\Psi$ of the field, $Q = \int \cos z \, \Psi^\dagger B \Psi \, d^7x$ (the integral over the seven directions other than x_4); it is the only number of the theory that could play the role of matter minus antimatter. It obeys an exact LOCAL conservation law, $\sum_\mu \partial_\mu(\cos z \, J^\mu) = 0$ for every solution of the field equation: the charge of a region changes only by what flows through its boundary (PROVED; lead check `u1_noether_matrix_identity`). The TOTAL charge of a universe is constant only if no charge flows through the brane $z = \pi/2$; this no-flux condition is ASSUMED, not derived (OPEN), and Section 21.18 shows an exact solution whose charge changes by exactly what flows out through the brane. (Sections 21.1, 21.7, 21.16, 21.17, 21.18 and 21.35.)
- **U(1) symmetry**: the multiplication of every component of a field by one and the same complex number of absolute value 1, which changes no equation; it is the reason why the charge obeys its local conservation law: at no point with $0 < z < \pi/2$ is charge created or destroyed, it can only flow from one place to another (Chapter 21). (Sections 0.2 and 20.22.)

- **Ulp**: A difference of one gap is called one unit in the last place, one ulp. (Section 0.22.)
- **Uncertainty**: What each can do is measure an uncertainty: a number U that, for reasons given in Sections 16.5 and 16.6, should be at least as large as the size $|x - X|$ of its error. (Sections 16.2 and 16.11.)
- **Undetermined function**: `sp.Function(name)(y)` makes an undetermined function of y: sympy knows nothing about it except that it depends on y, so an identity proved with it holds for every function. (Section 19.16.)
- **Uniform gas**: infinitely many fermions spread with the same density everywhere; it is studied in a large periodic box (a box whose opposite faces are glued together), whose volume is then made infinite. (Sections 13.15, 13.19 and 14.30.)
- **Unit circle**: First, $|e^{i\theta}|^2 = \cos^2\theta + \sin^2\theta = 1$ (the modulus of $a + ib$ with $a = \cos\theta$, $b = \sin\theta$; then $\cos^2 + \sin^2 = 1$): the number $e^{i\theta}$ lies on the circle of radius 1, the unit circle, at the angle θ. (Section 1.11.)
- **Unit columns**: Proof, line by line, with the unit columns $e_1, \dots, e_n$ (e_j has 1 in place j and 0 elsewhere) (the formula is displayed in that section). (Section 4.2.)
- **Unit in the last place**: A difference of one gap is called one unit in the last place, one ulp. (Section 0.22.)
- **Unit vector**: eight numbers $v = (v_{x0}, \dots, v_{x7})$ with metric product $\eta(v, v) = \sum_a \eta_{aa} v_a^2 = +1$ (*space-like*) or -1 (*time-like*); $\eta_{aa} = +1$ for $x0, x1, x2, x3$ and -1 for $x4, x5, x6, x7$. The basic unit vectors are $e_{x0}, \dots, e_{x7}$ (one entry 1, the others 0). (Sections 1.40, 5.12, 5.21 and 5.26.)
- **Unitary**: an evolution that keeps the total probability equal to 1. (Sections 10.34, 10.37, 14.5, 14.10 and 22.11.)
- **Unite values**: the supernova fits quoted by the record, $w = -0.764$ (constant w) and $(w_0, w_a) = (-0.861, -0.60)$. (Sections 22.16 and 22.22.)
- **Units**: the plots use $H = 1$ and $\kappa = 1$, so $\kappa\rho$, κp and Λ are in units of H^2; $\alpha_2 H^2$ and $\alpha_3 H^4$ are pure numbers. (Sections 12.19, 12.24, 12.29, 13.35, 17.2, 20.15 and 20.20.)
- **Universal**: F is universal: it does not depend on v. (Section 13.8.)
- **Universe** (of mass m): a solution of the field equation with the mass parameter m of the field's Lagrangian, in the author's gravitational field. The sign of m alone does not say which of two physically different kinds of universe one has: theorem T2 shows that the image of a solution with $(-m, \lambda)$ under the reflection of one space-like frame direction is a solution with (m, λ) with the same energy-momentum tensor. Section 20.12 builds one example, a solution of the commuting field dirac16complex00 that is by itself the complete source of the author's metric. (Sections 20.3 and 20.12.)
- **Unpack**: The first two lines unpack the four components of each. (Section 4.8.)
- **Unrestricted**: Hartree-Fock (HF): the best single determinant; restricted (both labels in the same orbital) or unrestricted (each label its own orbital). (Sections 13.7 and 13.13.)

- **Unspecified function**: Eight real symbols for the coordinates (`x[k]` is x_k: `x[0]` is x_0, `x[4]` is x_4), a positive symbol H, and an unspecified function $a_4(x_4)$: sympy knows nothing about it except that it depends on x_4, so every result below holds for every history, the deflating one included. (Section 21.23.)
- **Unsymmetrised**: Call $K_u = \bar{\Psi}\gamma^\mu D_\mu \Psi = \Psi^\dagger (C\gamma^\mu)(D_\mu \Psi)$ the unsymmetrised kinetic term. (Section 7.20.)
- **Upper**: A pair of index lists is a lower list $(l_1, \ldots, l_p)$ and an upper list $(u_1, \ldots, u_p)$ of the same length. (Sections 11.2 and 11.8.)
- **Upper and lower index**: v^a and v_a are two lists of eight numbers that belong to the same vector (section 6 of Notebook 01e says how one is made from the other). An upper index is a label, not a power: v^3 is a component, and its square is written $(v^3)^2$. (Section 1.32.)
- **Upper index**: A vector v has the components $v^0, \ldots, v^7$, written with an upper index: the component of v along x_3 is v^3, which Python stores as `v[3]` (the author and Python both count from 0). (Section 1.26.)

V

- **Vacuum**: in quantum theory, the state with no particles: every mode empty, written $|0\rangle$. In gravity (Section 20.2), a solution of the vacuum equations, the field equations of gravity with zero source. (Sections 5.34, 5.37, 10.11, 10.18, 10.20, 10.25, 12.2, 12.15, 12.19, 13.4, 18.2 and 20.2.)
- **Vacuum decay**: the quantum transition of a state that has the lowest energy only among its neighbouring states (a false vacuum) into a state of still lower energy; its rate per unit volume is computed from the quantum theory. (Sections 18.2 and 20.2.)
- **Vacuum equations**: the field equations of gravity with zero source, $\sum_k \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda \delta^\mu_\nu = 0$. (Sections 20.2 and 20.10.)
- **Vacuum value**: Vacuum value $\langle 0|X|0\rangle$ of an operator X and normal ordering $:X:= X - \langle 0|X|0\rangle$ (for an operator built from two field operators; for products of b, b^*, d, d^* this is the same as moving every creation operator to the left of every annihilation operator, with a sign -1 for each exchange). (Section 5.37.)
- **Validation**: a test of a stated uncertainty against a more accurate number. (Section 16.11.)
- **Variable**: A variable is a name for a value; this line gives the name `NOTEBOOK_ID` to the text `"00a"` (a text in quotes is called a string). (Sections 0.13, 1.9, 2.11, 3.13, 4.8, 5.10, 6.14, 7.9, 8.15, 9.17, 10.10, 11.9, 12.16, 14.11, 15.9, 17.11, 18.9, 20.11 and 21.15.)
- **Variation**: a shape $\xi(t)$ with $\xi(0) = \xi(T) = 0$; the varied path is $q + \epsilon\xi$ with a small number ϵ. (Section 7.8.)
- **Variation tensor**: Its result, which we call the variation tensor $T_{\rm var}$, is (the formula is displayed in that section). (Section 9.6.)

- **Variational form**: The solver also computes the variational form, $\sum g f \varepsilon - \langle (M_{in} - m) S_{out} + v_{in} n_{out} \rangle + \langle e_{int}(S_{out}, n_{out}) \rangle$, with the input potentials and output densities of the last iteration; the two agree to 2.2×10^{-13} relative in all 75 ground states (check ground_energy_two_forms). (Section 15.5.)

- **The variational principle for the density**: (We ASSUME that the minimum is attained.) The variational principle for the density then reads $E_0 = \min_n \left(F[n] + \int v\, n\, dx \right)$. (Section 13.8.)

- **Varied path**: To make "changed a little" precise, take a fixed shape $\xi(t)$ with $\xi(0) = \xi(T) = 0$ (so that the changed path keeps the end values) and a small number ϵ, and form the varied path $q + \epsilon\xi$. (Section 7.2.)

- **Vector**: an ordered list of numbers, such as $v = (1, 2, 0)$. (Sections 1.18, 1.24, 2.2, 3.14, 5.12 and 5.21.)

- **Vector components**: a vector $V = V^r e_r + V^\varphi e_\varphi$ is written with the coordinate basis vectors e_r (length 1) and e_φ (length r). (Section 3.21.)

- **Vector matrix** $\Lambda(g)$: the 8×8 matrix with $\alpha(g)\gamma^c g^{-1} = \sum_d \Lambda_{dc} \gamma^d$, where $\alpha(g) = g$ for an even and $-g$ for an odd g (the *twisted* action). (Sections 5.12 and 5.26.)

- **Vector potential**: where the effective mass $M_{\text{eff}} = m + \frac{15}{16}\lambda S$ and the vector potential $v_v = -\frac{1}{16}\lambda n$ are made by all the quanta through their scalar density S and number density n. (Section 14.3.)

- **Vector rule**: Chapter 5 proved the vector rule $[S^{ab}, \gamma^c] = \eta^{bc}\gamma^a - \eta^{ac}\gamma^b$. (Section 6.7.)

- **Vectorised**: Vectorised: one numpy operation acts on whole arrays of cases at once. (Sections 22.11 and 22.12.)

- **Vectorized computation**: numpy applies one operation to millions of numbers in an array at once, much faster than a Python loop. (Section 1.47.)

- **Velocity** $u^a = dx^a/d\tau$: how fast each coordinate changes per unit of proper time. (Sections 3.14, 3.34, 7.2 and 7.8.)

- **Velocity kernel**: so the Lagrangian contains $\frac{i}{2}\sqrt{|g|}\,\Psi^\dagger N \partial_4 \Psi$ (plus its partner term) with the velocity kernel $N = B$. (Section 18.22.)

- **Verdict**: A report lists its checks; each check has a name, a verdict (PASS or FAIL) and a detail text that says exactly what was verified. (Sections 0.4, 0.20 and 23.2.)

- **Verifier** and **checker**: a program of the Revision record that recomputes a result (exactly, with Wolfram or with sympy, or numerically, with Rust or Python) and writes a report: a JSON file that lists named checks, each with a verdict such as PASS. (Sections 0.20 and 23.2.)

- **Version number**: A version number such as 3.14.5 names one release of a program: the first number changes rarely, the second for new features, the third for corrections. (Section 0.8.)

- **Vertex**: the matrix that sits between the field components in an interaction; for dirac16complex the contact interaction is $(\lambda/2)\, S^2$ with $S = \bar{\Psi}\Psi = \Psi^\dagger C\, \Psi$, so the vertex is the 16×16 matrix C. (Sections 13.4 and 13.19.)

- **Vielbein** $e^a{}_\mu$: a matrix with $g_{\mu\nu} = \sum_{a,b} e^a{}_\mu \eta_{ab} e^b{}_\nu$; for a diagonal metric the diagonal matrix of the scale factors. (Sections 3.7, 3.12, 5.28, 6.2, 6.13, 6.21, 7.18, 7.26, 8.2, 12.30, 14.2, 18.19 and 21.22.)
- **Vielbein factors**: The author's metric is diagonal, $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$ with the positive vielbein factors (Chapter 3 calls them scale factors h_a; they are the same numbers). (Sections 6.2, 9.2 and 18.3.)
- **Vielbein postulate**: The canonical one is fixed by the vielbein postulate (below). (Sections 6.4, 6.13, 7.18, 8.4, 18.3 and 21.23.)
- **Violation**: the violation of C2. (Section 17.5.)
- **Volume element**: $\sqrt{|g|} = \cos z$; an integral over the hidden direction is $\int \cos z \, (\ldots)\, dx_0$. (Section 10.31.)
- **Volume factor**: This number is the volume factor: a small box with the coordinate sides $dx_0, \ldots, dx_7$ has the sides $f_0\, dx_0, \ldots, f_7\, dx_7$ in length, so its volume is $f_0 f_1 \cdots f_7\, dx_0 \cdots dx_7$, and the product of the length factors is $f_0 \cdots f_7 = \sqrt{|g_{00}| \cdots |g_{77}|} = \sqrt{|\det g|}$ (a product of square roots is the square root of the product). (Sections 0.14, 2.19, 3.6 and 7.18.)

W

- **Wall time**: the time a clock on the wall shows between the start and the end of a command. (Sections 23.2 and 23.11.)
- **Warp factor** $W = \sin^{1/6} z$: the factor that the scale factors of the six transverse directions $x_1, x_2, x_3, x_5, x_6, x_7$ share; the six transverse entries $g_{11}, g_{22}, g_{33}, g_{55}, g_{66}, g_{77}$ of the metric contain its square $W^2 = \sin^{1/3} z$. (Sections 3.7, 3.12, 14.2 and 14.10.)
- **Warped form**: Inserting dy^2 and W^2 into the line element of Section 3.5 gives the warped form. (Sections 3.9 and 14.2.)
- **Wave function** $u(x)$: the eigenfunction of the Schroedinger equation; $u(x)^2$ is the probability density of finding the particle at x, so we *normalise* it: $\int u^2\, dx = 1$. (Sections 2.13, 2.16, 13.1 and 13.2.)
- **Wave function of the universe**: in quantum cosmology, a quantum state assigned to a whole universe, its geometry included: a function of the few numbers that describe the whole geometry, such as a scale factor. It must obey the Wheeler-DeWitt equation. None is formulated for this 8-dimensional theory. (Sections 18.2, 22.2 and 22.4.)
- **Wave number**: A plane wave $\phi = \cos(kx_1)\cos(\omega x_4)$, with wave number k and angular frequency ω, has $\partial_1^2 \phi = -k^2 \phi$ and $\partial_4^2 \phi = -\omega^2 \phi$, so $E = (-k^2 + \omega^2 - m^2)\phi$, which vanishes exactly when. (Sections 7.5 and 7.8.)
- **Weighted average over the hidden direction** $\bar{X}$ (also called the **moment** of X): the integral of $e^{6Hy} X$ over the patch divided by the integral of e^{6Hy}. (Section 17.20.)
- **Weighted mean**: $\int e^{6Hy} p_0\, dy / \int e^{6Hy} dy$, the average of p_0 over the proper volume. (Sections 17.2, 17.7 and 17.20.)

- **Weighted variance**: The bracket is $\sum_a w_a$ times the weighted variance of the numbers $\epsilon_a - \mu$ with the weights w_a, which is never negative (it equals $\sum_a w_a(\epsilon_a - \bar{\epsilon})^2$ with the weighted mean $\bar{\epsilon}$, a sum of non-negative terms). (Section 13.26.)

- **Well posed**: A problem of the kind "given the field at one time, find it at later times" is called well posed (in the sense of the mathematician Jacques Hadamard) when a solution exists, is unique, and changes only a little when the given data change a little. (Sections 4.9 and 8.16.)

- **Wheeler-DeWitt equation**: the equation that the wave function of the universe must obey in quantum cosmology: the analogue, for a geometry, of the Schroedinger equation of a particle. It needs a boundary condition to fix its solution. It is named in this book, not used. (Sections 22.2 and 22.4.)

- **Whole numbers** (integers): $\ldots, -2, -1, 0, 1, 2, \ldots$. Python computes with them exactly, however large they are. (Sections 1.2 and 1.8.)

- **Wick ordered**: There it holds as an exact operator identity, for the solution of the interacting operator field equation, if and only if the potential and the tensor are both Wick ordered (the whole product of field operators is normal ordered at once: the potential as $\frac{\lambda}{2}{:}SS{:}$, not as $\frac{\lambda}{2}{:}S{:}{:}S{:}$, and the tensor as a Wick product, not by subtracting its value in the empty state); with every other ordering tested it fails, already in expectation values (PROVED in that model; its report, named in the table below, passes 21 of 21 checks). (Section 9.13.)

- **Wick's theorem**: $\langle a_p^\dagger a_q^\dagger a_s a_r \rangle = \rho_{rp}\rho_{sq} - \rho_{sp}\rho_{rq}$ for determinants and thermal ensembles of non-interacting fermions. (Sections 13.4 and 13.13.)

- **Winding**: So θ is defined everywhere, and we let it grow continuously, counting every full turn (winding), so that it can exceed 2π. (Section 2.24.)

- **Witness**: an explicit example that proves that something exists. (Sections 9.26, 9.29 and 12.29.)

- **WKB approximation** (after Wentzel, Kramers and Brillouin): when the growth rate κ changes slowly, the size grows like e^{2W} with $W = \int \kappa \, dx_4$. (Sections 8.25 and 8.28.)

- **Wolfram Language**: Engine: the program that did the computation: Wolfram Language (the language of Mathematica, run with wolframscript), Python (with the packages sympy, numpy and mpmath), or Rust (a fast compiled language). (Section 0.20.)

- **WolframScript**: WolframScript (the command `wolframscript`), for the exact Wolfram verifiers. (Section 23.3.)

- **Word**: A word is a list of items in the order of the matrix product: an exponential `("exp", a, b, theta)` or a gamma `("gamma", e)`. (Section 5.27.)

- **Wrapper**: Such a function, which calls another and adds something around it, is called a wrapper. (Section 16.12.)

Z

- **Z2 brane** (Z2 mirror brane): the brane $z = \pi/2$ together with the ASSUMED Z2 construction: the patch is glued there to a mirror copy of itself (the map $z \to \pi - z$; Z2 is the group of two elements, doing nothing and reflecting), and the mirror fixes a boundary condition for the field at that surface (the even or the odd brane parity). It is ASSUMED, not derived; the junction condition at the brane is OPEN. (Sections 8.31, 14.17, 18.2 and 20.2.)

- **Z2 construction**: Gluing the mirror patch to the patch at the brane is the Z2 construction of the Revision record; it is ASSUMED. (Sections 18.2 and 20.2.)

- **Z2 mirror**: a reflection across the edge $z = \pi/2$ of the hidden direction, imposed as a boundary condition; Z2 is the group of two elements, doing nothing and reflecting (Chapter 14). (Sections 0.2, 5.6, 14.12, 17.2 and 22.2.)

- **Z2 mirror brane**: the ASSUMED picture that the patch $y \leq 0$ is glued at $y = 0$ to a mirror copy and the field obeys the parity relation $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$; the relation (not the gluing alone) gives the even parity ($b(0) = 0$) and the odd parity ($a(0) = 0$). (Section 14.17.)

- **Zero modes,** $N = 8$: the eight brane-bound orbitals at zero 3-momentum, $\chi = (a, 0)$ with $a \propto e^{My}$; filling them gives the state $N = 8$. (Sections 2.24, 14.30, 15.2, 15.3, 16.13, 16.18, 19.2, 19.12 and 19.20.)
