            "Simpson's rule for $E(2) - E(0)$ in all ten moving series, in units of "
            f"$10^{{-4}}$ (largest ${tex_number(largest)}$): the energy-change law "
            "holds to "
            "the accuracy of the five slices.")
```

The caption, joined from its strings, inserts the two factors with two decimals, 6.45 and 6.16, and the largest relative Simpson error of In [18] in powers of ten, 2.2×10^{-4} (`$10^{{-4}}$` in an f-string prints as 10^{-4}). Output: figure 17b.5 and its saved line.

What figure 17b.5 shows. Left: horizontal axis the slice $a_{4,0}$; vertical axis $E/E(0)$, a pure number. The recorded energies of $N = 136$ and $N = 688$ fall to about 0.4 at $a_{4,0} = 1$ and to about 0.16 at $a_{4,0} = 2$, and the crosses predicted from $E(0)$ by the energy-change law sit on them; C3 would need the dashed line at 1. As 3-space inflates and the extra times deflate, the gas, with $p_t = 0$ and $\int p_3 > 0$ (the caption's short form is $p_3 > p_t = 0$), gives up energy, exactly as the energy law of the patch demands. Right: the relative Simpson errors of the ten moving series, between about 1.9 and 2.2 in units of 10^{-4}: the energy-change law holds to the accuracy that five slices allow.

In [20], the time law tested point by point.

```
def change_with_a4(n, tag):
    """d rho / d a4 at the slice a4,0 = 1 at every y (fourth order, step 0.5)."""
    v = [profiles[f"N{n}_{tag}_{s}"]["rho"] for s in SLICES]  # rho at 5 slices
    return (v[0] - 8 * v[1] + 8 * v[3] - v[4]) / (12 * 0.5)
```

`change_with_a4` collects, for one series, the five profiles of ρ at the slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$ (each an array of 151 values, one per grid point y) and applies the fourth-order central difference of In [11] in the variable a_4, centred on the middle slice $a_{4,0} = 1$ with the step $\delta = 0.5$: $[f(0) - 8f(0.5) + 8f(1.5) - f(2)]/(12 \times 0.5)$, the formula of In [11] with $f(1 - 2\delta) = f(0)$, $f(1 - \delta) = f(0.5)$, $f(1 + \delta) = f(1.5)$ and $f(1 + 2\delta) = f(2)$ (the middle value $f(1)$ does not enter). Because the arrays are subtracted element by element, the result is $\partial\rho/\partial a_4$ at every grid point at once.

```
weight = np.exp(6 * H_value * y)  # the volume weight e^(6Hy) on the grid

def patch_integral(values):
    """Simpson's rule for the integral of e^(6Hy) times values over the patch."""
    f = weight * values
    return h / 3 * (f[0] + f[-1] + 4 * f[1:-1:2].sum() + 2 * f[2:-1:2].sum())
```

`weight` is e^{6Hy} at the 151 grid points. `patch_integral` is Simpson's rule on the grid of step $h = 0.02$ (150 intervals, an even number): the two end values once, the values at odd positions (`f[1:-1:2]`, every second value from index 1 to the last but one) four times, the values at even inner positions (`f[2:-1:2]`) twice, all times $h/3$.

```
tip_ratio, integral_gap = {}, {}
for n, tag in moving:
    middle = profiles[f"N{n}_{tag}_a10"]  # the slice a4,0 = 1
    left_side = change_with_a4(n, tag)  # d rho / d a4 at every y
    right_side = -3 * (middle["p3"] - middle["p_t"])  # what the law needs there
    tip_ratio[(n, tag)] = float(left_side[0] / right_side[0])  # at y = -3
    integral_gap[(n, tag)] = float(abs(patch_integral(left_side)
                                       / patch_integral(right_side) - 1.0))
```

For each of the ten moving series of In [18] (`moving`, $N = 136$ and 688): the left side $\partial\rho/\partial a_4$ and the right side $-3(p_3 - p_t)$ of the pointwise law at the slice $a_{4,0} = 1$ (along the history $a_4' = H = 1$,

so $\partial\rho/\partial x_4 = \partial\rho/\partial a_4$). `tip_ratio` stores their ratio at the first grid point, the tip $y = -3$ (index 0); `integral_gap` stores the relative difference of the two sides after both are integrated over the patch with the weight e^{6Hy}, which is the law for the energy of the patch.

```
slice_one = profiles["N136_lam0_a10"]
rate136 = change_with_a4(136, "lam0")
for index, place in ((0, "-3 (tip)"), (75, "-1.5"), (150, "0 (brane)")):
    needed = -3 * (slice_one["p3"][index] - slice_one["p_t"][index])
    say(f"N = 136, lambda = 0, a4,0 = 1, y = {place}: d rho/d a4 = "
        f"{rate136[index]:.4g}, -3 (p3 - p_t) = {needed:.4g}")
```

For the canonical state $N = 136$, $\lambda = 0$, the two sides are printed at three grid points: index 0 ($y = -3$), 75 ($y = -3 + 75 \times 0.02 = -1.5$) and 150 ($y = 0$), with four significant digits (`.4g`). Output: at the tip 82.97 against -474.8; in the middle -0.4505 against -1.497; at the brane -0.002068 against -0.001174.

```
report("ratio of the two sides at the tip, 10 series",
       f"{min(tip_ratio.values()):.3f} to {max(tip_ratio.values()):.3f}")
report("largest relative difference of the two patch integrals",
       f"{max(integral_gap.values()):.1e}")
reproduces(all(r < 0.0 for r in tip_ratio.values())
           and max(integral_gap.values()) < 5e-3,
           "the x4 law fails point by point, holds for the energy of the patch",
           KS_PY, ["emt_x4_component"])
```

Output: the tip ratios lie between -0.327 and -0.106 (negative in every series: the two sides have opposite signs), and the patch integrals agree to 1.3×10^{-3}. The check passes when every tip ratio is negative and the integrals agree to better than 5×10^{-3} (the accuracy that a difference with the step 0.5 allows), and the theory report's check `emt_x4_component`, which states the law for the energy of the 7-volume, is PASS. (COMPUTED; Section 17.16 explains the result.)

In [21], the hidden-direction averages and the averaged C2.

```
MOMENTS = "Revision/field_equations_a4/ks_source/results/ks-source-moments.csv"
W = (1 - tip_weight) / (6 * H_value)  # the integral of e^(6Hy) over the patch

def mean(sid, column):
    """The weighted average of a column, from the record's integral."""
    return number(sid, f"int_{column}") / (2 * VOL7 * W)
```

`MOMENTS` names the record's table of hidden-direction averages (one row per state). `W` is $\int_{-L}^{0} e^{6Hy}dy = (1 - e^{-6HL})/(6H)$ of Section 17.17. `mean` turns a column `int_X` of the table of integrals into the weighted mean $\bar{X} = \int X/(2\,\mathrm{Vol}_7 W)$ of Section 17.7.

```
with repository_file(MOMENTS).open(encoding="utf-8", newline="") as handle:
    moments = {row["id"]: row for row in csv.DictReader(handle)}
agree = max(abs(mean(sid, "rho") / float(moments[sid]["rho_bar"]) - 1.0)
            for sid in nonzero)
```

The record's table is read into a dictionary by state name, as the table of integrals was in In [11]. `agree` is the largest relative difference between our $\bar{\rho}$ and the record's column `rho_bar` over the 70 nonzero states (the record computes its averages with Simpson's rule on the profiles, we from the solver's integrals, so they agree only to the accuracy of that rule).

```
defect = {}
for sid in nonzero:
    p3b, ptb, p0b = (mean(sid, column) for column in ("p3", "p_t", "p0"))
    defect[sid] = abs(p3b + ptb - 2 * p0b) / (abs(p3b) + abs(ptb) + 2 * abs(p0b))
low, high = min(defect, key=defect.get), max(defect, key=defect.get)
```

For each state the three averaged pressures are computed (the parentheses make a **generator**, which produces the three values one after the other, and the three names receive them in order), and the relative defect of the averaged C2 of Section 17.17 is stored. `low` and `high` are the states with the smallest and the largest defect.

```
report("largest relative difference of rho_bar from the record", f"{agree:.1e}")
report("defect of the averaged C2",
       f"{defect[low]:.6g} ({low}) to {defect[high]:.6g}")
detail = record_entry(KS_SOURCE, "C1_averaged_algebraic_condition_fails")["detail"]
reproduces(agree < 1e-6
           and f"[{defect[low]:.6g} ({low}), {defect[high]:.6g}]" in detail,
           "the averaged C2 fails by a defect of order 1 in all 70 states",
           KS_SOURCE, ["C1_averaged_algebraic_condition_fails"])
```

Output: $\bar{\rho}$ agrees with the record to 6.7×10^{-8}; the defect runs from 0.414086 (`N688_lamm2_a00`) to 0.806379. The check passes when the averages agree to 10^{-6} and the text of the record's check contains exactly this range, written as the record writes it, `[0.414086 (N688_lamm2_a00), 0.806379]`. (COMPUTED.)

In [22], the first integral and the turning points.

```
CASES = "Revision/field_equations_a4/ks_source/results/ks-source-a4-cases.csv"
series = "N136_lam0"  # the canonical series
ids = [f"{series}_{s}" for s in SLICES]  # its five states
rho_bar = np.array([mean(sid, "rho") for sid in ids])
rho_slope = np.array([-3 * (mean(sid, "p3") - mean(sid, "p_t")) for sid in ids])
```

`CASES` names the record's table of integrated histories. For the series $N = 136$, $\lambda = 0$ the cell collects $\bar{\rho}$ at the five slices and its slope $d\bar{\rho}/da_4 = -3(\bar{p}_3 - \bar{p}_t)$ there (the averaged energy relation of Section 17.17).

```
def rho_between(a):
    """rho_bar(a4) between the slices: cubic Hermite with the exact slopes."""
    k = min(int(a / 0.5), 3)  # the interval [0.5 k, 0.5 k + 0.5] that holds a
    t = (a - 0.5 * k) / 0.5  # the position inside it, from 0 to 1
    return ((2 * t**3 - 3 * t**2 + 1) * rho_bar[k]
            + (t**3 - 2 * t**2 + t) * 0.5 * rho_slope[k]
            + (-2 * t**3 + 3 * t**2) * rho_bar[k + 1]
            + (t**3 - t**2) * 0.5 * rho_slope[k + 1])
```

`rho_between` is the cubic Hermite interpolant. `int(a / 0.5)` is the number of the interval of length 0.5 that contains a (`min(..., 3)` keeps $a = 2$ in the last interval), and `t` runs from 0 at its left end to 1 at its right end. The four cubic polynomials in `t` are the standard Hermite weights: at $t = 0$ they are $1, 0, 0, 0$ and at $t = 1$ they are $0, 0, 1, 0$, so the curve passes through both tabulated values; their derivatives are chosen so that the slope of the curve (with respect to a, hence the factor 0.5, the interval length) equals the given slopes at both ends. `t**3` is t^3.

```
def rate_squared(a, sigma0):
    """(a4'/H)^2 at a4 = a from the Einstein first integral, a4'(0) = H."""
    return 1.0 + sigma0 / 3.0 * (1.0 - rho_between(a) / rho_bar[0])
```

The first integral of Section 17.17, $(a_4'/H)^2 = 1 + (\sigma_0/3)(1 - \bar{\rho}(a_4)/\bar{\rho}(0))$.

```
def turning_point(sigma0):
    """The a4 in [0, 0.5] where (a4'/H)^2 reaches 0, by bisection."""
    low_end, high_end = 0.0, 0.5
    for _ in range(60):  # each step halves the interval
        centre = (low_end + high_end) / 2
        if rate_squared(centre, sigma0) > 0.0:
            low_end = centre
        else:
            high_end = centre
    return low_end
```

Bisection: start with an interval whose left end has $(a_4'/H)^2 > 0$ and whose right end has $(a_4'/H)^2 < 0$; test the centre and keep the half in which the sign still changes. After 60 halvings the interval is $0.5/2^{60} \approx 4 \times 10^{-19}$ long, far below the precision of the numbers. (`_` is the name Python programmers give a loop variable that is not used.)

```
with repository_file(CASES).open(encoding="utf-8", newline="") as handle:
    cases = {(row["gravity"], row["series"], row["case"]): row
             for row in csv.DictReader(handle)}
rate_gap, turn_gap, halts = 0.0, 0.0, {}
```

The record's table is read into a dictionary whose key is the triple (gravity, series, case), for example `("einstein", "N136_lam0", "sigma0 = 1")`. Two numbers will hold the largest relative differences from the record, and `halts` the turning points.

```
for sigma0 in (10, 1, -1):
    ours = rate_squared(2.0, sigma0) ** 0.5  # a4'/H at a4 = 2
    theirs = float(cases[("einstein", series, f"sigma0 = {sigma0}")]["rate_a20"])
    rate_gap = max(rate_gap, abs(ours / theirs - 1.0))
    say(f"sigma0 = {sigma0:3d}: a4'/H at a4 = 2 is {ours:.6g} (record {theirs:.6g})")
```

For $\sigma_0 = 10, 1, -1$ the rate at $a_4 = 2$ (`** 0.5` is the square root) is compared with the record's column `rate_a20`, the rate a_4'/H at the slice $a_4 = 2$ (`{sigma0:3d}` prints the integer in a field of three characters, so the lines line up). Output: 1.95362, 1.1321 and 0.847549, each equal to the record's value.

```
for sigma0, case in ((-10, "sigma0 = -10"), (-24, "Lambda = 0")):
    halts[sigma0] = turning_point(sigma0)
    theirs = float(cases[("einstein", series, case)]["a4_end"])
    turn_gap = max(turn_gap, abs(halts[sigma0] / theirs - 1.0))
    say(f"{case}: the deflation halts at a4 = {halts[sigma0]:.6g} "
        f"(record {theirs:.6g})")
```

For $\sigma_0 = -10$ and for $\Lambda = 0$ (which needs $\sigma_0 = -24$, Section 17.17) the turning point is found and compared with the record's column `a4_end`, where the record's integration stopped. Output: 0.397998 and 0.149623, equal to the record's values.

```
reproduces(rate_gap < 1e-8, "Einstein first integral: a4'/H at a4 = 2 as recorded",
           KS_SOURCE, ["D2_einstein_first_integral"])
reproduces(turn_gap < 1e-6, "turning points for sigma0 = -10 and Lambda = 0",
           KS_SOURCE, ["D3_lambda_zero_cases_halt"])
```

Two checks: the rates agree with the record to 10^{-8} and the turning points to 10^{-6} (relative), and the record's checks `D2_einstein_first_integral` and `D3_lambda_zero_cases_halt` are PASS. Output: two PASS lines. (COMPUTED, within the ASSUMED approximation of Section 17.17. The agreement is not a test of the physics of the approximation, only of its arithmetic: the notebook and the record use the same first integral and the same interpolant.)

In [23], the first integral drawn (figure 6).

```
grid = np.linspace(0.0, 2.0, 401)  # a4 from 0 to 2 in steps of 0.005
STRENGTHS = [(10, "#eb6834"), (1, "#f2a541"), (-1, "#5598e7"), (-10, "#1c5cab"),
             (-24, "#104281")]  # sigma0 and its colour
fig, ax = plt.subplots(figsize=(6.4, 4.4))
```

`np.linspace(0.0, 2.0, 401)` gives 401 equally spaced values of a_4 from 0 to 2; `STRENGTHS` pairs each source strength with a colour (warm for $\sigma_0 > 0$, blue for $\sigma_0 < 0$).

```
for sigma0, colour in STRENGTHS:
    values = np.array([rate_squared(a, sigma0) for a in grid])
    keep = values >= 0.0  # a4'^2 cannot be negative: the curve ends at the turning point
    label = ("$\\Lambda = 0$ ($\\sigma_0 = -24$)" if sigma0 == -24
             else f"$\\sigma_0 = {sigma0}$")
    x_values, rates = grid[keep], np.sqrt(values[keep])
    if sigma0 in halts:  # end the curve exactly at its turning point
        x_values, rates = np.append(x_values, halts[sigma0]), np.append(rates, 0.0)
    ax.plot(x_values, rates, color=colour, lw=1.8, label=label)
```

For each strength the cell computes $(a_4'/H)^2$ on the grid and keeps only the points where it is not negative (`keep` is an array of True and False; `grid[keep]` picks the values where it is True): beyond a turning point the first integral would give $(a_4'/H)^2 < 0$, which no real rate has; the record's integration stops at the turning point, and what follows it is not computed (Section 17.17). The label is written in LaTeX. For the two strengths with a turning point the point $(a_4^*, 0)$ is appended (`np.append`), so that the curve ends exactly there; then the curve of a_4'/H (the square root) is drawn.

```
ax.plot(list(halts.values()), [0.0, 0.0], "kx", ms=8, mew=1.6,
        label="turning points ($a_4' = 0$)")
ax.axhline(1.0, color="#e34948", ls="--", lw=1.2,
           label="linear member $a_4 = Hx_4$")
ax.set_xlabel("$a_4$ (the extra times scale as $e^{-a_4}$)")
ax.set_ylabel("$a_4'/H$")
ax.legend(fontsize=7, loc="upper left")
end_rates = {s: rate_squared(2.0, s) ** 0.5 for s in (10, 1, -1)}
```

Black crosses mark the two turning points; the red dashed line is the constant rate of the history $a_4 = Hx_4$; then the axis labels and the legend. `end_rates` holds the rates at $a_4 = 2$ for the caption.

```
save_figure(fig, "first_integral",
            "The rate $a_4'/H$ of the deflation of the extra times against $a_4$ "
            "(pure numbers), from the first integral of the averaged $a_4$ "
            ...)
```

The caption, quoted shortened (it is printed in full under the figure), inserts the rates 1.954, 1.132 and 0.848 and the turning points 0.398 and 0.150 with three decimals. Output: figure 17b.6 and its saved line.

What figure 17b.6 shows. Horizontal axis: a_4 from 0 to 2 (pure number; the extra-time scale factor is proportional to e^{-a_4}); vertical axis: a_4'/H (pure number). All five curves start at 1, the chosen initial rate. With $\sigma_0 = 10$ the rate grows to 1.954 at $a_4 = 2$, with $\sigma_0 = 1$ to 1.132, with $\sigma_0 = -1$ it falls to 0.848; the curves flatten toward the right because the gas has already given up most of its averaged energy there (only the lost fraction enters the first integral). With $\sigma_0 = -10$ and with $\Lambda = 0$ the rate drops steeply to 0 at $a_4 = 0.398$ and 0.150 (crosses): the deflation halts, and the curves end there because the integration stops at the turning point; what follows it is not computed. None of the curves is selected by the equations: the starting value 1 is a choice, and the dashed line, the history on which the Kohn-Sham states were computed, is a solution of the approximate equations only for a source that does not change, like the $N = 8$ states. (COMPUTED within the ASSUMED approximation of Section 17.17.)

In [24], the last check.

```
figure_names = ["eight_gammas", "slope_identity", "difference_order",
                "brane_and_mean", "energy_exchange", "first_integral"]
paths = [output_file(f"{FIGURE_FOLDER}/17b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

As In [20] of Notebook 17a, for the six figures. Output: PASS every figure file of this notebook exists and ALL 20 CHECKS PASSED (notebook 17b).

The count. The 20 PASS lines are: one each in In [2] and In [3], two in In [4], one each in In [6], In [8], In [9], In [10], In [11], In [13], In [14], In [15], In [16], In [17], In [18], In [20] and In [21], two in In [22], and one in In [24]. Fourteen of them reproduce a Revision record and name it.

17.22 What a prescribed background is, and what remains open

What the record establishes. In the words of the record `Revision/field_equations_a4/reports/ks-source-conditions.json`: no Kohn-Sham state recorded in `Revision/kohn_sham` is an admissible source of the author's metric; C1 and C2 fail for every nonzero state (C2 also after integration over x_0), and the Kohn-Sham history uses the linear member as a prescribed background, without back-reaction. The record of the a_4 equations says the same (`Revision/field_equations_a4/a4-equations.json`, key `fields.dirac16complex.kohnSham`), and so does the Kohn-Sham theory record (`Revision/kohn_sham/ks-theory.json`, key `adiabaticity.historyStatus`). Sections 17.12 to 17.16 add the reason: the Kohn-Sham source is conserved along the hidden direction at every point, and in the time direction for the total energy of the patch (not point by point); but its hidden pressure is far from flat and its 3-space pressure is not balanced by an equal extra-time pressure ($\int p_3 > \int p_t$ along the history), and for a conserved source these are exactly the failures of C2 and C3. Section 17.17 adds that averaging over the hidden direction does not rescue it: the averaged C2 still fails, and the averaged equations can be integrated only after two of them are dropped, an approximation whose error is of order 1.

What "prescribed background" means. A prescribed background is a metric chosen by hand, in which matter is placed and studied while its own gravity is ignored. The matter is then a **test field**, and the effect it would have on the metric, its **back-reaction**, is left out. This is a common and useful approximation in physics, much like computing the motion of a cork on a river whose flow is given: the cork follows the flow, and nobody asks how the cork changes the river. Quantum fields in a given expanding universe are usually studied this way. The approximation is good when the matter is too dilute to change the metric noticeably; whether that holds here cannot be decided without the back-reaction itself.

What follows for the other chapters. Every number computed along the history $a_4 = Hx_4$ in Chapters 14 to 16 (the Kohn-Sham levels, the energies and gaps, the temperatures, the energy densities, pressures and equations of state) is a property of a test gas in a chosen geometry. It is correctly computed (COMPUTED, with the accuracies stated there), but it is not a consequence of the coupled field equations of gravity and matter. Any equation of state derived from it, in particular for the dark-sector hypotheses discussed in Chapter 22, inherits this status: it describes the gas in the prescribed background, not a self-consistent universe.

What this chapter does NOT say.

- It does not say that the author's metric cannot be a solution of the field equations. Chapter 12 shows what source the linear member requires, and builds exact examples with a condensate of the commuting field dirac16complex00, whose pressures are equal and do not depend on x_0 (a computation of the book, Section 12.26).
- It does not say that no state of dirac16complex can be an admissible source. Only the 75 recorded ground states (zero temperature), whose profiles the record stores, are tested; the 135 thermal states of the canonical matrix (Chapter 15) store no profiles and are not tested. The record of the a_4 equations states what such a state would need: $p_3 + p_t = 2p_0$, every expectation value independent of x_0, and every off-diagonal expectation value zero (keys `fields.dirac16complex.kohnSham` and `fields.dirac16complex.offDiagonal`); for the linear member, in addition, equal expectation values of the 3-space and the extra-time kinetic terms (key `fields.dirac16complex.homogeneousSingleMode`). It also states that

no state with unequal kinetic terms that meets the other conditions, and so would drive a_4'', is constructed in the Revision record (key `fields.dirac16complex.evolution`); and the many-quantum states of dirac16complex that the Revision record does construct, the Kohn-Sham states, fail the conditions (this chapter). Whether an admissible state exists is OPEN.

- It does not say what metric the Kohn-Sham gas would produce. That needs back-reaction, which nobody has computed. It is OPEN.
- It says nothing about the creation of universes, about pairs of universes of masses $+m$ and $-m$, or about matter and antimatter. Those questions are treated, with the precise statement of what is proved and what is not, in Chapters 18 to 21.

What back-reaction would require. By C1, a source that depends on x_0 cannot sit on the right-hand side of the field equations of a metric whose left-hand side does not depend on x_0. A self-consistent treatment therefore needs a metric with more freedom: functions of both the time x_4 and the hidden coordinate (for example separate warp factors for 3-space and for the extra times that depend on y), the Kohn-Sham equations in that metric, and the field equations, all solved together. Beyond that, the Kohn-Sham states themselves are instantaneous (adiabatic) states; the time-dependent problem along the history is also OPEN. Chapter 22 describes how a student could attack both.

17.23 What we proved, what we computed, what we assumed

PROVED (exact; each with the record file and check, and the notebook cell that reproduces it):

statement	**where verified**	**notebook**
C1: the left-hand sides are diagonal and free of x_0, so a source must be independent of x_0 with $q_{40} = q_{04} = 0$	`wolfram-a4-report.json`: `P1_structure`, `P2_structure`, `P3_structure`, `independent_components`	17a, In [4]
C2: $p_3 + p_t = 2p_0$ for every source	`wolfram-a4-report.json`: `algebraic_identity_x1_plus_x5_minus_2x0`; `python-a4-report.json`: `algebraic_identity`	17a, In [4]
C3: the linear member needs $p_3 = p_t = p_0$ and constant ρ	`python-a4-report.json` and `wolfram-a4-report.json`: `linear_member_equal_pressures`	17a, In [4]
Einstein gravity: $T = 0$ has no solution for $H > 0$	`wolfram-a4-report.json`: `einstein_no_vacuum_solution`	17a, In [19]
the Bianchi identity: every source must be conserved	both reports: `E1_divergence_free`, `E2_divergence_free`, `E3_divergence_free`	(Section 17.12)

ASSUMED.

- The history $a_4 = Hx_4$ ($A = 1$) on which the Kohn-Sham states were computed: it is a PRESCRIBED BACKGROUND, chosen and not solved for (this chapter shows that it is not a solution with the Kohn-Sham source).
- The ingredients of the Kohn-Sham model (Chapter 14): the good sector without extra-time dependence, the Z2 mirror at the brane, the tip cutoff $y = -3$, the box of 3-space and the

chosen particle numbers and couplings.

- In Section 17.17 only: the truncation of the averaged equations to the x_4 moment and the $x_1 - x_5$ moment (an approximation whose error, the dropped residuals, is of order 1), the initial rate $a_4'(0) = H$, and the interpolation of $\bar{\rho}$ between the slices.
- The overall sign convention $\sigma_T = +1$ of the source (record `a4-equations.json`, key `fields.emtConvention`). It does not affect C1, C2 or C3, which do not change when every component of T changes sign.

HYPOTHESIS. None in this chapter.

OPEN. What metric the Kohn-Sham gas would produce with back-reaction; whether any state of dirac16complex is an admissible source of the author's metric; the time-dependent (non-adiabatic) evolution of the gas along the history; the source beyond $a_4 = 2$ and at nonzero temperature; the evolution after a turning point (the record's integration stops there, Section 17.17); the six series with 3-momentum that are not integrated.

17.24 Exercises

Exercise 1 (the pattern of the Lovelock components). The record stores ${E_{(2)}}^{x_1}{}_{x_1} = 12a'^4 - 24a'^2a'' + 168a'^2H^2 - 40a''H^2 - 180H^4$, ${E_{(2)}}^{x_5}{}_{x_5} = 12a'^4 + 24a'^2a'' + 168a'^2H^2 + 40a''H^2 - 180H^4$ and ${E_{(2)}}^{x_0}{}_{x_0} = 12a'^4 + 168a'^2H^2 - 180H^4$. (a) Show that they have the form $P_2 + a''Q_2$, $P_2 - a''Q_2$, P_2, and find P_2 and Q_2. (b) Verify C2 for $k = 2$. (c) Find the Gauss-Bonnet part of F.

Answer. (a) In ${E_{(2)}}^{x_1}{}_{x_1}$ the terms without a'' are $12a'^4 + 168a'^2H^2 - 180H^4$, which is exactly ${E_{(2)}}^{x_0}{}_{x_0}$; call it P_2. The terms with a'' are $-24a'^2a'' - 40a''H^2 = a''(-24a'^2 - 40H^2)$ (rule: take out the common factor a''); call the bracket $Q_2 = -24a'^2 - 40H^2$. In ${E_{(2)}}^{x_5}{}_{x_5}$ the terms without a'' are again P_2, and the terms with a'' are $+24a'^2a'' + 40a''H^2 = -a''Q_2$. (b) $(P_2 + a''Q_2) + (P_2 - a''Q_2) - 2P_2 = 0$: the a'' terms cancel and $P_2 + P_2 - 2P_2 = 0$. (c) ${E_{(2)}}^{x_1}{}_{x_1} - {E_{(2)}}^{x_5}{}_{x_5} = 2a''Q_2 = a''(-48a'^2 - 80H^2)$, so the Gauss-Bonnet part of F is $\alpha_2(-48a'^2 - 80H^2)$, as in the record's `evolution_F`.

Exercise 2 (the two sides of C2 at three points). Use the three lines printed by Notebook 17a, In [12], for the state $N = 136$, $\lambda = 0$, $a_{4,0} = 1$. (a) Compute V in the middle and at the brane. (b) Compute $2p_0/(p_3 + p_t)$ at both points. (c) At the tip, compute $V/\max|T|$, given that the largest component of this state is $|p_0|$ at the tip (figure 2 of Notebook 17b shows $p_0/\max|T| = -1$ there).

Answer. (a) Middle: $V = 0.498835 + 0 - 2 \times 0.643324 = 0.498835 - 1.286648 = -0.787813$. Brane: $V = 0.000391237 + 0 - 2 \times 0.000942049 = 0.000391237 - 0.001884098 = -0.001492861$, printed as -0.00149286. (b) Middle: $1.286648/0.498835 = 2.579$, the 2.58 of figure 17a.5; brane: $0.001884098/0.000391237 = 4.816$, the 4.82. (c) $\max|T| = 431.733$, so $V/\max|T| = 1021.73/431.733 = 2.367$, inside the range 2.36 to 2.37 quoted in the caption of figure 17a.3.

Exercise 3 (the two forms of the hidden conservation law). Starting from the record's law in the coordinate x_0 for a diagonal source, $\partial_0 p_0 + 3H\cot z\,(2p_0 - p_3 - p_t) = 0$, derive the law in the coordinate y. Why may you divide by $\cot z$?

Answer. By the chain rule, $\partial_0 p_0 = (dy/dx_0)\,dp_0/dy = \cot z\,p_0'$, because $dy/dx_0 = \cot z$ (Section 17.4). The law becomes $\cot z\,p_0' + 3H\cot z\,(2p_0 - p_3 - p_t) = 0$, that is $\cot z\,[p_0' + 6Hp_0 - 3H(p_3 + p_t)] = 0$ (rule: take out the common factor; $3H \cdot 2p_0 = 6Hp_0$). On the patch $0 < z < \pi/2$ both $\cos z$ and $\sin z$ are positive, so $\cot z > 0$ and we may divide by it: $p_0' + 6Hp_0 = 3H(p_3 + p_t)$.

Exercise 4 (C2 and C1 for a conserved source). A conserved diagonal source in the author's metric has $p_0 = 5$ at every point (units of m^8, $H = 1$) and $p_t = 1$. (a) What is p_3? (b) Does it satisfy C2? (c) Can a conserved source with a flat p_0 still fail C1?

Answer. (a) The y law with $p_0' = 0$: $0 + 6 \times 5 = 3(p_3 + 1)$, so $p_3 + 1 = 10$ and $p_3 = 9$. (b) $p_3 + p_t = 10 = 2p_0$: yes, as Section 17.14 predicts for a flat p_0. (c) Yes. C1 also asks that ρ, p_3 and p_t do not depend on x_0. The hidden law fixes only the sum $p_3 + p_t$ and says nothing about ρ. For example $p_0 = 5$, $p_t = 1 + \sin y$ and $p_3 = 9 - \sin y$ satisfy the hidden law ($6 \times 5 = 3 \times 10$) and C2, but p_3 and p_t depend on y, so C1 fails. C2 is only the p_0 part of C1.

Exercise 5 (the averaged ratio by hand). For the state $N = 136$, $\lambda = 0$, $a_{4,0} = 0$ the record's table `Revision/kohn_sham/results/ground/emt-integrals.csv` gives $\int p_3 = 23.8133$, $\int p_t = 0$, $\int p_0 = 35.0435$, $p_0(\text{brane}) = 0.00224994$ and $p_0(\text{tip}) = -6.59995$; and $\text{Vol}_7 = 15875.2$, $H = 1$, $L = 3$. (a) Compute R from the integrals. (b) Compute the weighted mean $\bar{p}_0$. (c) Compute R from the brane and tip values and the mean, with the formula of Section 17.15. (d) Check the integrated conservation law.

Answer. (a) $R = (23.8133 + 0)/(2 \times 35.0435) = 23.8133/70.0870 = 0.33977$, the 0.339767 of the record. (b) The volume factor is $2\,\text{Vol}_7(1 - e^{-18})/6 = 31750.4 \times (1 - 1.5 \times 10^{-8})/6 = 5291.73$ (the e^{-18} changes nothing at this precision), so $\bar{p}_0 = 35.0435/5291.73 = 0.0066223$. (c) $e^{-18} \times (-6.59995) = -1.005 \times 10^{-7}$, so the numerator is $0.00224994 + 0.0000001005 = 0.00225004$, and $R = 0.00225004/0.0066223 = 0.33977$: the same number, as the conservation law demands. The brane value is about a third of the mean. (d) Left side: $2\,\text{Vol}_7 \times 0.00225004 = 31750.4 \times 0.00225004 = 71.440$; right side: $3H \times 23.8133 = 71.440$. They agree to the digits given.

Exercise 6 (every conserved profile with a constant sum). Suppose $p_3 + p_t = P$ is a constant. (a) Find every $p_0(y)$ that satisfies the y law. (b) Which of them satisfies C2? (c) Write the answer in the coordinate z.

Answer. (a) The law is $p_0' + 6Hp_0 = 3HP$. Multiply by e^{6Hy}: $(e^{6Hy}p_0)' = 3HPe^{6Hy}$ (rule: the product rule read backwards). Integrate: $e^{6Hy}p_0 = 3HP\,e^{6Hy}/(6H) + c = \frac{P}{2}e^{6Hy} + c$ with a constant c (rule: an antiderivative of e^{6Hy} is $e^{6Hy}/(6H)$; integration adds a constant). Divide by e^{6Hy}: $p_0 = \frac{P}{2} + c\,e^{-6Hy}$. Check: $p_0' = -6Hc\,e^{-6Hy}$, and $p_0' + 6Hp_0 = -6Hce^{-6Hy} + 3HP + 6Hce^{-6Hy} = 3HP$. (b) $V = p_0'/(3H) = -2c\,e^{-6Hy}$, which is zero everywhere only for $c = 0$: only the flat profile $p_0 = P/2$ satisfies C2. (c) Since $e^{6Hy} = \sin z$, $p_0 = P/2 + c/\sin z$: every non-flat conserved profile grows like $1/\sin z$ toward the tip.

Exercise 7 (Simpson's rule along the history). The record's table gives, for $N = 136$, $\lambda = 0$ at $a_{4,0} = 0, 0.5, 1, 1.5, 2$: $\int p_3 = 23.8133$, 15.4903, 10.0397, 6.44655, 4.06205 and $\int p_t = 0$; and $E(0) = 80.2822$, $E(2) = 12.4451$. (a) Compute the five rates $dE/da_{4,0}$. (b) Integrate them with Simpson's rule from 0 to 2 and compare with $E(2) - E(0)$. (c) Do the same with the trapezoidal rule, $h[\frac{1}{2}f_0 + f_1 + f_2 + f_3 + \frac{1}{2}f_4]$, and compare.

Answer. (a) $dE/da_{4,0} = -3\int p_3$: -71.4399, -46.4709, -30.1191, -19.33965, -12.18615. (b) $\frac{0.5}{3}[-71.4399 + 4(-46.4709) + 2(-30.1191) + 4(-19.33965) - 12.18615] = \frac{1}{6}(-71.4399 - 185.8836 - 60.2382 - 77.3586 - 12.18615) = \frac{1}{6}(-407.10645) = -67.8511$. The recorded change is $12.4451 - 80.2822 = -67.8371$ (Notebook 17b prints -67.8372, because it subtracts the unrounded numbers of the table). The difference is 0.0140, a relative error of $0.0140/67.837 = 2.1 \times 10^{-4}$, the value of Notebook 17b, In [18]. (c) $0.5[-35.71995 - 46.4709 - 30.1191 - 19.33965 - 6.093075] = 0.5 \times (-137.7427) = -68.8713$, a relative error of $1.034/67.837 = 1.5 \times 10^{-2}$, about seventy times larger: Simpson's rule, of order 4, is far better than the trapezoidal rule, of order 2, with the same five

values.

Exercise 8 (the order of the finite differences). For the state `N136_lam0_a10` Notebook 17b, In [13], found the difference 4.6×10^{-7} of max|T| at the step 0.02. Predict the differences at the steps 0.04, 0.06 and 0.10 if the error is of order 4, and compare with the printed values 7.5×10^{-6}, 3.8×10^{-5} and 3.0×10^{-4}.

Answer. An error of order 4 is $C\delta^4$, so doubling the step multiplies it by $2^4 = 16$: $16 \times 4.6 \times 10^{-7} = 7.4 \times 10^{-6}$. Tripling: $3^4 = 81$, $81 \times 4.6 \times 10^{-7} = 3.7 \times 10^{-5}$. Five times: $5^4 = 625$, $625 \times 4.6 \times 10^{-7} = 2.9 \times 10^{-4}$. The predictions agree with the printed values to within a few per cent, and the printed values are a little larger, more so for the larger steps (for the step 0.10 the printed 3.0×10^{-4} was at least 2.95×10^{-4} before rounding, while every number that rounds to 4.6×10^{-7}, at most 4.65×10^{-7}, gives at most $625 \times 4.65 \times 10^{-7} = 2.91 \times 10^{-4}$: the rounding cannot explain the gap). The excess is the next term of the error: a fourth-order difference has the error $C\delta^4 + D\delta^6 + \ldots$, and the term $D\delta^6$, small beside $C\delta^4$ for small δ, grows faster with the step. That is why the fitted order is 4.04 and not exactly 4.00. A failure of the conservation law would show up as a floor below which the differences stop falling; there is none.

Exercise 9 (the constraint in Einstein gravity). In Einstein gravity $\mathcal{C} = 3a_4'^2 + 21H^2 + \Lambda + \kappa\rho$ and $\mathcal{E} = 2a_4'' - \kappa(p_3 - p_t)$. (a) Show by hand that $d\mathcal{C}/dx_4 = 3a_4'\,\mathcal{E}$ for a source that obeys $\rho' = -3a_4'(p_3 - p_t)$. (b) For the linear member with $A = 1$ and the Kohn-Sham gas at $\lambda = 0$, what is the sign of $d\mathcal{C}/dx_4$, and what does it mean?

Answer. (a) $d\mathcal{C}/dx_4 = 6a_4'a_4'' + \kappa\rho'$ (rule: the chain rule for $a_4'^2$; H and Λ are constants) $= 6a_4'a_4'' - 3\kappa a_4'(p_3 - p_t)$ (rule: insert the conservation law) $= 3a_4'[2a_4'' - \kappa(p_3 - p_t)] = 3a_4'\,\mathcal{E}$ (rule: take out $3a_4'$). (b) With $a_4'' = 0$ and $a_4' = H$: $d\mathcal{C}/dx_4 = -3H\kappa(p_3 - p_t)$. At $\lambda = 0$ the gas has $p_t = 0$ exactly, and its p_3 is not zero (at the three points of In [12] of Notebook 17a it is positive, and its integral $\int p_3$ is positive at every slice, In [16]). Wherever $p_3 \neq 0$, $d\mathcal{C}/dx_4 \neq 0$, and integrated over the patch it is negative: even if the constraint held at one slice, it would be violated at the next. The linear member cannot carry this gas as its source.

Exercise 10 (the size of the patch). (a) Compute e^{-18} from $e^{-6} \approx 0.0024788$, and the angle z of the tip cutoff. (b) What fraction of the proper volume of the patch lies in $-1 \leq y \leq 0$?

Answer. (a) $e^{-18} = (e^{-6})^3 \approx 0.0024788^3 = 1.523 \times 10^{-8}$ (rule: $e^{3u} = (e^u)^3$). The tip cutoff has $\sin z = e^{6Hy} = e^{-18}$; for so small a number $\arcsin u \approx u$, so $z \approx 1.5 \times 10^{-8}$, the value in the caption of figure 17a.1. (b) The proper volume between $y = a$ and $y = 0$ is proportional to $\int_a^0 e^{6y}dy = (1 - e^{6a})/6$. For $a = -1$: $(1 - e^{-6})/6$; for the whole patch, $a = -3$: $(1 - e^{-18})/6$. The fraction is $(1 - 0.0024788)/(1 - 1.5 \times 10^{-8}) = 0.9975$: more than 99.7 per cent of the volume lies within one unit of the brane. The integral of a density, however, also depends on how large the density is where the volume is. For the states with 3-momentum ($N = 136$ and $N = 688$) the volume wins: Notebook 17b, In [15], finds that the last unit supplies between 0.812 and 0.969 of the integral of $e^{6Hy}p_0$, so their weighted mean $\bar{p}_0$ is decided near the brane. For the $N = 8$ brane zero modes it does not: their p_0 grows toward the tip almost like e^{-6Hy}, so $e^{6Hy}p_0$ is nearly flat, the last unit supplies only 0.439 to 0.441 of the integral, and the whole patch, the tip included, matters (Section 17.15).

18 The pairing theorems T1, T2 and Q

The author asked for a proof that "Universes of masses {+mass, -mass} are created in pairs", for the fermion field dirac16complex and for the commuting field dirac16complex00. This chapter gives, with complete line-by-line proofs, everything that the equations of this book actually establish about such pairs, and it says exactly where that stops. Three theorems are proved. **T1** (the chirality pairing): multiplying a field by the chirality matrix Γ turns every configuration of the theory with mass m and coupling λ into a configuration of the theory with $-m$ and $-\lambda$, in every gravitational field, and reverses its energy, momentum, stresses, current and charge. **T2** (the mirror pairing): multiplying by the gamma matrix of the hidden direction and reflecting the hidden coordinate across the surface $z = \pi/2$ turns a solution with $(-m, \lambda)$ into a solution with (m, λ) at EQUAL, not opposite, energy and charge; this uses the Z2 mirror construction, which is an assumption. **Q** (the quantum reading): for the quantised field dirac16complex the T1 image carries the opposite Krein matrix $-B$, so it is the same quantum system relabelled, while two independently quantised universes of masses $+m$ and $-m$ have identical one-particle spectra (the $\lambda = 0$ spectra, in flat 4+4 space or with frozen coefficients at a point) and energies that do not cancel. All three are exact maps between sets of solutions. None of them describes a process in which a universe, or a pair of universes, comes into being: no creation process, rate, probability or amplitude follows from these equations. Section 18.28 lists precisely what is not established.

18.1 What this chapter does

The question, and the honest answer. In this book a **universe of mass** m means a configuration of one of the two fields, with mass parameter m and coupling λ, in the author's primordial gravitational field; usually it is a **solution**, a configuration that obeys the field equations. Two universes are **paired** when an explicit invertible rule takes every solution of the theory with mass m to a solution of the theory with mass $-m$, and takes its Lagrangian, its energy-momentum tensor and its current to stated multiples of those of the partner. The author's request asks for more: that such universes are *created* in pairs at the big bang. That statement is a HYPOTHESIS of the author. The field equations of this book are equations for a field on a given gravitational background, together with their canonical quantisation; no equation of the book produces a universe from anything, so the creation of pairs cannot be proved from them, and it is not proved here. What can be proved is that the solutions come in partnered families, and with which signs their energies and charges are partnered. That is the content of this chapter.

The plan. Sections 18.2 to 18.4 set the stage: the words, the author's metric, its spin connection, the Lagrangian, the field equation, the energy-momentum tensor and the current. Section 18.5 proves four matrix lemmas; everything later rests on them. Notebook 18a checks them exactly (Sections 18.6 to 18.9). Sections 18.10 to 18.13 state and prove T1; Sections 18.14 to 18.16 state and prove T2. Notebook 18b proves both theorems again, as exact polynomial identities, in the author's metric with an arbitrary deflating history (Sections 18.17 to 18.20). Section 18.21 derives a family of exact solutions, the fields that depend only on the time; Sections 18.22 and 18.23 state and prove Q. Notebook 18c solves the field equations numerically and shows each theorem at work on actual solutions (Sections 18.24 to 18.27). Section 18.28 states what is not established, Section 18.29 collects the status of every result, and Sections 18.30 and 18.31 give exercises and their complete worked answers. The Kohn-Sham version of the pairing, theorem T3, is the subject of Chapter 19; the corollary C1 and the question of the title of Chapter 20, "Do universes come in pairs?", are

treated there; matter and antimatter are the subject of Chapter 21.

The three worked examples. Each is a complete Jupyter notebook, complete in itself; you may run them in any order.

notebook	what it computes	checks	figures
18a	the author's gammas rebuilt from their formulas; the four matrix lemmas, exactly	16	7
18b	T1 and T2 as exact sympy identities in the author's metric, both statistics	20	5
18c	T1, T2 and Q on actual solutions: Runge-Kutta, spectra, Krein norms	21	7

Notation. The author's coordinates are written $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates (scale factor $e^{a_4} \sin^{1/6} z$); x_4 is the time; x_5, x_6, x_7 are the three extra times, which are time-like and DEFLATE EXPONENTIALLY (scale factor $e^{-a_4} \sin^{1/6} z$, with a_4 increasing); x_0 is the hidden space direction, with $z = 6Hx_0$ between 0 and $\pi/2$ and $H > 0$ the author's constant. The author's metric of 2026-10-14 has a second function $b_4(x_4) > 0$ in the extra-time factor (Chapter 3); this chapter works on the background $b_4 = 1$, and Sections 18.3, 18.16 and 18.21 say what a changing b_4 changes. The flat frame metric is $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$; its entry for the direction a is η_{aa}, and $\eta_{ab} = 0$ for $a \neq b$. The gamma matrices are the author's eight real 16×16 matrices; the one of the direction x_a is written $\gamma^{(x_a)}$, or $\gamma^{(a)}$ for short. I_{16} (also written 1) is the 16×16 identity matrix and I_8 the 8×8 one. For a matrix M, M^T is its transpose (rows and columns exchanged), M^* the matrix of the complex-conjugate entries and $M^\dagger = (M^T)^*$; for a real matrix $M^\dagger = M^T$. The letters m and λ are the mass and the coupling of the field. A statement is labelled PROVED (exact, with the verifying record and its check), COMPUTED (a numerical result with its accuracy), ASSUMED, HYPOTHESIS or OPEN.

The records this chapter uses. Every formula and number comes from these Revision records or from the chapter's own notebooks, which reproduce the records where they overlap (each such check prints the record file and the check name):

record	what it holds
`Revision/algebra/gammas.json`	the eight gammas, C, Γ and B
`Revision/pairing/pairing-theory.json`	the theorems T1, T2, Q with hypotheses, proofs and data tables
`Revision/pairing/reports/wolfram-pairing.json`	the WolframScript verification of T1, T2, Q (101 checks, all PASS)
`Revision/pairing/reports/python-pairing.json`	the independent sympy verification (66 checks, all PASS)
`Revision/theory/reports/`	the field-theory checks used here: `python-field-theory.json`, `wolfram-field-theory.json`, `python-scope.json`

record	what it holds
`Revision/lead_checks/reports/charge-conjugation-and-u1.json`	the charge-conjugation matrices and the charge (12 checks, all PASS)
`Revision/kohn_sham/results/parameters.json`	the canonical deflating history $a_4 = AHx_4$, $A = 1$

The Wolfram side and the sympy side share no code; the sympy side rebuilds the gammas from the author's formulas and compares them entry by entry with `gammas.json`. A report is a file in which a verifying program has recorded every check with its name, its verdict and a detail text; every check cited in this chapter has the verdict PASS. Below, a report is named by its file name only, for example "`python-pairing.json`, check `gammas.Gamma`". The Revision document that collects these proofs is `Revision/docs/PAIR_CREATION_PROOFS.md`; this chapter follows its logic and adds every intermediate line.

18.2 The words of this chapter

- **Configuration**: any field Ψ, that is, 16 components $\Psi_1(x), \ldots, \Psi_{16}(x)$ given at every point x, whether or not it obeys the field equations. A statement that holds for every configuration holds **off shell**; one that holds only for solutions holds **on shell**. An off-shell identity holds in particular on shell.
- **Statistics**: dirac16complex has complex ANTICOMMUTING components, called **Grassmann** numbers ($\theta_1\theta_2 = -\theta_2\theta_1$, so $\theta\theta = 0$); dirac16complex00 has complex COMMUTING components (ordinary complex numbers). "Both statistics" means: the statement and its proof hold for both kinds of components.
- **Parameters**: the mass m and the coupling λ of the potential $U(S) = \frac{\lambda}{2}S^2$. The theory with the parameters (m, λ) and the theory with $(-m, -\lambda)$ are two DIFFERENT theories: their Lagrangians are different functions of the field.
- **Map**: a rule that turns a field Ψ into a new field Ψ'. All maps of this chapter are of the form $\Psi'(x) = M\Psi(x)$ with a constant 16×16 matrix M, possibly combined with a change of the coordinate x_0.
- **Bilinear**: an expression $\Psi^\dagger X \Phi = \sum_{A,B} \Psi^*_A X_{AB} \Phi_B$ with a matrix X of numbers or of ordinary functions; X is its **kernel**.
- **Signed permutation matrix**: a matrix with exactly one nonzero entry, $+1$ or -1, in each row and in each column. Multiplying a column of 16 numbers by it reorders the numbers and changes the signs of some of them. Each of the author's gammas is such a matrix.
- **Projector**: a matrix P with $PP = P$. It keeps one part of a column and removes the rest; doing it twice changes nothing more. The **chiral projectors** $P_- = \frac{1}{2}(1-\Gamma)$ and $P_+ = \frac{1}{2}(1+\Gamma)$ keep the components 1 to 8, respectively 9 to 16, and set the other eight to zero.
- **Dirac adjoint**: the row $\bar\Psi = \Psi^\dagger C$, with the charge matrix C of Chapter 5. The **scalar** is $S = \bar\Psi\Psi = \Psi^\dagger C \Psi$.
- **Chirality**: the matrix $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\cdots\gamma^{(x_7)}$, the product of all eight gammas in the author's order (the author's T16[8]).

- **Chiral halves**: the components 1 to 8 of Ψ, written ψ_- (where $\Gamma = -1$), and 9 to 16, written ψ_+ (where $\Gamma = +1$).
- **Reflection** R_n: the 8×8 diagonal matrix with -1 in place n and $+1$ elsewhere; it reverses the direction n and keeps η: $R_n \eta R_n = \eta$.
- **Pin(4,4)**: the group of all products of unit vectors $v = \sum_a v_a \gamma^{(a)}$ with $\sum_a \eta_{aa} v_a^2 = \pm 1$ (Chapter 5). Each single gamma is such a unit vector, so every product of gammas belongs to Pin(4,4).
- **Character** of a map M: the sign χ in $M^\dagger C M = \chi C$. It says whether S keeps ($\chi = +1$) or reverses ($\chi = -1$) its sign under $\Psi \to M\Psi$.
- **Krein matrix** $B = -iC\gamma^{(x_4)}$: the charge density is $\Psi^\dagger B \Psi$, and B is the matrix of the canonical anticommutator of the quantised field (Chapter 10). B has eight eigenvalues $+1$ and eight -1; the number $u^\dagger B u$ of a column u is its **Krein norm**, which can be negative. The **Krein sign** of a map M is the sign σ in $MBM^\dagger = \sigma B$.
- **Patch, mirror patch, brane**: $z = 6Hx_0$ runs over the **patch** $0 < z < \pi/2$. The map $z \to \pi - z$ takes it to the **mirror patch** $\pi/2 < z < \pi$. The surface $z = \pi/2$ between them is the **brane**. Gluing the mirror patch to the patch at the brane is the **Z2 construction** of the Revision record; it is ASSUMED.
- **Isometry**: a change of coordinates that does not change the metric.
- **Jet**: at one point, the values of the 16 components, of their 16 complex conjugates and of their $8 \times 16 + 8 \times 16$ first derivatives: 288 numbers. A Lagrangian at a point is a polynomial in these 288 numbers.
- **Negative control**: a computation that must FAIL. It shows that a test can detect a wrong statement.
- **Junction condition**: an equation that says how the fields and the geometry must match across a surface, here across the brane $z = \pi/2$. **Brane tension**: an energy per unit area carried by such a surface itself (for the brane, per unit of its seven-dimensional area).
- **Legendre transform**: the rule that turns a Lagrangian into the energy (Hamiltonian) density: for each field, its time derivative times its canonical momentum, summed over the fields, minus the Lagrangian.
- Words used only in Section 18.28, in the list of what is NOT established: a **vacuum** is a state with no particles, and **vacuum decay** is its change into a state of lower energy; **tunnelling** is a quantum transition through a region that the classical equations forbid, for example through an energy barrier; a **cross-section** is a number, with the units of an area, that measures how likely a collision or a reaction is; a **Bogoliubov coefficient** says how much of the particles of one choice of vacuum the vacuum of another choice contains, and so how many particles a changing background creates; the **wave function of the universe** is a quantum state assigned to a whole universe, its geometry included; a **path integral** computes a quantum amplitude by adding one contribution for every possible history of the fields.

18.3 The stage: the author's metric, its frame and its spin connection

The metric. The author's line element, in their coordinates, is

$$\begin{aligned} ds^2 = {} & \cot^2 z\, dx_0^2 + e^{2a_4} \sin^{1/3} z\, (dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2 \\ & - e^{-2a_4} \sin^{1/3} z\, (dx_5^2 + dx_6^2 + dx_7^2), \end{aligned}$$

with $a_4 = a_4(x_4)$ and $z = 6Hx_0$. This is the author's metric of 2026-10-14 on its background $b_4 = 1$: the metric has a second function $b_4(x_4) > 0$, which multiplies the three extra-time components, $-b_4 e^{-2a_4} \sin^{1/3} z\, (dx_5^2 + dx_6^2 + dx_7^2)$ (Chapter 3; `wolfram-field-theory-b4.json`, check `metric_is_the_authors_b4`). The pairing records and the three notebooks of this chapter work at $b_4 = 1$; the end of this section and Sections 18.16 and 18.21 say what a changing b_4 changes. The metric is diagonal: $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$ with the **vielbein factors**

$$f_0 = \cot z, \quad f_1 = f_2 = f_3 = e^{a_4} \sin^{1/6} z, \quad f_4 = 1, \quad f_5 = f_6 = f_7 = e^{-a_4} \sin^{1/6} z.$$

The **diagonal vielbein** is $e^a{}_\mu = f_\mu \delta^a_\mu$, its inverse $e^\mu{}_a = \delta^\mu_a / f_a$, and the curved gammas are $\gamma^\mu = e^\mu{}_a \gamma^{(a)} = \gamma^{(\mu)} / f_\mu$ (no sum) and $\gamma_\mu = g_{\mu\mu} \gamma^\mu = \eta_{\mu\mu} f_\mu \gamma^{(\mu)}$. The volume factor is the product of the eight factors:

$$\sqrt{|g|} = f_0 f_1 \cdots f_7 = \cot z \cdot \left(e^{a_4} \sin^{1/6} z\right)^3 \cdot 1 \cdot \left(e^{-a_4} \sin^{1/6} z\right)^3.$$

The rule $\sqrt{|\det g|} = \prod_\mu |g_{\mu\mu}|^{1/2}$ for a diagonal metric gave this line.

$$\sqrt{|g|} = e^{3a_4 - 3a_4} \sin^{6/6} z \cdot \frac{\cos z}{\sin z} = \cos z.$$

The powers of e^{a_4} cancel (the inflation of 3-space is compensated by the deflation of the extra times), the six powers $\sin^{1/6} z$ multiply to $\sin z$, and $\cot z = \cos z / \sin z$. So $\sqrt{|g|} = \cos z$ for every history a_4 (record: `wolfram-pairing.json`, check `primordial_vielbein`; Notebook 18b checks it). With a changing b_4 each extra-time factor carries $b_4^{1/2}$, and $\sqrt{|g|} = b_4^{3/2} \cos z$ (`wolfram-field-theory-b4.json`, check `sqrt_det_g`).

The canonical spin connection, derived for a diagonal vielbein. A spinor field needs a **spin connection** $\omega_{\mu ab}$ to define its covariant derivative (Chapter 6). The canonical one is fixed by the **vielbein postulate**, which says that the gammas are covariantly constant; its solution is

$$\omega_\mu{}^a{}_b = e^a{}_\nu (\partial_\mu e^\nu{}_b + \Gamma^\nu{}_{\mu\lambda} e^\lambda{}_b), \qquad \omega_{\mu ab} = \eta_{aa}\, \omega_\mu{}^a{}_b,$$

where $\Gamma^\nu{}_{\mu\lambda}$ are the Christoffel symbols of the metric (Chapter 3). (In this chapter the symbol Γ WITH indices is a Christoffel symbol; WITHOUT indices it is the chirality matrix.) For a diagonal metric the Christoffel symbols with three different indices vanish, and for $a \neq b$

$$\Gamma^a{}_{ab} = \frac{\partial_b g_{aa}}{2 g_{aa}}, \qquad \Gamma^a{}_{bb} = -\frac{\partial_a g_{bb}}{2 g_{aa}}.$$

These are the Christoffel formula $\Gamma^{\nu}{}_{\mu\lambda} = \frac{1}{2} g^{\nu\nu}(\partial_\mu g_{\nu\lambda} + \partial_\lambda g_{\nu\mu} - \partial_\nu g_{\mu\lambda})$ with a diagonal g, in which only the terms with two equal indices survive. Now take a direction a and a different direction b, and compute the component of the connection whose derivative index is $\mu = a$:

$$\omega_a{}^a{}_b = e^a{}_a(\partial_a e^a{}_b + \Gamma^a{}_{a\lambda} e^\lambda{}_b) = f_a\Big(0 + \Gamma^a{}_{ab}\frac{1}{f_b}\Big).$$

The inverse vielbein is diagonal, so $e^a{}_b = 0$ for $a \neq b$ and $e^\lambda{}_b = \delta^\lambda_b / f_b$ keeps only $\lambda = b$.

$$\Gamma^a{}_{ab} = \frac{\partial_b(\eta_{aa} f_a^2)}{2\eta_{aa} f_a^2} = \frac{2\eta_{aa} f_a\, \partial_b f_a}{2\eta_{aa} f_a^2} = \frac{\partial_b f_a}{f_a}.$$

We inserted $g_{aa} = \eta_{aa} f_a^2$ and used the chain rule $\partial_b(f_a^2) = 2 f_a \partial_b f_a$.

$$\omega_a{}^a{}_b = f_a\,\frac{\partial_b f_a}{f_a}\,\frac{1}{f_b} = \frac{\partial_b f_a}{f_b}, \qquad \omega_{a,ab} = \eta_{aa}\frac{\partial_b f_a}{f_b}.$$

The first equation inserts the line before into the line before that; the second lowers the index a with η_{aa}. Now the component with the derivative index $\mu = b$, line by line:

$$\omega_b{}^a{}_b = e^a{}_a(\partial_b e^a{}_b + \Gamma^a{}_{b\lambda} e^\lambda{}_b) = f_a\Big(0 + \Gamma^a{}_{bb}\frac{1}{f_b}\Big).$$

The same two facts as before: $e^a{}_\nu$ keeps only $\nu = a$, $e^a{}_b = 0$ for $a \neq b$, and $e^\lambda{}_b = \delta^\lambda_b / f_b$ keeps only $\lambda = b$.

$$\Gamma^a{}_{bb} = -\frac{\partial_a(\eta_{bb} f_b^2)}{2\eta_{aa} f_a^2} = -\frac{2\eta_{bb} f_b\, \partial_a f_b}{2\eta_{aa} f_a^2} = -\eta_{aa}\eta_{bb}\,\frac{f_b\,\partial_a f_b}{f_a^2}.$$

We inserted $g_{bb} = \eta_{bb} f_b^2$ and $g_{aa} = \eta_{aa} f_a^2$ into the second Christoffel formula, used the chain rule, and replaced $1/\eta_{aa}$ by η_{aa} (it is $+1$ or -1).

$$\omega_b{}^a{}_b = f_a\Big(-\eta_{aa}\eta_{bb}\frac{f_b\,\partial_a f_b}{f_a^2}\Big)\frac{1}{f_b} = -\eta_{aa}\eta_{bb}\,\frac{\partial_a f_b}{f_a}, \qquad \omega_{b,ab} = \eta_{aa}\,\omega_b{}^a{}_b = -\eta_{bb}\,\frac{\partial_a f_b}{f_a}.$$

The first equation inserts the line before and cancels f_b and one f_a; the second lowers the index a with η_{aa} and uses $\eta_{aa}^2 = 1$. Compare with the formula $\omega_{a,ab} = \eta_{aa}\,\partial_b f_a / f_b$ found first: exchanging the names a and b in it gives $\omega_{b,ba} = \eta_{bb}\,\partial_a f_b / f_a$, so $\omega_{b,ab} = -\omega_{b,ba}$, the antisymmetry $\omega_{\mu ab} = -\omega_{\mu ba}$. Components whose three indices are all different contain a Christoffel symbol with three different indices and vanish, and $\omega_\mu{}^a{}_a = f_a(-\partial_\mu f_a / f_a^2 + \partial_\mu f_a / f_a^2) = 0$. So **the only nonzero components are $\omega_{a,ab} = \eta_{aa}\,\partial_b f_a / f_b$ and $\omega_{a,ba} = -\omega_{a,ab}$, for $a \neq b$.**

The twelve components in the author's metric. The factors depend only on x_4 (through a_4) and on x_0 (through z), and $\partial_0 = 6H\,d/dz$ because $z = 6Hx_0$. Write $a_4' = da_4/dx_4$.

- $a = 1$, $b = 4$: $\eta_{11} = 1$, $\partial_4 f_1 = a_4' e^{a_4} \sin^{1/6} z$ (chain rule), $f_4 = 1$, so $\omega_{x_1,x_1x_4} = a_4' e^{a_4} \sin^{1/6} z$.

- $a=1$, $b=0$: $\partial_0 f_1 = 6H\,e^{a_4}\,\frac{1}{6}\sin^{-5/6} z\cos z = He^{a_4}\sin^{-5/6} z\cos z$ (power rule and chain rule); dividing by $f_0 = \cos z/\sin z$ gives $\omega_{x_1,x_1x_0} = He^{a_4}\sin^{1/6} z$, and by antisymmetry $\omega_{x_1,x_0x_1} = -He^{a_4}\sin^{1/6} z$.
- $a=5$, $b=4$: $\eta_{55}=-1$, $\partial_4 f_5 = -a_4' e^{-a_4}\sin^{1/6} z$, so $\omega_{x_5,x_5x_4} = +a_4' e^{-a_4}\sin^{1/6} z$, and by antisymmetry $\omega_{x_5,x_4x_5} = -a_4' e^{-a_4}\sin^{1/6} z$.
- $a=5$, $b=0$: $\partial_0 f_5 = He^{-a_4}\sin^{-5/6} z\cos z$; with $\eta_{55}=-1$ and the division by f_0: $\omega_{x_5,x_5x_0} = -He^{-a_4}\sin^{1/6} z$, and by antisymmetry $\omega_{x_5,x_0x_5} = +He^{-a_4}\sin^{1/6} z$.
- x_2, x_3 repeat x_1, and x_6, x_7 repeat x_5. $f_4 = 1$ is constant and f_0 depends only on x_0, so $a=4$ and $a=0$ give nothing.

That is $3\times 2 + 3\times 2 = 12$ nonzero components with $a<b$ in the order $x_0,\ldots,x_7$ (the hidden index first: ω_{x_1,x_0x_1}, ω_{x_1,x_1x_4}, ω_{x_5,x_0x_5}, ω_{x_5,x_4x_5}, ...), exactly the list of the record (`python-pairing.json`, check `geometry.spin_connection_components`); Notebooks 18b and 18c reproduce the list character for character. Note that $\Omega_{x_4} = \Omega_{x_0} = 0$: no component has the derivative index 4 or 0.

What enters the field equation: $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$. The spinor connection is $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$ with the generators $S^{ab} = \frac{1}{4}[\gamma^{(a)},\gamma^{(b)}]$, which equal $\frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ for $a\neq b$ (two different gammas anticommute, so $\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)} = 2\gamma^{(a)}\gamma^{(b)}$). For the inflating direction x_1:

$$\Omega_{x_1} = \omega_{x_1,x_1x_4}S^{14} + \omega_{x_1,x_1x_0}S^{10} = \tfrac{1}{2}\omega_{x_1,x_1x_4}\gamma^{(1)}\gamma^{(4)} + \tfrac{1}{2}\omega_{x_1,x_1x_0}\gamma^{(1)}\gamma^{(0)}.$$

The two terms $\omega_{\mu ab}S^{ab}$ and $\omega_{\mu ba}S^{ba}$ of the sum are equal (both factors change sign), which cancels the $\frac{1}{2}$ of the definition; then $S^{ab} = \frac{1}{2}\gamma^{(a)}\gamma^{(b)}$.

$$\gamma^{x_1}\Omega_{x_1} = \frac{\gamma^{(1)}}{f_1}\,\Omega_{x_1} = \frac{1}{2f_1}\big(\omega_{x_1,x_1x_4}\gamma^{(4)} + \omega_{x_1,x_1x_0}\gamma^{(0)}\big) = \frac{a_4'}{2}\gamma^{(4)} + \frac{H}{2}\gamma^{(0)}.$$

We used $\gamma^{(1)}\gamma^{(1)} = \eta_{11} = +1$ (Clifford relation), and the factor $1/f_1 = e^{-a_4}\sin^{-1/6} z$ cancels the factor $e^{a_4}\sin^{1/6} z$ of both components. For the deflating extra time x_5:

$$\gamma^{x_5}\Omega_{x_5} = \frac{\gamma^{(5)}}{2f_5}\big(\omega_{x_5,x_4x_5}\gamma^{(4)}\gamma^{(5)} + \omega_{x_5,x_5x_0}\gamma^{(5)}\gamma^{(0)}\big).$$

This is the same construction with the two components of x_5 ($S^{45} = \frac{1}{2}\gamma^{(4)}\gamma^{(5)}$ and $S^{50} = \frac{1}{2}\gamma^{(5)}\gamma^{(0)}$).

$$\gamma^{(5)}\gamma^{(4)}\gamma^{(5)} = -\gamma^{(4)}\gamma^{(5)}\gamma^{(5)} = -\gamma^{(4)}(-1) = \gamma^{(4)}, \qquad \gamma^{(5)}\gamma^{(5)}\gamma^{(0)} = -\gamma^{(0)}.$$

Two different gammas anticommute, and a time-like gamma squares to $\eta_{55} = -1$.

$$\gamma^{x_5}\Omega_{x_5} = \frac{1}{2f_5}\big(-a_4' e^{-a_4}\sin^{1/6} z\,\gamma^{(4)} + He^{-a_4}\sin^{1/6} z\,\gamma^{(0)}\big) = -\frac{a_4'}{2}\gamma^{(4)} + \frac{H}{2}\gamma^{(0)}.$$

We inserted the two components and cancelled $f_5 = e^{-a_4}\sin^{1/6} z$. Adding the three inflating and the three deflating directions (and nothing from x_4 and x_0):

$$\gamma^\mu\Omega_\mu = 3\Big(\frac{a_4'}{2}\gamma^{(4)} + \frac{H}{2}\gamma^{(0)}\Big) + 3\Big(-\frac{a_4'}{2}\gamma^{(4)} + \frac{H}{2}\gamma^{(0)}\Big) = 3H\gamma^{(x_0)}.$$

The a_4' terms of the three inflating directions and of the three deflating extra times cancel exactly; the hidden-direction terms add. This is PROVED for every history $a_4(x_4)$ (`python-field-theory.json`, check `gamma_mu_Omega_mu_equals_3H_gamma_x0`; `wolfram-field-theory.json`, check `gammaOmega_equals_3H_gamma_x0`; Notebook 18b recomputes it direction by direction and draws it in its figure 1). The value $3H\gamma^{(x_0)}$ belongs to the diagonal vielbein: in another frame it changes (`python-scope.json`; Chapter 8). None of the theorems below depends on it: T1 holds for every connection, and T2 uses only the transformation of the connection.

With a changing b_4. In the metric with $b_4(x_4)$ the extra-time factors are $f_5 = f_6 = f_7 = e^{-a_4} b_4^{1/2} \sin^{1/6} z$. Each extra time then contributes $(-\frac{a_4'}{2} + \frac{b_4'}{4b_4})\gamma^{(x_4)} + \frac{H}{2}\gamma^{(x_0)}$, and

$$\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)} + \frac{3}{4}\,\frac{b_4'}{b_4}\,\gamma^{(x_4)}$$

(Chapter 7; the checks `gammaOmega_per_direction` and `gammaOmega_total` of `python-field-theory-b4.json` and of `wolfram-field-theory-b4.json`). The extra term vanishes on the background $b_4 = 1$ and for every constant b_4.

18.4 The Lagrangian, the field equation, the energy-momentum tensor and the current

The Lagrangian. Both fields have the same Lagrangian density; only the statistics of the components differ:

$$\mathcal{L}_{m,\lambda}[\Psi] = \sqrt{|g|}\,\Big[K[\Psi] - mS - \frac{\lambda}{2}S^2\Big], \qquad K = \frac{1}{2}(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi), \qquad S = \bar\Psi\Psi,$$

with the covariant derivatives $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, and a sum over $\mu = 0, \ldots, 7$ (the eight coordinates $x_0, \ldots, x_7$) in K. K is the **kinetic term**, mS the **mass term**, $\frac{\lambda}{2}S^2$ the **potential**. For a general potential $U(S)$ we write $\mathcal{L}_{m,U}$. The Lagrangian is real for both statistics (Chapter 7).

The kinetic term written out. Inserting $\gamma^\mu = e^\mu{}_a\gamma^{(a)}$ and the two covariant derivatives into K:

$$K = \frac{1}{2}\sum_{\mu,a} e^\mu{}_a(\bar\Psi\gamma^{(a)}\partial_\mu\Psi - \partial_\mu\bar\Psi\gamma^{(a)}\Psi) + \frac{1}{2}\sum_{\mu,a} e^\mu{}_a(\bar\Psi\gamma^{(a)}\Omega_\mu\Psi + \bar\Psi\Omega_\mu\gamma^{(a)}\Psi).$$

The derivative parts give the first sum; the connection parts $+\bar\Psi\gamma^{(a)}\Omega_\mu\Psi$ (from $D_\mu\Psi$) and $-(-\bar\Psi\Omega_\mu)\gamma^{(a)}\Psi$ (from $D_\mu\bar\Psi$) give the second.

$$K = \frac{1}{2}\sum_{\mu,a} e^\mu{}_a(\bar\Psi\gamma^{(a)}\partial_\mu\Psi - \partial_\mu\bar\Psi\gamma^{(a)}\Psi) + \frac{1}{4}\sum_{\mu,a,b,c} e^\mu{}_a\,\omega_{\mu bc}\,\bar\Psi\{\gamma^{(a)}, S^{bc}\}\Psi.$$

We inserted $\Omega_\mu = \frac{1}{2}\sum_{b,c}\omega_{\mu bc}S^{bc}$ and wrote $\gamma^{(a)}S^{bc} + S^{bc}\gamma^{(a)} = \{\gamma^{(a)}, S^{bc}\}$, the **anticommutator**. This form shows the structure that every proof below uses: K is a sum of **coefficient functions** of the gravitational field ($e^\mu{}_a$, $\omega_{\mu bc}$; and $\sqrt{|g|}$ in front of $\mathcal{L}$) times **bilinears** whose kernels are $C\gamma^{(a)}$ and $C\gamma^{(a)}S^{bc}$, $CS^{bc}\gamma^{(a)}$, products of one or three gammas after C.

The field equation. Chapter 7 derived the Euler-Lagrange equations of $\mathcal{L}_{m,U}$; for both statistics they are

$$E_{m,U}[\Psi] \equiv \gamma^\mu D_\mu\Psi - \big(m + U'(S)\big)\Psi = 0, \qquad (D_\mu\bar\Psi)\gamma^\mu = -\big(m + U'(S)\big)\bar\Psi,$$

with $U'(S) = \lambda S$ for $U = \frac{\lambda}{2}S^2$; we write $E_{m,\lambda}$. The record proves that the Euler-Lagrange expression of Ψ^*_A derived from $\mathcal{L}$ is exactly $\sqrt{|g|}\,[CE_{m,\lambda}]_A$ (`python-pairing.json`, check `T1.metric.commuting.euler_lagrange_derived` and its Grassmann twin; Notebook 18b repeats it). In the author's metric at $b_4 = 1$, with $\gamma^\mu = \gamma^{(\mu)}/f_\mu$, $\partial_0 = 6H\,d/dz$ and $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$, the field equation reads

$$\begin{aligned} &e^{-a_4}\sin^{-1/6} z\,\big(\gamma^{(1)}\partial_1 + \gamma^{(2)}\partial_2 + \gamma^{(3)}\partial_3\big)\Psi + \gamma^{(4)}\partial_4\Psi \\ &\quad + e^{a_4}\sin^{-1/6} z\,\big(\gamma^{(5)}\partial_5 + \gamma^{(6)}\partial_6 + \gamma^{(7)}\partial_7\big)\Psi \\ &\quad + \tan z\,\gamma^{(0)}\partial_0\Psi + 3H\gamma^{(0)}\Psi = (m + \lambda S)\Psi. \end{aligned}$$

The derivative terms are $\gamma^\mu\partial_\mu\Psi$ with $1/f_\mu$ written out ($1/\cot z = \tan z$); the last term on the left is $\gamma^\mu\Omega_\mu\Psi$. The deflation of the extra times appears as the growing factor e^{a_4} in front of their derivatives. With a changing b_4 that factor is $e^{a_4}b_4^{-1/2}\sin^{-1/6} z$, and the left side gains the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}\Psi$ (`wolfram-field-theory-b4.json`, checks `Dirac_operator_explicit_G` and `Dirac_operator_explicit_C`; Chapter 7).

The energy-momentum tensor and the current. The pairing record uses the symmetric tensor

$$T_{\mu\nu} = \frac{1}{4}\big(\bar\Psi\gamma_\mu D_\nu\Psi + \bar\Psi\gamma_\nu D_\mu\Psi - (D_\mu\bar\Psi)\gamma_\nu\Psi - (D_\nu\bar\Psi)\gamma_\mu\Psi\big) - g_{\mu\nu}\frac{\mathcal{L}}{\sqrt{|g|}},$$

which is minus the tensor of Chapter 9; in this convention the energy density is $\rho = -T_{x_4x_4}$ and the pressure of a direction $\mu \neq x_4$ is $p_\mu = -g^{\mu\mu}T_{\mu\mu}$. The current is a multiple of $\bar\Psi\gamma^\mu\Psi$: the theory record and Notebook 18c use $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, whose time component is the charge density $J^{x_4} = -i\Psi^\dagger C\gamma^{(x_4)}\Psi = \Psi^\dagger B\Psi$, with the charge $Q = \int\cos z\,\Psi^\dagger B\Psi\,d^7x$ of a slice $x_4 = \text{const}$ (the integral runs over the seven coordinates other than x_4, with x_0 over the patch; in a formula the letter Q always means this charge, while the plain name Q, without a formula, is the quantum theorem of Section 18.22); the sympy pairing checker and Notebook 18b use $i\bar\Psi\gamma^\mu\Psi$, the Wolfram checker $\bar\Psi\gamma^\mu\Psi$. Every statement of this chapter about T and J has the form $T' = \pm T$ or $J' = \pm J$; such a statement is unchanged when T or J is multiplied by any fixed number, so the different conventions do not matter.

18.5 Four matrix lemmas

Every map of this chapter multiplies the field by a constant matrix. The lemmas below say what such a multiplication does to the adjoint, to bilinears, to the connection and to the Krein matrix. They are exact identities between the author's matrices. We use only the Clifford relation

$\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta_{ab} I_{16}$, the reality of the gammas, $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$, and the facts about C proved in Chapter 5: $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ is real and symmetric, $CC = 1$, and

$$C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T \qquad \text{for every } a.$$

Rule P (moving a gamma through a product). If X is a product of k gammas, $\gamma^{(a)}X = \pm X\gamma^{(a)}$, with one factor -1 for each factor of X different from $\gamma^{(a)}$ (they anticommute) and $+1$ for each factor equal to $\gamma^{(a)}$ (it commutes with itself). This is the Clifford relation applied once per factor.

Lemma 1 (the chirality). Γ is real and symmetric, $\Gamma\Gamma = 1$, $\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$ for every a, $\Gamma C = C\Gamma$ and $\Gamma S^{ab} = S^{ab}\Gamma$. Hence $\Gamma\Omega_\mu = \Omega_\mu\Gamma$ for EVERY connection $\Omega_\mu = \frac{1}{2}\sum \omega_{\mu ab} S^{ab}$, and

$$D_\mu(\Gamma\Psi) = \Gamma D_\mu\Psi, \qquad D_\mu(\bar\Psi\Gamma) = (D_\mu\bar\Psi)\Gamma.$$

Proof. Γ is the product of all eight different gammas. Moving $\gamma^{(b)}$ through it passes the seven factors $\gamma^{(a)}$, $a \neq b$, and the factor $\gamma^{(b)}$ itself; by Rule P the sign is $(-1)^7 = -1$, so $\gamma^{(b)}\Gamma = -\Gamma\gamma^{(b)}$. C is a product of four gammas and S^{ab} $(a \neq b)$ is $\frac{1}{2}$ times a product of two; moving Γ through them costs $(-1)^4 = +1$ and $(-1)^2 = +1$, so both commute with Γ ($S^{aa} = 0$ trivially). The product Γ of the author's gammas is computed exactly: $\Gamma = \mathrm{diag}(-I_8, I_8)$, which is real, symmetric and squares to 1. Since every Ω_μ is a combination of the S^{ab} with ordinary numbers as coefficients, Γ commutes with it. Finally

$$D_\mu(\Gamma\Psi) = \partial_\mu(\Gamma\Psi) + \Omega_\mu\Gamma\Psi = \Gamma\partial_\mu\Psi + \Gamma\Omega_\mu\Psi = \Gamma D_\mu\Psi.$$

The constant Γ passes through ∂_μ (a constant factor comes out of a derivative), and $\Omega_\mu\Gamma = \Gamma\Omega_\mu$. The adjoint statement, written out from the right:

$$D_\mu(\bar\Psi\Gamma) = \partial_\mu(\bar\Psi\Gamma) - \bar\Psi\Gamma\Omega_\mu = (\partial_\mu\bar\Psi)\Gamma - \bar\Psi\Omega_\mu\Gamma = (\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu)\Gamma = (D_\mu\bar\Psi)\Gamma.$$

The first equality is the rule $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$ of Section 18.4, applied to the row $\bar\Psi\Gamma$ (by Lemma 2 below it is the adjoint of $\Gamma\Psi$); the second takes the constant Γ out of ∂_μ and uses $\Gamma\Omega_\mu = \Omega_\mu\Gamma$; the third takes out the common factor Γ on the right, and the last recognises $D_\mu\bar\Psi$. QED.

statement	**status**	**where it is verified**
Lemma 1	PROVED	`wolfram-pairing.json`, check `Gamma_properties`; `python-pairing.json`, checks `gammas.Gamma` and `gammas.Gamma_ant icommutes`; Notebook 18a, In [6] and In [7]

Lemma 2 (bilinears under $\Psi \to \Gamma\Psi$). For $\Psi' = \Gamma\Psi$: $\bar\Psi' = \bar\Psi\Gamma$, and $\bar\Psi' X \Psi' = (-1)^k\, \bar\Psi X \Psi$ for every product X of k gammas. In particular S is unchanged and every bilinear with the kernel $C\gamma^{(a)}$, $C\gamma^{(a)}S^{bc}$ or $CS^{bc}\gamma^{(a)}$ changes sign. Moreover $\Gamma B\Gamma = -B$.

Proof. Line by line:

$$\bar{\Psi}' = (\Gamma\Psi)^\dagger C = \Psi^\dagger \Gamma^\dagger C.$$

This is the definition of the adjoint and the rule $(MN)^\dagger = N^\dagger M^\dagger$ (the dagger of a product reverses the order).

$$\Psi^\dagger \Gamma^\dagger C = \Psi^\dagger \Gamma C = \Psi^\dagger C \Gamma = \bar{\Psi}\Gamma.$$

Γ is real and symmetric, so $\Gamma^\dagger = \Gamma^T = \Gamma$; then $\Gamma C = C\Gamma$ (Lemma 1); then the definition $\bar{\Psi} = \Psi^\dagger C$.

$$\bar{\Psi}' X \Psi' = \bar{\Psi}\,\Gamma X \Gamma\,\Psi.$$

We inserted $\bar{\Psi}' = \bar{\Psi}\Gamma$ and $\Psi' = \Gamma\Psi$.

$$\Gamma X \Gamma = (-1)^k X\,\Gamma\Gamma = (-1)^k X.$$

Moving the left Γ through the k factors of X costs $(-1)^k$ (Lemma 1: Γ anticommutes with each gamma); then $\Gamma\Gamma = 1$. For S, $X = 1$ and $k = 0$; for the kinetic kernels $k = 1$; for the connection kernels $\gamma^{(a)} S^{bc}$ and $S^{bc}\gamma^{(a)}$ with $b \neq c$, $k = 3$ (when a equals b or c, two factors combine to η_{aa} and one gamma is left, $k = 1$: odd in every case). Finally

$$\Gamma B \Gamma = -i\,\Gamma C \gamma^{(x_4)} \Gamma = -i\,C\,\Gamma\gamma^{(x_4)}\Gamma = -i\,C(-\gamma^{(x_4)}) = +iC\gamma^{(x_4)} = -B.$$

The definition $B = -iC\gamma^{(x_4)}$; then $\Gamma C = C\Gamma$; then the line before with $k = 1$. QED. Nowhere were two field components exchanged: only the numbers of the matrices were moved, and every Ψ^* still stands to the left of every Ψ. So Lemma 2 holds for commuting and for Grassmann components alike.

statement	status	where it is verified
the sign $(-1)^k$ for all 256 products of different gammas	PROVED	Notebook 18a, In [9] and In [10]

Lemma 3 (the eight reflections). Let n be one of the eight directions and R_n its reflection.

1. $(\gamma^{(n)})^T C \gamma^{(n)} = -\eta_{nn} C$.
2. $\gamma^{(n)}\gamma^{(a)}(\gamma^{(n)})^{-1} = -(R_n)_{aa}\gamma^{(a)}$, and $\gamma^{(n)} S^{ab} (\gamma^{(n)})^{-1} = (R_n)_{aa}(R_n)_{bb} S^{ab}$.
3. $P_n := \Gamma\gamma^{(n)}$ is plus or minus the product of the seven other gammas, hence an element of Pin(4,4); $P_n^{-1}\gamma^{(a)}P_n = (R_n)_{aa}\gamma^{(a)}$ (it **covers** the reflection R_n: it acts on the gammas exactly as R_n acts on the directions); its character is $\chi_n = -\eta_{nn}$, that is $P_n^\dagger C P_n = -\eta_{nn} C$: -1 for the space-like x_0, x_1, x_2, x_3 and $+1$ for the time-like x_4, x_5, x_6, x_7; and $\Gamma P_n = \gamma^{(n)}$.

Proof of 1. Multiply $C\gamma^{(n)}C^{-1} = -(\gamma^{(n)})^T$ on the right by C: $C\gamma^{(n)} = -(\gamma^{(n)})^T C$. Then

$$(\gamma^{(n)})^T C \gamma^{(n)} = (\gamma^{(n)})^T\big(-(\gamma^{(n)})^T C\big) = -\big((\gamma^{(n)})^T\big)^2 C = -\big((\gamma^{(n)})^2\big)^T C = -\eta_{nn} C.$$

We replaced $C\gamma^{(n)}$, collected the two transposes, used $(M^T)^2 = (M^2)^T$ and the Clifford relation $(\gamma^{(n)})^2 = \eta_{nn} I_{16}$.

Proof of 2. $(\gamma^{(n)})^{-1} = \eta_{nn}\gamma^{(n)}$, because $\gamma^{(n)}\eta_{nn}\gamma^{(n)} = \eta_{nn}^2 = 1$. For $a \neq n$: $\gamma^{(n)}\gamma^{(a)}(\gamma^{(n)})^{-1} = -\gamma^{(a)}\gamma^{(n)}(\gamma^{(n)})^{-1} = -\gamma^{(a)}$ (anticommute, then cancel), and $-(R_n)_{aa} = -1$. For $a = n$: $\gamma^{(n)}\gamma^{(n)}(\gamma^{(n)})^{-1} = \gamma^{(n)}$, and $-(R_n)_{nn} = +1$. The statement for $S^{ab} = \frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ $(a \neq b)$ follows by inserting $(\gamma^{(n)})^{-1}\gamma^{(n)} = 1$ between the two factors: the two signs $-(R_n)_{aa}$ and $-(R_n)_{bb}$ multiply to $(R_n)_{aa}(R_n)_{bb}$.

Proof of 3. $\Gamma\gamma^{(n)}$ is the ordered product of the eight gammas followed by $\gamma^{(n)}$. Moving the last factor to its place next to the factor $\gamma^{(n)}$ inside Γ passes some of the other gammas, each costing a sign (Rule P); then $\gamma^{(n)}\gamma^{(n)} = \eta_{nn}$. So $P_n = \pm\eta_{nn}\times$ (the product of the seven other gammas in their order), a product of unit vectors, which lies in Pin(4,4). Next, with $(\gamma^{(n)})^{-1} = \eta_{nn}\gamma^{(n)}$ and $\Gamma^{-1} = \Gamma$:

$$P_n^{-1}\gamma^{(a)}P_n = (\gamma^{(n)})^{-1}\Gamma\gamma^{(a)}\Gamma\gamma^{(n)} = -(\gamma^{(n)})^{-1}\gamma^{(a)}\gamma^{(n)} = (R_n)_{aa}\gamma^{(a)}.$$

The inverse of a product reverses the order; $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$ (Lemma 2 with $k = 1$); and item 2, read with $(\gamma^{(n)})^{-1}$ on the left, which gives the same signs. For the character, P_n is real, so $P_n^\dagger = P_n^T = (\gamma^{(n)})^T\Gamma^T = (\gamma^{(n)})^T\Gamma$:

$$P_n^\dagger C P_n = (\gamma^{(n)})^T\,\Gamma C \Gamma\,\gamma^{(n)} = (\gamma^{(n)})^T C \gamma^{(n)} = -\eta_{nn} C.$$

We used $\Gamma C\Gamma = C\Gamma\Gamma = C$ (Lemma 1) and item 1. Finally $\Gamma P_n = \Gamma\Gamma\gamma^{(n)} = \gamma^{(n)}$. QED. The signs of P_n relative to the product of the other seven gammas, in the order of Γ, are $-1, +1, -1, +1, +1, -1, +1, -1$ for $n = x_0, \ldots, x_7$ (computed exactly; they equal the data table `reflections` of `pairing-theory.json`).

statement	status	where it is verified
Lemma 3, items 1 to 3	PROVED	`wolfram-pairing.json`, checks `T2_Pn_in_Pin44`, `T2_Pn_covers_the_reflection`, `T2_character_of_Pn`, `T2_Gamma_times_Pn_is_gamma_n` and `T2_kernels_gamma_n_with_frame_reflection`
the reflection table	PROVED	`python-pairing.json`, checks `T2.general_field.matrix_identities`, `T2.general_field.reflection_table` and `compare.theory.reflection_table`; Notebook 18a, In [12] and In [13]

Lemma 4 (the Krein signs of the maps). $MBM^\dagger = \sigma_M B$, with $\sigma_\Gamma = -1$; $\sigma_{\gamma^{(n)}} = +1$ for $n = x_0, x_1, x_2, x_3, x_4$ and -1 for $n = x_5, x_6, x_7$; and $\sigma_{P_n} = -\sigma_{\gamma^{(n)}}$.

Proof. Γ is real and symmetric, so $\Gamma B \Gamma^\dagger = \Gamma B \Gamma = -B$ by Lemma 2. For $M = \gamma^{(n)}$: transposing $C\gamma^{(n)}C^{-1} = -(\gamma^{(n)})^T$ and using $C^T = C = C^{-1}$ gives $\gamma^{(n)}C = -C(\gamma^{(n)})^T$. Then

$$\begin{aligned}\gamma^{(n)} B (\gamma^{(n)})^\dagger &= -i\,\gamma^{(n)} C \gamma^{(x_4)} (\gamma^{(n)})^T = i\,C(\gamma^{(n)})^T \gamma^{(x_4)} (\gamma^{(n)})^T \\ &= i\,\eta_{nn}^2\, C\gamma^{(n)}\gamma^{(x_4)}\gamma^{(n)} = i\,C\gamma^{(n)}\gamma^{(x_4)}\gamma^{(n)}.\end{aligned}$$

The definition of B and $(\gamma^{(n)})^\dagger = (\gamma^{(n)})^T$ (real matrix); then the relation $\gamma^{(n)}C = -C(\gamma^{(n)})^T$; then $(\gamma^{(n)})^T = \eta_{nn}\gamma^{(n)}$ twice; then $\eta_{nn}^2 = 1$. For $n \neq 4$: $\gamma^{(n)}\gamma^{(x_4)}\gamma^{(n)} = -\gamma^{(x_4)}\gamma^{(n)}\gamma^{(n)} = -\eta_{nn}\gamma^{(x_4)}$, so the result is $-i\eta_{nn}C\gamma^{(x_4)} = \eta_{nn}B$: $+B$ for x_0, x_1, x_2, x_3 and $-B$ for x_5, x_6, x_7. For $n = 4$: $\gamma^{(4)}\gamma^{(4)}\gamma^{(4)} = -\gamma^{(4)}$, so the result is $-iC\gamma^{(4)} = +B$. For $P_n = \Gamma\gamma^{(n)}$: $P_n B P_n^\dagger = \Gamma\,\gamma^{(n)} B (\gamma^{(n)})^\dagger\,\Gamma = \sigma_{\gamma^{(n)}}\Gamma B \Gamma = -\sigma_{\gamma^{(n)}} B$. QED.

statement	status	where it is verified
Lemma 4, the 17 Krein signs	PROVED	`wolfram-pairing.json`, check `Q_Krein_metric_of_images`; `python-pairing.json`, checks `compare.theory.krein_signs` and `Q.T2_image_keeps_B`; data table `Krein_signs_M_B_Mdagger` of `pairing-theory.json`; Notebook 18a, In [17]

The block form. Split $\Psi = (\psi_-, \psi_+)$ into its components 1 to 8 and 9 to 16. Because every gamma anticommutes with $\Gamma = \mathrm{diag}(-I_8, I_8)$, every gamma has nonzero entries only in the two off-diagonal

8×8 blocks (Chapter 5): it exchanges the two halves. The author's $\gamma^{(x_0)}$ has the identity I_8 in both off-diagonal blocks, so $\gamma^{(x_0)}(\psi_-, \psi_+) = (\psi_+, \psi_-)$. C, a product of four gammas, commutes with Γ and is block diagonal; for the author's gammas $C = \mathrm{diag}(-\sigma, \sigma)$ with a real symmetric 8×8 matrix σ, so

$$S = \Psi^\dagger C \Psi = -\psi_-^\dagger \sigma \psi_- + \psi_+^\dagger \sigma \psi_+ .$$

Reading this line: reversing the sign of one half (Γ) keeps S; exchanging the two halves ($\gamma^{(x_0)}$) reverses S. The two halves are the two inequivalent irreducible 8-dimensional representations of Spin(4,4) (Chapter 5).

18.6 Example: Notebook 18a checks the four lemmas

Notebook 18a first answers the question that every later step depends on: are the matrices of the Revision record really the author's? It rebuilds the eight matrices T16A[0], ..., T16A[7] from the author's own formulas (the tau matrices), maps the author's frame order (0 = hidden, 1 to 3 = 3-space, 4 = time, 5 to 7 = extra times) to the coordinates $x_0, \ldots, x_7$, and compares them entry by entry with `Revision/algebra/gammas.json`; it checks that they are real signed permutation matrices with entries -1, 0, $+1$ and that the 64 Clifford relations hold. Then it proves Lemmas 1 to 4 and the block form with exact whole-number arithmetic, compares the reflection table and the table of Krein signs with the data tables of the pairing record row by row, and draws seven teaching figures: the eight gammas, the sign flip $\Gamma\gamma^{(x_1)}\Gamma = -\gamma^{(x_1)}$, the parity of the 256 products, the reflection table, the chiral projectors, the block form and the Krein signs. Its last line is ALL 16 CHECKS PASSED (notebook 18a); it runs in about 15 seconds.

18.7 How to run Notebook 18a

Step 1. What this notebook does and what it needs.

Notebook 18a (The matrix facts behind the pairing theorems T1, T2 and Q) is the file `Revision/textbook/notebooks/18a_pairing_matrices.ipynb` of the repository Dirac_claude. It rebuilds the author's eight real 16 by 16 gamma matrices from the author's own formulas (the tau matrices),

checks that they equal the matrices of the Revision record, that every entry is -1, 0 or +1 and that they obey the Clifford relations, and builds C, the chirality Gamma, the chiral projectors, the Krein matrix B and the generators S^ab. With exact whole-number matrix arithmetic it then proves the four lemmas on which the pairing theorems rest: Gamma anticommutes with every gamma and commutes with C and with every S^ab; under the map from Psi to Gamma Psi a bilinear with k gamma factors gets the sign (-1)^k, so the scalar S is unchanged while all 456 kinetic and connection matrices of the Lagrangian change sign; the eight reflections P_n = Gamma gamma^n lie in Pin(4,4), act on the gammas as the reflections of the eight directions and have the character -1 for the space-like and +1 for the time-like directions; and the Krein signs of the 17 maps. It reproduces the reflection table and the Krein table of the Revision pairing record and the matrix checks of its two reports, and draws seven teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 18a_pairing_matrices.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18a_pairing_matrices.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 18a_pairing_matrices.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/18a.captions.json`
- `Revision/textbook/figures/18a_1_eight_gammas.png`
- `Revision/textbook/figures/18a_2_chirality_flips_gammas.png`
- `Revision/textbook/figures/18a_3_parity_of_products.png`
- `Revision/textbook/figures/18a_4_reflection_table.png`
- `Revision/textbook/figures/18a_5_chiral_projectors.png`
- `Revision/textbook/figures/18a_6_chiral_blocks.png`
- `Revision/textbook/figures/18a_7_krein_signs.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 16 CHECKS PASSED (notebook 18a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/18a_pairing_matrices.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 18a_pairing_matrices.ipynb
python -m nbconvert --execute --inplace 18a_pairing_matrices.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or pairing-theory.json: the notebook reads four files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.

18.8 Notebook 18a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/18a_pairing_matrices.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The pairing theorems of this chapter say what happens to the Lagrangian, the field
equations, the energy-momentum tensor and the current of the fields dirac16complex
and dirac16complex00 when the field $\Psi$ is replaced by $M\Psi$ for a fixed
$16 \times 16$ matrix $M$. Every step of their proofs is a statement about such
matrices. This notebook first shows that the matrices used are exactly the
author's: it rebuilds the eight real $16 \times 16$ gamma matrices from the
author's own formulas and compares them entry by entry with the Revision record.
Then it proves all the matrix statements of the theorems exactly, with
whole-number arithmetic (no rounding anywhere):

- **Lemma 1 (the chirality).** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots
  \gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$ is real and symmetric, $\Gamma^2 = 1$,
  $\Gamma$ anticommutes with each of the eight gammas and commutes with $C$ and with
  every generator $S^{ab}$; hence it commutes with every spin connection.
- **Lemma 2 (bilinears).** Under $\Psi \to \Gamma\Psi$ a bilinear
  $\bar\Psi M\Psi$ whose matrix $M$ is a product of $k$ gammas is multiplied by
  $(-1)^k$. The notebook checks this for all 256 products of different gammas and
  for all 456 matrices that occur in the kinetic and connection terms of the
  Lagrangian (they all change sign), while the scalar $S = \bar\Psi\Psi$ does not.
- **Lemma 3 (reflections).** For each direction $n$ the matrix
  $P_n = \Gamma\gamma^{(n)}$ is, up to a sign, the product of the other seven
  gammas (so it belongs to the group Pin(4,4)); it acts on the gammas as the
  reflection of the direction $n$; its *character* is $-1$ for the space-like
  directions $x_0, x_1, x_2, x_3$ and $+1$ for the time-like ones
  $x_4, x_5, x_6, x_7$. The notebook rebuilds the reflection table of the Revision
  pairing record row by row.
- **Lemma 4 (Krein signs).** $MBM^\dagger = \pm B$ for the 17 maps
  $M = \Gamma, \gamma^{(n)}, P_n$, with the signs of the Revision record.

It also builds the two chiral projectors and the block form behind the theorems
(the two chiral halves) and draws seven teaching figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 18a (The matrix facts behind the pairing theorems T1, T2 and Q) is the file
```

‘Revision/textbook/notebooks/18a_pairing_matrices.ipynb‘ of the repository Dirac_claude. It rebuilds the author’s eight real 16 by 16 gamma matrices from the author’s own formulas (the tau matrices), checks that they equal the matrices of the Revision record, that every entry is -1, 0 or +1 and that they obey the Clifford relations, and builds C, the chirality Gamma, the chiral projectors, the Krein matrix B and the generators S^ab. With exact whole-number matrix arithmetic it then proves the four lemmas on which the pairing theorems rest: Gamma anticommutes with every gamma and commutes with C and with every S^ab; under the map from Psi to Gamma Psi a bilinear with k gamma factors gets the sign (-1)^k, so the scalar S is unchanged while all 456 kinetic and connection matrices of the Lagrangian change sign; the eight reflections P_n = Gamma gamma^n lie in Pin(4,4), act on the gammas as the reflections of the eight directions and have the character -1 for the space-like and +1 for the time-like directions; and the Krein signs of the 17 maps. It reproduces the reflection table and the Krein table of the Revision pairing record and the matrix checks of its two reports, and draws seven teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 18a_pairing_matrices.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18a_pairing_matrices.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 18a_pairing_matrices.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/18a.captions.json‘
- ‘Revision/textbook/figures/18a_1_eight_gammas.png‘
- ‘Revision/textbook/figures/18a_2_chirality_flips_gammas.png‘
- ‘Revision/textbook/figures/18a_3_parity_of_products.png‘
- ‘Revision/textbook/figures/18a_4_reflection_table.png‘
- ‘Revision/textbook/figures/18a_5_chiral_projectors.png‘
- ‘Revision/textbook/figures/18a_6_chiral_blocks.png‘
- ‘Revision/textbook/figures/18a_7_krein_signs.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 16 CHECKS PASSED (notebook 18a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
    python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/18a_pairing_matrices.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
    python -m jupyterlab 18a_pairing_matrices.ipynb
    python -m nbconvert --execute --inplace 18a_pairing_matrices.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or pairing-theory.json: the notebook reads four files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository (a notebook copied alone to another folder cannot find them). Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 18a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 18a (The matrix facts behind the pairing theorems T1, T2 and Q) is the file
```

```
# Revision/textbook/notebooks/18a_pairing_matrices.ipynb of the repository Dirac_claude.
# It rebuilds the author's eight real 16 by 16 gamma matrices from the author's own
# formulas (the tau matrices), checks that they equal the matrices of the Revision
# record, that every entry is -1, 0 or +1 and that they obey the Clifford relations, and
# builds C, the chirality Gamma, the chiral projectors, the Krein matrix B and the
# generators S^ab. With exact whole-number matrix arithmetic it then proves the four
# lemmas on which the pairing theorems rest: Gamma anticommutes with every gamma and
# commutes with C and with every S^ab; under the map from Psi to Gamma Psi a bilinear
# with k gamma factors gets the sign (-1)^k, so the scalar S is unchanged while all 456
# kinetic and connection matrices of the Lagrangian change sign; the eight reflections
# P_n = Gamma gamma^n lie in Pin(4,4), act on the gammas as the reflections of the eight
# directions and have the character -1 for the space-like and +1 for the time-like
# directions; and the Krein signs of the 17 maps. It reproduces the reflection table and
# the Krein table of the Revision pairing record and the matrix checks of its two
# reports, and draws seven teaching figures. It needs a computer with Windows 11, macOS
# or Linux, an internet connection for the installation, the program Git, and Python 3.12
# or newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
```

```
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip

#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 18a_pairing_matrices.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 18a_pairing_matrices.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
```

```
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 18a_pairing_matrices.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/18a.captions.json
# - Revision/textbook/figures/18a_1_eight_gammas.png
# - Revision/textbook/figures/18a_2_chirality_flips_gammas.png
# - Revision/textbook/figures/18a_3_parity_of_products.png
# - Revision/textbook/figures/18a_4_reflection_table.png
# - Revision/textbook/figures/18a_5_chiral_projectors.png
# - Revision/textbook/figures/18a_6_chiral_blocks.png
# - Revision/textbook/figures/18a_7_krein_signs.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 16 CHECKS PASSED (notebook 18a)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/18a_pairing_matrices.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
```

```
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 18a_pairing_matrices.ipynb
#     python -m nbconvert --execute --inplace 18a_pairing_matrices.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for gammas.json or pairing-theory.json: the notebook reads four
#   files of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository (a notebook copied
#   alone to another folder cannot find them). Clone the repository again and open the
#   notebook there.
#

## 3. The words used in this notebook

- **Matrix, entry, product**: a matrix is a table of numbers; $M_{AB}$ is the entry
  in row $A$ and column $B$; in code ‘M @ N‘ is the matrix product and
  ‘np.eye(16)‘ the identity $I_{16}$ (1 on the diagonal, 0 elsewhere).
- **Transpose, dagger**: $M^T$ exchanges rows and columns; $M^\dagger = (M^T)^*$
  also replaces every $i$ by $-i$. For a real matrix $M^\dagger = M^T$.
- **Real matrix**: a matrix whose entries are real numbers (no $i$). The author’s
```

```
  gammas are even simpler: every entry is $-1$, $0$ or $+1$.
- **Signed permutation matrix**: a matrix with exactly one nonzero entry, $+1$ or
  $-1$, in every row and in every column. Multiplying a column of 16 numbers by it
  reorders the numbers and changes some signs.
- **Symmetric, antisymmetric**: $M^T = M$, respectively $M^T = -M$.
- **Commute, anticommute**: $MN = NM$, respectively $MN = -NM$.
- **Gamma matrices** $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$: the author's real
  $16 \times 16$ matrices with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}
  = 2\eta^{ab}I_{16}$ (the *Clifford relation*), $\eta = \mathrm{diag}(+1, +1, +1,
  +1, -1, -1, -1, -1)$ in the order $x_0, \dots, x_7$.
- **Space-like, time-like direction**: $\eta_{nn} = +1$ ($x_1, x_2, x_3$ and the
  hidden direction $x_0$), respectively $\eta_{nn} = -1$ (the time $x_4$ and the
  three EXTRA TIMES $x_5, x_6, x_7$, which deflate exponentially in the author's
  metric).
- **$C$**: $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, the
  product of the four space-like gammas (the author's sigma16). The Dirac adjoint
  is $\bar\Psi = \Psi^\dagger C$.
- **Chirality** $\Gamma$: the product of all eight gammas in the order
  $x_0, x_1, \dots, x_7$ (the author's T16A[8]).
- **Projector**: a matrix $P$ with $P^2 = P$. The *chiral projectors*
  $P_- = \frac12(1 - \Gamma)$ and $P_+ = \frac12(1 + \Gamma)$ (the author's P_L and
  P_R) keep one half of the 16 components and set the other half to zero.
- **$B$**: $B = -iC\gamma^{(x_4)}$, the Krein matrix; the charge density of the
  field is $\Psi^\dagger B\Psi$ and $B$ is the matrix of the canonical
  anticommutator of the quantised field.
- **Generators** $S^{ab} = \frac14[\gamma^{(a)}, \gamma^{(b)}]$, where
  $[M, N] = MN - NM$ is the commutator; for $a \neq b$, $S^{ab} = \frac12
  \gamma^{(a)}\gamma^{(b)}$. A spin connection is $\Omega_\mu = \frac12\sum_{a,b}
  \omega_{\mu ab}S^{ab}$ with numbers or functions $\omega_{\mu ab}$.
- **Bilinear**: an expression $\Psi^\dagger X\Phi = \sum_{A,B}\Psi_A^* X_{AB}
  \Phi_B$ with a matrix $X$ of numbers; $X$ is called its *kernel*.
- **Reflection** $R_n$: the $8 \times 8$ diagonal matrix with $-1$ in place $n$
  and $+1$ elsewhere; it reverses the direction $n$.
- **Pin(4,4)**: the group of all products of unit vectors $\sum_a v_a\gamma^{(a)}$
  with $\sum_a\eta_{aa}v_a^2 = \pm1$ and their inverses; each single
  $\gamma^{(a)}$ is such a unit vector, so every product of gammas belongs to it.
- **Character** $\chi$ of a map $M$: the sign in $M^\dagger CM = \chi C$; it tells
  whether the scalar $S = \bar\Psi\Psi$ keeps ($\chi = +1$) or changes ($\chi = -1$)
  its sign under $\Psi \to M\Psi$.
- **Krein sign** $\sigma$ of a map $M$: the sign in $MBM^\dagger = \sigma B$.
- **Chiral halves**: the components 1 to 8 of $\Psi$ (where $\Gamma = -1$, written
  $\psi_-$) and 9 to 16 (where $\Gamma = +1$, written $\psi_+$).
- **Exact**: the gammas, $C$, $\Gamma$, $4S^{ab}$ and $B/i$ have whole-number
  entries; numpy multiplies whole numbers without rounding, so every equality
  checked here is an exact identity, a proof for that identity.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's coordinates are $x_1, x_2, x_3$ (ordinary 3-space, inflating),
$x_4$ (the time), $x_5, x_6, x_7$ (the three extra times, deflating exponentially:
their scale factor is $e^{-a_4}\sin^{1/6}z$ with $a_4$ increasing) and $x_0$ (the
```

hidden space direction, $z = 6Hx_0$). Both fields have the Lagrangian density

$$\mathcal{L}_{m,\lambda}[\Psi] = \sqrt{|g|}\,\Big[K - mS - \frac{\lambda}{2}S^2
\Big],\qquad K = \frac12\big(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)
\gamma^\mu\Psi\big),\qquad S = \bar\Psi\Psi ,$$

with $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $\gamma^\mu =
\sum_a e^\mu{}_a\gamma^{(a)}$. The pairing theorems are:

- **T1**: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$ in
  every gravitational field; solutions of the (m, λ) equations go to
  solutions of the $(-m, -\lambda)$ equations; the energy-momentum tensor and the
  current change sign.
- **T2**: with the reflection of a space-like direction n,
  $\mathcal{L}_{m,\lambda}[\gamma^{(n)}\Psi;\,R_ne] =
  +\mathcal{L}_{-m,\lambda}[\Psi;\,e]$: the mass changes sign, the coupling does
  not, and the energy-momentum tensor is NOT reversed.
- **Q** (the quantised dirac16complex): the image $\Gamma\Psi$ carries the Krein
  matrix $-B$ instead of B.

Why matrix identities are enough, line by line. Let $\Psi' = M\Psi$ with a
constant real matrix M. The dagger of a product reverses the order:

$$\Psi'^\dagger = (M\Psi)^\dagger = \Psi^\dagger M^\dagger = \Psi^\dagger M^T .$$

Multiply on the right by C to get the adjoint of the new field:

$$\bar\Psi' = \Psi'^\dagger C = \Psi^\dagger M^TC .$$

For $M = \Gamma$: $\Gamma^T = \Gamma$ (Lemma 1) and $\Gamma C = C\Gamma$ (Lemma 1),
so $\bar\Psi' = \Psi^\dagger\Gamma C = \Psi^\dagger C\Gamma = \bar\Psi\Gamma$. A
bilinear with a matrix X in the middle therefore becomes

$$\bar\Psi' X\Psi' = \bar\Psi\,\Gamma X\Gamma\,\Psi .$$

If X is a product of k gammas, moving the left Γ through the k
factors costs k signs (Lemma 1: $\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$), and
then $\Gamma\Gamma = 1$:

$$\Gamma X\Gamma = (-1)^k X\,\Gamma\Gamma = (-1)^k X .$$

So $S = \bar\Psi\Psi$ ($k = 0$) is unchanged, and every kinetic term
$\bar\Psi\gamma^{(a)}\partial_\mu\Psi$ ($k = 1$) changes sign. Only constant
numbers were moved, never two field components, so the same lines hold for
commuting components (dirac16complex00) and for anticommuting (Grassmann)
components (dirac16complex). The coefficients $\sqrt{|g|}$, $e^\mu{}_a$ and
$\omega_{\mu ab}$ of the gravitational field are ordinary functions that multiply
these bilinears; they are untouched by the map. That is why T1 holds in EVERY
gravitational field, and why this notebook needs only matrices.

Text cell:

5. The author's eight real gamma matrices, C, Γ and B

The next cell imports numpy, defines the helpers that read the Revision records, reads the author's gamma matrices from `Revision/algebra/gammas.json` (whole numbers) and checks the 64 Clifford relations. The helper `reproduces` is a check that passes only when this notebook's own result holds AND the named checks of the named Revision reports have the verdict PASS; it prints the report files and the check names.

In [2]:

```

Text cell:

```
**Are these the author's matrices?** The author's notebook defines its gamma
matrices T16A[0], ..., T16A[7] by explicit formulas, and the next cell repeats
those formulas step by step and compares the result with the record. The steps:

1. For $h = 1, 2, 3$ two $4 \times 4$ matrices with entries
   $(s_h)_{pq} = Q_a - Q_b$ and $(t_h)_{pq} = Q_a + Q_b$ ($p, q = 1, \dots, 4$),
   where $Q_a$ is the sign of the arrangement $(h, p, q, 4)$ (the *permutation
   sign*: $+1$ or $-1$ according to whether an even or odd number of exchanges
   sorts it, and 0 when two of the four numbers are equal) and
   $Q_b = \delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4}$ with the Kronecker
   delta ($\delta_{pq} = 1$ for $p = q$, else 0).
2. Eight $8 \times 8$ matrices $\tau_0 = I_8$, $\tau_h = \begin{pmatrix} 0 & s_h
   \\ s_h & 0 \end{pmatrix}$, $\tau_{7-h} = \begin{pmatrix} 0 & t_h \\ -t_h & 0
   \end{pmatrix}$ ($h = 1, 2, 3$) and $\tau_7 = \tau_1\tau_2\cdots\tau_6$.
3. $\bar\tau_A = \sigma\tau_A^T\sigma$ with $\sigma = \begin{pmatrix} 0 & I_4 \\
   I_4 & 0 \end{pmatrix}$.
4. $\mathrm{T16A}[A] = \begin{pmatrix} 0 & \bar\tau_A \\ \tau_A & 0
   \end{pmatrix}$, $A = 0, \dots, 7$.
5. The author's notebook counts its frame from 0 (0 = hidden direction, 1 to 3 =
   3-space, 4 = time, 5 to 7 = extra times); in the author's coordinates
   $\gamma^{(x_0)} = $ T16A[0], $\gamma^{(x_n)} = $ T16A[n] for $n = 1, \dots, 7$.

The cell then checks that the record holds exactly eight matrices, each with 16
rows and 16 columns, each REAL with every entry equal to $-1$, $0$ or $+1$, each a
signed permutation matrix, with $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$, and that
they equal the rebuilt T16A entry by entry.

## 6. Lemma 1: the chirality $\Gamma$

The next cell checks every part of Lemma 1 exactly: $\Gamma =
\mathrm{diag}(-I_8, I_8)$; $\Gamma$ is real and symmetric and $\Gamma^2 = 1$;
$\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$ for each of the eight gammas;
```

```
$\Gamma C = C\Gamma$; and $\Gamma S^{ab} = S^{ab}\Gamma$ for all 64 pairs
$(a, b)$. Since $S^{ab} = \frac14(\gamma^{(a)}\gamma^{(b)} -
\gamma^{(b)}\gamma^{(a)})$ has quarters and halves as entries, the cell uses
$4S^{ab}$, which has whole-number entries; $\Gamma$ commutes with $S^{ab}$ exactly
when it commutes with $4S^{ab}$.

Why these hold: $\Gamma$ is the product of all eight different gammas. Moving
$\gamma^{(b)}$ through it passes seven factors that anticommute with $\gamma^{(b)}$
and one ($\gamma^{(b)}$ itself) that commutes with it: the sign is $(-1)^7 = -1$.
$C$ (four gammas) and $S^{ab}$ (two gammas when $a \neq b$) contain an even number
of gammas, so $\Gamma$ passes them with the sign $(-1)^{\mathrm{even}} = +1$.
```

In [6]:

```
four_S = {(a, b): gamma[a] @ gamma[b] - gamma[b] @ gamma[a]  # 4 S^ab, whole numbers

Text cell:

```
Lemma 1 says that $\Gamma$ commutes with EVERY spin connection
$\Omega_\mu = \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$, whatever the numbers
$\omega_{\mu ab}$ are, because it commutes with each $S^{ab}$. The next cell
illustrates this with numbers: it draws an arbitrary antisymmetric table
$\omega_{ab} = -\omega_{ba}$ of random numbers (with a fixed seed, so that every run
draws the same numbers), forms $\Omega = \frac12\sum_{a,b}\omega_{ab}S^{ab}$ and
measures the largest entry of $\Gamma\Omega - \Omega\Gamma$. This is an
illustration (floating-point numbers); the proof is the exact check above.
```

In [7]:

```

## 7. Lemma 2: the sign of every bilinear under $\Psi \to \Gamma\Psi$

Section 4 showed that the map $\Psi \to \Gamma\Psi$ turns a bilinear
$\bar\Psi X\Psi$ into $\bar\Psi\,\Gamma X\Gamma\,\Psi$. The next cell forms all
$2^8 = 256$ products $X = \gamma^{(a_1)}\cdots\gamma^{(a_k)}$ of different gammas
($a_1 < \dots < a_k$, $k = 0, \dots, 8$; the empty product $k = 0$ is $I_{16}$),
determines for each the sign $s$ in $\Gamma X\Gamma = sX$, and checks that
$s = (-1)^k$ every time. It also counts the products of each length $k$; there are
$\binom{8}{k}$ of them (the number of ways to choose $k$ of 8 directions).
```

In [9]:

```

Text cell:

```
The next cell checks the matrices that actually occur in the Lagrangian. Written
out with the vielbein $e^\mu{}_a$ and the connection $\omega_{\mu bc}$, the kinetic
term is

$$K = \frac12\sum_{\mu,a}e^\mu{}_a\big(\bar\Psi\gamma^{(a)}\partial_\mu\Psi -
\partial_\mu\bar\Psi\gamma^{(a)}\Psi\big) + \frac14\sum_{\mu,a,b,c}e^\mu{}_a
\omega_{\mu bc}\,\bar\Psi\{\gamma^{(a)}, S^{bc}\}\Psi ,$$

where $\{M, N\} = MN + NM$. As bilinears in $\Psi^\dagger$ and $\Psi$ their kernels
are $C\gamma^{(a)}$ (8 matrices) and $C\gamma^{(a)}S^{bc}$, $CS^{bc}\gamma^{(a)}$
with $b < c$ (224 each): 456 matrices in all, the list of the sympy verifier.
Since $\Gamma$ is real and symmetric, the kernel $X$ of $\Psi^\dagger X\Psi$
becomes $\Gamma^TX\Gamma = \Gamma X\Gamma$. The cell checks $\Gamma X\Gamma = -X$
for all 456 kernels and $\Gamma C\Gamma = +C$ for the kernel of $S$. It also checks
the form used by the Wolfram verifier, $\Gamma C\{\gamma^{(a)}, S^{bc}\}\Gamma =
-C\{\gamma^{(a)}, S^{bc}\}$ for all $8^3 = 512$ triples $(a, b, c)$, the
field-equation kernels $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$ and
$\Gamma S^{bc}\Gamma = S^{bc}$, and $\Gamma B\Gamma = -B$ (the last part of
Lemma 2). Products with $S^{bc}$ are formed with $4S^{bc}$ (whole numbers).
```

Text cell:

```
## 8. Lemma 3: the eight reflections and their Pin(4,4) lifts

For each direction $n = x_0, \dots, x_7$ the next cell forms $P_n = \Gamma
\gamma^{(n)}$ and checks, exactly:

1. $P_n$ equals $+$ or $-$ the product of the other seven gammas in the order of
   $\Gamma$ ($x_0, x_1, \dots, x_7$ without $n$), so it is a product of unit
   vectors and lies in Pin(4,4); the signs are recorded.
2. $P_n$ is a signed permutation matrix, so $P_n^{-1} = P_n^T$, and
   $P_n^{-1}\gamma^{(a)}P_n = (R_n)_{aa}\gamma^{(a)}$ for all $a$: $P_n$ acts on the
   gammas exactly as the reflection $R_n$ of the direction $n$.
3. The character: $P_n^\dagger CP_n = \chi_nC$ with $\chi_n = -\eta_{nn}$.
4. $\Gamma P_n = \gamma^{(n)}$ (because $\Gamma\Gamma = 1$): "$\Gamma$ combined with
   the reflection $P_n$" acts on the field as the single matrix $\gamma^{(n)}$.
5. For $M = \gamma^{(n)}$ together with the reflected frame: the scalar sign
   $M^TCM = -\eta_{nn}C$; the kinetic kernels $M^TC\gamma^{(a)}M =
   \eta_{nn}(R_n)_{aa}C\gamma^{(a)}$ (the factor $(R_n)_{aa}$ is absorbed by the
   reflected frame, so the kinetic term gets the sign $\eta_{nn}$); and the 512
   connection kernels $M^TC\{\gamma^{(a)}, S^{bc}\}M = \eta_{nn}(R_n)_{aa}
   (R_n)_{bb}(R_n)_{cc}C\{\gamma^{(a)}, S^{bc}\}$ (the connection of the reflected
   frame is $R_n\omega R_n$, which absorbs the other two factors).

From items 3 and 5: for a space-like $n$ the kinetic term is unchanged and $S$
changes sign, so $\mathcal{L}_{m,\lambda} \to \mathcal{L}_{-m,\lambda}$ (T2); for a
time-like $n$ the kinetic term changes sign and $S$ does not, so
$\mathcal{L}_{m,\lambda} \to -\mathcal{L}_{-m,-\lambda}$ (a map of the T1 type).

## 9. The chiral projectors and the two halves

The author's notebook also defines the two *chiral projectors*
$P_L = \frac12(1 - \Gamma)$ and $P_R = \frac12(1 + \Gamma)$; we write them
$P_- = P_L$ and $P_+ = P_R$. Since $\Gamma = \mathrm{diag}(-I_8, I_8)$,
$P_- = \mathrm{diag}(I_8, 0)$ keeps the components 1 to 8 ($\psi_-$) and $P_+ =
\mathrm{diag}(0, I_8)$ keeps 9 to 16 ($\psi_+$). The next cell checks, exactly:

- $P_\pm^2 = P_\pm$ (projectors), $P_- + P_+ = 1$, $P_-P_+ = 0$, each of rank 8;
- $\Gamma = P_+ - P_-$: the T1 image is $\Gamma\Psi = P_+\Psi - P_-\Psi$, the field
  with the relative sign of its two halves reversed;
- $\gamma^{(a)}P_- = P_+\gamma^{(a)}$ for all eight gammas: a gamma takes the
  $\psi_-$ half into the $\psi_+$ half (and back), because it anticommutes with
  $\Gamma$;
- $CP_\pm = P_\pm C$ and $S^{ab}P_\pm = P_\pm S^{ab}$: $C$ and the generators of
  Spin(4,4) keep each half, which is why the two halves are separate
  representations of Spin(4,4).
```

In [15]:

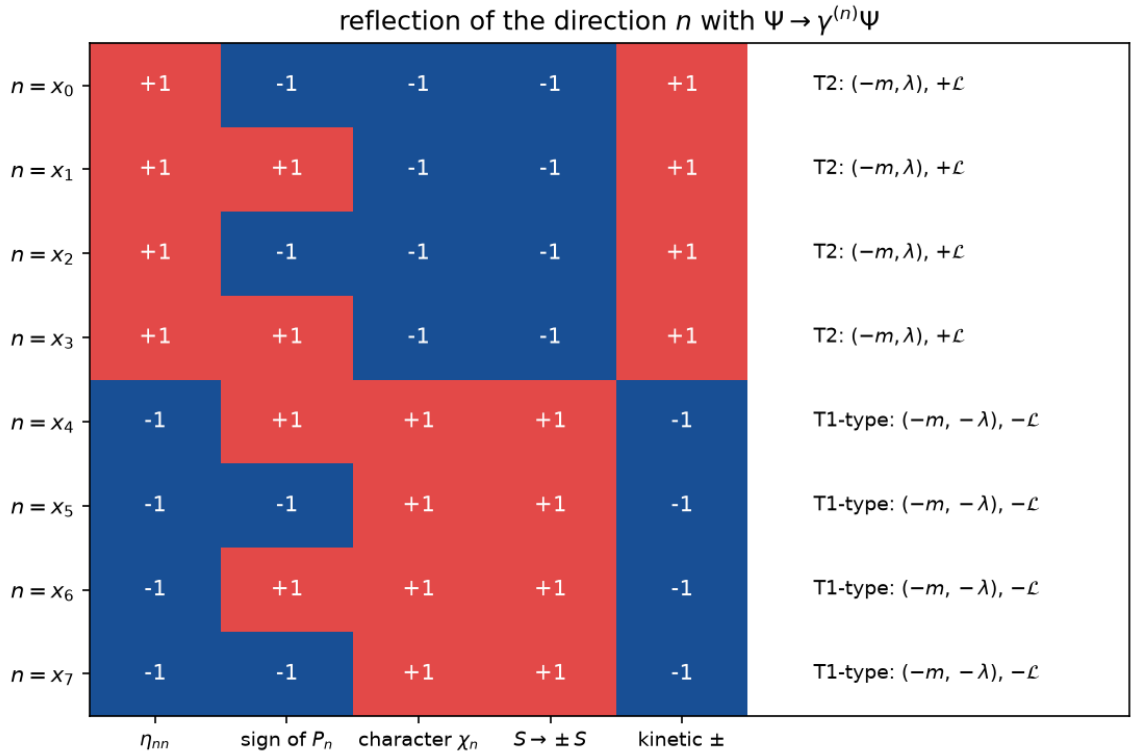

Figure 475: The reflection table of Lemma 3, one row for each direction n (the space-like x_0, x_1, x_2, x_3 and the time-like x_4 to x_7). Columns: the sign η_{nn} of the direction; the sign of $P_n = \Gamma\gamma^{(n)}$ relative to the product of the other seven gammas; the character χ_n in $P_n^\dagger C P_n = \chi_n C$; the sign of S and of the kinetic term under $\Psi \to \gamma^{(n)}\Psi$ with the reflected frame. Red is $+1$, blue is -1. The character is always $-\eta_{nn}$. A space-like reflection keeps the kinetic term and reverses S: the mass changes sign and the coupling does not (theorem T2). A time-like reflection does the opposite, which gives a map of the T1 type. The table equals the Revision record row by row. (Notebook 18a, figure 4.)

The next cell checks the block form behind the theorems. Split
$\Psi = (\psi_-, \psi_+)$ into its first and second eight components. Then

- $\Gamma(\psi_-, \psi_+) = (-\psi_-, \psi_+)$: the T1 image reverses the
  relative sign of the two halves;
- every gamma has nonzero entries only in the two off-diagonal $8 \times 8$ blocks
  (it exchanges the halves), and $\gamma^{(x_0)}$ has the identity $I_8$ in both
```

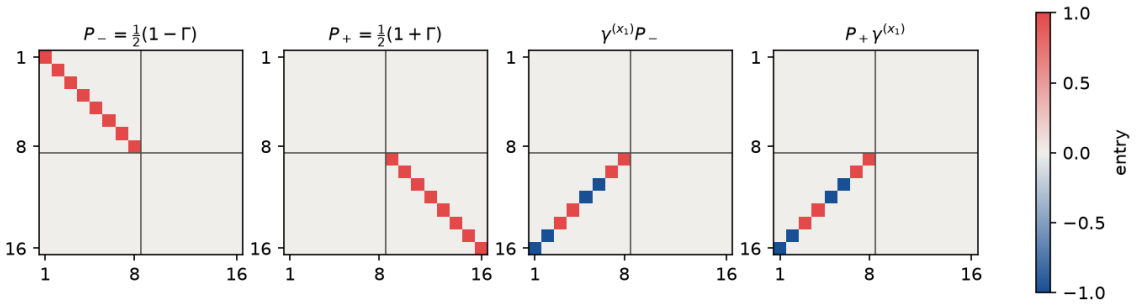

Figure 476: Heat maps of the two chiral projectors and of one gamma between them; columns horizontal, rows vertical, red +1, blue −1, grey 0, thin lines between the halves. P_- (first picture, the author's P_L) is the identity on the components 1 to 8 and zero elsewhere; P_+ (second, the author's P_R) is the identity on 9 to 16. Their difference is Γ. The third and fourth pictures are equal: $\gamma^{(x_1)} P_- = P_+ \gamma^{(x_1)}$, so the gamma takes a field that lives in the first half into the second half. The T1 image $\Gamma\Psi = P_+\Psi - P_-\Psi$ reverses the relative sign of the two halves. (Notebook 18a, figure 5.)

```
  of them, so $\gamma^{(x_0)}(\psi_-, \psi_+) = (\psi_+, \psi_-)$: the T2 image
  exchanges the two halves;
- $C$ (a product of four gammas, an even number of exchanges) is block diagonal,
  $C = \mathrm{diag}(-\sigma, \sigma)$ with an $8 \times 8$ matrix $\sigma$, so
  $S = -\psi_-^\dagger\sigma\psi_- + \psi_+^\dagger\sigma\psi_+$. Exchanging the
  halves therefore reverses $S$, and reversing one half keeps $S$.
```

## 10. Lemma 4: the Krein signs of the 17 maps

For the quantised field dirac16complex the canonical anticommutator is
$\{\Psi_A, \Psi_B^\dagger\} = B_{AB}\,\delta/\sqrt{|g|}$. For the image field
$M\Psi$ it becomes $(MBM^\dagger)_{AB}\,\delta/\sqrt{|g|}$. The next cell computes
the sign $\sigma$ in $MBM^\dagger = \sigma B$ for the 17 maps $M = \Gamma$,
$M = \gamma^{(n)}$ and $M = P_n$, and compares the list with the data table
‘Krein_signs_M_B_Mdagger‘ of the pairing record. It uses $B = i\,$‘B_over_i‘:
$MBM^\dagger = i\,M\,$‘B_over_i‘$\,M^T$ for a real $M$, so whole numbers suffice.
```

In [17]:

## 12. What this notebook showed

- PROVED (exact whole-number comparison): the eight matrices used by the Revision
  record, and by every notebook of this chapter, are the author's own: they are
  real $16 \times 16$ signed permutation matrices with entries $-1, 0, +1$, they
  obey the 64 Clifford relations of signature (4,4), and they equal the matrices
  T16A[0..7] rebuilt here from the author's formulas, in the author's coordinates
  $x_0, \dots, x_7$.
- PROVED (exact whole-number identities of the author's gammas, the same as the
  Revision pairing record's): Lemma 1, $\Gamma = \mathrm{diag}(-I_8, I_8)$
  anticommutes with every gamma and commutes with $C$, with every $S^{ab}$ and
  therefore with every spin connection.
- PROVED: Lemma 2, under $\Psi \to \Gamma\Psi$ a bilinear with $k$ gamma factors
  gets the sign $(-1)^k$ (all 256 products); all 456 kinetic and connection
  kernels of the Lagrangian change sign while the scalar $S$ is unchanged; and
  $\Gamma B\Gamma = -B$. Together with the linearity of the Lagrangian in the
  coefficients of the gravitational field this is the proof of theorem T1 in every
  gravitational field, for commuting and for Grassmann components.
- PROVED: Lemma 3, the reflection table: $P_n = \Gamma\gamma^{(n)}$ lies in
  Pin(4,4), acts on the gammas as the reflection $R_n$, has the character
  $-\eta_{nn}$; a space-like reflection maps $(m, \lambda)$ to $(-m, \lambda)$ with
  $\mathcal{L} \to +\mathcal{L}$ (theorem T2), a time-like one gives a map of the
  T1 type. The table equals the record's row by row.
- PROVED: the chiral projectors $P_\mp = \frac12(1 \mp \Gamma)$ split the 16
  components into two halves of 8; every gamma exchanges the halves, $C$ and the
  $S^{ab}$ keep them.
- PROVED: Lemma 4, the Krein signs of the 17 maps, equal to the record's: the T1
  image carries $-B$, the T2 image $+B$.
- NOT shown here: anything about a particular solution, the author's metric or
  the creation of universes; the matrix lemmas are the algebraic input of the
  theorems, which map solutions to solutions and say nothing about how any
  universe comes into being.
```

18.9 Line-by-line walk-through of Notebook 18a

The notebook has 19 code cells, In [1] to In [19]. This section explains every line of every one of them. The words of the notebook's section 3 are defined there, and in this chapter as follows: matrix and transpose in the Notation paragraph of Section 18.1 (matrices themselves in Chapter 1); signed permutation matrix, projector, character and Krein sign in Section 18.2; the characters and the Krein signs of the maps again in Lemmas 3 and 4 of Section 18.5.

In [1], the set-up cell. Its first part repeats the complete run instructions of Section 18.7 as **comment lines**: every line that starts with `#` is a comment, which Python skips; they are there so that the notebook file carries its own instructions. The code starts below the line THE SET-UP between two lines of `=` signs. This code is the same in every notebook of the book except for the line that names the notebook; it is explained here once, and the walk-throughs of Notebooks 18b

and 18c refer back to this explanation. The texts in triple quotes below a `def` line are **docstrings**: they describe the function and do nothing when the code runs.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json` reads and writes JSON files (text files that hold names, lists and numbers), `os` reads environment variables, `textwrap` breaks long texts into lines, and `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system. matplotlib is the plotting package; its drawing functions are loaded under the short name `plt`. `Image` and `display` come from IPython, the part of Jupyter that runs Python code; together they show a saved picture below a cell.

```
NOTEBOOK_ID = "18a"  # this notebook: chapter 18, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"18a"`; the figure files and the last printed line use it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` lists its parent folder, the parent of that, and so on; `[here, *here.parents]` is the list that starts with `here` and continues with all of them. The `for` loop takes the folders one after the other; `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If there is none, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

`REPO` is the repository folder found by the function; it is never printed, because it differs from computer to computer while the printed output of a notebook must not. `OUTPUT_ROOT` is the folder below which files are written. `os.environ` holds the **environment variables** (named texts that a program receives from the computer); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and the repository folder otherwise. When you run the notebook the variable is not set; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` returns the full path of a repository file, for reading a Revision record. `output_file("Revision/...")` returns the full path at which to write a file; before that, `path.parent.mkdir(parents=True, exist_ok=True)` creates its folder (and every missing folder above it) and does nothing if the folder exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of the book: `textwrap.fill` breaks the text at blanks, and every line after the first starts with four blanks. `str(text)` first turns any value into text.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings of matplotlib, so that the figures are the same on every computer. `plt.rcParams.update({...})` then sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid behind the curves. The braces make a **dictionary**, a collection of pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: each name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/18a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary `{}` and a line end into the captions file, which `save_figure` then fills; `encoding="utf-8"` fixes how letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` is called once for every figure. `setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far; so the figures are numbered 1, 2, 3, and a cell run twice keeps its number. The file name joins the notebook id, the number and the name, for example `18a_1_eight_gammas.png`. `fig.savefig` writes the picture as a PNG file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory (otherwise Jupyter would draw it a second time). The caption is stored, and the whole dictionary of captions is written to the captions file (`json.dumps` turns it into JSON text with sorted keys). `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
```

```
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list**, an ordered collection written with square brackets. `check` is the function behind every check of the book. `condition` is either `True` or `False`. If it is false, `raise AssertionError(...)` stops the notebook with an error that names the check (Python's own statement `assert` is not used here, because Python started with the option `-O` skips it). If it is true, the name is appended to `PASSED` and the line PASS name is printed; when the optional third argument `record` names a Revision record, a second line says which record and which check the result reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT, followed by the unit when one is given (`a if condition else b` is `a` when the condition holds and `b` otherwise). `all_checks_passed` prints the last line of the notebook with the number of checks that passed (`len` is the length of a list). The last statement prints the single output line of In [1].

In [2], the record helpers, the gammas and the Clifford relations.

```
import itertools  # all subsets of a list (for the 256 products of gammas)
from math import comb  # binomial coefficients: comb(8, k) = number of k-subsets

import numpy as np  # arrays and matrices

GAMMAS = "Revision/algebra/gammas.json"
THEORY = "Revision/pairing/pairing-theory.json"
PY = "Revision/pairing/reports/python-pairing.json"  # the sympy verifier's report
WL = "Revision/pairing/reports/wolfram-pairing.json"  # the Wolfram verifier's report
```

`itertools` provides `combinations`, used in In [9] to list all subsets of the eight directions; `comb(8, k)` is the binomial coefficient $\binom{8}{k}$, the number of ways to choose k things out of 8. numpy, the

package for arrays and matrices, is loaded under the short name `np`. The four constants are the repository paths of the four Revision records the notebook reads: the gammas, the pairing theory record and the two reports of the pairing verifiers.

```
def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

def verdict(report_file, name):
    """The recorded verdict (PASS or FAIL) of the check name of a report."""
    for entry in read_json(report_file)["checks"]:
        if entry["name"] == name:
            return entry["verdict"].upper()
    return "MISSING"
```

`read_json` reads a record file as text and turns it into Python objects (`json.loads`). `verdict` reads a report and looks through its list `"checks"`; each entry is a dictionary with the keys `name`, `verdict` and `detail`. It returns the verdict of the check with the given name in capital letters (`.upper()`; the two pairing reports write PASS, but some other Revision reports write pass in small letters, and the comparison should not depend on that), or `"MISSING"` if the report has no such check.

```
def reproduces(condition, name, *sources, table=None):
    """check(condition, name), which also requires every named check of every
    source (report_file, [check names]) to have the recorded verdict PASS; table
    names a data table of the theory record that the result equals."""
    recorded = all(verdict(report_file, n) == "PASS"
                   for report_file, names in sources for n in names)
    parts = [f"{report_file}, check {', '.join(names)}"
             for report_file, names in sources]
    if table is not None:
        parts.insert(0, f"{THEORY}, data table {table}")
    check(condition and recorded, name, record="; ".join(parts))
```

`reproduces` is the check used whenever a result repeats a Revision record. `*sources` collects any number of pairs (report file, list of check names). `recorded` is true only when every named check of every named report has the verdict PASS: `all(...)` is true when every item of the following **generator expression** (a `for` loop written inside parentheses) is true. `parts` builds the text that names the reports and checks (`", ".join(names)` joins the names with commas); if a data table of the theory record is named, its text is put first. Finally `check` is called: the check passes only when the notebook's own result (`condition`) holds AND the record says PASS.

```
fixture = read_json(GAMMAS)
gamma = {a: np.array(fixture["gamma"][a], dtype=np.int64) for a in range(8)}
eta = {a: int(fixture["eta"][a]) for a in range(8)}  # +1 or -1
I16 = np.eye(16, dtype=np.int64)

def same(M, N):
    """True when the two matrices are equal entry by entry (exact for integers)."""
    return np.array_equal(M, N)
```

`fixture` is the dictionary read from `gammas.json`. Its entry `"gamma"` is a list of eight matrices, each a list of 16 rows of 16 whole numbers; the **dictionary comprehension** `{a: ... for a in range(8)}` stores the matrix of the direction x_a under the key `a`, as a numpy array of 64-bit whole numbers (`dtype=np.int64`). With whole numbers every product below is exact: nothing is rounded. `range(8)` runs through 0, 1, ..., 7 (the end is excluded), and `fixture["gamma"][a]` takes the entry number `a`: the record lists the matrices in the order $x_0, \ldots, x_7$, and Python counts list places from 0. `eta` holds η_{aa}, and `I16` is the identity matrix (`np.eye`). `same(M, N)` is true when two matrices are equal entry by entry; for whole numbers that comparison is exact.

```
say("eta = " + str([eta[a] for a in range(8)]) + " for x0, ..., x7")
reproduces(all(same(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                    2 * (eta[a] if a == b else 0) * I16)
                for a in range(8) for b in range(8)),
           "the 64 Clifford relations hold exactly",
           (WL, ["fixture_Clifford_relation"]), (PY, ["gammas.clifford"]))
```

The first line prints the list of the eight values η_{aa}: `[1, 1, 1, 1, -1, -1, -1, -1]`, the signature (4,4) in the order $x_0, \ldots, x_7$. The second statement checks the Clifford relation for all $8 \times 8 = 64$ pairs (a, b): `@` is the matrix product, so `gamma[a] @ gamma[b] + gamma[b] @ gamma[a]` is $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}$, compared with $2\eta_{aa} I_{16}$ when $a = b$ and with the zero matrix otherwise. It names the Wolfram check `fixture_Clifford_relation` and the sympy check `gammas.clifford`. Out [2] shows the PASS line and the record line.

In [3], are these the author's matrices? The markdown cell before it lists the author's five construction steps; the code follows them one by one.

```
def perm_sign(seq):
    """The permutation sign of a list of numbers: +1 (even number of exchanges
    sorts it), -1 (odd number), 0 (two entries are equal)."""
    if len(set(seq)) != len(seq):
        return 0
    inversions = sum(1 for i in range(len(seq)) for j in range(i + 1, len(seq))
                     if seq[i] > seq[j])  # pairs in the wrong order
    return -1 if inversions % 2 else 1

def kd(p, q):
    """The Kronecker delta: 1 if p = q, else 0."""
    return 1 if p == q else 0
```

`perm_sign` computes the **permutation sign** of a list of numbers. `set(seq)` keeps each different number once; if it is shorter than the list, two entries are equal and the sign is 0. Otherwise the code counts the **inversions**, the pairs of places $i < j$ whose numbers stand in the wrong order (`seq[i] > seq[j]`); sorting the list needs an even number of exchanges exactly when this count is even, so the sign is $+1$ for an even and -1 for an odd count (`inversions % 2` is the remainder after division by 2). `kd(p, q)` is the Kronecker delta.

```
I4, Z4 = np.eye(4, dtype=np.int64), np.zeros((4, 4), dtype=np.int64)
I8, Z8 = np.eye(8, dtype=np.int64), np.zeros((8, 8), dtype=np.int64)
```

```
s4, t4 = {}, {}
for h in (1, 2, 3):  # step 1: the self-dual and anti-self-dual 4 x 4 blocks
    Qa = np.array([[perm_sign([h, p, q, 4]) for q in range(1, 5)]
                   for p in range(1, 5)])
    Qb = np.array([[kd(p, 4) * kd(q, h) - kd(p, h) * kd(q, 4) for q in range(1, 5)]
                   for p in range(1, 5)])
    s4[h], t4[h] = Qa - Qb, Qa + Qb
```

`np.eye(4)` and `np.zeros((4, 4))` are the 4×4 identity and zero matrices; the line with `I8, Z8` makes the 8×8 ones. Step 1: for $h = 1, 2, 3$, `Qa` is the 4×4 table of the permutation signs of the arrangements $(h, p, q, 4)$ for $p, q = 1, \ldots, 4$ (rows p, columns q), and `Qb` the table $\delta_{p4}\delta_{qh} - \delta_{ph}\delta_{q4}$; the author's blocks are $s_h = Q_a - Q_b$ and $t_h = Q_a + Q_b$.

```
tau = {0: I8}  # step 2: the eight tau matrices
for h in (1, 2, 3):
    tau[h] = np.block([[Z4, s4[h]], [s4[h], Z4]])
    tau[7 - h] = np.block([[Z4, t4[h]], [-t4[h], Z4]])
tau[7] = tau[1] @ tau[2] @ tau[3] @ tau[4] @ tau[5] @ tau[6]
sigma4 = np.block([[Z4, I4], [I4, Z4]])  # step 3: tau-bar
taubar = {A: sigma4 @ tau[A].T @ sigma4 for A in range(8)}
T16A = {A: np.block([[Z8, taubar[A]], [tau[A], Z8]]) for A in range(8)}  # step 4
frame_index = {a: a for a in range(8)}  # step 5: x_a -> A = a
rebuilt_equal = all(same(T16A[frame_index[a]], gamma[a]) for a in range(8))
```

Step 2: `tau[0]` is I_8; for $h = 1, 2, 3$, `np.block` assembles an 8×8 matrix from four 4×4 blocks: τ_h has s_h in both off-diagonal blocks, τ_{7-h} has t_h above and $-t_h$ below; τ_7 is the product $\tau_1\tau_2\cdots\tau_6$. Step 3: $\bar{\tau}_A = \sigma\tau_A^T\sigma$ with σ the 8×8 matrix with I_4 in both off-diagonal blocks (`.T` is the transpose). Step 4: the 16×16 matrix T16A[A] has $\bar{\tau}_A$ in the upper-right and τ_A in the lower-left block. Step 5: `frame_index` maps the author's coordinate x_a to their frame number, which is the same number a: the author's notebook counts its frame in the order $x_0, \ldots, x_7$, with 0 the hidden direction. `rebuilt_equal` is true when every rebuilt matrix equals the record's matrix of the same direction.

```
raw = fixture["gamma"]  # the numbers exactly as stored in the record
eight_real = (len(raw) == 8 and all(len(M) == 16 and all(len(row) == 16 for row in M)
                                    for M in raw)
              and all(type(x) is int and x in (-1, 0, 1)
                      for M in raw for row in M for x in row))
signed_perm = all((np.abs(gamma[a]).sum(axis=0) == 1).all()
                  and (np.abs(gamma[a]).sum(axis=1) == 1).all() for a in range(8))
transpose_rule = all(same(gamma[a].T, eta[a] * gamma[a]) for a in range(8))
say(f"8 matrices of 16 x 16 real entries -1, 0, +1: {eight_real}; signed "
    f"permutation matrices: {signed_perm}; transpose = eta_aa times the matrix: "
    f"{transpose_rule}; equal to the author's T16A rebuilt from the formulas: "
    f"{rebuilt_equal}")
reproduces(eight_real and signed_perm and transpose_rule and rebuilt_equal,
           "the record holds the author's eight real 16 x 16 gamma matrices",
           (PY, ["gammas.equal_wolfram_fixture"]))
```

`raw` is the list of numbers exactly as stored in the record (before numpy touched them). `eight_real` checks that there are 8 matrices, each with 16 rows of 16 entries, and that every entry is a

Python whole number (`type(x) is int`, so no complex number and no fraction) equal to -1, 0 or $+1$. `signed_perm` checks the defining property of a signed permutation matrix: the absolute values `np.abs` sum to 1 in every column (`axis=0`) and in every row (`axis=1`). `transpose_rule` checks $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$: the space-like gammas are symmetric and the time-like ones antisymmetric. The cell prints the four results and checks them together against `gammas.equal_wolfram_fixture`, the sympy check that compared its own rebuilt gammas with the record. Out [3] prints True four times and the PASS line: **the record holds the author's eight real** 16×16 **matrices**, and every computation of this chapter uses them.

In [4], the first figure: the eight gammas.

```
from matplotlib.colors import LinearSegmentedColormap  # colour scales

BLUE, ORANGE, GREEN, GREY = "#2a78d6", "#eb6834", "#1baf7a", "#52514e"
DIVERGING = LinearSegmentedColormap.from_list(
    "blue_grey_red", ["#184f95", "#f0efec", "#e34948"])
```

`LinearSegmentedColormap.from_list` makes a **colour scale** that runs from dark blue (for -1) through light grey (0) to red ($+1$). The four colour constants are a blue, an orange, a green and a grey that colour-blind readers can tell apart; they are written as hexadecimal colour codes.

```
def draw_matrix(ax, matrix, title, ticks=True):
    """Heat map of a real 16 x 16 matrix with entries between -1 and +1."""
    image = ax.imshow(matrix, cmap=DIVERGING, vmin=-1.0, vmax=1.0)
    places = [0, 7, 15] if ticks else []  # label rows and columns 1, 8, 16
    ax.set_xticks(places, [str(t + 1) for t in places])
    ax.set_yticks(places, [str(t + 1) for t in places])
    ax.axhline(7.5, color=GREY, linewidth=0.8)  # the border between the halves
    ax.axvline(7.5, color=GREY, linewidth=0.8)
    ax.grid(False)  # no grid lines on top of the squares
    ax.set_title(title, fontsize=10)
    return image
```

`draw_matrix` draws one matrix as a **heat map**, a grid of coloured squares, one per entry. `ax` is one panel of a figure. `imshow` draws the squares with the colour scale fixed between -1 and $+1$ (`vmin`, `vmax`), so that equal numbers always get equal colours. The tick marks label the rows and columns 1, 8 and 16 (Python counts from 0, so the places are 0, 7 and 15 and the labels add 1). `axhline(7.5)` and `axvline(7.5)` draw thin lines between the rows 8 and 9 and the columns 8 and 9, the border between the two chiral halves. `ax.grid(False)` removes the grid, and the title is written above the panel. The function returns the drawn image, which the colour bar needs.

```
fig, axes = plt.subplots(2, 4, figsize=(11.0, 6.0))
for a, ax in zip(range(8), axes.flat):
    kind = "space-like" if eta[a] == 1 else "time-like"
    image = draw_matrix(ax, gamma[a], f"$\\gamma^{{(x_{a})}}$ ({kind})")
fig.colorbar(image, ax=list(axes.flat), shrink=0.7, label="entry")
save_figure(fig, "eight_gammas",
            "The author's eight real 16 by 16 gamma matrices, one heat map each, in "
            "the order $x_0$ to $x_7$ of the author's coordinates (top row: "
```

```
            "$x_1, x_2, x_3, x_4$; bottom row: $x_5, x_6, x_7, x_0$). Horizontal "
            "axis: column number, vertical axis: row number; red is $+1$, blue is "
            "$-1$, light grey is 0; thin lines separate the components 1 to 8 "
            "from 9 to 16. Every row and every column holds exactly one red or "
            "blue square (signed permutation matrices), no entry is complex, and "
            "every matrix has its squares only in the two off-diagonal blocks, so "
            "each gamma exchanges the two halves of a 16-component field.")
```

`plt.subplots(2, 4)` makes a figure with two rows of four panels, 11 by 6 inches. `zip` pairs the directions $x_0, \ldots, x_7$ (`range(8)`) with the panels (`axes.flat` lists the panels row by row). Each panel is titled with $\gamma^{(x_a)}$ and the word space-like or time-like; in the f-string, double braces `{{` and `}}` print single braces, and `\\` prints one backslash, so the title is LaTeX code. `fig.colorbar` adds the colour key. `save_figure` saves figure 18a.1 with its caption. **What you see in Figure 18a.1:** in every panel each row and each column has exactly one coloured square (signed permutation matrices), the squares lie only in the upper-right and lower-left 8×8 blocks (each gamma exchanges the two halves), and there are only the colours of $+1$ and -1: no entry is complex.

In [5], C, Γ and B.

```
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]  # the four space-like gammas
Gamma = I16.copy()
for a in range(8):  # the order x0, ..., x7 of the factors of Gamma
    Gamma = Gamma @ gamma[a]
B_over_i = -(C @ gamma[4])  # B = -i C gamma^(x4) = i * (-C gamma^(x4))
B = 1j * B_over_i  # the complex matrix B (entries 0, +i, -i)
B_file = np.array(fixture["B"]["re"]) + 1j * np.array(fixture["B"]["im"])
stored = (same(C, np.array(fixture["C"])) and same(Gamma, np.array(fixture["Gamma"]))
          and np.array_equal(B, B_file))
reproduces(stored, "C, Gamma and B built here equal the matrices of the gammas record",
           (WL, ["fixture_definitions"]))
```

C is the product of the four space-like gammas in the author's order x_0, x_1, x_2, x_3. Γ starts as a copy of the identity (`.copy()`, so that `I16` itself is not changed) and is multiplied on the right by the eight gammas in the order $x_0, x_1, \ldots, x_7$. Because $B = -iC\gamma^{(x_4)}$ is i times the real whole-number matrix $-C\gamma^{(x_4)}$, the cell keeps that real matrix as `B_over_i` and forms the complex matrix `B` with `1j`, Python's name for i. The record stores B as a real part `"re"` and an imaginary part `"im"`, and `B_file` rebuilds it. `stored` compares the three matrices built here with the record's; the check names the Wolfram check `fixture_definitions`.

```
basic = (same(C.T, C) and same(C @ C, I16)
         and all(same((C @ gamma[a]).T, -(C @ gamma[a])) for a in range(8))
         and np.array_equal(B.conj().T, B) and np.array_equal(B @ B, np.eye(16))
         and np.array_equal(C @ gamma[4], 1j * B))
reproduces(basic, "C real symmetric, C^2 = 1, B Hermitian, B^2 = 1, C gamma^(x4) = i B",
           (WL, ["C_and_B_basic"]), (PY, ["gammas.C", "gammas.B"]))
```

`basic` checks five facts: $C^T = C$, $CC = 1$, every $C\gamma^{(a)}$ antisymmetric, $B^\dagger = B$ (`.conj().T` is the conjugate transpose) with $BB = 1$ (`np.eye(16)` is the identity), and $C\gamma^{(x_4)} = iB$. The last one is how B enters the time-derivative term of the Lagrangian (Section 18.23). Out [5] shows two PASS lines.

In [6], Lemma 1.

```
four_S = {(a, b): gamma[a] @ gamma[b] - gamma[b] @ gamma[a]  # 4 S^ab, whole numbers
          for a in range(8) for b in range(8)}
diagonal = same(Gamma, np.diag([-1] * 8 + [1] * 8))  # diag(-I8, I8)
real_symmetric_involution = same(Gamma.T, Gamma) and same(Gamma @ Gamma, I16)
anticommutes = all(same(Gamma @ gamma[a], -gamma[a] @ Gamma) for a in range(8))
commutes_C = same(Gamma @ C, C @ Gamma)
commutes_S = all(same(Gamma @ M, M @ Gamma) for M in four_S.values())  # 64 pairs
say(f"Gamma = diag(-I8, I8): {diagonal}; real symmetric with Gamma^2 = 1: "
    f"{real_symmetric_involution}; anticommutes with all 8 gammas: {anticommutes}; "
    f"commutes with C: {commutes_C}; commutes with all 64 S^ab: {commutes_S}")
reproduces(diagonal and real_symmetric_involution and anticommutes and commutes_C
           and commutes_S, "Lemma 1: the chirality Gamma",
           (WL, ["Gamma_properties"]),
           (PY, ["gammas.Gamma", "gammas.Gamma_anticommutes"]))
```

`four_S` holds $4S^{ab} = \gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)}$ for all 64 pairs; with the factor 4 the entries are whole numbers, and a matrix commutes with S^{ab} exactly when it commutes with $4S^{ab}$. `np.diag([-1] * 8 + [1] * 8)` is the diagonal matrix with eight entries -1 and eight $+1$ (`[-1] * 8` repeats the list eight times, `+` joins lists). The five results are: $\Gamma = \mathrm{diag}(-I_8, I_8)$; $\Gamma^T = \Gamma$ and $\Gamma\Gamma = 1$; $\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$ for all eight a; $\Gamma C = C\Gamma$; $\Gamma S^{ab} = S^{ab}\Gamma$ for all 64 pairs. Out [6] prints True five times and the PASS line for Lemma 1, with the records `Gamma_properties`, `gammas.Gamma` and `gammas.Gamma_anticommutes`.

In [7], Γ commutes with a random connection.

```
rng = np.random.default_rng(12345)  # a fixed seed: the same numbers every run
omega = rng.normal(size=(8, 8))  # rows and columns 0..7 stand for x0, ..., x7
omega = omega - omega.T  # antisymmetric: omega[a, b] = -omega[b, a]
Omega = sum(0.5 * omega[a, b] * four_S[(a, b)] / 4.0
            for a in range(8) for b in range(8))  # (1/2) omega_ab S^ab
commutator = np.abs(Gamma @ Omega - Omega @ Gamma).max()
check(commutator < 1e-12 and np.abs(Omega).max() > 0.1,
      "Gamma commutes with a random spin connection Omega (largest entry of the "
      "commutator below 1e-12)")
```

`np.random.default_rng(12345)` is a random-number generator with a fixed **seed**, so every run draws the same numbers. `rng.normal(size=(8, 8))` draws an array of 8×8 numbers from the normal (bell-curve) distribution; row and column a stand for x_a. `omega - omega.T` makes it antisymmetric, $\omega_{ab} = -\omega_{ba}$, as a connection must be. `Omega` is $\frac{1}{2}\sum_{a,b}\omega_{ab}S^{ab}$, with S^{ab} written as `four_S / 4.0`; `sum(...)` adds the 64 matrices. `commutator` is the largest absolute entry of $\Gamma\Omega - \Omega\Gamma$. The check requires it below 10^{-12} and requires Ω itself not to be tiny (largest entry above 0.1), so that the test is not empty. This is an illustration with floating-point numbers; the proof is the exact check of In [6].

In [8], the second figure: Γ reverses every gamma.

```
flips = all(same(Gamma @ gamma[a] @ Gamma, -gamma[a]) for a in range(8))
check(flips, "Gamma gamma^(a) Gamma = -gamma^(a) for all eight directions")
```

`flips` checks $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$ for all eight directions, the identity behind T1.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
draw_matrix(axes[0], Gamma, "$\\Gamma = \\mathrm{diag}(-I_8, I_8)$")
draw_matrix(axes[1], gamma[1], "$\\gamma^{(x_1)}$")
image = draw_matrix(axes[2], Gamma @ gamma[1] @ Gamma,
                    "$\\Gamma\\gamma^{(x_1)}\\Gamma = -\\gamma^{(x_1)}$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry")
save_figure(fig, "chirality_flips_gammas",
            "Heat maps of three 16 by 16 matrices: the chirality $\\Gamma$ (left), "
            "the gamma matrix $\\gamma^{(x_1)}$ of the first direction of 3-space "
            "(middle) and $\\Gamma\\gamma^{(x_1)}\\Gamma$ (right). Horizontal axis: "
            "column number, vertical axis: row number; red is $+1$, blue is $-1$, "
            "light grey is 0; thin lines separate the chiral halves, components 1 "
            "to 8 and 9 to 16. $\\Gamma$ is $-1$ on the first half and $+1$ on the "
            "second. $\\gamma^{(x_1)}$ has its entries only in the two off-diagonal "
            "blocks: it exchanges the halves. The right picture is the middle one "
            "with every colour reversed, because $\\Gamma$ anticommutes with every "
            "gamma. This sign is the whole content of the pairing theorem T1.")
```

A figure with three panels: Γ, $\gamma^{(x_1)}$ and $\Gamma\gamma^{(x_1)}\Gamma$, drawn with `draw_matrix`, a colour key, and `save_figure`. **What you see in Figure 18a.2:** Γ is blue on the first eight diagonal places and red on the last eight; $\gamma^{(x_1)}$ has its squares only in the off-diagonal blocks; the right panel is the middle one with every colour reversed. Why: Γ multiplies the rows 1 to 8 by -1 from the left and the columns 1 to 8 by -1 from the right, and every square of an off-diagonal block lies in exactly one of these rows or columns.

In [9], Lemma 2 for all 256 products.

```
def sign_between(M, N):
    """+1 if M = N, -1 if M = -N, 0 otherwise (exact comparison)."""
    if same(M, N):
        return 1
    if same(M, -N):
        return -1
    return 0
```

`sign_between(M, N)` returns $+1$ if $M = N$, -1 if $M = -N$ and 0 otherwise, with exact comparisons.

```
parity_ok = True
counts = {k: {1: 0, -1: 0} for k in range(9)}  # k -> number of products per sign
for k in range(9):
    for subset in itertools.combinations(range(8), k):
        X = I16.copy()
        for a in subset:  # the product gamma^(a1) ... gamma^(ak)
            X = X @ gamma[a]
        s = sign_between(Gamma @ X @ Gamma, X)
        parity_ok = parity_ok and s == (-1) ** k
        counts[k][s] += 1
```

`counts[k]` counts, for each length $k = 0, \ldots, 8$, the products with the sign $+1$ and with the sign -1. `itertools.combinations(range(8), k)` lists every set of k different directions in increasing

order. For each, `X` is the product of their gammas (the empty product, $k = 0$, is the identity). `s` is the sign in $\Gamma X \Gamma = sX$; `parity_ok` stays true only if `s` equals $(-1)^k$ every time (`**` is the power).

```
say("number of products of k different gammas, by the sign s: "
    + "; ".join(f"k={k}: {counts[k][1]} with s=+1, {counts[k][-1]} with s=-1"
                for k in range(9)))
check(parity_ok and all(counts[k][1] + counts[k][-1] == comb(8, k) for k in range(9)),
      "Gamma X Gamma = (-1)^k X for all 256 products X of k different gammas")
```

The cell prints the counts and checks that $s = (-1)^k$ always and that the number of products of length k is $\binom{8}{k}$. Out [9] reads: $k = 0$: 1 product with $s = +1$; $k = 1$: 8 with $s = -1$; $k = 2$: 28 with $+1$; $k = 3$: 56 with -1; $k = 4$: 70 with $+1$; $k = 5$: 56 with -1; $k = 6$: 28 with $+1$; $k = 7$: 8 with -1; $k = 8$: 1 with $+1$. The total is $2^8 = 256$.

In [10], the kernels of the Lagrangian.

```
kinetic = [C @ gamma[a] for a in range(8)]
connection = [C @ gamma[a] @ four_S[(b, c)] for a in range(8)
              for b in range(8) for c in range(b + 1, 8)]
connection += [C @ four_S[(b, c)] @ gamma[a] for a in range(8)
               for b in range(8) for c in range(b + 1, 8)]
kernels = kinetic + connection
all_flip = all(same(Gamma @ X @ Gamma, -X) for X in kernels)
scalar_kept = same(Gamma @ C @ Gamma, C)
```

`kinetic` holds the 8 kernels $C\gamma^{(a)}$ of the kinetic bilinears. `connection` holds $C\gamma^{(a)}(4S^{bc})$ and $C(4S^{bc})\gamma^{(a)}$ for all a and all $b < c$: $8 \times 28 = 224$ of each kind (`+=` appends the second list to the first). With the 8 kinetic kernels these are $8 + 224 + 224 = 456$ matrices, the list of the sympy verifier. `all_flip` checks $\Gamma X \Gamma = -X$ for all of them; since Γ is real and symmetric, this is the change of the kernel of $\Psi^\dagger X \Psi$ under $\Psi \to \Gamma\Psi$. `scalar_kept` checks $\Gamma C \Gamma = C$, the kernel of S.

```
triples = [C @ (gamma[a] @ four_S[(b, c)] + four_S[(b, c)] @ gamma[a])
           for a in range(8) for b in range(8) for c in range(8)]
triples_flip = all(same(Gamma @ X @ Gamma, -X) for X in triples)
field_kernels = (all(same(Gamma @ gamma[a] @ Gamma, -gamma[a]) for a in range(8))
                 and all(same(Gamma @ M @ Gamma, M) for M in four_S.values()))
krein_reversed = np.array_equal(Gamma @ B @ Gamma, -B)
```

`triples` holds the form of the Wolfram verifier, $C\{\gamma^{(a)}, 4S^{bc}\}$ for all $8^3 = 512$ triples (a, b, c), and `triples_flip` checks that each changes sign. `field_kernels` checks the two kernels of the field equation: $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$ and $\Gamma S^{bc}\Gamma = S^{bc}$. `krein_reversed` checks $\Gamma B \Gamma = -B$ (the last part of Lemma 2).

```
report("number of kinetic and connection kernels", len(kernels))
report("number of triples (a, b, c)", len(triples))
reproduces(len(kernels) == 456 and all_flip and scalar_kept,
           "Lemma 2: all 456 kinetic and connection kernels flip, C is kept",
           (PY, ["T1.general_field.matrix_identities"]),
           (WL, ["T1_kernel_scalar", "T1_kernel_kinetic"]))
```

```
reproduces(len(triples) == 512 and triples_flip and field_kernels and krein_reversed,
           "Lemma 2: 512 connection triples flip; field-equation kernels; GBG = -B",
           (WL, ["T1_kernel_connection", "T1_kernel_field_equation"]),
           (PY, ["Q.image_krein_metric"]))
```

The cell prints the two counts, 456 and 512, as RESULT lines and makes two checks with their records. Out [10] shows both PASS lines.

In [11], the third figure: the parity of the 256 products.

```
ks = np.arange(9)
heights = [comb(8, int(k)) for k in ks]
colours = ["#e34948" if k % 2 == 0 else "#184f95" for k in ks]
fig, ax = plt.subplots(figsize=(8.0, 4.6))
ax.bar(ks, heights, color=colours, width=0.7)
ax.set_xticks(ks)
ax.set_xlabel("number $k$ of gamma factors in the matrix $X$ of $\\bar\\Psi X\\Psi$")
ax.set_ylabel("number of products $\\binom{8}{k}$")
ax.set_ylim(0, 85)
notes = {0: "$S = \\bar\\Psi\\Psi$", 1: "kinetic, $J^\\mu$, $\\Psi^\\dagger B\\Psi$",
         3: "connection", 8: "$\\bar\\Psi\\Gamma\\Psi$"}
for k, text in notes.items():
    ax.text(k, heights[k] + 3, text, ha="center", fontsize=8.5, rotation=90,
            va="bottom")
ax.bar([0], [0], color="#e34948", label="sign kept, $(-1)^k = +1$")
ax.bar([0], [0], color="#184f95", label="sign reversed, $(-1)^k = -1$")
ax.legend(loc="upper right")
```

`ks` is the array $0, 1, \ldots, 8$ and `heights` the numbers $\binom{8}{k}$. `colours` is red for even k and blue for odd k (`k % 2 == 0` tests evenness). `ax.bar` draws one bar per k. The axis labels are set, the vertical axis runs to 85, and `notes` writes, rotated by 90 degrees above four bars, which bilinear of the theory belongs there: S at $k = 0$; the kinetic terms, the current and the charge density at $k = 1$; the connection terms at $k = 3$; $\bar\Psi\Gamma\Psi$ at $k = 8$. The two bars of height zero only create the two entries of the legend.

```
save_figure(fig, "parity_of_products",
            "The 256 products $X$ of different gamma matrices, sorted by the number "
            "$k$ of factors (horizontal axis); the bar height is the number of "
            "such products, $\\binom{8}{k}$ (vertical axis). Red bars: the "
            "bilinear $\\bar\\Psi X\\Psi$ keeps its value under the chirality map "
            "$\\Psi \\to \\Gamma\\Psi$; blue bars: it changes sign. The sign is "
            "$(-1)^k$ for every one of the 256 products. The scalar $S$ sits in "
            "the red bar $k = 0$; the kinetic terms, the current $J^\\mu$ and the "
            "charge density $\\Psi^\\dagger B\\Psi$ in the blue bar $k = 1$; the "
            "spin-connection terms in the blue bar $k = 3$. This is why T1 "
            "reverses the kinetic term but not the mass term.")
```

The figure is saved as 18a.3. **What you see in Figure 18a.3:** a symmetric row of bars of heights 1, 8, 28, 56, 70, 56, 28, 8, 1, alternately red and blue. Why it matters: the mass term sits in a red bar (unchanged by Γ) and the kinetic term in blue bars (reversed); that difference is the whole of theorem T1.

In [12], Lemma 3: the reflection table.

```
order = list(range(8))  # the order x0, ..., x7 of the factors of Gamma
names = {a: f"x{a}" for a in range(8)}
rows = []  # one row of the reflection table per direction n
lemma3_ok = True
for n in range(8):
    P = Gamma @ gamma[n]
    others = I16.copy()
    for a in order:
        if a != n:
            others = others @ gamma[a]  # the product of the other seven gammas
    R = {a: (-1 if a == n else 1) for a in range(8)}  # the diagonal of R_n
    orthogonal = same(P.T @ P, I16)  # so P^-1 = P^T
    covers = all(same(P.T @ gamma[a] @ P, R[a] * gamma[a]) for a in range(8))
```

`order` is the order of the factors of Γ, and `names` gives the labels x0, ..., x7. For each direction n: `P` is $P_n = \Gamma\gamma^{(n)}$; `others` is the product of the seven other gammas in the order of Γ; `R` is the diagonal of the reflection R_n (`-1 if a == n else 1`). `orthogonal` checks $P_n^T P_n = 1$, so that $P_n^{-1} = P_n^T$ (true for every signed permutation matrix); `covers` checks $P_n^{-1}\gamma^{(a)}P_n = (R_n)_{aa}\gamma^{(a)}$ for all eight a: P_n acts on the gammas as the reflection of the direction n (Lemma 3, item 3).

```
    M = gamma[n]  # Gamma P_n = gamma^(n)
    kinetic_sign = eta[n]
    kinetic_ok = all(same(M.T @ C @ gamma[a] @ M, kinetic_sign * R[a] * C @ gamma[a])
                     for a in range(8))
    connection_ok = all(
        same(M.T @ C @ (gamma[a] @ four_S[(b, c)] + four_S[(b, c)] @ gamma[a]) @ M,
             kinetic_sign * R[a] * R[b] * R[c]
             * C @ (gamma[a] @ four_S[(b, c)] + four_S[(b, c)] @ gamma[a]))
        for a in range(8) for b in range(8) for c in range(8))
```

`M` is $\gamma^{(n)} = \Gamma P_n$, the matrix of the T2 map. `kinetic_ok` checks $M^T C\gamma^{(a)} M = \eta_{nn}(R_n)_{aa} C\gamma^{(a)}$ for all a: with the reflected frame the factor $(R_n)_{aa}$ is absorbed (Section 18.15), so the kinetic term gets the sign η_{nn}. `connection_ok` checks the same for the 512 connection kernels, with the three factors $(R_n)_{aa}(R_n)_{bb}(R_n)_{cc}$, two of which are absorbed by the reflected connection $R_n\omega R_n$.

```
    row = {"direction": names[n], "eta_nn": eta[n],
           "product_sign": sign_between(P, others),
           "character": sign_between(P.T @ C @ P, C),
           "S_sign": sign_between(M.T @ C @ M, C),
           "kinetic_sign": kinetic_sign if kinetic_ok else 0}
    row["map"] = ("(m, lambda) -> (-m, lambda), L -> +L (T2)"
                  if (row["S_sign"], row["kinetic_sign"]) == (-1, 1)
                  else "(m, lambda) -> (-m, -lambda), L -> -L (T1-type)")
    rows.append(row)
    lemma3_ok = (lemma3_ok and orthogonal and covers and connection_ok and kinetic_ok
                 and same(Gamma @ P, gamma[n]) and row["character"] == -eta[n]
                 and row["product_sign"] in (1, -1))
```

One row of the table: the direction, η_{nn}, the sign of P_n against the product of the other seven, the character (the sign in $P_n^T C P_n = \chi C$), the sign of S under $\Psi \to \gamma^{(n)}\Psi$ (the sign in $M^T C M = \pm C$), and the kinetic sign (0 if the kinetic check failed, which would make the table differ from the record). `row["map"]` writes the resulting map of the parameters: if S changes sign and the kinetic term does not, $(m, \lambda) \to (-m, \lambda)$ with $\mathcal{L} \to +\mathcal{L}$ (T2); otherwise a map of the T1 type. `lemma3_ok` collects all the conditions, including $\Gamma P_n = \gamma^{(n)}$ and the character $-\eta_{nn}$.

```
for row in rows:
    say(f"{row['direction']}: eta {row['eta_nn']:+d}, P_n = {row['product_sign']:+d} "
        f"x (other seven), character {row['character']:+d}, S -> "
        f"{row['S_sign']:+d} S, kinetic {row['kinetic_sign']:+d}: {row['map']}")
product_signs = [r["product_sign"] for r in rows]
reproduces(lemma3_ok and product_signs == [-1, 1, -1, 1, 1, -1, 1, -1],
           "Lemma 3: P_n in Pin(4,4), covers R_n, character -eta_nn, Gamma P_n = g^n",
           (WL, ["T2_Pn_in_Pin44", "T2_Pn_covers_the_reflection", "T2_character_of_Pn",
                 "T2_Gamma_times_Pn_is_gamma_n",
                 "T2_kernels_gamma_n_with_frame_reflection"]),
           (PY, ["T2.general_field.matrix_identities",
                 "T2.general_field.reflection_table"]))
```

The loop prints one line per direction (`:+d` writes a whole number with its sign); then the check requires all conditions and the recorded signs $-1, +1, -1, +1, +1, -1, +1, -1$, with five Wolfram checks and two sympy checks. Out [12] shows the eight rows: the space-like x_0, x_1, x_2, x_3 have character -1, reverse S and keep the kinetic term (T2); the time-like $x_4, \ldots, x_7$ have character $+1$, keep S and reverse the kinetic term (T1 type).

In [13], the table against the record.

```
theory = read_json(THEORY)
recorded_rows = theory["data"]["reflections"]
keys = [("eta_nn", "eta_nn"),
        ("product_sign", "P_n_equals_sign_times_product_of_other_seven"),
        ("character", "character_of_P_n"), ("S_sign", "S_sign_under_gamma_n"),
        ("kinetic_sign", "kinetic_sign_under_gamma_n_with_frame_reflection"),
        ("map", "mass_coupling_map")]
table_equal = len(recorded_rows) == 8 and all(
    recorded["direction"] == mine["direction"]
    and all(mine[k_mine] == recorded[k_rec] for k_mine, k_rec in keys)
    for mine, recorded in zip(rows, recorded_rows))
say("status of the theory record: " + theory["status"])
reproduces(table_equal and theory["status"] == "all checks of the report passed",
           "the reflection table equals the record's, row by row",
           (PY, ["compare.theory.reflection_table"]), table="reflections")
```

`theory` is the pairing theory record; `recorded_rows` its data table `reflections`, a list of eight dictionaries. `keys` pairs each field name of the notebook's rows with the field name of the record. `table_equal` requires eight recorded rows and, for each pair of rows (`zip` pairs them in order), the same direction and equal values in all six fields. The cell prints the status line of the record ("all checks of the report passed") and checks the table together with the sympy check `compare.theory.reflection_table`.

In [14], the fourth figure: the reflection table.

```
columns = ["$\\eta_{nn}$", "sign of $P_n$", "character $\\chi_n$",
           "$S \\to \\pm S$", "kinetic $\\pm$"]
grid = np.array([[r["eta_nn"], r["product_sign"], r["character"], r["S_sign"],
                  r["kinetic_sign"]] for r in rows], dtype=float)
fig, ax = plt.subplots(figsize=(8.6, 5.6))
ax.imshow(grid, cmap=DIVERGING, vmin=-1.0, vmax=1.0, aspect="auto")
for i in range(8):
    for j in range(5):
        ax.text(j, i, f"{int(grid[i, j]):+d}", ha="center", va="center",
                color="white", fontsize=10)
    label = "T2: $(-m, \\lambda)$, $+\\mathcal{L}$" if rows[i]["S_sign"] == -1 \
        else "T1-type: $(-m, -\\lambda)$, $-\\mathcal{L}$"
    ax.text(5.0, i, label, ha="left", va="center", fontsize=9)
ax.set_xticks(range(5), columns, fontsize=9)
ax.set_yticks(range(8), [f"$n = x_{a}$" for a in range(8)])
ax.set_xlim(-0.5, 7.4)
ax.grid(False)
ax.set_title("reflection of the direction $n$ with $\\Psi \\to \\gamma^{(n)}\\Psi$")
```

`columns` names the five columns of signs; `grid` is the 8×5 array of the signs (`dtype=float` because `imshow` draws numbers). `imshow` colours each sign (red $+1$, blue -1; `aspect="auto"` lets the cells be wider than high). The double loop writes each sign as white text in its cell; then the map of each row is written to the right of the grid (a backslash at the end of a line continues the statement on the next line). The axis ticks name the columns and the rows; `set_xlim(-0.5, 7.4)` leaves room for the text on the right.

```
save_figure(fig, "reflection_table",
            "The reflection table of Lemma 3, one row for each direction $n$ (the "
            "space-like $x_0, x_1, x_2, x_3$ and the time-like $x_4$ to $x_7$). "
            "Columns: the sign $\\eta_{nn}$ of the direction; the sign of "
            "$P_n = \\Gamma\\gamma^{(n)}$ relative to the product of the other "
            "seven gammas; the character $\\chi_n$ in $P_n^\\dagger CP_n = "
            "\\chi_nC$; the sign of $S$ and of the kinetic term under "
            "$\\Psi \\to \\gamma^{(n)}\\Psi$ with the reflected frame. Red is "
            "$+1$, blue is $-1$. The character is always $-\\eta_{nn}$. A "
            "space-like reflection keeps the kinetic term and reverses $S$: the "
            "mass changes sign and the coupling does not (theorem T2). A "
            "time-like reflection does the opposite, which gives a map of the T1 "
            "type. The table equals the Revision record row by row.")
```

The figure is saved as 18a.4. **What you see in Figure 18a.4:** the columns of the character, of the sign of S and of η_{nn} form the same pattern up to sign: character $= -\eta_{nn}$ in every row; the four space-like rows read "T2", the four time-like rows "T1-type".

In [15], the fifth figure: the chiral projectors.

```
P_minus = (I16 - Gamma) // 2  # whole numbers 0 and 1: the author's P_L
P_plus = (I16 + Gamma) // 2  # the author's P_R
projectors = (same(P_minus @ P_minus, P_minus) and same(P_plus @ P_plus, P_plus)
```

```
             and same(P_minus + P_plus, I16) and not (P_minus @ P_plus).any()
             and int(np.trace(P_minus)) == 8 and int(np.trace(P_plus)) == 8)
gamma_is_difference = same(Gamma, P_plus - P_minus)
gammas_swap = all(same(gamma[a] @ P_minus, P_plus @ gamma[a]) for a in range(8))
halves_kept = (same(C @ P_minus, P_minus @ C)
               and all(same(M @ P_minus, P_minus @ M) for M in four_S.values()))
say(f"projectors of rank 8: {projectors}; Gamma = P+ - P-: {gamma_is_difference}; "
    f"every gamma maps the minus half to the plus half: {gammas_swap}; C and all "
    f"S^ab keep each half: {halves_kept}")
check(projectors and gamma_is_difference and gammas_swap and halves_kept,
      "the chiral projectors: P-^2 = P-, P+^2 = P+, Gamma = P+ - P-, gammas swap")
```

`P_minus` is $\frac{1}{2}(1-\Gamma)$; since $1-\Gamma$ has entries 0 and 2, the whole-number division `// 2` gives exactly 0 and 1. `projectors` checks $P_-P_- = P_-$, $P_+P_+ = P_+$, $P_- + P_+ = 1$, $P_-P_+ = 0$ (`.any()` is false when all entries are 0, so `not (...).any()` means "is the zero matrix") and that each has trace 8 (the trace of a projector is its rank, the number of components it keeps). `gamma_is_difference` checks $\Gamma = P_+ - P_-$; `gammas_swap` checks $\gamma^{(a)}P_- = P_+\gamma^{(a)}$ for all a; `halves_kept` checks that C and all S^{ab} commute with P_- (hence also with $P_+ = 1 - P_-$). One check combines them.

```
fig, axes = plt.subplots(1, 4, figsize=(12.0, 3.6))
draw_matrix(axes[0], P_minus, "$P_- = \\frac{1}{2}(1 - \\Gamma)$")
draw_matrix(axes[1], P_plus, "$P_+ = \\frac{1}{2}(1 + \\Gamma)$")
draw_matrix(axes[2], gamma[1] @ P_minus, "$\\gamma^{(x_1)}P_-$")
image = draw_matrix(axes[3], P_plus @ gamma[1], "$P_+\\gamma^{(x_1)}$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry")
save_figure(fig, "chiral_projectors",
            "Heat maps of the two chiral projectors and of one gamma between them; "
            "columns horizontal, rows vertical, red $+1$, blue $-1$, grey 0, thin "
            "lines between the halves. $P_-$ (first picture, the author's P_L) is "
            "the identity on the components 1 to 8 and zero elsewhere; $P_+$ "
            "(second, the author's P_R) is the identity on 9 to 16. Their "
            "difference is $\\Gamma$. The third and fourth pictures are equal: "
            "$\\gamma^{(x_1)}P_- = P_+\\gamma^{(x_1)}$, so the gamma takes a field "
            "that lives in the first half into the second half. The T1 image "
            "$\\Gamma\\Psi = P_+\\Psi - P_-\\Psi$ reverses the relative sign of "
            "the two halves.")
```

Four heat maps: P_-, P_+, $\gamma^{(x_1)}P_-$ and $P_+\gamma^{(x_1)}$; saved as 18a.5. **What you see in Figure 18a.5:** P_- is red on the first eight diagonal places, P_+ on the last eight; the third and the fourth panels are identical and occupy only the lower-left block: a field that lives in the first half is moved by the gamma into the second half.

In [16], the sixth figure: the block form.

```
def blocks(M):
    """The four 8 x 8 blocks of a 16 x 16 matrix: upper left, upper right, lower
    left, lower right."""
    return M[:8, :8], M[:8, 8:], M[8:, :8], M[8:, 8:]
```

`blocks(M)` returns the four 8×8 blocks of a 16×16 matrix: `M[:8, :8]` is rows 1 to 8 and columns 1 to 8 (in Python, `:8` means the places 0 to 7), `M[:8, 8:]` rows 1 to 8 and columns 9 to 16, and so on.

```
off_diagonal = all(not blocks(gamma[a])[0].any() and not blocks(gamma[a])[3].any()
                   for a in range(8))  # .any() is False when all entries are 0
g0_swaps = (same(blocks(gamma[0])[1], I8) and same(blocks(gamma[0])[2], I8))
C_ul, C_ur, C_ll, C_lr = blocks(C)
C_block_diagonal = not C_ur.any() and not C_ll.any() and same(C_ul, -C_lr)
P0 = Gamma @ gamma[0]
say(f"every gamma off-diagonal: {off_diagonal}; gamma^(x0) = [[0, I8], [I8, 0]]: "
    f"{g0_swaps}; C = diag(-sigma, sigma): {C_block_diagonal}")
check(off_diagonal and g0_swaps and C_block_diagonal,
      "block form: gammas exchange the halves, gamma^(x0) swaps them, C is diagonal")
```

`off_diagonal` checks that the upper-left and lower-right blocks of every gamma are zero. `g0_swaps` checks that both off-diagonal blocks of $\gamma^{(x_0)}$ are I_8, so that $\gamma^{(x_0)}(\psi_-, \psi_+) = (\psi_+, \psi_-)$. `C_block_diagonal` checks that the off-diagonal blocks of C vanish and that its upper-left block is minus its lower-right block: $C = \mathrm{diag}(-\sigma, \sigma)$. `P0` is $P_0 = \Gamma\gamma^{(x_0)}$, drawn below. One check combines the three facts.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
draw_matrix(axes[0], C, "$C = \\mathrm{diag}(-\\sigma, \\sigma)$")
draw_matrix(axes[1], gamma[0], "$\\gamma^{(x_0)}$: exchanges the halves")
image = draw_matrix(axes[2], P0, "$P_0 = \\Gamma\\gamma^{(x_0)}$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry")
save_figure(fig, "chiral_blocks",
            "Heat maps of $C$ (left), $\\gamma^{(x_0)}$ (middle) and the reflection "
            "$P_0 = \\Gamma\\gamma^{(x_0)}$ of the hidden direction (right); axes "
            "as in the first figure (columns horizontal, rows vertical, red $+1$, "
            "blue $-1$, grey 0), thin lines between the chiral halves. $C$ lives "
            "in the two diagonal blocks, with opposite signs: "
            "$S = -\\psi_-^\\dagger\\sigma\\psi_- + \\psi_+^\\dagger\\sigma\\psi_+$. "
            "$\\gamma^{(x_0)}$ is the identity in both off-diagonal blocks: it "
            "exchanges $\\psi_-$ and $\\psi_+$, which reverses $S$ (the T2 image). "
            "$P_0$ differs from $\\gamma^{(x_0)}$ by the sign of one block, the "
            "work of $\\Gamma$.")
```

Three heat maps, C, $\gamma^{(x_0)}$ and P_0; saved as 18a.6. **What you see in Figure 18a.6:** C fills the two diagonal blocks with patterns of opposite colours; $\gamma^{(x_0)}$ is two red diagonals in the off-diagonal blocks; P_0 is $\gamma^{(x_0)}$ with one of its two blocks turned blue. Why: $S = -\psi_-^\dagger\sigma\psi_- + \psi_+^\dagger\sigma\psi_+$, so swapping the halves (the T2 image) reverses S.

In [17], Lemma 4: the 17 Krein signs.

```
maps = [("Gamma", Gamma)]
maps += [(f"gamma^x{n}", gamma[n]) for n in range(8)]
maps += [(f"P_x{n}", Gamma @ gamma[n]) for n in range(8)]
krein = {name: sign_between(M @ B_over_i @ M.T, B_over_i) for name, M in maps}
say("M B M^dagger = sigma B: " + ", ".join(f"{name} {s:+d}"
                                           for name, s in krein.items()))
```

`maps` is a list of 17 pairs (name, matrix): Γ, the eight $\gamma^{(n)}$ and the eight P_n. For a real M, $MBM^\dagger = i\,M(B/i)M^T$, so the sign σ in $MBM^\dagger = \sigma B$ is the sign between `M @ B_over_i @ M.T` and `B_over_i`, exact whole numbers. `krein` stores the 17 signs and the cell prints them in one line.

```
recorded_krein = {row["map"]: row["sign"]
                  for row in theory["data"]["Krein_signs_M_B_Mdagger"]}
reproduces(krein == recorded_krein and krein["Gamma"] == -1 and krein["gamma^x0"] == 1,
           "Lemma 4: the 17 Krein signs equal the record's; Gamma -1, gamma^(x0) +1",
           (WL, ["Q_Krein_metric_of_images"]),
           (PY, ["compare.theory.krein_signs", "Q.T2_image_keeps_B"]),
           table="Krein_signs_M_B_Mdagger")
```

`recorded_krein` turns the record's data table `Krein_signs_M_B_Mdagger` into a dictionary from the map's name to its sign; the check requires the two dictionaries to be equal (same names, same signs) and names the Wolfram check `Q_Krein_metric_of_images` and the sympy checks `compare.theory.krein_signs` and `Q.T2_image_keeps_B`. Out [17] lists: Γ: -1; $\gamma^{(x_0)}, \gamma^{(x_1)}, \gamma^{(x_2)}, \gamma^{(x_3)}, \gamma^{(x_4)}$: $+1$; $\gamma^{(x_5)}, \gamma^{(x_6)}, \gamma^{(x_7)}$: -1; $P_{x_0}, \ldots, P_{x_4}$: -1; $P_{x_5}, P_{x_6}, P_{x_7}$: $+1$.

In [18], the seventh figure: the Krein signs.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
draw_matrix(axes[0], B_over_i, "imaginary part of $B$")
draw_matrix(axes[1], Gamma @ B_over_i @ Gamma.T,
            "imaginary part of $\\Gamma B\\Gamma^\\dagger = -B$")
image = draw_matrix(axes[2], gamma[0] @ B_over_i @ gamma[0].T,
                    "imaginary part of $\\gamma^{(x_0)}B\\gamma^{(x_0)\\dagger} = B$")
fig.colorbar(image, ax=list(axes), shrink=0.8, label="entry divided by $i$")
save_figure(fig, "krein_signs",
            "Heat maps of the imaginary parts of three 16 by 16 matrices (their "
            "real parts are zero): the Krein matrix $B = -iC\\gamma^{(x_4)}$ (left), "
            "$\\Gamma B\\Gamma^\\dagger$ (middle) and "
            "$\\gamma^{(x_0)}B\\gamma^{(x_0)\\dagger}$ (right); columns horizontal, "
            "rows vertical, red $+1$, blue $-1$, grey 0. The middle picture is the "
            "left one with all colours reversed: the chirality image "
            "$\\Gamma\\Psi$ of a quantised field has the anticommutator $-B$. The "
            "right picture equals the left one: the mirror image "
            "$\\gamma^{(x_0)}\\Psi$ of theorem T2 keeps $+B$, so it is an ordinary "
            "copy of the theory with equal energies.")
```

Three heat maps of the imaginary parts (that is, of `B_over_i` and its images): B, $\Gamma B \Gamma^T$ and $\gamma^{(x_0)} B \gamma^{(x_0)T}$; saved as 18a.7. **What you see in Figure 18a.7:** the middle panel is the left one with every colour reversed (the T1 image carries $-B$), and the right panel is identical to the left one (the T2 image keeps $+B$). Section 18.23 explains what this means for the quantised field.

In [19], the last check.

```
figure_names = ["eight_gammas", "chirality_flips_gammas", "parity_of_products",
                "reflection_table", "chiral_projectors", "chiral_blocks",
                "krein_signs"]
paths = [output_file(f"{FIGURE_FOLDER}/18a_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

`figure_names` lists the seven figure names in order; `enumerate(figure_names, 1)` pairs each with its number, starting at 1, so `paths` holds the seven file paths. The check requires all seven files to exist, and `all_checks_passed()` prints the last line: ALL 16 CHECKS PASSED (notebook 18a).

What Notebook 18a established. PROVED by exact whole-number arithmetic: the matrices of the record are the author's (rebuilt from their formulas); Lemma 1; Lemma 2 for all 256 products and all 456 Lagrangian kernels; Lemma 3 with the reflection table of the record; the block form; Lemma 4 with the 17 Krein signs of the record. Nothing in the notebook concerns a particular solution or any process that creates a universe.

18.10 Theorem T1: the chirality pairing

Hypotheses.

- (H1) The gravitational field: ANY vielbein $e^a{}_\mu$ (so any metric $g_{\mu\nu} = \sum_a \eta_{aa} e^a{}_\mu e^a{}_\nu$ of signature (4,4)) and ANY spin connection $\omega_{\mu ab} = -\omega_{\mu ba}$, in particular the canonical connection of the author's metric with any history $a_4(x_4)$ and any second function $b_4(x_4)$. The field is a fixed background: it is not varied, and both members of the pair live in the SAME field.
- (H2) The statistics: Ψ has Grassmann components (dirac16complex) or commuting components (dirac16complex00). The map acts at the same point, $\Psi'(x) = \Gamma\Psi(x)$, with no change of coordinates.
- (H3) The potential: $U(S) = \frac{\lambda}{2} S^2$; more generally any function U (commuting field) or any polynomial U (Grassmann field), mapped to $-U$.
- (H4) $\mathcal{L}$, E, T and J as in Section 18.4, with any fixed overall sign or factor of T and J.

Theorem T1. Under (H1) to (H4), for both fields:

- (T1a) $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$ for every configuration (off shell); for a general potential $\mathcal{L}_{m,U}[\Gamma\Psi] = -\mathcal{L}_{-m,-U}[\Psi]$. Separately, $S[\Gamma\Psi] = S[\Psi]$ and $K[\Gamma\Psi] = -K[\Psi]$.
- (T1b) $E_{m,\lambda}[\Gamma\Psi] = -\Gamma E_{-m,-\lambda}[\Psi]$: $\Gamma\Psi$ solves the field equations with (m, λ) if and only if Ψ solves those with $(-m, -\lambda)$. Equivalently, because $\Gamma\Gamma = 1$: Ψ solves the (m, λ) equations if and only if $\Gamma\Psi$ solves the $(-m, -\lambda)$ equations.
- (T1c) $T_{\mu\nu}^{(-m,-\lambda)}[\Gamma\Psi] = -T_{\mu\nu}^{(m,\lambda)}[\Psi]$ and $J^\mu[\Gamma\Psi] = -J^\mu[\Psi]$, at every point, off and on shell.
- (T1d) The pair (Ψ with (m, λ); $\Gamma\Psi$ with $(-m, -\lambda)$) has the total energy-momentum density $T + T' = 0$, the total current $J + J' = 0$ and the total charge $Q + Q' = 0$, as classical bilinears: ordinary numbers for dirac16complex00, elements of the Grassmann algebra for dirac16complex.

Status: PROVED. Records: `wolfram-pairing.json`, the 51 checks of the T1 group (four gravitational fields, both statistics; their names begin with `T1_`, plus `Gamma_properties`); `python-pairing.json`, the 23 checks whose names begin with `T1.` (the comparison check `compare.theorem_T1` lists the 17 of them that confirm the Wolfram theorem independently); the theorem record `pairing-theory.json`, theorem T1. Notebook 18b proves it again in the author's metric (In [10] to In [12]); Notebook 18c shows it on actual solutions (In [7] to In [11]).

18.11 The proof of T1, line by line

Step 1: the adjoint and the derivatives. By Lemma 2, $\overline{\Gamma\Psi} = \bar{\Psi}\Gamma$. By Lemma 1,

$$D_\mu(\Gamma\Psi) = \Gamma D_\mu\Psi, \qquad D_\mu\overline{\Gamma\Psi} = D_\mu(\bar{\Psi}\Gamma) = (D_\mu\bar{\Psi})\Gamma.$$

These hold for every connection, because Γ commutes with every S^{ab}.

Step 2: the scalar and the kinetic term. Insert $\Psi' = \Gamma\Psi$ into S:

$$S[\Gamma\Psi] = \overline{\Gamma\Psi}\,\Gamma\Psi = \bar{\Psi}\Gamma\Gamma\Psi = \bar{\Psi}\Psi = S[\Psi].$$

The first equality is the definition of S; the second is Step 1; the third is $\Gamma\Gamma = 1$ (Lemma 1). Now the first half of the kinetic term:

$$\overline{\Gamma\Psi}\,\gamma^\mu D_\mu(\Gamma\Psi) = \bar{\Psi}\,\Gamma\gamma^\mu\Gamma\,D_\mu\Psi = -\bar{\Psi}\gamma^\mu D_\mu\Psi.$$

The first equality is Step 1 twice. The second uses $\Gamma\gamma^\mu\Gamma = -\gamma^\mu$: $\gamma^\mu = \sum_a e^\mu{}_a\gamma^{(a)}$ is a combination of gammas with ordinary functions as coefficients, and each $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}$ (Lemma 2 with $k = 1$). The second half changes sign in the same way:

$$(D_\mu\overline{\Gamma\Psi})\gamma^\mu\,\Gamma\Psi = (D_\mu\bar{\Psi})\,\Gamma\gamma^\mu\Gamma\,\Psi = -(D_\mu\bar{\Psi})\gamma^\mu\Psi.$$

Subtracting the two lines and multiplying by $\frac{1}{2}$ gives

$$K[\Gamma\Psi] = -K[\Psi].$$

In the written-out form of Section 18.4, K is a sum of coefficient functions of the gravitational field times bilinears with an odd number of gammas; each such bilinear changes sign by Lemma 2, whatever the coefficients are.

Step 3: the Lagrangian. $U(S)$ is unchanged because S is. So

$$\mathcal{L}_{m,U}[\Gamma\Psi] = \sqrt{|g|}\,[\,-K - mS - U(S)].$$

This inserts Step 2 into the definition of $\mathcal{L}$; $\sqrt{|g|}$ is a property of the field, not of Ψ.

$$\sqrt{|g|}\,[\,-K - mS - U(S)] = -\sqrt{|g|}\,[K - (-m)S - (-U)(S)] = -\mathcal{L}_{-m,-U}[\Psi].$$

We took out the factor -1 and recognised the Lagrangian with the mass $-m$ and the potential $-U$. For $U = \frac{\lambda}{2}S^2$, $-U = \frac{-\lambda}{2}S^2$, which is (T1a).

Step 4: the field equations. Using Step 1 and $\gamma^\mu\Gamma = -\Gamma\gamma^\mu$:

$$\gamma^\mu D_\mu(\Gamma\Psi) = \gamma^\mu\Gamma D_\mu\Psi = -\Gamma\gamma^\mu D_\mu\Psi.$$

Insert this and $S[\Gamma\Psi] = S$ into $E_{m,\lambda}$:

$$E_{m,\lambda}[\Gamma\Psi] = -\Gamma\gamma^\mu D_\mu\Psi - (m+\lambda S)\Gamma\Psi = -\Gamma\big[\gamma^\mu D_\mu\Psi - (-m-\lambda S)\Psi\big] = -\Gamma E_{-m,-\lambda}[\Psi].$$

The middle step takes out $-\Gamma$ (a constant matrix commutes with the numbers m, λ, S); the last is the definition of E with $(-m,-\lambda)$. Since Γ is invertible, $E_{m,\lambda}[\Gamma\Psi] = 0$ exactly when $E_{-m,-\lambda}[\Psi] = 0$: this is (T1b). The same holds for the Euler-Lagrange expressions derived directly from $\mathcal{L}$, whatever their explicit form: (T1a) is an identity between functions of Ψ, and $\Psi \to \Gamma\Psi$ is a constant invertible linear substitution, so by the chain rule the Euler-Lagrange expressions of $\mathcal{L}_{m,\lambda}$ at $\Gamma\Psi$, multiplied by Γ, equal minus those of $\mathcal{L}_{-m,-\lambda}$ at Ψ; they vanish together. (The overall sign of a Lagrangian does not change its Euler-Lagrange equations: $-\mathcal{L}$ and $\mathcal{L}$ have the same solutions.)

Step 5: the energy-momentum tensor and the current. $T_{\mu\nu}$ is a sum of the kinetic bilinears $\bar\Psi\gamma_\mu D_\nu\Psi$ and $(D_\mu\bar\Psi)\gamma_\nu\Psi$ (one gamma each) and of $-g_{\mu\nu}\mathcal{L}/\sqrt{|g|}$. By Step 2 each kinetic bilinear changes sign under $\Psi \to \Gamma\Psi$: the lines of Step 2 hold with the free index ν on D_ν and with $\gamma_\mu = \sum_\rho g_{\mu\rho}\gamma^\rho$ in place of γ^μ, because γ_μ is again a combination of gammas with ordinary functions as coefficients, so $\Gamma\gamma_\mu\Gamma = -\gamma_\mu$; for example $\overline{\Gamma\Psi}\,\gamma_\mu D_\nu(\Gamma\Psi) = \bar\Psi\,\Gamma\gamma_\mu\Gamma\,D_\nu\Psi = -\bar\Psi\gamma_\mu D_\nu\Psi$. By Step 3 with m replaced by $-m$ and λ by $-\lambda$, $\mathcal{L}_{-m,-\lambda}[\Gamma\Psi] = -\mathcal{L}_{m,\lambda}[\Psi]$. Therefore

$$T^{(-m,-\lambda)}_{\mu\nu}[\Gamma\Psi] = -\frac{1}{4}(\cdots)_\Psi - g_{\mu\nu}\frac{-\mathcal{L}_{m,\lambda}[\Psi]}{\sqrt{|g|}} = -T^{(m,\lambda)}_{\mu\nu}[\Psi],$$

where $(\cdots)_\Psi$ is the bracket of kinetic bilinears of Ψ. The current is a multiple of $\bar\Psi\gamma^\mu\Psi$, a bilinear with one gamma, so $J^\mu[\Gamma\Psi] = -J^\mu[\Psi]$; and the charge $Q = \int\sqrt{|g|}\,J^{x_4}\,d^7x$ changes sign with it. This is (T1c).

Step 6: the pair. Add (T1c) to the quantities of Ψ: $T^{(m,\lambda)}[\Psi]+T^{(-m,-\lambda)}[\Gamma\Psi] = 0$, $J[\Psi]+J[\Gamma\Psi] = 0$, $Q + Q' = 0$. This is (T1d).

Step 7: both statistics. $\Gamma = \mathrm{diag}(-I_8, I_8)$ multiplies each component by $+1$ or -1. No two Grassmann components are ever exchanged, so every line above holds word for word for anticommuting components, as identities between elements of the Grassmann algebra.

The proof used only Lemmas 1 and 2 and the fact that $\mathcal{L}$, T and J are sums of coefficient functions of the gravitational field ($\sqrt{|g|}$, $e^\mu{}_a$, $\omega_{\mu ab}$) times bilinears. It therefore holds in every gravitational field (H1). QED.

18.12 T1 in the block form of the author's field

In the author's field the proof can also be read off the field equation itself. In the chiral block form $\Psi = (\psi_-, \psi_+)$ every gamma is block off-diagonal; write its upper-right block $\bar\tau^a$ and its lower-left block τ^a (for the author's gammas these are their matrices $\bar\tau_A$ and τ_A, and $\bar\tau^0 = \tau^0 = I_8$). Then $\gamma^{(a)}(\psi_-,\psi_+) = (\bar\tau^a\psi_+, \tau^a\psi_-)$, and the 16 equations of Section 18.4 become the two 8-component equations

$$\sum_a f_a^{-1}\bar\tau^a\partial_a\psi_+ + 3H\psi_+ = V\psi_-, \qquad \sum_a f_a^{-1}\tau^a\partial_a\psi_- + 3H\psi_- = V\psi_+, \qquad V = m+\lambda S.$$

The first equation is the upper half (rows 1 to 8) of $\gamma^\mu\partial_\mu\Psi + 3H\gamma^{(x_0)}\Psi = V\Psi$, the second the lower half; $3H\gamma^{(x_0)}$ contributes $3H\psi_+$ to the upper and $3H\psi_-$ to the lower half because both blocks of $\gamma^{(x_0)}$ are I_8. Now apply T1: $\Gamma(\psi_-,\psi_+) = (-\psi_-,\psi_+)$, $S = -\psi_-^\dagger\sigma\psi_- + \psi_+^\dagger\sigma\psi_+$ is unchanged (the sign of ψ_- appears twice), and with the parameters $(-m,-\lambda)$ the coefficient becomes $-m-\lambda S = -V$. The two equations for the new field with $(-m,-\lambda)$ read

$$\sum_a f_a^{-1}\bar\tau^a\partial_a\psi_+ + 3H\psi_+ = (-V)(-\psi_-), \qquad -\Big(\sum_a f_a^{-1}\tau^a\partial_a\psi_- + 3H\psi_-\Big) = -V\psi_+,$$

which are the old equations: the first is unchanged because $(-V)(-\psi_-) = V\psi_-$, and the second is the old one multiplied by -1. None of the gravitational factors, $e^{\mp a_4}\sin^{-1/6}z$, $\tan z$ and $3H$, changed. This is T1 in the author's metric, PROVED again in this form by the records `wolfram-pairing.json`, checks `T1_field_equation_covariance_primordial_commuting` and `T1_field_equation_covariance_primordial_grassmann`.

18.13 What T1 says, and what it does not say

Both m and λ must change sign. The mass term keeps its sign under Γ only if m is replaced by $-m$, and the potential only if λ is replaced by $-\lambda$. The **negative controls** of the record show that nothing weaker works: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{m,\lambda}[\Psi] \neq 0$ and $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,\lambda}[\Psi] \neq 0$ (`wolfram-pairing.json`, checks `T1_Lagrangian_negative_controls_primordial_commuting` and its Grassmann, diagonal8 and pointwise twins; `python-pairing.json`, checks `T1.metric.commuting.negative_controls` and `T1.metric.grassmann.negative_controls`; Notebook 18b, In [10] and In [11]; Notebook 18c, In [7], where the wrong partner $(-m,+\lambda)$ drifts away from $\Gamma\Psi$ by 1.641). So for $\lambda \neq 0$, T1 is not a pure $+m$ / $-m$ pairing; for $\lambda = 0$ (free fields) it pairs $+m$ with $-m$ exactly.

The partner's energy density, pressures and equations of state. By (T1c), $\rho' = -\rho$ and $p'_\mu = -p_\mu$ in every direction. For homogeneous solutions (Section 18.21) the record gives $\rho = mS + \frac{\lambda}{2}S^2$ and $p = \frac{\lambda}{2}S^2$ in every direction (`python-field-theory.json`, check `commuting_homogeneous_on_shell_rho_p`); the partner has $S' = S$ and $\rho' = -mS - \frac{\lambda}{2}S^2$, $p' = -\frac{\lambda}{2}S^2$. Every ratio of two components is the same for both members, in particular the equations of state $w_3 = p_3/\rho$, $w_t = p_t/\rho$ and $w_0 = p_0/\rho$.

T1 is not a symmetry of one theory. A **symmetry** maps the solutions of one theory to solutions of the SAME theory. T1 changes the parameters and the sign of the action; it maps the theory (m,λ) onto the theory $(-m,-\lambda)$. Because $-\mathcal{L}$ and $\mathcal{L}$ have the same field equations, $\Gamma\Psi$ is a solution of the $(-m,-\lambda)$ theory; nothing more is asserted.

What the map does to the components. Γ is -1 on one irreducible half of Spin(4,4) and $+1$ on the other; the partner differs from Ψ only by the relative sign of its two inequivalent halves (Figure 18a.5). Γ is itself an element of Pin(4,4), a product of eight unit vectors.

T1 and charge conjugation (rule of this book: charge conjugation is a matrix). Chapter 5 derived the two charge-conjugation matrices of the author's gammas. Every matrix M with $M(\gamma^{(a)})^* = s\,\gamma^{(a)}M$ for all a is a multiple of 1 when $s = +1$ and a multiple of Γ when $s = -1$ (`charge-conjugation-and-u1.json`, checks `intertwiners_same_mass` and `intertwiners_reversed_mass`). This gives two charge-conjugation matrices: $\mathcal{C}_+ = C$, with $\mathcal{C}_+^{-1}\gamma^{(a)}\mathcal{C}_+ = -(\gamma^{(a)})^T$, which keeps the mass and gives the conjugate field $\Psi^c = \mathcal{C}_+\bar\Psi^T = \Psi^*$; and $\mathcal{C}_- = \Gamma C$, with $\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = +(\gamma^{(a)})^T$, which REVERSES the mass and gives $\Psi^c = \mathcal{C}_-\bar\Psi^T = \Gamma\Psi^*$ (checks `charge_c`

onjugation_matrix_plus and charge_conjugation_matrix_minus). Because the author's gammas, C and the spin connection are REAL, plain complex conjugation of a REAL field does nothing: a real commuting field is its own $\mathcal{C}_+$ conjugate and carries no U(1) charge ($J^\mu = 0$ identically), so for a real field complex conjugation cannot be what exchanges matter and antimatter (checks representation_real and real_fields_charge_conjugation). For a COMPLEX field the conjugations are defined by the matrices and act differently: the same-mass conjugation by $\mathcal{C}_+$, whose result happens to be $\Psi^c = \mathcal{C}_+\bar{\Psi}^T = \Psi^*$, keeps S and REVERSES J for commuting components, $(S, J) \to (S, -J)$; for Grassmann components it gives $(S, J) \to (-S, +J)$ as classical bilinears, and normal ordering adds no sign (it subtracts the vacuum value, a number), so the quantised field has the same $(S, J) \to (-S, +J)$ (the record's corrected detail text of that check; Section 5.34 and Section 21.26 make the Fock-space computation); the mass-reversing conjugation by $\mathcal{C}_-$, $\Psi^c = \Gamma\Psi^*$, gives $(S, +J)$ for commuting and $(-S, -J)$ for Grassmann components (check bilinears_under_charge_conjugation). In every case the charge conjugation is the matrix $\mathcal{C}_+$ or $\mathcal{C}_-$ applied to $\bar{\Psi}^T$; complex conjugation by itself is not called charge conjugation in this book. For such a real field, $\Psi^* = \Psi$, so the $\mathcal{C}_-$ conjugate $\Gamma\Psi^*$ is exactly the T1 image $\Gamma\Psi$: **on real fields, T1 is the mass-reversing charge conjugation by the matrix** Γ, and it maps solutions with (m, λ) to solutions with $(-m, -\lambda)$ (same check). For complex fields the two maps differ: T1 is linear ($\Psi \to \Gamma\Psi$) and reverses J, while the $\mathcal{C}_-$ conjugation is antilinear ($\Psi \to \Gamma\Psi^*$); for commuting components it keeps J (check bilinears_under_charge_conjugation). For the quantised field the conjugation that preserves the canonical anticommutator is $\Psi \to \Gamma\Psi^{\dagger T}$, and it too reverses the mass (check quantum_charge_conjugation_unitary_type). Chapter 21 uses these facts for matter and antimatter.

18.14 Theorem T2: the mirror pairing

T1 reverses the energy and needs $\lambda \to -\lambda$. Is there a map that pairs (m, λ) with $(-m, \lambda)$, the same coupling? Lemma 3 points to it: the reflections of the space-like directions have the character -1, so they reverse S and keep the kinetic term.

Hypotheses.

- (H5) n is a space-like frame direction (x_0, x_1, x_2 or x_3), and $P_n = \Gamma\gamma^{(n)}$ is the Pin(4,4) lift of the reflection R_n, of character -1 (Lemma 3).
- (H6) General-field version: the frame is reflected, $e' = R_n e$, that is ${e'}^a{}_\mu = (R_n)_{aa} e^a{}_\mu$ (the same metric, since $R_n \eta R_n = \eta$, and the same $\sqrt{|g|}$), with its own canonical connection; and $\Psi'(x) = \Gamma P_n \Psi(x) = \gamma^{(n)}\Psi(x)$ at the same point.
- (H7) Author's-field version: the map ϕ: $x_0 \to \pi/(6H) - x_0$, that is $z \to \pi - z$, takes the patch $0 < z < \pi/2$ onto the mirror patch $\pi/2 < z < \pi$; each patch carries its own positive vielbein ($f_0 = |\cot z|$, which is $-\cot z$ on the mirror patch); and $\Psi'(\phi(x)) = \gamma^{(x_0)}\Psi(x)$. The brane $z = \pi/2$ is a degenerate surface of the metric ($g_{00} = \cot^2 z = 0$ and $\sqrt{|g|} = \cos z = 0$ there); extending the field to the mirror patch is the Z2 construction, ASSUMED.
- (H8) Both statistics; $U(S) = \frac{\lambda}{2}S^2$, or any even function of S.

Theorem T2. Under (H5) to (H8), for both fields:

- (T2a) $\mathcal{L}_{m,\lambda}[\gamma^{(n)}\Psi;\, R_n e] = +\mathcal{L}_{-m,\lambda}[\Psi;\, e]$ in every gravitational field; in the author's field $\mathcal{L}_{m,\lambda}[\Psi'](\phi(x)) = \mathcal{L}_{-m,\lambda}[\Psi](x)$.
- (T2b) $S' = -S$, and $E_{m,\lambda}[\gamma^{(n)}\Psi;\, R_n e] = -\gamma^{(n)} E_{-m,\lambda}[\Psi;\, e]$: Ψ solves the $(-m,\lambda)$ equations if and only if its image solves the (m,λ) equations (in the author's field: on the patch and on the mirror patch respectively).
- (T2c) In the general-field version $T'_{\mu\nu} = T^{(-m,\lambda)}_{\mu\nu}[\Psi]$ and $J'^{\mu} = J^{\mu}[\Psi]$. In the author's field the coordinate components pick up the reflection of x_0: $T_{\mu\nu}[\Psi'](\phi(x)) = \Lambda_\mu \Lambda_\nu\, T^{(-m,\lambda)}_{\mu\nu}[\Psi](x)$ and $J'^{\mu} = \Lambda_\mu J^{\mu}$, with $\Lambda = \mathrm{diag}(-1,1,1,1,1,1,1,1)$. The energy density, the charge density and every component without an index x_0 are EQUAL, not opposite. T2 pairs $+m$ with $-m$ at equal energy-momentum.
- (T2d) For a time-like n (character $+1$) the same construction gives $\mathcal{L} \to -\mathcal{L}_{-m,-\lambda}$, a map of the T1 type. The character -1 is what makes T2 a pairing $(m,\lambda) \to (-m,\lambda)$ with $\mathcal{L} \to +\mathcal{L}$.

Status: PROVED, the author's-field version under the ASSUMED Z2 construction. Records: `wolfram-pairing.json`, the 28 checks of the T2 group (the frame reflections of all eight directions in a general field at a point, both statistics, and the mirror in the author's field); `python-pairing.json`, the 16 checks of the T2 group (names beginning with `T2.` and the two geometry checks of the mirror); theorem T2 of `pairing-theory.json`. Notebook 18b proves it in the author's metric (In [15] to In [19]); Notebook 18c shows it on actual solutions (In [12] and In [13]).

18.15 The proof of T2 in a general field

Fix a space-like n in the end, but keep η_{nn} general as long as possible, so that (T2d) comes out too.

Step 1: the geometry. The reflected frame gives the same metric:

$$g'_{\mu\nu} = \sum_a \eta_{aa}\,(R_n)_{aa} e^a{}_\mu\,(R_n)_{aa} e^a{}_\nu = \sum_a \eta_{aa} e^a{}_\mu e^a{}_\nu = g_{\mu\nu}.$$

$(R_n)^2_{aa} = 1$. Its canonical connection is $R_n \omega R_n$: in the formula $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu e^\nu{}_b + \Gamma^\nu{}_{\mu\lambda} e^\lambda{}_b)$ the new vielbein carries a factor $(R_n)_{aa}$, its inverse a factor $(R_n)_{bb}$, the constant factors come out of ∂_μ, and the Christoffel symbols of the unchanged metric are unchanged:

$$\omega'_{\mu ab} = (R_n)_{aa}(R_n)_{bb}\,\omega_{\mu ab}.$$

By Lemma 3, item 2, $(R_n)_{aa}(R_n)_{bb} S^{ab} = \gamma^{(n)} S^{ab} (\gamma^{(n)})^{-1}$, so

$$\Omega'_\mu = \frac{1}{2}\sum_{a,b} (R_n)_{aa}(R_n)_{bb}\,\omega_{\mu ab} S^{ab} = \gamma^{(n)}\,\Omega_\mu\,(\gamma^{(n)})^{-1},$$

and therefore $D'_\mu(\gamma^{(n)}\Psi) = \gamma^{(n)}\partial_\mu\Psi + \gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1}\gamma^{(n)}\Psi = \gamma^{(n)} D_\mu \Psi$.

Step 2: the adjoint. $\gamma^{(n)}$ is real with $(\gamma^{(n)})^T = \eta_{nn}\gamma^{(n)}$, and from $C\gamma^{(n)}C^{-1} = -(\gamma^{(n)})^T = -\eta_{nn}\gamma^{(n)}$ we get $C\gamma^{(n)} = -\eta_{nn}\gamma^{(n)}C$ (multiply on the right by C) and then $\gamma^{(n)}C = -\eta_{nn}C\gamma^{(n)}$ (multiply both sides by $-\eta_{nn}$ and use $\eta_{nn}^2 = 1$). Then

$$\bar\Psi' = \Psi^\dagger(\gamma^{(n)})^T C = \eta_{nn}\Psi^\dagger\gamma^{(n)}C = \eta_{nn}\Psi^\dagger(-\eta_{nn}C\gamma^{(n)}) = -\bar\Psi\gamma^{(n)}.$$

The definition of the adjoint with $(M\Psi)^\dagger = \Psi^\dagger M^T$ for a real M; the transpose rule; the relation just derived; $\eta_{nn}^2 = 1$. Now the derivative of the adjoint, with the connection Ω'_μ of Step 1:

$$D'_\mu\bar\Psi' = \partial_\mu\bar\Psi' - \bar\Psi'\Omega'_\mu = -(\partial_\mu\bar\Psi)\gamma^{(n)} + \bar\Psi\gamma^{(n)}\gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1}.$$

The definition $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$; then $\bar\Psi' = -\bar\Psi\gamma^{(n)}$ (the constant $\gamma^{(n)}$ comes out of ∂_μ) and $\Omega'_\mu = \gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1}$ (Step 1); the two minus signs of the second term multiply to $+1$.

$$\bar\Psi\gamma^{(n)}\gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1} = \eta_{nn}\,\bar\Psi\Omega_\mu\,\eta_{nn}\gamma^{(n)} = \bar\Psi\Omega_\mu\gamma^{(n)}.$$

The Clifford relation $\gamma^{(n)}\gamma^{(n)} = \eta_{nn}$, the inverse $(\gamma^{(n)})^{-1} = \eta_{nn}\gamma^{(n)}$ (Lemma 3, proof of 2), and $\eta_{nn}^2 = 1$.

$$D'_\mu\bar\Psi' = -(\partial_\mu\bar\Psi)\gamma^{(n)} + \bar\Psi\Omega_\mu\gamma^{(n)} = -(\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu)\gamma^{(n)} = -(D_\mu\bar\Psi)\gamma^{(n)}.$$

We inserted the line before, took out the common factor $-(\cdots)\gamma^{(n)}$ on the right, and recognised $D_\mu\bar\Psi$.

Step 3: the gammas of the reflected frame. $\gamma'^\mu = \sum_a e'^\mu{}_a\gamma^{(a)} = \sum_a e^\mu{}_a(R_n)_{aa}\gamma^{(a)}$. For $a \neq n$, $(R_n)_{aa}\gamma^{(a)}\gamma^{(n)} = \gamma^{(a)}\gamma^{(n)} = -\gamma^{(n)}\gamma^{(a)}$; for $a = n$, $(R_n)_{nn}\gamma^{(n)}\gamma^{(n)} = -\gamma^{(n)}\gamma^{(n)}$. So in both cases $(R_n)_{aa}\gamma^{(a)}\gamma^{(n)} = -\gamma^{(n)}\gamma^{(a)}$, and summing with the coefficients $e^\mu{}_a$:

$$\gamma'^\mu\gamma^{(n)} = -\gamma^{(n)}\gamma^\mu.$$

Step 4: the bilinears. Insert Steps 1 to 3:

$$\bar\Psi'\gamma'^\mu D'_\mu\Psi' = -\bar\Psi\gamma^{(n)}\,\gamma'^\mu\gamma^{(n)}D_\mu\Psi = -\bar\Psi\gamma^{(n)}(-\gamma^{(n)}\gamma^\mu)D_\mu\Psi = \eta_{nn}\,\bar\Psi\gamma^\mu D_\mu\Psi.$$

The first step inserts $\bar\Psi' = -\bar\Psi\gamma^{(n)}$ (Step 2), $D'_\mu\Psi' = \gamma^{(n)}D_\mu\Psi$ (Step 1); the second is Step 3; the last step is $\gamma^{(n)}\gamma^{(n)} = \eta_{nn}$ and $(-1)(-1) = 1$. The second half of K, line by line:

$$(D'_\mu\bar\Psi')\gamma'^\mu\Psi' = -(D_\mu\bar\Psi)\gamma^{(n)}\gamma'^\mu\gamma^{(n)}\Psi.$$

We inserted $D'_\mu\bar\Psi' = -(D_\mu\bar\Psi)\gamma^{(n)}$ (Step 2) and $\Psi' = \gamma^{(n)}\Psi$.

$$\gamma^{(n)}\gamma'^\mu\gamma^{(n)} = \gamma^{(n)}\big(-\gamma^{(n)}\gamma^\mu\big) = -\eta_{nn}\gamma^\mu.$$

Step 3 replaced $\gamma'^\mu\gamma^{(n)}$ by $-\gamma^{(n)}\gamma^\mu$; then $\gamma^{(n)}\gamma^{(n)} = \eta_{nn}$.

$$(D'_\mu\bar\Psi')\gamma'^\mu\Psi' = -(D_\mu\bar\Psi)\big(-\eta_{nn}\gamma^\mu\big)\Psi = \eta_{nn}\,(D_\mu\bar\Psi)\gamma^\mu\Psi.$$

We inserted the line before; the two minus signs multiply to +1. Both halves of K are multiplied by η_{nn}, so $K' = \eta_{nn} K$. And

$$S' = \bar{\Psi}'\Psi' = -\bar{\Psi}\gamma^{(n)}\gamma^{(n)}\Psi = -\eta_{nn} S.$$

Step 5: the Lagrangian. For a space-like n, $\eta_{nn} = +1$: $K' = K$ and $S' = -S$, so

$$\mathcal{L}_{m,\lambda}[\Psi'; e'] = \sqrt{|g|}\Big[K - m(-S) - \frac{\lambda}{2}(-S)^2\Big] = \sqrt{|g|}\Big[K - (-m)S - \frac{\lambda}{2}S^2\Big] = \mathcal{L}_{-m,\lambda}[\Psi; e],$$

which is (T2a); the potential is even in S, so it does not change. For a time-like n, $\eta_{nn} = -1$: $K' = -K$ and $S' = S$, so $\mathcal{L}_{m,\lambda}[\Psi'; e'] = \sqrt{|g|}[-K - mS - \frac{\lambda}{2}S^2] = -\mathcal{L}_{-m,-\lambda}[\Psi; e]$, which is (T2d).

Step 6: the field equations (space-like n). With Step 1, Step 3 and $S' = -S$:

$$E_{m,\lambda}[\Psi'; e'] = \gamma'^{\mu}\gamma^{(n)} D_\mu\Psi - (m - \lambda S)\gamma^{(n)}\Psi = -\gamma^{(n)}\big[\gamma^\mu D_\mu\Psi - (-m + \lambda S)\Psi\big] = -\gamma^{(n)} E_{-m,\lambda}[\Psi; e],$$

which is (T2b), since $\gamma^{(n)}$ is invertible.

Step 7: the energy-momentum tensor and the current. The tensor of Section 18.4 contains the kinetic bilinears with free indices and the lowered gammas $\gamma_\mu = \sum_\rho g_{\mu\rho}\gamma^\rho$. The reflected frame has the same metric (Step 1), so $\gamma'_\mu = \sum_\rho g_{\mu\rho}\gamma'^\rho$, and the line $\gamma^{(n)}\gamma'^\rho\gamma^{(n)} = -\eta_{nn}\gamma^\rho$ of Step 4, multiplied by $g_{\mu\rho}$ and summed over ρ, gives

$$\gamma^{(n)}\gamma'_\mu\gamma^{(n)} = \sum_\rho g_{\mu\rho}\,\gamma^{(n)}\gamma'^\rho\gamma^{(n)} = -\eta_{nn}\sum_\rho g_{\mu\rho}\gamma^\rho = -\eta_{nn}\gamma_\mu.$$

Now the first kind of kinetic bilinear, line by line:

$$\bar{\Psi}'\gamma'_\mu D'_\nu\Psi' = -\bar{\Psi}\gamma^{(n)}\gamma'_\mu\gamma^{(n)} D_\nu\Psi = -\bar{\Psi}\big(-\eta_{nn}\gamma_\mu\big) D_\nu\Psi = \eta_{nn}\,\bar{\Psi}\gamma_\mu D_\nu\Psi.$$

The first step inserts $\bar{\Psi}' = -\bar{\Psi}\gamma^{(n)}$ (Step 2) and $D'_\nu\Psi' = \gamma^{(n)} D_\nu\Psi$ (Step 1); the second is the line before; the two minus signs multiply to +1. The second kind:

$$(D'_\mu\bar{\Psi}')\gamma'_\nu\Psi' = -(D_\mu\bar{\Psi})\gamma^{(n)}\gamma'_\nu\gamma^{(n)}\Psi = -(D_\mu\bar{\Psi})\big(-\eta_{nn}\gamma_\nu\big)\Psi = \eta_{nn}\,(D_\mu\bar{\Psi})\gamma_\nu\Psi.$$

The first step inserts $D'_\mu\bar{\Psi}' = -(D_\mu\bar{\Psi})\gamma^{(n)}$ (Step 2) and $\Psi' = \gamma^{(n)}\Psi$; the second is the line before with ν in place of μ. For a space-like n, $\eta_{nn} = +1$, so all four kinetic bilinears of $T_{\mu\nu}$ (the two lines with μ and ν exchanged give the other two) are unchanged. Insert them, $g'_{\mu\nu} = g_{\mu\nu}$, $\sqrt{|g'|} = \sqrt{|g|}$ and Step 5 into the tensor of Section 18.4, the tensor of the theory (m, λ) evaluated at Ψ' in the frame e':

$$T'_{\mu\nu} = \frac{1}{4}\big(\bar{\Psi}\gamma_\mu D_\nu\Psi + \bar{\Psi}\gamma_\nu D_\mu\Psi - (D_\mu\bar{\Psi})\gamma_\nu\Psi - (D_\nu\bar{\Psi})\gamma_\mu\Psi\big) - g_{\mu\nu}\frac{\mathcal{L}_{-m,\lambda}[\Psi; e]}{\sqrt{|g|}} = T^{(-m,\lambda)}_{\mu\nu}[\Psi].$$

The kinetic bracket contains neither m nor λ; only the Lagrangian of the last term changes, and Step 5 turns it into $\mathcal{L}_{-m,\lambda}[\Psi; e]$. Likewise $\bar{\Psi}'\gamma'^{\mu}\Psi' = -\bar{\Psi}\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)}\Psi = \eta_{nn}\bar{\Psi}\gamma^{\mu}\Psi$ gives $J' = J$. This is (T2c) in the general-field version.

Step 8: both statistics. $\gamma^{(n)}$ is a constant signed permutation matrix: it reorders the components and changes some signs, but in every bilinear each Ψ^* still stands to the left of each Ψ. No two Grassmann components are exchanged, so Steps 1 to 7 hold for both statistics. QED.

18.16 T2 in the author's field: the mirror across the brane

The mirror is an isometry. Under $z \to \pi - z$: $\sin(\pi - z) = \sin z$, so the factors $\sin^{1/3} z$ of the 3-space and extra-time components are unchanged; $\cot(\pi - z) = -\cot z$, so $g_{00} = \cot^2 z$ is unchanged; the factors $e^{\pm 2a_4}$ (and the second function $b_4(x_4)$ of the metric with b_4) do not depend on z. So every $g_{\mu\mu}$ takes the same value at the mirror point (`python-pairing.json`, check `geometry.mirror_isometry`; `wolfram-pairing.json`, check `T2_mirror_is_isometry`; Notebook 18b, In [15], and its Figure 18b.4).

The pulled-back frame is the reflected frame. On the mirror patch the positive hidden vielbein factor is $f_0 = -\cot z$ (positive there, because $\cot z < 0$ for $\pi/2 < z < \pi$). Pull the hidden leg $e^0 = f_0\, dx_0$ back by ϕ: $x_0 \to \pi/(6H) - x_0$ replaces dx_0 by $-dx_0$ and z by $\pi - z$:

$$-\cot(\pi - z)\, d\big(\tfrac{\pi}{6H} - x_0\big) = \cot z\,(-dx_0) = -e^0.$$

The other seven legs are unchanged. So the pulled-back vielbein is $R_0 e$, the frame reflected in the direction x_0, and $\sqrt{|g|}\, d^8x$ is unchanged ($|\cos z|$ is unchanged and the Jacobian of ϕ has modulus 1). Pulling the Lagrangian of the mirror patch back by ϕ therefore gives exactly the frame-reflected Lagrangian of Section 18.15 with $n = x_0$, which proves (T2a) and (T2b) in the author's field. The coordinate components of T and J pick up the Jacobian R_0 of ϕ, one factor -1 for each index x_0, which gives (T2c) with $\Lambda = R_0$. QED.

The spin-connection term on the mirror patch. With $f_0 = -\cot z$ the twelve components of Section 18.3 keep their form, except that the six components with an index x_0 change sign (they contain $1/f_0$). In the sum of Section 18.3 the a_4' terms still cancel and the hidden terms add with the opposite sign: $\gamma^{\mu}\Omega_{\mu} = -3H\gamma^{(x_0)}$ on the mirror patch (Notebook 18c, In [3]). In block form, $\gamma^{(x_0)}(\psi_-, \psi_+) = (\psi_+, \psi_-)$: the mirror image exchanges the two inequivalent Spin(4,4) halves, and $S = -\psi_-^{\dagger}\sigma\psi_- + \psi_+^{\dagger}\sigma\psi_+$ changes sign.

Which matrix makes the mirror a pairing? The sympy record searched four candidates P for the map $\Psi'(\phi(x)) = P\Psi(x)$ and all eight sign choices of a relation $\mathcal{L}^{\text{mirror}}_{m,\lambda}[\Psi'] = \sigma\mathcal{L}^{\text{patch}}_{\pm m,\pm\lambda}[\Psi]$. The result (`python-pairing.json`, checks `T2.metric.commuting.reflection_table` and `T2.metric.grassmann.reflection_table`; Notebook 18b, In [17], Figure 18b.5):

matrix P	**relation found**
1 (the plain mirror)	none
Γ	none
$\gamma^{(x_0)} = \Gamma P_0$	$+\mathcal{L}_{-m,\lambda}$: theorem T2
$\Gamma\gamma^{(x_0)} = P_0$ (the reflection alone)	$-\mathcal{L}_{m,-\lambda}$

The plain mirror fails because the pull-back reverses the hidden leg of the frame: the part of the kinetic term along x_0 (and the connection terms with one index x_0) changes sign while the rest does not, so the pulled-back Lagrangian is neither + nor − a Lagrangian of the patch. The matrix $\gamma^{(x_0)}$ repairs exactly this sign (Steps 3 and 4 of Section 18.15 with $n = x_0$).

The eight reflections. For completeness, the frame reflections of all eight directions (the data table `reflections` of `pairing-theory.json`, recomputed exactly by Notebook 18a, In [12] and In [13], Figure 18a.4):

direction	η_{nn}	**character of** P_n	S **under** $\gamma^{(n)}$	**kinetic term**	**map**
x_0	$+1$	-1	$-S$	$+K$	$(-m, \lambda)$, $+\mathcal{L}$ (T2)
x_1	$+1$	-1	$-S$	$+K$	$(-m, \lambda)$, $+\mathcal{L}$ (T2)
x_2	$+1$	-1	$-S$	$+K$	$(-m, \lambda)$, $+\mathcal{L}$ (T2)
x_3	$+1$	-1	$-S$	$+K$	$(-m, \lambda)$, $+\mathcal{L}$ (T2)
x_4	-1	$+1$	$+S$	$-K$	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)
x_5	-1	$+1$	$+S$	$-K$	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)
x_6	-1	$+1$	$+S$	$-K$	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)
x_7	-1	$+1$	$+S$	$-K$	$(-m, -\lambda)$, $-\mathcal{L}$ (T1 type)

In the author's field only the reflection of x_0 is realised by an isometry that maps the patch onto another patch, the mirror across the Z2 brane; the reflections of x_1, x_2, x_3 are statements about frames.

With a changing b_4. The general-field version of T2 (Section 18.15) holds for every vielbein, so also for the author's metric with any $b_4(x_4)$, and so does T1. The mirror $z \to \pi - z$ does not touch x_4: $b_4(x_4)$ is unchanged by it, and the mirror is still an isometry. The records check the author's-field version of T2 at $b_4 = 1$ only; this book has no recorded check of it with a changing b_4.

What T2 says and does not say. T2 pairs a solution with mass $-m$ on the patch with a solution with mass $+m$ on the mirror patch, at the SAME coupling and with EQUAL energy density and charge density: nothing cancels in a T2 pair. The gluing of the two patches at the degenerate brane is an assumption; no junction condition (an equation that says how the fields and the geometry must match across the brane), brane tension (an energy per unit area carried by the brane itself) or matching of the field across the brane is derived (`pairing-theory.json`, the list `not_esta blished`).

18.17 Example: Notebook 18b proves T1 and T2 in the author's metric

Notebook 18b repeats the proofs of Sections 18.11 and 18.15 as exact computer algebra, without taking any step on trust. It builds the author's metric on the background $b_4 = 1$ with an UNKNOWN

history $a_4(x_4)$ (so every result holds for every deflating history), computes its Christoffel symbols and canonical spin connection with sympy, checks the vielbein postulate and the twelve components of Section 18.3, and recomputes $\gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ direction by direction. Then it writes the Lagrangian, the field operator, all 36 components of $T_{\mu\nu}$ and the 8 components of J^μ as polynomials in the 288 values of the first jet, in an algebra that can treat the jet values as commuting numbers (dirac16complex00) or as Grassmann numbers (dirac16complex), and proves T1 and T2 as identities in which every coefficient is zero. It reproduces 35 checks of `python-pairing.json` and the corresponding Wolfram checks, including the numbers of monomials of the Lagrangian recorded by the Wolfram verifier, 408 for commuting and 392 for Grassmann components, and draws five figures. Its last line is ALL 20 CHECKS PASSED (notebook 18b); it runs in about 2 minutes.

18.18 How to run Notebook 18b

Step 1. What this notebook does and what it needs.

Notebook 18b (T1 and T2 proved symbolically in the author's deflating metric) is the file `Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb` of the repository Dirac_claude. With sympy it builds the author's metric with an arbitrary history a4(x4) of the three exponentially deflating extra times, its diagonal vielbein and its canonical spin connection, and checks the connection (antisymmetry, the vielbein postulate, its nonzero components, gamma^mu Omega_mu = 3 H gamma^(x0) with the deflation terms cancelling). It then writes the Lagrangian, the field equation, the energy-momentum tensor and the current of the two fields on the first jet, with commuting components (dirac16complex00) and with Grassmann components (dirac16complex), and proves as exact polynomial identities the pairing theorem T1 (L_m,lambda of Gamma Psi = minus L_-m,-lambda of Psi, the field equations, T and J reversed, the pair sums zero, a general cubic potential, a random general field) with its negative controls, and the pairing theorem T2 across the Z2 mirror z to pi minus z (L to plus L_-m,lambda, S reversed, T and J pulled back, not reversed). It reproduces 35 checks of the sympy pairing report and the monomial counts and checks of the Wolfram pairing report, and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 18b_t1_t2_symbolic.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18b_t1_t2_symbolic.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 18b_t1_t2_symbolic.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/18b.captions.json`
- `Revision/textbook/figures/18b_1_connection_history.png`
- `Revision/textbook/figures/18b_2_lagrangian_cancellation.png`
- `Revision/textbook/figures/18b_3_emt_signs.png`
- `Revision/textbook/figures/18b_4_mirror_metric.png`
- `Revision/textbook/figures/18b_5_mirror_candidates.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 20 CHECKS PASSED (notebook 18b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 18b_t1_t2_symbolic.ipynb
python -m nbconvert --execute --inplace 18b_t1_t2_symbolic.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or one of the pairing reports: the notebook reads four files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository. Clone the repository again and open the notebook there.
- a cell runs for several minutes: the symbolic checks take about a minute and a half in all on the computer on which the book was built; on a slow computer they may take five minutes. Wait for the PASS lines; the star in the margin of a running cell turns into a number when it ends.

18.19 Notebook 18b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The pairing theorems T1 and T2 are statements about the Lagrangian, the field
equations, the energy-momentum tensor and the current of the two fields
dirac16complex (anticommuting, Grassmann components) and dirac16complex00
(commuting components). Notebook 18a proved the matrix facts behind them. This
notebook proves the theorems themselves, in the author's primordial
gravitational field, as exact identities computed with sympy:

1. It builds the author's metric with an ARBITRARY history $a_4(x_4)$ (the three
   extra times $x_5, x_6, x_7$ deflate exponentially as $a_4$ grows), its
   diagonal vielbein and its canonical spin connection, and checks the connection.
2. It writes every quantity of the theory as a polynomial in the values of the
   field and of its first derivatives at a point (the *first jet*), with
   commuting components and with Grassmann components.
3. **T1**: it proves $\mathcal{L}_{m,\lambda}[\Gamma\Psi] =
```

```
   -\mathcal{L}_{-m,-\lambda}[\Psi]$, the map of the field equations, $T_{\mu\nu}
   \to -T_{\mu\nu}$ and $J^\mu \to -J^\mu$, so that the pair has zero total
   energy-momentum and current; and it shows with *negative controls* that the
   coupling $\lambda$ must change sign too.
4. **T2**: it proves that the reflection of the hidden direction across the
   brane $z = \pi/2$, with $\Psi \to \gamma^{(x_0)}\Psi$, maps a solution with
   $(-m, \lambda)$ to a solution with $(m, \lambda)$, reverses $S$ and keeps the
   energy-momentum tensor and the current (pulled back, not reversed).

Every result is compared with the checks of the two Revision pairing reports
(the sympy report and the Wolfram report), and five figures show what cancels and
what does not.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 18b (T1 and T2 proved symbolically in the author's deflating metric) is the file
`Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb` of the repository Dirac_claude.
With sympy it builds the author's metric with an arbitrary history a4(x4) of the three
exponentially deflating extra times, its diagonal vielbein and its canonical spin
connection, and checks the connection (antisymmetry, the vielbein postulate, its nonzero
components, gamma^mu Omega_mu = 3 H gamma^(x0) with the deflation terms cancelling). It
then writes the Lagrangian, the field equation, the energy-momentum tensor and the
current of the two fields on the first jet, with commuting components (dirac16complex00)
and with Grassmann components (dirac16complex), and proves as exact polynomial identities
the pairing theorem T1 (L_m,lambda of Gamma Psi = minus L_-m,-lambda of Psi, the field
equations, T and J reversed, the pair sums zero, a general cubic potential, a random
general field) with its negative controls, and the pairing theorem T2 across the Z2
mirror z to pi minus z (L to plus L_-m,lambda, S reversed, T and J pulled back, not
reversed). It reproduces 35 checks of the sympy pairing report and the monomial counts
and checks of the Wolfram pairing report, and draws five teaching figures. It needs a
computer with Windows 11, macOS or Linux, an internet connection for the installation,
the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".
```

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
```

```
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 18b_t1_t2_symbolic.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18b_t1_t2_symbolic.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 18b_t1_t2_symbolic.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/18b.captions.json‘
- ‘Revision/textbook/figures/18b_1_connection_history.png‘
- ‘Revision/textbook/figures/18b_2_lagrangian_cancellation.png‘
- ‘Revision/textbook/figures/18b_3_emt_signs.png‘
- ‘Revision/textbook/figures/18b_4_mirror_metric.png‘
- ‘Revision/textbook/figures/18b_5_mirror_candidates.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS every figure file of this notebook exists
    ALL 20 CHECKS PASSED (notebook 18b)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 18b_t1_t2_symbolic.ipynb
      python -m nbconvert --execute --inplace 18b_t1_t2_symbolic.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or one of the pairing reports: the notebook reads four files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository. Clone the repository

  again and open the notebook there.
- a cell runs for several minutes: the symbolic checks take about a minute and a half in all on the computer on which the book was built; on a slow computer they may take five minutes. Wait for the PASS lines; the star in the margin of a running cell turns into a number when it ends.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 18b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 18b (T1 and T2 proved symbolically in the author's deflating metric) is the
# file Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb of the repository
# Dirac_claude. With sympy it builds the author's metric with an arbitrary history a4(x4)
# of the three exponentially deflating extra times, its diagonal vielbein and its
# canonical spin connection, and checks the connection (antisymmetry, the vielbein
# postulate, its nonzero components, gamma^mu Omega_mu = 3 H gamma^(x0) with the
# deflation terms cancelling). It then writes the Lagrangian, the field equation, the
# energy-momentum tensor and the current of the two fields on the first jet, with
# commuting components (dirac16complex00) and with Grassmann components (dirac16complex),
# and proves as exact polynomial identities the pairing theorem T1 (L_m,lambda of Gamma
# Psi = minus L_-m,-lambda of Psi, the field equations, T and J reversed, the pair sums
# zero, a general cubic potential, a random general field) with its negative controls,
# and the pairing theorem T2 across the Z2 mirror z to pi minus z (L to plus L_-m,lambda,
# S reversed, T and J pulled back, not reversed). It reproduces 35 checks of the sympy
# pairing report and the monomial counts and checks of the Wolfram pairing report, and
# draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
```

```
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
```

```
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 18b_t1_t2_symbolic.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
```

```
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 18b_t1_t2_symbolic.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 18b_t1_t2_symbolic.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/18b.captions.json
# - Revision/textbook/figures/18b_1_connection_history.png
# - Revision/textbook/figures/18b_2_lagrangian_cancellation.png
# - Revision/textbook/figures/18b_3_emt_signs.png
# - Revision/textbook/figures/18b_4_mirror_metric.png
# - Revision/textbook/figures/18b_5_mirror_candidates.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 20 CHECKS PASSED (notebook 18b)
#
# and the notebook must show 5 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
```

```
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/18b_t1_t2_symbolic.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 18b_t1_t2_symbolic.ipynb
#     python -m nbconvert --execute --inplace 18b_t1_t2_symbolic.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for gammas.json or one of the pairing reports: the notebook reads
#   four files of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository. Clone the
#   repository again and open the notebook there.
# - a cell runs for several minutes: the symbolic checks take about a minute and a half
#   in all on the computer on which the book was built; on a slow computer they may take
#   five minutes. Wait for the PASS lines; the star in the margin of a running cell turns
#   into a number when it ends.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Metric, vielbein**: the metric $g_{\mu\nu}$ measures lengths and times; a
  *vielbein* $e^a{}_\mu$ writes it as $g_{\mu\nu} = \sum_a\eta_{aa}e^a{}_\mu
  e^a{}_\nu$ with $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$. For the
  author's diagonal metric $e^a{}_\mu = f_\mu\delta^a_\mu$ with
  $f_\mu = \sqrt{|g_{\mu\mu}|}$.
- **Christoffel symbols** $\Gamma^\nu{}_{\mu\lambda}$: the numbers (functions)
  built from the first derivatives of the metric that say how the coordinate
  directions turn from point to point.
- **Canonical spin connection** $\omega_{\mu ab}$: the connection that makes the
  gammas $\gamma^\mu = e^\mu{}_a\gamma^{(a)}$ covariantly constant (the *vielbein
  postulate*); it is antisymmetric in $a, b$. $\Omega_\mu =
  \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$ enters the covariant derivative
  $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$.
- **Jet**: at one point, the 16 components $\Psi_A$, their complex conjugates
  $\Psi_A^*$, and the $8 \times 16$ first derivatives $\partial_\mu\Psi_A$ and
  $\partial_\mu\Psi_A^*$: 288 numbers. Every quantity of this notebook at that
  point is a polynomial in these 288 numbers, with coefficients that depend on the
  point.
- **Generator, monomial**: the notebook treats each of the 288 jet values as a
  symbol, a *generator*; a *monomial* is a product of generators, and a
  polynomial is a sum of monomials times coefficients.
- **Grassmann generators**: symbols that anticommute, $\theta_1\theta_2 =
  -\theta_2\theta_1$, so $\theta_1\theta_1 = 0$. They model the anticommuting
  components of dirac16complex.
- **Identity in the jets**: a polynomial whose every coefficient is zero. It is
  zero for EVERY value of the jet, that is, for every field at every point,
  whether the field solves the field equations or not (*off shell*). An identity
  off shell holds in particular for solutions (*on shell*).
- **Euler-Lagrange expression**: $\partial\mathcal{L}/\partial\Psi^*_A -
  \sum_\mu\partial_\mu\big(\partial\mathcal{L}/\partial(\partial_\mu\Psi^*_A)\big)$;
  the field equations say it is zero.
- **Negative control**: a computation that must FAIL; it shows that the test can
  detect a wrong statement.
- **Isometry**: a change of coordinates that does not change the metric.
- **Patch, mirror patch, brane**: the author's coordinate $z = 6Hx_0$ runs over
  the *patch* $0 < z < \pi/2$. The map $z \to \pi - z$ takes it to the *mirror
  patch* $\pi/2 < z < \pi$; the surface $z = \pi/2$ between them is the *brane*,
  where $g_{00} = \cot^2 z = 0$. Gluing the mirror patch to the patch there is
  the Z2 construction, an ASSUMPTION of the Revision record.
```

Text cell:

```
## 4. The physical and mathematical situation

**The metric.** In the author's coordinates ($x_1, x_2, x_3$ 3-space, $x_4$ the
time, $x_5, x_6, x_7$ the extra times, $x_0$ hidden, $z = 6Hx_0$)

$$ds^2 = e^{2a_4}\sin^{1/3}z\,(dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2
- e^{-2a_4}\sin^{1/3}z\,(dx_5^2 + dx_6^2 + dx_7^2) + \cot^2 z\,dx_0^2 ,$$

with $a_4 = a_4(x_4)$. As $a_4$ grows, 3-space inflates ($e^{a_4}$) and the three
extra times deflate exponentially ($e^{-a_4}$). The vielbein factors are
$f_1 = f_2 = f_3 = e^{a_4}\sin^{1/6}z$, $f_4 = 1$, $f_5 = f_6 = f_7 =
e^{-a_4}\sin^{1/6}z$, $f_0 = \cot z$, and $\sqrt{|g|} = f_0f_2\cdots f_7 =
\cos z$. The notebook keeps $a_4$ as an unknown function of $x_4$, so every result
holds for every history, deflating or not.

**The theory.** With $\bar\Psi = \Psi^\dagger C$, $S = \bar\Psi\Psi$ and
$D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$,

$$\mathcal{L}_{m,\lambda} = \sqrt{|g|}\Big[\tfrac12\big(\bar\Psi\gamma^\mu
D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi\big) - mS - \tfrac{\lambda}{2}S^2\Big],
\qquad E_{m,\lambda} = \gamma^\mu D_\mu\Psi - (m + \lambda S)\Psi ,$$

$$T_{\mu\nu} = \tfrac14\big(\bar\Psi\gamma_\mu D_\nu\Psi + \bar\Psi\gamma_\nu
D_\mu\Psi - (D_\mu\bar\Psi)\gamma_\nu\Psi - (D_\nu\bar\Psi)\gamma_\mu\Psi\big)
- g_{\mu\nu}\mathcal{L}/\sqrt{|g|},\qquad J^\mu = i\bar\Psi\gamma^\mu\Psi .$$

The field equation is $E_{m,\lambda} = 0$. $T_{\mu\nu}$ and $J^\mu$ are written
exactly as in the sympy pairing report of the Revision record; another overall
sign or factor changes nothing below, because every statement is of the form
$T' = \pm T$, $J' = \pm J$. (In this convention the energy density of the theory
record is $\rho = -T_{x_4x_4}$.)

**Why a polynomial identity in the jet is a proof.** Every quantity above, at a
point, is a polynomial in the 288 jet values whose coefficients are functions of
$x_4$ and $z$ (through $a_4$, $a_4' = da_4/dx_4$, $\sin z$, $\cot z$, $H$). If
the polynomial $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,-\lambda}
[\Psi]$ has only zero coefficients, it vanishes for every field, at every point,
for every history $a_4$: that IS the theorem. For dirac16complex the jet values
are Grassmann generators; the same computation in an algebra of anticommuting
symbols proves the theorem for that field.
```

Text cell:

```
## 5. The gamma matrices as exact sympy matrices

The next cell imports sympy and numpy, defines the helpers that read the Revision
records (`reproduces` passes only when the notebook's own result holds AND every
named check of the named report has the verdict PASS), reads the author's gamma
matrices and builds $C$, $\Gamma$ and $S^{ab} = \frac14[\gamma^{(a)},
\gamma^{(b)}]$ as exact sympy matrices (whole numbers and halves, no rounding).
```

In [2]:

```
import itertools  # all combinations of signs
import random  # Python's random numbers with a fixed seed (the random field)

import numpy as np  # numbers for the figures
import sympy as sp  # exact symbolic algebra

GAMMAS = "Revision/algebra/gammas.json"
PY = "Revision/pairing/reports/python-pairing.json"  # the sympy verifier's report

```

Out [2]:

```
PASS eight real 16 x 16 gammas with the Clifford relations; Gamma = diag(-I8, I8)
```

Text cell:

```
## 6. The author's metric and its canonical spin connection

The next cell defines the symbols: the time $x_4$, the hidden angle $z$, the
author's constant $H$, the mass $m$, the coupling $\lambda$ and the unknown
function $a_4(x_4)$. A derivative along $x_0$ is a derivative along $z$ times
$6H$ (because $z = 6Hx_0$); nothing depends on $x_1, x_2, x_3, x_5, x_6, x_7$.

The class `Geometry` then computes, for the diagonal vielbein with the factors
$f_\mu$ of section 4 (with $f_0 = s_0\cot z$, where the sign $s_0 = +1$ on the
patch and $s_0 = -1$ on the mirror patch keeps $f_0$ positive):

- the metric $g_{\mu\mu} = \eta_{\mu\mu}f_\mu^2$ and $\sqrt{|g|} = f_0\cdots f_7$;
- the Christoffel symbols of a diagonal metric,
  $\Gamma^\nu{}_{\mu\lambda} = \frac{1}{2g_{\nu\nu}}\big(\delta_{\nu\lambda}
  \partial_\mu g_{\nu\nu} + \delta_{\nu\mu}\partial_\lambda g_{\nu\nu} -
  \delta_{\mu\lambda}\partial_\nu g_{\mu\mu}\big)$;
- the canonical spin connection $\omega_\mu{}^a{}_b = e^a{}_\nu\big(\partial_\mu
  e^\nu{}_b + \Gamma^\nu{}_{\mu\lambda}e^\lambda{}_b\big)$ with the inverse
  vielbein $e^\nu{}_b = \delta^\nu_b/f_b$, lowered to $\omega_{\mu ab} =
  \eta_{aa}\,\omega_\mu{}^a{}_b$;
- $\Omega_\mu = \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$, the curved gammas
  $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and $\gamma_\mu = g_{\mu\mu}\gamma^\mu$.

Every expression is simplified exactly by sympy.
```

In [3]:

```
x4, z, H = sp.symbols("x4 z H", real=True)

## 7. An algebra for the jets: commuting or Grassmann

The next cell defines a small algebra of polynomials in numbered generators. An
element is a Python dictionary: each key is a monomial, written as the sorted
tuple of its generator numbers, and each value is its sympy coefficient. Adding
merges the dictionaries. Multiplying multiplies every monomial of the first
factor with every monomial of the second. For COMMUTING generators the product
```

monomial is just the sorted joined tuple. For GRASSMANN generators (‘odd=True‘)
two more rules apply: a monomial that contains a generator twice is zero
($\theta\theta = 0$), and sorting the joined tuple costs the sign $(-1)^p$, where
p is the number of pairs that must be exchanged (each exchange of two
anticommuting symbols gives a minus sign). ‘is_zero‘ decides whether every
coefficient vanishes, first with ‘expand‘ and, if needed, with ‘simplify‘.

In [7]:

```

```
The next cell defines the matrix operations on columns of 16 algebra elements (matrix
times column, row times matrix, row times column) and the first jet. The 288
generators are numbered: $\Psi^*_A$ is $A$ ($A = 0, \dots, 15$), $\Psi_A$ is $16 +
A$, $\partial_\mu\Psi^*_A$ is $32 + 16\mu + A$ and $\partial_\mu\Psi_A$ is $160 +
16\mu + A$ ($\mu = 0, \dots, 7$ for $x_0, \dots, x_7$). The function ‘transform‘
returns the jet of the new field $\Psi'(x) = P\Psi(Rx)$: the components are
multiplied by the matrix $P$ (their conjugates by $P^*$), and the derivative along
$x_\mu$ gets the sign ‘signs[mu]‘ of the coordinate reflection $R$ (all $+1$ for T1;
$-1$ for $x_0$ in the mirror map of T2).

## 8. The Lagrangian, the field equation, $T_{\mu\nu}$ and $J^\mu$ on the jet

The next cell writes the quantities of section 4 on a jet `J` in a geometry
`geo`, line by line as in the formulas: the covariant derivatives
$D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $D_\mu\bar\Psi =
(\partial_\mu\Psi^*)^TC - \Psi^{*T}C\Omega_\mu$; the scalar $S = \Psi^{*T}C\Psi$;
the Lagrangian (its argument `upoly`, used once, replaces $\frac{\lambda}{2}S^2$ by
a general cubic $U(S) = u_1S + u_2S^2 + u_3S^3$); the field-equation operator
$E$; the energy-momentum tensor $T_{\mu\nu}$ for $\mu \le \nu$ (36 components);
the current $J^\mu$; and the Euler-Lagrange expressions derived from the
Lagrangian. The derivation uses the rule $\partial_\mu(c\,\Psi_B) =
(\partial_\mu c)\Psi_B + c\,\partial_\mu\Psi_B$ for a coefficient $c$ that
depends on the point (the metric functions).
```

## 9. Theorem T1 in the author's metric, both fields

The next cell defines the complete T1 test for one statistics and runs it for
commuting components (dirac16complex00). With $\Psi' = \Gamma\Psi$ (the jet
transformed by $\Gamma$, no coordinate change) it checks, each as an identity in
the 288 jet values:

1. $S[\Gamma\Psi] - S[\Psi] = 0$;
2. $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,-\lambda}[\Psi] = 0$,
   and it counts the monomials of $\mathcal{L}$ with a nonzero coefficient (the
   Wolfram report records this count);
3. negative controls: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] +
   \mathcal{L}_{m,\lambda}[\Psi] \neq 0$ and $\mathcal{L}_{m,\lambda}[\Gamma\Psi] +
   \mathcal{L}_{-m,\lambda}[\Psi] \neq 0$ (the mass AND the coupling must change
   sign);
4. the Euler-Lagrange expressions derived from $\mathcal{L}$ equal
   $\sqrt{|g|}\,[CE_{m,\lambda}]_A$ for all 16 $A$ (so $E = 0$ IS the field
   equation);
5. $E_{m,\lambda}[\Gamma\Psi] + \Gamma E_{-m,-\lambda}[\Psi] = 0$ (16 components):
   $\Gamma\Psi$ solves the $(m, \lambda)$ equations exactly when $\Psi$ solves
   the $(-m, -\lambda)$ equations;
6. $T_{\mu\nu}[\Gamma\Psi; m, \lambda] + T_{\mu\nu}[\Psi; -m, -\lambda] = 0$ and,
   for the pair, $T_{\mu\nu}[\Psi; m, \lambda] + T_{\mu\nu}[\Gamma\Psi; -m,
   -\lambda] = 0$ (36 components each);
7. $J^\mu[\Gamma\Psi] + J^\mu[\Psi] = 0$ (8 components).

The cell also stores the monomial counts used by the figures. To count the
nonzero coefficients quickly it evaluates each coefficient at one point with
numbers (an exact zero gives 0; this count is a description, not a proof).

The next cell runs the same test with Grassmann components (dirac16complex).
Because $\Gamma$ only multiplies each component by $+1$ or $-1$, no two
anticommuting factors are ever exchanged by the map, and all checks pass in the
same way; the Lagrangian has fewer monomials, because every monomial of $S^2$ that
contains one generator twice vanishes ($\theta\theta = 0$).

The next cell draws the 36 components of the energy-momentum tensor. Left: the
number of monomials of each component $T_{\mu\nu}[\Psi; m, \lambda]$ of a field
with commuting components (the table is symmetric, $T_{\nu\mu} = T_{\mu\nu}$, and
is drawn in full). Right: the sign $s$ with $T_{\mu\nu}[\Gamma\Psi; -m, -\lambda]
```

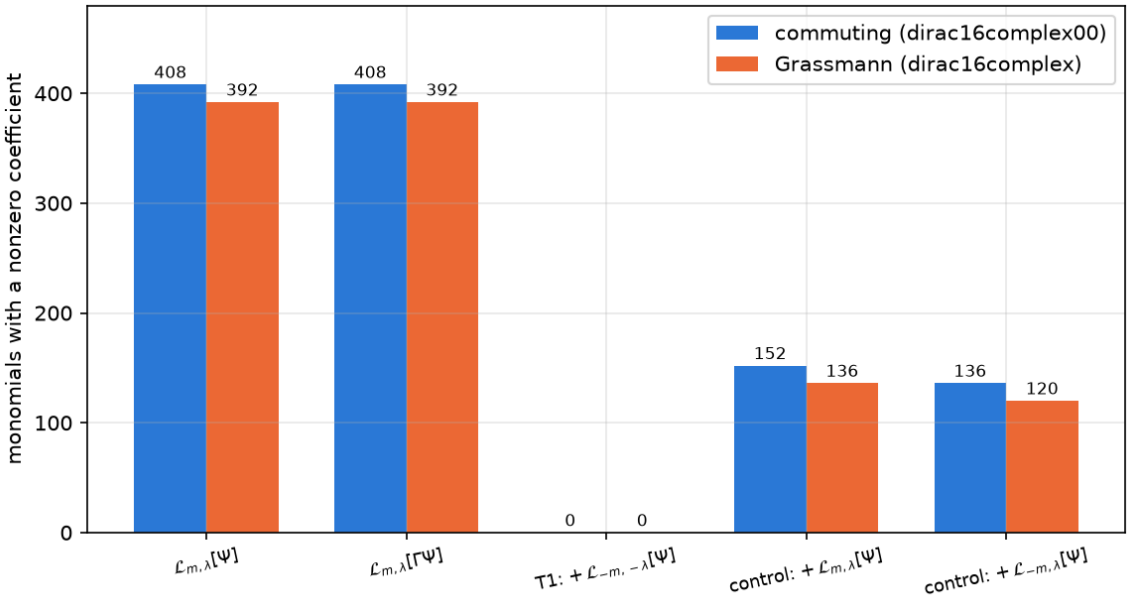

Figure 480: What cancels in theorem T1, in the author's metric with an arbitrary deflating history. Vertical axis: the number of monomials in the 288 jet values whose coefficient is not zero. The first two bars of each colour: the Lagrangian of a field and of its chirality image, 408 monomials for commuting components and 392 for Grassmann components. Third: the T1 sum with the reversed mass and coupling, exactly zero. Fourth and fifth, the negative controls: with the same mass and coupling the mass term and the S^2 term survive; with only the mass reversed the S^2 term survives. So both m and λ must change sign. (Notebook 18b, figure 2.)

```
= s\,T_{\mu\nu}[\Psi; m, \lambda]$, which the cell above proved to be $-1$ for
every component: the T1 partner carries exactly the opposite energy density,
momentum density and pressures.

## 12. What this notebook showed

- PROVED (exact sympy identities in the first jet, for an arbitrary history
  $a_4(x_4)$ of the deflating extra times): the diagonal vielbein gives the
  author's metric with $\sqrt{|g|} = \cos z$; its canonical spin connection has
  exactly the 12 nonzero components of the Revision record and obeys the vielbein
  postulate; $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$, because the $a_4'$ terms of
  the three inflating directions and of the three deflating extra times cancel.
- PROVED, theorem T1, for dirac16complex00 (commuting) and dirac16complex
  (Grassmann) in the author's metric: $S[\Gamma\Psi] = S[\Psi]$;
  $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$ (the
  Lagrangian has 408, respectively 392, monomials, as in the Wolfram report); the
  Euler-Lagrange expressions are $\sqrt{|g|}\,CE$; $\Gamma\Psi$ solves the
  $(m, \lambda)$ equations exactly when $\Psi$ solves the $(-m, -\lambda)$ ones;
  all 36 components of $T_{\mu\nu}$ and all 8 of $J^\mu$ change sign, so the pair
  has zero total energy-momentum and current as classical bilinears. The negative
  controls fail: both $m$ and $\lambda$ must change sign. The same holds for a
  general cubic potential and in a random general gravitational field.
- PROVED, theorem T2: with the mirror $z \to \pi - z$ (an isometry; the brane
  $z = \pi/2$ is degenerate) and $\Psi \to \gamma^{(x_0)}\Psi$, the Lagrangian of
  the image with $(m, \lambda)$ on the mirror patch equals the Lagrangian of the
  field with $(-m, \lambda)$ on the patch; the field equations are mapped;
  $T_{\mu\nu}$ and $J^\mu$ are pulled back (equal energy density, not opposite)
  and $S$ is reversed. Neither $1$ nor $\Gamma$ gives such a relation.
- ASSUMED: the gluing of the mirror patch to the patch at the degenerate brane
  (the Z2 construction). The gravitational field is a fixed background in both
  theorems; nothing here derives back-reaction.
- NOT shown, and not following from these identities: that any universe is
  created, in pairs or otherwise. T1 and T2 map solutions to solutions; they
  contain no process, rate or amplitude.
```

18.20 Line-by-line walk-through of Notebook 18b

The notebook has 20 code cells. **In [1]** is the set-up cell, word for word the set-up cell of Notebook 18a explained line by line in Section 18.9, except that its comment lines hold the run instructions

of Section 18.18 and its line `NOTEBOOK_ID = "18b"` names this notebook, so its figures are saved as `18b_<k>_<name>.png` and their captions in `18b.captions.json`. It prints one line, Set-up of notebook 18b complete: repository folder found, helpers defined.

The idea of the notebook in one paragraph. At one point x, every quantity of the theory (the Lagrangian, the 16 components of the field operator, the 36 components of $T_{\mu\nu}$, the 8 of J^μ) is a polynomial in the 288 numbers of the **first jet**: the 16 values Ψ_A, the 16 values Ψ^*_A and the $2 \times 8 \times 16 = 256$ first derivatives $\partial_\mu \Psi_A$, $\partial_\mu \Psi^*_A$. The coefficients of the polynomial are functions of the point: of x_4 through $a_4(x_4)$ and a'_4, of z, and of H, m, λ. If a polynomial has only zero coefficients, it is zero for EVERY field at EVERY point and for EVERY history a_4. So proving "$\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,-\lambda}[\Psi]$ has only zero coefficients" proves T1 in the author's metric. To handle dirac16complex, the 288 jet values are made ANTICOMMUTING symbols; the same computation then proves the theorem for Grassmann components.

In [2], the exact gammas.

```
import itertools  # all combinations of signs
import random  # Python's random numbers with a fixed seed (the random field)

import numpy as np  # numbers for the figures
import sympy as sp  # exact symbolic algebra

GAMMAS = "Revision/algebra/gammas.json"
PY = "Revision/pairing/reports/python-pairing.json"  # the sympy verifier's report
WL = "Revision/pairing/reports/wolfram-pairing.json"  # the Wolfram verifier's report
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
```

`itertools` gives `product`, which lists all combinations (used for index triples and sign choices); `random` is Python's own random-number module (used with a fixed seed in In [12]); numpy is used only for the figures; **sympy** (`sp`) is the package for exact symbolic algebra: it computes with symbols such as z and H, with fractions and with functions, without rounding. The four constants name the records the notebook reads: the gammas, the two pairing reports, and the Kohn-Sham parameter file that holds the canonical history.

```
def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

RECORDS = {PY: read_json(PY), WL: read_json(WL)}

def recorded(report_file, name):
    """The recorded entry (verdict and detail) of the check name of a report."""
    for entry in RECORDS[report_file]["checks"]:
        if entry["name"] == name:
            return entry
    return {"verdict": "MISSING", "detail": ""}

def reproduces(condition, name, *sources):
```

```
    """check(condition, name), which also requires every named check of every
    source (report_file, [check names]) to have the recorded verdict PASS."""
    ok = all(recorded(f, n)["verdict"].upper() == "PASS"
             for f, names in sources for n in names)
    text = "; ".join(f"{f}, check {', '.join(names)}" for f, names in sources)
    check(condition and ok, name, record=text)
```

`read_json` is the reader of Notebook 18a. `RECORDS` reads the two reports once and keeps them. `recorded(report_file, name)` returns the whole entry of a check (its verdict and its detail text), or a placeholder with the verdict MISSING. `reproduces` works as in Notebook 18a: the check passes only when the notebook's own result holds and every named record check has the verdict PASS.

```
fixture = read_json(GAMMAS)
G = {a: sp.Matrix(fixture["gamma"][a]) for a in range(8)}  # gamma^(x_a), a = 0..7
ETA = {a: int(fixture["eta"][a]) for a in range(8)}
I16 = sp.eye(16)
C = G[0] * G[1] * G[2] * G[3]  # the four space-like gammas
GAM = G[0] * G[1] * G[2] * G[3] * G[4] * G[5] * G[6] * G[7]  # the chirality Gamma
SAB = {(a, b): (G[a] * G[b] - G[b] * G[a]) / 4  # the generators S^ab
       for a in range(8) for b in range(8)}
check(all(G[a] * G[b] + G[b] * G[a] == (2 * ETA[a] if a == b else 0) * I16
          for a in range(8) for b in range(8))
      and GAM == sp.diag(*([-1] * 8 + [1] * 8)),
      "eight real 16 x 16 gammas with the Clifford relations; Gamma = diag(-I8, I8)")
```

`sp.Matrix(...)` makes an exact sympy matrix from the lists of whole numbers of the record, one for each direction; `G[a]` is $\gamma^{(x_a)}$. `ETA` holds η_{aa} and `I16` is the exact identity. `C` and `GAM` (Γ) are the products of Section 18.5, written with `*`, which is the matrix product for sympy matrices. `SAB` holds the 64 generators $S^{ab} = \frac{1}{4}[\gamma^{(a)}, \gamma^{(b)}]$ exactly (entries 0 and $\pm\frac{1}{2}$). The check confirms the 64 Clifford relations and $\Gamma = \mathrm{diag}(-I_8, I_8)$ (`sp.diag(*list)` makes a diagonal matrix from the entries of the list). Out [2] shows one PASS line.

In [3], the metric and its canonical connection.

```
x4, z, H = sp.symbols("x4 z H", real=True)
m, lam = sp.symbols("m lambda", real=True)
a4 = sp.Function("a4")(x4)  # the history: any function of the time x4
```

`sp.symbols` creates the symbols x_4, z, H, m and λ, declared real. `sp.Function("a4")(x4)` is an UNKNOWN function $a_4(x_4)$: sympy differentiates it formally, writing its derivative as `Derivative(a4(x4), x4)`. Leaving a_4 unknown is what makes every result of this notebook hold for every history, in particular for the deflating ones.

```
def d(expr, mu):
    """The derivative of a coefficient along the coordinate x_mu."""
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)  # z = 6 H x0
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7
```

`d(expr, mu)` is the derivative of a coefficient function along the coordinate x_μ: along x_4 it is `sp.diff(expr, x4)`; along x_0 it is $6H\,d/dz$, the chain rule for $z = 6Hx_0$; along the other six coordinates it is zero, because no coefficient depends on them.

```
class Geometry:
    """The author's metric with the diagonal vielbein; s0 = +1 on the patch,
    s0 = -1 on the mirror patch (then f0 = -cot z > 0)."""

    def __init__(self, s0):
        up, down = sp.exp(a4), sp.exp(-a4)  # inflating and deflating factors
        s6 = sp.sin(z) ** sp.Rational(1, 6)
        f = {0: s0 * sp.cot(z), 1: up * s6, 2: up * s6, 3: up * s6,
             4: sp.Integer(1), 5: down * s6, 6: down * s6, 7: down * s6}
        self.f = f
        self.g = {mu: ETA[mu] * f[mu] ** 2 for mu in f}  # g_mu mu
        self.sqrtg = sp.simplify(sp.Mul(*f.values()))  # sqrt|g|
        g = self.g
```

A **class** is a recipe for an object that holds several named values; `Geometry(s0)` builds one, and `__init__` is the code that runs when it is built (`self` is the object being built). The factors f_μ of Section 18.3 are stored in the dictionary `f`, with $f_0 = s_0 \cot z$: $s_0 = +1$ on the patch and -1 on the mirror patch, where $\cot z < 0$, so that f_0 is positive on both. `self.g` holds $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$, and `self.sqrtg` the product of the eight factors (`sp.Mul(*values)` multiplies them), simplified exactly.

```
        self.chr = {}  # Christoffel symbols Gamma^nu_(mu lambda)
        for nu, mu, la in itertools.product(range(8), repeat=3):
            v = 0
            if nu == la:
                v += d(g[nu], mu)
            if nu == mu:
                v += d(g[nu], la)
            if mu == la:
                v -= d(g[mu], nu)
            self.chr[nu, mu, la] = sp.simplify(v / (2 * g[nu]))
```

The Christoffel symbols of a diagonal metric, $\Gamma^\nu{}_{\mu\lambda} = \frac{1}{2g_{\nu\nu}}(\delta_{\nu\lambda}\partial_\mu g_{\nu\nu} + \delta_{\nu\mu}\partial_\lambda g_{\nu\nu} - \delta_{\mu\lambda}\partial_\nu g_{\mu\mu})$, for all $8^3 = 512$ index triples (`itertools.product(range(8), repeat=3)` lists them). Each `if` adds one of the three terms when its Kronecker delta is 1. This is the formula of Section 18.3 written for all indices at once.

```
        self.om = {}  # omega_mu ab
        for mu, a, b in itertools.product(range(8), repeat=3):
            v = self.chr[a, mu, b] / f[b]  # e^a_nu Gamma^nu_mu lam e^lam_b ...
            if a == b:
                v += d(1 / f[b], mu)  # ... + e^a_nu d_mu e^nu_b
            self.om[mu, a, b] = sp.simplify(ETA[a] * f[a] * v)
```

The canonical connection $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu e^\nu{}_b + \Gamma^\nu{}_{\mu\lambda} e^\lambda{}_b)$ for the diagonal vielbein: $e^\lambda{}_b = \delta^\lambda_b / f_b$ turns the second term into $\Gamma^a{}_{\mu b}/f_b$; the first term exists only for $a = b$, where it is $\partial_\mu(1/f_b)$; the factor $e^a{}_a = f_a$ multiplies both; and η_{aa} lowers the index a. So `self.om[mu, a, b]` is $\omega_{\mu ab}$.

```
        self.Om = {}  # Omega_mu = (1/2) omega_mu ab S^ab
        for mu in range(8):
            M = sp.zeros(16)
            for a, b in itertools.product(range(8), repeat=2):
                if self.om[mu, a, b] != 0:
                    M += self.om[mu, a, b] * SAB[a, b] / 2
            self.Om[mu] = M.applyfunc(sp.simplify)
        self.gup = {mu: G[mu] / f[mu] for mu in f}  # gamma^mu
        self.glow = {mu: ETA[mu] * f[mu] * G[mu] for mu in f}  # gamma_mu
```

$\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$, summed over the nonzero components only and simplified entry by entry (`applyfunc` applies a function to every entry of a matrix). `gup` holds the curved gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and `glow` the lowered ones $\gamma_\mu = \eta_{\mu\mu}f_\mu\gamma^{(\mu)}$.

```
patch = Geometry(1)  # the author's patch 0 < z < pi/2
author = {0: sp.cot(z) ** 2, 1: sp.exp(2 * a4) * sp.sin(z) ** sp.Rational(1, 3),
          4: -1, 5: -sp.exp(-2 * a4) * sp.sin(z) ** sp.Rational(1, 3)}
author.update({2: author[1], 3: author[1], 6: author[5], 7: author[5]})
metric_ok = all(sp.simplify(patch.g[mu] - author[mu]) == 0 for mu in range(8))
say(f"sqrt|g| on the patch = {patch.sqrtg}")
reproduces(metric_ok and sp.simplify(patch.sqrtg - sp.cos(z)) == 0,
           "the vielbein gives the author's metric and sqrt|g| = cos z",
           (WL, ["primordial_vielbein"]))
```

`patch` is the geometry of the author's patch. `author` writes the eight components of the author's metric exactly as the author gave them ($e^{2a_4}\sin^{1/3} z$ for 3-space, -1 for the time, $-e^{-2a_4}\sin^{1/3} z$ for the extra times, $\cot^2 z$ for the hidden direction); `update` fills in the repeated ones. `metric_ok` checks that the vielbein reproduces all eight. Out [3] prints $\sqrt{|g|} = \cos z$ and the PASS line with the Wolfram check `primordial_vielbein`.

In [4], the connection checked three ways.

```
COORDS = {a: f"x{a}" for a in range(8)}
antisymmetric = all(sp.simplify(patch.om[mu, a, b] + patch.om[mu, b, a]) == 0
                    for mu, a, b in itertools.product(range(8), repeat=3))
postulate = True
for mu, nu in itertools.product(range(8), repeat=2):
    M = patch.gup[nu].applyfunc(lambda e: d(e, mu))  # d_mu gamma^nu
    for la in range(8):
        if patch.chr[nu, mu, la] != 0:
            M = M + patch.chr[nu, mu, la] * patch.gup[la]
    M = M + patch.Om[mu] * patch.gup[nu] - patch.gup[nu] * patch.Om[mu]
    postulate = postulate and all(sp.simplify(e) == 0 for e in M)
```

`antisymmetric` checks $\omega_{\mu ab} + \omega_{\mu ba} = 0$ for all 512 triples. The loop then checks the vielbein postulate for all 64 pairs (μ, ν): `M` starts as $\partial_\mu\gamma^\nu$ (the derivative of each entry; `lambda e: d(e, mu)` is a one-line function), adds $\sum_\lambda \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda$ and the commutator $\Omega_\mu\gamma^\nu - \gamma^\nu\Omega_\mu$; every entry of the result must simplify to zero.

```
a4p = sp.Symbol("a4p")  # a short name for the derivative a4'
```

```
def short(expr):
    """Write a4' as a4p and a4(x4) as a4, as in the Revision report."""
    expr = sp.simplify(expr).subs(sp.Derivative(a4, x4), a4p)
    return expr.subs(a4, sp.Symbol("a4"))

nonzero = [(mu, a, b) for mu in range(8) for a in range(8)
           for b in range(a + 1, 8) if sp.simplify(patch.om[mu, a, b]) != 0]
listing = "; ".join(f"omega_{COORDS[mu]} {COORDS[a]}{COORDS[b]} = "
                    f"{short(patch.om[mu, a, b])}" for mu, a, b in nonzero)
for mu, a, b in nonzero:
    say(f"omega_{COORDS[mu]} {COORDS[a]}{COORDS[b]} = {short(patch.om[mu, a, b])}")
same_list = recorded(PY, "geometry.spin_connection_components")["detail"] == (
    "nonzero components (a < b): " + listing)
```

`a4p` is a plain symbol used to write a_4' in the format of the record, and `short` replaces the derivative of a_4 by `a4p` and the function $a_4(x_4)$ by the plain symbol `a4`. `nonzero` lists the triples (μ, a, b) with $a < b$ whose component is not zero; `listing` writes them in one line, separated by semicolons, and the loop prints them one per line. `same_list` compares that line, character for character, with the detail text of the sympy check `geometry.spin_connection_components`.

```
reproduces(antisymmetric and postulate, "the canonical spin connection is "
           "antisymmetric and obeys the vielbein postulate",
           (PY, ["geometry.omega_antisymmetric",
                 "geometry.gamma_covariantly_constant"]),
           (WL, ["connection_primordial"]))
reproduces(len(nonzero) == 12 and same_list,
           "the 12 nonzero connection components equal the recorded list",
           (PY, ["geometry.spin_connection_components"]))
```

Two checks: the connection is antisymmetric and canonical (three records), and it has exactly the 12 recorded components. Out [4] prints the twelve components with $a < b$, which are those derived by hand in Section 18.3: $\omega_{x_i,x_0x_i} = -He^{a_4}\sin^{1/6} z$ and $\omega_{x_i,x_ix_4} = a_4' e^{a_4}\sin^{1/6} z$ for each inflating direction x_i, $\omega_{x_t,x_0x_t} = He^{-a_4}\sin^{1/6} z$ and $\omega_{x_t,x_4x_t} = -a_4' e^{-a_4}\sin^{1/6} z$ for each deflating extra time x_t.

In [5], $\gamma\hat{}\mu\ \Omega_\mu$ direction by direction.

```
def coefficient(X, a):
    """The coefficient of gamma^(a) in the matrix X (exact, by a trace)."""
    return sp.simplify((G[a] * X).trace() / (16 * ETA[a]))
```

`coefficient(X, a)` extracts the coefficient of $\gamma^{(a)}$ in a matrix X. The rule behind it: the **trace** (the sum of the diagonal entries) of $\gamma^{(a)}\gamma^{(b)}$ is $16\eta_{aa}$ if $a = b$ and 0 otherwise. So if $X = \sum_b c_b\gamma^{(b)} +$ (products of several gammas), then $\mathrm{tr}(\gamma^{(a)}X) = 16\eta_{aa}c_a$, and $c_a = \mathrm{tr}(\gamma^{(a)}X)/(16\eta_{aa})$.

```
contributions = {mu: (patch.gup[mu] * patch.Om[mu]).applyfunc(sp.simplify)
                 for mu in range(8)}
```

```
for mu in range(8):
    c4, c0 = coefficient(contributions[mu], 4), coefficient(contributions[mu], 0)
    rest = (contributions[mu] - c4 * G[4] - c0 * G[0]).applyfunc(sp.simplify)
    assert rest == sp.zeros(16)  # nothing but gamma^(x4) and gamma^(x0)
    say(f"direction {COORDS[mu]}: coefficient of gamma^(x4) = {short(c4)}, "
        f"of gamma^(x0) = {short(c0)}")
total = sp.zeros(16)
for mu in range(8):
    total += contributions[mu]
check(total.applyfunc(sp.simplify) == 3 * H * G[0],
      "gamma^mu Omega_mu = 3 H gamma^(x0): the a4' terms of the deflation cancel")
```

`contributions[mu]` is $\gamma^{\mu}\Omega_{\mu}$ for one direction (no sum). For each direction the loop extracts the coefficients of $\gamma^{(x_4)}$ and $\gamma^{(x_0)}$ and asserts that nothing else is left (`assert` stops the notebook if the condition is false). Then `total` adds the eight contributions and the check requires $3H\gamma^{(x_0)}$. Out [5] prints, exactly as derived in Section 18.3: $a_4'/2$ and $H/2$ for x_1, x_2, x_3; $-a_4'/2$ and $H/2$ for x_5, x_6, x_7; zero for x_0 and x_4.

In [6], Figure 18b.1: the connection along the deflating history.

```
params = read_json(PARAMETERS)["physics"]
A_hist, H_hist = params["historyA"], params["H"]  # 1.0 and 1.0
history = {a4: A_hist * H_hist * x4, H: H_hist}  # a4 = A H x4

def along(expr, times, zv=sp.pi / 4):
    """Evaluate expr along the history at the times x4 (numbers for the figure)."""
    e = expr.subs(sp.Derivative(a4, x4), A_hist * H_hist).subs(history)
    f = sp.lambdify(x4, e.subs(z, zv), "numpy")
    return np.broadcast_to(np.asarray(f(times), dtype=float), times.shape)
```

`params` is the physics block of the Kohn-Sham parameter record; it gives the canonical history $a_4 = AHx_4$ with $A = 1$ and $H = 1$. `history` is a substitution rule. `along(expr, times)` turns a sympy expression into numbers for the figure: it replaces a_4' by AH (the derivative of AHx_4), then a_4 by AHx_4 and H by its value, sets $z = \pi/4$, and `sp.lambdify` turns the result into a numpy function of x_4. `np.broadcast_to` makes sure that a constant expression also returns one number per time.

```
times = np.linspace(0.0, 2.0, 201)  # x4 from 0 to 2, a4 from 0 to 2
infl = along(patch.om[1, 1, 4], times)
defl = along(-patch.om[5, 4, 5], times)
c_infl = along(3 * coefficient(contributions[1], 4), times)
c_defl = along(3 * coefficient(contributions[5], 4), times)
```

`times` holds 201 evenly spaced times from 0 to 2 (`np.linspace`). `infl` is the component $\omega_{x_1,x_1x_4} = a_4' e^{a_4} \sin^{1/6} z$ of an inflating direction and `defl` the component $-\omega_{x_5,x_4x_5} = a_4' e^{-a_4} \sin^{1/6} z$ of a deflating extra time. `c_infl` and `c_defl` are three times the coefficient of $\gamma^{(x_4)}$ from one inflating and from one deflating direction: the contributions of the three directions of each kind.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
axes[0].semilogy(times, infl, color="#2a78d6", label="inflating, $x_1$")
```

```
axes[0].semilogy(times, defl, color="#eb6834", label="deflating extra time, $x_5$")
axes[0].set_xlabel("time $x_4$ (units $1/H$); $a_4 = AHx_4$")
axes[0].set_ylabel("connection coefficient (units $H$)")
axes[0].legend()
axes[1].plot(times, c_infl, color="#2a78d6", label="$x_1, x_2, x_3$ together")
axes[1].plot(times, c_defl, color="#eb6834", label="$x_5, x_6, x_7$ together")
axes[1].plot(times, c_infl + c_defl, color="#52514e", linestyle="--", label="sum")
axes[1].set_xlabel("time $x_4$ (units $1/H$)")
axes[1].set_ylabel("coefficient of $\\gamma^{(x_4)}$ in $\\gamma^\\mu\\Omega_\\mu$")
axes[1].set_ylim(-2.0, 2.0)
axes[1].legend(loc="center right")
save_figure(fig, "connection_history",
            "The spin connection of the author's metric along the canonical "
            "deflating history $a_4 = AHx_4$ with $A = 1$, $H = 1$, at $z = \\pi/4$. "
            "Left, logarithmic vertical axis: the coefficient "

            "so only $3H\\gamma^{(x_0)}$ survives.")
```

The left panel draws the two components with a logarithmic vertical axis (`semilogy`), the right panel the two contributions and their sum (dashed). **What you see in Figure 18b.1:** on the left a rising straight line (the inflating component grows like e^{a_4}, a straight line on a logarithmic axis) and a falling one (the deflating component decays like e^{-a_4}); on the right two horizontal lines at $+3AH/2 = +1.5$ and -1.5 and their sum at zero. Why: the factor $1/f_\mu$ of γ^μ undoes the growth and the decay exactly, and the two kinds of directions contribute with opposite signs; only $3H\gamma^{(x_0)}$ survives.

In [7], an algebra for the jets.

```
class Jet:
    """A polynomial in numbered generators with sympy coefficients."""

    __slots__ = ("terms", "odd")

    def __init__(self, terms, odd):
        self.terms = terms  # {(generator numbers, sorted): coefficient}
        self.odd = odd  # True: Grassmann generators, False: commuting ones

    @staticmethod
    def symbol(number, odd):
        return Jet({(number,): sp.Integer(1)}, odd)
```

An object of the class `Jet` is a polynomial: `terms` is a dictionary whose keys are **monomials**, written as sorted tuples of generator numbers (the tuple `(3, 17)` is the product of generators 3 and 17), and whose values are sympy coefficients. `odd` says whether the generators anticommute (Grassmann) or commute. `__slots__` only fixes the two attribute names. `Jet.symbol(number,`

odd) is the polynomial consisting of one generator with coefficient 1 (@staticmethod marks a function that belongs to the class but needs no object).

```
    def __add__(self, other):
        terms = dict(self.terms)
        for key, c in other.terms.items():
            terms[key] = terms[key] + c if key in terms else c
        return Jet(terms, self.odd)

    def __neg__(self):
        return Jet({key: -c for key, c in self.terms.items()}, self.odd)

    def __sub__(self, other):
        return self + (-other)

    def times(self, number):
        """Multiply by a number or a sympy coefficient."""
        if number == 0:
            return Jet({}, self.odd)
        return Jet({key: number * c for key, c in self.terms.items()}, self.odd)
```

__add__ defines what + does: copy the terms of the first polynomial and add the coefficients of the second, monomial by monomial (terms[key] + c if key in terms else c adds when the monomial is already present and inserts it otherwise). __neg__ defines -p (every coefficient negated) and __sub__ defines p - q as p + (-q). times(number) multiplies every coefficient by a number or a sympy expression; multiplying by 0 returns the empty polynomial.

```
    def __mul__(self, other):
        terms = {}
        for k1, c1 in self.terms.items():
            for k2, c2 in other.terms.items():
                sign = 1
                if self.odd:
                    if set(k1) & set(k2):  # a generator twice: theta theta = 0
                        continue
                    swaps = sum(1 for p in k1 for q in k2 if p > q)
                    sign = -1 if swaps % 2 else 1  # sorting costs (-1)^swaps
                key = tuple(sorted(k1 + k2))
                c = sign * c1 * c2
                terms[key] = terms[key] + c if key in terms else c
        return Jet(terms, self.odd)
```

__mul__ defines p * q: every monomial of p is multiplied by every monomial of q. For commuting generators the product monomial is the sorted joined tuple. For Grassmann generators two more rules apply. If the two monomials share a generator, the product is zero ($\theta\theta = 0$) and is skipped (set(k1) & set(k2) is the set of common generators). Otherwise the joined tuple must be sorted, and each exchange of two anticommuting generators costs a sign: the number of exchanges needed is the number of pairs (p, q) with p from the first and q from the second monomial and $p > q$, and the sign is $(-1)^{\text{swaps}}$.

```
    def derivative(self, number):
        """The left derivative with respect to the generator number."""
        terms = {}
        for key, c in self.terms.items():
            if number not in key:
                continue
            place = key.index(number)
            rest = key[:place] + key[place + 1:]
            if self.odd:  # move the generator to the front first
                c = c if place % 2 == 0 else -c
            else:  # an ordinary power rule
                c = key.count(number) * c
            terms[rest] = terms[rest] + c if rest in terms else c
        return Jet(terms, self.odd)
```

`derivative(number)` is the **left derivative** with respect to one generator: in each monomial that contains it, the generator is removed. For commuting generators this is the power rule (the coefficient is multiplied by the number of times the generator occurs). For Grassmann generators the generator is first moved to the front of the monomial, which passes the `place` generators before it and costs $(-1)^{\text{place}}$; then it is removed. The left derivative is the one used for the Euler-Lagrange expressions of a Grassmann field.

```
    def substitute(self, rule):
        """Replace symbols in every coefficient (rule: {old: new})."""
        return Jet({key: c.subs(rule) for key, c in self.terms.items()}, self.odd)

    def is_zero(self):
        """True when every coefficient is exactly zero."""
        for c in self.terms.values():
            e = sp.expand(c)
            if e != 0 and sp.simplify(e) != 0:
                return False
        return True

def zero(odd):
    return Jet({}, odd)

def all_zero(items):
    return all(item.is_zero() for item in items)
```

`substitute` replaces symbols in every coefficient (a helper that the later cells do not need). `is_zero` decides whether a polynomial is zero: every coefficient is first expanded (`sp.expand` multiplies out products and powers) and, if that does not give 0, simplified (`sp.simplify` uses identities such as $\sin^2 + \cos^2 = 1$). If any coefficient is not zero, the answer is False. `zero(odd)` is the empty polynomial and `all_zero(items)` tests a whole list.

In [8], matrices acting on columns of polynomials, and the jet.

```
def mat_vec(M, v, odd):
    """The matrix M times the column v of algebra elements."""
```

```
    out = []
    for A in range(16):
        acc = zero(odd)
        for B in range(16):
            if M[A, B] != 0:
                acc = acc + v[B].times(M[A, B])
        out.append(acc)
    return out

def row_mat(v, M, odd):
    """The row v of algebra elements times the matrix M."""
    out = []
    for B in range(16):
        acc = zero(odd)
        for A in range(16):
            if M[A, B] != 0:
                acc = acc + v[A].times(M[A, B])
        out.append(acc)
    return out

def dot(u, v, odd):
    """The row u times the column v (the order of the factors is kept)."""
    acc = zero(odd)
    for p, q in zip(u, v):
        if p.terms and q.terms:
            acc = acc + p * q
    return acc
```

A spinor at one point is a column of 16 polynomials. `mat_vec(M, v)` is the matrix M times the column v: component A is $\sum_B M_{AB} v_B$ (only the nonzero entries are used). `row_mat(v, M)` is the row v times M: component B is $\sum_A v_A M_{AB}$. `dot(u, v)` is the row u times the column v, $\sum_A u_A v_A$, with the factor of u always written LEFT of the factor of v; this order matters for Grassmann generators, and it is the order of the bilinears $\Psi^\dagger X \Psi$.

```
def number_psi_star(A):
    return A

def number_psi(A):
    return 16 + A

def number_dpsi_star(mu, A):
    return 32 + 16 * mu + A

def number_dpsi(mu, A):
    return 160 + 16 * mu + A

def jets(odd):
```

```
    """The first jet (Psi^*, Psi, d Psi^*, d Psi) as algebra generators."""
    return ([Jet.symbol(number_psi_star(A), odd) for A in range(16)],
            [Jet.symbol(number_psi(A), odd) for A in range(16)],
            {mu: [Jet.symbol(number_dpsi_star(mu, A), odd) for A in range(16)]
             for mu in range(8)},
            {mu: [Jet.symbol(number_dpsi(mu, A), odd) for A in range(16)]
             for mu in range(8)})
```

The numbering of the 288 generators: Ψ^*_A is number A ($A = 0, \ldots, 15$; Python counts from 0), Ψ_A is $16+A$, $\partial_\mu \Psi^*_A$ is $32+16\mu+A$ and $\partial_\mu \Psi_A$ is $160+16\mu+A$, for $\mu = 0, \ldots, 7$ (the coordinates $x_0, \ldots, x_7$). `jets(odd)` returns the jet as four parts: the column Ψ^*, the column Ψ, and two dictionaries of columns for the derivatives.

```
NO_REFLECTION = {mu: 1 for mu in range(8)}
MIRROR = {mu: (-1 if mu == 0 else 1) for mu in range(8)}  # x0 -> const - x0

def transform(J, P, signs, odd):
    """The jet of Psi'(x) = P Psi(R x)."""
    psi_star, psi, dpsi_star, dpsi = J
    Pc = P.conjugate()
    return (mat_vec(Pc, psi_star, odd), mat_vec(P, psi, odd),
            {mu: [x.times(signs[mu]) for x in mat_vec(Pc, dpsi_star[mu], odd)]
             for mu in range(8)},
            {mu: [x.times(signs[mu]) for x in mat_vec(P, dpsi[mu], odd)]
             for mu in range(8)})
```

`NO_REFLECTION` and `MIRROR` hold the signs of a coordinate reflection R: all $+1$, or -1 for x_0 only (the mirror $x_0 \to \pi/(6H) - x_0$). `transform(J, P, signs)` returns the jet of the new field $\Psi'(x) = P\Psi(Rx)$: the components are multiplied by P, their conjugates by P^* (`P.conjugate()`, the matrix of conjugate entries; for the real matrices used here it equals P), and each derivative along x_μ also gets the sign of the reflection of x_μ, by the chain rule.

In [9], the theory on the jet.

```
def covariant(geo, J, odd):
    """D_mu Psi and D_mu Psibar for mu = 1..8."""
    psi_star, psi, dpsi_star, dpsi = J
    Dpsi = {mu: [p + q for p, q in zip(dpsi[mu], mat_vec(geo.Om[mu], psi, odd))]
            for mu in range(8)}
    Dbar = {mu: [p - q for p, q in zip(row_mat(dpsi_star[mu], C, odd),
                                       row_mat(psi_star, C * geo.Om[mu], odd))]
            for mu in range(8)}
    return Dpsi, Dbar
```

`covariant` returns, for each μ, the columns $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and the rows $D_\mu\bar\Psi = (\partial_\mu\Psi^*)^T C - \Psi^{*T} C \Omega_\mu$; the second is $\partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$ written with $\bar\Psi = \Psi^\dagger C$ (the row of the conjugates times C).

```
def scalar(J, odd):
    """S = Psibar Psi = Psi^dagger C Psi."""
    return dot(J[0], mat_vec(C, J[1], odd), odd)
```

$S = \Psi^\dagger C \Psi$: the row of conjugates times the column $C\Psi$.

```
def lagrangian(geo, J, odd, mass, coup, upoly=None, density=True):
    """L = sqrt|g| [ K - m S - U(S) ] (density=False: without sqrt|g|)."""
    Dpsi, Dbar = covariant(geo, J, odd)
    kin = zero(odd)
    for mu in range(8):
        kin = kin + dot(J[0], mat_vec(C * geo.gup[mu], Dpsi[mu], odd), odd)
        kin = kin - dot(Dbar[mu], mat_vec(geo.gup[mu], J[1], odd), odd)
    S = scalar(J, odd)
    L = kin.times(sp.Rational(1, 2)) - S.times(mass)
    if upoly is None:  # U = (lambda/2) S^2
        L = L - (S * S).times(coup / 2)
    else:  # U = u1 S + u2 S^2 + u3 S^3
        L = L - S.times(upoly[1]) - (S * S).times(upoly[2])
        L = L - (S * S * S).times(upoly[3])
    return L.times(geo.sqrtg) if density else L
```

The Lagrangian of Section 18.4, term by term: `kin` adds, for each μ, $\bar\Psi\gamma^\mu D_\mu\Psi$ (the row $\Psi^\dagger$ times $C\gamma^\mu D_\mu\Psi$) and subtracts $(D_\mu\bar\Psi)\gamma^\mu\Psi$. Then $\mathcal{L}/\sqrt{|g|} = \frac{1}{2}K_{\rm sum} - mS - U(S)$, with $U = \frac{\lambda}{2}S^2$, or, when the argument `upoly` is given, the cubic $U = u_1 S + u_2 S^2 + u_3 S^3$. With `density=True` the result is multiplied by $\sqrt{|g|}$.

```
def field_operator(geo, J, odd, mass, coup):
    """E = gamma^mu D_mu Psi - (m + lambda S) Psi (16 algebra elements)."""
    Dpsi, _ = covariant(geo, J, odd)
    S = scalar(J, odd)
    out = [zero(odd) for _ in range(16)]
    for mu in range(8):
        out = [p + q for p, q in zip(out, mat_vec(geo.gup[mu], Dpsi[mu], odd))]
    return [out[A] - J[1][A].times(mass) - (S * J[1][A]).times(coup)
            for A in range(16)]
```

`field_operator` returns the 16 components of $E = \gamma^\mu D_\mu\Psi - (m + \lambda S)\Psi$: the sum over μ of $\gamma^\mu D_\mu\Psi$, minus $m\Psi_A$, minus $\lambda S\Psi_A$.

```
def emt(geo, J, odd, mass, coup):
    """T_mu nu for mu <= nu (36 components)."""
    Dpsi, Dbar = covariant(geo, J, odd)
    L = lagrangian(geo, J, odd, mass, coup, density=False)
    T = {}
    for mu in range(8):
        for nu in range(mu, 8):
            t = (dot(J[0], mat_vec(C * geo.glow[mu], Dpsi[nu], odd), odd)
                 + dot(J[0], mat_vec(C * geo.glow[nu], Dpsi[mu], odd), odd)
                 - dot(Dbar[mu], mat_vec(geo.glow[nu], J[1], odd), odd)
                 - dot(Dbar[nu], mat_vec(geo.glow[mu], J[1], odd), odd))
            t = t.times(sp.Rational(1, 4))
            if mu == nu:
                t = t - L.times(geo.g[mu])
            T[mu, nu] = t
    return T
```

`emt` returns the 36 components $T_{\mu\nu}$ with $\mu \le \nu$ of the tensor of Section 18.4: the four kinetic bilinears with the lowered gammas, times $\frac{1}{4}$, and, on the diagonal, minus $g_{\mu\mu}\mathcal{L}/\sqrt{|g|}$ (the off-diagonal $g_{\mu\nu}$ vanish).

```
def current(geo, J, odd):
    """J^mu = i Psibar gamma^mu Psi (8 components)."""
    return {mu: dot(J[0], mat_vec(sp.I * C * geo.gup[mu], J[1], odd), odd)
            for mu in range(8)}
```

`current` returns the 8 components $J^\mu = i\bar{\Psi}\gamma^\mu\Psi$ (the convention of the sympy pairing report; `sp.I` is i).

```
def euler_lagrange(geo, J, odd, mass, coup):

            for key, c in q.terms.items():
                B = key[0] - 16  # the component Psi_B of this term
                e = e - Jet({key: d(c, mu)}, odd)  # (d_mu c) Psi_B
                e = e - Jet({(number_dpsi(mu, B),): c}, odd)  # c d_mu Psi_B
        out.append(e)
    return out
```

`euler_lagrange` derives the Euler-Lagrange expressions from the Lagrangian itself, without using the formula for E: for each A, the derivative of $\mathcal{L}$ with respect to the generator Ψ^*_A, minus $\sum_\mu \partial_\mu$ of the derivative with respect to $\partial_\mu\Psi^*_A$. That second derivative, `q`, is a sum of terms $c\,\Psi_B$ with coefficient functions c of the point (the kinetic term contains $\partial_\mu\Psi^*$ only multiplied by Ψ). Its total derivative is computed with the product rule, $\partial_\mu(c\Psi_B) = (\partial_\mu c)\Psi_B + c\,\partial_\mu\Psi_B$: the first piece keeps the monomial and differentiates the coefficient; the second replaces Ψ_B by the generator of $\partial_\mu\Psi_B$.

In [10], theorem T1 for dirac16complex00.

```
SAMPLE = {z: sp.Rational(7, 10), H: sp.Rational(13, 10), m: sp.Rational(11, 10),
          lam: sp.Rational(3, 5)}  # a sample point for counting only
SAMPLE_A4 = {"a4p": sp.Rational(9, 10), "a4": sp.Rational(2, 5)}

def count_nonzero(element):
    """The number of monomials whose coefficient is not zero at the sample."""
    n = 0
    for c in element.terms.values():
        c = c.subs(sp.Derivative(a4, x4), SAMPLE_A4["a4p"])  # a4' first,
        c = c.subs(a4, SAMPLE_A4["a4"]).subs(SAMPLE)  # then a4 and the rest
        value = complex(sp.N(c, 30))
        n += abs(value) > 1e-20
    return n
```

```
COUNTS = {}  # the monomial counts for the figures
```

Counting the monomials of a polynomial whose coefficients are long expressions is slow if every coefficient is simplified. `count_nonzero` evaluates each coefficient at one sample point (the fractions in `SAMPLE` and `SAMPLE_A4`: $z = 0.7$, $H = 1.3$, $m = 1.1$, $\lambda = 0.6$, $a_4' = 0.9$, $a_4 = 0.4$) with 30 digits (`sp.N(c, 30)`) and counts those that are not zero. The count only describes the size of a polynomial; it is not part of any proof. `COUNTS` keeps the counts for the figures.

```

               (WL, [f"T1_Euler_Lagrange_derived_{tag}",
                     f"T1_field_equation_covariance_{tag}"]))
```

`E` is the field operator, `CE` is C times it, and `EL` the Euler-Lagrange expressions derived from $\mathcal{L}$. `derived` checks $\mathrm{EL}_A = \sqrt{|g|}\,(CE)_A$ for all 16 A: the field equation $E = 0$ IS the Euler-Lagrange equation of this Lagrangian. `mapped` checks $E_{m,\lambda}[\Gamma\Psi] + \Gamma E_{-m,-\lambda}[\Psi] = 0$, statement (T1b).

```
    T_image = emt(patch, JG, odd, m, lam)
    T_partner = emt(patch, J, odd, -m, -lam)
    T_plain = emt(patch, J, odd, m, lam)
    T_pair = emt(patch, JG, odd, -m, -lam)
    emt_ok = all_zero([T_image[k] + T_partner[k] for k in T_image])
    pair_ok = all_zero([T_plain[k] + T_pair[k] for k in T_plain])
    COUNTS[stat]["T"] = {k: count_nonzero(T_plain[k]) for k in T_plain}
    COUNTS[stat]["T1 sign"] = {k: -1 for k in T_plain if emt_ok}
    J_image, J_plain = current(patch, JG, odd), current(patch, J, odd)
    current_ok = all_zero([J_image[mu] + J_plain[mu] for mu in range(8)])
    reproduces(emt_ok and pair_ok and current_ok and len(T_image) == 36,
               f"T1 {field}: T -> -T (36), pair T sum 0, J -> -J (8)",
               (PY, [f"T1.metric.{stat}.emt", f"T1.metric.{stat}.pair_total_emt_zero",
                     f"T1.metric.{stat}.current"]),
               (WL, [f"T1_energy_momentum_{tag}", f"T1_current_{tag}"]))
```

Four tensors: of the image with (m, λ), of Ψ with $(-m, -\lambda)$, of Ψ with (m, λ) and of the image with $(-m, -\lambda)$. `emt_ok` checks $T[\Gamma\Psi; m, \lambda] + T[\Psi; -m, -\lambda] = 0$ for all 36 components (T1c, read from the other side), and `pair_ok` checks the pair statement $T[\Psi; m, \lambda] + T[\Gamma\Psi; -m, -\lambda] = 0$ (T1d). The counts of the 36 components and the proved signs -1 are stored for Figure 18b.3. `current_ok` checks $J[\Gamma\Psi] + J[\Psi] = 0$ for the 8 components. One check combines them, with three sympy and two Wolfram records.

```
t1_checks(False)  # dirac16complex00: commuting components
```

The test is run for commuting components. Out [10] prints RESULT dirac16complex00: monomials of L with a nonzero coefficient = 408 and four PASS lines.

In [11], theorem T1 for dirac16complex.

```
t1_checks(True)  # dirac16complex: Grassmann components
say("monomials of L with a nonzero coefficient: commuting "
    f"{COUNTS['commuting']['L']}, Grassmann {COUNTS['grassmann']['L']}")
```

The same test with Grassmann generators, then a line with both counts. Out [11]: 392 monomials and four PASS lines; the last line reads commuting 408, Grassmann 392. Why fewer: in S^2, products in which the same Grassmann generator occurs twice vanish ($\theta\theta = 0$), so some monomials of the commuting case are absent.

In [12], a general potential and a random gravitational field.

```
u1, u2, u3 = sp.symbols("u1 u2 u3", real=True)
cubic_ok = True
for odd in (False, True):
    J = jets(odd)
    JG = transform(J, GAM, NO_REFLECTION, odd)
    L1 = lagrangian(patch, JG, odd, m, 0, upoly={1: u1, 2: u2, 3: u3})
    L2 = lagrangian(patch, J, odd, -m, 0, upoly={1: -u1, 2: -u2, 3: -u3})
    cubic_ok = cubic_ok and (L1 + L2).is_zero()
reproduces(cubic_ok, "T1 with a general cubic potential: L_m,U[Gamma Psi] = "
           "-L_-m,-U[Psi]", (PY, ["T1.metric.commuting.general_potential",
                                  "T1.metric.grassmann.general_potential"]))
```

Three symbols u_1, u_2, u_3 for a general cubic potential. For both statistics: the Lagrangian of the image with (m, U) (the coupling argument is 0 and unused when `upoly` is given) plus the Lagrangian of Ψ with $(-m, -U)$, where $-U$ has the coefficients $-u_1, -u_2, -u_3$, must vanish. This is (T1a) for a general potential.

```
rng = random.Random(20261001)  # the seed of the Revision report

def fraction():
    return sp.Rational(rng.randint(-9, 9), rng.randint(1, 5))

class RandomField:
    """A general gravitational field at one point (only what L and E use)."""

field = RandomField()
E8 = [[fraction() for _ in range(8)] for _ in range(8)]  # e^mu_a, not diagonal
field.gup = {mu: sum((E8[mu][a] * G[a] for a in range(8)), sp.zeros(16))
             for mu in range(8)}
field.Om = {}
for mu in range(8):
    M = sp.zeros(16)
    for a in range(8):
        for b in range(a + 1, 8):
            M += fraction() * SAB[a, b]  # an antisymmetric omega
    field.Om[mu] = M
field.sqrtg = abs(fraction()) + 1
```

`random.Random(20261001)` is a random-number generator with the seed number used by the Revision report (the instance drawn here is the notebook's own). `fraction()` returns a random fraction p/q with p from -9 to 9 and q from 1 to 5. `RandomField` is an empty class that serves

as a container. The field gets 64 random entries $e^{\mu}{}_{a}$ (a non-diagonal vielbein; `field.gup[mu]` is $\gamma^{\mu} = \sum_a e^{\mu}{}_{a}\gamma^{(a)}$), for each μ a connection $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$ with 28 random independent components (antisymmetry is built in by summing over $a < b$ only), and a positive volume factor. It is not the author's field and not a solution of anything: it stands for an arbitrary gravitational field at one point.

```
random_ok = True
for odd in (False, True):
    J = jets(odd)
    JG = transform(J, GAM, NO_REFLECTION, odd)
    L_sum = (lagrangian(field, JG, odd, m, lam)
             + lagrangian(field, J, odd, -m, -lam))
    E1 = field_operator(field, JG, odd, m, lam)
    E2 = mat_vec(GAM, field_operator(field, J, odd, -m, -lam), odd)
    random_ok = random_ok and all_zero([L_sum] + [E1[A] + E2[A] for A in range(16)])
reproduces(random_ok, "T1 in a random general field (seed 20261001), both fields",
           (PY, ["T1.general_field.random_instance.commuting",
                 "T1.general_field.random_instance.grassmann"]))
```

For both statistics: the T1 identity of the Lagrangian and the map of the 16 components of the field operator must hold in this random field. This shows, by an example with no special structure, why T1 holds in every gravitational field: the proof never used the form of the coefficients. Out [12] shows two PASS lines.

In [13], Figure 18b.2: what cancels.

```
labels = ["L", "L[Gamma Psi]", "T1 sum", "control (m, 1)", "control (-m, 1)"]
texts = ["$\\mathcal{L}_{m,\\lambda}[\\Psi]$",
         "$\\mathcal{L}_{m,\\lambda}[\\Gamma\\Psi]$",
         "T1: $+\\,\\mathcal{L}_{-m,-\\lambda}[\\Psi]$",
         "control: $+\\,\\mathcal{L}_{m,\\lambda}[\\Psi]$",
         "control: $+\\,\\mathcal{L}_{-m,\\lambda}[\\Psi]$"]
fig, ax = plt.subplots(figsize=(9.0, 4.6))
xs = np.arange(len(labels))
for shift, stat, colour in [(-0.18, "commuting", "#2a78d6"),
                            (0.18, "grassmann", "#eb6834")]:
    values = [COUNTS[stat][k] for k in labels]
    ax.bar(xs + shift, values, width=0.36, color=colour,
           label="commuting (dirac16complex00)" if stat == "commuting"
           else "Grassmann (dirac16complex)")
    for x, v in zip(xs + shift, values):
        ax.text(x, v + 6, str(v), ha="center", fontsize=8)
ax.set_xticks(xs, texts, fontsize=8.5, rotation=12)
ax.set_ylabel("monomials with a nonzero coefficient")
ax.set_ylim(0, 480)
ax.legend(loc="upper right")
save_figure(fig, "lagrangian_cancellation",
            "What cancels in theorem T1, in the author's metric with an arbitrary "
            "deflating history. Vertical axis: the number of monomials in the 288 "
            "jet values whose coefficient is not zero. The first two bars of each "
            "colour: the Lagrangian of a field and of its chirality image, "
            "$408$ monomials for commuting components and $392$ for Grassmann "
```

```
            "components. Third: the T1 sum with the reversed mass and coupling, "
            "exactly zero. Fourth and fifth, the negative controls: with the "
            "same mass and coupling the mass term and the $S^2$ term survive; "
            "with only the mass reversed the $S^2$ term survives. So both $m$ and "
            "$\\lambda$ must change sign.")
```

Five groups of two bars (commuting in blue, Grassmann in orange; `xs + shift` moves the two bars of a group apart), with the number written above each bar. **What you see in Figure 18b.2:** 408 and 392 monomials for $\mathcal{L}_{m,\lambda}[\Psi]$ and the same numbers for $\mathcal{L}_{m,\lambda}[\Gamma\Psi]$; zero for the T1 sum; and nonzero bars for the two negative controls. In the first control only the mass term and the S^2 term survive (the kinetic terms cancel, the potential terms add), in the second only the S^2 term. Why: Γ reverses exactly the kinetic part, so a cancellation needs both $m \to -m$ and $\lambda \to -\lambda$.

In [14], Figure 18b.3: the 36 components of the tensor.

```
counts = np.zeros((8, 8))
signs = np.zeros((8, 8))
for (mu, nu), n in COUNTS["commuting"]["T"].items():
    counts[mu, nu] = counts[nu, mu] = n
for (mu, nu), s in COUNTS["commuting"]["T1 sign"].items():
    signs[mu, nu] = signs[nu, mu] = s
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.6))
image = axes[0].imshow(counts, cmap="Blues")
fig.colorbar(image, ax=axes[0], shrink=0.85, label="monomials")
axes[1].imshow(signs, cmap="coolwarm", vmin=-1, vmax=1)
for i in range(8):
    for j in range(8):
        axes[0].text(j, i, str(int(counts[i, j])), ha="center", va="center",
                     fontsize=7, color="black" if counts[i, j] < 200 else "white")
        axes[1].text(j, i, f"{int(signs[i, j]):+d}", ha="center", va="center",
                     fontsize=8, color="white")
for ax, title in [(axes[0], "monomials of $T_{\\mu\\nu}[\\Psi; m, \\lambda]$"),
                  (axes[1], "sign of the T1 partner's $T_{\\mu\\nu}$")]:
    ax.set_xticks(range(8), [f"$x_{a}$" for a in range(8)])
    ax.set_yticks(range(8), [f"$x_{a}$" for a in range(8)])
    ax.grid(False)
    ax.set_title(title, fontsize=10)
```

`counts` and `signs` are 8×8 arrays filled symmetrically from the 36 stored components ($T_{\nu\mu} = T_{\mu\nu}$). The left panel draws the counts with a blue colour scale and writes each number in its cell (white text on dark cells); the right panel draws the proved signs. The ticks name the coordinates.

```
save_figure(fig, "emt_signs",
            "The 36 independent components of the energy-momentum tensor in the "
            "author's metric, row index $\\mu$ and column index $\\nu$ from $x_0$ "
            "to $x_7$. Left: the number of jet monomials in each component for a "
            "field with commuting components; the diagonal components carry the "
            "whole Lagrangian, the off-diagonal ones only kinetic terms. Right: "
            "the sign that relates the component of the T1 partner "
            "$\\Gamma\\Psi$ with $(-m, -\\lambda)$ to that of $\\Psi$ with "
            "$(m, \\lambda)$, proved to be $-1$ everywhere: energy density, "
```

```
            "momentum densities and pressures are all reversed, and the pair has "
            "a zero total.")
```

What you see in Figure 18b.3: on the left, 376 monomials in each diagonal component (those components contain the whole Lagrangian through $-g_{\mu\mu}\mathcal{L}/\sqrt{|g|}$) and 64 or 80 in each off-diagonal one (only kinetic bilinears); on the right, -1 in every one of the 64 cells. The T1 partner carries exactly the opposite energy density, momentum densities and pressures.

In [15], the mirror patch.

```
mirror = Geometry(-1)  # the mirror patch pi/2 < z < pi, f0 = -cot z > 0
to_mirror = {z: sp.pi - z}

class Reflected:
    """The patch's coefficient functions evaluated at the mirror point pi - z."""

reflected = Reflected()
reflected.sqrtg = sp.expand(patch.sqrtg.subs(to_mirror))
reflected.g = {mu: sp.expand(patch.g[mu].subs(to_mirror)) for mu in range(8)}
for name in ("Om", "gup", "glow"):
    setattr(reflected, name, {mu: getattr(patch, name)[mu].subs(to_mirror)
                              .applyfunc(sp.expand) for mu in range(8)})
```

`mirror` is the geometry of the mirror patch ($s_0 = -1$, so $f_0 = -\cot z > 0$ there). `to_mirror` is the substitution $z \to \pi - z$. `reflected` holds the patch's coefficient functions evaluated at the mirror point: $\sqrt{|g|}$, the metric, Ω_μ and both kinds of curved gammas, each with z replaced by $\pi - z$ and expanded (`setattr(object, name, value)` stores a value under a name given as a string).

```
isometry = all(sp.simplify(patch.g[mu].subs(to_mirror) - patch.g[mu]) == 0
               for mu in range(8))
degenerate = (sp.limit(patch.g[0], z, sp.pi / 2) == 0
              and sp.limit(patch.sqrtg, z, sp.pi / 2) == 0)
reproduces(isometry and degenerate, "z -> pi - z is an isometry; the brane "
           "z = pi/2 is degenerate (g00 = 0, sqrt|g| = 0)",
           (PY, ["geometry.mirror_isometry", "geometry.brane_degenerate"]),
           (WL, ["T2_mirror_is_isometry"]))
```

`isometry` checks $g_{\mu\mu}(\pi - z) = g_{\mu\mu}(z)$ for all eight components; `degenerate` checks with limits (`sp.limit`) that $g_{00} \to 0$ and $\sqrt{|g|} \to 0$ as $z \to \pi/2$. One check, three records.

```
mirror_postulate = all(
    sp.simplify(mirror.om[mu, a, b] + mirror.om[mu, b, a]) == 0
    for mu, a, b in itertools.product(range(8), repeat=3))
for mu, nu in itertools.product(range(8), repeat=2):
    M = mirror.gup[nu].applyfunc(lambda e: d(e, mu))
    for la in range(8):
        if mirror.chr[nu, mu, la] != 0:
            M = M + mirror.chr[nu, mu, la] * mirror.gup[la]
```

```
    M = M + mirror.Om[mu] * mirror.gup[nu] - mirror.gup[nu] * mirror.Om[mu]
    mirror_postulate = mirror_postulate and all(sp.simplify(e) == 0 for e in M)
say(f"sqrt|g| on the mirror patch = {mirror.sqrtg} (positive there, cos z < 0)")
reproduces(mirror_postulate, "the mirror patch's own connection is canonical",
           (WL, ["connection_mirror_patch"]))
```

The mirror patch's own connection is antisymmetric and obeys the vielbein postulate (the same test as In [4]). Out [15] prints $\sqrt{|g|} = -\cos z$ on the mirror patch, positive there because $\cos z < 0$ for $\pi/2 < z < \pi$, and two PASS lines.

In [16], Figure 18b.4: the metric on both patches.

```
zs = np.linspace(0.02, np.pi - 0.02, 400)
fig, ax = plt.subplots(figsize=(8.0, 4.4))
ax.plot(zs, np.sin(zs) ** (1.0 / 3.0), color="#2a78d6",
        label="$\\sin^{1/3}z$ (factor of $g_{11}$ and $-g_{55}$)")
ax.plot(zs, 1.0 / np.tan(zs) ** 2, color="#eb6834", label="$g_{00} = \\cot^2 z$")
ax.plot(zs, np.abs(np.cos(zs)), color="#1baf7a", label="$\\sqrt{|g|} = |\\cos z|$")
ax.axvline(np.pi / 2, color="#52514e", linestyle="--")
ax.text(np.pi / 2 + 0.04, 2.6, "brane $z = \\pi/2$", fontsize=9)
ax.axvspan(0.0, np.pi / 2, color="#2a78d6", alpha=0.05)
ax.text(0.25, 2.6, "patch", fontsize=9)
ax.text(2.35, 2.6, "mirror patch", fontsize=9)
ax.set_xlim(0.0, np.pi)
ax.set_ylim(0.0, 3.0)
ax.set_xlabel("hidden angle $z = 6Hx_0$ (radians)")
ax.set_ylabel("metric function (no unit)")
ax.legend(loc="center left", bbox_to_anchor=(0.02, 0.62), fontsize=8.5)
save_figure(fig, "mirror_metric",
            "The functions of the hidden angle that enter the author's metric, "
            "against $z = 6Hx_0$ from 0 to $\\pi$ (horizontal axis, radians; "
            "vertical axis, pure numbers): $\\sin^{1/3}z$, the factor of the "
            "3-space and extra-time components; $g_{00} = \\cot^2 z$; and "
            "$\\sqrt{|g|} = |\\cos z|$. The shaded half is the author's patch, the "
            "other half its mirror patch. Every curve is mirror-symmetric about "
            "the dashed brane $z = \\pi/2$, so $z \\to \\pi - z$ is an isometry. "
            "At the brane $g_{00}$ and $\\sqrt{|g|}$ vanish: the metric is "
            "degenerate there, and gluing the two patches is an assumption.")
```

400 values of z from just above 0 to just below π (the end points are avoided because $\cot^2 z$ is infinite there). Three curves: $\sin^{1/3} z$, $g_{00} = \cot^2 z$ (`1.0 / np.tan(zs) ** 2`) and $|\cos z|$; a dashed vertical line at the brane, a faint shading of the patch and three labels. **What you see in Figure 18b.4:** every curve is mirror-symmetric about $z = \pi/2$, so $z \to \pi - z$ is an isometry; at the brane $\sin^{1/3} z$ reaches its maximum 1 while g_{00} and $\sqrt{|g|}$ touch zero: the metric is degenerate there, which is why gluing the two patches is an assumption and not a result.

In [17], which matrix makes the mirror a pairing.

```
CANDIDATES = [("1", I16), ("Gamma", GAM), ("gamma^(x0)", G[0]),
              ("Gamma gamma^(x0)", GAM * G[0])]
FOUND = {}
```

```
for odd in (False, True):
    J = jets(odd)
    for name, P in CANDIDATES:
        JP = transform(J, P, MIRROR, odd)
        L_mirror = lagrangian(mirror, JP, odd, m, lam)
        hit = None
        for sigma, sm, sl in itertools.product((1, -1), repeat=3):
            L_patch = lagrangian(reflected, J, odd, sm * m, sl * lam)
            if (L_mirror - L_patch.times(sigma)).is_zero():
                hit = (sigma, sm, sl)
                break
        FOUND[odd, name] = hit
```

Four candidate matrices: 1, Γ, $\gamma^{(x_0)}$ and $\Gamma\gamma^{(x_0)} = P_0$. For each statistics and each candidate, `JP` is the jet of $\Psi'(x) = P\Psi(Rx)$ with the mirror reflection, and `L_mirror` its Lagrangian with (m, λ) in the mirror geometry. The inner loop tries the eight sign choices (σ, s_m, s_λ) and compares with $\sigma\,\mathcal{L}_{s_m m, s_\lambda \lambda}[\Psi]$ in the reflected patch geometry; `break` stops at the first relation that holds exactly. `FOUND` stores the result (or `None`).

```
for name, _ in CANDIDATES:
    hit = FOUND[False, name]
    text = "no relation" if hit is None else (
        f"L = {'+' if hit[0] > 0 else '-'}L_({'' if hit[1] > 0 else '-'}m, "
        f"{'' if hit[2] > 0 else '-'}lambda)")
    say(f"P = {name}: {text} (the same for Grassmann components: "
        f"{FOUND[True, name] == hit})")
```

For each candidate the cell prints the relation found for commuting components and whether the Grassmann result is the same (the nested f-string writes the signs as + or − and leaves out a + in front of m and λ).

```
expected = {"1": None, "Gamma": None, "gamma^(x0)": (1, -1, 1),
            "Gamma gamma^(x0)": (-1, 1, -1)}
reproduces(all(FOUND[odd, name] == expected[name]
               for odd in (False, True) for name, _ in CANDIDATES),
           "T2: only gamma^(x0) maps (m, lambda) to (-m, lambda) with L -> +L",
           (PY, ["T2.metric.commuting.reflection_table",
                 "T2.metric.grassmann.reflection_table"]),
           (WL, ["T2_mirror_Lagrangian_commuting", "T2_mirror_Lagrangian_grassmann"]))
```

The expected results of the sympy record: none for 1 and Γ; $(+1, -1, +1)$, that is $+\mathcal{L}_{-m,\lambda}$, for $\gamma^{(x_0)}$; $(-1, +1, -1)$, that is $-\mathcal{L}_{m,-\lambda}$, for P_0. Out [17] shows exactly these four lines and the PASS line.

In [18], T2 completed.

```
t2_ok = True
T2_SIGNS = {}

        T2_SIGNS = {k: MIRROR[k[0]] * MIRROR[k[1]] for k in T1_ if emt_ok}
    J1, J2 = current(mirror, JP, odd), current(reflected, J, odd)
    current_ok = all_zero([J1[mu] - J2[mu].times(MIRROR[mu]) for mu in range(8)])
    s_odd = (scalar(JP, odd) + scalar(J, odd)).is_zero()
    stat = "grassmann" if odd else "commuting"
    say(f"{stat}: field equations mapped {el_ok}, T pulled back {emt_ok}, "
        f"J pulled back {current_ok}, S reversed {s_odd}")
    t2_ok = t2_ok and el_ok and emt_ok and current_ok and s_odd
```

For both statistics with $P = \gamma^{(x_0)}$ and the mirror reflection: `el_ok` checks $E^{\mathrm{mirror}}_{m,\lambda}[\Psi'] + \gamma^{(x_0)} E^{\mathrm{patch}}_{-m,\lambda}[\Psi] = 0$ (T2b); `emt_ok` checks $T_{\mu\nu}[\Psi'] = \Lambda_\mu \Lambda_\nu T_{\mu\nu}[\Psi; -m, \lambda]$ with $\Lambda =$ `MIRROR` (T2c), and for commuting components the signs $\Lambda_\mu \Lambda_\nu$ are stored for the figure; `current_ok` checks $J'^\mu = \Lambda_\mu J^\mu$; `s_odd` checks $S[\gamma^{(x_0)}\Psi] + S[\Psi] = 0$. The cell prints the four results for each statistics.

```
reproduces(t2_ok, "T2: field equations mapped, T and J pulled back (equal energy), "
           "S reversed", (PY, [f"T2.metric.{s}.{c}" for s in ("commuting", "grassmann")
                               for c in ("euler_lagrange_map", "emt", "current",
                                         "S_odd")]),
           (WL, ["T2_mirror_energy_momentum_and_current_commuting",
                 "T2_mirror_energy_momentum_and_current_grassmann",

                 "T2_mirror_Euler_Lagrange_grassmann"]))
```

One check with eight sympy and four Wolfram records (the list comprehension builds the eight sympy names). Out [18] prints True eight times and the PASS line.

In [19], Figure 18b.5: the two summaries of T2.

```
choices = list(itertools.product((1, -1), repeat=3))
grid = np.zeros((len(CANDIDATES), len(choices)))
for i, (name, _) in enumerate(CANDIDATES):
    if FOUND[False, name] is not None:
        grid[i, choices.index(FOUND[False, name])] = 1.0
t2_signs = np.zeros((8, 8))
for (mu, nu), s in T2_SIGNS.items():
    t2_signs[mu, nu] = t2_signs[nu, mu] = s
```

`choices` lists the eight sign choices in the order of the search. `grid` has one row per candidate and one column per choice, with 1 where a relation was found (`choices.index` finds the column). `t2_signs` is the 8×8 array of the stored signs $\Lambda_\mu \Lambda_\nu$.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.4),
                         gridspec_kw={"width_ratios": [1.4, 1.0]})
```

```
axes[0].imshow(grid, cmap="Greens", vmin=0, vmax=1.4, aspect="auto")

axes[1].set_xticks(range(8), [f"$x_{a}$" for a in range(8)])
axes[1].set_yticks(range(8), [f"$x_{a}$" for a in range(8)])
axes[1].set_title("sign of the mirror image's $T_{\\mu\\nu}$", fontsize=10)
axes[1].grid(False)
```

Two panels of different widths (`width_ratios`). The left one draws `grid` in shades of green, with the sign choices as three-line column labels (`\n` starts a new line); the right one draws the signs with their values written in the cells.

```
save_figure(fig, "mirror_candidates",
            "Theorem T2 in the author's metric. Left: for four candidate matrices "
            "$P$ (rows), the eight possible relations between the Lagrangian of "
            "the mirror image on the mirror patch and the Lagrangian of $\\Psi$ on "
            "the patch (columns: overall sign $\\sigma$, sign of $m$, sign of "
            "$\\lambda$); a green square marks the relation that holds exactly. "
            "$P = 1$ and $P = \\Gamma$ give none; $P = \\gamma^{(x_0)}$ gives "
            "$+\\mathcal{L}_{-m,\\lambda}$, theorem T2; $P = \\Gamma\\gamma^{(x_0)}$ "
            "gives $-\\mathcal{L}_{m,-\\lambda}$. Right: the sign of each component "
            "of the mirror image's $T_{\\mu\\nu}$ relative to that of the "
            "$(-m, \\lambda)$ field, $+1$ except the mixed components with one "
            "$x_0$ index: the energy density is equal, not opposite.")
```

What you see in Figure 18b.5: on the left, the rows of 1 and Γ are empty, the row of $\gamma^{(x_0)}$ has its green square under $+\mathcal{L}$, $-m$, $+\lambda$, and the row of P_0 under $-\mathcal{L}$, $+m$, $-\lambda$; on the right, $+1$ everywhere except the 14 cells of the row and the column x_0 off the diagonal (the seven mixed components with one index x_0, drawn twice), where the sign is -1. The energy density ($T_{x_4x_4}$, sign $+1$) of the mirror partner is EQUAL to that of the field it mirrors.

In [20], the last check.

```
figure_names = ["connection_history", "lagrangian_cancellation", "emt_signs",
                "mirror_metric", "mirror_candidates"]
paths = [output_file(f"{FIGURE_FOLDER}/18b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
```

```
      "every figure file of this notebook exists")
all_checks_passed()
```

The five figure files must exist; the last line is ALL 20 CHECKS PASSED (notebook 18b).

What Notebook 18b established. PROVED, as exact identities in the 288 jet values, for an arbitrary history $a_4(x_4)$ and for both statistics: the canonical connection and $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$; T1 in the author's metric (Lagrangian, field equations derived from the Lagrangian, all 36 components of T, all 8 of J, the pair totals, the negative controls), for a general cubic potential and in a random general field; T2 across the mirror, with the search that singles out $\gamma^{(x_0)}$. ASSUMED: the gluing at the degenerate brane. NOT shown: any process that creates a universe; the identities map solutions to solutions.

18.21 A family of exact solutions: the fields that depend only on the time

The theorems speak about every solution. To SEE them at work we need actual solutions, and the field equation of the author's metric has a family of exact ones: the **homogeneous** fields, which depend on the time x_4 only. We derive them line by line for the commuting field dirac16complex00, whose components are ordinary complex numbers (the Revision record also gives the Grassmann version). The family is derived on the background $b_4 = 1$; the end of the next paragraphs says what a changing b_4 does to it.

The field equation becomes an ordinary differential equation. For $\Psi = \Psi(x_4)$ every derivative except ∂_4 vanishes, and $\gamma^{x_4} = \gamma^{(x_4)}/f_4 = \gamma^{(x_4)}$. The spin connection still acts, through $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ (Section 18.3). With $V = m + \lambda S$ the field equation of Section 18.4 is therefore

$$\gamma^{(x_4)}\frac{d\Psi}{dx_4} + 3H\gamma^{(x_0)}\Psi = V\Psi.$$

Subtract $3H\gamma^{(x_0)}\Psi$ and multiply on the left by $-\gamma^{(x_4)}$; since $\gamma^{(x_4)}\gamma^{(x_4)} = \eta_{44} = -1$, the left side becomes $d\Psi/dx_4$:

$$\frac{d\Psi}{dx_4} = M\Psi, \qquad M = -\gamma^{(x_4)}\big(V - 3H\gamma^{(x_0)}\big) = -V\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}.$$

S is constant. M is real (V is real because $S = \Psi^\dagger C\Psi$ is real for a real symmetric C, and the gammas are real), so $M^\dagger = M^T$. By the product rule,

$$\frac{dS}{dx_4} = \Big(\frac{d\Psi}{dx_4}\Big)^\dagger C\Psi + \Psi^\dagger C\frac{d\Psi}{dx_4} = \Psi^\dagger\big(M^TC + CM\big)\Psi.$$

Now $(\gamma^{(x_4)})^T = -\gamma^{(x_4)}$ and $(\gamma^{(x_0)})^T = \gamma^{(x_0)}$, and from $C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T$: C commutes with $\gamma^{(x_4)}$ and anticommutes with $\gamma^{(x_0)}$. Hence

$$M^T = V\gamma^{(x_4)} + 3H(\gamma^{(x_0)})^T(\gamma^{(x_4)})^T = V\gamma^{(x_4)} - 3H\gamma^{(x_0)}\gamma^{(x_4)} = V\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}.$$

The transpose of a product reverses the order; then the two transpose rules; then $\gamma^{(x_0)}\gamma^{(x_4)} = -\gamma^{(x_4)}\gamma^{(x_0)}$.

$$M^TC + CM = VC\gamma^{(x_4)} - 3HC\gamma^{(x_4)}\gamma^{(x_0)} - VC\gamma^{(x_4)} + 3HC\gamma^{(x_4)}\gamma^{(x_0)} = 0.$$

We moved C to the left in M^TC: past $\gamma^{(x_4)}$ without a sign and past $\gamma^{(x_0)}$ with a sign. So $dS/dx_4 = 0$: S keeps its initial value S_0, and $V = m + \lambda S_0$ and M are constant along the solution (`python-field-theory.json`, check `exact_nonlinear_homogeneous_solution`).

The square of M. Move the second $\gamma^{(x_4)}$ to the left through $(V - 3H\gamma^{(x_0)})$, which turns it into $(V + 3H\gamma^{(x_0)})$:

$$M^2 = \gamma^{(x_4)}(V-3H\gamma^{(x_0)})\gamma^{(x_4)}(V-3H\gamma^{(x_0)}) = \gamma^{(x_4)}\gamma^{(x_4)}(V+3H\gamma^{(x_0)})(V-3H\gamma^{(x_0)}) = -(V^2-9H^2).$$

The two signs in front of $\gamma^{(x_4)}$ cancel; then $\gamma^{(x_4)}\gamma^{(x_4)} = -1$ and $(\gamma^{(x_0)})^2 = 1$ in the product of the brackets. So $M^2 = (9H^2 - V^2)I_{16}$.

The exact solution. When $V^2 > 9H^2$ put $w = \sqrt{V^2 - 9H^2}$, so that $M^2 = -w^2$. Then

$$\Psi(x_4) = \cos(wx_4)\,\Psi(0) + \frac{\sin(wx_4)}{w}\,M\Psi(0).$$

Check: the derivative is $-w\sin(wx_4)\Psi(0) + \cos(wx_4)M\Psi(0)$, and $M\Psi(x_4) = \cos(wx_4)M\Psi(0) + \frac{\sin(wx_4)}{w}M^2\Psi(0)$ is the same, because $M^2 = -w^2$. At $x_4 = 0$ the formula gives $\Psi(0)$. The solution **oscillates** with the frequency w. When $V^2 < 9H^2$, cosine and sine become cosh and sinh and the solution **grows** exponentially: inside the window $|m + \lambda S_0| < 3H$ these modes are not oscillations but growth (`python-scope.json`, check `good_sector_x0_independent_modes_without_boundary_condition`; Chapter 8). PROVED: `python-field-theory.json`, check `exact_nonlinear_homogeneous_solution`; `wolfram-field-theory.json`, check `exact_solution_nonlinear_homogeneous_C`. The history a_4 does not enter M, but it enters the energy-momentum tensor through the vielbein factors $e^{\pm a_4}$ and through the spin connection (Notebook 18c, Figure 18c.3).

With a changing b_4. In the metric with $b_4(x_4)$ the homogeneous equation gains one term: $d\Psi/dx_4 = M\Psi - \frac{3}{4}(b_4'/b_4)\Psi$ (`wolfram-field-theory-b4.json`, check `evolution_form_C`, which states that the extra term is the factor $b_4^{-3/4}$). Writing $\Psi = b_4^{-3/4}\Phi$ removes it: Φ obeys $d\Phi/dx_4 = M\Phi$, where M contains $V = m + \lambda S[\Psi] = m + \lambda b_4^{-3/2}S[\Phi]$. The argument above still gives $dS[\Phi]/dx_4 = 0$, because it never used that V is constant. So for $\lambda = 0$ the solutions are $b_4^{-3/4}$ times those of $b_4 = 1$; for $\lambda \neq 0$ the coefficient V changes with b_4, the matrices M at different times do not commute, and this book does not solve that case. (DERIVED here from the recorded equation; there is no record check of this paragraph of its own.)

What the theory record says about these solutions. For homogeneous solutions, on shell, the energy density is $\rho = mS + \frac{\lambda}{2}S^2$, every pressure (3-space, extra times, hidden direction) is $p = \frac{\lambda}{2}S^2$, and the mixed component $T_{x_4x_0}$ vanishes (`python-field-theory.json`, checks `commuting_homogeneous_on_shell_rho_p` and `commuting_T_x4x0_homogeneous`). The charge density $J^{x_4} = \Psi^\dagger B\Psi$ is NOT constant: the conservation law $\partial_4 J^{x_4} + \frac{1}{\sqrt{|g|}}\partial_0(\sqrt{|g|}J^{x_0}) = 0$ holds with a flow along the hidden direction. For a homogeneous field $J^{x_0} = -i\bar\Psi\gamma^{(x_0)}\Psi/f_0 = \tan z\, q_0$ with the **frame current** $q_0 = -i\bar\Psi\gamma^{(x_0)}\Psi$ (a number that depends on x_4 only; it is NOT the charge Q), and $\sqrt{|g|}J^{x_0} = \cos z \tan z\, q_0 = \sin z\, q_0$, so

$$\frac{1}{\sqrt{|g|}}\partial_0(\sqrt{|g|}J^{x_0}) = \frac{6H\cos z\, q_0}{\cos z} = 6Hq_0, \qquad \frac{dJ^{x_4}}{dx_4} = -6Hq_0.$$

The derivative $\partial_0 = 6H\, d/dz$ acts only on $\sin z$, because q_0 does not depend on x_0; the second equation is the conservation law solved for $\partial_4 J^{x_4}$. Notebook 18c checks this law along its solution (`python-field-theory.json`, check `commuting_current_conservation`).

The local law does not make the total charge constant. The law above is LOCAL: it says that charge can leave a small region only by flowing through its surface. The total charge of the patch is constant only if nothing flows through the boundary of the patch. For a homogeneous field take a box of coordinate volume V_6 in the six directions $x_1, x_2, x_3, x_5, x_6, x_7$ (for a homogeneous field the current J^μ is the same at every point of the slice, so whatever flows in through one face of the box in these directions flows out through the opposite face: these faces add nothing), and the whole patch $0 < z < \pi/2$ in x_0. Its charge is

$$Q(x_4) = \int \cos z\, J^{x_4}\, d^7x = V_6\, J^{x_4}(x_4) \int_0^{\pi/(12H)} \cos(6Hx_0)\, dx_0 = V_6\, J^{x_4}(x_4)\, \frac{1}{6H}.$$

J^{x_4} does not depend on the seven coordinates of the slice, so it comes out of the integral; the integral over the six directions of the box gives V_6; the substitution $z = 6Hx_0$, $dx_0 = dz/(6H)$, gives $\frac{1}{6H}\int_0^{\pi/2}\cos z\, dz = \frac{1}{6H}[\sin z]_0^{\pi/2} = \frac{1}{6H}$.

$$\frac{dQ}{dx_4} = \frac{V_6}{6H}\,\frac{dJ^{x_4}}{dx_4} = \frac{V_6}{6H}\,(-6Hq_0) = -V_6\, q_0.$$

We differentiated the line before (V_6 and H are constants) and inserted the law $dJ^{x_4}/dx_4 = -6Hq_0$. The same result comes from integrating the flow: $\int_0^{\pi/(12H)} \partial_0(\sin z\, q_0)\, dx_0 = [\sin z\, q_0]_{z=0}^{z=\pi/2} = q_0$, because $\sin z = 0$ at the tip $z = 0$ and $\sin z = 1$ at the brane $z = \pi/2$. So the charge of the patch changes at the rate $-V_6 q_0$, which is the charge flowing out through the brane. Notebook 18c prints the range of q_0 along its solution, from -0.3454 to 0.3454 (Out [10]): it is not zero, and the charge density J^{x_4} of Figure 18c.3 oscillates accordingly. The Revision record states the same boundary term: the flux $\sin z\, u^\dagger M_0 v$ "vanishes at the tip z -> 0 but not at the patch end z = pi/2" (`python-scope.json`, check `good_sector_hermiticity_up_to_the_brane_flux`). The T2 mirror partner has the EQUAL charge density at every time (T2c), so the charge of the mirror patch changes at the same rate, and the two glued patches together change at twice the rate: gluing does not stop the flow. A constant total charge needs a **no-flux condition** at the brane, $\sqrt{|g|}J^{x_0} = 0$ at $z = \pi/2$, that is $q_0 = 0$ for these solutions. No such condition is derived in this book: it would be part of the junction condition at the brane, which is OPEN (Section 18.28, item 7).

What T1 and T2 predict for this family. T1: if Ψ solves the equation with (m, λ), then $\Gamma\Psi$ solves it with $(-m, -\lambda)$. Directly: Γ anticommutes with $\gamma^{(x_4)}$ and commutes with $\gamma^{(x_4)}\gamma^{(x_0)}$, and $S[\Gamma\Psi] = S$, so $\Gamma M_{m,\lambda}\Gamma = +V\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)} = M_{-m,-\lambda}$: the partner's generator is the similar matrix $\Gamma M\Gamma$, with the same eigenvalues. T2: on the mirror patch the connection term is $-3H\gamma^{(x_0)}$ (Section 18.16), so the equation there has $M^{\text{mirror}} = -V\gamma^{(x_4)} - 3H\gamma^{(x_4)}\gamma^{(x_0)}$; with $S[\gamma^{(x_0)}\Psi] = -S$ and the parameters $(-m, \lambda)$, $V \to -m - \lambda S = -V$, and $\gamma^{(x_0)}M_{m,\lambda}\gamma^{(x_0)} = V\gamma^{(x_4)} - 3H\gamma^{(x_4)}\gamma^{(x_0)}$, which is exactly $M^{\text{mirror}}_{-m,\lambda}$. So $\gamma^{(x_0)}\Psi$ solves the mirror equation with $(-m, \lambda)$. (We used $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)} = -\gamma^{(x_4)}$ and $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_0)} = -\gamma^{(x_4)}\gamma^{(x_0)}$.) Notebook 18c checks both by solving the partner equations independently.

18.22 The quantum reading Q

From fields to quantum fields, in one paragraph. Chapter 10 quantised dirac16complex canonically, with x_4 as the time. The recipe reads off the term of the Lagrangian that contains the time derivative. With $\gamma^{x_4} = \gamma^{(x_4)}$ and $C\gamma^{(x_4)} = iB$ (Notebook 18a, In [5]), the time-derivative part of K is

$$\frac{1}{2}(\Psi^\dagger C\gamma^{(x_4)}\partial_4\Psi - \partial_4\Psi^\dagger C\gamma^{(x_4)}\Psi) = \frac{i}{2}(\Psi^\dagger B\partial_4\Psi - \partial_4\Psi^\dagger B\Psi),$$

so the Lagrangian contains $\frac{i}{2}\sqrt{|g|}\,\Psi^\dagger N\partial_4\Psi$ (plus its partner term) with the **velocity kernel** $N = B$. The canonical rule then fixes the anticommutator of the field operators on a slice $x_4 = \text{const}$: the momentum is $\pi = i\sqrt{|g|}\Psi^\dagger N$, and $\{\Psi_A(x), \pi_B(y)\} = i\delta_{AB}\delta^7(x-y)$ forces

$$\{\Psi_A(x), \Psi_B^\dagger(y)\} = (N^{-1})_{AB}\,\frac{\delta^7(x-y)}{\sqrt{|g|}} = B_{AB}\,\frac{\delta^7(x-y)}{\sqrt{|g|}},$$

because $N^{-1} = B^{-1} = B$ ($BB = 1$). Here $\{X, Y\} = XY + YX$ is the anticommutator of two operators and δ^7 the delta function of the seven coordinates other than x_4. Because B has eight eigenvalues $+1$ and eight -1, the state space carries an indefinite **Krein** form when $\Psi^\dagger$ is read as the ordinary adjoint (Chapter 10).

statement	status	where it is verified
the canonical anticommutator is $B\,\delta^7/\sqrt{\lvert g\rvert}$	PROVED	`python-field-theory.json`, check `canonical_anticommutator_B`; `python-pairing.json`, check `Q.canonical_anticommutator`

One-particle waves. In flat 4+4 space ($H = 0$, a_4 constant, all $f_\mu = 1$) and for $\lambda = 0$, a plane wave $\Psi = u\,e^{-iwx_4 + i\sum_{a\neq 4} k_a x_a}$ turns the field equation $\sum_a \gamma^{(a)}\partial_a\Psi = m\Psi$ into $-iw\gamma^{(x_4)}u + i\sum_{a\neq 4} k_a\gamma^{(a)}u = mu$. Multiply on the left by $-i\gamma^{(x_4)}$ and use $\gamma^{(x_4)}\gamma^{(x_4)} = -1$:

$$wu = h_m(k)u, \qquad h_m(k) = -im\gamma^{(x_4)} - \gamma^{(x_4)}\sum_{a\neq x_4} k_a\gamma^{(a)}.$$

The frequencies w are the eigenvalues of the **one-particle matrix** $h_m(k)$. Its square: write $h = -\gamma^{(x_4)}(im + K)$ with $K = \sum_{a\neq 4} k_a\gamma^{(a)}$; moving $\gamma^{(x_4)}$ through $(im + K)$ turns it into $(im - K)$, so

$$\begin{aligned} h^2 &= \gamma^{(x_4)}\gamma^{(x_4)}(im - K)(im + K) = -(-m^2 - K^2) = m^2 + K^2 \\ &= (m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2)I_{16}. \end{aligned}$$

$K^2 = \sum_a k_a^2\eta_{aa}$ by the Clifford relation (the mixed products cancel in pairs). So $h^2 = w^2 I_{16}$ with $w^2 = m^2 + k_0^2 + k_1^2 + k_2^2 + k_3^2 - k_5^2 - k_6^2 - k_7^2$: real frequencies when $w^2 > 0$; imaginary ones, growing modes, when the extra-time momentum is large enough to make $w^2 < 0$.

Hypotheses.

- (HQ1) dirac16complex is canonically quantised with x_4 as the evolution time and the anticommutator fixed by the velocity kernel of its Lagrangian, as above.
- (HQ2) dirac16complex00 is a classical field and has no quantum reading.

The statements.

- (Q1) The chirality image $\chi = \Gamma\Psi$ carries the Krein matrix $-B$: $\{\chi_A, \chi_B^\dagger\} = -B_{AB}\,\delta^7/\sqrt{|g|}$. This is also the anticommutator demanded by its own Lagrangian $\mathcal{L}_{m,\lambda}[\Gamma\chi] = -\mathcal{L}_{-m,-\lambda}[\chi]$.
- (Q2) The image's own generators (energy, momentum and charge from its own Lagrangian) coincide with those of Ψ: the pair Ψ, $\Gamma\Psi$ is ONE quantum system, and the T1 identity $T^{(-m,-\lambda)}[\Gamma\Psi] = -T^{(m,\lambda)}[\Psi]$ is an identity between operators of that one system.
- (Q3) An independently quantised universe with $(-m, -\lambda)$ has the anticommutator $+B$ (from its own Lagrangian $\mathcal{L}_{-m,-\lambda}$), its own vacuum and its own generators. It cannot be identified with $\Gamma\Psi$. On the product state space the generators of two independent universes add, $P_{\text{total}} = P_1 \otimes 1 + 1 \otimes P_2$, and no cancellation $P_1 + P_2 = 0$ follows.
- (Q4) The one-particle matrices satisfy $\Gamma h_m(k)\Gamma = h_{-m}(k)$ and $\gamma^{(x_0)} h_m(k) \gamma^{(x_0)} = h_{-m}(R_0 k)$ ($R_0 k$: the momentum with k_0 reversed): the $+m$ and $-m$ one-particle spectra are IDENTICAL, not opposite. For every real frequency each of the two eigenspaces (for $+w$ and for $-w$) has dimension 8 and Krein inertia (4,4), for $+m$ and $-m$ alike; for imaginary or zero frequency the eigenspaces are Krein-neutral (B vanishes on them). The same similarity holds in a general field at a point, with frozen coefficients.
- (Q5) The T2 image $\gamma^{(x_0)}\Psi$ keeps the anticommutator $+B$: the mirror $(-m, \lambda)$ universe is an ordinary, independently quantisable copy with equal energies.

Status: PROVED under (HQ1). Records: `wolfram-pairing.json`, the 12 checks of the Q group (names beginning with `Q_`); `python-pairing.json`, the 10 checks whose names begin with `Q.`; theorem Q of `pairing-theory.json`. Notebook 18a checks the Krein signs (In [17], In [18]); Notebook 18c checks Q4 and Q5 on plane waves (In [16] to In [20]). Chapter 10 treats the same quantum reading in its own Notebook 10g.

18.23 The proofs of Q1 to Q5

Q1. The field operators of the image are $\chi_A = \sum_C \Gamma_{AC}\Psi_C$ and $\chi_B^\dagger = \sum_D \Psi_D^\dagger \Gamma_{BD}$ (Γ is real). The anticommutator is linear in each argument, so

$$\{\chi_A, \chi_B^\dagger\} = \sum_{C,D} \Gamma_{AC}\{\Psi_C, \Psi_D^\dagger\}\Gamma_{BD} = \sum_{C,D} \Gamma_{AC} B_{CD} \Gamma_{DB}\,\frac{\delta^7}{\sqrt{|g|}} = (\Gamma B \Gamma)_{AB}\,\frac{\delta^7}{\sqrt{|g|}} = -B_{AB}\,\frac{\delta^7}{\sqrt{|g|}}.$$

We used $\Gamma_{BD} = \Gamma_{DB}$ (Γ symmetric) and Lemma 2, $\Gamma B \Gamma = -B$. For the image's own Lagrangian: written in terms of χ, the Lagrangian of the theory is $\mathcal{L}_{m,\lambda}[\Psi] = \mathcal{L}_{m,\lambda}[\Gamma\chi]$; its velocity term is

$\frac{i}{2}\sqrt{|g|}\,\chi^\dagger\Gamma B\Gamma\partial_4\chi = \frac{i}{2}\sqrt{|g|}\,\chi^\dagger(-B)\partial_4\chi$, so its velocity kernel is $N=-B$ and the canonical rule gives the anticommutator $N^{-1}=-B$. The two agree.

Q2. The image's own Lagrangian, evaluated at $\chi=\Gamma\Psi$, is $\mathcal{L}_{m,\lambda}[\Gamma\Gamma\Psi]=\mathcal{L}_{m,\lambda}[\Psi]$: the same function of the same operators. Its energy density (obtained by the Legendre transform: for each field, its time derivative times its canonical momentum, summed, minus the Lagrangian) and its Noether densities are therefore the same operators as those of Ψ. At the one-particle level: the energy of a plane wave is $\Psi^\dagger\mathcal{E}_m(k)\Psi$ with the **energy kernel** $\mathcal{E}_m(k)=Bh_m(k)$, and the evolution is $i\partial_4\Psi=$ (anticommutator matrix)(energy kernel)$\Psi=B\mathcal{E}_m\Psi=h_m\Psi$. The image's own Lagrangian is $-\mathcal{L}_{-m,-\lambda}[\chi]$, so its anticommutator matrix is $-B$ (Q1) and its energy kernel is $-\mathcal{E}_{-m}$; its evolution generator is

$$(-B)(-\mathcal{E}_{-m})=B\mathcal{E}_{-m}=h_{-m}=\Gamma h_m\Gamma,$$

which is exactly how $\Gamma\Psi$ must evolve: $i\partial_4(\Gamma\Psi)=\Gamma h_m\Psi=(\Gamma h_m\Gamma)(\Gamma\Psi)$. The sign of the Krein matrix and the sign of the energy kernel compensate: the image is the same quantum system relabelled.

Q3. An independent universe χ_2 with the Lagrangian $\mathcal{L}_{-m,-\lambda}[\chi_2]$ has the velocity kernel $+B$ and therefore $\{\chi_2,\chi_2^\dagger\}=+B\,\delta^7/\sqrt{|g|}$, while $\{\Gamma\Psi_1,(\Gamma\Psi_1)^\dagger\}=-B\,\delta^7/\sqrt{|g|}$. Since $B\neq -B$, $\chi_2=\Gamma\Psi_1$ is impossible. Independence also requires $\{\Psi_1,\chi_2^\dagger\}=0$, whereas $\{\Gamma\Psi_1,\Psi_1^\dagger\}=\Gamma B\,\delta^7/\sqrt{|g|}$ is a matrix of rank 16, not zero. On the product of the two state spaces the generators of the two systems add; the T1 identity relates operators of universe 1 only and gives no relation $P_2=-P_1$. At zero momentum the one-particle generator of the two universes together has the eigenvalues $-m$ and $+m$, 16 times each, all nonzero for $m\neq 0$: nothing cancels.

Q4. $\Gamma\gamma^{(x_4)}\Gamma=-\gamma^{(x_4)}$ (one gamma) and $\Gamma\gamma^{(x_4)}\gamma^{(a)}\Gamma=\gamma^{(x_4)}\gamma^{(a)}$ (two gammas), so

$$\Gamma h_m(k)\Gamma=+im\gamma^{(x_4)}-\gamma^{(x_4)}\sum_{a\neq 4}k_a\gamma^{(a)}=h_{-m}(k).$$

With $(\gamma^{(x_0)})^2=1$: $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)}=-\gamma^{(x_4)}$; for $a\neq 0,4$, $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(a)}\gamma^{(x_0)}=\gamma^{(x_4)}\gamma^{(a)}$ (two exchanges); and $\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)}\gamma^{(x_0)}=-\gamma^{(x_4)}\gamma^{(x_0)}$. So the mass term and the k_0 term change sign and the others do not: $\gamma^{(x_0)}h_m(k)\gamma^{(x_0)}=h_{-m}(R_0k)$. **Similar matrices have equal spectra**: if $hu=wu$, then $(MhM^{-1})(Mu)=w(Mu)$. So $+m$ and $-m$ have the same frequencies.

The Krein inertia, in three steps. (i) $Bh_m=h_m^\dagger B$; this follows from the reality of the gammas and the relations of C with $\gamma^{(x_4)}$ and $\gamma^{(a)}$ (Exercise 18.5 asks you to verify it). For a real $w>0$ the matrices $P_\pm=\frac{1}{2}(1\pm h/w)$ are the projectors onto the eigenspaces of $\pm w$ (because $h^2=w^2$), and

$$P_+^\dagger BP_-=\tfrac{1}{4}(1+h^\dagger/w)B(1-h/w)=\tfrac{1}{4}B(1+h/w)(1-h/w)=\tfrac{1}{4}B(1-h^2/w^2)=0.$$

We moved B to the left with $h^\dagger B=Bh$, then multiplied out; $h^2=w^2$. So the two eigenspaces are B-orthogonal, and B is nondegenerate on each (it is invertible on the whole space). (ii) Without extra-time momentum ($k_5=k_6=k_7=0$) B commutes with h, and $\operatorname{tr}B=\operatorname{tr}(Bh)=0$, so $\operatorname{tr}(BP_\pm)=0$: on each 8-dimensional eigenspace B is an involution with trace 0, which has four eigenvalues $+1$ and four -1, Krein inertia (4,4). (iii) The region $w^2>0$ is connected and contains the case without extra-time momentum (lowering k_5,k_6,k_7 to zero only increases w^2),

and the projectors change continuously with k; a nondegenerate form cannot change its inertia continuously, so (4,4) holds at every real frequency. For an imaginary w: if $hu = wu$ and $hv = wv$, then $w\,u^\dagger Bv = u^\dagger Bhv = u^\dagger h^\dagger Bv = \bar{w}\,u^\dagger Bv$ ($\bar{w}$ the complex conjugate), so $(w - \bar{w})u^\dagger Bv = 0$ and $u^\dagger Bv = 0$: the eigenspace is **Krein-neutral**. For $w = 0$, $h^2 = 0$ with rank 8 and the null space of h equals its range, also B-neutral. The records are listed in the table at the end of this section. The recorded samples, all reproduced by Notebook 18c (In [16]):

m	**momentum** $(k_0, \ldots, k_7)$	w	**dimensions of the $+w$ and $-w$ eigenspaces**	**Krein inertia on $+w$ and on $-w$**
± 2	(4, 1, 2, 0, 0, 0, 0, 0)	5	8 and 8	(4,4) and (4,4)
± 3	(0, 0, 0, 0, 0, 0, 0, 0)	3	8 and 8	(4,4) and (4,4)
± 1	(0, 1, 0, 0, 0, 0, 0, 0)	$\sqrt{2}$	8 and 8	(4,4) and (4,4)
± 2	(0, 0, 0, 0, 0, 1, 0, 0)	$\sqrt{3}$	8 and 8	(4,4) and (4,4)

(Each row stands for the two recorded samples with $+m$ and $-m$; the entry k_4 is not used. The last row has an extra-time momentum and still a real frequency: $w^2 = 4 - 1 = 3$.)

Q5. Lemma 4 gives $\gamma^{(x_0)} B (\gamma^{(x_0)})^\dagger = +B$, so the anticommutator of $\gamma^{(x_0)}\Psi$ is $+B\,\delta^7/\sqrt{|g|}$, the same as that of an ordinary field. QED.

What Q does not say. Q1 to Q5 are statements about the canonical anticommutator. They neither use nor establish a positive-norm state space for either universe. The theory record constructs, separately, a positive Fock representation in the good sector without extra-time momentum (Chapter 10); it is not used here. And the vanishing total energy-momentum and charge of a T1 pair holds for classical bilinears and as an operator identity within ONE quantum system; it does not hold for two independently quantised universes, whose generators add without cancelling.

18.24 Example: Notebook 18c sees the theorems in numbers

Notebook 18c takes one homogeneous solution of dirac16complex00 in the author's metric (Section 18.21), with values chosen as an ILLUSTRATION: units in which $m = 1$, $H = 0.2$, $\lambda = 0.3$, the

hidden angle $z_0 = \pi/4$, and an initial value of 16 complex numbers drawn with the fixed seed 2026. Only the history $a_4 = AHx_4$ with $A = 1$ is read from the Revision record `Revision/kohn_sham/results/parameters.json`. The notebook solves the equation with the classical Runge-Kutta method of fourth order and checks it against the exact formula; solves the T1 partner equation $(-m, -\lambda)$ and the mirror equation $(-m, \lambda)$ INDEPENDENTLY and finds $\Gamma\Psi$ and $\gamma^{(x_0)}\Psi$; computes S, all 8 components of J^μ and all 36 of $T_{\mu\nu}$ along the deflating history; compares the spectra of the evolution matrices; and, for the quantum reading, reproduces the plane-wave samples of the pairing record and follows the Krein norms of single eigenvectors under Γ and $\gamma^{(x_0)}$. Its last line is ALL 21 CHECKS PASSED (notebook 18c); it runs in about 30 seconds.

18.25 How to run Notebook 18c

Step 1. What this notebook does and what it needs.

Notebook 18c (T1 and T2 numerically: solutions, partners, currents and spectra) is the file `Revision/textbook/notebooks/18c_pairs_numerically.ipynb` of the repository Dirac_claude. It takes the exact family of solutions of the field equation of dirac16complex00 in the author's metric that depend on the time x4 only (recorded in the Revision theory reports), integrates one solution with the Runge-Kutta method and compares it with the exact formula, and then solves its two partners independently: the T1 partner with mass and coupling reversed, starting from Gamma times the initial value, and the T2 partner on the mirror patch beyond the brane, starting from gamma^(x0) times the initial value. It checks that the partners are exactly Gamma Psi and gamma^(x0) Psi, that the T1 partner has the opposite charge density, current and energy-momentum tensor (all 36 components, along the canonical deflating history a4 = A H x4), that the T2 partner has the same ones and the opposite scalar S, that the charge obeys its local conservation law (with a flow through the brane, so the total charge of the patch is not constant), and that the spectra of the partners are equal. For the quantum reading Q it reproduces the one-particle samples of the Revision pairing record (frequencies, eigenspace dimensions, Krein inertia (4,4), the Krein-neutral imaginary and zero frequencies) and shows that the chirality image reverses every Krein norm while the mirror image keeps it. Seven teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 18c_pairs_numerically.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18c_pairs_numerically.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 18c_pairs_numerically.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/18c.captions.json`
- `Revision/textbook/figures/18c_1_rk4_convergence.png`
- `Revision/textbook/figures/18c_2_partner_components.png`
- `Revision/textbook/figures/18c_3_t1_pair_densities.png`
- `Revision/textbook/figures/18c_4_t2_mirror_densities.png`
- `Revision/textbook/figures/18c_5_family_spectrum.png`
- `Revision/textbook/figures/18c_6_flat_dispersion.png`

- `Revision/textbook/figures/18c_7_krein_norms.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 21 CHECKS PASSED (notebook 18c)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/18c_pairs_numerically.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 18c_pairs_numerically.ipynb
python -m nbconvert --execute --inplace 18c_pairs_numerically.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or one of the reports: the notebook reads nine files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository. Clone the repository again and open the notebook there.

18.26 Notebook 18c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/18c_pairs_numerically.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Notebook 18b proved the pairing theorems T1 and T2 as identities. This notebook
SEES them in numbers. It uses an exact family of solutions of the field equation
of dirac16complex00 (16 commuting complex components) in the author's metric: the
fields that depend on the time $x_4$ only. For such a field the 16 field equations
become 16 ordinary differential equations in $x_4$, which a computer can solve.

1. It solves one such field $\Psi$ (mass $m$, coupling $\lambda$) with the
   Runge-Kutta method and checks it against the exact formula of the Revision
   theory record.
2. **T1.** It solves, independently, the theory with $(-m, -\lambda)$ starting
   from $\Gamma\Psi(0)$, and finds exactly $\Gamma\Psi(x_4)$ at every time; it
   computes the charge density, the current and all 36 components of the
   energy-momentum tensor of both along the canonical deflating history
   $a_4 = AHx_4$ of the Revision record: they are exactly opposite.
3. **T2.** It solves, independently, the theory with $(-m, \lambda)$ on the
   mirror patch beyond the brane $z = \pi/2$, starting from
   $\gamma^{(x_0)}\Psi(0)$, and finds exactly $\gamma^{(x_0)}\Psi(x_4)$; the charge
   density and the energy density are EQUAL, the scalar $S$ is opposite.
4. **Spectra.** It shows that the evolution generators of a universe and of its
   partners have the same eigenvalues, and, for plane waves in flat 4+4 space (the
```

```
   quantum reading Q), it reproduces the one-particle samples of the Revision
   pairing record and shows how $\Gamma$ reverses every Krein norm while
   $\gamma^{(x_0)}$ keeps it.

Seven figures show the solutions, the partners, their densities and spectra.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 18c (T1 and T2 numerically: solutions, partners, currents and spectra) is the
file ‘Revision/textbook/notebooks/18c_pairs_numerically.ipynb‘ of the repository
Dirac_claude. It takes the exact family of solutions of the field equation of
dirac16complex00 in the author’s metric that depend on the time x4 only (recorded in the
Revision theory reports), integrates one solution with the Runge-Kutta method and
compares it with the exact formula, and then solves its two partners independently: the
T1 partner with mass and coupling reversed, starting from Gamma times the initial value,
and the T2 partner on the mirror patch beyond the brane, starting from gamma^(x0) times
the initial value. It checks that the partners are exactly Gamma Psi and gamma^(x0) Psi,
that the T1 partner has the opposite charge density, current and energy-momentum tensor
(all 36 components, along the canonical deflating history a4 = A H x4), that the T2
partner has the same ones and the opposite scalar S, that the charge obeys its local
conservation law (with a flow through the brane, so the total charge of the patch is not
constant), and that the spectra of the partners are equal. For the quantum reading Q it
reproduces the one-particle samples of the Revision pairing record (frequencies,
eigenspace dimensions, Krein inertia (4,4), the Krein-neutral imaginary and zero
frequencies) and shows that the chirality image reverses every Krein norm while the
mirror image keeps it. Seven teaching figures. It needs a computer with Windows 11, macOS
or Linux, an internet connection for the installation, the program Git, and Python 3.12
or newer (the notebooks were built with Python 3.14.5) with these packages at exactly
these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the
program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):
```

```
    xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 18c_pairs_numerically.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 18c_pairs_numerically.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 18c_pairs_numerically.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/18c.captions.json‘
- ‘Revision/textbook/figures/18c_1_rk4_convergence.png‘
- ‘Revision/textbook/figures/18c_2_partner_components.png‘
- ‘Revision/textbook/figures/18c_3_t1_pair_densities.png‘
- ‘Revision/textbook/figures/18c_4_t2_mirror_densities.png‘
- ‘Revision/textbook/figures/18c_5_family_spectrum.png‘
- ‘Revision/textbook/figures/18c_6_flat_dispersion.png‘
- ‘Revision/textbook/figures/18c_7_krein_norms.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 21 CHECKS PASSED (notebook 18c)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/18c_pairs_numerically.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 18c_pairs_numerically.ipynb
  python -m nbconvert --execute --inplace 18c_pairs_numerically.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for gammas.json or one of the reports: the notebook reads nine files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository. Clone the repository again and open the notebook there.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 18c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 18c (T1 and T2 numerically: solutions, partners, currents and spectra) is the
# file Revision/textbook/notebooks/18c_pairs_numerically.ipynb of the repository
# Dirac_claude. It takes the exact family of solutions of the field equation of
# dirac16complex00 in the author's metric that depend on the time x4 only (recorded in
# the Revision theory reports), integrates one solution with the Runge-Kutta method and
# compares it with the exact formula, and then solves its two partners independently: the
# T1 partner with mass and coupling reversed, starting from Gamma times the initial
# value, and the T2 partner on the mirror patch beyond the brane, starting from
# gamma^(x0) times the initial value. It checks that the partners are exactly Gamma Psi
# and gamma^(x0) Psi, that the T1 partner has the opposite charge density, current and
# energy-momentum tensor (all 36 components, along the canonical deflating history a4 = A
# H x4), that the T2 partner has the same ones and the opposite scalar S, that the charge
# obeys its local conservation law (with a flow through the brane, so the total charge of
# the patch is not constant), and that the spectra of the partners are equal. For the
# quantum reading Q it reproduces the one-particle samples of the Revision pairing record
# (frequencies, eigenspace dimensions, Krein inertia (4,4), the Krein-neutral imaginary
# and zero frequencies) and shows that the chirality image reverses every Krein norm
# while the mirror image keeps it. Seven teaching figures. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
```

```
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

```
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 18c_pairs_numerically.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
```

```
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 18c_pairs_numerically.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 18c_pairs_numerically.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/18c.captions.json
# - Revision/textbook/figures/18c_1_rk4_convergence.png
# - Revision/textbook/figures/18c_2_partner_components.png
# - Revision/textbook/figures/18c_3_t1_pair_densities.png
# - Revision/textbook/figures/18c_4_t2_mirror_densities.png
# - Revision/textbook/figures/18c_5_family_spectrum.png
# - Revision/textbook/figures/18c_6_flat_dispersion.png
# - Revision/textbook/figures/18c_7_krein_norms.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 21 CHECKS PASSED (notebook 18c)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
```

```
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/18c_pairs_numerically.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 18c_pairs_numerically.ipynb
#     python -m nbconvert --execute --inplace 18c_pairs_numerically.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for gammas.json or one of the reports: the notebook reads nine
#   files of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository. Clone the
#   repository again and open the notebook there.
#
# ------------------------------------------------------------------------------------
# ====================================================================================
# THE SET-UP (the same in every notebook of this book; it computes no physics)
# ====================================================================================
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

```
NOTEBOOK_ID = "18c"  # this notebook: chapter 18, example c

## 3. The words used in this notebook

- **Ordinary differential equation (ODE)**: an equation for functions of ONE
  variable (here the time $x_4$) and their first derivatives.
- **Runge-Kutta method (RK4)**: a recipe that advances the solution of an ODE by
  a step $h$ using four evaluations of the right-hand side; its error after a fixed
  time shrinks like $h^4$ (*fourth order*).
- **Homogeneous field**: a field that does not depend on $x_1, x_2, x_3, x_5, x_6,
  x_7, x_0$, only on the time $x_4$.
- **Scalar** $S = \bar\Psi\Psi = \Psi^\dagger C\Psi$; **charge density**
  $J^{x_4} = \Psi^\dagger B\Psi$ with the Krein matrix $B = -iC\gamma^{(x_4)}$;
  **current** $J^\mu = -i\bar\Psi\gamma^\mu\Psi$ (the convention of the theory
  record, so that $J^{x_4}$ is the charge density).
- **Energy-momentum tensor** $T_{\mu\nu}$: 36 independent numbers at each point
  that say how much energy and momentum there is and how it flows; in the
  convention of the pairing record used here the energy density is
  $\rho = -T_{x_4x_4}$.
- **Deflating history**: $a_4 = AHx_4$ with $A = 1$ (the canonical choice of the
  Revision Kohn-Sham record): as $x_4$ grows, 3-space inflates by $e^{a_4}$ and
  the three extra times $x_5, x_6, x_7$ deflate by $e^{-a_4}$.
- **Patch, mirror patch, brane**: $z = 6Hx_0$ runs over the patch $0 < z <
  \pi/2$; the mirror patch $\pi/2 < z < \pi$ is its image under $z \to \pi - z$;
  the brane $z = \pi/2$ joins them (an ASSUMED construction).
- **Eigenvalue, eigenvector**: $Mu = wu$ with a number $w$ and a column $u \neq
  0$; the set of eigenvalues is the *spectrum* of $M$.
- **Similar matrices**: $N = PMP^{-1}$; they have the same spectrum.
- **Krein norm** of a column $u$: the real number $u^\dagger Bu$, which can be
  positive or negative because $B$ has eight eigenvalues $+1$ and eight $-1$.
- **Krein inertia** of a set of columns: how many independent directions have a
  positive and how many a negative Krein norm.
```

Text cell:

```
## 4. The physical and mathematical situation

**The field equation for homogeneous fields.** The field equation of both fields
is $\gamma^\mu D_\mu\Psi = (m + \lambda S)\Psi$. For a field that depends on $x_4$
only, every derivative except $\partial_4$ vanishes, $\gamma^{x_4} =
\gamma^{(x_4)}$ (the vielbein factor of $x_4$ is 1), and the spin connection
contributes $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ on the patch (the deflation
terms cancel). So the 16 field equations are EXACTLY

$$\gamma^{(x_4)}\frac{d\Psi}{dx_4} + 3H\gamma^{(x_0)}\Psi = (m + \lambda S)\Psi .$$

Multiply on the left by $-\gamma^{(x_4)}$ and use $(\gamma^{(x_4)})^2 = -1$:
```

```
$$\frac{d\Psi}{dx_4} = M\Psi,\qquad M = -\gamma^{(x_4)}\big((m + \lambda S) -
3H\gamma^{(x_0)}\big) = -(m + \lambda S)\gamma^{(x_4)} +
3H\gamma^{(x_4)}\gamma^{(x_0)} .$$

The Revision theory record proves that $S$ is constant along such a solution, so
$M$ is a constant matrix with $M^2 = \big(9H^2 - (m + \lambda S)^2\big)I_{16}$,
and the exact solution is

$$\Psi(x_4) = \cos(wx_4)\,\Psi(0) + \frac{\sin(wx_4)}{w}\,M\Psi(0),\qquad
w = \sqrt{(m + \lambda S)^2 - 9H^2}$$

when $(m + \lambda S)^2 > 9H^2$ (an oscillation; otherwise the cosine and sine
become cosh and sinh, a growth). The history $a_4$ does not enter this
equation, but it enters the energy-momentum tensor through the vielbein factors
$e^{\pm a_4}$ and the spin connection, as the figures will show. (The value
$3H\gamma^{(x_0)}$ belongs to the diagonal vielbein; $S$, $J^\mu$ and
$T_{\mu\nu}$, the quantities plotted here, do not depend on that choice.)

**The mirror patch.** On the mirror patch the hidden vielbein factor is
$-\cot z > 0$ and the spin connection term changes sign: $\gamma^\mu\Omega_\mu =
-3H\gamma^{(x_0)}$. The equation there is $d\Psi/dx_4 = -\gamma^{(x_4)}\big((m +
\lambda S) + 3H\gamma^{(x_0)}\big)\Psi$.

**What the theorems predict.** T1: if $\Psi$ solves the $(m, \lambda)$ equation,
$\Gamma\Psi$ solves the $(-m, -\lambda)$ equation, with $T \to -T$ and
$J \to -J$. T2: if $\Psi$ solves the $(m, \lambda)$ equation on the patch,
$\gamma^{(x_0)}\Psi$ (taken at the mirror point) solves the $(-m, \lambda)$
equation on the mirror patch, with $S \to -S$ and $T$, $J$ pulled back (the
components with one $x_0$ index change sign, all others are equal).

**Plane waves in flat 4+4 space.** For the quantum reading Q the Revision record
uses the one-particle matrix $h_m(k) = -im\gamma^{(x_4)} - \gamma^{(x_4)}
\sum_{a\neq x_4}k_a\gamma^{(a)}$ of a plane wave $e^{-iwx_4 + ik\cdot x}$; its
eigenvalues are the frequencies $w$, with $h_m^2 = (m^2 + k_0^2 + k_1^2 + k_2^2 +
k_3^2 - k_5^2 - k_6^2 - k_7^2)I_{16}$.
```

Text cell:

```
## 5. The matrices

The next cell imports numpy and sympy, defines the record helpers (‘reproduces‘
passes only when the notebook’s own result holds AND every named check of the
named reports has the verdict PASS), reads the author’s eight real gamma matrices
and builds $C$, $\Gamma$ and $B$ as numpy arrays of floating-point numbers
(whole numbers and $\pm i$, which floating-point numbers store exactly).
```

## 6. The spin connection on the patch and on the mirror patch

For a diagonal vielbein $e^a{}_\mu = f_\mu\delta^a_\mu$ whose factors depend on
$x_4$ and $x_0$ only, the canonical spin connection has one simple formula: for
two different directions $a$ and $b$,

$$\omega_{a,ab} = \eta_{aa}\,\frac{\partial_bf_a}{f_b},\qquad
\omega_{a,ba} = -\omega_{a,ab},$$

and every other component is zero (the first index is the direction of the
derivative $D_a$). The next cell writes the author's factors $f_1 = f_2 = f_3 =
e^{a_4}\sin^{1/6}z$, $f_4 = 1$, $f_5 = f_6 = f_7 = e^{-a_4}\sin^{1/6}z$, $f_0 =
s_0\cot z$ ($s_0 = +1$ on the patch, $-1$ on the mirror patch) with sympy, lists
the nonzero components on the patch in the format of the sympy pairing report
($a_4'$ written `a4p`) and compares the list with the recorded one word for word.
It then computes $\gamma^\mu\Omega_\mu$ in the *divergence form* of the theory
record, $\gamma^\mu\Omega_\mu = \frac{1}{2\sqrt{|g|}}\sum_\mu\partial_\mu
\big(\sqrt{|g|}\gamma^{(\mu)}/f_\mu\big)$, on both patches: $+3H\gamma^{(x_0)}$
and $-3H\gamma^{(x_0)}$.
```

```
The next cell fixes the numbers. The history is the canonical one of the Revision
Kohn-Sham record, $a_4 = AHx_4$ with $A = 1$ (read from
‘Revision/kohn_sham/results/parameters.json‘). The other values are an
ILLUSTRATION chosen by this notebook (the theorems hold for every value): units in
which $m = 1$, $H = 0.2$, $\lambda = 0.3$, the hidden angle $z_0 = \pi/4$ on the
patch (its mirror point is $3\pi/4$), and an initial value $\Psi(0)$ of 16
complex numbers drawn with the fixed seed 2026, weighted towards the eigenvalue
$+1$ of $C$ (so that $S = \Psi^\dagger C\Psi$ is clearly positive: $C$ is real and
symmetric with $C^2 = 1$, its projectors are $P_{C\pm} = \frac12(1 \pm C)$, and
$S = |P_{C+}\Psi|^2 - |P_{C-}\Psi|^2$), and scaled to length 1. With these values
$(m + \lambda S)^2 > 9H^2$, so the solution oscillates. The cell then turns
the spin connection into numerical $16 \times 16$ matrices
$\Omega_\mu = \sum_{a<b}\omega_{\mu ab}S^{ab}$ at any time $x_4$ and angle $z$,
and defines the curved gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ and
$\gamma_\mu = \eta_{\mu\mu}f_\mu\gamma^{(\mu)}$.

## 7. The solution: Runge-Kutta against the exact formula

The next cell defines the right-hand side $M\Psi$ of the ODE (with $s_0 = +1$ on
the patch and $-1$ on the mirror patch), one RK4 step and an integrator that
returns the solution at every step, and the exact formula of section 4. It
integrates $\Psi$ from $x_4 = 0$ to $x_4 = 20$ with 2000 steps of length 0.01 and
checks: $S$ stays equal to $S(0)$; the RK4 solution agrees with the exact formula;
$M^2 = (9H^2 - (m + \lambda S)^2)I_{16}$. It repeats the integration with 250 to
4000 steps to measure the order of the method (the error should fall by
$2^4 = 16$ when the step is halved).
```

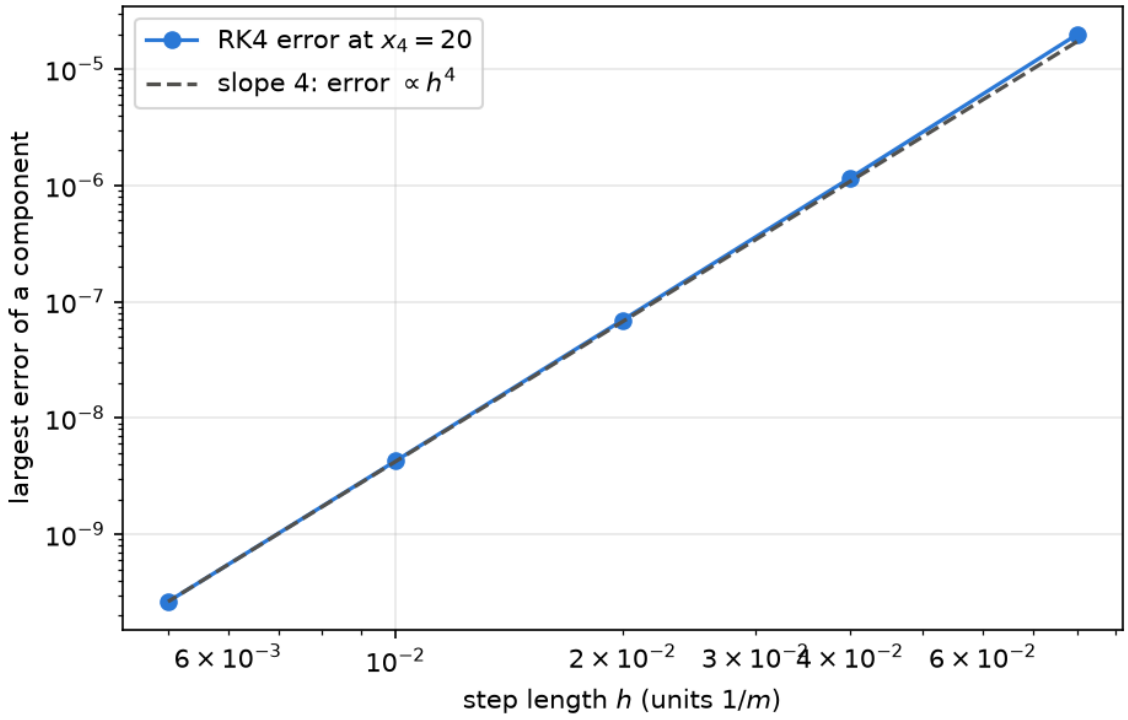

Figure 484: Accuracy of the Runge-Kutta solution of the homogeneous field equation in the author's metric: the largest difference between a component of the computed field and of the exact solution of the Revision theory record at the time $x_4 = 20$ (vertical axis, logarithmic), against the step length h in units of $1/m$ (horizontal axis, logarithmic), for 250 to 4000 steps. The points follow the dashed line of slope 4: halving the step divides the error by 16, the fourth order of the method. With 2000 steps the error is far below every difference studied in this notebook. (Notebook 18c, figure 1.)

Text cell:

```
## 8. Theorem T1 in numbers

The next cell solves, INDEPENDENTLY, the theory with $(-m, -\lambda)$ on the patch,
starting from $\Gamma\Psi(0)$, and compares the result $\Phi(x_4)$ with
$\Gamma\Psi(x_4)$ at all 2001 times. Since $\Gamma = \mathrm{diag}(-I_8, I_8)$,
T1 predicts $\Phi_A = -\Psi_A$ for the components $A = 1, \dots, 8$ and
$\Phi_A = +\Psi_A$ for $A = 9, \dots, 16$. As a negative control the cell also
solves the WRONG partner theory $(-m, +\lambda)$ from the same start, which must
NOT give $\Gamma\Psi$: the coupling has to change sign together with the mass.
```

In [7]:

```
phi = rk4(Gamma @ psi0, -m, -lam, 1, STEPS)  # the T1 partner, solved on its own
t1_gap = np.abs(phi - psi @ Gamma.T).max()  # row by row: Gamma psi(x4)

Text cell:

```
The next cell checks three facts of the theory record about homogeneous solutions,
at all sampled times: the energy density is $\rho = -T_{x_4x_4} = mS +
\frac{\lambda}{2}S^2$; the three kinds of pressure $p_\mu = -g^{\mu\mu}T_{\mu\mu}$
(3-space, extra times, hidden direction) all equal $\frac{\lambda}{2}S^2$; and the
mixed component $T_{x_4x_0}$ vanishes. It also checks the LOCAL conservation law
of the charge: the charge density can change in time only by flowing along the
hidden direction, $\partial_4J^{x_4} + \frac{1}{\sqrt{|g|}}\partial_0(\sqrt{|g|}
J^{x_0}) = 0$; for a homogeneous field $J^{x_0} = \tan z\,q_0$ with the frame
current $q_0 = -i\bar\Psi\gamma^{(x_0)}\Psi$ (a number that does not depend on
$x_0$) and $\sqrt{|g|} = \cos z$, so the law reads $\partial_4J^{x_4} = -6Hq_0$,
where $\partial_4J^{x_4} = 2\,\mathrm{Re}(\Psi^\dagger BM\Psi)$ follows from the
field equation. The flow through the brane $z = \pi/2$ is $\sqrt{|g|}J^{x_0} =
\sin z\,q_0 = q_0$ there; the cell prints the range of $q_0$: it is not zero, so
the total charge of the patch is NOT constant for this solution (charge flows
through the brane), although the local law holds exactly.
```

## 9. Theorem T2 in numbers: the mirror partner

The next cell solves, INDEPENDENTLY, the theory with $(-m, \lambda)$ on the mirror
patch (the spin connection term is $-3H\gamma^{(x_0)}$ there), starting from
$\gamma^{(x_0)}\Psi(0)$, and compares the result $X(x_4)$ with
$\gamma^{(x_0)}\Psi(x_4)$. Then it computes the bilinears of $X$ at the mirror
point $z = \pi - z_0$ and checks the T2 predictions at all sampled times:
$S[X] = -S[\Psi]$; $J^\mu[X] = \Lambda_\mu J^\mu[\Psi]$ and $T_{\mu\nu}[X] =
\Lambda_\mu\Lambda_\nu T_{\mu\nu}[\Psi]$ with $\Lambda = \mathrm{diag}(-1, 1, 1, 1,
1, 1, 1, 1)$ (only the components with an $x_0$ index change sign; the charge
density and the energy density are EQUAL).
```

```
## 10. Spectra: the partners evolve with the same eigenvalues

The evolution generator $M$ of the homogeneous family is a constant matrix along a
solution. The next cell computes its 16 eigenvalues for the field (mass $m$,
coupling $\lambda$, scalar $S$), for the T1 partner ($-m$, $-\lambda$, the same
$S$) and for the T2 partner on the mirror patch ($-m$, $\lambda$, scalar $-S$),
and checks that the three spectra are equal: $\Gamma M\Gamma$ and
$\gamma^{(x_0)}M\gamma^{(x_0)}$ are exactly the partners' generators (similar
matrices). It then repeats the computation for masses from $-2$ to $2$ at the same
$\lambda$ and $S$: the eigenvalues are $\pm iw$ (8 times each) with $w^2 = (m +
\lambda S)^2 - 9H^2$, real (an oscillation) outside the window
$|m + \lambda S| < 3H$ and imaginary (a growth) inside it, the same for every
universe and its partner.
```

In [14]:

```
def spectrum(Mx):
    """The 16 eigenvalues, sorted by imaginary part, then real part (rounded)."""

## 13. What this notebook showed

- COMPUTED (RK4, fourth order measured, checked against the exact solution of the
  Revision theory record): a homogeneous solution of dirac16complex00 in the
  author's metric with $m = 1$, $H = 0.2$, $\lambda = 0.3$ (illustrative values),
  with constant $S$, oscillating at the frequency $w = \sqrt{(m + \lambda S)^2 -
  9H^2}$, and with the charge flowing along the hidden direction exactly as the
  local conservation law requires. The flow through the brane $z = \pi/2$ is not
  zero, so the total charge of the patch is not constant for this solution; a
  constant total charge would need a no-flux condition at the brane, which is
  not derived (OPEN).
- COMPUTED, theorem T1: the theory with $(-m, -\lambda)$, solved on its own from
  $\Gamma\Psi(0)$, gives $\Gamma\Psi(x_4)$ at all times; its charge density,
  current and all 36 components of $T_{\mu\nu}$ along the deflating history
  $a_4 = AHx_4$ are exactly opposite, so the pair sums to zero at every time (as
  classical bilinears).
- COMPUTED, theorem T2: the theory with $(-m, \lambda)$ on the mirror patch, solved
  on its own from $\gamma^{(x_0)}\Psi(0)$, gives $\gamma^{(x_0)}\Psi(x_4)$; $S$ is
  opposite, the charge density and the energy density are EQUAL, the other
  components are pulled back by the reflection of $x_0$.
- COMPUTED and PROVED (similar matrices): the field and its partners have equal
  spectra; for plane waves in flat 4+4 space the masses $+m$ and $-m$ have the
  same frequencies, every real frequency has Krein inertia (4,4) in the eight
  recorded samples, the imaginary and zero frequencies are Krein-neutral, and
  $\Gamma$ reverses every Krein norm while $\gamma^{(x_0)}$ keeps it (the quantum
  reading Q).
- ASSUMED: the mirror patch glued at the degenerate brane (Z2 construction); the
  gravitational field is a fixed background.
- NOT shown: any process that creates a universe or a pair. The partners here are
  solutions of OTHER parameter sets, computed from the first one; nothing in these
  equations makes them appear.
```

18.27 Line-by-line walk-through of Notebook 18c

The notebook has 21 code cells. **In [1]** is the set-up cell, word for word the set-up cell of Notebook 18a explained line by line in Section 18.9, except that its comment lines hold the run instructions of Section 18.25 and its line `NOTEBOOK_ID = "18c"` names this notebook, so its figures are saved as `18c_<k>_<name>.png` and their captions in `18c.captions.json`. It prints one line, Set-up of notebook 18c complete: repository folder found, helpers defined.

The idea of the notebook in one paragraph. Notebooks 18a and 18b computed with exact numbers: whole numbers, fractions and symbols. This notebook computes with **floating-point numbers**, the ordinary numbers of a computer, which carry about 16 significant decimal digits and are rounded after every operation. So an identity such as $\Phi = \Gamma\Psi$ is checked by requiring the largest difference to be smaller than a **tolerance**, usually 10^{-12}: far below the size of the quantities compared (about 0.1 to 3) and far above the rounding errors (about 10^{-16}). The notebook takes one solution of the homogeneous family of Section 18.21, computes it in two independent ways (step by step with the Runge-Kutta method, and from the exact formula), then solves the two partner equations of T1 and T2 on their own, and compares the solutions and all their bilinears along the deflating history.

In [2], the records and the matrices.

```
import numpy as np  # arrays, matrices, eigenvalues
import sympy as sp  # exact symbolic algebra for the spin connection

GAMMAS = "Revision/algebra/gammas.json"
PY = "Revision/pairing/reports/python-pairing.json"
WL = "Revision/pairing/reports/wolfram-pairing.json"
THEORY = "Revision/pairing/pairing-theory.json"
TH_PY = "Revision/theory/reports/python-field-theory.json"
TH_WL = "Revision/theory/reports/wolfram-field-theory.json"
SCOPE = "Revision/theory/reports/python-scope.json"
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
```

numpy (`np`) is the package for arrays of floating-point numbers: matrix products, eigenvalues, the singular value decomposition. sympy (`sp`) is used once more, in In [3], to compute the spin connection exactly before it is turned into numbers. The eight constants are the repository paths of the eight Revision records the notebook reads: the gammas; the two reports of the pairing verifiers and the pairing theory record (for the plane-wave samples of the quantum reading); the two field-theory reports and the scope report (for the exact homogeneous solution and the conservation of the charge); and the Kohn-Sham parameter record, which holds the canonical deflating history.

```
def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

RECORDS = {f: read_json(f) for f in (PY, WL, TH_PY, TH_WL, SCOPE)}

def recorded(report_file, name):
    """The recorded entry (verdict and detail) of the check name of a report."""
    for entry in RECORDS[report_file]["checks"]:
        if entry["name"] == name:
            return entry
    return {"verdict": "MISSING", "detail": ""}

def reproduces(condition, name, *sources):
    """check(condition, name), which also requires every named check of every
    source (report_file, [check names]) to have the recorded verdict PASS."""
    ok = all(recorded(f, n)["verdict"].upper() == "PASS"
             for f, names in sources for n in names)
    text = "; ".join(f"{f}, check {', '.join(names)}" for f, names in sources)
    check(condition and ok, name, record=text)
```

The record helpers of Notebook 18b. `read_json` reads a record. `RECORDS` reads the five reports once, with the file name as the key (a dictionary comprehension). `recorded(report_file, name)` returns the entry of a named check, or a placeholder with the verdict MISSING. `reproduces` passes only when the notebook's own result holds AND every named check has the recorded verdict PASS; `.upper()` makes the comparison independent of capitalisation, which matters here, because the field-theory report writes its verdicts as pass in small letters.

```
fixture = read_json(GAMMAS)
gamma = {a: np.array(fixture["gamma"][a], dtype=float) for a in range(8)}
ETA = {a: int(fixture["eta"][a]) for a in range(8)}
I16 = np.eye(16)
C = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3]
Gamma = gamma[0] @ gamma[1] @ gamma[2] @ gamma[3] @ gamma[4] @ gamma[5] @ gamma[6] \
    @ gamma[7]
B = -1j * C @ gamma[4]  # the Krein matrix
check(all(np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                         2.0 * (ETA[a] if a == b else 0) * I16)
          for a in range(8) for b in range(8))
      and np.array_equal(Gamma, np.diag([-1.0] * 8 + [1.0] * 8))
      and np.array_equal(B.conj().T, B),
      "eight real 16 x 16 gammas (Clifford relations), Gamma = diag(-I8, I8), "
      "B Hermitian")
```

The gammas are read as numpy arrays of floating-point numbers (`dtype=float`). Their entries are -1, 0 and $+1$, which floating-point numbers store exactly, and sums and products of such whole numbers are again exact; so `np.array_equal`, an exact comparison, is still correct for them. `C`, `Gamma` and `B` are built as in Section 18.5 (a backslash at the end of a line continues the statement on the next line; `1j` is i). The check confirms the 64 Clifford relations, $\Gamma = \mathrm{diag}(-I_8, I_8)$ and $B^\dagger = B$ (`.conj().T` is the conjugate transpose). Out [2] shows one PASS line.

In [3], the spin connection on the patch and on the mirror patch.

```
x4, z, H_sym = sp.symbols("x4 z H", real=True)
a4 = sp.Function("a4")(x4)
a4p = sp.Symbol("a4p")

def d(expr, b):
    """The derivative of a coefficient along the coordinate x_b (z = 6 H x0)."""
    if b == 4:
        return sp.diff(expr, x4)
    if b == 0:
        return 6 * H_sym * sp.diff(expr, z)
    return sp.Integer(0)
```

As in Notebook 18b: the symbols x_4, z and H (here named `H_sym`, because from In [4] on the name `H` holds the number 0.2), the unknown history $a_4(x_4)$, the plain symbol `a4p` for a_4', and the derivative `d(expr, b)` along the coordinate x_b: d/dx_4 along x_4, $6H\,d/dz$ along x_0 (because $z = 6Hx_0$), and zero along the six coordinates on which no coefficient depends.

```
def factors(s0):
    s6 = sp.sin(z) ** sp.Rational(1, 6)
    f = {a: sp.exp(a4) * s6 for a in (1, 2, 3)}
    f.update({a: sp.exp(-a4) * s6 for a in (5, 6, 7)})
    f.update({4: sp.Integer(1), 0: s0 * sp.cot(z)})
    return f
```

`factors(s0)` returns the eight vielbein factors of Section 18.3: $e^{a_4}\sin^{1/6} z$ for x_1, x_2, x_3; $e^{-a_4}\sin^{1/6} z$ for the deflating extra times x_5, x_6, x_7; 1 for x_4; and $s_0 \cot z$ for x_0, with $s_0 = +1$ on the patch and

$s_0 = -1$ on the mirror patch, where $\cot z < 0$, so that $f_0 > 0$ on both. `f.update({...})` adds entries to the dictionary.

```
def connection(s0):
    """{(mu, a, b) with a < b: omega_mu ab} for the diagonal vielbein."""
    f, om = factors(s0), {}
    for a in range(8):
        for b in range(8):
            if a != b:
                value = sp.simplify(ETA[a] * d(f[a], b) / f[b])
                if value != 0:  # omega_a,ab (or -omega_a,ba when b < a)
                    om[(a, a, b) if a < b else (a, b, a)] = (
                        value if a < b else -value)
    return dict(sorted(om.items()))
```

`connection(s0)` uses the short formula derived in Section 18.3, $\omega_{a,ab} = \eta_{aa}\,\partial_b f_a / f_b$ for $a \neq b$, instead of the general Christoffel computation of Notebook 18b. Each nonzero value is stored under the key (μ, a, b) with $a < b$, the format of the record: when $a < b$ the value is $\omega_{a,ab}$ itself, stored under (a, a, b); when $b < a$ the component with the smaller index first is $\omega_{a,ba} = -\omega_{a,ab}$, stored under (a, b, a). `dict(sorted(...))` orders the keys, so that the list is printed in the order of the record.

```
def short(expr):
    expr = sp.simplify(expr).subs(sp.Derivative(a4, x4), a4p)
    return expr.subs(a4, sp.Symbol("a4"))

patch_om, mirror_om = connection(1), connection(-1)
listing = "; ".join(f"omega_x{mu} x{a}x{b} = {short(v)}"
                    for (mu, a, b), v in patch_om.items())
say("patch: " + listing)
same = recorded(PY, "geometry.spin_connection_components")["detail"] == (
    "nonzero components (a < b): " + listing)
reproduces(len(patch_om) == 12 and same,
           "the formula gives the 12 recorded spin connection components",
           (PY, ["geometry.spin_connection_components"]))
```

`short` writes a_4' as `a4p` and $a_4(x_4)$ as `a4`, as in Notebook 18b. The twelve components of the patch are printed in one line (the output wraps it) and compared, character for character, with the detail text of the sympy check `geometry.spin_connection_components`; the check requires 12 components and the agreement. So two different computations, the general Christoffel formula of Notebook 18b and the short formula of this cell, reproduce the same record.

```
flips = all(sp.simplify(mirror_om[k] + patch_om[k]) == 0 if 0 in k[1:]
            else sp.simplify(mirror_om[k] - patch_om[k]) == 0 for k in patch_om)
```

`flips` compares the two patches component by component: the six components with an index x_0 (`0 in k[1:]` looks at the two frame indices of the key) must change sign, because they contain $1/f_0$, and the six others must be equal.

```
divergence = {}
for s0 in (1, -1):
    f = factors(s0)
    sqrtg = sp.simplify(sp.Mul(*f.values()))
    divergence[s0] = {mu: sp.simplify(d(sqrtg / f[mu], mu) / (2 * sqrtg))
                      for mu in range(8)}
say(f"divergence form, patch: coefficient of gamma^(x0) = {divergence[1][0]}, of "
    f"gamma^(x4) = {divergence[1][4]}; mirror patch: {divergence[-1][0]}, "
    f"{divergence[-1][4]}")
reproduces(flips and divergence[1][0] == 3 * H_sym and divergence[-1][0] == -3 * H_sym
           and all(divergence[s][mu] == 0 for s in (1, -1) for mu in range(1, 8)),
           "gamma^mu Omega_mu = +3 H gamma^(x0) (patch), -3 H gamma^(x0) (mirror)",
           (TH_PY, ["gamma_mu_Omega_mu_equals_3H_gamma_x0",
                    "divergence_of_sqrtg_gamma"]),
           (TH_WL, ["gammaOmega_equals_3H_gamma_x0", "gammaOmega_divergence_form"]))
```

The **divergence form** of the theory record, $\gamma^\mu\Omega_\mu = \frac{1}{2\sqrt{|g|}}\sum_\mu \partial_\mu(\sqrt{|g|}\,\gamma^{(\mu)}/f_\mu)$, computed on both patches: `divergence[s0][mu]` is the coefficient of $\gamma^{(\mu)}$, $\partial_\mu(\sqrt{|g|}/f_\mu)/(2\sqrt{|g|})$. Why this formula holds for a diagonal vielbein, line by line. Only the components $\omega_{\mu,\mu b}$ (and their partners $\omega_{\mu,b\mu} = -\omega_{\mu,\mu b}$) are nonzero (Section 18.3), so

$$\gamma^\mu\Omega_\mu = \sum_\mu \frac{\gamma^{(\mu)}}{f_\mu}\sum_{b\neq\mu}\omega_{\mu,\mu b}S^{\mu b}.$$

The two equal terms $\omega_{\mu,\mu b}S^{\mu b}$ and $\omega_{\mu,b\mu}S^{b\mu}$ of $\Omega_\mu = \frac12\sum_{a,b}\omega_{\mu ab}S^{ab}$ cancel the factor $\frac12$, as in Section 18.3.

$$\gamma^{(\mu)}S^{\mu b} = \tfrac12\gamma^{(\mu)}\gamma^{(\mu)}\gamma^{(b)} = \tfrac12\eta_{\mu\mu}\gamma^{(b)}.$$

$S^{\mu b} = \frac12\gamma^{(\mu)}\gamma^{(b)}$ for $b\neq\mu$; then the Clifford relation $\gamma^{(\mu)}\gamma^{(\mu)} = \eta_{\mu\mu}$.

$$\gamma^\mu\Omega_\mu = \sum_b \gamma^{(b)}\sum_{\mu\neq b}\frac{\eta_{\mu\mu}}{2f_\mu}\,\eta_{\mu\mu}\frac{\partial_b f_\mu}{f_b} = \sum_b\frac{\gamma^{(b)}}{2f_b}\sum_{\mu\neq b}\frac{\partial_b f_\mu}{f_\mu}.$$

We inserted $\omega_{\mu,\mu b} = \eta_{\mu\mu}\partial_b f_\mu/f_b$, exchanged the order of the two sums, and used $\eta_{\mu\mu}^2 = 1$.

$$\sum_{\mu\neq b}\frac{\partial_b f_\mu}{f_\mu} = \partial_b\ln\prod_{\mu\neq b}f_\mu = \partial_b\ln\frac{\sqrt{|g|}}{f_b}, \qquad \frac{1}{2f_b}\,\partial_b\ln\frac{\sqrt{|g|}}{f_b} = \frac{1}{2\sqrt{|g|}}\,\partial_b\frac{\sqrt{|g|}}{f_b}.$$

The first equation is the rule $\partial\ln F = \partial F/F$ applied to each factor (the logarithm of a product is the sum of the logarithms), with $\sqrt{|g|} = \prod_\mu f_\mu$; the second is the same rule read backwards, with $F = \sqrt{|g|}/f_b$ and $\frac{1}{f_b}\cdot\frac{f_b}{\sqrt{|g|}} = \frac{1}{\sqrt{|g|}}$. Together they give the divergence form. On the patch, $\sqrt{|g|}/f_0 = \cos z/\cot z = \sin z$ and $\partial_0\sin z = 6H\cos z$, so the coefficient of $\gamma^{(x_0)}$ is $6H\cos z/(2\cos z) = 3H$; $\sqrt{|g|}/f_4 = \cos z$ does not depend on x_4, so the coefficient of $\gamma^{(x_4)}$ is 0. On the mirror patch $\sqrt{|g|} = -\cos z$ and $f_0 = -\cot z$ give the same quotient $\sin z$, but it is divided by $2\sqrt{|g|} = -2\cos z$:

the coefficient is $-3H$. The check requires the sign flips, the two coefficients $\pm 3H$ and zero for the seven other directions, and names two checks of each field-theory report. Out [3] prints the twelve components, then $3H$, *0, -3*H, 0, and two PASS lines.

In [4], the numbers of the illustration and the geometry as numbers.

```
A_hist = read_json(PARAMETERS)["physics"]["historyA"]  # A = 1
m, H, lam = 1.0, 0.2, 0.3  # an illustration (units m = 1)
Z0 = np.pi / 4  # the patch point; the mirror point is pi - Z0
rng = np.random.default_rng(2026)
raw = rng.normal(size=16) + 1j * rng.normal(size=16)
P_C = 0.5 * (I16 + C)  # the projector on the eigenvalue +1 of C
psi0 = 2.0 * P_C @ raw + 0.5 * (I16 - P_C) @ raw  # mostly in the +1 part: S > 0
psi0 = psi0 / np.linalg.norm(psi0)  # length 1
S0 = float((psi0.conj() @ C @ psi0).real)  # S of the initial value
report("S of the initial value", f"{S0:.6f}")
report("m + lambda S", f"{m + lam * S0:.6f}")
report("3 H", f"{3 * H:.6f}")
```

`A_hist` is the number $A = 1$ of the canonical history $a_4 = AHx_4$, read from the Kohn-Sham parameter record. The next two lines fix the ILLUSTRATION chosen by this notebook: $m = 1$ (so lengths and times are measured in units of $1/m$), $H = 0.2$, $\lambda = 0.3$ and the patch point $z_0 = \pi/4$. `np.random.default_rng(2026)` is a random-number generator with the fixed seed 2026; `raw` is a column of 16 complex numbers whose real and imaginary parts are drawn from the normal distribution. The initial value is built so that $S > 0$. Since C is real and symmetric with $CC = 1$, the matrices $P_{C\pm} = \frac{1}{2}(1 \pm C)$ are projectors: $P_{C\pm}^\dagger = P_{C\pm}$, $P_{C\pm}P_{C\pm} = P_{C\pm}$, $P_{C+}P_{C-} = \frac{1}{4}(1 - CC) = 0$ and $P_{C+} - P_{C-} = C$. Hence

$$S = \Psi^\dagger C \Psi = \Psi^\dagger P_{C+} \Psi - \Psi^\dagger P_{C-} \Psi = |P_{C+}\Psi|^2 - |P_{C-}\Psi|^2,$$

where $|v|^2 = v^\dagger v$ is the squared length; the last step writes $\Psi^\dagger P_{C\pm} \Psi = \Psi^\dagger P_{C\pm}^\dagger P_{C\pm} \Psi = (P_{C\pm}\Psi)^\dagger (P_{C\pm}\Psi)$. Weighting the part of P_{C+} by 2 and the part of P_{C-} by 0.5 makes the first term larger. `np.linalg.norm` is the length of a column, and dividing by it gives a column of length 1. `S0` is S of the initial value (`.real` drops the imaginary part, which is zero up to rounding because C is real and symmetric). Out [4] prints $S = 0.897319$, $m + \lambda S = 1.269196$ and $3H = 0.600000$.

```
S_AB = {(a, b): 0.5 * gamma[a] @ gamma[b] for a in range(8) for b in range(8)}
history = {sp.Derivative(a4, x4): A_hist * H_sym}  # a4' = A H

def numeric(table):
    """Turn the sympy components into functions of (x4, z) for this H and A."""
    out = {}
    for key, value in table.items():
        e = value.subs(history).subs(a4, A_hist * H_sym * x4).subs(H_sym, H)
        out[key] = sp.lambdify((x4, z), e, "numpy")
    return out

OMEGA = {1: numeric(patch_om), -1: numeric(mirror_om)}
```

```
FACTOR = {s0: {mu: sp.lambdify((x4, z), e.subs(a4, A_hist * H_sym * x4)
                                .subs(H_sym, H), "numpy")
               for mu, e in factors(s0).items()} for s0 in (1, -1)}
```

`S_AB` holds $S^{ab} = \frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ (correct for $a \neq b$; the entries with $a = b$ are never used). `history` replaces a_4' by AH. `numeric(table)` turns each sympy component into a numpy function of (x_4, z): it substitutes $a_4' = AH$, then $a_4 = AHx_4$ and $H = 0.2$, and `sp.lambdify` makes a function that evaluates the resulting expression for numbers. `OMEGA` holds these functions for both patches (keys 1 and -1), and `FACTOR` the eight vielbein factors of both patches as functions of (x_4, z).

```
def geometry_at(t, zv, s0):
    """Numbers at the time t and angle zv: f, g, gamma^mu, gamma_mu, Omega_mu."""
    f = {mu: float(FACTOR[s0][mu](t, zv)) for mu in range(8)}
    Om = {mu: np.zeros((16, 16)) for mu in range(8)}
    for (mu, a, b), fn in OMEGA[s0].items():
        Om[mu] = Om[mu] + float(fn(t, zv)) * S_AB[a, b]
    return {"f": f, "g": {mu: ETA[mu] * f[mu] ** 2 for mu in f},
            "sqrtg": abs(np.prod(list(f.values()))),
            "up": {mu: gamma[mu] / f[mu] for mu in f},
            "down": {mu: ETA[mu] * f[mu] * gamma[mu] for mu in f}, "Om": Om}
```

`geometry_at(t, zv, s0)` returns the numbers of the geometry at the time $x_4 = t$ and the angle $z =$ `zv`: the eight factors f_μ (`float` turns a numpy number into a Python number); the matrices $\Omega_\mu = \sum_{a<b} \omega_{\mu ab} S^{ab}$; the metric components $g_{\mu\mu} = \eta_{\mu\mu} f_\mu^2$; $\sqrt{|g|}$ (`abs` of the product of the factors); the curved gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (key `"up"`) and $\gamma_\mu = \eta_{\mu\mu} f_\mu \gamma^{(\mu)}$ (key `"down"`).

```
for s0, zv in ((1, Z0), (-1, np.pi - Z0)):
    geo = geometry_at(1.3, zv, s0)
    total = sum(geo["up"][mu] @ geo["Om"][mu] for mu in range(8))
    assert np.allclose(total, 3 * s0 * H * gamma[0], atol=1e-12)
check(abs(m + lam * S0) > 3 * H,
      "|m + lambda S| > 3 H: the solution and both partners oscillate")
```

A numerical test of the matrices just built: at the time 1.3 on each patch, $\sum_\mu \gamma^\mu \Omega_\mu$ must equal $3 s_0 H \gamma^{(x_0)}$ entry by entry to 10^{-12} (`np.allclose`; `assert` stops the notebook if not). Then the check $|m + \lambda S| = 1.269 > 3H = 0.6$: by Section 18.21 the solution oscillates. The partners oscillate too, because their generators have the same eigenvalues (In [14]). Out [4] ends with this PASS line.

In [5], the solution: Runge-Kutta against the exact formula.

```
X_END = 20.0  # integrate from x4 = 0 to 20 (a4 from 0 to A H 20 = 4)

def generator(psi, mass, coup, s0):
    """The matrix M of d psi/dx4 = M psi (s0 = +1 patch, -1 mirror patch)."""
    S = (psi.conj() @ C @ psi).real
    return -gamma[4] @ ((mass + coup * S) * I16 - 3 * s0 * H * gamma[0])
```

`X_END` is the end time 20. Along the history $a_4 = AHx_4$ with $AH = 0.2$, a_4 runs from 0 to 4, so between $x_4 = 0$ and 20 the extra times deflate by the factor $e^{-4} \approx 0.018$ and 3-space inflates by $e^4 \approx$

54.6. `generator(psi, mass, coup, s0)` returns the matrix $M = -\gamma^{(x_4)}\big((m+\lambda S)I_{16} - 3s_0 H\gamma^{(x_0)}\big)$ of Section 18.21. S is computed from the column `psi` itself, because the equation is nonlinear (M depends on the field through S), and $s_0 = -1$ selects the mirror patch, where the connection term is $-3H\gamma^{(x_0)}$.

```
def rk4(psi_start, mass, coup, s0, steps):
    """The RK4 solution at x4 = 0, h, 2h, ..., X_END (steps + 1 rows)."""
    h = X_END / steps
    out = np.empty((steps + 1, 16), dtype=complex)
    psi = psi_start.astype(complex)
    out[0] = psi
    for n in range(steps):
        k1 = generator(psi, mass, coup, s0) @ psi
        k2 = generator(psi + 0.5 * h * k1, mass, coup, s0) @ (psi + 0.5 * h * k1)
        k3 = generator(psi + 0.5 * h * k2, mass, coup, s0) @ (psi + 0.5 * h * k2)
        k4 = generator(psi + h * k3, mass, coup, s0) @ (psi + h * k3)
        psi = psi + h / 6.0 * (k1 + 2 * k2 + 2 * k3 + k4)
        out[n + 1] = psi
    return out
```

`rk4` is the **classical Runge-Kutta method of fourth order** (Chapter 2). With the step h and $F(\Psi) = M(\Psi)\Psi$, one step from Ψ_n at the time $x_4 = nh$ computes four slopes,

$$k_1 = F(\Psi_n), \qquad k_2 = F\big(\Psi_n + \tfrac{h}{2}k_1\big), \qquad k_3 = F\big(\Psi_n + \tfrac{h}{2}k_2\big), \qquad k_4 = F(\Psi_n + hk_3),$$

and moves on to $\Psi_{n+1} = \Psi_n + \frac{h}{6}(k_1 + 2k_2 + 2k_3 + k_4)$. `np.empty` reserves an array of `steps + 1` rows of 16 complex numbers; row n receives Ψ_n. `astype(complex)` makes a complex copy of the start column.

```
def exact(psi_start, mass, coup, s0, times):
    """The exact solution cos(w x4) psi(0) + sin(w x4)/w M psi(0)."""
    M = generator(psi_start, mass, coup, s0)
    S = (psi_start.conj() @ C @ psi_start).real
    w = np.sqrt((mass + coup * S) ** 2 - 9 * H ** 2)
    return (np.cos(w * times)[:, None] * psi_start[None, :]
            + (np.sin(w * times) / w)[:, None] * (M @ psi_start)[None, :])
```

`exact` evaluates the formula $\Psi(x_4) = \cos(wx_4)\Psi(0) + \frac{\sin(wx_4)}{w}M\Psi(0)$ with $w = \sqrt{(m+\lambda S)^2 - 9H^2}$ (Section 18.21) at many times at once: `[:, None]` makes a column of the time values and `[None, :]` a row of the components, and their product is the table with one row per time (numpy's **broadcasting**).

```
STEPS = 2000
times = np.linspace(0.0, X_END, STEPS + 1)
psi = rk4(psi0, m, lam, 1, STEPS)  # the universe of mass m on the patch
S_t = np.einsum("ti,ij,tj->t", psi.conj(), C, psi).real
error = np.abs(psi - exact(psi0, m, lam, 1, times)).max()
M0 = generator(psi0, m, lam, 1)
square_ok = np.allclose(M0 @ M0, (9 * H ** 2 - (m + lam * S0) ** 2) * I16, atol=1e-13)
```

The solution with 2000 steps of length 0.01, at the 2001 times `times`, evenly spaced from 0 to 20 (`np.linspace`). `S_t` is S at every time: `np.einsum("ti,ij,tj->t", ...)` computes, for each time t, the sum $\sum_{i,j} \Psi^*_{ti} C_{ij} \Psi_{tj}$ (the letters say which indices are summed and which one is kept). `error` is the largest difference between the Runge-Kutta table and the exact one, over all times and components. `square_ok` checks $M^2 = (9H^2 - (m + \lambda S)^2) I_{16}$ numerically.

```
errors = {}
for n in (250, 500, 1000, 2000, 4000):
    sol = rk4(psi0, m, lam, 1, n)
    errors[n] = float(np.abs(sol[-1] - exact(psi0, m, lam, 1, np.array([X_END]))[0])
                      .max())
orders = [np.log2(errors[n] / errors[2 * n]) for n in (250, 500, 1000, 2000)]
say("RK4 error at x4 = 20 for 250, 500, 1000, 2000, 4000 steps: "
    + ", ".join(f"{errors[n]:.1e}" for n in errors))
say("measured orders: " + ", ".join(f"{p:.2f}" for p in orders))
report("largest RK4 error with 2000 steps (all times, all components)",
       f"{error:.1e}")
```

The **order** of the method is measured. If the error at the end time behaves like $e(h) = ch^p$, halving the step gives $e(h/2) = ch^p/2^p$, so $e(h)/e(h/2) = 2^p$ and $p = \log_2 \left(e(h)/e(h/2)\right)$. The loop solves with 250, 500, 1000, 2000 and 4000 steps and stores the error at $x_4 = 20$; `orders` holds the four values of p. Out [5] prints the errors 2.0e-05, 1.2e-06, 6.9e-08, 4.3e-09 and 2.6e-10 (2.0e-05 means 2.0×10^{-5}), the measured orders 4.10, 4.06, 4.03 and 4.01, and the largest error with 2000 steps over all times and components, 4.3e-09.

```
reproduces(np.abs(S_t - S0).max() < 1e-9 and error < 1e-7 and square_ok,
           "S is constant and RK4 equals the exact homogeneous solution (2000 steps)",
           (TH_PY, ["exact_nonlinear_homogeneous_solution"]),
           (TH_WL, ["exact_solution_nonlinear_homogeneous_C"]),
           (SCOPE, ["good_sector_x0_independent_modes_without_boundary_condition"]))
check(all(3.8 < p < 4.2 for p in orders), "RK4 is of fourth order here")
```

The first check requires S to stay constant to 10^{-9}, the error to be below 10^{-7}, and the square of M; it names the exact homogeneous solution of the two field-theory reports and the scope report's check on these modes. The second requires every measured order between 3.8 and 4.2. COMPUTED: the Runge-Kutta solution agrees with the exact formula of the record to 4.3×10^{-9}, and the method is of fourth order.

In [6], Figure 18c.1: the convergence of the method.

```
steps_list = sorted(errors)
hs = np.array([X_END / n for n in steps_list])
errs = np.array([errors[n] for n in steps_list])
fig, ax = plt.subplots(figsize=(7.0, 4.4))
ax.loglog(hs, errs, "o-", color="#2a78d6", label="RK4 error at $x_4 = 20$")
ax.loglog(hs, errs[-1] * (hs / hs[-1]) ** 4, "--", color="#52514e",
          label="slope 4: error $\\propto h^4$")
ax.set_xlabel("step length $h$ (units $1/m$)")
ax.set_ylabel("largest error of a component")
ax.legend()
```

`hs` holds the five step lengths $20/n$ and `errs` the five errors. `ax.loglog` draws with logarithmic axes on both sides: a power law $e = ch^p$ becomes a straight line of slope p, because $\log e = \log c + p \log h$. The dashed comparison line $e_{\text{last}}(h/h_{\text{last}})^4$ has the slope 4 and passes through the last point.

```
save_figure(fig, "rk4_convergence",
            "Accuracy of the Runge-Kutta solution of the homogeneous field equation "
            "in the author's metric: the largest difference between a component of "
            "the computed field and of the exact solution of the Revision theory "
            "record at the time $x_4 = 20$ (vertical axis, logarithmic), against "
            "the step length $h$ in units of $1/m$ (horizontal axis, logarithmic), "
            "for 250 to 4000 steps. The points follow the dashed line of slope 4: "
            "halving the step divides the error by 16, the fourth order of the "
            "method. With 2000 steps the error is far below every difference "
            "studied in this notebook.")
```

What you see in Figure 18c.1: five points on a straight line parallel to the dashed line of slope 4, falling from about 2×10^{-5} at $h = 0.08$ to about 3×10^{-10} at $h = 0.005$. Why it matters for the theorems: the differences studied below are either zero by a theorem (they must come out below 10^{-12}) or of order 1 (the negative control). Moreover the map $\Psi \to \Gamma\Psi$ commutes with every step of the method: the slopes of the T1 partner are Γ times the slopes of the field, because $F_{-m,-\lambda}(\Gamma\Psi) = \Gamma F_{m,\lambda}(\Psi)$ (the same computation as $\Gamma M \Gamma$ in Section 18.21), and in the same way $F^{\text{mirror}}_{-m,\lambda}(\gamma^{(x_0)}\Psi) = \gamma^{(x_0)} F_{m,\lambda}(\Psi)$. So a partner computed with the same steps equals the mapped field up to rounding, whatever the integration error; the comparison with the exact formula shows, in addition, that both are the true solutions to 10^{-9}.

In [7], theorem T1 in numbers.

```
phi = rk4(Gamma @ psi0, -m, -lam, 1, STEPS)  # the T1 partner, solved on its own
t1_gap = np.abs(phi - psi @ Gamma.T).max()  # row by row: Gamma psi(x4)
wrong = rk4(Gamma @ psi0, -m, lam, 1, STEPS)  # the negative control (-m, +lambda)
wrong_gap = np.abs(wrong - psi @ Gamma.T).max()
report("largest difference of the wrong partner (-m, +lambda) from Gamma Psi",
       f"{wrong_gap:.3f}")
check(t1_gap < 1e-12, "T1: the (-m, -lambda) solution from Gamma Psi(0) is Gamma "
      "Psi(x4) at all 2001 times (difference below 1e-12)")
check(wrong_gap > 0.1, "negative control: the (-m, +lambda) solution from Gamma "
      "Psi(0) is not Gamma Psi(x4)")
```

`phi` is the solution of the partner theory $(-m, -\lambda)$ started from $\Gamma\Psi(0)$, computed by the same Runge-Kutta function with no knowledge of `psi`. In `psi @ Gamma.T` each row of the table `psi` is $\Psi(x_4)$ written as a row, and a row times Γ^T is $(\Gamma\Psi)^T$; so this table holds $\Gamma\Psi(x_4)$ at all 2001 times, and `t1_gap` is its largest difference from `phi`. `wrong` is the negative control, the theory $(-m, +\lambda)$ from the same start, and `wrong_gap` its largest difference from $\Gamma\Psi$. Out [7] prints RESULT largest difference of the wrong partner (-m, +lambda) from Gamma Psi = 1.641 and two PASS lines: the T1 partner equals $\Gamma\Psi$ to better than 10^{-12} at every time, while the wrong partner is off by 1.641, as much as the field itself (the column has length 1). Why it fails: with S unchanged its coefficient is $V = -m + \lambda S = -1 + 0.269196 = -0.730804$ instead of -1.269196, so it oscillates with the frequency $\sqrt{0.730804^2 - 0.36} = 0.4172$ instead of 1.1184.

In [8], Figure 18c.2: the partner, component by component.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.0), sharey=True)
every = slice(0, STEPS + 1, 40)  # a dot every 40 steps
for ax, A in zip(axes, (0, 8)):
    ax.plot(times, psi[:, A].real, color="#2a78d6",
            label=f"$\\Psi_{{{A + 1}}}$, mass $m$, coupling $\\lambda$")
    ax.plot(times[every], phi[every, A].real, "o", color="#eb6834", markersize=3.5,
            label=f"$\\Phi_{{{A + 1}}}$, mass $-m$, coupling $-\\lambda$")
    ax.plot(times, wrong[:, A].real, "--", color="#52514e", linewidth=0.9,
            label="wrong partner: $-m$, $+\\lambda$")
    ax.set_xlabel("time $x_4$ (units $1/m$)")
    ax.set_title(f"component {A + 1}: " + ("$\\Phi = -\\Psi$" if A < 8
                                           else "$\\Phi = +\\Psi$"), fontsize=10)
    ax.legend(loc="lower left", fontsize=8)
axes[0].set_ylabel("real part of the component")
```

Two panels side by side that share the vertical axis (`sharey=True`). `every` is a **slice** that takes every 40th of the 2001 times, so that the dots do not hide the line. The loop draws component 1 (Python place 0) in the left panel and component 9 (place 8) in the right one: the real part of Ψ_A as a blue line, of the partner Φ_A as orange dots, and of the wrong partner as a thin dashed line. In the f-strings, `{{{A + 1}}}` prints a brace, the number $A+1$ and a brace, so that the label reads Ψ_1 or Ψ_9 in LaTeX. The title of each panel says which relation holds in that half.

```
save_figure(fig, "partner_components",
            "A solution and its T1 partner, computed separately. Lines: the real "
            "part of component 1 (left) and component 9 (right) of the homogeneous "
            "solution $\\Psi$ with mass $m = 1$ and coupling $\\lambda = 0.3$, "
            "against the time $x_4$ in units of $1/m$. Dots: the same components "
            "of the solution $\\Phi$ of the theory with $-m$ and $-\\lambda$, "

            "$+\\lambda$, which drifts away because it oscillates with another "
            "frequency.")
```

What you see in Figure 18c.2: on the left, the dots lie on the mirror image of the blue line in the horizontal axis ($\Phi_1 = -\Psi_1$: they start near $+0.21$ where the line starts near -0.21); on the right, the dots lie on the line ($\Phi_9 = +\Psi_9$). The dashed wrong partner starts at the same values as the dots but oscillates with the period $2\pi/0.4172 \approx 15.1$ instead of $2\pi/1.1184 \approx 5.62$ and drifts away. This is $\Gamma = \mathrm{diag}(-I_8, I_8)$ at work on an actual solution.

In [9], the bilinears of a homogeneous field, and T1 for them.

```
def bilinears(field, mass, coup, t, zv, s0):
    """S, J^mu (8 numbers) and T_mu nu (8 x 8) of a homogeneous field at (t, zv)."""
    geo = geometry_at(t, zv, s0)
    D = {mu: geo["Om"][mu] @ field for mu in range(8)}
    D[4] = D[4] + generator(field, mass, coup, s0) @ field  # d field / dx4
    bar = field.conj() @ C  # the adjoint row Psibar = Psi^dagger C
    Dbar = {mu: D[mu].conj() @ C for mu in range(8)}
    S = (bar @ field).real
```

`bilinears(field, mass, coup, t, zv, s0)` computes, for one column `field` at the time `t` and the angle `zv`, every quantity the theorems speak about. `geo` holds the geometry there. The covariant derivatives: a homogeneous field has $\partial_\mu\Psi = 0$ for $\mu \neq 4$, so $D_\mu\Psi = \Omega_\mu\Psi$, and $\partial_4\Psi = M\Psi$ by the field equation, which the line `D[4] = D[4] + ...` adds to $\Omega_4\Psi$ (zero here). `bar` is the row $\bar\Psi = \Psi^\dagger C$ (`field.conj() @ C`: the conjugate column used as a row, times C). `Dbar` uses $D_\mu\bar\Psi = (D_\mu\Psi)^\dagger C$, which follows from the reality of Ω_μ:

$$(D_\mu\Psi)^\dagger C = (\partial_\mu\Psi)^\dagger C + \Psi^\dagger\Omega_\mu^T C = \partial_\mu\bar\Psi - \Psi^\dagger C\Omega_\mu = D_\mu\bar\Psi.$$

The rule $(XY)^\dagger = Y^\dagger X^\dagger$ with $\Omega_\mu^\dagger = \Omega_\mu^T$ (Ω_μ is real); then $\Omega_\mu^T C = -C\Omega_\mu$ (Exercise 18.4 derives it from $C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T$); then the definition of $D_\mu\bar\Psi$. `S` is $\bar\Psi\Psi$.

```
    L = 0.5 * sum(bar @ geo["up"][mu] @ D[mu] - Dbar[mu] @ geo["up"][mu] @ field
                  for mu in range(8)) - mass * S - 0.5 * coup * S ** 2
    T = np.zeros((8, 8), dtype=complex)
    for mu in range(8):
        for nu in range(8):
            T[mu, nu] = 0.25 * (
                bar @ geo["down"][mu] @ D[nu] + bar @ geo["down"][nu] @ D[mu]
                - Dbar[mu] @ geo["down"][nu] @ field
                - Dbar[nu] @ geo["down"][mu] @ field)
            if mu == nu:
                T[mu, nu] -= geo["g"][mu] * L
    J = np.array([-1j * bar @ geo["up"][mu] @ field for mu in range(8)])
    assert np.abs(T.imag).max() < 1e-12 and np.abs(J.imag).max() < 1e-12
    return S, J.real, T.real
```

`L` is $\mathcal{L}/\sqrt{|g|}$ of Section 18.4: half the sum over μ of $\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi$, minus mS, minus $\frac{\lambda}{2}S^2$. `T` is the 8×8 table of $T_{\mu\nu}$ of the pairing record (Section 18.4), built from the lowered gammas γ_μ (`geo["down"]`), with $-g_{\mu\mu}\mathcal{L}/\sqrt{|g|}$ added on the diagonal; it is stored at the place `[mu, nu]` (the place k is x_k). `J` holds $J^\mu = -i\bar\Psi\gamma^\mu\Psi$, the convention of the theory record, for $\mu = 0, \ldots, 7$. For a commuting field all these numbers are real (the Lagrangian is real, Chapter 7); `assert` confirms that their imaginary parts are below 10^{-12}, and the function returns the real parts.

```
SAMPLE = range(0, STEPS + 1, 20)  # 101 sampled times
sampled = times[list(SAMPLE)]
data = {"psi": [bilinears(psi[n], m, lam, times[n], Z0, 1) for n in SAMPLE],
        "phi": [bilinears(phi[n], -m, -lam, times[n], Z0, 1) for n in SAMPLE]}
scale_T = max(np.abs(T).max() for _, _, T in data["psi"])
scale_J = max(np.abs(J).max() for _, J, _ in data["psi"])
t1_T = max(np.abs(Tp + Tq).max() for (_, _, Tp), (_, _, Tq)
           in zip(data["psi"], data["phi"])) / scale_T
t1_J = max(np.abs(Jp + Jq).max() for (_, Jp, _), (_, Jq, _)
           in zip(data["psi"], data["phi"])) / scale_J
t1_S = max(abs(Sp - Sq) for (Sp, _, _), (Sq, _, _) in zip(data["psi"], data["phi"]))
reproduces(t1_T < 1e-12 and t1_J < 1e-12 and t1_S < 1e-12,
           "T1: S kept, J -> -J (8) and T -> -T (36) at all 101 sampled times",
           (PY, ["T1.metric.commuting.emt", "T1.metric.commuting.current"]))
```

SAMPLE takes every 20th time, $x_4 = 0, 0.2, 0.4, \ldots, 20$: 101 times. data holds the bilinears of the field with (m, λ) and of its T1 partner with $(-m, -\lambda)$ at the same point z_0 of the patch. scale_T and scale_J are the largest absolute entries of T and J of the field over all sampled times; the differences are divided by them, so that the test measures a relative error. t1_T is the largest relative entry of $T[\Psi] + T[\Phi]$, t1_J that of $J[\Psi] + J[\Phi]$, and t1_S the largest difference of the two values of S. The check requires all three below 10^{-12} and names the sympy checks T1.metric.commuting.emt and T1.metric.commuting.current. Out [9] shows the PASS line. COMPUTED on an actual solution along the deflating history: the 36 independent components of $T_{\mu\nu}$ (the table is symmetric) and the 8 of J^μ of the partner are the negatives of those of the field, and S is the same.

In [10], three facts of the theory record, and the local conservation law of the charge.

```
rho_ok = p_ok = mixed_ok = flow_ok = True
q0_values = []  # the frame current q0 at the sampled times
for n, (S, J, T) in zip(SAMPLE, data["psi"]):
    geo = geometry_at(times[n], Z0, 1)
    rho_ok = rho_ok and abs(-T[4, 4] - (m * S + 0.5 * lam * S ** 2)) < 1e-12
    p = [-T[mu, mu] / geo["g"][mu] for mu in (0, 1, 2, 3, 5, 6, 7)]
    p_ok = p_ok and max(abs(x - 0.5 * lam * S ** 2) for x in p) < 1e-12
    mixed_ok = mixed_ok and abs(T[4, 0]) < 1e-12 * scale_T
    field = psi[n]
    dJ4 = 2 * (field.conj() @ B @ generator(field, m, lam, 1) @ field).real
    q0 = (-1j * field.conj() @ C @ gamma[0] @ field).real
    q0_values.append(q0)
    flow_ok = flow_ok and abs(dJ4 + 6 * H * q0) < 1e-12
```

q0_values starts as an empty list; the loop appends one number to it at each sampled time. The loop runs over the sampled times of the field (zip pairs the time indices with the stored bilinears). T[4, 4] is $T_{x_4x_4}$ (place 4 is x_4), so -T[4, 4] is the energy density ρ of the pairing convention, compared with $mS + \frac{\lambda}{2}S^2$. p holds the seven pressures $p_\mu = -g^{\mu\mu}T_{\mu\mu} = -T_{\mu\mu}/g_{\mu\mu}$ of x_0, of x_1, x_2, x_3 and of the deflating extra times x_5, x_6, x_7, each compared with $\frac{\lambda}{2}S^2$. T[4, 0] is $T_{x_4x_0}$, which must vanish (relative to scale_T). Then the conservation law of Section 18.21: dJ4 is $\partial_4 J^{x_4}$, computed from the field equation $\partial_4\Psi = M\Psi$,

$$\frac{d}{dx_4}(\Psi^\dagger B\Psi) = (M\Psi)^\dagger B\Psi + \Psi^\dagger BM\Psi = 2\,\mathrm{Re}(\Psi^\dagger BM\Psi).$$

The product rule; then $(M\Psi)^\dagger B\Psi = \Psi^\dagger M^\dagger B\Psi$ is the complex conjugate of $\Psi^\dagger B^\dagger M\Psi = \Psi^\dagger BM\Psi$ (B is Hermitian), and a number plus its complex conjugate is twice its real part. q0 is the frame current $q_0 = -i\bar\Psi\gamma^{(x_0)}\Psi$ of Section 18.21 (not the charge Q), q0_values.append(q0) stores it, and the local law of Section 18.21 requires $\partial_4 J^{x_4} = -6Hq_0$.

```
reproduces(rho_ok and p_ok and mixed_ok,
           "rho = m S + (1/2) S^2, all pressures (1/2) S^2, T_x4x0 = 0 (homogeneous)",
           (TH_PY, ["commuting_homogeneous_on_shell_rho_p",
                    "commuting_T_x4x0_homogeneous"]))
reproduces(flow_ok, "local charge conservation: d4 J^x4 = -6 H q0 (flow along x0)",
           (TH_PY, ["commuting_current_conservation"]))
say(f"q0 lies between {min(q0_values):.4f} and {max(q0_values):.4f}: the flow "
```

```
    "sin z q0 through the brane z = pi/2 is not zero, so the charge of the "
    "patch changes in time")
```

Two checks and one printed line. The first check names two checks of the field-theory report `python-field-theory.json`, one for the energy density and the pressures and one for $T_{x_4x_0}$ of homogeneous solutions; the second names its check of the LOCAL conservation law of the charge. Out [10] shows both PASS lines. The `say` line prints the smallest and the largest value of q_0 over the 101 sampled times (`min` and `max` of the list; `:.4f` writes four decimals): -0.3454 and 0.3454. At the brane $z = \pi/2$ the flow $\sqrt{|g|}J^{x_0} = \sin z\, q_0$ equals q_0, so it is not zero, and by Section 18.21 the charge of the patch changes at the rate $-V_6 q_0$: the local law holds exactly, but the total charge of the patch is NOT constant for this solution. With the numbers of Out [4] the energy density is $\rho = mS + \frac{\lambda}{2}S^2 = 0.897319 + 0.15 \times 0.805181 = 1.0181$ and every pressure is $0.15 \times 0.805181 = 0.1208$; Exercise 18.2 continues this computation.

In [11], Figure 18c.3: the T1 pair in numbers.

```
def series(name, pick):
    return np.array([pick(S, J, T) for S, J, T in data[name]])

panels = [("charge density $J^{x_4}$", lambda S, J, T: J[4]),
          ("energy density $\\rho = -T_{x_4x_4}$", lambda S, J, T: -T[4, 4]),
          ("$T_{x_4x_1}$ (history-dependent)", lambda S, J, T: T[4, 1])]
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.0))
for ax, (title, pick) in zip(axes, panels):
    a, b = series("psi", pick), series("phi", pick)
    ax.plot(sampled, a, color="#2a78d6", label="$\\Psi$: $(m, \\lambda)$")
    ax.plot(sampled, b, color="#eb6834", label="T1 partner: $(-m, -\\lambda)$")
    ax.plot(sampled, a + b, color="#52514e", linestyle="--", label="sum")
    ax.set_title(title, fontsize=10)
    ax.set_xlabel("time $x_4$ (units $1/m$)")
axes[0].legend(fontsize=8, loc="lower left")
```

`series(name, pick)` returns the time series of one quantity; `pick` is a small function that chooses it from (S, J, T). `panels` lists three choices, each a title and a one-line function (`lambda S, J, T: ...`): J^{x_4} (`J[4]`), $\rho = -T_{x_4x_4}$ and $T_{x_4x_1}$ (`T[4, 1]`). For each panel the field (blue), its T1 partner (orange) and their sum (dashed) are drawn against the sampled times.

```
save_figure(fig, "t1_pair_densities",
            "The T1 pair in numbers, along the deflating history $a_4 = AHx_4$ "
            "($A = 1$, $H = 0.2$, $m = 1$, $\\lambda = 0.3$, at $z = \\pi/4$). "
            "Horizontal axes: the time $x_4$ in units of $1/m$. Left: the charge "
            "density $J^{x_4}$; middle: the energy density $\\rho$; right: the "
            "mixed component $T_{x_4x_1}$, which grows with the factor $e^{a_4}$ "
            "of the inflating direction. Blue: the solution with $(m, \\lambda)$; "
            "orange: its partner $\\Gamma\\Psi$ with $(-m, -\\lambda)$; dashed: "
            "their sum. Every orange curve is the mirror image of the blue one in "
            "the horizontal axis, and the sum is zero at every time: the pair has "
            "zero total charge and energy-momentum as classical bilinears.")
```

What you see in Figure 18c.3: on the left, the blue charge density oscillates between about -0.04 and -0.40 and the orange one between $+0.04$ and $+0.40$, seven times between $x_4 = 0$ and 20 (the density is quadratic in the field, so it oscillates with the period $\pi/w = 2.81$, half the period of the field); in the middle, two constant lines at $+1.018$ and -1.018; on the right, the blue component rises from about 0.05 to 3 and the orange one falls from -0.05 to -3. In each panel the dashed sum is zero at every time. Why the right panel grows: $T_{x_4x_1}$ contains $\gamma_{x_1} = f_1\gamma^{(x_1)}$ and the connection Ω_{x_1}, both proportional to $e^{a_4} = e^{0.2x_4}$, which grows by the factor $e^4 \approx 54.6$ between $x_4 = 0$ and 20; this is where the deflating history enters the energy-momentum tensor. COMPUTED: $T + T' = 0$ and $J + J' = 0$ at every sampled time.

In [12], theorem T2 in numbers: the mirror partner.

```
chi = rk4(gamma[0] @ psi0, -m, lam, -1, STEPS)  # the mirror partner, on its own
t2_gap = np.abs(chi - psi @ gamma[0].T).max()
data["chi"] = [bilinears(chi[n], -m, lam, times[n], np.pi - Z0, -1) for n in SAMPLE]
LAM = np.array([-1, 1, 1, 1, 1, 1, 1, 1], dtype=float)  # x0, ..., x7
t2_S = max(abs(Sp + Sx) for (Sp, _, _), (Sx, _, _) in zip(data["psi"], data["chi"]))
t2_J = max(np.abs(Jx - LAM * Jp).max() for (_, Jp, _), (_, Jx, _)
           in zip(data["psi"], data["chi"])) / scale_J
t2_T = max(np.abs(Tx - np.outer(LAM, LAM) * Tp).max() for (_, _, Tp), (_, _, Tx)
           in zip(data["psi"], data["chi"])) / scale_T
```

`chi` is the mirror partner: the theory $(-m, \lambda)$ on the mirror patch ($s_0 = -1$), started from $\gamma^{(x_0)}\Psi(0)$ and solved on its own. `t2_gap` compares it with $\gamma^{(x_0)}\Psi(x_4)$ (`psi @ gamma[0].T`, as in In [7]). `data["chi"]` holds its bilinears at the MIRROR point $z = \pi - z_0 = 3\pi/4$, in the geometry of the mirror patch. `LAM` is $\Lambda = R_0 = \mathrm{diag}(-1, 1, 1, 1, 1, 1, 1, 1)$. `t2_S` measures $S[X] + S[\Psi]$, which must vanish because S is reversed; `t2_J` measures $J[X] - \Lambda J[\Psi]$ and `t2_T` measures $T[X] - \Lambda_\mu\Lambda_\nu T[\Psi]$ (`np.outer(LAM, LAM)` is the 8×8 table of the products $\Lambda_\mu\Lambda_\nu$), both relative.

```
check(t2_gap < 1e-12, "T2: the (-m, lambda) mirror solution from gamma^(x0) Psi(0) "
      "is gamma^(x0) Psi(x4) at all 2001 times")
reproduces(t2_S < 1e-12 and t2_J < 1e-12 and t2_T < 1e-12,
           "T2: S -> -S, J and T pulled back (charge and energy density equal)",
           (PY, ["T2.metric.commuting.S_odd", "T2.metric.commuting.emt",
                 "T2.metric.commuting.current"]))
```

Two checks: the mirror partner is $\gamma^{(x_0)}\Psi$ at all 2001 times, and S is reversed while J and T are pulled back, with the sympy checks `T2.metric.commuting.S_odd`, `T2.metric.commuting.emt` and `T2.metric.commuting.current`. Out [12] shows both PASS lines. Note what is compared: the field at $z_0 = \pi/4$ on the patch and its partner at $3\pi/4$ on the mirror patch, the two points that the mirror $z \to \pi - z$ exchanges.

In [13], Figure 18c.4: the T2 pair in numbers.

```
panels = [("scalar $S$", lambda S, J, T: S),
          ("charge density $J^{x_4}$", lambda S, J, T: J[4]),
          ("$T_{x_4x_1}$ (history-dependent)", lambda S, J, T: T[4, 1])]
fig, axes = plt.subplots(1, 3, figsize=(13.0, 4.0))
for ax, (title, pick) in zip(axes, panels):
```

```
    ax.plot(sampled, series("psi", pick), color="#2a78d6",
            label="$\\Psi$ on the patch: $(m, \\lambda)$")
    ax.plot(sampled[::4], series("chi", pick)[::4], "o", color="#1baf7a",
            markersize=4, label="mirror partner: $(-m, \\lambda)$")
    ax.set_title(title, fontsize=10)
    ax.set_xlabel("time $x_4$ (units $1/m$)")
axes[0].set_ylim(-1.1, 1.1)
axes[0].legend(fontsize=8, loc="center left")
```

Three panels, S, J^{x_4} and $T_{x_4x_1}$, with the field as a blue line and the mirror partner as green dots at every fourth sampled time (`[::4]` takes every fourth entry). `set_ylim(-1.1, 1.1)` fixes the vertical range of the first panel so that both values of S are visible.

```
save_figure(fig, "t2_mirror_densities",
            "The T2 pair in numbers, same values as in the previous figure. Blue "
            "line: the solution $\\Psi$ with $(m, \\lambda)$ on the patch at "
            "$z = \\pi/4$; green dots: its mirror partner $\\gamma^{(x_0)}\\Psi$, "
            "solved on its own with $(-m, \\lambda)$ on the mirror patch at "
            "$z = 3\\pi/4$. Horizontal axes: the time $x_4$ in units of $1/m$. "
            "Left: the scalar $S$, constant and exactly opposite for the partner. "
            "Middle and right: the charge density $J^{x_4}$ and the component "
            "$T_{x_4x_1}$, EQUAL for the partner. T2 pairs the mass $m$ with $-m$ "
            "at the same charge and energy-momentum; nothing cancels.")
```

What you see in Figure 18c.4: on the left two constant lines, $S = 0.897$ for the field and $S = -0.897$ for the partner; in the middle and on the right the green dots lie ON the blue curves: the mirror partner has the same charge density and the same $T_{x_4x_1}$. Compare Figure 18c.3, where the T1 partner was the mirror image in the horizontal axis. T2 pairs m with $-m$ at EQUAL charge and energy-momentum: nothing cancels in a T2 pair.

In [14], the spectra of the generators.

```
def spectrum(Mx):
    """The 16 eigenvalues, sorted by imaginary part, then real part (rounded)."""
    ev = np.linalg.eigvals(Mx)
    return ev[np.lexsort((np.round(ev.real, 9), np.round(ev.imag, 9)))]

M_psi = generator(psi0, m, lam, 1)
M_t1 = generator(Gamma @ psi0, -m, -lam, 1)
M_t2 = generator(gamma[0] @ psi0, -m, lam, -1)
similar = (np.array_equal(Gamma @ M_psi @ Gamma, M_t1)
           and np.allclose(gamma[0] @ M_psi @ gamma[0], M_t2, atol=1e-15))
sp_psi, sp_t1, sp_t2 = spectrum(M_psi), spectrum(M_t1), spectrum(M_t2)
w_exact = np.sqrt((m + lam * S0) ** 2 - 9 * H ** 2)
report("frequency w of the solution and of both partners", f"{w_exact:.6f}")
check(similar and np.abs(sp_psi - sp_t1).max() < 1e-12
      and np.abs(sp_psi - sp_t2).max() < 1e-12
      and np.allclose(np.sort(np.abs(sp_psi.imag)), w_exact, atol=1e-12),
      "the generators of the field and of its T1 and T2 partners are similar: "
      "equal spectra +-i w")
```

`spectrum(Mx)` returns the 16 eigenvalues of a matrix (`np.linalg.eigvals`) in a fixed order: `np.lexsort` sorts by its last key first, here by the imaginary part and then by the real part, both rounded to 9 decimals so that rounding differences do not change the order. `M_psi`, `M_t1` and `M_t2` are the generators of the field, of the T1 partner and of the mirror partner at the start. `similar` checks $\Gamma M \Gamma = M_{\mathrm{T1}}$ with the exact comparison `np.array_equal` (Γ only changes the signs of rows and columns, which floating-point arithmetic does exactly) and $\gamma^{(x_0)} M \gamma^{(x_0)} = M_{\mathrm{T2}}$ to 10^{-15}. Similar matrices have the same eigenvalues (Section 18.23), and the check compares the three sorted spectra. It also requires the absolute imaginary parts to equal w: since $M^2 = -w^2 I_{16}$, every eigenvalue μ of M obeys $\mu^2 = -w^2$, so $\mu = \pm iw$. Out [14] prints the frequency $w = 1.118417$ of the solution and of both partners, and the PASS line.

```
masses = np.linspace(-2.0, 2.0, 161)
family = {}
for label, sign_m, sign_l in (("field", 1, 1), ("T1 partner", -1, -1)):
    rows = []
    for mv in masses:
        V = sign_m * mv + sign_l * lam * S0
        Mx = -V * gamma[4] + 3 * H * gamma[4] @ gamma[0]
        rows.append(spectrum(Mx))
    family[label] = np.array(rows)
check(np.abs(family["field"] - family["T1 partner"]).max() < 1e-9,
      "for every mass from -2 to 2 the field and its T1 partner have equal spectra")
```

The same comparison for a whole family: 161 masses from -2 to 2 (`np.linspace(-2.0, 2.0, 161)`), at the fixed λ and S_0. For the field the generator has $V = m + \lambda S_0$; for the T1 partner the mass $-m$ and the coupling $-\lambda$ give $V = -m - \lambda S_0$. The generator $-V\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}$ is built directly and its sorted spectrum stored, one row per mass. The check requires the two tables to agree to 10^{-9} at every mass; Out [14] ends with its PASS line.

In [15], Figure 18c.5: the spectrum against the mass.

```
fig, ax = plt.subplots(figsize=(8.0, 4.4))
for label, colour, style in (("field", "#2a78d6", "-"),
                             ("T1 partner", "#eb6834", "o")):
    rows = family[label]
    kw = {"markersize": 3} if style == "o" else {}
    ax.plot(masses, rows.imag.max(axis=1), style, color=colour,
            label=f"frequency $w$, {label}", **kw)
    ax.plot(masses, rows.real.max(axis=1), style, color=colour, alpha=0.45,
            label=f"growth rate, {label}", **kw)
ax.axvline(m, color="#52514e", linestyle=":", label="the solution of this notebook")
ax.set_xlabel("mass $m$ of the field (the partner has $-m$, $-\\lambda$)")
ax.set_ylabel("eigenvalue part (units $m = 1$)")
ax.legend(fontsize=8, loc="upper center")
```

For the field (lines, style `"-"`) and the partner (dots, style `"o"`; `**kw` passes the marker size only for the dots): the largest imaginary part of the 16 eigenvalues at each mass (`rows.imag.max(axis=1)`, the oscillation frequency w) in full colour, and the largest real part (the growth rate) in a lighter shade (`alpha=0.45`). A dotted vertical line marks the mass $m = 1$ of the solution of the notebook.

```
save_figure(fig, "family_spectrum",
            "The spectrum of the evolution generator of the homogeneous solutions, "
            "against the mass $m$ (horizontal axis) at the fixed coupling "
            "$\\lambda = 0.3$ and scalar $S$ of this notebook, $H = 0.2$. Dark "
            "curves: the oscillation frequency $w$, the largest imaginary part of "
            "the eigenvalues; light curves: the growth rate, the largest real part. "
            "Lines: the field with $(m, \\lambda)$; dots: its T1 partner with "
            "$(-m, -\\lambda)$. They coincide everywhere. Inside the window "
            "$|m + \\lambda S| < 3H$ the frequency is zero and the solutions grow; "
            "outside it they oscillate. The dotted line marks the solution "
            "plotted above.")
```

What you see in Figure 18c.5: the dots lie on the lines everywhere. Outside a window of masses the growth rate is zero and the frequency $w = \sqrt{(m + \lambda S_0)^2 - 9H^2}$ rises from 0 at the edges of the window towards the straight lines $|m + \lambda S_0|$; at the dotted line, $m = 1$, it is 1.118. Inside the window $|m + \lambda S_0| < 3H$, that is $-0.869 < m < 0.331$, the frequency is zero and the growth rate is an arc with the top $3H = 0.6$ at $m = -\lambda S_0 = -0.269$. Why an arc: inside the window the eigenvalues are $\pm\kappa$ with $\kappa^2 = 9H^2 - (m + \lambda S_0)^2$, so $\kappa^2 + (m + \lambda S_0)^2 = (3H)^2$, the equation of a circle of radius $3H$ (drawn with different scales on the two axes). The field and its T1 partner have the same spectrum for every mass: T1 never turns an oscillating universe into a growing one.

In [16], plane waves in flat space: the quantum reading Q.

```
def h_matrix(mass, k):
    """h_m(k) = -i m gamma^(x4) - gamma^(x4) sum_(a != 4) k_a gamma^(a)."""
    out = -1j * mass * gamma[4]
    for a in (0, 1, 2, 3, 5, 6, 7):
        out = out - k[a] * gamma[4] @ gamma[a]
    return out

def w_squared(mass, k):
    return mass ** 2 + sum(k[a] ** 2 for a in (0, 1, 2, 3)) - sum(
        k[a] ** 2 for a in (5, 6, 7))

def eigenspace(Mx, value, tol=1e-9):
    """Orthonormal columns spanning the null space of Mx - value I."""
    _, sv, vh = np.linalg.svd(Mx - value * I16)
    return vh[sv < tol].conj().T

def inertia(V):
    """(positive, negative) eigenvalue counts of V^dagger B V."""
    ev = np.linalg.eigvalsh(V.conj().T @ B @ V)
    return int((ev > 1e-9).sum()), int((ev < -1e-9).sum())
```

Four helpers. The first, `h_matrix(mass, k)`, builds the one-particle matrix of Section 18.22,

$$h_m(k) = -im\gamma^{(x_4)} - \gamma^{(x_4)} \sum_{a \neq 4} k_a \gamma^{(a)},$$

where `k[a]` is k_a (the entry k_4 is never used). `w_squared` returns $m^2+k_0^2+k_1^2+k_2^2+k_3^2-k_5^2-k_6^2-k_7^2$. `eigenspace(Mx, value)` returns orthonormal columns that span the eigenspace of the eigenvalue `value`, that is the null space of $M_x - wI_{16}$. It uses the **singular value decomposition** `np.linalg.svd`, which writes a matrix as $A = U\Sigma V^\dagger$ with U and V unitary (orthonormal columns) and Σ diagonal with the singular values $\sigma_j \geq 0$; since $Av_j = \sigma_j u_j$ for the columns u_j of U and v_j of V, the columns v_j with $\sigma_j = 0$ (in floating point: below 10^{-9}) span the null space. numpy returns $V^\dagger$ (`vh`), so the selected rows are conjugated and transposed into columns. `inertia(V)` counts the positive and the negative eigenvalues of the 8×8 Hermitian matrix $V^\dagger B V$, the Krein form restricted to the eigenspace (`np.linalg.eigvalsh` computes the eigenvalues of a Hermitian matrix).

```
R0 = np.array([-1, 1, 1, 1, 1, 1, 1, 1], dtype=float)  # the reflection of x0
rand = np.random.default_rng(7)
square_ok = maps_ok = True
for _ in range(50):
    k, mv = rand.normal(size=8), rand.normal()
    h = h_matrix(mv, k)
    square_ok = square_ok and np.allclose(h @ h, w_squared(mv, k) * I16, atol=1e-12)
    maps_ok = (maps_ok and np.allclose(Gamma @ h @ Gamma, h_matrix(-mv, k))
               and np.allclose(gamma[0] @ h @ gamma[0], h_matrix(-mv, R0 * k)))
```

`R0` reverses k_0. With the fixed seed 7, fifty random masses and momenta are drawn; for each, `square_ok` checks $h^2 = w^2 I_{16}$ and `maps_ok` checks $\Gamma h_m(k) \Gamma = h_{-m}(k)$ and $\gamma^{(x_0)} h_m(k) \gamma^{(x_0)} = h_{-m}(R_0 k)$ (`R0 * k` multiplies entry by entry).

```
samples = read_json(THEORY)["data"]["one_particle_flat"]["samples"]
rows_ok = True
for row in samples:
    k = np.array(row["k"], dtype=float)
    w = float(sp.sympify(row["w"].replace("Sqrt[", "sqrt(").replace("]", ")")))
    h = h_matrix(row["m"], k)
    Vp, Vn = eigenspace(h, w), eigenspace(h, -w)
    mine = (np.isclose(np.sqrt(w_squared(row["m"], k)), w), Vp.shape[1],
            Vn.shape[1], inertia(Vp), inertia(Vn))
    rows_ok = rows_ok and mine == (True, row["dim_plus_w"], row["dim_minus_w"],
                                   tuple(row["B_inertia_plus_w"]),
                                   tuple(row["B_inertia_minus_w"]))
    (pp, pn), (qp, qn) = inertia(Vp), inertia(Vn)
    say(f"m = {row['m']:+d}, k = {row['k']}: w = {w:.6f}, dimensions "
        f"{Vp.shape[1]} and {Vn.shape[1]}, Krein inertia ({pp},{pn}) and "
        f"({qp},{qn})")
```

`samples` is the data table `one_particle_flat` of `pairing-theory.json`: eight rows, each with m, k, the frequency w as text (for example `Sqrt[2]`, the Wolfram way of writing $\sqrt{2}$), the dimensions of the two eigenspaces and their Krein inertias. The text of w is translated into sympy's `sqrt(2)`, read by `sp.sympify` and turned into a number by `float`. For each row the cell computes the eigenspaces of $+w$ and $-w$, their dimensions (`shape[1]`, the number of columns) and their inertias; `mine` collects them in the order of the record, and `rows_ok` requires equality with the record. One line per sample is printed.

```
reproduces(square_ok and maps_ok,
           "h_m^2 = w^2 I16; Gamma h_m Gamma = h_-m; gamma^(x0) h_m gamma^(x0) = "
```

```
           "h_-m(R0 k)", (WL, ["Q_one_particle_flat_dispersion", "Q_one_particle_maps"]),
           (PY, ["Q.one_particle_maps"]))
reproduces(rows_ok and len(samples) == 8,
           "the eight recorded samples: w, dimensions 8 and 8, Krein inertia (4,4)",
           (WL, ["Q_one_particle_Krein_signatures"]),
           (PY, ["compare.theory.one_particle", "Q.one_particle_Krein_inertia_proof"]))
```

Two checks with their records. Out [16] prints the eight samples, each with the dimensions 8 and 8 and the Krein inertias (4,4) and (4,4), and two PASS lines. COMPUTED in floating point, they agree with the exact samples of the record.

In [17], imaginary and zero frequencies.

```
neutral_ok = True
for k in ([0, 0, 0, 0, 0, 2, 0, 0], [0, 1, 0, 0, 0, 2, 0, 0],
          [0, 0, 0, 0, 0, 1, 0, 0]):  # (k0, ..., k7)
    k = np.array(k, dtype=float)
    h, w2 = h_matrix(1.0, k), w_squared(1.0, k)
    if w2 == 0:
        spaces = [eigenspace(h, 0.0)]
        neutral_ok = neutral_ok and np.allclose(h @ h, 0.0)
    else:
        w = 1j * np.sqrt(-w2)
        spaces = [eigenspace(h, w), eigenspace(h, -w)]
    dims = [V.shape[1] for V in spaces]
    largest = max(np.abs(V.conj().T @ B @ V).max() for V in spaces)
    neutral_ok = neutral_ok and all(dim == 8 for dim in dims) and largest < 1e-9
    say(f"k = {k.astype(int).tolist()}: w^2 = {w2:+.0f}, eigenspace dimensions "
        f"{dims}, Krein form zero on them: {largest < 1e-9}")
```

Three momenta with an extra-time component k_5 at $m = 1$: $w^2 = 1 - 4 = -3$, $w^2 = 1 + 1 - 4 = -2$ and $w^2 = 1 - 1 = 0$. For $w^2 < 0$ the frequencies are $\pm i\sqrt{-w^2}$ (`1j * np.sqrt(-w2)`) and both eigenspaces are computed; for $w^2 = 0$ the eigenspace of 0 is computed and $h^2 = 0$ is checked. `largest` is the largest absolute entry of $V^\dagger B V$ over the eigenspaces; **Krein-neutral** means that it vanishes. The check requires the dimension 8 everywhere and `largest` below 10^{-9}.

```
reproduces(neutral_ok, "imaginary and zero frequencies: eigenspaces of dimension 8 "
           "are Krein-neutral",
           (PY, ["Q.one_particle_complex_frequency_Krein_neutral"]),
           (WL, ["Q_one_particle_complex_and_zero_frequencies_Krein_neutral"]))
```

Out [17] prints the three cases (eigenspace dimensions [8, 8], [8, 8] and [8]; Krein form zero on them: True) and the PASS line, with the checks `Q.one_particle_complex_frequency_Krein_neutral` and `Q_one_particle_complex_and_zero_frequencies_Krein_neutral`. These are the growing extra-time waves: they carry no Krein norm at all (Section 18.23).

In [18], Figure 18c.6: the mapped spectra of plane waves.

```
ks = np.linspace(0.0, 3.0, 121)
curves = {}
```

```
for label, mass in (("plus", 1.0), ("minus", -1.0)):
    for axis in (1, 5):
        rows = []
        for kv in ks:
            k = np.zeros(8)
            k[axis] = kv
            rows.append(spectrum(h_matrix(mass, k)))
        curves[label, axis] = np.array(rows)
away = np.abs(ks - 1.0) > 0.05
equal = max(np.abs(curves["plus", axis][away] - curves["minus", axis][away]).max()
            for axis in (1, 5))
check(equal < 1e-6, "the plane-wave spectra of the masses +1 and -1 are equal")
```

The cell uses 121 momenta from 0 to 3. For the masses $+1$ and -1, and for a momentum along x_1 (`axis = 1`) or along x_5 (`axis = 5`), the 16 sorted eigenvalues of $h_m(k)$ are stored. `away` excludes the momenta within 0.05 of $k = 1$: there the extra-time wave has $w = 0$ and $h^2 = 0$, and the eigenvalues of such a matrix are very sensitive to rounding (a change of its entries by 10^{-16} can move them by about 10^{-8}, the square root). The check requires the two spectra to agree to 10^{-6} at all other momenta.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2))
for ax, axis, name in ((axes[0], 1, "3-space momentum $k_1$"),
                       (axes[1], 5, "extra-time momentum $k_5$")):
    ax.plot(ks, np.sqrt(np.clip(1.0 + (ks ** 2 if axis == 1 else -ks ** 2), 0, None)),
            color="#2a78d6", label="real part, mass $+1$")
    ax.plot(ks, np.sqrt(np.clip(-1.0 + (ks ** 2 if axis == 5 else -ks ** 2), 0,
                                None)), color="#eb6834",
            label="imaginary part, mass $+1$")
    dots = curves["minus", axis]
    ax.plot(ks[::5], np.abs(dots.real).max(axis=1)[::5], "o", color="#2a78d6",
            markersize=3.5, alpha=0.6, label="mass $-1$ (dots)")
    ax.plot(ks[::5], np.abs(dots.imag).max(axis=1)[::5], "o", color="#eb6834",
            markersize=3.5, alpha=0.6)
    ax.set_xlabel(name + " (units $m$)")
    ax.set_ylim(-0.1, 3.3)
axes[0].set_ylabel("frequency $|w|$: real and imaginary parts")
axes[0].legend(fontsize=8, loc="upper left")
```

Two panels. The lines are the exact formulas for the mass $+1$: the real part $\sqrt{1 + k_1^2}$ (left) or $\sqrt{1 - k_5^2}$ (right, where it exists) and the imaginary part, zero on the left and $\sqrt{k_5^2 - 1}$ on the right for $k_5 > 1$; `np.clip(x, 0, None)` replaces negative numbers by 0 before the square root. The dots are the largest absolute real part and the largest absolute imaginary part of the computed eigenvalues for the mass -1, at every fifth momentum.

```
save_figure(fig, "flat_dispersion",
            "Mapped spectra of plane waves in flat 4+4 space: the frequencies, the "
            "eigenvalues of the one-particle matrix $h_m(k)$, for the mass $+1$ "
            "(lines) and $-1$ (dots), against a 3-space momentum $k_1$ (left) and "
            "an extra-time momentum $k_5$ (right), in units of the mass. Blue: "
            "the real part $\\sqrt{1 + k_1^2}$ or $\\sqrt{1 - k_5^2}$; orange: the "
```

```
        "imaginary part, which appears when the extra-time momentum exceeds the "
        "mass (a growing mode). Each value is 8-fold, with both signs. The "
        "dots lie on the lines: the universes of mass $+m$ and $-m$ have the "
        "same one-particle spectrum, because $\\Gamma h_m\\Gamma = h_{-m}$.")
```

What you see in Figure 18c.6: on the left the frequency rises from 1 along $\sqrt{1+k_1^2}$ and the imaginary part stays zero; on the right the real part falls from 1 to 0 at $k_5 = 1$ and from there the imaginary part rises along $\sqrt{k_5^2 - 1}$, a growing wave whose growth rate increases without limit as k_5 grows. The dots of the mass -1 lie on the lines of the mass $+1$ everywhere: the universes of masses $+m$ and $-m$ have the same one-particle spectrum (Q4), because $\Gamma h_m \Gamma = h_{-m}$.

In [19], the Krein norms of single modes.

```
row = samples[0]
k = np.array(row["k"], dtype=float)
w = 5.0
h = h_matrix(row["m"], k)
columns, freqs = [], []
for value in (w, -w):
    V = eigenspace(h, value)
    ev, U = np.linalg.eigh(V.conj().T @ B @ V)  # diagonalise the Krein form
    for j in np.argsort(-ev):  # positive norms first
        u = V @ U[:, j] / np.sqrt(abs(ev[j]))  # Krein norm +1 or -1
        columns.append(u)
        freqs.append(value)
```

The first recorded sample, $m = 2$, $k = (k_0, \ldots, k_7) = (4, 1, 2, 0, 0, 0, 0, 0)$, with $w = \sqrt{4 + 16 + 1 + 4} = 5$. For each of the two eigenspaces ($+5$ and -5), `V` holds 8 orthonormal columns. The Krein form on the eigenspace is the 8×8 Hermitian matrix $V^\dagger B V$; `np.linalg.eigh` returns its eigenvalues `ev` and an orthonormal set of eigenvectors, the columns of `U`. The loop takes them in the order of decreasing eigenvalue (`np.argsort(-ev)`) and forms $u = VU_j/\sqrt{|\epsilon_j|}$, where U_j is column j of `U` and ϵ_j its eigenvalue. Its Krein norm is

$$u^\dagger B u = \frac{U_j^\dagger (V^\dagger B V) U_j}{|\epsilon_j|} = \frac{\epsilon_j U_j^\dagger U_j}{|\epsilon_j|} = \pm 1.$$

The first step inserts u; the second uses $(V^\dagger B V)U_j = \epsilon_j U_j$; the last uses $U_j^\dagger U_j = 1$. So the 16 columns have the Krein norms $+1$ or -1, and `freqs` records the frequency of each.

```
norms = np.array([(u.conj() @ B @ u).real for u in columns])
norms_G = np.array([((Gamma @ u).conj() @ B @ (Gamma @ u)).real for u in columns])
norms_0 = np.array([((gamma[0] @ u).conj() @ B @ (gamma[0] @ u)).real
                    for u in columns])
eig_G = all(np.allclose(h_matrix(-row["m"], k) @ (Gamma @ u), f * (Gamma @ u))
            for u, f in zip(columns, freqs))
eig_0 = all(np.allclose(h_matrix(-row["m"], R0 * k) @ (gamma[0] @ u),
                        f * (gamma[0] @ u)) for u, f in zip(columns, freqs))
say("Krein norms of the 16 columns: " + " ".join(f"{x:+.0f}" for x in norms))
reproduces(eig_G and eig_0 and np.allclose(norms_G, -norms)
```

```
          and np.allclose(norms_0, norms) and int((norms > 0).sum()) == 8,
          "Gamma u: eigenvector of h_-m, Krein norm reversed; gamma^(x0) u: kept",
          (WL, ["Q_Krein_metric_of_images"]),
          (PY, ["Q.image_krein_metric", "Q.T2_image_keeps_B"]))
```

`norms`, `norms_G` and `norms_0` are the Krein norms of u, of Γu and of $\gamma^{(x_0)}u$. `eig_G` checks that Γu is an eigenvector of $h_{-m}(k)$ with the same frequency, and `eig_0` that $\gamma^{(x_0)}u$ is one of $h_{-m}(R_0 k)$ (the maps of Q4). The check requires these, $(\Gamma u)^\dagger B(\Gamma u) = -u^\dagger B u$, $(\gamma^{(x_0)}u)^\dagger B(\gamma^{(x_0)}u) = u^\dagger B u$, and eight positive norms among the sixteen. Why the norms behave so: $(Mu)^\dagger B(Mu) = u^\dagger M^\dagger B M u$, and for the real symmetric matrices $M = \Gamma$ and $M = \gamma^{(x_0)}$ Lemma 4 gives $M^\dagger B M = M B M^\dagger = \sigma_M B$ with $\sigma_\Gamma = -1$ and $\sigma_{\gamma^{(x_0)}} = +1$ (Exercise 18.6). Out [19] prints the norms $+1, +1, +1, +1, -1, -1, -1, -1$ twice, once for each eigenspace, and the PASS line.

In [20], Figure 18c.7: the Krein norms as bars.

```
fig, ax = plt.subplots(figsize=(10.0, 4.2))
idx = np.arange(16)
ax.bar(idx - 0.27, norms, width=0.27, color="#2a78d6", label="$u^\\dagger Bu$")
ax.bar(idx, norms_G, width=0.27, color="#eb6834",
       label="$(\\Gamma u)^\\dagger B(\\Gamma u)$: T1 image")
ax.bar(idx + 0.27, norms_0, width=0.27, color="#1baf7a",
       label="$(\\gamma^{(x_0)}u)^\\dagger B(\\gamma^{(x_0)}u)$: T2 image")
ax.axvline(7.5, color="#52514e", linewidth=0.8)
ax.text(3.5, 1.35, "frequency $+5$", ha="center", fontsize=9)
ax.text(11.5, 1.35, "frequency $-5$", ha="center", fontsize=9)
ax.set_xticks(idx, [str(j + 1) for j in idx])
ax.set_xlabel("column number $j$ (eight per eigenspace)")
ax.set_ylabel("Krein norm")
ax.set_ylim(-1.6, 1.6)
ax.legend(fontsize=8, loc="lower left", ncol=3)
```

Three bars per column: the norm of u (blue, shifted left by 0.27), of Γu (orange, in the middle) and of $\gamma^{(x_0)}u$ (green, shifted right). A thin vertical line separates the two eigenspaces and two labels name their frequencies; `set_xticks` labels the columns 1 to 16.

```
save_figure(fig, "krein_norms",
            "Krein norms of plane-wave eigenvectors and of their images, for the "
            "recorded sample $m = 2$, $k = (1, 2, 0, 0, 0, 0, 0, 4)$, frequency "
            "$w = \\pm5$. Horizontal axis: the 16 eigenvector columns $u$, eight "
            "for $+5$ and eight for $-5$; vertical axis: the Krein norm. Blue: "
            "$u^\\dagger Bu$, four $+1$ and four $-1$ in each eigenspace (Krein "
            "inertia (4,4)). Orange: the chirality image $\\Gamma u$, an "
            "eigenvector of the mass $-m$ with every norm reversed. Green: the "
            "mirror image $\\gamma^{(x_0)}u$, an eigenvector of the mass $-m$ with "
            "every norm kept. This is the quantum reading Q at the level of single "
            "modes.")
```

What you see in Figure 18c.7: in each eigenspace four blue bars at $+1$ and four at -1 (the Krein inertia (4,4)); every orange bar points the other way; every green bar equals its blue bar. The chirality image (T1) of a mode with a positive Krein norm is a mode of the mass $-m$ with

a negative norm; the mirror image (T2) keeps the norm. This is Q1 and Q5 at the level of single modes.

In [21], the last check.

```
figure_names = ["rk4_convergence", "partner_components", "t1_pair_densities",
                "t2_mirror_densities", "family_spectrum", "flat_dispersion",
                "krein_norms"]
paths = [output_file(f"{FIGURE_FOLDER}/18c_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

The seven figure files must exist; the last line is ALL 21 CHECKS PASSED (notebook 18c).

What Notebook 18c established. The following results are COMPUTED for one homogeneous solution of the commuting field dirac16complex00, with the illustrative values ($m = 1$, $H = 0.2$, $\lambda = 0.3$, $z_0 = \pi/4$, seed 2026) along the canonical deflating history $a_4 = AHx_4$ ($A = 1$, from the Revision record): the Runge-Kutta solution equals the exact solution of the theory record to 4.3×10^{-9} (fourth order measured); its charge density obeys the local conservation law, with a nonzero flow through the brane, so the charge of the patch is not constant; the T1 partner, solved on its own, is $\Gamma\Psi$, with opposite charge density, current and energy-momentum tensor at every time, while the wrong partner $(-m, +\lambda)$ is not; the T2 partner on the mirror patch is $\gamma^{(x_0)}\Psi$, with S reversed and EQUAL charge and energy densities; the generators of the field and of both partners have equal spectra; and for plane waves the eight recorded samples of Q are reproduced, the growing waves are Krein-neutral, Γ reverses every Krein norm and $\gamma^{(x_0)}$ keeps it. ASSUMED: the mirror patch glued at the degenerate brane, and a fixed gravitational field. NOT shown: any process that creates a universe or a pair. The partners are solutions of OTHER parameter sets, computed from the first one; nothing in these equations makes them appear.

18.28 What the pairing theorems do not establish

T1, T2 and Q are exact. Their content is precisely this: explicit invertible maps between the solutions of two theories with different parameters, with stated signs for the Lagrangian, the energy-momentum tensor, the current and the canonical anticommutator. Both Revision verifiers wrote, independently of each other, a list of what these theorems do NOT establish, and a comparison check confirms that the two lists cover the same topics (`python-pairing.json`, check `compare.theory.not_established`; the lists are the entries `not_established` of `pairing-theory.json` and of `python-pairing.json`). Merged, with the reason for each item:

1. **No creation process.** The theorems map solutions to solutions and quantities to quantities. Nothing in these equations produces a universe, a pair of universes, or a change of the number of universes; no transition from "no universe" to "two universes", no initial state, no vacuum decay (the change of a state without particles into one of lower energy) and no tunnelling process (a quantum transition through a region that the classical equations forbid) is derived.
2. **No rate, probability or amplitude.** No transition amplitude, probability, cross-section (a measure, with the units of an area, of how likely a reaction is), rate or Bogoliubov coefficient

(the number that says how many particles a changing background creates from a vacuum) for creating universes of masses $+m$ and $-m$ is computed or implied; no wave function of the universe (a quantum state of a whole universe, geometry included) and no path integral (a sum over every possible history of the fields) is part of the theorems.

3. **No dynamical necessity.** No equation and no conservation law forces the partner to exist. A single universe of mass $+m$ is an equally valid solution without its partner. T1 and T2 are correspondences between the solutions of two parameter sets, not a mechanism.

4. **T1 is not a symmetry of one theory, and for $\lambda \neq 0$ it is not a pure $+m$ / $-m$ pairing.** It changes the parameters to $(-m, -\lambda)$ and the sign of the action. The pairing $(m, \lambda) \to (-m, \lambda)$ at fixed coupling is T2, at EQUAL, not opposite, energy-momentum.

5. **The zero total of a T1 pair has a limited meaning.** $T + T' = 0$, $J + J' = 0$ and $Q + Q' = 0$ hold for classical bilinears (a configuration and its image) and as an operator identity within ONE quantum system (Q2). They do not hold for two independently quantised universes, whose generators add without cancelling (Q3).

6. **Test field only.** The gravitational field is fixed and the same for both members. The back-reaction through the field equations for a_4 is not part of the theorems. The only statement about it is the corollary C1 of Chapter 20: a T1 pair taken as the complete classical source of the author's metric is a zero source, and the Einstein equations then have no solution for $H > 0$. That is a statement about sources in one common geometry, not a derivation that the geometry, or the pair, is created.

7. **The Z2 brane is assumed.** The mirror across $z = \pi/2$ uses the ASSUMED Z2 construction; the metric is degenerate there ($g_{00} = 0$ and $\sqrt{|g|} = 0$), and no junction condition, brane tension or matching of the field across the brane is derived.

8. **Quantum positivity is not established.** Every real-frequency eigenspace of the one-particle matrix has the Krein inertia (4,4), and the growing waves are Krein-neutral (Q4); a positive-norm Fock space for either universe is not established by these theorems.

9. **dirac16complex00 is a classical field**: no quantum statement is made for it.

10. **The Kohn-Sham level is separate.** Theorem T3 is proved in Chapter 19 with its own hypotheses (the ASSUMED Z2 brane, instantaneous mean-field Kohn-Sham states); nothing in this chapter establishes it.

The author's hypothesis. The statement that the big bang CREATES universes in pairs of masses $+m$ and $-m$ is the author's HYPOTHESIS. This chapter proves that the solutions come in partnered families (T1 and T2) and how a quantised partner must be read (Q); it does not prove, and the equations of this book cannot prove, that any universe is created, in pairs or otherwise. Chapter 20 takes up the question "Do universes come in pairs?" and states the hypothesis as a hypothesis.

Matter and antimatter. Where this chapter touches matter and antimatter, the exact statements are these. PROVED: the theory has an exact U(1) symmetry, and its current obeys the exact LOCAL conservation law $\partial_\mu(\cos z\, J^\mu) = 0$ on shell (`charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity`; Notebook 18c checks the local law along its solution in In [10], with the frame current q_0). The charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, d^7x$ of a slice $x_4 = \text{const}$ is constant only if

no charge flows through the boundary of the patch, that is through the brane $z = \pi/2$. There the flow $\sqrt{|g|}J^{x_0} = \sin z\,(-i\bar{\Psi}\gamma^{(x_0)}\Psi)$ does not vanish in general (`python-scope.json`, check `good_sector_hermiticity_up_to_the_brane_flux`: the boundary term vanishes at the tip $z \to 0$ but not at $z = \pi/2$). The homogeneous solutions of Section 18.21 exchange charge through the brane: their patch charge changes at the rate $-V_6 q_0$, and Notebook 18c prints q_0 between -0.3454 and 0.3454 (Out [10]; the oscillating charge density of Figure 18c.3); the T2 mirror partner has the equal charge density, so gluing the two patches does not restore a constant total. Hence the statement "no net charge can be generated inside one universe" holds only under a **no-flux condition at the brane**, $\sqrt{|g|}J^{x_0} = 0$ at $z = \pi/2$; that condition is ASSUMED where it is used, and deriving it is OPEN: it belongs to the junction condition at the brane, which is not derived (item 7). A T1 partner carries the opposite charge, so a T1 pair has total charge zero as classical bilinears (T1d); this is a universe and anti-universe statement about solutions. Such ideas form a class in the published literature; one example is L. Boyle, K. Finn and N. Turok, "CPT-Symmetric Universe", Phys. Rev. Lett. 121, 251301 (2018); it is cited only as an example of the class, and nothing in this chapter is taken from it. On real fields T1 is the mass-reversing charge conjugation by the matrix Γ (Section 18.13). The theory as built does NOT solve the matter-antimatter problem. In 1967 Sakharov showed that an excess of matter can grow from an equal start only if three conditions hold: a process that changes the baryon number, a violation of the symmetries C and CP, and a departure from thermal equilibrium (Chapter 21). The theory as built has no baryons, no process that changes the baryon number (its U(1) current is conserved locally, and globally under the no-flux condition at the brane), no violation of CP built in or computed, and no computation of a departure from thermal equilibrium. To solve the problem it would need all of these, and a computed excess of matter that agrees with the measured one. Every scenario in which our universe is one member of such a pair, or in which the pairing explains the excess of matter, is a HYPOTHESIS. Chapter 21 treats matter and antimatter from zero.

18.29 What we proved, what we computed, what we assumed

Proved. Exactly, for both fields unless something else is said, each with the Revision record that verifies it and the notebook of this chapter that reproduces it:

statement	**where it is verified**	**notebook**
the gammas of the record are the author's eight real 16×16 signed permutation matrices, rebuilt from their formulas	`python-pairing.json`, check `gammas.equal_wolfram_fixture`	18a
$\sqrt{\|g\|} = \cos z$; the 12 components of the canonical spin connection; $\gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ for every history a_4 (the deflation terms cancel), $-3H\gamma^{(x_0)}$ on the mirror patch	`wolfram-pairing.json`, check `primordial_vielbein`; `python-pairing.json`, check `geometry.spin_connection_components`; `python-field-theory.json`, checks `gamma_mu_Omega_mu_equals_3H_gamma_x0` and `divergence_of_sqrtg_gamma`	18b, 18c

statement	where it is verified	notebook
with a changing $b_4(x_4)$: $\sqrt{\lvert g\rvert} = b_4^{3/2}\cos z$ and $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)} + \frac{3}{4}(b_4'/b_4)\gamma^{(x_4)}$	`wolfram-field-theory-b4.json`, checks `sqrt_det_g` and `gammaOmega_total`; `python-field-theory-b4.json`, check `gammaOmega_total`	Chapter 7 (07b)
Lemma 1: Γ real, symmetric, $\Gamma\Gamma = 1$, anticommuting with every gamma, commuting with C and every S^{ab}	`wolfram-pairing.json`, check `Gamma_properties`; `python-pairing.json`, checks `gammas.Gamma` and `gammas.Gamma_anticommutes`	18a
Lemma 2: $\bar\Psi X\Psi \to (-1)^k\bar\Psi X\Psi$ under $\Psi\to\Gamma\Psi$; $\Gamma B\Gamma = -B$	`wolfram-pairing.json`, checks `T1_kernel_scalar`, `T1_kernel_kinetic`, `T1_kernel_connection` and `T1_kernel_field_equation`; `python-pairing.json`, checks `T1.general_field.matrix_identities` and `Q.image_krein_metric`	18a
Lemma 3: the eight reflections P_n in Pin(4,4), their characters $-\eta_{nn}$, the reflection table	`wolfram-pairing.json`, checks `T2_Pn_in_Pin44`, `T2_Pn_covers_the_reflection`, `T2_character_of_Pn` and `T2_Gamma_times_Pn_is_gamma_n`; `python-pairing.json`, checks `T2.general_field.reflection_table` and `compare.theory.reflection_table`	18a
Lemma 4: the 17 Krein signs	`wolfram-pairing.json`, check `Q_Krein_metric_of_images`; `python-pairing.json`, check `compare.theory.krein_signs`	18a
T1 (T1a to T1d), in every gravitational field taken as a fixed background, both statistics	`wolfram-pairing.json`, the 51 checks of T1; `python-pairing.json`, the 23 checks whose names begin with `T1.`, and `compare.theory.theorem_T1`	18b, 18c
T2 (T2a to T2d); the author's-field version under the ASSUMED Z2 construction	`wolfram-pairing.json`, the 28 checks of T2; `python-pairing.json`, the 16 checks of T2 and `compare.theory.theorem_T2`	18b, 18c

statement	where it is verified	notebook
Q1 to Q5, for the canonically quantised dirac16complex	`wolfram-pairing.json`, the 12 checks whose names begin with `Q_`; `python-pairing.json`, the 10 checks whose names begin with `Q.`, and `compare.theory.theorem_Q`	18a, 18c
the homogeneous solutions: S constant, $M^2 = (9H^2 - (m+\lambda S)^2) I_{16}$, the exact formula; $\rho = mS + \frac{\lambda}{2}S^2$, every pressure $\frac{\lambda}{2}S^2$, $T_{x_4 x_0} = 0$; the LOCAL conservation law of the charge, $dJ^{x_4}/dx_4 = -6Hq_0$ with $q_0 = -i\bar{\Psi}\gamma^{(x_0)}\Psi$ (for these solutions the flow $\sin z\, q_0$ through the brane does not vanish, so the charge of the patch is not constant)	`python-field-theory.json`, checks `exact_nonlinear_homogeneous_solution`, `commuting_homogeneous_on_shell_rho_p`, `commuting_T_x4x0_homogeneous` and `commuting_current_conservation`; `wolfram-field-theory.json`, check `exact_solution_nonlinear_homogeneous_C`	18c
the two charge-conjugation matrices $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$; on real fields T1 is the mass-reversing conjugation by Γ; the exact U(1) symmetry and its LOCAL conservation law $\partial_\mu(\cos z\, J^\mu) = 0$ (a constant total charge needs the no-flux condition at the brane, listed under Assumed and Open)	`charge-conjugation-and-u1.json`, checks `intertwiners_same_mass`, `intertwiners_reversed_mass`, `charge_conjugation_matrix_plus`, `charge_conjugation_matrix_minus`, `real_fields_charge_conjugation` and `u1_noether_matrix_identity`	none (Chapters 5 and 21)

Computed. Numerical results of the notebooks, with their accuracy:

- Notebook 18a: every result is exact whole-number arithmetic, except the illustration of In [7], where Γ commutes with a random connection to below 10^{-12}.
- Notebook 18b: every result is exact (sympy). The monomial counts, evaluated at one sample point, are 408 (commuting) and 392 (Grassmann) for the Lagrangian, equal to the counts recorded by the Wolfram verifier, and 376 (diagonal) or 64 and 80 (off-diagonal) for the components of $T_{\mu\nu}$; they describe the size of the polynomials and prove nothing.
- Notebook 18c (illustrative values $m = 1$, $H = 0.2$, $\lambda = 0.3$, $z_0 = \pi/4$, seed 2026; history $A = 1$ from the record): $S = 0.897319$, $m + \lambda S = 1.269196$, $w = 1.118417$; Runge-Kutta errors at $x_4 = 20$ for 250 to 4000 steps from 2.0×10^{-5} to 2.6×10^{-10}, measured orders 4.10, 4.06, 4.03 and 4.01, largest error with 2000 steps 4.3×10^{-9} against the exact formula of the record; the T1 partner equals $\Gamma\Psi$ and the T2 partner equals $\gamma^{(x_0)}\Psi$ to below 10^{-12} at all 2001 times, while the wrong partner $(-m, +\lambda)$ is off by 1.641; S, J^μ and $T_{\mu\nu}$ of the partners as predicted,

to a relative 10^{-12} at 101 sampled times; the local conservation law $dJ^{x_4}/dx_4 = -6Hq_0$ to 10^{-12} at the same times, with the frame current q_0 between -0.3454 and 0.3454, so a nonzero flow through the brane; the eight plane-wave samples of the record reproduced (dimensions 8 and 8, Krein inertia (4,4)); the plane-wave spectra of the masses ± 1 equal to 10^{-6} at 121 momenta (away from $k_5 = 1$); the Krein norms ± 1 of the 16 modes of the first sample reversed by Γ and kept by $\gamma^{(x_0)}$.

Assumed.

- The gravitational field is a fixed background (a test field) in every theorem of this chapter: it is not varied, and both members of a pair live in the same field.
- The Z2 mirror construction: gluing the mirror patch to the patch at the degenerate brane $z = \pi/2$; it enters T2 in the author's field, the mirror universe of Q5 and the mirror partner of Notebook 18c (`pairing-theory.json`, theorem T2, its hypothesis on the primordial field).
- For Q: the canonical quantisation of dirac16complex with x_4 as the time and with anticommutators (part of its definition as a fermion field); flat 4+4 space, or frozen coefficients at one point, for the one-particle statements.
- The history $a_4 = AHx_4$ with $A = 1$ used in the figures is the PRESCRIBED BACKGROUND of the Revision Kohn-Sham record (`parameters.json`; `ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`). The theorems themselves hold for every history.
- The value $3H\gamma^{(x_0)}$ of $\gamma^\mu \Omega_\mu$ belongs to the diagonal vielbein (`python-scope.json`; Chapter 8); none of the theorems depends on it.
- The background $b_4 = 1$ of the author's metric of 2026-10-14, in every statement about the author's field and in all three notebooks. T1 and the general-field version of T2 hold for every vielbein, so for any $b_4(x_4)$ as well (Sections 18.3, 18.16 and 18.21).
- The illustrative values of Notebook 18c.
- Wherever a constant total charge of one universe is used (the statement that no net charge can be generated inside one universe): the no-flux condition $\sqrt{|g|}J^{x_0} = 0$ at the brane $z = \pi/2$. It is not derived (see Open).

Hypothesis.

- That the big bang creates universes in pairs of masses $+m$ and $-m$: the author's HYPOTHESIS, not derived from any equation of this book.
- That our universe has an anti-universe partner, or that the pairing explains the observed excess of matter over antimatter.

Open.

- Any creation process, rate or amplitude for universes, which these equations do not contain.

- The gravitational back-reaction of a pair: the pair as part of the source of the field equations for a_4 (C1 treats only the case in which a T1 pair is the complete source).
- A junction condition at the brane $z = \pi/2$ that would replace the assumed Z2 construction.
- The no-flux condition $\sqrt{|g|}J^{x_0} = 0$ at the brane, which a constant total charge of one universe needs; the homogeneous solutions of Section 18.21 violate it (Notebook 18c, Out [10]), and no equation of this book imposes it.
- A positive Hilbert space for the whole quantised field (all momenta, the curved metric), and the fate of the growing extra-time waves.

18.30 Exercises

Exercise 18.1. The factors of Γ are $\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}\gamma^{(x_4)}\gamma^{(x_5)}\gamma^{(x_6)}\gamma^{(x_7)}$, in this order. Use Rule P (Section 18.5) to write $P_n = \Gamma\gamma^{(n)}$ as a sign times the product of the seven other gammas in the order of Γ, for $n = x_1$, x_4, x_5 and x_0. Find the general rule for the sign and check it against all eight signs $-1, +1, -1, +1, +1, -1, +1, -1$ of the record.

Exercise 18.2. Notebook 18c has $S = 0.897319$, $m = 1$ and $\lambda = 0.3$ (Out [4]). For homogeneous solutions the record gives $\rho = mS + \frac{\lambda}{2}S^2$ and $p = \frac{\lambda}{2}S^2$ in every direction. (a) Compute ρ, p and the equation of state $w = p/\rho$ of the solution, and compare w with the formula $w = \lambda S/(2m + \lambda S)$ of the record. (b) The same for the T1 partner ($-m$, $-\lambda$, the same S). (c) The same for the T2 partner ($-m$, λ, the scalar $-S$). (d) Add the energy densities of each pair.

Exercise 18.3. (a) With $m + \lambda S = 1.269196$ and $3H = 0.6$, compute the frequency w of the solution of Notebook 18c, the period of the field and the period of its charge density J^{x_4}, and the number of oscillations of J^{x_4} between $x_4 = 0$ and 20 (Figure 18c.3). (b) Compute the coefficient V, the frequency and the period of the wrong partner $(-m, +\lambda)$ started from $\Gamma\Psi(0)$ (Figure 18c.2). (c) For which masses m (at the same λ and S) do the homogeneous solutions grow instead of oscillating, and what is the largest growth rate (Figure 18c.5)?

Exercise 18.4. (a) From $C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T$ show that $(S^{ab})^T C = -CS^{ab}$ for $a \neq b$. (b) Conclude that $\Omega_\mu^T C = -C\Omega_\mu$ for every real connection, and that $D_\mu\bar{\Psi} = (D_\mu\Psi)^\dagger C$, the formula used by Notebook 18c in In [9].

Exercise 18.5. Show that $Bh_m(k) = h_m(k)^\dagger B$ for real m and real momenta k, with $h_m(k) = -im\gamma^{(x_4)} - \gamma^{(x_4)}K$, $K = \sum_{a\neq 4} k_a\gamma^{(a)}$ and $B = -iC\gamma^{(x_4)}$. Use only the reality of the gammas, $(\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$, the Clifford relation and $C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T$.

Exercise 18.6. Let $h_m(k)u = wu$ with a real w and the Krein norm $u^\dagger Bu = 1$. (a) Show that Γu is an eigenvector of $h_{-m}(k)$ with the same w and the Krein norm -1. (b) Show that $\gamma^{(x_0)}u$ is an eigenvector of $h_{-m}(R_0 k)$ with the same w and the Krein norm $+1$. (c) Which bars of Figure 18c.7 show (a) and (b)?

Exercise 18.7. Write $\mathcal{L}_{m,\lambda}[\Psi] = \sqrt{|g|}\,[K - mS - \frac{\lambda}{2}S^2]$. (a) Compute $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{m,\lambda}[\Psi]$, $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,\lambda}[\Psi]$ and $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,-\lambda}[\Psi]$. (b) Which terms survive in each, and which bars of Figure 18b.2 show it? (c) For which λ is T1 a pure $+m$ / $-m$ pairing?

Exercise 18.8. (a) Compute $\sin^{1/6} z$, f_0 and $\sqrt{|g|}$ at $z = \pi/4$ on the patch and at $z = 3\pi/4$ on the mirror patch, and check that the metric takes the same values at the two points. (b) Use the

divergence form of Section 18.27 to compute the coefficient of $\gamma^{(x_0)}$ in $\gamma^\mu\Omega_\mu$ on the mirror patch, with $H = 0.2$. (c) Pull the hidden leg $e^0 = f_0\,dx_0$ of the mirror patch back by ϕ: $x_0 \to \pi/(6H) - x_0$, and say which frame reflection results.

Exercise 18.9. A student writes: "Theorem T1 proves that the big bang creates every universe of mass m together with a universe of mass $-m$: the two have opposite energies, so the pair costs no energy, and nothing forbids it." Name every step of this sentence that the equations of this book do not establish, and say what they do establish instead.

18.31 Answers to the exercises

Answer 18.1. Write $\gamma^{(a)}$ as γ_a for short. For $n = x_1$: $\Gamma\gamma_1 = \gamma_0\gamma_1\gamma_2\gamma_3\gamma_4\gamma_5\gamma_6\gamma_7\gamma_1$. Move the last γ_1 to the left past $\gamma_7, \gamma_6, \gamma_5, \gamma_4, \gamma_3, \gamma_2$: six different gammas, each exchange costs -1 (Rule P), so the sign is $(-1)^6 = +1$, and $\Gamma\gamma_1 = \gamma_0\gamma_1\gamma_1\gamma_2\gamma_3\gamma_4\gamma_5\gamma_6\gamma_7$. Then $\gamma_1\gamma_1 = \eta_{11} = +1$ (Clifford relation): $P_{x_1} = +\gamma_0\gamma_2\gamma_3\gamma_4\gamma_5\gamma_6\gamma_7$, sign $+1$. For $n = x_4$: three exchanges (past $\gamma_7, \gamma_6, \gamma_5$), $(-1)^3 = -1$, then $\gamma_4\gamma_4 = \eta_{44} = -1$: the sign is $(-1)(-1) = +1$. For $n = x_5$: two exchanges, $(+1)$, then $\eta_{55} = -1$: the sign is -1. For $n = x_0$: seven exchanges (past $\gamma_7, \dots, \gamma_1$), $(-1)^7 = -1$, then $\eta_{00} = +1$: the sign is -1, $P_{x_0} = -\gamma_1\gamma_2\cdots\gamma_7$. General rule: the sign is $(-1)^{N_n}\eta_{nn}$, where N_n is the number of factors that stand to the right of $\gamma^{(n)}$ in Γ, $N_n = 7 - n$. With $N = 7, 6, 5, 4, 3, 2, 1, 0$ for $x_0, \dots, x_7$ and $\eta = (+1, +1, +1, +1, -1, -1, -1, -1)$: x_0: $(-1)^7 = -1$; x_1: $+1$; x_2: $(-1)^5 = -1$; x_3: $+1$; x_4: $(-1)^3(-1) = +1$; x_5: $(+1)(-1) = -1$; x_6: $(-1)(-1) = +1$; x_7: $(+1)(-1) = -1$. These are the eight signs of the record (data table `reflections` of `pairing-theory.json`; Notebook 18a, Out [12]).

Answer 18.2. $S^2 = 0.897319^2 = 0.805181$. (a) $p = \frac{0.3}{2} \times 0.805181 = 0.120777$; $\rho = 1 \times 0.897319 + 0.120777 = 1.018096$; $w = 0.120777/1.018096 = 0.11863$. The record's formula: $\lambda S/(2m + \lambda S) = 0.269196/2.269196 = 0.11863$, the same, as it must be: dividing p and ρ by $S/2$ gives $w = \lambda S/(2m + \lambda S)$. (b) With $-m$ and $-\lambda$ and the same S: $\rho' = -mS - \frac{\lambda}{2}S^2 = -1.018096$ and $p' = -\frac{\lambda}{2}S^2 = -0.120777$ (for $U = -\frac{\lambda}{2}S^2$, $p' = SU' - U = -\lambda S^2 + \frac{\lambda}{2}S^2$); $w' = p'/\rho' = 0.11863$, the same equation of state, as T1 says (Section 18.13). (c) With $-m$, λ and the scalar $-S$: $\rho'' = (-m)(-S) + \frac{\lambda}{2}(-S)^2 = 1.018096$ and $p'' = \frac{\lambda}{2}S^2 = 0.120777$: equal to those of the solution. (d) $\rho + \rho' = 0$: the T1 pair has zero total energy density as classical bilinears. $\rho + \rho'' = 2.036192$: nothing cancels in a T2 pair.

Answer 18.3. (a) $w^2 = 1.269196^2 - 0.6^2 = 1.610858 - 0.36 = 1.250858$, so $w = 1.11842$ (Out [14] prints 1.118417, computed with the unrounded S). The field oscillates with the period $2\pi/w = 5.618$. $J^{x_4} = \Psi^\dagger B\Psi$ is quadratic in $\Psi = \cos(wx_4)\Psi(0) + \frac{\sin(wx_4)}{w}M\Psi(0)$, so it contains $\cos^2$, $\sin^2$ and $\sin\cos$, which are combinations of 1, $\cos(2wx_4)$ and $\sin(2wx_4)$: its period is $\pi/w = 2.809$, and $20/2.809 = 7.1$, so seven full oscillations, as in Figure 18c.3. (b) $S[\Gamma\Psi] = S$, so $V = -m + \lambda S = -1 + 0.269196 = -0.730804$; $w^2 = 0.534075 - 0.36 = 0.174075$, $w = 0.41722$, period $2\pi/0.41722 = 15.06$: in Figure 18c.2 the dashed curve completes about $20/15.06 = 1.3$ oscillations. (c) The solutions grow when $(m + \lambda S)^2 < 9H^2$, that is $-0.6 < m + 0.269196 < 0.6$, or $-0.869196 < m < 0.330804$. There $M^2 = (9H^2 - V^2)I_{16}$ is positive, the eigenvalues are $\pm\kappa$ with $\kappa = \sqrt{9H^2 - V^2}$, and the largest growth rate is $3H = 0.6$, at $V = 0$, that is $m = -0.269196$: the top of the arc in Figure 18c.5.

Answer 18.4. (a) The given relation, solved for the transpose: $(\gamma^{(a)})^T = -C\gamma^{(a)}C^{-1}$. For $a \neq b$, $S^{ab} = \frac{1}{2}\gamma^{(a)}\gamma^{(b)}$ and

$$(S^{ab})^T = \tfrac{1}{2}(\gamma^{(b)})^T(\gamma^{(a)})^T = \tfrac{1}{2}\big(-C\gamma^{(b)}C^{-1}\big)\big(-C\gamma^{(a)}C^{-1}\big)$$
$$= \tfrac{1}{2}C\gamma^{(b)}\gamma^{(a)}C^{-1} = -\tfrac{1}{2}C\gamma^{(a)}\gamma^{(b)}C^{-1} = -CS^{ab}C^{-1}.$$

The transpose of a product reverses the order; the two minus signs multiply to $+1$; $C^{-1}C = 1$; two different gammas anticommute. Multiplying on the right by C gives $(S^{ab})^TC = -CS^{ab}$. (b) $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$ with real numbers $\omega_{\mu ab}$; transposing is linear, so $\Omega_\mu^T C = \frac{1}{2}\sum\omega_{\mu ab}(S^{ab})^TC = -C\Omega_\mu$. Then, with C constant and $\Omega_\mu^\dagger = \Omega_\mu^T$ (real),

$$(D_\mu\Psi)^\dagger C = (\partial_\mu\Psi)^\dagger C + \Psi^\dagger\Omega_\mu^T C = \partial_\mu(\Psi^\dagger C) - \Psi^\dagger C\Omega_\mu = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu = D_\mu\bar\Psi.$$

Answer 18.5. Step 1, the adjoint of h. The gammas are real, so $(\gamma^{(a)})^\dagger = (\gamma^{(a)})^T = \eta_{aa}\gamma^{(a)}$; in particular $(\gamma^{(x_4)})^\dagger = -\gamma^{(x_4)}$. Write $\tilde K = K^\dagger = \sum_{a\neq 4}k_a\eta_{aa}\gamma^{(a)}$ (k_a real). With $(XY)^\dagger = Y^\dagger X^\dagger$ and $(-i)^* = i$:

$$h^\dagger = im(\gamma^{(x_4)})^\dagger - K^\dagger(\gamma^{(x_4)})^\dagger = -im\gamma^{(x_4)} + \tilde K\gamma^{(x_4)}.$$

Step 2, two facts about C. From $C\gamma^{(a)}C^{-1} = -(\gamma^{(a)})^T = -\eta_{aa}\gamma^{(a)}$: for $a = 4$ ($\eta_{44} = -1$), C commutes with $\gamma^{(x_4)}$; and summing with the coefficients k_a, $CKC^{-1} = -\tilde K$, that is $CK = -\tilde KC$. Step 3, the two products, using $\gamma^{(x_4)}\gamma^{(x_4)} = -1$:

$$Bh = -iC\gamma^{(x_4)}\big(-im\gamma^{(x_4)} - \gamma^{(x_4)}K\big) = (-i)(-i)m\,C\gamma^{(x_4)}\gamma^{(x_4)} + iC\gamma^{(x_4)}\gamma^{(x_4)}K = mC - iCK,$$

$$h^\dagger B = \big(-im\gamma^{(x_4)} + \tilde K\gamma^{(x_4)}\big)(-iC\gamma^{(x_4)}) = -m\,\gamma^{(x_4)}C\gamma^{(x_4)} - i\tilde K\gamma^{(x_4)}C\gamma^{(x_4)} = mC + i\tilde KC.$$

In the second line $\gamma^{(x_4)}C\gamma^{(x_4)} = C\gamma^{(x_4)}\gamma^{(x_4)} = -C$ (Step 2). By Step 2, $-iCK = i\tilde KC$, so $Bh = h^\dagger B$. (The result $Bh = mC - iCK$ is the energy kernel $\mathcal{E}_m(k)$ of Section 18.23, which the sympy record writes as $m\,C - i\,k_aC\gamma^{(a)}$.)

Answer 18.6. (a) By Q4, $\Gamma h_m(k)\Gamma = h_{-m}(k)$, and $\Gamma\Gamma = 1$, so $h_{-m}(k)\Gamma u = \Gamma h_m(k)\Gamma\Gamma u = \Gamma h_m(k)u = w\,\Gamma u$. The Krein norm: $(\Gamma u)^\dagger B(\Gamma u) = u^\dagger\Gamma^\dagger B\Gamma u = u^\dagger\Gamma B\Gamma u = -u^\dagger Bu = -1$, because Γ is real and symmetric ($\Gamma^\dagger = \Gamma$) and $\Gamma B\Gamma = -B$ (Lemma 2). (b) By Q4, $\gamma^{(x_0)}h_m(k)\gamma^{(x_0)} = h_{-m}(R_0k)$, and $\gamma^{(x_0)}\gamma^{(x_0)} = \eta_{00} = 1$, so $h_{-m}(R_0k)\gamma^{(x_0)}u = \gamma^{(x_0)}h_m(k)u = w\,\gamma^{(x_0)}u$. $\gamma^{(x_0)}$ is real and symmetric (space-like), so $(\gamma^{(x_0)}u)^\dagger B(\gamma^{(x_0)}u) = u^\dagger\gamma^{(x_0)}B\gamma^{(x_0)}u = u^\dagger Bu = 1$ by Lemma 4 ($\sigma_{\gamma^{(x_0)}} = +1$). (c) In Figure 18c.7 every orange bar (Γu) is the blue bar (u) turned upside down, which is (a), and every green bar ($\gamma^{(x_0)}u$) equals the blue bar, which is (b).

Answer 18.7. (a) By T1, $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = \sqrt{|g|}\,[-K - mS - \frac{\lambda}{2}S^2]$ (K reversed, S kept). Adding $\mathcal{L}_{m,\lambda}[\Psi] = \sqrt{|g|}\,[K - mS - \frac{\lambda}{2}S^2]$ gives $-\sqrt{|g|}\,(2mS + \lambda S^2)$. Adding $\mathcal{L}_{-m,\lambda}[\Psi] = \sqrt{|g|}\,[K + mS - \frac{\lambda}{2}S^2]$ gives $-\sqrt{|g|}\,\lambda S^2$. Adding $\mathcal{L}_{-m,-\lambda}[\Psi] = \sqrt{|g|}\,[K + mS + \frac{\lambda}{2}S^2]$ gives 0. (b) In the first sum the kinetic terms cancel and the mass term and the S^2 term survive: the fourth pair of bars of Figure 18b.2. In the second only the S^2 term survives: the fifth pair, the shortest nonzero bars. The third sum is the zero bar of T1. (c) For $\lambda = 0$ the second sum vanishes, and T1 pairs $(m, 0)$ with $(-m, 0)$: a pure $+m$ / $-m$ pairing of free fields.

Answer 18.8. (a) $\sin(\pi/4) = \sin(3\pi/4) = 1/\sqrt{2} = 0.707107$, so $\sin^{1/6} z = 2^{-1/12} = 0.943874$ at both points, and the components $e^{\pm 2a_4} \sin^{1/3} z$ are equal. On the patch $f_0 = \cot(\pi/4) = 1$; on the mirror patch $f_0 = -\cot(3\pi/4) = -(-1) = 1$; so $g_{00} = f_0^2 = 1$ at both. $\sqrt{|g|} = \cos(\pi/4) = 0.707107$ on the patch and $-\cos(3\pi/4) = 0.707107$ on the mirror patch. The metric takes the same values: the mirror is an isometry. (b) On the mirror patch $\sqrt{|g|}/f_0 = (-\cos z)/(-\cot z) = \sin z$, whose derivative along x_0 is $6H \cos z$; divided by $2\sqrt{|g|} = -2\cos z$ this gives $-3H = -0.6$. (c) At the image point the hidden leg is $-\cot(\pi - z)\, d(\frac{\pi}{6H} - x_0) = \cot z\, (-dx_0) = -\cot z\, dx_0 = -e^0$, because $\cot(\pi - z) = -\cot z$ and $d(\text{const} - x_0) = -dx_0$. The other seven legs are unchanged, so the pulled-back frame is the original frame with the direction x_0 reflected, $R_0 e$ (Section 18.16).

Answer 18.9. Step by step. "Theorem T1 proves that the big bang creates": no. T1 maps the solutions of the theory (m, λ) onto those of $(-m, -\lambda)$; no equation of this book describes the creation of a universe, in pairs or otherwise, and no process, rate, probability or amplitude follows (Section 18.28, items 1 and 2). "every universe of mass m together with a universe of mass $-m$": no. A universe of mass m is an equally valid solution without any partner (item 3), and the T1 partner has the coupling $-\lambda$, so for $\lambda \neq 0$ it is not merely a universe of mass $-m$ (item 4). "the two have opposite energies": true for the classical bilinears of a configuration and its image, and as an operator identity within one quantum system (T1c, Q2); false for two independently quantised universes, whose energies add without cancelling (Q3; item 5). "so the pair costs no energy": the theorems contain no energy balance of a creation process; the only statement about the pair as a source of gravity is the corollary C1 of Chapter 20, which says that a T1 pair taken as the complete source of the author's metric is a zero source, for which the Einstein equations have no solution with $H > 0$ (item 6). "and nothing forbids it": not established either way; the equations neither forbid nor produce it. What the equations do establish: the exact maps T1 and T2 between solution sets, with their signs, and the quantum reading Q. That the big bang creates universes in pairs remains the author's HYPOTHESIS.

19 T3: the Kohn-Sham universes of mass $+M$ and $-M$

Chapter 18 proved exact pairing theorems for the fields themselves: multiplied by the chirality matrix Γ, a field configuration of the theory with the mass m and the coupling λ becomes a configuration of the theory with $-m$ and $-\lambda$ (theorem T1). But the numbers that Chapters 15 and 16 computed, the levels, energies, densities and pressures of a gas of quanta of the field dirac16complex in the author's primordial universe, are not field configurations. They are **Kohn-Sham states**: quanta that fill one-quantum levels in a common, self-made mean field, with densities computed by the expectation-value rule of the quantised field, with boundary conditions at the two ends of the hidden direction, at one instant of the history in which ordinary 3-space inflates while the three extra times x_5, x_6, x_7 deflate exponentially. For these states the pairing question must be asked again, and it has a different answer. Theorem **T3** of the Revision record says: every self-consistent Kohn-Sham state of the universe with the bare mass $+M$ has an exact partner in the universe with the bare mass $-M$, with the **same** coupling $+\lambda$ and a transformed boundary condition at the tip, and the partner has the **same** levels, occupations, energies and energy-momentum profiles, while its scalar density is the mirror image. This chapter proves T3 line by line, shows by exact formulas what goes wrong when the boundary condition is not transformed, and watches the theorem at work in two complete notebooks: one that repeats every step of the proof by hand, and one that runs the Revision Rust Kohn-Sham solver 62 times on universes of mass $+M$, their partners and two kinds of wrong partners. Like every pairing theorem of this book, T3 is an exact map between two sets of

solutions; it does not describe the creation of anything, and Section 19.22 says precisely what it does not establish.

19.1 What this chapter does

Why a separate theorem for the Kohn-Sham states. A theorem about a field equation does not automatically carry over to an approximation of it. Three things are new at the Kohn-Sham level. First, the densities that make the mean field are not the classical bilinears of the field but expectation values in the quantised theory, computed with the indefinite matrix B of Chapter 10; the chirality matrix Γ reverses the sign of B, and that sign decides which partner the theorem finds. Second, the Kohn-Sham problem has boundary conditions: the ASSUMED Z2 mirror at the brane $y = 0$ and a chosen condition at the tip $y = -L$; a map of solutions must map the boundary conditions too. Third, a Kohn-Sham state is self-consistent: the mean field is made by the occupied orbitals, so the map must carry the whole loop from densities to potentials to orbitals and back. T3 handles all three, and the answer is the pairing $(m, \lambda, \theta) \to (-m, +\lambda, \pi - \theta)$ at EQUAL energies, not the T1 pairing $(m, \lambda) \to (-m, -\lambda)$ at opposite energies.

What is done, in order.

- The words of the chapter (Section 19.2).
- The Kohn-Sham problem of one orbital: the slice, the hidden coordinate, the eight blocks, the block Hamiltonian, the boundary conditions (Section 19.3); and of the whole gas: the densities, the mean field, the occupations, the energies and the energy-momentum profiles (Section 19.4).
- Why the chirality Γ acts on the blocks as the Pauli matrix σ_2, and what it does to the Krein sign (Section 19.5).
- The proof of T3 in four steps: the orbitals (Section 19.6), the boundary conditions (Section 19.7), the densities and the mean field, with the reason why the coupling must keep its sign (Section 19.8), and self-consistency with the equality of every energy and every energy-momentum profile (Section 19.9).
- The theorem with its hypotheses and its verification records, and its completion of 2026-10-08: the gaps that an adversarial verification found and closed, statement S6 (the 16-component expectation rule: every component of the energy-momentum tensor and of the current is unchanged), and the two numerical demonstrations of the record (Section 19.10); why T3 is not T1, and the mirror copy inside the Z2 orbifold (Section 19.11).
- The exact levels at zero 3-momentum, and the three things that go wrong when the tip is not transformed: the zero modes move to the tip, a level appears inside the mass gap, and the brane band gets a seven times steeper slope (Section 19.12).
- Notebook 19b, the proof by hand (Sections 19.13 to 19.16).
- The four universes A, B, C, D of the Rust runs and Notebook 19a (Sections 19.17 to 19.21).
- What T3 says about pairs of universes and what it does not (Section 19.22), the closing summary (Section 19.23) and exercises with complete answers (Section 19.24).

The two notebooks.

notebook	what it computes	Rust	PASS lines	figures
19b	the gammas and the block map; every step of the proof of T3 in exact sympy algebra; the exact zero-momentum spectra of A, B and the control C; shooting; the brane-band slopes	no	19	6
19a	the gammas and the block map; 62 runs of the Rust Kohn-Sham solver for A, B, C, D with 8, 136 and 688 quanta, along the history, for five couplings and three temperatures; comparison with the record's numerical demonstration of T3	yes	37	10

Notebook 19b is placed first, because it follows the proof step by step; Notebook 19a then shows the theorem in the full self-consistent computation. Each notebook is complete in itself; you may run them in either order.

The status of every statement. Every statement of this chapter carries one of the labels of Chapter 0.

- PROVED: theorem T3 itself, with every step derived line by line in Sections 19.5 to 19.12. In the Revision record T3 is proved by WolframScript (`Revision/pairing/kohn_sham/reports/wolfram-t3.json`, 10 of 10 checks PASS) and by sympy (`Revision/pairing/kohn_sham/reports/python-t3.json`, 13 of 13 checks PASS); the theorem record with its hypotheses, statement, proof and limits is `Revision/pairing/kohn_sham/t3-theory.json`. An adversarial verification (2026-10-08) found no error in the statement or the proof, but gaps in its verification; the **completion** record `Revision/pairing/kohn_sham/t3-completion.json` closes the three exact ones (`Revision/pairing/kohn_sham/reports/wolfram-t3-completion.json`, 3 of 3 checks PASS; `Revision/pairing/kohn_sham/reports/python-t3-completion.json`, 7 of 7): the Kohn-Sham coefficients read from the record in both engines (Section 19.8), the

filling convention carried onto the partner (Section 19.9), and statement S6, the 16-component expectation rule (Section 19.10). The facts about the blocks come from the Kohn-Sham theory reports `Revision/kohn_sham/reports/ks-theory-python.json` (in its present state 58 of 58 checks PASS) and `Revision/kohn_sham/reports/ks-theory-wolfram.json` (46 of 46).

- COMPUTED: every number of the Rust solver and of the notebooks, with its measured difference. The record's two numerical demonstrations of T3 (Section 19.10): `Revision/pairing/kohn_sham/reports/t3-rust-demo.json` (the Rust solver on all 210 states of the canonical matrix, 7 of 7 checks PASS) and `Revision/pairing/kohn_sham/reports/t3-reference-demo.json` (the independent reference solver on 18 states, 7 of 7). The solver's own T3 self-test is the check t3_block_map_solver_selftest of `Revision/kohn_sham/reports/ks-rust-solver.json` (in its present state 42 of 42 checks PASS). All of them are demonstrations, not part of the proof, and the Rust agreement is at the rounding level by construction (Section 19.17).

- ASSUMED: the good sector (no dependence on the extra times); the Z2 mirror construction at the brane $y = 0$; the cut of the hidden direction at the tip $y = -L$ with $L = 3$ and the chosen tip condition (T3 needs its transformed form); the mean field of Hartree plus the exact exchange of the uniform gas, without correlation. CONVENTION: which levels count as particles (the filling convention, Section 19.4); its justification is OPEN.

- PRESCRIBED BACKGROUND: the history $a_4 = AHx_4$ with $A = 1$, on the background $b_4 = 1$ of the author's metric of 2026-10-14 (Chapter 14); the Kohn-Sham states are not an admissible source of the a_4 field equations (`Revision/field_equations_a4/reports/ks-source-conditions.json`, with the checks `ks_profiles_violate_algebraic_condition` and `ks_history_is_a_prescribed_background`).

- OPEN: the time-dependent (non-adiabatic) Kohn-Sham problem; the justification of the filling convention.

- HYPOTHESIS: the author's statement that universes are created in pairs is a HYPOTHESIS. This chapter neither uses it nor proves it.

Notation and units. The author's coordinates are $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates with the scale factor $e^{a_4} \sin^{1/6} z$; x_4 is the time; x_5, x_6, x_7 are the three extra times, which are time-like and deflate exponentially with the scale factor $e^{-a_4} \sin^{1/6} z$ while a_4 grows; x_0 is the hidden space direction, with $z = 6Hx_0$ between 0 and $\pi/2$ and the author's constant $H > 0$. The frame metric is $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in this order, and $\gamma^{(x_a)}$ is the author's real 16×16 gamma matrix of the direction x_a (Chapters 4 and 5), with $\gamma^{(x_a)}\gamma^{(x_b)} + \gamma^{(x_b)}\gamma^{(x_a)} = 2\eta_{ab}$ times the unit matrix. The **universe of mass** $+M$ of the title is the Kohn-Sham problem with the bare mass $m = +M$, the **universe of mass** $-M$ the one with $m = -M$; in all numbers $M = 1$ and $H = 1$, so energies, momenta and temperatures are in units of $|m|$, lengths in units of $1/H$. A state of the record is named like N136_lamp1_a10: $N = 136$ quanta, the coupling $+\lambda_1$ (the tags lam0, lamp1, lamm1, lamp2, lamm2 stand for $\lambda = 0, +\lambda_1, -\lambda_1, +\lambda_2, -\lambda_2$), the slice $a_{4,0} = 1.0$ (the two digits are ten times the slice). The two couplings are fixed per particle number in `Revision/kohn_sham/results/parameters.json` so that the first-order mean field stays below 0.1 and 0.3 along the whole history: for $N = 8$, $\lambda_1 = 0.01946$ and $\lambda_2 = 0.05838$; for $N = 136$, $\lambda_1 = 0.0009298$ and $\lambda_2 = 0.002789$; for $N = 688$, $\lambda_1 = 0.0001846$ and $\lambda_2 = 0.0005538$.

19.2 The words of this chapter

- **Kohn-Sham state**: an approximate state of N identical quanta built from one-quantum wave functions, the **orbitals**, each of which solves a one-quantum equation in a common **mean field**; the mean field is made from the densities of the occupied orbitals.
- **Self-consistent**: the orbitals reproduce the mean field that made them. A computer finds such a state by repeating "densities, then mean field, then orbitals, then densities" until nothing changes.
- **Slice**: one instant of the history $a_4 = AHx_4$; $a_{4,0}$ is the value of a_4 there. An **instantaneous** (adiabatic) Kohn-Sham state is the self-consistent state of the Kohn-Sham problem written at that one instant, with $a_4 = a_{4,0}$; along the history the extra times keep deflating, and the states are computed slice after slice.
- **Hidden coordinate** y: $y = \ln(\sin z)/(6H)$; the **brane** is $y = 0$ ($z = \pi/2$), the **tip** is the cut $y = -L$ with $L = 3$.
- **Block**: one of the eight pairs of spinor components into which the 16 components split exactly; labelled (j, s_2, s_3) with three signs. The **block type** is $j = \pm 1$. An orbital of a block is a pair of functions $\chi(y) = (\chi_1(y), \chi_2(y))$.
- **Level** ε: an allowed energy of one orbital; **occupation** f between 0 and 1: how much of a quantum sits in that orbital; **degeneracy** g: how many orbitals share one level.
- **Brane parity**: even means $\chi_2(0) = 0$, odd means $\chi_1(0) = 0$; both kinds of orbitals belong to every state. **Tip angle** θ: the angle of the tip condition $(1 - Q(\theta))\chi(-L) = 0$.
- **Zero mode**: an orbital with $\varepsilon = 0$ at zero 3-momentum. **Brane band**: the levels that grow out of the zero modes when the 3-momentum is switched on. **Mass gap**: the energies $-|M| < \varepsilon < |M|$, in which a free quantum of mass M in an unbounded space has no level.
- **Image**: the orbital, state or problem obtained by applying the map of T3. **Partner**: the problem whose solutions are exactly the images. A map is an **involution** when applying it twice gives back the start.
- **Krein sign** of a block: the number ± 1 by which the matrix B acts in the block.
- **Negative control**: a computation that must FAIL to agree; it shows that an agreement is not automatic. In this chapter the **control** C is the universe of mass $-M$ with the UNtransformed tip, and the **wrong partner** D the one with the reversed coupling.
- **Characteristic function**: a function of ε whose zeros are exactly the levels.
- **Hellmann-Feynman rule**: a small change δh of a Hamiltonian moves a non-degenerate level by $\langle\chi|\delta h|\chi\rangle/\langle\chi|\chi\rangle$ to first order.

19.3 The Kohn-Sham problem of one orbital

This section collects, from Chapter 14 and the record `Revision/kohn_sham/ks-theory.json`, every formula of the problem for one orbital that the proof will use. Each is PROVED in the Kohn-Sham theory reports; the check names are given.

The slice and the hidden coordinate. The Kohn-Sham states are computed at the slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$ of the history $a_4 = AHx_4$, $A = 1$ (`Revision/kohn_sham/results/parameters.json`). In the hidden coordinate y the author's metric is

$$ds^2 = e^{2Hy}\left[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2 + dx_7^2)\right] - dx_4^2 + dy^2,$$

the volume factor is $\sqrt{|g|} = e^{6Hy}$ (the inflation e^{3a_4} of 3-space and the deflation e^{-3a_4} of the extra times cancel). This is the author's metric on the background $b_4 = 1$, on which the Kohn-Sham record works (Chapter 14): the metric of 2026-10-14 has a second function $b_4(x_4)$ that multiplies the extra-time components (Chapter 3), and T3 and all its records are statements on this background. A 3-momentum k enters every equation through the **momentum weight**

$$\kappa(y) = e^{-Hy - a_{4,0}}.$$

(Checks geometry_hidden_coordinate, geometry_sqrt_det and geometry_warped_form.) The slice enters the problem only through κ. The proof below never changes κ, so it works at every slice.

The orbital. In the good sector (no dependence on the extra times) an orbital of 3-momentum $\mathbf{k} = (k, 0, 0)$ along x_1 is

$$\Psi_{16} = \frac{e^{-i\varepsilon x_4}\, e^{ikx_1}\, e^{-3Hy}}{\sqrt{\ell^3 v_t}}\, V_\beta\, \chi(y), \qquad \int_{-L}^{0} \chi^\dagger \chi \, dy = 1,$$

where V_β are the two columns of the block β in the unitary 16×16 matrix V of the record, ℓ is the size of the 3-torus of 3-space and v_t the coordinate volume of the extra times. A rotation of 3-space does not change the levels, so turning $\mathbf{k}$ along x_1 loses nothing (check rotation_invariance). The allowed momenta are Δk times triples of whole numbers, with $\Delta k = 0.25$; a **shell** is the set of momenta with the same $|\mathbf{k}|^2 = \Delta k^2 n_2$.

The eight blocks. The three matrices $J = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_4)}$, $K_1 = \gamma^{(x_2)}\gamma^{(x_3)}$ and $K_2 = \gamma^{(x_5)}\gamma^{(x_6)}$ commute with each other and with the Hamiltonian; their eigenvalues $j = \pm 1$, is_2 and is_3 ($s_2, s_3 = \pm 1$) label eight blocks of two components each (checks blocks_commuting_set, blocks_projectors, blocks_basis_unitary; Section 14.5). In the basis V_β of the block (j, s_2, s_3) the matrices that the proof needs act as 2×2 matrices or numbers (check blocks_forms):

matrix	**in the block** (j, s_2, s_3)
$\gamma^{(x_0)}$	σ_3
$\gamma^{(x_0)}\gamma^{(x_4)}$	$j\sigma_1$
$B = -iC\gamma^{(x_4)}$	the number js_2
C	$s_2\sigma_2$
BC	$j\sigma_2$
$B\gamma^{(x_0)}$	$js_2\sigma_3$

Here $\sigma_1, \sigma_2, \sigma_3$ are the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Each squares to the unit matrix **1**, two different ones anticommute ($\sigma_a\sigma_b = -\sigma_b\sigma_a$ for $a \neq b$), each is Hermitian ($\sigma_a^\dagger = \sigma_a$, where † means: transpose and replace every entry by its complex conjugate), and their products are $\sigma_1\sigma_2 = i\sigma_3$, $\sigma_2\sigma_3 = i\sigma_1$, $\sigma_3\sigma_1 = i\sigma_2$, with the opposite sign in the reversed order.

The block Hamiltonian. In a block of type j the orbital solves $h_j\chi = \varepsilon\chi$ with

$$h_j(M, v) = j\left[-i\sigma_1\frac{d}{dy} + M(y)\,\sigma_2 + \kappa(y)\,k\,\sigma_3\right] + v(y),$$

where $M(y) = M_{\text{eff}}(y)$ is the effective mass and $v(y) = v_v(y)$ the potential of the mean field (Section 19.4); the Hamiltonian depends on j but not on s_2, s_3, so there are two types of blocks, four blocks of each type (check block_hamiltonian). We write $h_j(M, v)$ when we want to show which mass and potential it contains. Multiplying $h_j\chi = \varepsilon\chi$ from the left by $ij\sigma_1$ gives the first-order form (check block_ode_equivalent; Section 14.5)

$$\frac{d\chi}{dy} = N\chi, \qquad N = M\sigma_3 - \kappa k\,\sigma_2 + ij(\varepsilon - v)\,\sigma_1,$$

and with $\chi = (a, ib)$, a and b real, the **real form**

$$\frac{da}{dy} = Ma - \big(\kappa k + j(\varepsilon - v)\big)\,b, \qquad \frac{db}{dy} = \big(j(\varepsilon - v) - \kappa k\big)\,a - Mb.$$

The boundary conditions. At the brane the record ASSUMES the Z2 mirror (orbifold) construction: the field on the mirror side $y > 0$ is the reflected field, $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$, and continuity at $y = 0$ gives $(1 \mp \gamma^{(x_0)})\chi(0) = 0$, that is, in every block,

$$\text{even parity: } \chi_2(0) = 0 \quad (b(0) = 0), \qquad \text{odd parity: } \chi_1(0) = 0 \quad (a(0) = 0).$$

Both parities are solved and filled together; they are the two sectors of the doubled system "universe plus mirror image" (check bc_brane_parity_conditions). At the tip the record CHOOSES a regular condition from the family

$$(1 - Q(\theta))\chi(-L) = 0, \qquad Q(\theta) = \cos\theta\,\sigma_3 + \sin\theta\,\sigma_2,$$

with the canonical angle $\theta = 0$: $(1 - \sigma_3)\chi(-L) = 0$, that is $\chi_2(-L) = 0$ ($b(-L) = 0$). For $\theta = \pi$, $Q(\pi) = -\sigma_3$ and the condition is $(1 + \sigma_3)\chi(-L) = 0$, that is $\chi_1(-L) = 0$ ($a(-L) = 0$) (check bc_tip_family).

Why these conditions make sense: the current. For two pairs of functions ϕ, χ the record proves (check bc_self_adjoint_boundary_term)

$$\phi^\dagger(h_j\chi) - (h_j\phi)^\dagger\chi = \frac{d}{dy}\Big[-ij\,\phi^\dagger\sigma_1\chi\Big].$$

Integrated from $-L$ to 0, the left side becomes the difference between "h_j acting to the right" and "h_j acting to the left", and the right side the value of the bracket at $y = 0$ minus its value at $y = -L$.

If both boundary conditions make the **current** $\phi^\dagger\sigma_1\chi$ vanish at the ends, the two integrals are equal: h_j is self-adjoint, its levels are real and its orbitals of different levels are orthogonal. Both brane conditions and every tip condition of the family do this; Exercise 19.4 proves it for the tip.

19.4 The Kohn-Sham problem of the whole gas

The expectation-value rule. The quantised field (Chapter 10) gives every density as an expectation value. For the quasi-free states of the Kohn-Sham model the record uses the rule

$$\langle\Psi^\dagger X\Psi\rangle = \mathrm{Tr}(X\rho), \qquad \rho = \sum_{\text{occupied}} f\,u\,u^\dagger B,$$

where X is a 16×16 matrix, u runs over the occupied 16-component orbitals, f is the occupation and $B=-iC\gamma^{(x_4)}$ is the Krein matrix ($B^2=1$, eigenvalues $+1$ eight times and -1 eight times). For one orbital, line by line:

$$\mathrm{Tr}(X\,u\,u^\dagger B) = \mathrm{Tr}((u^\dagger B)(Xu)) = u^\dagger BXu.$$

Rule: the trace of a product does not change when the factors are moved around in a circle, $\mathrm{Tr}(PR)=\mathrm{Tr}(RP)$, here with $P=Xu$ (a column) and $R=u^\dagger B$ (a row); a row times a column is a single number, its own trace. (Check gas_densities.) The three densities that matter are the **number density** (the U(1) charge density, whose integral counts the quanta), the **scalar density** and a third density Q:

$$n=\langle\Psi^\dagger B\Psi\rangle=\sum f\,u^\dagger BBu=\sum f\,u^\dagger u, \qquad S=\langle\bar\Psi\Psi\rangle=\langle\Psi^\dagger C\Psi\rangle=\sum f\,u^\dagger BCu,$$

$$Q=\langle\Psi^\dagger B\gamma^{(x_0)}\Psi\rangle=\sum f\,u^\dagger BB\gamma^{(x_0)}u=\sum f\,u^\dagger\gamma^{(x_0)}u.$$

Rule: $X=B$, C, $B\gamma^{(x_0)}$ in the line above, and $BB=B^2=1$.

The densities of one orbital. Put in $u=\Psi_{16}$ of Section 19.3. The phases $e^{-i\varepsilon x_4}e^{ikx_1}$ cancel against their conjugates, and e^{-3Hy} appears twice, so

$$u^\dagger Xu=\frac{e^{-6Hy}}{\ell^3 v_t}\,\chi^\dagger(V_\beta^\dagger XV_\beta)\chi = P\,\chi^\dagger(V_\beta^\dagger XV_\beta)\chi, \qquad P=\frac{e^{-6Hy}}{\ell^3v_t}.$$

The middle matrix is the block form of X (the table of Section 19.3). With $V_\beta^\dagger V_\beta=\mathbf{1}$, $BC\to j\sigma_2$ and $\gamma^{(x_0)}\to\sigma_3$:

$$n_o=P\,\chi^\dagger\chi, \qquad s_o=P\,\chi^\dagger j\sigma_2\chi, \qquad q_o=P\,\chi^\dagger\sigma_3\chi.$$

The record adds two more (`ks-theory.json`, densities.perOrbital): the density of the 3-momentum current along $\mathbf{k}$, $t_o=P\,\chi^\dagger j\sigma_3\chi=j\,q_o$, and the current along y, $c_o=P\,\chi^\dagger j\sigma_1\chi$. In the real form $\chi=(a,ib)$ they are simple: $\sigma_2\chi=(-i\cdot ib,\ ia)=(b,ia)$ and $\chi^\dagger=(a,-ib)$, so

$$\chi^\dagger\chi = a^2 + b^2, \qquad \chi^\dagger\sigma_2\chi = ab + (-ib)(ia) = 2ab,$$

$$\chi^\dagger\sigma_3\chi = a^2 - b^2, \qquad \chi^\dagger\sigma_1\chi = a(ib) + (-ib)a = 0.$$

Rule: multiply out, with $i \cdot i = -1$. So $c_o = 0$ for every orbital of real form: no current flows along the hidden direction.

The totals. Each level ε of the block type j, the brane parity p and the momentum shell n_2 has the degeneracy $g = 4r_3(n_2)$ (four blocks (s_2, s_3) of the type j times the number $r_3(n_2)$ of lattice momenta in the shell). Then

$$n(y) = \sum_{\text{levels}} w\, g\, f\, n_o(y), \qquad S(y) = \sum_{\text{levels}} w\, g\, f\, s_o(y),$$

and the same for $t(y)$ and $Q(y)$, with $w = w_{Z2} = \frac{1}{2}$: every orbital is normalised on the patch $-L \le y \le 0$, which is half of the doubled interval of the Z2 construction. The particle number is $N = \sum gf$ over all levels of both parities; it counts the quanta of the doubled system, $N/2$ per copy (`ks-theory.json`, densities.total; the conventions of `Revision/kohn_sham/results/parameters.json`).

The mean field. The contact interaction is $U = \frac{\lambda}{2}S^2$. For the quasi-free states of the model, Hartree plus the exact exchange of the uniform gas give the **interaction energy density** (check exchange_uniform_gas; Chapter 14)

$$e_{\text{int}}(n, S) = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2,$$

without a correlation term. The two potentials are its derivatives, line by line:

$$M_{\text{eff}} = m + \frac{\partial e_{\text{int}}}{\partial S} = m + \frac{15}{32} \cdot 2\,\lambda S = m + \frac{15}{16}\lambda S, \qquad v_v = \frac{\partial e_{\text{int}}}{\partial n} = -\frac{1}{32} \cdot 2\,\lambda n = -\frac{\lambda n}{16}.$$

Rule: the derivative of cx^2 is $2cx$; the bare mass m is added to the derivative with respect to S because the mass term of the Lagrangian is mS (check ks_potentials). Note for later: e_{int} contains S only as S^2, and $M_{\text{eff}} - m$ is proportional to λS.

The occupations. At the temperature T the occupations are Mermin's (Fermi's) $f = 1/(1 + e^{(\varepsilon-\mu)/T})$, with the chemical potential μ fixed by $\sum gf = N$; at $T = 0$ the lowest particle levels are filled. Which levels count as particle levels is a CONVENTION of the record (`ks-theory.json`, thermodynamics.fillingConvention): the levels of the positive branch of the problem without interaction, together with the zero modes at zero 3-momentum, each followed continuously as λ is switched on; the negative branch is the normal-ordered sea and contributes nothing. Its justification is OPEN.

The energies. With $\text{Vol}_7 = \ell^3 v_t$ the record defines (`ks-theory.json`, thermodynamics)

$$E_{KS} = \sum gf\varepsilon - 2\,\text{Vol}_7 \int_{-L}^{0} e^{6Hy} e_{\text{int}}\, dy, \qquad S_{\text{ent}} = -\sum g[f \ln f + (1-f)\ln(1-f)],$$

$$\Omega = -T\sum g\ln\left(1+e^{-(\varepsilon-\mu)/T}\right) - 2\,\mathrm{Vol}_7\int_{-L}^{0} e^{6Hy}e_{\mathrm{int}}\,dy, \qquad F=\Omega+\mu N = E_{KS}-TS_{\mathrm{ent}}:$$

the Kohn-Sham energy, the entropy, the grand potential and the free energy (Exercise 19.7 derives the last equality).

The energy-momentum profiles. The energy density and the three pressures of the gas, per unit proper volume, are (`ks-theory.json`, emt; check emt_orbital_components)

$$\rho = \sum wgf\,\varepsilon\,n_o - e_{\mathrm{int}}, \qquad p_3 = \sum wgf\,\frac{\kappa|k|}{3}\,t_o + e_{\mathrm{int}}, \qquad p_t = e_{\mathrm{int}},$$

$$p_0 = \sum wgf\Big[(\varepsilon-v_v)\,n_o - M_{\mathrm{eff}}\,s_o - \kappa|k|\,t_o\Big] + e_{\mathrm{int}}:$$

ρ is the energy density, p_3 the pressure of 3-space, p_t the pressure of the deflating extra times and p_0 the pressure of the hidden direction. Every self-consistent state obeys the conservation law along y, $p_0' + 6Hp_0 = 3H(p_3+p_t)$ (check emt_y_conservation_selfconsistent).

The loop. A self-consistent state is found by repeating: from $n(y)$ and $S(y)$ build $M_{\mathrm{eff}}(y)$ and $v_v(y)$; solve $h_j\chi = \varepsilon\chi$ for both block types, every momentum shell and both parities with the boundary conditions; fill the levels; compute new $n(y)$ and $S(y)$. A state that reproduces itself is a **fixed point** of this loop. Chapter 15 describes how the Rust solver does it.

19.5 The chirality Γ on the blocks

Γ and the gammas. The chirality is the product of all eight gammas in the author's order,

$$\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}\gamma^{(x_4)}\gamma^{(x_5)}\gamma^{(x_6)}\gamma^{(x_7)} = \mathrm{diag}(-1,\ldots,-1,+1,\ldots,+1),$$

with -1 eight times and then $+1$ eight times (`Revision/algebra/reports/wolfram-algebra.json`, check Gamma_diag). Moving one gamma $\gamma^{(x_c)}$ from the left of Γ to its right passes the seven other factors, each with a sign -1, and itself, without a sign: $\gamma^{(x_c)}\Gamma = (-1)^7\Gamma\gamma^{(x_c)} = -\Gamma\gamma^{(x_c)}$. So Γ **anticommutes with every gamma**, hence with every product of an odd number of gammas, and **commutes with every product of an even number**. It is real and diagonal, so $\Gamma^\dagger = \Gamma$ and $\Gamma^2 = 1$.

Γ moves every block to its partner block. $J = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_4)}$ has three factors, K_1 and K_2 have two. Let v be a column of the block (j, s_2, s_3), that is $Jv = jv$, $K_1v = is_2v$, $K_2v = is_3v$. Then, line by line:

$$J(\Gamma v) = -\Gamma Jv = -j\,(\Gamma v), \qquad K_1(\Gamma v) = \Gamma K_1 v = is_2\,(\Gamma v), \qquad K_2(\Gamma v) = is_3\,(\Gamma v).$$

Rule: Γ anticommutes with the odd product J and commutes with the even products K_1, K_2; then use the eigenvalue equations of v. So Γv lies in the block $(-j, s_2, s_3)$: the **partner block**, with the opposite type and the same s_2, s_3 (check blocks_relation_to_Gamma).

Γ acts as $\pm\sigma 2$ between the partner blocks. Let V_b be the two basis columns of the block $b = (j, s_2, s_3)$ and V_p those of the partner block $p = (-j, s_2, s_3)$. Because ΓV_b lies in the block p, it is a combination of the columns V_p: $\Gamma V_b = V_p G$ for some 2×2 matrix G. The block forms say $\gamma^{(x_0)} V_b = V_b \sigma_3$ and $\gamma^{(x_0)} V_p = V_p \sigma_3$ (in both blocks $\gamma^{(x_0)}$ is σ_3), and $\gamma^{(x_0)}\gamma^{(x_4)} V_b = V_b(j\sigma_1)$, $\gamma^{(x_0)}\gamma^{(x_4)} V_p = V_p(-j\sigma_1)$ (the type of p is $-j$). Now line by line:

$$\Gamma\gamma^{(x_0)} V_b = \Gamma V_b \sigma_3 = V_p G \sigma_3, \qquad -\gamma^{(x_0)}\Gamma V_b = -\gamma^{(x_0)} V_p G = -V_p \sigma_3 G.$$

Rule: the block forms and the definition of G. The two left sides are equal, because Γ anticommutes with $\gamma^{(x_0)}$; the columns of V_p are independent, so

$$G\sigma_3 = -\sigma_3 G.$$

The same with the even product $\gamma^{(x_0)}\gamma^{(x_4)}$, which commutes with Γ:

$$\Gamma(\gamma^{(x_0)}\gamma^{(x_4)}) V_b = V_p G\,(j\sigma_1), \qquad (\gamma^{(x_0)}\gamma^{(x_4)})\Gamma V_b = V_p(-j\sigma_1)\,G, \qquad \text{so} \qquad G\sigma_1 = -\sigma_1 G.$$

Rule: equate the two lines and divide by $j = \pm 1$. Every 2×2 matrix can be written as $G = g_0\mathbf{1} + g_1\sigma_1 + g_2\sigma_2 + g_3\sigma_3$ with four numbers $g_0, \ldots, g_3$ (four numbers for four entries). Multiply $G\sigma_3 = -\sigma_3 G$ from the left by σ_3: $\sigma_3 G \sigma_3 = -G$. Line by line:

$$\sigma_3 G \sigma_3 = g_0\mathbf{1} - g_1\sigma_1 - g_2\sigma_2 + g_3\sigma_3 = -g_0\mathbf{1} - g_1\sigma_1 - g_2\sigma_2 - g_3\sigma_3.$$

Rule: $\sigma_3\sigma_3\sigma_3 = \sigma_3$, and $\sigma_3\sigma_a\sigma_3 = -\sigma_a\sigma_3\sigma_3 = -\sigma_a$ for $a = 1, 2$; the right side is $-G$. Comparing the coefficients gives $g_0 = -g_0$ and $g_3 = -g_3$, so $g_0 = g_3 = 0$. The same steps with σ_1 ($\sigma_1 G \sigma_1 = g_0 + g_1\sigma_1 - g_2\sigma_2 - g_3\sigma_3 = -G$) give $g_0 = g_1 = 0$. Hence

$$G = \tau\,\sigma_2, \qquad |\tau| = 1,$$

where $|\tau| = 1$ because Γ and V are unitary, so G is unitary too. The record computes the number τ for all eight blocks: $\tau = s_2$, that is $\Gamma V_{(j,s_2,s_3)} = V_{(-j,s_2,s_3)}\,(s_2\sigma_2)$ (checks blocks_relation_to_Gamma of `ks-theory-python.json`, T3_Gamma_is_the_block_map of `wolfram-t3.json`, T3.Gamma_is_the_block_map of `python-t3.json`). Notebooks 19a and 19b compute it again (Notebook 19b, figure 2, shows where the entries sit).

The map of T3. For a 16-component orbital Ψ_{16} built from χ in the block (j, s_2, s_3), the orbital $\Gamma\Psi_{16}$ is built from $s_2\sigma_2\chi$ in the block $(-j, s_2, s_3)$, at the same 3-momentum and the same point. The constant sign s_2 changes no density (every density contains the orbital twice, and $s_2^2 = 1$), so we drop it. On the reduced problem the chirality is the map

$$(\chi,\ j) \longrightarrow (\sigma_2\chi,\ -j), \qquad \text{in the real form} \qquad (a, b, j) \longrightarrow (b, a, -j),$$

because $\sigma_2(a, ib) = (b, ia)$: the map exchanges a and b and reverses the block type.

Γ **reverses the Krein sign.** In the block (j, s_2, s_3) the matrix B is the number js_2, its Krein sign; in the partner block it is $-js_2$. In 16 components: $B = -iC\gamma^{(x_4)}$ is $-i$ times a product of five gammas (four in C, one more), an odd product, so $\Gamma B = -B\Gamma$ and

$$\Gamma B \Gamma^\dagger = \Gamma B \Gamma = -B\Gamma\Gamma = -B$$

(`Revision/pairing/reports/python-pairing.json`, check Q.image_krein_metric). This one sign is why T3 differs from T1 (Section 19.11).

19.6 Step 1 of the proof: an orbital and its image

The block Hamiltonian under $\sigma 2$. We conjugate $h_j(M, v)$ with σ_2, that is, we compute $\sigma_2 h_j(M, v)\sigma_2$, term by term. The matrix σ_2 is constant, so it can be moved past the derivative: $\frac{d}{dy}(\sigma_2\chi) = \sigma_2 \frac{d\chi}{dy}$. Line by line:

$$\sigma_2\Big(-i\sigma_1\frac{d}{dy}\Big)\sigma_2 = -i\,\sigma_2\sigma_1\sigma_2\,\frac{d}{dy} = +i\sigma_1\frac{d}{dy}.$$

Rule: $\sigma_2\sigma_1\sigma_2 = -\sigma_1\sigma_2\sigma_2 = -\sigma_1$ (the two anticommute, and $\sigma_2^2 = \mathbf{1}$).

$$\sigma_2(M\sigma_2)\sigma_2 = M\,\sigma_2\sigma_2\sigma_2 = M\sigma_2, \qquad \sigma_2(\kappa k\,\sigma_3)\sigma_2 = \kappa k\,\sigma_2\sigma_3\sigma_2 = -\kappa k\,\sigma_3, \qquad \sigma_2\,v\,\sigma_2 = v.$$

Rule: $\sigma_2^2 = \mathbf{1}$; $\sigma_2\sigma_3\sigma_2 = -\sigma_3\sigma_2\sigma_2 = -\sigma_3$; the numbers M, κk, v (functions of y) commute with every matrix. Adding the four terms, with the factor j in front of the first three:

$$\sigma_2 h_j(M, v)\sigma_2 = j\Big[+i\sigma_1\frac{d}{dy} + M\sigma_2 - \kappa k\,\sigma_3\Big] + v = (-j)\Big[-i\sigma_1\frac{d}{dy} + (-M)\sigma_2 + \kappa k\,\sigma_3\Big] + v = h_{-j}(-M, v).$$

Rule: take the factor -1 out of the bracket and give it to j; then compare with the definition of h_j in Section 19.3. This holds for every function $M(y)$, $\kappa(y)$, $v(y)$ and every k.

The image orbital. Suppose $h_j(M, v)\chi = \varepsilon\chi$. Then, line by line:

$$h_{-j}(-M, v)(\sigma_2\chi) = \sigma_2 h_j(M, v)\sigma_2\,\sigma_2\chi = \sigma_2 h_j(M, v)\chi = \sigma_2\,\varepsilon\chi = \varepsilon\,(\sigma_2\chi).$$

Rule: replace $h_{-j}(-M, v)$ by $\sigma_2 h_j(M, v)\sigma_2$ (the line above); $\sigma_2\sigma_2 = \mathbf{1}$; the eigenvalue equation; a number commutes with σ_2. So $\sigma_2\chi$ **is an orbital of the partner block type $-j$, in the mass $-M$ and the SAME potential v, with the SAME level ε and the same 3-momentum**. Because $\sigma_2^2 = \mathbf{1}$, the argument also runs backwards. Without the change of the mass the identity fails: $h_{-j}(-M, v) - h_{-j}(M, v) = (-j)(-2M)\sigma_2 = 2jM\sigma_2$, which is not zero for $M \neq 0$. Status: PROVED; checks T3_block_hamiltonian_map of `wolfram-t3.json` and T3.block_hamiltonian_map of `python-t3.json` (each with this control), and block_Gamma_map of both Kohn-Sham theory reports.

The same in the first-order form. The solver integrates $d\chi/dy = N\chi$. Line by line, with $N_j(M) = M\sigma_3 - \kappa k\sigma_2 + ij(\varepsilon - v)\sigma_1$:

$$\sigma_2 N_j(M)\sigma_2 = M\sigma_2\sigma_3\sigma_2 - \kappa k\,\sigma_2\sigma_2\sigma_2 + ij(\varepsilon - v)\sigma_2\sigma_1\sigma_2 = -M\sigma_3 - \kappa k\,\sigma_2 - ij(\varepsilon - v)\sigma_1 = N_{-j}(-M).$$

Rule: the three conjugation rules above; then compare with $N_{-j}(-M) = (-M)\sigma_3 - \kappa k\sigma_2 + i(-j)(\varepsilon - v)\sigma_1$. Hence if $d\chi/dy = N_j(M)\chi$, then $\frac{d}{dy}(\sigma_2\chi) = \sigma_2 N_j(M)\sigma_2\,\sigma_2\chi = N_{-j}(-M)\,(\sigma_2\chi)$ (checks T3_ode_map and T3.ode_map).

The same in the real form. In the real form the map is $(a, b, j, M) \to (b, a, -j, -M)$. Check it directly: call the image $A = b$, $\mathcal{B} = a$. The real form with $(-j, -M)$ asks

$$\frac{dA}{dy} = (-M)A - \big(\kappa k + (-j)(\varepsilon - v)\big)\mathcal{B} = -Mb + \big(j(\varepsilon - v) - \kappa k\big)a,$$

and this is exactly the second equation of the original, $db/dy = (j(\varepsilon - v) - \kappa k)a - Mb$. Likewise

$$\frac{d\mathcal{B}}{dy} = \big((-j)(\varepsilon - v) - \kappa k\big)A - (-M)\mathcal{B} = Ma - \big(\kappa k + j(\varepsilon - v)\big)b,$$

which is the first equation of the original, da/dy. Rule: insert $A = b$, $\mathcal{B} = a$ and multiply out the signs. Notebook 19b uses this form for its shooting.

Every slice at once. The slice $a_{4,0}$ and the 3-momentum enter only through κk, which the map does not touch. So everything in this section, and therefore T3, holds at every slice of the deflating history, and for every 3-momentum.

19.7 Step 2 of the proof: the boundary conditions

The tip. Line by line:

$$\begin{aligned}\sigma_2 Q(\theta)\sigma_2 &= \cos\theta\,\sigma_2\sigma_3\sigma_2 + \sin\theta\,\sigma_2\sigma_2\sigma_2 = -\cos\theta\,\sigma_3 + \sin\theta\,\sigma_2 \\ &= \cos(\pi - \theta)\,\sigma_3 + \sin(\pi - \theta)\,\sigma_2 = Q(\pi - \theta).\end{aligned}$$

Rule: the conjugation rules of Section 19.6; then $\cos(\pi - \theta) = -\cos\theta$ and $\sin(\pi - \theta) = \sin\theta$. Therefore

$$\sigma_2(1 - Q(\theta))\chi = \sigma_2\chi - \sigma_2 Q(\theta)\sigma_2\,\sigma_2\chi = \big(1 - Q(\pi - \theta)\big)\,\sigma_2\chi.$$

Rule: insert $\sigma_2\sigma_2 = \mathbf{1}$ between $Q(\theta)$ and χ. Since σ_2 is invertible, the left side vanishes exactly when $(1 - Q(\theta))\chi = 0$. So χ **obeys the tip condition with the angle** θ **exactly when** $\sigma_2\chi$ **obeys the tip condition with the angle** $\pi - \theta$. The canonical $\theta = 0$ ($\chi_2(-L) = 0$) becomes $\theta = \pi$ ($\chi_1(-L) = 0$); in components this is plain, because $\sigma_2\chi = (-i\chi_2,\ i\chi_1)$ has the first component $-i\chi_2$. A control: the solution $(1, 0)$ of the condition $\theta = 0$ has the image $\sigma_2(1, 0) = (0, i)$, and $(1 - Q(0))(0, i) = (1 - \sigma_3)(0, i) = (0, 2i) \neq 0$: the image violates the UNtransformed condition, while

$(1-Q(\pi))(0,i) = (1+\sigma_3)(0,i) = (0,0)$. Status: PROVED; checks T3_tip_condition_map and T3.tip_condition_map.

The brane. Line by line:

$$\sigma_2(1-\sigma_3)\sigma_2 = \sigma_2\sigma_2 - \sigma_2\sigma_3\sigma_2 = 1+\sigma_3.$$

So the even condition $(1-\sigma_3)\chi(0)=0$, that is $\chi_2(0)=0$, holds exactly when $(1+\sigma_3)\sigma_2\chi(0)=0$, the odd condition for the image. **The map exchanges the two brane parities.** Both parities belong to every Kohn-Sham problem of the record (they are the two sectors of the ASSUMED Z2 construction, solved and filled together), so the set of boundary problems is mapped onto itself and only the names "even" and "odd" are exchanged. The tip is the only boundary condition that really changes.

The current and the norm. For the image orbitals of type $-j$, line by line:

$$(\sigma_2\phi)^\dagger(\sigma_2\chi) = \phi^\dagger\sigma_2\sigma_2\chi = \phi^\dagger\chi, \qquad -i(-j)\,(\sigma_2\phi)^\dagger\sigma_1(\sigma_2\chi) = ij\,\phi^\dagger\sigma_2\sigma_1\sigma_2\chi = -ij\,\phi^\dagger\sigma_1\chi.$$

Rule: $(\sigma_2\phi)^\dagger = \phi^\dagger\sigma_2^\dagger = \phi^\dagger\sigma_2$; $\sigma_2\sigma_1\sigma_2 = -\sigma_1$. The norm and the current of Section 19.3 are unchanged. So normalised orbitals go to normalised orbitals, orthogonal ones to orthogonal ones, and the image problem is self-adjoint with real levels, like the original. Status: PROVED; checks T3_brane_parities_exchanged and T3.brane_parities_exchanged.

What Steps 1 and 2 give together. Write $\mathcal{P}_j(M,v,\theta,p)$ for the boundary-value problem of the block type j with the mass $M(y)$, the potential $v(y)$, the tip angle θ and the brane parity p. Then χ is a normalised eigen-orbital of $\mathcal{P}_j(M,v,\theta,\text{even})$ with the level ε exactly when $\sigma_2\chi$ is a normalised eigen-orbital of $\mathcal{P}_{-j}(-M,v,\pi-\theta,\text{odd})$ with the same level, and the same with "even" and "odd" exchanged. The correspondence is one to one and onto, because σ_2 undoes itself. So **the two problems have the same levels, level by level, with the same multiplicities**. The degeneracies agree too: the map sends the four blocks of the type j one to one onto the four blocks of the type $-j$, at the same momenta.

19.8 Step 3 of the proof: the densities and the mean field

The densities of one orbital. Under $(\chi, j) \to (\sigma_2\chi, -j)$ the five densities of Section 19.4 become, line by line:

$$n_o \to P(\sigma_2\chi)^\dagger(\sigma_2\chi) = P\chi^\dagger\sigma_2\sigma_2\chi = P\chi^\dagger\chi = +n_o,$$

$$s_o \to P(\sigma_2\chi)^\dagger(-j)\sigma_2(\sigma_2\chi) = -jP\chi^\dagger\sigma_2\sigma_2\sigma_2\chi = -jP\chi^\dagger\sigma_2\chi = -s_o,$$

$$t_o \to -jP\chi^\dagger\sigma_2\sigma_3\sigma_2\chi = -jP\chi^\dagger(-\sigma_3)\chi = +t_o,$$

$$q_o \to P\chi^\dagger\sigma_2\sigma_3\sigma_2\chi = -q_o, \qquad c_o \to -jP\chi^\dagger\sigma_2\sigma_1\sigma_2\chi = +c_o.$$

Rule: $(\sigma_2\chi)^\dagger = \chi^\dagger\sigma_2$; $\sigma_2^2 = \mathbf{1}$; $\sigma_2\sigma_3\sigma_2 = -\sigma_3$, $\sigma_2\sigma_1\sigma_2 = -\sigma_1$; the factor P is the same because the map acts at the same point. In the real form it is even simpler: $(a, b, j) \to (b, a, -j)$ turns $a^2 + b^2$ into $b^2 + a^2$ (no change), $2jab$ into $2(-j)ba$ (sign change) and $a^2 - b^2$ into $b^2 - a^2$ (sign change). Status: PROVED; checks T3_orbital_densities and T3.orbital_densities (for arbitrary complex χ and both j).

The densities of the gas. If the image state has the same levels, degeneracies and occupations (Step 4 shows that it does), the sums of Section 19.4 give

$$n(y) \to n(y), \qquad t(y) \to t(y), \qquad S(y) \to -S(y), \qquad Q(y) \to -Q(y).$$

Which partner closes the mean field. For the image orbitals to be orbitals of the partner problem, Step 1 demands that the partner's mean field be $(-M_{\text{eff}}, v_v)$: the opposite mass and the same potential. Let the partner have the bare mass m' and the coupling λ'; its mean field, built from the image densities $(n, -S)$, is $m' + \frac{15}{16}\lambda'(-S)$ and $-\lambda' n/16$. The potential decides the coupling, line by line:

$$-\frac{\lambda' n}{16} = -\frac{\lambda n}{16} \quad \Longrightarrow \quad \lambda' = \lambda \qquad (n \neq 0).$$

Rule: multiply by $-16/n$. Then the mass decides the bare mass:

$$m' - \frac{15}{16}\lambda S = -m - \frac{15}{16}\lambda S \quad \Longrightarrow \quad m' = -m.$$

Rule: insert $\lambda' = \lambda$, and add $\frac{15}{16}\lambda S$ to both sides. Check, line by line, that $(m', \lambda') = (-m, +\lambda)$ works:

$$M'_{\text{eff}} = -m + \frac{15}{16}\lambda(-S) = -\Big(m + \frac{15}{16}\lambda S\Big) = -M_{\text{eff}}, \qquad v'_v = -\frac{\lambda n}{16} = v_v,$$

$$e_{\text{int}}(n, -S) = \frac{15}{32}\lambda(-S)^2 - \frac{1}{32}\lambda n^2 = e_{\text{int}}(n, S).$$

Rule: take -1 out of the bracket; $(-S)^2 = S^2$. **The coupling keeps its sign; only the bare mass is reversed.** With the parameter change of T1, $(m', \lambda') = (-m, -\lambda)$, the mean field comes out wrong:

$$-m + \frac{15}{16}(-\lambda)(-S) = -M_{\text{eff}} + \frac{15}{8}\lambda S, \qquad -\frac{(-\lambda)n}{16} = v_v + \frac{\lambda n}{8},$$

both off whenever $\lambda S \neq 0$ or $\lambda n \neq 0$. Status: PROVED; checks T3_mean_field_map and T3.mean_field_map (with the control $(-m, -\lambda)$). The sympy check also verifies that the potentials are the derivatives of e_{int}. Notebook 19b, figure 3, draws these three mass lines; Notebook 19a, figure 9, shows the energies of $(-m, -\lambda)$.

A gap in the verification of this step, and how it was closed. The adversarial verification of 2026-10-08 (`Revision/pairing/kohn_sham/t3-completion.json`, entry adversarial_verification,

Gap 1) found two weaknesses in the Wolfram verifier of T3 as it then stood: it wrote the four coefficients $\frac{15}{16}$, $-\frac{1}{16}$, $\frac{15}{32}$, $-\frac{1}{32}$ into its script instead of reading them from `Revision/kohn_sham/ks-theory.json`, and its clause about v_v compared an expression with itself (`vvf[lam, n] === vvf[lam, n]`), which is true for every v_v whatever. So, for v_v, the statement "two independent verifiers" did not hold at that time: only the sympy check, which reads the coefficients from the record, verified the potential. The algebra above was never in doubt; what was missing was an independent machine check of it. The completion closes the gap with the checks T3C_mean_field_coefficients_from_ks_theory (`Revision/pairing/kohn_sham/reports/wolfram-t3-completion.json`) and T3C.mean_field_coefficients_from_ks_theory (`Revision/pairing/kohn_sham/reports/python-t3-completion.json`): both engines read the potentials from `ks-theory.json`, check that $M_{\text{eff}} - m = \partial e_{\text{int}}/\partial S$ and $v_v = \partial e_{\text{int}}/\partial n$ (the two derivatives of Section 19.4), and repeat the map $M_{\text{eff}}[-m, +\lambda, -S] = -M_{\text{eff}}[m, \lambda, S]$, e_{int} even in S, v_v free of S, with the control $(-m, -\lambda)$, which fails. Afterwards, on the same day, the T3 verifier itself was fixed at the root: it now reads the coefficients from `ks-theory.json`, and its check T3_mean_field_map writes v_v as a function of (m, λ, n, S) and compares its values at the original and at the image arguments, so that a wrong coefficient makes the check fail; it still has 10 of 10 checks PASS (`Revision/pairing/kohn_sham/README.md`; `Revision/pairing/kohn_sham/wolfram/WOLFRAMSCRIPT_PROVENANCE.md`, section 6.5). Status of Step 3 now: PROVED, by two independent verifiers in the T3 records and again by the completion checks in both engines.

19.9 Step 4 of the proof: self-consistency, energies and energy-momentum

Let A be a self-consistent Kohn-Sham state of the problem with (m, λ, θ) at a slice $a_{4,0}$, with N quanta at the temperature T: its orbitals χ with the levels ε and the occupations f give the densities n, S, these give M_{eff}, v_v, and the eigen-orbitals of this mean field with both parities and the tip angle θ are again the orbitals χ. Define the state B: the orbitals $\sigma_2\chi$ in the partner blocks, with the same occupations. We show that B is a self-consistent state of the problem with $(-m, +\lambda, \pi - \theta)$, at the same slice, with the same N and T.

- (i) The densities of B are $(n, -S)$ (Step 3).
- (ii) The partner problem builds from them the mean field $(-M_{\text{eff}}, v_v)$ (Step 3).
- (iii) In this mean field, with the tip angle $\pi - \theta$ and both parities, the eigen-orbitals of the partner problem are exactly the orbitals $\sigma_2\chi$, with the same levels and degeneracies (Steps 1 and 2).
- (iv) The occupations. A Mermin occupation depends only on ε, μ and T. The particle number $N(\mu) = \sum g f(\varepsilon; \mu, T)$ is the same function of μ for both problems, because the levels and degeneracies are the same, so the same μ solves $N(\mu) = N$. Which levels are particle levels is decided by following the problem without interaction; at $\lambda = 0$ the two free problems ($M = m$ and $M = -m$, $v = 0$) are themselves mapped onto each other by Steps 1 and 2, so every image level carries the label of its original. In particular the zero mode $(e^{my}, 0)$ of A goes to $\sigma_2(e^{my}, 0) = (0, ie^{my})$, a zero mode of B. And because the coupling is the same, the continuous path from $\lambda = 0$ to λ along which the labels are followed is the same path for both problems. Hence the partner problem gives every orbital $\sigma_2\chi$ the occupation f. This item was the second gap of the adversarial verification (`t3-completion.json`, Gap 2): the record's proof used the filling convention (hypothesis H5, defined for the member with $m > 0$ and $\theta = 0$) for

the image with the remark that both block types and both parities belong to each problem, without showing that the image's set of particle levels is the image of the original's set. The argument of this item is what the completion checks: for every coupling λ' on the path from 0 to λ and any $S(y)$, $\sigma_2 h_j(m + \frac{15}{16}\lambda' S)\sigma_2 = h_{-j}(-(m + \frac{15}{16}\lambda' S))$ for both j (Step 1 with the mass $m + \frac{15}{16}\lambda' S$), so the map keeps the levels with $\varepsilon > 0$ at $\lambda = 0$ and commutes with the continuation in λ; the brane zero mode $(e^{My}, 0)$ goes to $(0, ie^{My})$, the brane zero mode of the image in its own boundary conditions (odd parity, tip angle π); with the untransformed tip the image mode violates the tip condition (the control). Checks T3C_filling_convention_mapped and T3C.filling_convention_mapped (statement "H5 for the pair" of `t3-completion.json`). Status: PROVED; the filling convention itself remains a CONVENTION whose justification is OPEN.

- (v) So the densities that the partner problem computes from its own orbitals and occupations are $(n, -S)$, the densities we started from in (ii): B is a fixed point of the partner's loop, a **self-consistent state**.

Applying the map twice gives back A, because $\sigma_2^2 = \mathbf{1}$ and $(-(-m), \lambda, \pi - (\pi - \theta)) = (m, \lambda, \theta)$: the map is an **involution**, and every self-consistent state of the partner problem is the image of a self-consistent state of the original. The self-consistent states of the two problems are in one-to-one correspondence.

Equal energies. Line by line, for the quantities of Section 19.4:

- $\sum g f \varepsilon$ is the same: the same g, f and ε.
- $e_{\text{int}}(n, -S) = e_{\text{int}}(n, S)$ at every y (Step 3), so $2\,\text{Vol}_7 \int e^{6Hy} e_{\text{int}}\, dy$ is the same.
- Hence E_{KS} is the same; S_{ent} is the same (it contains only g and f); Ω is the same (the same levels, μ, T and interaction integral); and $F = \Omega + \mu N$ is the same.

Equal energy-momentum profiles. Term by term in the formulas of Section 19.4:

- $\rho = \sum w g f\, \varepsilon n_o - e_{\text{int}}$: n_o and e_{int} are unchanged, so $\rho(y)$ is unchanged.
- $p_3 = \sum w g f\, \frac{\kappa|k|}{3} t_o + e_{\text{int}}$: t_o is unchanged, and so are κ and $|k|$; $p_3(y)$ is unchanged.
- $p_t = e_{\text{int}}$: unchanged.
- $p_0 = \sum w g f [(\varepsilon - v_v) n_o - M_{\text{eff}} s_o - \kappa|k| t_o] + e_{\text{int}}$: the only term with odd factors is $M_{\text{eff}} s_o$, and it becomes $(-M_{\text{eff}})(-s_o) = M_{\text{eff}} s_o$, a product of two odd factors; $p_0(y)$ is unchanged.

So the four profiles are equal at every point y, while $S(y)$, $Q(y)$ and $M_{\text{eff}}(y)$ change sign and $n(y)$, $t(y)$, $v_v(y)$, $e_{\text{int}}(y)$ do not. The Kohn-Sham gap (the lowest empty level minus the highest occupied level) is a difference of two levels and is the same as well. Status: PROVED; checks `T3_energies_and_emt_profiles_equal` of `wolfram-t3.json` and `T3.energies_and_emt_profiles_equal` of `python-t3.json`; the sympy check takes three general occupied orbitals of both block types with arbitrary complex χ, levels, occupations, degeneracies and momenta, and also verifies the control: with $(-m, -\lambda)$ the energy density differs. These are the four diagonal components of the energy-momentum tensor of the 2×2 reduction; that every other component and the current are equal too is statement S6 of the completion (Section 19.10; the third gap of the adversarial verification).

19.10 Theorem T3: the statement, its hypotheses and its records

Hypotheses (`Revision/pairing/kohn_sham/t3-theory.json`, hypotheses H1 to H6, in words):

- H1, the problem: the instantaneous Kohn-Sham problem of `Revision/kohn_sham/ks-theory.json` at a fixed slice $a_{4,0}$ of the author's metric, in the good sector, with a lattice of 3-momenta and the block Hamiltonians h_j on $-L \le y \le 0$.
- H2, the functional: Hartree plus the exact exchange of the uniform gas, $M_{\text{eff}} = m + \frac{15}{16}\lambda S$, $v_v = -\lambda n/16$, no correlation; the energy-momentum tensor of that record.
- H3, the brane, ASSUMED: the Z2 mirror construction at $y = 0$; both parities are solved and filled together with the weight $w_{Z2} = \frac{1}{2}$.
- H4, the tip, chosen: $(1 - Q(\theta))\chi(-L) = 0$.
- H5, the occupations: Mermin's at fixed N, with the filling convention of the record.
- H6, the same remaining data for both members: the same H, L, $a_{4,0}$, lattice, extra-time volume, N and T; mean-field (quasi-free) states only.

Theorem T3 (the Kohn-Sham level of the pairing). Under H1 to H6, the map $(\chi, j) \to (\sigma_2\chi, -j)$ at the same 3-momentum, which is the chirality Γ of the 16-component orbital (up to the sign s_2 of each block), with the two brane parities exchanged and the tip angle $\theta \to \pi - \theta$, maps every self-consistent instantaneous Kohn-Sham state with (m, λ, θ) onto a self-consistent Kohn-Sham state with $(-m, +\lambda, \pi - \theta)$, and conversely (the map is an involution). The two states have:

- S1: the same levels, orbital by orbital: the orbital of the type j and the parity p goes to the type $-j$ and the other parity, at the same momentum and the same level;
- S2: with the untransformed tip the spectra differ (Section 19.12);
- S3: the densities transform as $n \to n$, $t \to t$, $S \to -S$, $Q \to -Q$, so $M_{\text{eff}} \to -M_{\text{eff}}$ and $v_v \to v_v$; with $(-m, -\lambda)$ instead of $(-m, +\lambda)$ the map fails;
- S4: equal levels with their degeneracies, occupations, chemical potential, particle number, entropy, Kohn-Sham energy E_{KS}, grand potential Ω and free energy F, and equal profiles $\rho(y)$, $p_3(y)$, $p_t(y)$, $p_0(y)$; $S(y)$ and $Q(y)$ change sign;
- S5: inside the ASSUMED Z2 orbifold the mirror copy of a self-consistent state carries $(-m, +\lambda)$ (Section 19.11).

The records. Each step of the proof is a named check of two independent verifiers that share no code (with one exception at the time of the adversarial verification, the v_v clause of Step 3, Section 19.8, closed by the completion below). Every check below has the verdict PASS.

step	what it shows	wolfram-t3.json	python-t3.json
1	$\sigma_2 h_j(M)\sigma_2 = h_{-j}(-M)$, also for N	T3_block_hamiltonian_map, T3_ode_map	T3.block_hamiltonian_map, T3.ode_map
2	tip $\theta \to \pi - \theta$; parities exchanged; current and norm kept	T3_tip_condition_map, T3_brane_parities_exchanged	T3.tip_condition_map, T3.brane_parities_exchanged
3	n, t even, S, Q odd; the mean field closes for $(-m, +\lambda)$ only	T3_orbital_densities, T3_mean_field_map	T3.orbital_densities, T3.mean_field_map
4	equal energies and profiles	T3_energies_and_emt_profiles_equal	T3.energies_and_emt_profiles_equal
confirmations	exact $k = 0$ spectra; Γ is the block map; the mirror copy	T3_exact_k0_spectra, T3_Gamma_is_the_block_map, T3_z2_mirror_copy_carries_minus_m_plus_lambda	T3.exact_k0_spectra, T3.Gamma_is_the_block_map, T3.z2_mirror_copy_carries_minus_m_plus_lambda
comparison	the sympy side confirms the Wolfram theorem record and its list of limits	none	compare.t3_theory.theorem, compare.t3_theory.not_established
numbers	the Rust solver's self-test (a confirmation, not a proof)	none	T3.rust_selftest_numerical_confirmation

So `wolfram-t3.json` has 10 checks and `python-t3.json` 13 (the ten counterparts, the two comparisons and the numerical confirmation). The record `Revision/docs/PAIR_CREATION_PROOFS.md` (its section 8) collects the same proof.

The numerical confirmation. The Rust solver's report `Revision/kohn_sham/reports/ks-rust-solver.json` holds the check t3_block_map_solver_selftest: the problems $(m, \lambda, \theta = 0)$ and $(-m, \lambda, \theta = \pi)$, solved independently at the slice $a_{4,0} = 1$, gave the same sorted levels, occupations, Kohn-Sham energies and integrated energy-momentum components and the opposite S, with the worst difference 9.95×10^{-14} against the tolerance 10^{-9} fixed in advance. For $N = 8$ and $\lambda = 0.01946$: $E_{KS} = -9.868426190876 \times 10^{-4}$ against $-9.868426190868 \times 10^{-4}$ (80 levels), while the control with the untransformed tip gave -2.0145243719. For $N = 136$ and $\lambda = 0.0009298$: $E_{KS} = 32.39294915318$ in both runs (160 levels), control 29.283751318. Status: COMPUTED; the report itself labels it "NOT a proof of T3". Notebook 19a reproduces these numbers. This self-test of two states was the only numerical confirmation recorded with T3 (the fourth gap of the adversarial verification); the completion replaces it by the two demonstrations below.

The completion of 2026-10-08. An adversarial verification re-ran both T3 verifiers (they reproduce `t3-theory.json` and the two T3 reports byte for byte) and re-derived every step of the proof by hand. It found no error in the statement or the proof of T3, and five gaps, listed in `Revision/pairing/kohn_sham/t3-completion.json`, entry adversarial_verification. The completion is a separate record; T3, its hypotheses H1 to H6 and its statements S1 to S5 are unchanged. Its exact checks are those of `Revision/pairing/kohn_sham/reports/wolfram-t3-completion.json`

(3 of 3 PASS) and `Revision/pairing/kohn_sham/reports/python-t3-completion.json` (7 of 7 PASS):

gap	what was missing	Wolfram check	sympy check
1	the coefficients of the mean field were typed into the Wolfram script, and its v_v clause compared an expression with itself (Section 19.8; the script has since been fixed at the root)	`T3C_mean_field_coefficients_from_ks_theory`	`T3C.mean_field_coefficients_from_ks_theory`
2	the filling convention was used for the partner without showing that its particle levels are the images of the original's (Section 19.9, item (iv))	`T3C_filling_convention_mapped`	`T3C.filling_convention_mapped`
3	only the four diagonal energy-momentum components of the 2×2 reduction were proved equal (statement S6 below)	`T3C_krein_rule_16_component`	`T3C.krein_rule_16_component`
4	the numerical confirmation was the two-state self-test (the demonstrations below)	none	`T3C.rust_demo_numerical_demonstration`, `T3C.reference_demo_numerical_demonstration`
5	`t3-theory.json` does not name the history of the numerical states a PRESCRIBED BACKGROUND; the completion record does	none	none
all	the T3 reports pass; the sympy side confirms the completion record	none	`T3C.t3_reports_pass`, `compare.t3_completion`

Statement S6: the 16-component expectation rule. Steps 3 and 4 work with the 2×2 blocks and the four diagonal components ρ, p_3, p_t, p_0. S6 says: with the expectation rule $\rho = \sum f\, uu^\dagger B$ of Section 19.4 (here ρ is the 16×16 matrix of the rule, not the energy density), the image state, whose orbitals are $u' = \Gamma u$, has $\rho' = -\Gamma\rho\Gamma$, so n is unchanged, S and Q change sign, and every component of the energy-momentum tensor and of the current $J^a = \langle\bar{\Psi}\gamma^{(x_a)}\Psi\rangle$ is unchanged. The derivation, line by line. First, because $B^2 = 1$, multiplying $\rho = \sum f\, uu^\dagger B$ from the right by B gives

$$\sum f\, uu^\dagger = \rho B.$$

Rule: $BB = 1$. Then, for the image orbitals,

$$\rho' = \sum f\,(\Gamma u)(\Gamma u)^\dagger B = \sum f\,\Gamma u u^\dagger \Gamma^\dagger B = \Gamma\Big(\sum f\, uu^\dagger\Big)\Gamma B = \Gamma\rho B\Gamma B.$$

Rule: $(\Gamma u)^\dagger = u^\dagger\Gamma^\dagger$; $\Gamma^\dagger = \Gamma$ (real and diagonal, Section 19.5); the constant matrix Γ comes out of the sum; the line before. Now $\Gamma B = -B\Gamma$ (Section 19.5), so

$$B\Gamma B = -\Gamma BB = -\Gamma, \qquad \rho' = \Gamma\rho(B\Gamma B) = -\Gamma\rho\Gamma.$$

Rule: replace $B\Gamma$ by $-\Gamma B$, then $BB = 1$. The expectation value of any 16×16 matrix X in the image state is then

$$\langle X\rangle' = \mathrm{Tr}(X\rho') = -\mathrm{Tr}(X\Gamma\rho\Gamma) = -\mathrm{Tr}(\Gamma X\Gamma\rho).$$

Rule: the trace does not change when the factors are moved around in a circle; here the last factor Γ is moved to the front. Section 19.5 showed $\Gamma X\Gamma = +X$ when X is a number times a product of an even number of gammas, and $\Gamma X\Gamma = -X$ for an odd number. Hence **an even product changes sign**, $\langle X\rangle' = -\langle X\rangle$, and **an odd product is unchanged**, $\langle X\rangle' = +\langle X\rangle$. Line by line for the quantities of the theory:

quantity	**matrix X**	**gammas in X**	**in the image state**
charge density n	$B = -iC\gamma^{(x_4)}$	5, odd	unchanged
scalar density S	C	4, even	sign reversed
density Q	$B\gamma^{(x_0)}$	6, even	sign reversed
current J^a	$C\gamma^{(x_a)}$	5, odd	unchanged
kinetic bilinears $\bar\Psi\gamma^{(x_a)}\partial\Psi$	$C\gamma^{(x_a)}$	5, odd	unchanged
spin-connection bilinears $\bar\Psi\gamma^{(x_a)}S^{bc}\Psi$	$C\gamma^{(x_a)}S^{bc}$	7, odd	unchanged

Rule for the table: C has four gammas, so $B = -iC\gamma^{(x_4)}$ has five, $B\gamma^{(x_0)}$ six and $C\gamma^{(x_a)}$ five, and $S^{bc} = \frac{1}{4}(\gamma^{(x_b)}\gamma^{(x_c)} - \gamma^{(x_c)}\gamma^{(x_b)})$ adds two; a constant factor such as $-i$ or $\frac{1}{4}$ does not matter, and Γ is constant, so it passes through the derivative ∂. The energy-momentum tensor is built from the kinetic and spin-connection bilinears (unchanged), from the mass term mS and from $U = \frac{\lambda}{2}S^2$: with $m\to -m$ and $S\to -S$ the product mS is unchanged, and with the same λ so is U. So every component of the 16-component energy-momentum tensor and every component of the current are the same in the two members, while S and Q change sign. The record verifies each ingredient with the author's matrices of `Revision/algebra/gammas.json`: $\Gamma^2 = 1$, $\Gamma B\Gamma = -B$, $\Gamma C\Gamma = C$, $\Gamma\gamma^{(x_a)}\Gamma = -\gamma^{(x_a)}$ for all eight a, $\Gamma S^{ab}\Gamma = S^{ab}$ for all 64 pairs, $(\Gamma u)(\Gamma u)^\dagger B = -\Gamma(uu^\dagger B)\Gamma$ for a general 16-component u, and the $8 + 512$ kinetic bilinears. Status: PROVED; checks T3C_krein_rule_16_component and T3C.krein_rule_16_component. S6 is an equality of expectation values in Kohn-Sham (quasi-free) states with the fixed Krein matrix B, not a statement about two independently quantised universes.

The two numerical demonstrations (status COMPUTED; demonstrations, not part of the proof). Each solves, at the slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$ of the PRESCRIBED BACKGROUND history, three members of every state: **plus**, the universe (m, λ) with the tip angle 0 (the A of Section 19.17); **image**, the universe $(-m, +\lambda)$ with the tip angle π (B); and **control**, $(-m, +\lambda)$ with the untransformed tip angle 0 (C).

- The Rust solver (`Revision/pairing/kohn_sham/reports/t3-rust-demo.json`, 7 of 7 checks PASS; table `Revision/pairing/kohn_sham/numerics/results/t3-rust-states.csv`) on all 210 states of the canonical matrix: 75 ground states ($N = 8,136,688$; $\lambda = 0, \pm\lambda_1, \pm\lambda_2$; five slices) and 135 Mermin states ($\lambda = 0, \pm\lambda_1$ at $T = 0.01, 0.02, 0.05$), 630 runs in all. The plus members reproduce the committed canonical matrix to 2.538×10^{-10}. Image equals plus to 2.179×10^{-13} in the ground states and 3.877×10^{-12} in the thermal states (tolerance 10^{-9}): the levels label by label with the sector map $(n_2, j, \text{parity}) \to (n_2, -j, \text{other parity})$, the occupations, E_{KS}, μ, the entropy, Ω, F, the gap, the energy-momentum integrals, the even profiles point by point, and S, Q, M_{eff} with the opposite sign. The control differs from plus: its density profile $n(y)$ differs by at least 4.750 times the maximum of n (state N8_lamm1_a15) in the 196 states where the solver found a control state; in the other 14 states, all with $\lambda < 0$, the self-consistency loop of the control diverges, which the record reports as such and not as a proof that no such state exists. A second control, the T1 parameters $(-m, -\lambda)$ with the tip angle π, differs from plus by at least 1.21×10^{-2} in all 150 states with $\lambda \neq 0$: the Kohn-Sham partner carries $+\lambda$. The agreement of image and plus is at the rounding level **by construction**, because the solver's shooting is covariant under the map (Section 19.17 shows why); it tests the solver's handling of the transformed boundary conditions, the labels, the filling convention, the self-consistency loop and the Mermin root, not the discretisation.
- The independent reference solver (`Revision/pairing/kohn_sham/reports/t3-reference-demo.json`, 7 of 7 checks PASS; Chapter 16): finite differences on grids of 300, 600 and 1200 points, combined by Richardson extrapolation (the combination of the three grids in which the leading discretisation error cancels), on 18 states (13 ground, 5 Mermin). Its frame for the image is not the discrete image of the plus frame, so on a single grid the levels of the two members differ by up to 2.23×10^{-4}; after the extrapolation image equals plus to 2.043×10^{-14} (ground) and 3.038×10^{-14} (thermal). This is the test that does not depend on the discretisation: a statement about the continuum problem. The exact zero-momentum image spectra are reproduced to 2.80×10^{-14}; the control's density differs by at least 5.296 times the maximum (3 states without a converged control, all with $\lambda < 0$); and the $-M$ universe of the reference solver equals the $-M$ universe of the Rust solver to 1.255×10^{-11}.

What the completion adds to the list of what is not established (`t3-completion.json`, entry not_established): the demonstrations show the equalities only on the states solved, to their stated tolerances, and control states for which a solver found no self-consistent solution are reported as such, not as a proof that none exists; S6 is not a statement about two independently quantised universes; the filling convention is a CONVENTION whose justification is OPEN. Section 19.22 collects the whole list.

19.11 Why T3 is not T1, and the mirror copy in the Z2 orbifold

Two theorems, one matrix. T1 (Chapter 18) and T3 are both built on the chirality Γ, yet T1 pairs (m, λ) with $(-m, -\lambda)$ at opposite energies and T3 pairs (m, λ, θ) with $(-m, +\lambda, \pi - \theta)$ at equal energies. There is no contradiction, because they speak about different quantities.

- T1 is about the **classical bilinears** $\Psi^\dagger X \Psi$ of the field. Under $\Psi \to \Gamma\Psi$ such a bilinear becomes $\Psi^\dagger \Gamma X \Gamma \Psi$, and $\Gamma X \Gamma = +X$ for an even product of gammas, $-X$ for an odd one (Section 19.5).
- T3 is about the **expectation values** $u^\dagger B X u$ of the quantised theory (Section 19.4), which contain one more factor, the Krein matrix B. Under $u \to \Gamma u$ they become $u^\dagger \Gamma B X \Gamma u = u^\dagger (\Gamma B \Gamma)(\Gamma X \Gamma) u = -u^\dagger B (\Gamma X \Gamma) u$, because $\Gamma B \Gamma = -B$ (Section 19.5) and $\Gamma\Gamma = 1$.

So every sign of T1 is reversed at the Kohn-Sham level. Line by line for the two densities that matter:

quantity	**matrix X**	**gammas in X**	**classical bilinear (T1)**	**Kohn-Sham density (T3)**
scalar density S	C	4, even	unchanged	sign reversed
charge density n	B	5, odd	sign reversed	unchanged

The classical scalar density is unchanged under Γ (`Revision/pairing/reports/python-pairing.json`, checks T1.metric.grassmann.S_invariant and T1.metric.commuting.S_invariant) and the classical current is reversed (checks T1.metric.grassmann.current and T1.metric.commuting.current); then self-consistency of the mass term $m + \lambda S$ in the field equation $\gamma^\mu D_\mu \Psi = (m + \lambda S)\Psi$, whose left side changes sign under Γ, requires $(m, \lambda) \to (-m, -\lambda)$. At the Kohn-Sham level S changes sign and n does not, and the same requirement gives $(m, \lambda) \to (-m, +\lambda)$, as Step 3 found. The record states this comparison as an interpretation, labelled as such and not as a theorem: in its parameters the Kohn-Sham map is of the T2 type (same coupling, equal energies), although its matrix is the chirality of T1 (`t3-theory.json`, entry relation_to_T1_T2; section 8.4 of the record `Revision/docs/PAIR_CREATION_PROOFS.md`).

The mirror copy inside the Z2 orbifold. The brane condition of Section 19.3 comes from the ASSUMED Z2 construction: the patch $-L \le y \le 0$ is glued at $y = 0$ to its mirror image $0 \le y \le L$. On the doubled interval the record uses the reflection P_A: $\chi(y) \to \phi(y) = \sigma_3 \chi(-y)$. Write $h(M, \kappa, v) = -i\sigma_1 \frac{d}{dy} + M\sigma_2 + \kappa k \sigma_3 + v$ (the type j is a common factor and plays no role here). Line by line, with $\frac{d\phi}{dy}(y) = -\sigma_3 \chi'(-y)$ (chain rule):

$$
\begin{aligned}
h(-M(-y), \kappa(-y), v(-y))\phi = {} & i\sigma_1\sigma_3\chi'(-y) - M(-y)\sigma_2\sigma_3\chi(-y) \\
& + \kappa(-y)k\,\sigma_3\sigma_3\chi(-y) + v(-y)\sigma_3\chi(-y),
\end{aligned}
$$

$$
\begin{aligned}
\sigma_3\big(h(M, \kappa, v)\chi\big)(-y) = {} & -i\sigma_3\sigma_1\chi'(-y) + M(-y)\sigma_3\sigma_2\chi(-y) \\
& + \kappa(-y)k\,\sigma_3\sigma_3\chi(-y) + v(-y)\sigma_3\chi(-y).
\end{aligned}
$$

Rule: insert ϕ in the first line; multiply $h\chi$ at the point $-y$ by σ_3 in the second. The two lines are equal term by term, because $\sigma_1\sigma_3 = -\sigma_3\sigma_1$ and $\sigma_2\sigma_3 = -\sigma_3\sigma_2$. So P_A maps an orbital of

the mass function $M(y)$ onto an orbital of the mass function $-M(-y)$, with the potential $v(-y)$ (check bc_mirror_map_PA of the Kohn-Sham theory reports). The doubled problem has one mass function on the whole interval, so it is symmetric under P_A exactly when $M_{\text{eff}}(y) = -M_{\text{eff}}(-y)$: the mass is **odd** across the brane. Under σ_3, n_o is unchanged and s_o changes sign ($\sigma_3\sigma_2\sigma_3 = -\sigma_2$), so on the mirror side $n(y) = n(-y)$ and $S(y) = -S(-y)$. If the mirror side has the parameters $(\tilde{m}, \tilde{\lambda})$, its mass at a point $y > 0$ is, line by line,

$$\tilde{m} + \frac{15}{16}\tilde{\lambda}S(y) = \tilde{m} - \frac{15}{16}\tilde{\lambda}S(-y),$$

and it must equal $-M_{\text{eff}}(-y) = -m - \frac{15}{16}\lambda S(-y)$ for every value of $S(-y)$; its potential $-\tilde{\lambda}n(y)/16 = -\tilde{\lambda}n(-y)/16$ must equal $v_v(-y) = -\lambda n(-y)/16$. Comparing the terms with and without the densities gives $\tilde{\lambda} = \lambda$ and $\tilde{m} = -m$: **inside the ASSUMED orbifold, the mirror copy of a self-consistent state of the universe of mass $+M$ is a universe of mass $-M$ with the same coupling**, the statement S5 (checks T3_z2_mirror_copy_carries_minus_m_plus_lambda and T3.z2_mirror_copy_carries_minus_m_plus_lambda; bc_mirror_parities_of_densities). This is a property of the assumed geometric construction, not a derivation that such a pair exists or was created.

19.12 The exact levels at zero momentum, and what goes wrong without the transformed tip

Without the 3-momentum ($k = 0$) and without the interaction ($M_{\text{eff}} = M$ constant, $v_v = 0$) the block equation can be solved exactly. This gives T3 a second, independent confirmation, and it shows exactly what happens to the **control** C: the universe of mass $-M$ with the UNtransformed tip angle $\theta = 0$.

The square of N. With $k = 0$ and $v = 0$, $N = M\sigma_3 + ij\varepsilon\sigma_1$. Line by line:

$$N^2 = M^2\sigma_3^2 + Mij\varepsilon\,(\sigma_3\sigma_1 + \sigma_1\sigma_3) + (ij\varepsilon)^2\sigma_1^2 = M^2\,\mathbf{1} + 0 - \varepsilon^2\,\mathbf{1} = (M^2 - \varepsilon^2)\,\mathbf{1}.$$

Rule: multiply out the square of a sum of two matrices, keeping the order of the factors; $\sigma_3^2 = \sigma_1^2 = \mathbf{1}$; $\sigma_3\sigma_1 + \sigma_1\sigma_3 = 0$; $(ij)^2 = i^2j^2 = -1$. Write $p = \sqrt{M^2 - \varepsilon^2}$; inside the mass gap ($\varepsilon^2 < M^2$) p is real, outside it $p = ir$ with the real $r = \sqrt{\varepsilon^2 - M^2}$.

The solution. $\chi(y) = e^{Ny}\chi(0)$, with the matrix exponential $e^{Ny} = \sum_{n\geq 0}(Ny)^n/n!$. The even powers are $N^{2r} = p^{2r}\mathbf{1}$ and the odd ones $N^{2r+1} = p^{2r}N$, so

$$e^{Ny} = \sum_{r\geq 0}\frac{(py)^{2r}}{(2r)!}\,\mathbf{1} + \sum_{r\geq 0}\frac{p^{2r}y^{2r+1}}{(2r+1)!}\,N = \cosh(py)\,\mathbf{1} + \frac{\sinh(py)}{p}\,N.$$

Rule: the series $\cosh x = \sum x^{2r}/(2r)!$ and $\sinh x = \sum x^{2r+1}/(2r+1)!$. Check: $\frac{d}{dy}e^{Ny} = p\sinh(py) + \cosh(py)N$ and $Ne^{Ny} = \cosh(py)N + \frac{\sinh(py)}{p}N^2 = \cosh(py)N + p\sinh(py)$: the same. At the tip $y = -L$, since cosh is even and sinh odd,

$$\chi(-L) = \Big[\cosh(pL)\,\mathbf{1} - \frac{\sinh(pL)}{p}\,N\Big]\chi(0).$$

The characteristic functions. Start at the brane with the parity, $\chi(0) = (1, 0)$ (even) or $(0, 1)$ (odd), go to the tip, and take the component that the tip condition must make zero: as a function of ε this is the **characteristic function** $D(\varepsilon)$, and its zeros are the levels. The matrix N has the columns $N(1, 0) = (M, ij\varepsilon)$ and $N(0, 1) = (ij\varepsilon, -M)$. Line by line, for the three universes:

universe	**mass, type, tip**	**even:** $\chi(0) = (1, 0)$	**odd:** $\chi(0) = (0, 1)$
A	M, j, $\theta = 0$: $\chi_2(-L) = 0$	$D = -ij\varepsilon \sinh(pL)/p$	$D = \cosh(pL) + M \sinh(pL)/p$
B	$-M$, $-j$, $\theta = \pi$: $\chi_1(-L) = 0$	$D = \cosh(pL) + M \sinh(pL)/p$	$D = +ij\varepsilon \sinh(pL)/p$
C	$-M$, j, $\theta = 0$: $\chi_2(-L) = 0$	$D = -ij\varepsilon \sinh(pL)/p$	$D = \cosh(pL) - M \sinh(pL)/p$

Rule, for example for B odd: with the mass $-M$ and the type $-j$, $N(0, 1) = (-ij\varepsilon, +M)$, and the first component of $\chi(-L)$ is $0 \cdot \cosh(pL) - \frac{\sinh(pL)}{p}(-ij\varepsilon) = ij\varepsilon \sinh(pL)/p$. The other entries follow the same way. Reading the table: **B even is A odd, and B odd is minus A even**: the two problems have the same levels, with the parities exchanged, as T3 says. **C even is A even, but C odd is not A odd**: the control differs in the odd sector. Status: PROVED; checks T3_exact_k0_spectra and T3.exact_k0_spectra (identically in ε, M, L and for both j, with the control).

The levels of A (and B). Even: $\varepsilon \sinh(pL)/p = 0$. Inside the gap $p > 0$ and $\sinh(pL) > 0$, so only $\varepsilon = 0$: the **zero mode**. Outside the gap $\sinh(irL)/(ir) = \sin(rL)/r$, so $\sin(rL) = 0$, $r = n\pi/L$ and $\varepsilon = \pm\sqrt{M^2 + (n\pi/L)^2}$, $n = 1, 2, 3, \ldots$ Odd: $\cosh(pL) + M \sinh(pL)/p = 0$. Inside the gap both terms are positive (for $M > 0$): **no level in the gap**. Outside, $\cos(rL) + M \sin(rL)/r = 0$, that is $\tan(rL) = -r/M$ (check bc_exact_k0_spectra of the Kohn-Sham theory reports).

The levels of C, and the level inside the gap. Odd: $\cosh(pL) - M \sinh(pL)/p = 0$. Inside the gap, with $p = q$ real, this is $\cosh(qL) = M \sinh(qL)/q$, that is

$$\tanh(qL) = \frac{q}{M}.$$

The function $u(q) = \tanh(qL) - q/M$ has $u(0) = 0$, the slope $u'(0) = L - 1/M = 2$ for $M = 1$, $L = 3$ (positive), and $u(M) = \tanh(ML) - 1 < 0$; it is concave for $q > 0$ (because tanh is), so it has exactly one root q in $(0, M)$. The level is, line by line,

$$\varepsilon_b^2 = M^2 - q^2 = M^2 - M^2 \tanh^2(qL) = \frac{M^2}{\cosh^2(qL)}, \qquad \varepsilon_b = \frac{M}{\cosh(qL)}.$$

Rule: $q = M \tanh(qL)$ from the condition; $1 - \tanh^2 = 1/\cosh^2$. For $M = 1$, $L = 3$: $q = 0.994901528453$ and $\varepsilon_b = 0.100851121375$ (Notebook 19a, Out [18]; Notebook 19b finds the same level as a zero of D). Outside the gap the odd levels of C obey $\tan(rL) = +r/M$, and no odd level of C equals an odd level of A: if $\cos(rL) + M \sin(rL)/r = 0$ and $\cos(rL) - M \sin(rL)/r = 0$ both held, their sum would give $\cos(rL) = 0$ and their difference $\sin(rL) = 0$, impossible because $\cos^2 + \sin^2 = 1$.

The numbers. For $M = 1$, $L = 3$, below $\varepsilon = 4$ (Notebook 19b, Out [13] and Out [16]):

sector	levels
A even = B odd = C even	0, 1.4479719304, 2.3208814802, 3.2969083095
A odd = B even	1.2922928281, 2.0106285600, 2.9119358754, 3.8829900326
C odd	0.1008511214, 1.6875789860, 2.6839784554, 3.7115109122

The even levels are $\sqrt{1+(n\pi/3)^2}$ for $n = 1, 2, 3$. The levels of A reproduce the analytic table `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv` to 8.9×10^{-16}, and the lowest odd level 1.2922928281 is the "bulk edge" of `Revision/kohn_sham/results/parameters.json`. For $v = 0$ the levels of the type $-j$ are the negatives of those of the type j, so each ladder is symmetric about zero.

Where the zero modes live. At $\varepsilon = 0$, $N = M\sigma_3$, so $\chi_1' = M\chi_1$ and $\chi_2' = -M\chi_2$. For A (even, $\chi_2(0) = 0$) this forces $\chi_2 = 0$ everywhere and $\chi = (e^{My}, 0)$, which also obeys the tip condition $\chi_2(-L) = 0$: a zero mode **largest at the brane**. For B (mass $-M$, so $\chi_1' = -M\chi_1$, $\chi_2' = M\chi_2$; odd, $\chi_1(0) = 0$) it gives $\chi = (0, e^{My})$, again largest at the brane, the image $\sigma_2(e^{My}, 0) = (0, ie^{My})$ up to the factor i. For C (mass $-M$, even) it gives $\chi = (e^{-My}, 0)$: a zero mode **largest at the tip**. The coordinate density $e^{6Hy}n(y)$ of a zero mode is $|\chi|^2/(\ell^3 v_t)$, proportional to e^{2My} for A and B and to e^{-2My} for C; its value at the brane divided by its value at the tip is $e^{2ML} = e^6 = 403.4288$ for A and B and $e^{-6} = 0.002478752$ for C (Notebook 19a, Out [17]).

The brane band and its slope. When a small 3-momentum k is switched on, the zero mode becomes the lowest level of the **brane band**. Its slope follows from the Hellmann-Feynman rule with $\delta h = \frac{\partial h_j}{\partial k}k = jk\kappa\sigma_3$, $\kappa = e^{-Hy}$ at the slice $a_{4,0} = 0$. For A ($j = 1$, $\chi = (e^{My}, 0)$, $\chi^\dagger\sigma_3\chi = e^{2My}$), line by line:

$$c = \frac{\int_{-L}^{0} e^{-Hy}e^{2My}\,dy}{\int_{-L}^{0} e^{2My}\,dy} = \frac{(1-e^{-(2M-H)L})/(2M-H)}{(1-e^{-2ML})/(2M)} = \frac{2M}{2M-H}\cdot\frac{1-e^{-(2M-H)L}}{1-e^{-2ML}}.$$

Rule: $\int_{-L}^{0} e^{\alpha y}dy = (1-e^{-\alpha L})/\alpha$, with $\alpha = 2M - H$ and $\alpha = 2M$. For B ($j = -1$, $\chi = (0, ie^{My})$): $j\chi^\dagger\sigma_3\chi = (-1)(-e^{2My}) = e^{2My}$, the same integrand: **the same slope**. For C ($j = 1$, $\chi = (e^{-My}, 0)$):

$$c_{\text{ctrl}} = \frac{\int_{-L}^{0} e^{-(2M+H)y}\,dy}{\int_{-L}^{0} e^{-2My}\,dy} = \frac{2M}{2M+H}\cdot\frac{e^{(2M+H)L}-1}{e^{2ML}-1}.$$

Rule: $\int_{-L}^{0} e^{-\beta y}dy = (e^{\beta L}-1)/\beta$. For $M = H = 1$, $L = 3$: $c = 2/(1+e^{-3}) = 1.9051482536449$ (`ks-theory.json`, entry checksNumeric; check brane_band_slope; `Revision/kohn_sham/results/spectrum/brane-band-slope.csv`) and $c_{\text{ctrl}} = 13.4219751976$, about seven times larger (Notebook 19b, Out [19]). The reason is visible in the integrands: the control's zero mode lives at the tip, where the redshift weight $\kappa = e^{-Hy}$ is largest (e^3 at $y = -3$), so a 3-momentum costs it much more energy. At a later slice both slopes are multiplied by $e^{-a_{4,0}}$, the redshift.

Summary of the control. With the untransformed tip, three things go wrong at once: the zero modes move from the brane to the tip; a level appears inside the mass gap, $\varepsilon_b = 0.1009$; and the brane band starts seven times steeper. The self-consistent states of C therefore differ from those

of A in every number, as Notebook 19a shows. T3 is not an automatic symmetry of the solver: it needs exactly the transformed tip.

19.13 Example: the proof of T3 by hand (Notebook 19b)

Notebook 19b repeats Sections 19.5 to 19.12 with the computer, as far as possible exactly. It reads the author's eight gammas from the record, checks with whole numbers that they are real signed permutation matrices obeying the anticommutation rule, forms the chirality Γ, and shows that Γ maps every block onto its partner block as $\pm\sigma_2$ (Section 19.5). With sympy it re-derives the four steps of the proof (Sections 19.6 to 19.9: the block Hamiltonian, the tip and brane conditions, the densities, the mean field), each time with the negative control, and reproduces the corresponding checks of `python-t3.json`. It computes the six characteristic functions of Section 19.12 symbolically, finds their zeros numerically, compares the levels of A with the analytic table of the record, finds the control's level inside the mass gap, finds all these levels a second time by shooting (Runge-Kutta integration from the tip to the brane), and measures the slopes of the brane band of A, B and C against the closed forms. It needs Python only (numpy, sympy, matplotlib), takes about 50 seconds (24.2 s in the recorded build on the computer that built this book), draws six figures and ends with the line ALL 19 CHECKS PASSED (notebook 19b).

19.14 How to run Notebook 19b

Step 1. What this notebook does and what it needs.

Notebook 19b (Theorem T3 by hand: the block map, the exact spectra and the control) is the file `Revision/textbook/notebooks/19b_t3_by_hand.ipynb` of the repository Dirac_claude. It reads the eight real 16 x 16 gamma matrices of the record, checks that they are real signed permutation matrices that obey the anticommutation rule of the signature (4,4), builds their product, the chirality Gamma, and shows that Gamma maps each 2 x 2 Kohn-Sham block onto its partner block as the Pauli matrix sigma2. It then re-derives with exact algebra (sympy) every step of the proof of theorem T3: the block Hamiltonian, the boundary conditions, the densities and the mean field. It computes the exact zero-momentum spectra of the universe of mass +M, of its T3 partner and of the negative control with the untransformed tip, finds the level that only the control has inside the mass gap, and solves the brane band at small momenta by shooting, comparing its slope with the closed forms. It reproduces the corresponding Revision records and draws six figures. Python only; no Rust is needed. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at

the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 19b_t3_by_hand.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 50 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 19b_t3_by_hand.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 19b_t3_by_hand.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/19b.captions.json`

- `Revision/textbook/figures/19b_1_eight_gammas.png`
- `Revision/textbook/figures/19b_2_gamma_block_map.png`
- `Revision/textbook/figures/19b_3_mean_field_map.png`
- `Revision/textbook/figures/19b_4_characteristic_functions.png`
- `Revision/textbook/figures/19b_5_k0_ladders.png`
- `Revision/textbook/figures/19b_6_brane_band.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 19 CHECKS PASSED (notebook 19b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/19b_t3_by_hand.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 19b_t3_by_hand.ipynb
python -m nbconvert --execute --inplace 19b_t3_by_hand.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- A sympy cell runs for more than a minute: the exact simplifications take a few seconds on a normal computer. If a cell runs much longer, check that the installed sympy is the version pinned in the requirements file, and run the notebook again.
- A shooting cell shows the label with the star for half a minute: this is normal: the shooting cells integrate the equations for thousands of levels at once (3000 Runge-Kutta steps each). Wait until the label shows a number.

19.15 Notebook 19b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/19b_t3_by_hand.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Theorem **T3** of the Revision record pairs every self-consistent Kohn-Sham state of
the universe with the bare mass $+m$, the coupling $\lambda$ and the tip angle
$\theta$ with a state of the universe with the bare mass $-m$, the **same** coupling
$+\lambda$ and the tip angle $\pi - \theta$, with equal levels, energies and
```

energy-momentum profiles and the opposite scalar density. This notebook does the proof by hand, with exact algebra where possible and with small, transparent numerical computations where a number is needed. It

- reads the author's eight real 16×16 gamma matrices, draws them, checks that they are real and obey the anticommutation rule, and builds their product, the chirality Γ;
- shows that Γ maps each 2×2 block of the Kohn-Sham problem onto its partner block as the Pauli matrix σ_2: this is the map of T3;
- re-derives every algebraic step of the proof of T3 exactly with sympy;
- computes the exact spectra at zero momentum of three universes: A (mass $+m$, tip angle 0), its T3 partner B (mass $-m$, tip angle π) and the control C (mass $-m$, tip angle 0, the tip NOT transformed), and finds the level that only C has inside the mass gap;
- solves the lowest band at small momenta by shooting and compares its slope with formulas derived here.

It needs Python only and takes about a minute.

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 19b (Theorem T3 by hand: the block map, the exact spectra and the control) is the file ‘Revision/textbook/notebooks/19b_t3_by_hand.ipynb‘ of the repository Dirac_claude. It reads the eight real 16 x 16 gamma matrices of the record, checks that they are real signed permutation matrices that obey the anticommutation rule of the signature (4,4), builds their product, the chirality Gamma, and shows that Gamma maps each 2 x 2 Kohn-Sham block onto its partner block as the Pauli matrix sigma2. It then re-derives with exact algebra (sympy) every step of the proof of theorem T3: the block Hamiltonian, the boundary conditions, the densities and the mean field. It computes the exact zero-momentum spectra of the universe of mass +M, of its T3 partner and of the negative control with the untransformed tip, finds the level that only the control has inside the mass gap, and solves the brane band at small momenta by shooting, comparing its slope with the closed forms. It reproduces the corresponding Revision records and draws six figures. Python only; no Rust is needed. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the

default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
```

```
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 19b_t3_by_hand.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 50 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 19b_t3_by_hand.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 19b_t3_by_hand.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/19b.captions.json‘
- ‘Revision/textbook/figures/19b_1_eight_gammas.png‘
- ‘Revision/textbook/figures/19b_2_gamma_block_map.png‘
- ‘Revision/textbook/figures/19b_3_mean_field_map.png‘
- ‘Revision/textbook/figures/19b_4_characteristic_functions.png‘
- ‘Revision/textbook/figures/19b_5_k0_ladders.png‘
- ‘Revision/textbook/figures/19b_6_brane_band.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on

another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 19 CHECKS PASSED (notebook 19b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/19b_t3_by_hand.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 19b_t3_by_hand.ipynb
  python -m nbconvert --execute --inplace 19b_t3_by_hand.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel

  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- A sympy cell runs for more than a minute: the exact simplifications take a few seconds
  on a normal computer. If a cell runs much longer, check that the installed sympy is the
  version pinned in the requirements file, and run the notebook again.
- A shooting cell shows the label with the star for half a minute: this is normal: the
  shooting cells integrate the equations for thousands of levels at once (3000
  Runge-Kutta steps each). Wait until the label shows a number.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 19b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 19b (Theorem T3 by hand: the block map, the exact spectra and the control) is
# the file Revision/textbook/notebooks/19b_t3_by_hand.ipynb of the repository
# Dirac_claude. It reads the eight real 16 x 16 gamma matrices of the record, checks that
# they are real signed permutation matrices that obey the anticommutation rule of the
# signature (4,4), builds their product, the chirality Gamma, and shows that Gamma maps
# each 2 x 2 Kohn-Sham block onto its partner block as the Pauli matrix sigma2. It then
# re-derives with exact algebra (sympy) every step of the proof of theorem T3: the block
# Hamiltonian, the boundary conditions, the densities and the mean field. It computes the
# exact zero-momentum spectra of the universe of mass +M, of its T3 partner and of the
# negative control with the untransformed tip, finds the level that only the control has
# inside the mass gap, and solves the brane band at small momenta by shooting, comparing
# its slope with the closed forms. It reproduces the corresponding Revision records and
# draws six figures. Python only; no Rust is needed. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
```

```
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
```

```
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 19b_t3_by_hand.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
```

```
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 50
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 19b_t3_by_hand.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 19b_t3_by_hand.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/19b.captions.json
# - Revision/textbook/figures/19b_1_eight_gammas.png
# - Revision/textbook/figures/19b_2_gamma_block_map.png
# - Revision/textbook/figures/19b_3_mean_field_map.png
# - Revision/textbook/figures/19b_4_characteristic_functions.png
# - Revision/textbook/figures/19b_5_k0_ladders.png
# - Revision/textbook/figures/19b_6_brane_band.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 19 CHECKS PASSED (notebook 19b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
```

```
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/19b_t3_by_hand.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 19b_t3_by_hand.ipynb
#     python -m nbconvert --execute --inplace 19b_t3_by_hand.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - A sympy cell runs for more than a minute: the exact simplifications take a few
#   seconds on a normal computer. If a cell runs much longer, check that the installed
#   sympy is the version pinned in the requirements file, and run the notebook again.
# - A shooting cell shows the label with the star for half a minute: this is normal: the
#   shooting cells integrate the equations for thousands of levels at once (3000
#   Runge-Kutta steps each). Wait until the label shows a number.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Coordinates** (the author's names): $x_1, x_2, x_3$ = ordinary 3-space, which
  inflates; $x_4$ = the time; $x_5, x_6, x_7$ = the three **extra times**, which
  **deflate exponentially**; $x_0$ = the hidden space direction.
- **Hidden coordinate** $y$: it runs from the **tip** $y = -L$ ($L = 3$) to the
  **brane** $y = 0$.
- **Matrix**: a square table of numbers; **heat map**: a picture of a matrix in which
  every entry is a coloured square. **Real** matrix: all entries are real numbers.
  **Signed permutation matrix**: every row and every column holds exactly one entry
  $\pm 1$, all others are $0$.
- **Gamma matrices** $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$: the author's eight real
  $16 \times 16$ matrices with $\gamma^a\gamma^b + \gamma^b\gamma^a =
  2\eta^{ab}\mathbf{1}$, where $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$
  in the order $x_0, \dots, x_7$ and $\mathbf{1}$ is the unit matrix.
  **Chirality** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$.
- **Pauli matrices** $\sigma_1 = \begin{pmatrix}0&1\\1&0\end{pmatrix}$,
  $\sigma_2 = \begin{pmatrix}0&-i\\i&0\end{pmatrix}$,
  $\sigma_3 = \begin{pmatrix}1&0\\0&-1\end{pmatrix}$. Each squares to $\mathbf{1}$,
  and any two of them anticommute ($\sigma_a\sigma_b = -\sigma_b\sigma_a$ for
  $a \ne b$).
- **Block**: one of the eight pairs of components into which the 16 components of
  the Kohn-Sham problem split; labelled $(j, s_2, s_3)$ with signs $\pm 1$.
- **Orbital** $\chi(y) = (\chi_1(y), \chi_2(y))$: a two-component wave function of
  one block; **level** $\varepsilon$: its energy.
- **Brane parity**: even means $\chi_2(0) = 0$, odd means $\chi_1(0) = 0$. **Tip
  angle** $\theta$: the boundary condition $(1 - Q(\theta))\chi(-L) = 0$ with
  $Q(\theta) = \cos\theta\,\sigma_3 + \sin\theta\,\sigma_2$.
- **Characteristic function**: a function of $\varepsilon$ whose zeros are exactly
  the levels.
- **Shooting**: integrate the equation from one end with the boundary condition
  there and adjust $\varepsilon$ until the condition at the other end holds.
- **Mass gap**: the energies $-m < \varepsilon < m$, where a free particle of mass
  $m$ has no level.
- **sympy**: a Python package that computes with exact symbols and fractions.
- Status labels: PROVED (exact), COMPUTED (numerical), ASSUMED (a choice),
  HYPOTHESIS, OPEN (not known).
- Units: $H = 1$ and $|m| = 1$.
```

Text cell:

```
## 4. The physical and mathematical situation
```

In the instantaneous Kohn-Sham model of the fermion field dirac16complex in the author's deflating primordial field (record 'Revision/kohn_sham/ks-theory.json'), an orbital of block type $j = \pm 1$ with 3-momentum k solves

$$h_j\chi = \varepsilon\chi,\qquad h_j = j\Big[-i\sigma_1\frac{d}{dy}
+ M_{eff}(y)\,\sigma_2 + \kappa(y)\,k\,\sigma_3\Big] + v_v(y)$$

on $-L \le y \le 0$, with $\kappa = e^{-Hy - a_{4,0}}$ (the redshift of the 3-momenta while 3-space inflates and the extra times deflate), the effective mass $M_{eff} = m + \frac{15}{16}\lambda S$ and the potential $v_v = -\frac{1}{16}\lambda n$. Move everything except the derivative to the right:
$-ij\sigma_1\,d\chi/dy = (\varepsilon - v_v)\chi - j(M_{eff}\sigma_2 +
\kappa k\sigma_3)\chi$. Multiply from the left by $ij\sigma_1$; on the left $(ij\sigma_1)(-ij\sigma_1) = -i^2j^2\sigma_1^2 = \mathbf{1}$, on the right use $j^2 = 1$, $\sigma_1\sigma_2 = i\sigma_3$ and $\sigma_1\sigma_3 = -i\sigma_2$:
$-ij^2(M_{eff}\,i\sigma_3 - \kappa k\,i\sigma_2) = M_{eff}\sigma_3 - \kappa k\sigma_2$. The result is the first-order form of the record, $d\chi/dy = N\chi$ with $N = M_{eff}\sigma_3 - \kappa k\sigma_2 + ij(\varepsilon - v_v)\sigma_1$. Writing $\chi = (a, ib)$ with real a, b it is real:

$$\frac{da}{dy} = M_{eff}\,a - (\kappa k + j(\varepsilon - v_v))\,b,\qquad
\frac{db}{dy} = (j(\varepsilon - v_v) - \kappa k)\,a - M_{eff}\,b .$$

The boundary conditions: at the brane the Z_2 mirror (ASSUMED), even or odd parity, both solved; at the tip $(1 - Q(\theta))\chi(-L) = 0$ (chosen), which is $\chi_2(-L) = 0$ for $\theta = 0$ and $\chi_1(-L) = 0$ for $\theta = \pi$.

T3 (PROVED; records 't3-theory.json', 'wolfram-t3.json', 'python-t3.json'): the map $(\chi, j) \to (\sigma_2\chi, -j)$ at the same momentum, with the brane parities exchanged and $\theta \to \pi - \theta$, sends every self-consistent state with (m, λ, θ) to one with $(-m, +\lambda, \pi - \theta)$, with equal levels, occupations, energies and energy-momentum profiles; S and Q change sign. In the real form, $\sigma_2(a, ib) = (b, ia)$: the map simply exchanges a and b and reverses j.

The three universes of this notebook ($m = 1$, no interaction where spectra are computed): A has the mass $+1$ and the tip angle 0; B, its T3 partner, the mass -1 and the tip angle π; C, the control, the mass -1 and the tip angle 0.

What is assumed and what is not shown. The Z_2 brane is ASSUMED, the tip is a chosen cutoff, the states are instantaneous mean-field states along a PRESCRIBED BACKGROUND history. T3 maps solutions onto solutions; no creation process, rate or amplitude of a pair of universes follows from it.

Text cell:

5. The eight real gamma matrices

The next cell imports the packages, reads the record 'Revision/algebra/gammas.json' and stores the eight matrices as arrays of **integers**, so that every product below is computed exactly. A complex matrix would be stored in the record as a pair (real part, imaginary part); a plain list of rows means a real matrix. The cell checks that every entry is -1, 0 or $+1$ and that every matrix is a signed

```
permutation matrix (exactly one nonzero entry in every row and every column).
```

In [2]:

```
import csv  # reads the tables (CSV files) of the record
import math  # sqrt, pi, exp, sinh, cosh, tanh of single numbers

import numpy as np  # arrays of numbers
import sympy as sp  # exact symbolic algebra
from matplotlib.colors import ListedColormap  # a colour map with three colours

GAMMAS = "Revision/algebra/gammas.json"  # the record of the gamma matrices
ALGEBRA = "Revision/algebra/reports/wolfram-algebra.json"  # its check report
fixture = json.loads(repository_file(GAMMAS).read_text(encoding="utf-8"))
stored_real = all(isinstance(g, list) for g in fixture["gamma"])  # no complex part
gamma = [np.array(g, dtype=int) for g in fixture["gamma"]]  # gamma[k] is xk
eta = [int(e) for e in fixture["eta"]]  # +1 +1 +1 +1 -1 -1 -1 -1 (x0, ..., x7)
names = fixture["coordinates"]  # "x0", ..., "x7"

```
The next cell checks the anticommutation rule
$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\mathbf{1}$ for all $8 \times 8 = 64$
```

```
pairs, exactly in integers. It also checks the symmetry pattern seen in the
figure. Why must it hold? A signed permutation matrix $P$ satisfies $P^TP =
\mathbf{1}$ (the transpose $P^T$, rows and columns exchanged, is its inverse), and the
rule with $a = b$ says $\gamma^a\gamma^a = \eta^{aa}\mathbf{1}$, so $\gamma^a$ is its
own inverse up to the sign $\eta^{aa}$. Hence $(\gamma^a)^T = \eta^{aa}\gamma^a$:
symmetric for $\eta = +1$, antisymmetric for $\eta = -1$.
```

## 6. The chirality and the map of T3

The next cell multiplies the eight matrices in the author's order,
$\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\cdots\gamma^{(x_7)}$, and checks:
$\Gamma$ is the diagonal matrix with $-1$ in the first eight places and $+1$ in the
last eight (the matrix stored in the record), $\Gamma^2 = \mathbf{1}$, and $\Gamma$
anticommutes with every gamma matrix. Then it reads the block basis $V$ of the
record `ks-theory.json`: 16 columns, two for each block $(j, s_2, s_3)$, written as
text (`0`, `1`, `-1`, `I`, `-I`, times $1/(2\sqrt2)$). It checks that $V$ is unitary
($V^\dagger V = \mathbf{1}$, where $V^\dagger$ is the transpose with every entry
complex-conjugated) and that $\Gamma$ sends the two columns of block
$(j, s_2, s_3)$ to the two columns of block $(-j, s_2, s_3)$ times $s_2\sigma_2$.
```

In [5]:

```
Gamma = gamma[0]  # gamma^(x0) first ...
for a in range(1, 8):
    Gamma = Gamma @ gamma[a]  # ... times gamma^(x1), ..., gamma^(x7)
```

```
diagonal = np.diag([-1] * 8 + [1] * 8)
anticommutes = all(np.array_equal(Gamma @ g, -(g @ Gamma)) for g in gamma)

## 7. The proof of T3, step by step, in exact algebra

**Step 1: the block Hamiltonian.** Conjugating a Pauli matrix with $\sigma_2$ gives
$\sigma_2\sigma_1\sigma_2 = -\sigma_1$, $\sigma_2\sigma_2\sigma_2 = \sigma_2$,
$\sigma_2\sigma_3\sigma_2 = -\sigma_3$ (because $\sigma_2$ anticommutes with
$\sigma_1$ and $\sigma_3$ and $\sigma_2^2 = \mathbf{1}$). The constant matrix
$\sigma_2$ also passes through $d/dy$. So
```

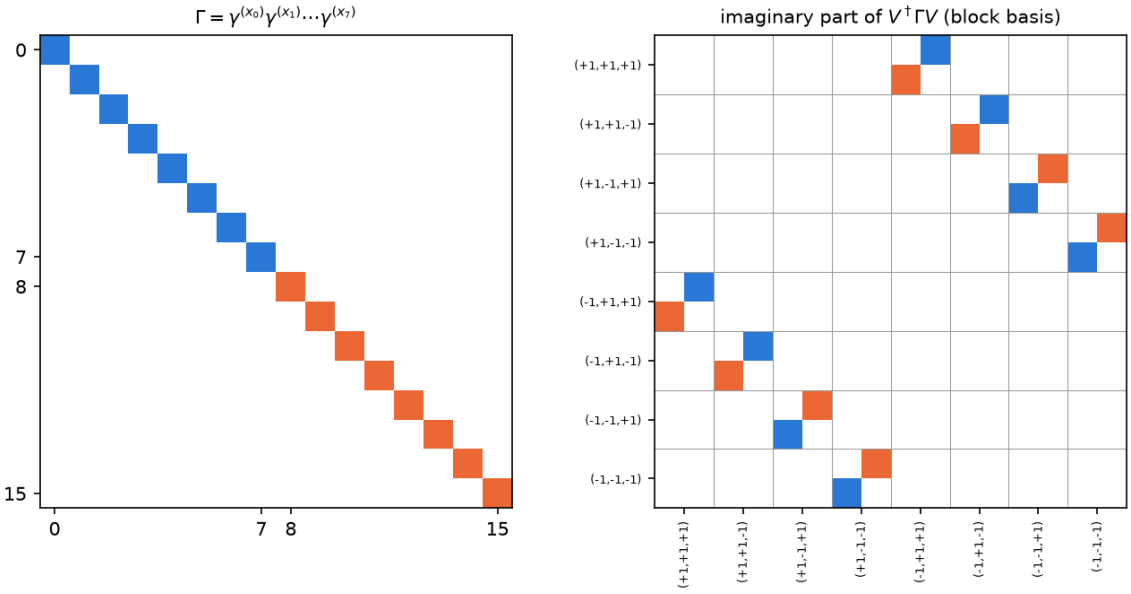

Figure 492: Left: the chirality Γ, the product of the eight real gamma matrices, as a heat map (blue -1, white 0, orange $+1$; indices 0 to 15): -1 on the first eight diagonal places, $+1$ on the last eight. Right: the imaginary part of Γ in the Kohn-Sham block basis, with the block labels (j, s_2, s_3) on the axes. The nonzero 2×2 squares join each block to the block with the opposite j and the same s_2, s_3, and each square is $\pm\sigma_2$: this is the map $(\chi, j) \to (\sigma_2\chi, -j)$ of theorem T3. (Notebook 19b, figure 2.)

```
$$\sigma_2 h_j(M)\sigma_2 = j\Big[+i\sigma_1\frac{d}{dy} + M\sigma_2 -
\kappa k\sigma_3\Big] + v_v = (-j)\Big[-i\sigma_1\frac{d}{dy} + (-M)\sigma_2 +
\kappa k\sigma_3\Big] + v_v = h_{-j}(-M).$$

If $h_j(M)\chi = \varepsilon\chi$, then $h_{-j}(-M)(\sigma_2\chi) =
\sigma_2h_j(M)\sigma_2\sigma_2\chi = \sigma_2h_j(M)\chi = \varepsilon\,\sigma_2\chi$:
the image is an orbital of the partner block with the mass $-M$ and the SAME level.
The next cell checks the three conjugation rules and the identity
$h_{-j}(-M)(\sigma_2\chi) = \sigma_2h_j(M)\chi$ for arbitrary functions $M(y)$,
$\kappa(y)$, $v_v(y)$, $\chi_1(y)$, $\chi_2(y)$ and both $j$, with sympy; as a
control it checks that without $M \to -M$ the identity fails. It also checks the
same statement for the first-order matrix: $\sigma_2N_j(M)\sigma_2 = N_{-j}(-M)$.
```

```
**Step 2: the boundary conditions.** At the tip, $\sigma_2Q(\theta)\sigma_2 =
\cos\theta\,\sigma_2\sigma_3\sigma_2 + \sin\theta\,\sigma_2 = -\cos\theta\,\sigma_3 +
\sin\theta\,\sigma_2 = Q(\pi - \theta)$, because $\cos(\pi - \theta) = -\cos\theta$
and $\sin(\pi - \theta) = \sin\theta$. Hence $(1 - Q(\theta))\chi = 0$ holds exactly
when $(1 - Q(\pi - \theta))\sigma_2\chi = \sigma_2(1 - Q(\theta))\chi = 0$: the image
obeys the tip condition with the angle $\pi - \theta$. At the brane, $\sigma_2(1 -
\sigma_3)\sigma_2 = 1 + \sigma_3$: the even condition $(1 - \sigma_3)\chi(0) = 0$
```

```
(that is $\chi_2(0) = 0$) becomes the odd one $(1 + \sigma_3)\sigma_2\chi(0) = 0$.
The next cell checks both, and as a control that the image $\sigma_2(1, 0)$ of the
solution $(1, 0)$ of the condition $\theta = 0$ violates the UNtransformed condition
and obeys the transformed one.
```

```

Text cell:

```
**Step 4: the mean field.** The record gives $M_{eff} = m + c_M\lambda S$ and
$v_v = c_v\lambda n$ with $c_M = 15/16$ and $c_v = -1/16$, and the interaction energy
density $e_{int} = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2$. The image
state has the densities $(n, -S)$ (step 3). For it to be self-consistent in the
partner block, its effective mass must be $-M_{eff}$ (step 1) and its potential
$v_v$ unchanged. With the bare mass $-m$ and the SAME coupling,
$-m + c_M\lambda(-S) = -(m + c_M\lambda S) = -M_{eff}$, and $c_v\lambda n$ is
unchanged. With $(-m, -\lambda)$ instead, $-m + c_M(-\lambda)(-S) = -m +
c_M\lambda S \ne -M_{eff}$ whenever $\lambda S \ne 0$. The next cell reads the two
coefficients from the record and checks this, the evenness of $e_{int}$ in $S$, and
that $M_{eff} - m$ and $v_v$ are the derivatives of $e_{int}$ with respect to $S$
and $n$.
```

In [10]:

## 8. The exact spectra at zero momentum

Take $k = 0$, no interaction ($M_{eff} = M$ constant, $v_v = 0$). Then
$N = M\sigma_3 + ij\varepsilon\sigma_1$ and $N^2 = M^2\sigma_3^2 +
(ij\varepsilon)^2\sigma_1^2 + Mij\varepsilon(\sigma_3\sigma_1 + \sigma_1\sigma_3) =
(M^2 - \varepsilon^2)\mathbf{1}$, because $\sigma_3^2 = \sigma_1^2 = \mathbf{1}$,
$(ij)^2 = -1$ and $\sigma_3\sigma_1 + \sigma_1\sigma_3 = 0$. Write
$p = \sqrt{M^2 - \varepsilon^2}$. In the series $e^{Ny} = \sum_n (Ny)^n/n!$ the even
powers give $p^{2r}y^{2r}\mathbf{1}$ and the odd ones $p^{2r}y^{2r+1}N$, so

$$\chi(y) = e^{Ny}\chi(0) = \Big[\cosh(py)\,\mathbf{1} +
\frac{\sinh(py)}{p}\,N\Big]\chi(0).$$

Start at the brane with the parity ($\chi(0) = (1, 0)$ for even, $(0, 1)$ for odd),
go to the tip $y = -L$ and ask the tip condition: the component that must vanish
there, as a function of $\varepsilon$, is the **characteristic function**, and its
zeros are the levels. For A ($M$, $j$, $\theta = 0$, the second component must
vanish) and B ($-M$, $-j$, $\theta = \pi$, the first component must vanish) and the
control C ($-M$, $j$, $\theta = 0$) the next cell computes all six functions with
sympy and checks: A even $= -$(B odd), A odd $=$ B even (so A and B have the SAME
levels, sector by sector after exchanging the parities); C even $=$ A even, but C
odd $\ne$ A odd (the control differs in the odd sector).

Dropping the constant factor $-ij$ of the even function, the three different
functions are, with $C = \cosh(pL)$ and $\Sigma = \sinh(pL)/p$:
A even $= \varepsilon\,\Sigma$, A odd $= C + M\Sigma$, C odd $= C - M\Sigma$. For
$\varepsilon^2 > M^2$, $p = ir$ with $r = \sqrt{\varepsilon^2 - M^2}$, and
$\cosh(irL) = \cos(rL)$, $\sinh(irL)/(ir) = \sin(rL)/r$: all three are real for real
$\varepsilon$. The next cell evaluates them for $M = 1$, $L = 3$ on a fine grid of
$\varepsilon$ between $0$ and $4$, finds every zero (a sign change between two grid
points, refined by bisection), and compares the levels of A with the analytic levels
of the record ‘Revision/kohn_sham/results/spectrum/free-k0-analytic.csv‘ (even:
$\varepsilon = 0$ and $\sqrt{M^2 + (n\pi/L)^2}$; odd: $\tan(rL) = -r/M$).

The control's odd function $C - M\Sigma$ has a zero inside the mass gap
$0 < \varepsilon < M$, where A has none. There $p = q$ is real and the zero is
$\cosh(qL) = M\sinh(qL)/q$, that is $\tanh(qL) = q/M$; the level is
$\varepsilon_b = \sqrt{M^2 - q^2} = M/\cosh(qL)$ (because $q^2 = M^2\tanh^2(qL)$
and $1 - \tanh^2 = 1/\cosh^2$). For A the condition would be $\tanh(qL) = -q/M$,
impossible for $q > 0$. The next cell checks the two forms of $\varepsilon_b$, that
the control's odd levels above the gap are NOT those of A, and draws the three
functions (left: the even function, common to all three universes after the
exchange of parities; right: the odd functions of A and C).

## 9. The same levels without formulas: shooting at zero momentum

The levels of section 8 came from formulas. The next cells find them again by
**shooting**, which needs no formula and works for every $k$ and every potential.
The real equations of section 4 are integrated from the tip, where the tip
condition fixes the start ($(a, b) = (1, 0)$ for $\theta = 0$, that is
$\chi_2(-L) = 0$; $(a, b) = (0, 1)$ for $\theta = \pi$), to the brane with the
```

classical Runge-Kutta method (RK4, 3000 steps of length 0.001). A level is a value of ε for which the brane condition holds: $b(0) = 0$ (even) or $a(0) = 0$ (odd). The function ‘brane_value‘ returns the component that must vanish; it works on whole numpy arrays of problems at once (every array entry is one problem: its level, momentum, mass, block type, tip angle and parity). The function ‘find_levels‘ scans ε on a grid, keeps every sign change, and refines each one with the **Illinois method** (a safeguarded secant rule: keep a bracket with a sign change, take the zero of the straight line through its ends as the new point, keep the part with the sign change, and halve the stored value at an end that is kept twice in a row, so that both ends move).

In [15]:

```

```

Text cell:

```
## 10. Small momenta: the brane band
```

```
At small $k$ the zero mode of A turns into the **brane band**, a level that grows
linearly with $k$. Its slope follows from first-order perturbation theory (the
Hellmann-Feynman rule: a small change $\delta h$ of $h$ moves a level by
$\langle\chi|\delta h|\chi\rangle/\langle\chi|\chi\rangle$, where
$\langle\chi|X|\chi\rangle = \int_{-L}^{0}\chi^\dagger X\chi\,dy$). Here
$\delta h = jk\kappa\sigma_3$ with $\kappa = e^{-Hy}$ at $a_{4,0} = 0$. For A,
$j = 1$ and $\chi = (e^{My}, 0)$, so $\chi^\dagger\sigma_3\chi = e^{2My}$ and

$$c = \frac{\int_{-L}^0 e^{(2M - H)y}dy}{\int_{-L}^0 e^{2My}dy} =
\frac{2M}{2M - H}\,\frac{1 - e^{-(2M - H)L}}{1 - e^{-2ML}} .$$

For B, $j = -1$ and $\chi = (0, ie^{My})$, so $j\chi^\dagger\sigma_3\chi =
(-1)(-e^{2My})$: the same slope. For the control C, $j = 1$ and $\chi =
(e^{-My}, 0)$, living at the tip where $\kappa$ is large:

$$c_{ctrl} = \frac{\int_{-L}^0 e^{-(2M + H)y}dy}{\int_{-L}^0 e^{-2My}dy} =
\frac{2M}{2M + H}\,\frac{e^{(2M + H)L} - 1}{e^{2ML} - 1} .$$

The next cell finds, by shooting, the lowest positive level of the band sector (A:
$j = +1$, even; B: $j = -1$, odd; C: $j = +1$, even) at 25 momenta between $0.01$
and $0.25$, for the three universes in one computation.
```

Text cell:

```
## 12. What this notebook showed

- PROVED in the records and re-checked here exactly (integers and sympy): the
  author's eight gamma matrices are real $16 \times 16$ signed permutation matrices
  with $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\mathbf{1}$; the chirality
  $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ is
  $\mathrm{diag}(-1, \dots, -1, +1, \dots, +1)$ and maps each Kohn-Sham block
  $(j, s_2, s_3)$ onto $(-j, s_2, s_3)$ as $s_2\sigma_2$.
- PROVED (sympy, reproducing the checks of `python-t3.json`): the four steps of T3:
  $\sigma_2h_j(M)\sigma_2 = h_{-j}(-M)$; the tip angle goes to $\pi - \theta$ and the
  brane parities are exchanged; $n$, $t$ keep and $S$, $Q$ change their sign; the
  mean field closes exactly for $(-m, +\lambda)$ and not for $(-m, -\lambda)$.
- PROVED (sympy) and COMPUTED (roots): at zero momentum A and B have the same
  levels; the control C, with the untransformed tip, has different odd levels and a
  level inside the mass gap, $\varepsilon_b = m/\cosh(qL)$ with $\tanh(qL) = q/m$.
- COMPUTED (shooting) against closed forms: the brane band of A and B starts with the
  slope $c = 1.9051482536$ of the record; the control's band with
  $c_{ctrl} = 13.42$, because its zero mode lives at the tip.
- ASSUMED: the $Z_2$ brane; the tip condition is a choice (T3 needs the transformed
  tip angle); instantaneous mean-field states on a PRESCRIBED BACKGROUND history.
- NOT shown: that a universe is created, in pairs or otherwise. T3 maps solutions
  onto solutions; it gives no creation process, rate or amplitude.
```

19.16 Line-by-line walk-through of Notebook 19b

The notebook has 21 code cells, In [1] to In [21]. This section explains every line of every one of them, in order; the numbers that the cells print are in Section 19.15 under the labels Out [k]. In the notebook each code cell is preceded by a text cell that says what the cell does.

In [1], the set-up cell. It is the same in every notebook of the book except for the notebook's name; in notebooks that run a Rust program it has two more imports and one more function (the walk-through of Notebook 19a in Section 19.21 explains them). Its first 236 lines repeat the complete run instructions of Section 19.14 as **comment lines**: Python skips every line that starts with `#`; they are there so that the notebook file carries its own instructions. Line 237, a line of dashes, ends the instructions, and two lines of `=` signs around the title THE SET-UP mark where the code begins.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "19b"  # this notebook: chapter 19, example b
```

`import` loads a **module** (a part of Python or of an installed package) so that the cell can use it; the text after `#` on each line says what it is for. `json` reads and writes JSON files, the text format in which most Revision records are stored. `os` gives access to the operating system, here to read an environment variable. `textwrap` breaks long printed text into lines. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on Windows, macOS and Linux. `matplotlib` is the plotting package and `matplotlib.pyplot` its drawing functions, called `plt` by convention. `Image` and `display` show a saved picture below a cell. The last line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"19b"`; the figure files are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called; the text in triple quotes under the `def` line is its **docstring**, a description that Python stores but does not run. `Path.cwd`

`()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. The list `[here, *here.parents]` holds this folder followed by its parent, the parent of that, and so on up to the top of the disk (the star unpacks the parents into the list); the `for` loop takes them one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back; if none does, `raise` stops the notebook with an error message that says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))

def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path

def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`REPO` is the repository folder; it is never printed, because it differs from computer to computer while the printed output must be the same everywhere. `os.environ.get(name, default)` reads an **environment variable** (a named text that a program receives from the computer) or returns the default; when you run the notebook the variable TEXTBOOK_OUTPUT_ROOT is not set, so `OUTPUT_ROOT` is the repository, while the book's checking tool sets it to a scratch folder so that a check never changes the repository. `repository_file` gives the full path of a repository file for reading; `output_file` gives the full path at which to write one, after creating its folder (`mkdir` with `parents=True` creates missing parent folders too, and `exist_ok=True` makes it do nothing if the folder exists). `say` prints a text in lines of at most 89 characters, continuation lines starting with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})

FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
```

```
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

`matplotlib.rcdefaults()` returns to the built-in plotting settings, so that the figures are the same on every computer, and `plt.rcParams.update` sets the figure size (7.0 by 4.2 inches), the letter size (10 points) and a faint grid. The braces `{...}` make a **dictionary**: pairs of a key and a value, written `key:  value`. A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/19b.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty dictionary `{}` into the captions file; `newline="\n"` stores the same line end on every operating system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` numbers the figures 1, 2, 3, ... in the order in which they are saved (`setdefault` returns the number already stored for this name, or stores one more than the count so far), saves the figure as a PNG file with 150 dots per inch, cut to its content and without the program's name in the file (so that two runs write the same bytes), closes it, records its caption in the captions file (`json.dumps` turns the dictionary into JSON text, one entry per line, keys sorted), shows the saved picture below the cell and prints where it was saved. The caption given to it is the caption that the book prints under the figure.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
```

```
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")

def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`PASSED` is an empty **list** (an ordered collection, in square brackets). `check` is the function behind every check of the notebook: if the statement `condition` is false, `raise AssertionError(...)` stops the notebook with an error that names the check; if it is true, the name is appended to `PASSED`, the line PASS followed by the name is printed, and a second line names the Revision record and its check when the argument `record` is given (`None` is Python's word for "nothing"). Python's own `assert` statement is not used, because Python started with the option `-O` skips it. `report` prints a key number as a line that starts with RESULT. `all_checks_passed` prints the last line of the notebook with the number of checks that passed (`len` is the length of a list). The last statement prints the one output line of In [1].

In [2], the eight gammas as whole numbers.

```
import csv  # reads the tables (CSV files) of the record
import math  # sqrt, pi, exp, sinh, cosh, tanh of single numbers

import numpy as np  # arrays of numbers
import sympy as sp  # exact symbolic algebra
from matplotlib.colors import ListedColormap  # a colour map with three colours
```

`csv` reads tables stored as CSV files (comma-separated values: one line per row, the entries separated by commas). `math` computes functions of single numbers. `numpy`, called `np`, holds arrays of numbers and multiplies matrices; `sympy`, called `sp`, computes with exact symbols, fractions and functions. `ListedColormap` makes a colour scale out of a short list of colours; it is used for the heat maps.

```
GAMMAS = "Revision/algebra/gammas.json"  # the record of the gamma matrices
ALGEBRA = "Revision/algebra/reports/wolfram-algebra.json"  # its check report
fixture = json.loads(repository_file(GAMMAS).read_text(encoding="utf-8"))
stored_real = all(isinstance(g, list) for g in fixture["gamma"])  # no complex part
gamma = [np.array(g, dtype=int) for g in fixture["gamma"]]  # gamma[k] is xk
```

```
eta = [int(e) for e in fixture["eta"]]  # +1 +1 +1 +1 -1 -1 -1 -1 (x0, ..., x7)
names = fixture["coordinates"]  # "x0", ..., "x7"
values = sorted({int(x) for g in gamma for x in g.flat})  # the values that occur
```

`GAMMAS` and `ALGEBRA` are the repository paths of the gamma record and of its Wolfram check report. `read_text` reads the record as text and `json.loads` turns it into Python objects: `fixture` is a dictionary whose keys are the names stored in the record. The record stores a real matrix as a plain list of rows and a complex one as a pair of real and imaginary parts (a dictionary), so `stored_real` is true when all eight entries of `fixture["gamma"]` are plain lists (`isinstance(g, list)` asks whether `g` is a list; `all` is true when every one is). `gamma` is the list of the eight matrices as numpy arrays of whole numbers (`dtype=int`), so that every product below is exact; the record lists the matrices in the order $x_0, \ldots, x_7$ and Python counts list positions from 0, so `gamma[k]` is $\gamma^{(x_k)}$: `gamma[0]` is $\gamma^{(x_0)}$ of the hidden direction and `gamma[7]` is $\gamma^{(x_7)}$. `eta` holds the eight signs of the frame metric, `names` the coordinate names. The **set comprehension** `{int(x) for g in gamma for x in g.flat}` collects every value that occurs in any matrix (`g.flat` runs through all 256 entries; a set keeps each value once), and `sorted` puts them in order.

```
one_per_line = all(
    np.array_equal(np.abs(g).sum(axis=0), np.ones(16, dtype=int))
    and np.array_equal(np.abs(g).sum(axis=1), np.ones(16, dtype=int))
    for g in gamma)  # every column and every row holds one entry +1 or -1
say(f"{len(gamma)} matrices of size {gamma[0].shape}, entries {values}, "
    f"eta = {eta}")
check(stored_real and values == [-1, 0, 1] and one_per_line,
      "the eight gammas are real signed permutation matrices",
      record=f"{ALGEBRA}, checks reality and signed_permutation_matrices")
```

`np.abs(g)` replaces every entry by its absolute value; `.sum(axis=0)` adds each column, `.sum(axis=1)` each row. If the entries are -1, 0, $+1$ and every column and every row sums to 1 in absolute value, then every row and every column holds exactly one nonzero entry ± 1: the matrix is a **signed permutation matrix**. `one_per_line` is true when this holds for all eight. Out [2] shows the line printed by `say` (eight 16×16 matrices, entries $-1, 0, 1$, and η) and the PASS line, which reproduces the checks reality and signed_permutation_matrices of `wolfram-algebra.json`.

In [3], the eight heat maps (Figure 19b.1).

```
THREE = ListedColormap(["#2a78d6", "#ffffff", "#eb6834"])  # -1, 0, +1
fig, axes = plt.subplots(2, 4, figsize=(9.0, 4.9))
for a, ax in enumerate(axes.flat):
    ax.imshow(gamma[a], cmap=THREE, vmin=-1, vmax=1, interpolation="nearest")
    ax.set_title(f"$\\gamma^{{({names[a][0]}_{names[a][1]})}}$, "
                 f"$\\eta = {eta[a]:+d}$", fontsize=9)
    ax.set_xticks([0, 15])
    ax.set_yticks([0, 15])
    ax.tick_params(labelsize=7)
    ax.grid(False)
fig.tight_layout()
```

A colour is written `"#rrggbb"`, three two-digit numbers in base 16 for its red, green and blue parts; `THREE` is a colour scale with blue for -1, white for 0 and orange for $+1$. `plt.subplots(2, 4, ...)`

makes a figure with a grid of two rows of four **axes** (drawing areas), 9.0 by 4.9 inches. `enumerate(axes.flat)` runs through the eight axes and counts them, $a = 0, \ldots, 7$. `imshow` draws a matrix as a picture, one coloured square per entry, with the colour scale fixed from -1 to $+1$ (`vmin`, `vmax`) and sharp squares (`interpolation="nearest"`). The title is an f-string that writes, for example, $\gamma^{(x_1)}$, $\eta = +1$: `names[a][0]` is the letter x and `names[a][1]` the digit, the doubled braces `{{` and `}}` produce single braces in the text, and `:+d` writes a whole number with its sign. The ticks are put only at 0 and 15, in small letters, and the grid is switched off. `tight_layout` arranges the eight pictures without overlaps.

```
save_figure(fig, "eight_gammas",
            "The author's eight real $16 \\times 16$ gamma matrices "
            "$\\gamma^{(x_0)}, \\dots, \\gamma^{(x_7)}$ as heat maps (row index "
            "down, column index across, both from 0 to 15): blue is $-1$, white "
            "$0$, orange $+1$. Each matrix has exactly one nonzero entry in every "
            "row and every column. The four with $\\eta = +1$ (3-space and the "
            "hidden direction) are symmetric about the diagonal; the four with "
            "$\\eta = -1$ (the time and the three deflating extra times) are "
            "antisymmetric.")
```

`save_figure` saves Figure 19b.1 with its caption (Python joins strings written next to each other into one; a doubled backslash writes one backslash). What the student should see: eight square pictures of 16×16 coloured squares; in each row and each column exactly one square is coloured, the rest white; the four pictures of x_0, x_1, x_2 and x_3 are mirror-symmetric about the diagonal from top left to bottom right, and the four of $x_4, \ldots, x_7$ are antisymmetric (a blue square on one side of the diagonal faces an orange one on the other). In [4] explains why.

In [4], the anticommutation rule, exactly.

```
unit = np.eye(16, dtype=int)
worst = 0  # largest violation of the anticommutation rule (an integer)
for a in range(8):
    for b in range(8):
        anti = gamma[a] @ gamma[b] + gamma[b] @ gamma[a]
        rule = 2 * eta[a] * (a == b) * unit  # 2 eta^ab times the unit matrix
        worst = max(worst, int(np.max(np.abs(anti - rule))))
pattern = all(np.array_equal(g.T, e * g) for g, e in zip(gamma, eta))
say(f"largest violation of the anticommutation rule over 64 pairs: {worst}")
check(worst == 0 and pattern,
      "g^a g^b + g^b g^a = 2 eta^ab exactly; g^T = eta g (symmetry pattern)",
      record=f"{ALGEBRA}, checks Clifford_relation and symmetry_pattern")
```

`np.eye(16, dtype=int)` is the 16×16 unit matrix of whole numbers. The two loops run over all $8 \times 8 = 64$ pairs (a, b); `@` multiplies matrices. `anti` is $\gamma^a\gamma^b + \gamma^b\gamma^a$ and `rule` is $2\eta^{ab}$ times the unit matrix: `(a == b)` is `True` (counted as 1) when $a = b$ and `False` (0) otherwise. `worst` keeps the largest absolute difference of any entry; with whole numbers it is exact. `pattern` checks the symmetry pattern seen in Figure 19b.1: `g.T` is the transpose, `zip(gamma, eta)` pairs each matrix with its sign, and the test is $(\gamma^a)^T = \eta^{aa}\gamma^a$. The reason, given in the text cell before the code: a signed permutation matrix P obeys $P^TP = \mathbf{1}$, and $\gamma^a\gamma^a = \eta^{aa}\mathbf{1}$, so $(\gamma^a)^T = (\gamma^a)^T\gamma^a\gamma^a\eta^{aa} = \eta^{aa}\gamma^a$. Out [4] prints the largest violation, 0, and the PASS line, which reproduces the checks Clifford_relation and symmetry_pattern of `wolfram-algebra.json`.

In [5], the chirality and the block map (Section 19.5).

```
Gamma = gamma[0]  # gamma^(x0) first ...
for a in range(1, 8):
    Gamma = Gamma @ gamma[a]  # ... times gamma^(x1), ..., gamma^(x7)
diagonal = np.diag([-1] * 8 + [1] * 8)
anticommutes = all(np.array_equal(Gamma @ g, -(g @ Gamma)) for g in gamma)
check(np.array_equal(Gamma, diagonal) and np.array_equal(Gamma @ Gamma, unit)
      and np.array_equal(Gamma, np.array(fixture["Gamma"])) and anticommutes,
      "Gamma = diag(-1 (8 times), +1 (8 times)), Gamma^2 = 1, Gamma g^a = -g^a Gamma",
      record=f"{ALGEBRA}, checks Gamma_diag and Gamma_anticommutes_with_gammas")
```

`Gamma` starts as $\gamma^{(x_0)}$ and is multiplied from the right by $\gamma^{(x_1)}, \ldots, \gamma^{(x_7)}$ in turn: the author's order of Section 19.5. `[-1] * 8 + [1] * 8` is the list of eight -1 followed by eight $+1$, and `np.diag` makes the diagonal matrix with these entries. `anticommutes` tests $\Gamma\gamma^a = -\gamma^a\Gamma$ for all eight. The check requires all four facts: Γ is this diagonal matrix, $\Gamma^2 = \mathbf{1}$, it equals the matrix stored in the record under the key `Gamma`, and it anticommutes with every gamma; it reproduces the checks Gamma_diag and Gamma_anticommutes_with_gammas of `wolfram-algebra.json`.

```
KS_THEORY = "Revision/kohn_sham/ks-theory.json"
ks = json.loads(repository_file(KS_THEORY).read_text(encoding="utf-8"))
ENTRY = {"0": 0.0, "1": 1.0, "-1": -1.0, "I": 1j, "-I": -1j}  # the record's text
V = np.array([[ENTRY[x] for x in row]
              for row in ks["blockBasis"]["unnormalisedColumns2Sqrt2V"]])
V = V / (2.0 * math.sqrt(2.0))  # the record stores 2 sqrt(2) V
labels = [tuple(int(x) for x in label) for label in ks["blockBasis"]["labels"]]
pauli1 = np.array([[0, 1], [1, 0]], dtype=complex)
pauli2 = np.array([[0, -1j], [1j, 0]])
pauli3 = np.array([[1, 0], [0, -1]], dtype=complex)
unitary = float(np.max(np.abs(V.conj().T @ V - np.eye(16))))
```

`ks` is the Kohn-Sham theory record. It stores the block basis as $2\sqrt{2}\,V$, entry by entry as text: `"0"`, `"1"`, `"-1"`, `"I"`, `"-I"`; the dictionary `ENTRY` translates each text into a number (Python writes the imaginary unit i as `1j`). The nested **list comprehension** `[[ENTRY[x] for x in row] for row in ...]` translates every entry of every row, `np.array` makes a 16×16 array of complex numbers, and the next line divides by $2\sqrt{2}$. `labels` is the list of the eight block labels (j, s_2, s_3) as **tuples** (fixed groups of numbers in round brackets) of whole numbers. `pauli1`, `pauli2`, `pauli3` are the Pauli matrices as complex arrays. `unitary` is the largest entry of $|V^\dagger V - \mathbf{1}|$: `.conj()` takes the complex conjugate of every entry and `.T` transposes, so `V.conj().T` is $V^\dagger$; for a unitary matrix this is 0 up to rounding.

```
worst_map, worst_form = 0.0, 0.0
for b, (j, s2, s3) in enumerate(labels):
    p = labels.index((-j, s2, s3))  # the partner block
    Vb, Vp = V[:, 2 * b:2 * b + 2], V[:, 2 * p:2 * p + 2]
    worst_map = max(worst_map, float(np.max(np.abs(Gamma @ Vb
                                                   - Vp @ (s2 * pauli2)))))
    g0 = Vb.conj().T @ gamma[0] @ Vb  # gamma^(x0) inside block b
    g04 = Vb.conj().T @ gamma[0] @ gamma[4] @ Vb  # gamma^(x0) gamma^(x4) there
    worst_form = max(worst_form, float(np.max(np.abs(g0 - pauli3))),
                     float(np.max(np.abs(g04 - j * pauli1))))
```

The loop runs over the eight blocks: `b` is the number of the block and `(j, s2, s3)` its label. `labels.index((-j, s2, s3))` finds the number `p` of the partner block. `V[:, 2 * b:2 * b + 2]` takes all rows and the two columns $2b$ and $2b+1$ (a **slice** `start:stop` runs up to, but not including, `stop`): the basis V_b of the block, and V_p likewise. `worst_map` keeps the largest entry of $|\Gamma V_b - V_p(s_2\sigma_2)|$: the statement $\Gamma V_b = V_p\, s_2\sigma_2$ of Section 19.5. `g0` is $V_b^\dagger \gamma^{(x_0)} V_b$, the block form of $\gamma^{(x_0)}$, and `g04` the block form of $\gamma^{(x_0)}\gamma^{(x_4)}$ (`gamma[4]` is $\gamma^{(x_4)}$); `worst_form` keeps their largest deviations from σ_3 and $j\sigma_1$, the two block forms that the proof of Section 19.5 uses.

```
say(f"largest deviations: unitarity {unitary:.1e}, block map {worst_map:.1e}, "
    f"forms gamma^(x0) = sigma3 and gamma^(x0) gamma^(x4) = j sigma1 "
    f"{worst_form:.1e}")
check(unitary < 1e-12 and worst_map < 1e-12 and worst_form < 1e-12,
      "Gamma maps block (j, s2, s3) onto block (-j, s2, s3) as s2 sigma2",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.Gamma_is_the_block_map")
```

`:.1e` writes a number in exponent form with one digit after the point. Out [5] shows the deviations: unitarity 1.1×10^{-16} (rounding of the division by $2\sqrt{2}$), block map exactly 0, block forms 1.1×10^{-16}; the check, with the tolerance 10^{-12}, reproduces T3.Gamma_is_the_block_map of `python-t3.json`. So the computer confirms $\tau = s_2$ of Section 19.5 for all eight blocks.

In [6], Γ in the block basis (Figure 19b.2).

```
in_blocks = V.conj().T @ Gamma @ V  # Gamma in the block basis
real_part = float(np.max(np.abs(in_blocks.real)))
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 4.4))
left.imshow(Gamma, cmap=THREE, vmin=-1, vmax=1, interpolation="nearest")
left.set_title("$\\Gamma = \\gamma^{(x_0)}\\gamma^{(x_1)}\\cdots\\gamma^{(x_7)}$",
               fontsize=10)
right.imshow(in_blocks.imag, cmap=THREE, vmin=-1, vmax=1, interpolation="nearest")
right.set_title("imaginary part of $V^\\dagger\\Gamma V$ (block basis)", fontsize=10)
```

$V^\dagger\Gamma V$ is Γ written in the block basis: its entry in row r and column c is the component along the r-th basis column of the image of the c-th one. `real_part` is the largest absolute real part of its entries. The figure has two axes side by side, `left` and `right` (the pair returned by `subplots(1, 2, ...)` is unpacked into two names). The left one shows Γ, the right one the imaginary part of $V^\dagger\Gamma V$ (`.imag`), both with the three-colour scale.

```
tags = [f"({j:+d},{s2:+d},{s3:+d})" for j, s2, s3 in labels]
right.set_xticks([2 * b + 0.5 for b in range(8)])
right.set_xticklabels(tags, rotation=90, fontsize=6)
right.set_yticks([2 * b + 0.5 for b in range(8)])
right.set_yticklabels(tags, fontsize=6)
for edge in range(1, 8):
    right.axhline(2 * edge - 0.5, color="0.6", lw=0.5)
    right.axvline(2 * edge - 0.5, color="0.6", lw=0.5)
for ax in (left, right):
    ax.grid(False)
left.set_xticks([0, 7, 8, 15])
left.set_yticks([0, 7, 8, 15])
fig.tight_layout()
```

`tags` are the block labels written like `(+1,+1,+1)`. On the right picture each label is put in the middle of its two rows and columns ($2b + 0.5$), turned by 90 degrees on the horizontal axis. `axhline` and `axvline` draw thin grey lines (`"0.6"` is a grey level between black 0 and white 1, `lw` the line width) on the borders between the blocks, so that the eight 2×2 squares can be seen. The grid is switched off in both pictures, and the left one gets ticks at 0, 7, 8 and 15, where Γ changes from -1 to $+1$.

```
save_figure(fig, "gamma_block_map",
            "Left: the chirality $\\Gamma$, the product of the eight real gamma "
            "matrices, as a heat map (blue $-1$, white $0$, orange $+1$; indices 0 "
            "to 15): $-1$ on the first eight diagonal places, $+1$ on the last "
            "eight. Right: the imaginary part of $\\Gamma$ in the Kohn-Sham block "
            "basis, with the block labels $(j, s_2, s_3)$ on the axes. The nonzero "
            "$2 \\times 2$ squares join each block to the block with the opposite "
            "$j$ and the same $s_2, s_3$, and each square is $\\pm\\sigma_2$: this "
            "is the map $(\\chi, j) \\to (\\sigma_2\\chi, -j)$ of theorem T3.")
report("largest real part of V^dagger Gamma V", f"{real_part:.1e}")
```

`save_figure` saves Figure 19b.2, and `report` prints that the real part is at most 2.2×10^{-17} (Out [6]), so the imaginary part is the whole matrix. What the student should see: on the left a diagonal line, blue in the upper half and orange in the lower half; on the right no square on the diagonal (no block is mapped into itself) but, in the upper-right and lower-left quarters, eight 2×2 squares, each joining a block (j, s_2, s_3) to $(-j, s_2, s_3)$. Each square holds the pattern of σ_2, whose imaginary part is -1 above and $+1$ below its diagonal, or its negative: the blocks with $s_2 = +1$ show $+\sigma_2$, those with $s_2 = -1$ show $-\sigma_2$. This is $G = s_2\sigma_2$ of Section 19.5.

In [7], Step 1 of the proof in sympy (Section 19.6).

```
y = sp.Symbol("y", real=True)  # the hidden coordinate
k, eps, vv = sp.symbols("k epsilon v_v", real=True)  # momentum, level, potential
Mf, kappa, vf = (sp.Function(name)(y) for name in ("M", "kappa", "v"))
chi = sp.Matrix([sp.Function("chi1")(y), sp.Function("chi2")(y)])  # any orbital
s1 = sp.Matrix([[0, 1], [1, 0]])  # the Pauli matrices, exactly
s2 = sp.Matrix([[0, -sp.I], [sp.I, 0]])
s3 = sp.Matrix([[1, 0], [0, -1]])
one = sp.eye(2)
```

`sp.Symbol("y", real=True)` makes an exact symbol y that sympy treats as a real number; `sp.symbols` makes several at once: k, ε and a constant potential v_v. `sp.Function(name)(y)` makes an **undetermined function** of y: sympy knows nothing about it except that it depends on y, so an identity proved with it holds for every function. `Mf`, `kappa`, `vf` are the functions $M(y)$, $\kappa(y)$, $v(y)$ (a generator expression in round brackets is unpacked into the three names), and `chi` is an arbitrary orbital $(\chi_1(y), \chi_2(y))$ as a sympy column. `s1`, `s2`, `s3` are the exact Pauli matrices (`sp.I` is i) and `one` the 2×2 unit matrix.

```
def h(j, mass, c):
    """h_j(mass) applied to the two-component function c."""
    return j * (-sp.I * s1 * c.diff(y) + mass * s2 * c + kappa * k * s3 * c) + vf * c
```

```
def is_zero(matrix):
    """True when every entry simplifies to exactly 0."""
    return all(sp.simplify(sp.expand(entry)) == 0 for entry in matrix)
```

`h` applies the block Hamiltonian h_j of Section 19.3, with the mass function `mass`, to a two-component function `c`: `c.diff(y)` is the derivative dc/dy, and the products `*` of sympy matrices are matrix products. `is_zero` is true when every entry of a matrix, multiplied out (`expand`) and simplified (`simplify`), is exactly 0.

```
rules = (s2 * s1 * s2 == -s1 and s2 * s2 * s2 == s2 and s2 * s3 * s2 == -s3)
maps = all(is_zero(h(-j, -Mf, s2 * chi) - s2 * h(j, Mf, chi)) for j in (1, -1))
control = not is_zero(h(-1, Mf, s2 * chi) - s2 * h(1, Mf, chi))  # no M -> -M
Ms = sp.Symbol("M", real=True)
jj = sp.Symbol("j", real=True)
```

`rules` tests the three conjugation rules $\sigma_2\sigma_1\sigma_2 = -\sigma_1$, $\sigma_2^3 = \sigma_2$, $\sigma_2\sigma_3\sigma_2 = -\sigma_3$ of Section 19.6 (`==` compares two exact matrices). `maps` tests, for both block types, the identity $h_{-j}(-M)(\sigma_2\chi) - \sigma_2 h_j(M)\chi = 0$ for the arbitrary functions: this is the statement "the image of every orbital is an orbital of the partner" in its strongest form, as an identity of differential operators. `control` is the negative control: without $M \to -M$ the difference is not zero. `Ms` and `jj` are a constant mass M and a symbolic type j for the next test.

```
def N(j, mass):
    """The first-order matrix N of d chi/dy = N chi (constant data)."""
    return mass * s3 - sp.Symbol("kappa") * k * s2 + sp.I * j * (eps - vv) * s1

ode = (s2 * N(jj, Ms) * s2 - N(-jj, -Ms)).applyfunc(sp.expand) == sp.zeros(2, 2)
say(f"conjugation rules: {rules}; block map for both j: {maps}; control fails "
    f"as it must: {control}; first-order form: {ode}")
```

`N` is the matrix $N_j(M) = M\sigma_3 - \kappa k\sigma_2 + ij(\varepsilon - v)\sigma_1$ of the first-order form, with a constant symbol κ. `ode` tests $\sigma_2 N_j(M)\sigma_2 - N_{-j}(-M) = 0$ with the symbolic j: `.applyfunc(sp.expand)` multiplies out every entry, and the result is compared with the 2×2 zero matrix. The `say` line prints the four truth values (Out [7]: all `True`).

```
check(rules and maps and control,
      "sigma2 h_j(M) sigma2 = h_(-j)(-M) for arbitrary M(y), kappa(y), v(y)",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.block_hamiltonian_map")
check(ode, "sigma2 N_j(M) sigma2 = N_(-j)(-M) for the first-order form",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check T3.ode_map")
```

Two checks, reproducing T3.block_hamiltonian_map and T3.ode_map of `python-t3.json`.

In [8], Step 2: the tip and the brane (Section 19.7).

```
theta = sp.Symbol("theta", real=True)

def Q(angle):
    """The tip matrix Q(angle) = cos(angle) sigma3 + sin(angle) sigma2."""
    return sp.cos(angle) * s3 + sp.sin(angle) * s2

tip = (s2 * Q(theta) * s2 - Q(sp.pi - theta)).applyfunc(sp.simplify) == sp.zeros(2, 2)
e1 = sp.Matrix([1, 0])  # the vector (1, 0)
zero2 = sp.zeros(2, 1)
tip_control = ((one - Q(0)) * e1 == zero2 and (one - Q(0)) * (s2 * e1) != zero2
               and (one - Q(sp.pi)) * (s2 * e1) == zero2)
brane = s2 * (one - s3) * s2 == one + s3
```

`theta` is a symbolic angle and `Q` the tip matrix $Q(\theta)$. `tip` tests $\sigma_2 Q(\theta)\sigma_2 = Q(\pi-\theta)$ for every θ (sympy simplifies $\cos(\pi-\theta)$ to $-\cos\theta$). `tip_control` is the control of Section 19.7: $(1,0)$ obeys the condition $\theta = 0$; its image $\sigma_2(1,0)$ violates it (`!=` means "is not equal") and obeys the condition $\theta = \pi$. `brane` tests $\sigma_2(1-\sigma_3)\sigma_2 = 1+\sigma_3$: the parities are exchanged.

```
say(f"tip: sigma2 Q(theta) sigma2 = Q(pi - theta): {tip}; control: {tip_control}; "
    f"brane parities exchanged: {brane}")
check(tip and tip_control and brane,
      "tip angle theta -> pi - theta and the brane parities are exchanged",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, checks "
             "T3.tip_condition_map and T3.brane_parities_exchanged")
```

Out [8] prints three `True` and the PASS line, reproducing two checks of `python-t3.json`.

In [9], Step 3: the densities of one orbital (Section 19.8).

```
a1, b1, a2, b2 = sp.symbols("a1 b1 a2 b2", real=True)
psi = sp.Matrix([a1 + sp.I * b1, a2 + sp.I * b2])  # an arbitrary complex orbital

def densities(j, c):
    """(n, s, t, q, c) of one orbital c of block type j."""
    dag = c.H  # the row of complex conjugates
    return [sp.expand((dag * m * c)[0, 0]) for m in
            (one, j * s2, j * s3, s3, j * s1)]
```

Four real symbols make an arbitrary complex orbital $\psi = (a_1 + ib_1, a_2 + ib_2)$ at one point. `densitie s` returns the five densities n_o, s_o, t_o, q_o, c_o without the common factor P: `c.H` is the conjugate transpose $c^\dagger$ (a row), and for each of the five matrices $\mathbf{1}$, $j\sigma_2$, $j\sigma_3$, σ_3, $j\sigma_1$ the product $c^\dagger X c$ is a 1×1 matrix whose only entry `[0, 0]` is multiplied out.

```
SIGNS = (1, -1, 1, -1, 1)  # expected: n, t, c even; s, q odd
signs_ok = all(sp.expand(after - sign * before) == 0
               for j in (1, -1)
               for after, before, sign in zip(densities(-j, s2 * psi),
```

```
                                            densities(j, psi), SIGNS))
say(f"n = {densities(1, psi)[0]},  s (j = +1) = {densities(1, psi)[1]}")
check(signs_ok, "under the map n, t, c keep their sign, s and q change it",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.orbital_densities")
```

`SIGNS` lists the expected signs of Section 19.8. For both j the test compares each density of the image $(\sigma_2\psi, -j)$ with the sign times the density of (ψ, j); `zip` runs through the three lists side by side. The `say` line prints two of the densities as formulas (Out [9]): $n_o = a_1^2 + a_2^2 + b_1^2 + b_2^2$ and $s_o = 2a_1b_2 - 2a_2b_1$ for $j = +1$ (sympy writes powers as `**`). For a real-form orbital, $a_1 = a$, $b_2 = b$ and $b_1 = a_2 = 0$, these are $a^2 + b^2$ and $2ab$, as in Section 19.4. The check reproduces T3.orbital_densities.

In [10], Step 4 of the record: the mean field (Section 19.8).

```
potentials = ks["exchange"]["kohnShamPotentials"]
cM = sp.Rational(potentials["Meff_coefficient_of_lambda_S"])  # 15/16
cv = sp.Rational(potentials["vv_coefficient_of_lambda_n"])  # -1/16
m, lam, S, n = sp.symbols("m lambda S n", real=True)

def M_eff(mass, coupling, scalar):
    """The effective mass m + cM lambda S of the record."""
    return mass + cM * coupling * scalar
```

The two coefficients are read from the Kohn-Sham record as texts, `"15/16"` and `"-1/16"`, and `sp.Rational` turns them into exact fractions. m, λ, S, n are symbols, and `M_eff` builds $M_{\text{eff}} = m + c_M\lambda S$ for any bare mass, coupling and scalar density.

```
e_int = sp.Rational(15, 32) * lam * S ** 2 - sp.Rational(1, 32) * lam * n ** 2
partner = sp.expand(M_eff(-m, lam, -S) + M_eff(m, lam, S)) == 0
wrong = sp.expand(M_eff(-m, -lam, -S) + M_eff(m, lam, S)) != 0
even = sp.expand(e_int.subs(S, -S) - e_int) == 0
derivatives = (sp.expand(sp.diff(e_int, S) - (M_eff(m, lam, S) - m)) == 0
               and sp.expand(sp.diff(e_int, n) - cv * lam * n) == 0)
```

`e_int` is $e_{\text{int}} = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2$. `partner` tests $M_{\text{eff}}(-m, +\lambda, -S) = -M_{\text{eff}}(m, \lambda, S)$; `wrong` tests that $(-m, -\lambda)$ does NOT give it; `even` tests $e_{\text{int}}(n, -S) = e_{\text{int}}(n, S)$ (`.subs(S, -S)` replaces S by $-S$); `derivatives` tests $\partial e_{\text{int}}/\partial S = M_{\text{eff}} - m$ and $\partial e_{\text{int}}/\partial n = v_v$ (`sp.diff` differentiates).

```
say(f"cM = {cM}, cv = {cv}; (-m, +lambda) works: {partner}; (-m, -lambda) fails: "
    f"{wrong}; e_int even in S: {even}; derivatives: {derivatives}")
check(partner and wrong and even and derivatives and (cM, cv) == (
    sp.Rational(15, 16), sp.Rational(-1, 16)),
    "M_eff(-m, +lambda, -S) = -M_eff(m, lambda, S); (-m, -lambda) fails",
    record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
           "T3.mean_field_map")
```

Out [10] prints the two coefficients and four `True`; the check also requires the coefficients to be exactly $15/16$ and $-1/16$, and reproduces T3.mean_field_map.

In [11], the mean-field map as a picture (Figure 19b.3).

```
S_values = np.linspace(-1.0, 1.0, 201)
lam_demo, m_demo, cM_value = 0.8, 1.0, float(cM)
need = -(m_demo + cM_value * lam_demo * S_values)  # -M_eff(m, lambda, S)
give_partner = -m_demo + cM_value * lam_demo * (-S_values)  # (-m, +lambda) at -S
give_wrong = -m_demo + cM_value * (-lam_demo) * (-S_values)  # (-m, -lambda) at -S
```

`np.linspace(-1.0, 1.0, 201)` is an array of 201 equally spaced values of S from -1 to 1. The coupling 0.8 is deliberately large so that the slopes are visible. The three arrays are, for every S, the mass the image needs, $-M_{\text{eff}}(m, \lambda, S)$, the mass the partner $(-m, +\lambda)$ gives to the image density $-S$, and the mass $(-m, -\lambda)$ would give (numpy computes each formula for all 201 values at once).

```
fig, ax = plt.subplots()
ax.plot(S_values, need, color="#2a78d6", lw=3.0,
        label="needed: $-M_{eff}(m, \\lambda, S)$")
ax.plot(S_values, give_partner, color="#eb6834", lw=1.6, ls="--",
        label="partner $(-m, +\\lambda)$ at $-S$")
ax.plot(S_values, give_wrong, color="#eda100", lw=1.6, ls=":",
        label="$(-m, -\\lambda)$ at $-S$")
ax.set_xlabel("scalar density $S$ (units of $|m|^7$)")
ax.set_ylabel("effective mass (units of $|m|$)")
ax.legend(fontsize=8, loc="upper right")
```

`plot` draws a curve through the points; `lw` is the line width, `ls` the line style (two hyphens in quotes mean dashed, a colon `":"` dotted), and `label` the text for the **legend** (the box that names the curves), which `legend` draws in the upper right corner. The axis labels name the quantities and units.

```
save_figure(fig, "mean_field_map",
            "Step 4 of the proof of T3: the effective mass that the image state "
            "needs, $-M_{eff}(m, \\lambda, S)$ (blue), against the scalar density "
            "$S$, with $m = 1$ and an exaggerated coupling $\\lambda = 0.8$ "
            "(units of $|m|$ and $|m|^7$). The partner universe with the bare mass "
            "$-m$ and the same coupling $+\\lambda$ gives exactly this mass to the "
            "image density $-S$ (orange dashed, on top of the blue line); the "
            "universe with $(-m, -\\lambda)$ gives a line with the opposite slope "
            "(yellow dotted), which agrees only at $S = 0$.")
check(float(np.max(np.abs(need - give_partner))) < 1e-15
      and float(np.max(np.abs(need - give_wrong))) > 1.0,
      "the drawn lines: the partner gives the needed mass, (-m, -lambda) does not")
```

`save_figure` saves Figure 19b.3; the check confirms what the picture shows. What the student should see: a thick blue line falling from -0.25 at $S = -1$ to -1.75 at $S = 1$ (slope $-\frac{15}{16} \cdot 0.8 = -0.75$), the orange dashed line exactly on top of it, and the yellow dotted line rising with the opposite slope, crossing the blue one only at $S = 0$, where both are $-m = -1$. (The caption's "Step 4" is the numbering of the record's proof list, where the mean field belongs to the third item; in this chapter it is part of Step 3.)

In [12], the characteristic functions at zero momentum (Section 19.12).

```
Mp, L = sp.symbols("M L", positive=True)
yy = sp.Symbol("yy", real=True)
p = sp.sqrt(Mp ** 2 - eps ** 2)

def propagator(j, mass):
    """exp(N yy) for k = 0, v = 0: cosh(p yy) 1 + sinh(p yy)/p N."""
    N0 = mass * s3 + sp.I * j * eps * s1
    return sp.cosh(p * yy) * one + sp.sinh(p * yy) / p * N0
```

M and L are positive symbols, `yy` the position, and $p = \sqrt{M^2 - \varepsilon^2}$. `propagator` is the matrix $e^{Ny} = \cosh(py)\mathbf{1} + \frac{\sinh(py)}{p} N$ of Section 19.12 with $N = M\sigma_3 + ij\varepsilon\sigma_1$, for any type and mass.

```
e2 = sp.Matrix([0, 1])  # the vector (0, 1)
at_tip = {yy: -L}
D = {}  # characteristic functions, for j = +1
D["A even"] = (propagator(1, Mp) * e1)[1].subs(at_tip)  # chi2(-L)
D["A odd"] = (propagator(1, Mp) * e2)[1].subs(at_tip)
D["B even"] = (propagator(-1, -Mp) * e1)[0].subs(at_tip)  # chi1(-L)
D["B odd"] = (propagator(-1, -Mp) * e2)[0].subs(at_tip)
D["C even"] = (propagator(1, -Mp) * e1)[1].subs(at_tip)  # chi2(-L)
D["C odd"] = (propagator(1, -Mp) * e2)[1].subs(at_tip)
for name in D:
    say(f"D({name}) = {sp.simplify(D[name])}")
```

The six entries of the table of Section 19.12, with $j = +1$: the propagator applied to the start at the brane, $(1, 0)$ for even or $(0, 1)$ for odd, evaluated at the tip ($y = -L$, the substitution `at_tip`), and the component that the tip condition must make zero: the second (index 1) for $\theta = 0$, the first (index 0) for $\theta = \pi$. A has $(M, +1, \theta = 0)$, B $(-M, -1, \theta = \pi)$, C $(-M, +1, \theta = 0)$. The loop prints them (Out [12]); sympy writes `I` for i, `sqrt` for the square root and `epsilon` for ε. Compare with the table of Section 19.12: D(A even) $= -i\varepsilon \sinh(pL)/p$, D(A odd) $= D$(B even) $= \cosh(pL) + M \sinh(pL)/p$, D(B odd) $= +i\varepsilon \sinh(pL)/p$, D(C even) $=$ D(A even), D(C odd) $= \cosh(pL) - M \sinh(pL)/p$.

```
pairs_equal = (sp.simplify(D["A even"] + D["B odd"]) == 0
               and sp.simplify(D["A odd"] - D["B even"]) == 0)
control_differs = (sp.simplify(D["C even"] - D["A even"]) == 0
                   and sp.simplify(D["C odd"] - D["A odd"]) != 0)
check(pairs_equal and control_differs,
      "k = 0: A and B have equal characteristic functions; C differs (odd sector)",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.exact_k0_spectra")
```

`pairs_equal` tests A even $= -$B odd and A odd $=$ B even, identically in ε, M, L; `control_differs` tests C even $=$ A even and C odd $\neq$ A odd. The check reproduces T3.exact_k0_spectra.

In [13], the zeros of the characteristic functions.

```
M_BARE, L_TIP = 1.0, 3.0  # the mass |m| and the tip distance L of the record
```

```
def C_and_Sigma(e):
    """cosh(pL) and sinh(pL)/p for the level(s) e, real for every real e."""
    pc = np.sqrt(M_BARE ** 2 - np.asarray(e, dtype=float) ** 2 + 0j)  # complex p
    small = np.abs(pc) < 1e-12  # p = 0: sinh(pL)/p -> L
    safe = np.where(small, 1.0, pc)
    sigma = np.where(small, L_TIP, np.sinh(safe * L_TIP) / safe)
    return np.cosh(pc * L_TIP).real, sigma.real
```

From here on the numbers $M = 1$, $L = 3$ of the record are used. `C_and_Sigma` computes the two building blocks $\cosh(pL)$ and $\Sigma = \sinh(pL)/p$ for one level or an array of levels. Adding `0j` makes the number under the square root complex, so that for $\varepsilon^2 > M^2$ numpy returns $p = ir$ instead of an error; as Section 19.12 showed, $\cosh(irL) = \cos(rL)$ and $\sinh(irL)/(ir) = \sin(rL)/r$ are real, so `.real` keeps everything. At $p = 0$ the quotient $\sinh(pL)/p$ has the limit L; `np.where(small, a, b)` takes `a` where `small` is true and `b` elsewhere, and `safe` avoids a division by zero.

```
def f_A_even(e):
    return np.asarray(e) * C_and_Sigma(e)[1]

def f_A_odd(e):
    c, sig = C_and_Sigma(e)
    return c + M_BARE * sig

def f_C_odd(e):
    c, sig = C_and_Sigma(e)
    return c - M_BARE * sig
```

The three different characteristic functions, without the constant factor $-ij$ of the even one: $\varepsilon\Sigma$, $\cosh(pL) + M\Sigma$ and $\cosh(pL) - M\Sigma$.

```
def zeros(f, top=4.0, points=40001):
    """All sign changes of f on (0, top], each refined by 80 bisection steps."""
    grid = np.linspace(1e-9, top, points)
    values = f(grid)
    found = []
    for i in np.nonzero(np.sign(values[:-1]) * np.sign(values[1:]) < 0)[0]:
        low, high = grid[i], grid[i + 1]
        for _ in range(80):
            middle = 0.5 * (low + high)
            if np.sign(f(middle)) == np.sign(f(low)):
                low = middle
            else:
                high = middle
        found.append(0.5 * (low + high))
    return found
```

`zeros` finds every zero of a function between 10^{-9} and `top`. It evaluates the function on 40001 grid points; `values[:-1]` are all values but the last and `values[1:]` all but the first, so their signs multiplied are negative exactly where the sign changes between two neighbouring points, and

`np.nonzero(...)[0]` lists those positions. Each sign change is refined by **bisection**: halve the interval, keep the half whose ends still have opposite signs, 80 times (the interval then is 2^{-80} times its first length, far below the rounding of the computer). The middle of the last interval is the zero.

```
levels = {"A even": [0.0] + zeros(f_A_even), "A odd": zeros(f_A_odd),
          "C odd": zeros(f_C_odd)}
for name, values in levels.items():
    say(f"{name}: " + ", ".join(f"{v:.10f}" for v in values))
```

The levels of the three sectors; the zero mode $\varepsilon = 0$ of the even sector is put in front by hand (the grid starts just above 0). `", ".join(...)` writes the numbers separated by commas, each with ten digits. Out [13] shows the three ladders of the table in Section 19.12.

```
SPECTRUM = "Revision/kohn_sham/results/spectrum/free-k0-analytic.csv"
with repository_file(SPECTRUM).open(encoding="utf-8", newline="") as handle:
    rows = [r for r in csv.DictReader(handle)
            if float(r["m"]) == 1.0 and float(r["L"]) == 3.0]
recorded = {parity: sorted(float(r["eps_analytic"]) for r in rows
                           if r["parity"] == parity
                           and 0.0 <= float(r["eps_analytic"]) < 4.0)
            for parity in ("even", "odd")}
```

The record's table of the analytic free levels is read with `csv.DictReader`, which gives each row as a dictionary from the column names to the texts (`with ... as handle:` opens the file and closes it again at the end of the block). Only the rows with $m = 1$ and $L = 3$ are kept. `recorded` holds, for each parity, the sorted recorded levels between 0 and 4.

```
worst = max(max(abs(x - y) for x, y in zip(levels["A even"], recorded["even"])),
            max(abs(x - y) for x, y in zip(levels["A odd"], recorded["odd"])))
report("largest difference of the levels of A from the record", f"{worst:.1e}")
check(len(levels["A even"]) == len(recorded["even"])
      and len(levels["A odd"]) == len(recorded["odd"]) and worst < 1e-12,
      "the k = 0 levels of A are the analytic levels of the record",
      record=f"{SPECTRUM}, rows m = 1, L = 3")
```

`worst` is the largest difference between our levels of A and the recorded ones: 8.9×10^{-16} (Out [13]). The check also requires the same number of levels.

In [14], the control's level in the gap (Figure 19b.4).

```
eps_b = levels["C odd"][0]  # the first zero: inside the gap?
q_b = math.sqrt(M_BARE ** 2 - eps_b ** 2)
two_forms = (abs(math.tanh(q_b * L_TIP) - q_b / M_BARE) < 1e-12
             and abs(M_BARE / math.cosh(q_b * L_TIP) - eps_b) < 1e-12)
report("sub-gap level of the control eps_b", f"{eps_b:.12f}", "|m|")
above = levels["C odd"][1:]  # the control's odd levels above the gap
distinct = min(abs(x - y) for x in above for y in levels["A odd"]) > 1e-3
check(0.0 < eps_b < M_BARE and two_forms and distinct,
      "only the control has a level in the gap, eps_b = M/cosh(qL), tanh(qL) = q/M")
```

`eps_b` is the lowest odd level of the control and `q_b` $= \sqrt{M^2 - \varepsilon_b^2}$. `two_forms` tests the two statements of Section 19.12: $\tanh(qL) = q/M$ and $\varepsilon_b = M/\cosh(qL)$. `above` holds the other odd levels of C, and `distinct` tests that none of them is within 10^{-3} of an odd level of A. The check requires $0 < \varepsilon_b < M$ (inside the gap) as well. Out [14] prints $\varepsilon_b = 0.100851121375$.

```
grid = np.linspace(0.0, 4.0, 2001)
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
left.plot(grid, f_A_even(grid), color="#2a78d6", lw=2.0,
          label="$\\varepsilon\\,\\sinh(pL)/p$ (even A = odd B = even C)")
left.plot(levels["A even"], np.zeros(len(levels["A even"])), "o", color="#2a78d6")
right.plot(grid, f_A_odd(grid), color="#2a78d6", lw=2.0,
           label="A odd $= $ B even: $\\cosh(pL) + M\\sinh(pL)/p$")
right.plot(grid, f_C_odd(grid), color="#1baf7a", lw=1.6, ls=":",
           label="C odd: $\\cosh(pL) - M\\sinh(pL)/p$")
right.plot(levels["A odd"], np.zeros(len(levels["A odd"])), "o", color="#2a78d6")
right.plot(levels["C odd"], np.zeros(len(levels["C odd"])), "^", color="#1baf7a")
```

The left picture draws the even function on 2001 points from 0 to 4 and marks its zeros, the levels, with dots on the axis (`"o"`; `np.zeros(n)` gives the height 0 for every dot). The right picture draws the odd functions of A and of the control C and marks their zeros with dots and triangles (`"^"`).

```
for ax in (left, right):
    ax.axhline(0.0, color="0.3", lw=0.8)
    ax.axvline(M_BARE, color="0.5", lw=0.8, ls="--")  # the edge of the mass gap
    ax.set_xlabel("level $\\varepsilon$ (units of $|m|$)")
    ax.set_ylim(-4.0, 6.0)
    ax.legend(fontsize=7, loc="upper right")
left.set_ylabel("characteristic function")
fig.tight_layout()
save_figure(fig, "characteristic_functions",
            "The characteristic functions of the zero-momentum spectra for "
            "$M = 1$, $L = 3$ (horizontal axis: the level $\\varepsilon$ in units "
            "of $|m|$; the dashed vertical line is the edge $\\varepsilon = M$ of "
            "the mass gap). Left: the function of the even sector of A, which is "
            "also that of the odd sector of the partner B and of the even sector of "
            "the control C; its zeros (dots) are $0$ and $\\sqrt{M^2 + "
            "(n\\pi/L)^2}$. Right: the odd sector of A (equal to the even sector of "
            "B) and the odd sector of the control C. Only C has a zero inside the "
            "gap, the level $\\varepsilon_b = 0.1009$, and its other zeros differ "
            "from those of A.")
```

In both pictures a horizontal line marks zero and a dashed vertical line the edge of the mass gap $\varepsilon = M$; the vertical range is cut to -4 to 6 because the functions grow like cosh inside the gap. `save_figure` saves Figure 19b.4. What the student should see: on the left a curve that is positive inside the gap (its only zero there is the zero mode at $\varepsilon = 0$) and oscillates like $\varepsilon \sin(rL)/r$ outside, crossing zero at 1.448, 2.321, 3.297; on the right the blue curve of A, which starts at $\cosh(3) + \sinh(3) = e^3$ (above the drawn range), stays above zero in the whole gap and crosses zero only above it, and the aqua dotted curve of the control, which starts at $\cosh(3) - \sinh(3) = e^{-3} = 0.05$, falls through zero at $\varepsilon_b = 0.1009$ inside the gap, and crosses zero above the gap at other places than the blue curve.

In [15], shooting: the functions `brane_value` and `find_levels`.

```
H, STEPS = 1.0, 3000  # the constant H and the number of RK4 steps

def brane_value(e, kk, mass, j, tip, odd):
    """Shoot from the tip y = -L to the brane y = 0 at the slice a4,0 = 0.  All
    arguments are numpy arrays of equal shape (one entry per problem); returns
    a(0) where odd is 1 and b(0) where odd is 0."""
    a = np.where(tip == 0.0, 1.0, 0.0)  # theta = 0: (a, b) = (1, 0) at the tip
    b = 1.0 - a  # theta = pi: (a, b) = (0, 1)
    step = L_TIP / STEPS
```

Shooting finds levels without a formula: start at the tip with the values that the tip condition allows, integrate the real form of Section 19.3 to the brane, and ask whether the brane condition holds. `brane_value` does this for many problems at once: every argument is a numpy array, and each array position is one problem (its level `e`, momentum `kk`, mass, type `j`, tip angle and parity). At the tip, $\theta = 0$ demands $b(-L) = 0$, so the start is $(a, b) = (1, 0)$; $\theta = \pi$ demands $a(-L) = 0$, so the start is $(0, 1)$ (the overall size does not matter, the equations are linear). The step length is $L/3000 = 0.001$.

```
    def slope(yv, a, b):
        w = math.exp(-H * yv) * kk  # kappa(y) k
        return mass * a - (w + j * e) * b, (j * e - w) * a - mass * b
```

`slope` is the right side of the real form at the point `yv`, with $v = 0$ and the momentum weight $\kappa k = e^{-Hy}k$ at the slice $a_{4,0} = 0$: it returns $da/dy = Ma - (\kappa k + j\varepsilon)b$ and $db/dy = (j\varepsilon - \kappa k)a - Mb$.

```
    for i in range(STEPS):
        yv = -L_TIP + i * step
        ka1, kb1 = slope(yv, a, b)
        ka2, kb2 = slope(yv + step / 2, a + step / 2 * ka1, b + step / 2 * kb1)
        ka3, kb3 = slope(yv + step / 2, a + step / 2 * ka2, b + step / 2 * kb2)
        ka4, kb4 = slope(yv + step, a + step * ka3, b + step * kb3)
        a = a + step / 6 * (ka1 + 2 * ka2 + 2 * ka3 + ka4)
        b = b + step / 6 * (kb1 + 2 * kb2 + 2 * kb3 + kb4)
    return np.where(odd == 1.0, a, b)
```

The loop makes 3000 steps of the classical **Runge-Kutta method** of fourth order (RK4, Chapter 2): from the slope at the start of a step, two slopes at its middle and one at its end, the step adds the weighted mean $\frac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4)$ times the step length. At the brane the function returns the component that must vanish there: $a(0)$ for the odd parity, $b(0)$ for the even parity. A level is a value of ε at which this **brane value** is zero.

```
def find_levels(problems, top, points=2001, rounds=16, first_only=False):
    """problems: rows (k, mass, j, tip, odd).  Returns (row index, level) for every
    sign change of brane_value on (0, top] (only the lowest one per row when
    first_only is True)."""
```

```
    P = np.array(problems, dtype=float)
    grid = np.linspace(1e-9, top, points)
    columns = [np.repeat(P[:, c:c + 1], points, axis=1) for c in range(5)]
    values = brane_value(np.tile(grid, (len(P), 1)), *columns)
```

`find_levels` takes a list of problems, each a row $(k, M, j, \theta, \text{odd})$, and a top energy. `P` is the table of the problems, one row each. The scan grid has `points` energies between 10^{-9} and `top`. To shoot all problems at all grid energies in one call, two tables of the same shape are made: `np.tile(grid, (len(P), 1))` repeats the grid once per problem (one row per problem), and `np.repeat(P[:, c:c + 1], points, axis=1)` repeats column `c` of the problem table along each row; `*columns` passes the five tables as the five last arguments. `values` holds the brane value of every problem at every grid energy.

```
    rows, cols = np.nonzero(np.sign(values[:, :-1]) * np.sign(values[:, 1:]) < 0)
    if first_only:  # keep the first sign change of every row
        keep = np.concatenate(([True], rows[1:] != rows[:-1]))
        rows, cols = rows[keep], cols[keep]
    lo, hi = grid[cols], grid[cols + 1]  # brackets with a sign change
    f_lo, f_hi = values[rows, cols], values[rows, cols + 1]
    data = [P[rows, c] for c in range(5)]  # the problem of every root
```

The sign changes between neighbouring grid energies are found as in In [13], now in every row at once: `rows` and `cols` list the problem and the grid position of each sign change, in order. With `first_only`, only the first sign change of each problem is kept (an entry is kept when its row differs from the row of the entry before it). Each sign change gives a **bracket** `lo`, `hi` with the brane values `f_lo`, `f_hi` of opposite signs, and `data` lists the problem data of each bracket.

```
    kept = np.zeros(len(rows))  # which end was kept last: +1 high, -1 low
    new = lo
    for _ in range(rounds):
        new = (lo * f_hi - hi * f_lo) / (f_hi - f_lo)  # zero of the straight line
        f_new = brane_value(new, *data)
        move_low = np.sign(f_new) == np.sign(f_lo)  # the zero lies above new
        f_hi = np.where(move_low & (kept == 1), f_hi / 2, f_hi)  # Illinois rule
        f_lo = np.where(~move_low & (kept == -1), f_lo / 2, f_lo)
        lo, f_lo = np.where(move_low, new, lo), np.where(move_low, f_new, f_lo)
        hi, f_hi = np.where(move_low, hi, new), np.where(move_low, f_hi, f_new)
        kept = np.where(move_low, 1, -1)
    return rows, new
```

All brackets are refined together, 16 rounds, by the **Illinois method**. In each round the new point is the zero of the straight line through $(\text{lo}, f_{\text{lo}})$ and $(\text{hi}, f_{\text{hi}})$: $\text{new} = (\text{lo}\, f_{\text{hi}} - \text{hi}\, f_{\text{lo}})/(f_{\text{hi}} - f_{\text{lo}})$. Its brane value decides which end moves: if it has the sign of the low end, the zero lies above `new` and the low end moves there (`move_low`), otherwise the high end moves. A plain straight-line rule can keep one end fixed for many rounds and converge slowly; the Illinois rule halves the stored value at an end that is kept twice in a row (the high end when the low end moved again, `& (kept == 1)`; the low end in the opposite case, `~` meaning "not"), which pulls the next straight line toward that end. `kept` remembers which end was kept. The function returns the problem number and the level of every root.

```
say("brane_value and find_levels defined")
```

The cell prints one line (Out [15]).

In [16], the six sectors at k = 0 by shooting.

```
SECTORS = {  # name: (mass, j, tip angle, odd)
    "A even": (1.0, 1.0, 0.0, 0.0), "A odd": (1.0, 1.0, 0.0, 1.0),
    "B even": (-1.0, -1.0, math.pi, 0.0), "B odd": (-1.0, -1.0, math.pi, 1.0),
    "C even": (-1.0, 1.0, 0.0, 0.0), "C odd": (-1.0, 1.0, 0.0, 1.0)}
names_k0 = list(SECTORS)
rows, found = find_levels([(0.0, *SECTORS[name]) for name in names_k0], top=4.0)
shot = {name: sorted(found[rows == r]) for r, name in enumerate(names_k0)}
```

`SECTORS` gives the data of the six problems: A has the mass +1, type +1 and tip angle 0; B the mass −1, type −1 and tip angle π; C the mass −1, type +1 and tip angle 0; each in both parities. `find_levels` shoots all six at $k = 0$ up to $\varepsilon = 4$. `found[rows == r]` picks the levels of the problem `r` (a comparison of an array with a number gives an array of truth values, which selects the matching entries), and `shot` stores them sorted under the sector's name.

```
zero_mode = {name: float(brane_value(np.zeros(1), np.zeros(1),
                                     *(np.full(1, x) for x in SECTORS[name]))[0])
             for name in ("A even", "B odd", "C even")}
for name in ("A even", "B odd", "C even"):
    shot[name] = [0.0] + shot[name]  # the zero mode at eps = 0
expected = {"A even": levels["A even"], "A odd": levels["A odd"],
            "B even": levels["A odd"], "B odd": levels["A even"],
            "C even": levels["A even"], "C odd": levels["C odd"]}
```

The zero modes sit exactly at $\varepsilon = 0$, where the scan cannot see a sign change. So `zero_mode` evaluates the brane value at $\varepsilon = 0$, $k = 0$ in the three sectors that have one (`np.full(1, x)` is an array of length one holding `x`), and the zero level is added to their lists. `expected` says what each sector must give according to Section 19.12: A its own levels; B even the levels of A odd and B odd those of A even (T3 exchanges the parities); C even those of A even; C odd the control's own levels.

```
worst_shot = 0.0
for name in names_k0:
    say(f"{name}: " + ", ".join(f"{e:.10f}" for e in shot[name]))
    if len(shot[name]) != len(expected[name]):
        worst_shot = math.inf  # a level is missing or extra
    else:
        worst_shot = max(worst_shot, max(abs(x - y) for x, y in
                                         zip(shot[name], expected[name])))
report("largest difference shooting - formula at k = 0", f"{worst_shot:.1e}")
check(worst_shot < 1e-9 and all(v == 0.0 for v in zero_mode.values()),
      "shooting finds exactly the formula levels of A, B and C at k = 0")
```

The loop prints the six ladders (Out [16]) and keeps the largest difference from the formula levels; a missing or extra level would make it infinite (`math.inf`). The largest difference is 5.9×10^{-12}, the

error of 3000 Runge-Kutta steps, and the brane values at $\varepsilon = 0$ are exactly 0: at $\varepsilon = 0$, $k = 0$ the starting value has no component that could grow into the forbidden one (for example, for A even b stays exactly 0 along the whole integration).

In [17], the ladders (Figure 19b.5).

```
COLOUR = {"A": "#2a78d6", "B": "#eb6834", "C": "#1baf7a"}
fig, ax = plt.subplots(figsize=(7.0, 5.0))
for x, kind in enumerate("ABC"):
    for parity, style in (("even", "-"), ("odd", "--")):
        for e in shot[f"{kind} {parity}"]:
            for sign in ((1,) if e == 0.0 else (1, -1)):
                ax.plot([x - 0.3, x + 0.3], [sign * e, sign * e],
                        color=COLOUR[kind], ls=style, lw=2.0)
ax.axhspan(-M_BARE, M_BARE, color="0.9", zorder=0)  # the mass gap
```

`COLOUR` gives each universe its colour: blue A, orange B, aqua C. For each universe (at the horizontal positions 0, 1, 2) and each parity (solid lines for even, dashed for odd) every level is drawn as a short horizontal line, and, except the zero mode, also its negative: at $k = 0$ the levels come in pairs $\pm\varepsilon$ (the characteristic functions are even or odd in ε). `axhspan` shades the mass gap $-1 < \varepsilon < 1$ in light grey behind everything (`zorder=0`).

```
ax.set_xticks([0, 1, 2])
ax.set_xticklabels(["A: $+m$, $\\theta = 0$", "B: $-m$, $\\theta = \\pi$",
                    "C: $-m$, $\\theta = 0$ (control)"])
ax.set_xlim(-0.6, 2.6)
ax.set_ylabel("level $\\varepsilon$ at $k = 0$ (units of $|m|$)")
ax.grid(axis="x", visible=False)
save_figure(fig, "k0_ladders",
            "The levels at zero momentum of the universes A (mass $+m$, tip angle "
            "0), B (mass $-m$, tip angle $\\pi$, the T3 partner) and C (mass $-m$, "
            "tip angle 0, the control), for $m = 1$, $L = 3$, no interaction, found "
            "by shooting (vertical axis: the level in units of $|m|$; solid lines "
            "even parity, dashed lines odd parity; grey band: the mass gap "
            "$|\\varepsilon| < m$). A and B have the same ladder with the parities "
            "exchanged; the control has different odd levels and the pair "
            "$\\pm\\varepsilon_b$ inside the gap.")
```

The three ladders are labelled under the horizontal axis, the vertical grid lines are switched off, and `save_figure` saves Figure 19b.5. What the student should see: the ladders of A and B at exactly the same heights, but where A has a solid line B has a dashed one and the other way round (the exchanged parities); the zero mode at 0; nothing else inside the grey gap for A and B; the control C with the zero mode, two dashed lines at ± 0.1009 inside the gap, and dashed lines above the gap at heights different from those of A.

```
ladder_A = np.array(sorted(shot["A even"] + shot["A odd"]))
ladder_B = np.array(sorted(shot["B even"] + shot["B odd"]))
check(len(ladder_A) == len(ladder_B)
      and float(np.max(np.abs(ladder_A - ladder_B))) < 1e-12,
      "the shooting ladders of A and B agree level by level")
```

The two complete ladders (both parities, sorted) of A and B are compared level by level; they agree to better than 10^{-12} although they were shot with different masses, types, tip conditions and parities.

In [18], the brane band at small momenta.

```
BAND = {"A": (1.0, 1.0, 0.0, 0.0), "B": (-1.0, -1.0, math.pi, 1.0),
        "C": (-1.0, 1.0, 0.0, 0.0)}  # mass, j, tip angle, odd
k_plot = np.linspace(0.0, 0.25, 26)[1:]  # 25 momenta for the figure
problems = [(kk, *BAND[kind]) for kind in "ABC" for kk in k_plot]
rows, found = find_levels(problems, top=2.0, points=401, first_only=True)
band = {kind: found[i * len(k_plot):(i + 1) * len(k_plot)]
        for i, kind in enumerate("ABC")}
```

`BAND` gives the sector of the zero mode of each universe: A type $+1$ even, B type -1 odd (its image), C type $+1$ even. `k_plot` are the 25 momenta $0.01, 0.02, \ldots, 0.25$ (26 points from 0 to 0.25 without the first). The 75 problems are shot together, and only the lowest positive level of each is kept (`first_only=True`); a scan with 401 points up to $\varepsilon = 2$ suffices. `band` cuts the 75 levels into the three lists of 25, in the order in which the problems were made.

```
band_gap = float(np.max(np.abs(band["A"] - band["B"])))
report("largest |eps_A - eps_B| on the band", f"{band_gap:.1e}")
check(len(rows) == 3 * len(k_plot) and band_gap < 1e-10
      and float(np.min(np.abs(band["A"] - band["C"]))) > 1e-3,
      "the band of B equals that of A at every momentum; the control differs")
```

The largest difference between the bands of A and B is exactly 0 (Out [18]): with σ_2 the shooting of B performs, step by step, the same arithmetic as that of A with a and b exchanged. The check also requires a level for every problem and a difference larger than 10^{-3} between A and C at every momentum.

In [19], the slopes at zero momentum.

```
small = 1e-4
problems = [(kk, *BAND[kind]) for kind in "ABC" for kk in (small, 2 * small)]
rows, found = find_levels(problems, top=0.01, points=401, first_only=True)
slopes = {kind: (4 * found[2 * i] / small - found[2 * i + 1] / (2 * small)) / 3
          for i, kind in enumerate("ABC")}
```

The band is an odd function of k, $\varepsilon(k) = ck + dk^3 + \ldots$, so $\varepsilon(k)/k = c + dk^2 + \ldots$. At k and $2k$: $\varepsilon(k)/k = c + dk^2$ and $\varepsilon(2k)/(2k) = c + 4dk^2$, so $4\varepsilon(k)/k - \varepsilon(2k)/(2k) = 3c$: the combination divided by 3 removes the k^2 term (**Richardson extrapolation**, Chapter 16). The cell shoots the three bands at $k = 10^{-4}$ and 2×10^{-4} (six problems; levels below 0.01) and forms this combination for each universe.

```
c_A = (2 * M_BARE / (2 * M_BARE - H) * (1 - math.exp(-(2 * M_BARE - H) * L_TIP))
       / (1 - math.exp(-2 * M_BARE * L_TIP)))
c_C = (2 * M_BARE / (2 * M_BARE + H) * (math.exp((2 * M_BARE + H) * L_TIP) - 1)
       / (math.exp(2 * M_BARE * L_TIP) - 1))
```

```
c_record = float(ks["checksNumeric"]["braneBandSlope_M1_H1_L3_a0"])
SLOPES = "Revision/kohn_sham/results/spectrum/brane-band-slope.csv"
with repository_file(SLOPES).open(encoding="utf-8", newline="") as handle:
    c_csv = float(next(csv.DictReader(handle))["c_theory"])  # the row a4,0 = 0
```

`c_A` and `c_C` are the closed forms c and c_{ctrl} of Section 19.12. `c_record` is the slope stored in `ks-theory.json` under checksNumeric, and `c_csv` the theoretical slope of the first row (the slice $a_{4,0} = 0$) of the record's slope table; `next(...)` takes the first row that the reader gives.

```
say(f"closed forms: c = {c_A:.13f}, c_ctrl = {c_C:.10f}; records: "
    f"{c_record:.13f} and {c_csv:.13f}")
for kind in "ABC":
    say(f"{kind}: shooting slope {slopes[kind]:.10f}")
check(len(rows) == 6 and abs(c_A - c_record) < 1e-13 and abs(c_A - c_csv) < 1e-13
      and abs(slopes["A"] / c_A - 1) < 1e-7 and abs(slopes["B"] / c_A - 1) < 1e-7,
      "the brane-band slope of A and of its partner B is c = 1.9051482536",
      record=f"{KS_THEORY}, checksNumeric braneBandSlope_M1_H1_L3_a0, and {SLOPES}")
check(abs(slopes["C"] / c_C - 1) < 1e-6 and c_C > 7 * c_A,
      "the control's band starts with the much larger slope c_ctrl = 13.42")
```

Out [19] shows $c = 1.9051482536449$ from the closed form and from both records, and $c_{\mathrm{ctrl}} = 13.4219751976$; the shooting slopes of A and B are 1.9051482536 and that of C 13.4219751976. The first check requires the closed form to equal both records to 10^{-13} and the shooting slopes of A and B to agree with it to a relative 10^{-7}; the second requires the control's slope to agree with its closed form and to be more than seven times larger.

In [20], the brane band (Figure 19b.6).

```
fig, ax = plt.subplots()
ax.plot(k_plot, band["A"], "o-", color=COLOUR["A"], lw=2.2, ms=6,
        label="A: $+m$, $\\theta = 0$")
ax.plot(k_plot, band["B"], "s--", color=COLOUR["B"], lw=1.4, ms=3,
        label="B: $-m$, $\\theta = \\pi$ (T3 partner)")
ax.plot(k_plot, band["C"], "^:", color=COLOUR["C"], lw=1.4, ms=5,
        label="C: $-m$, $\\theta = 0$ (control)")
k_line = np.linspace(0.0, 0.25, 51)
ax.plot(k_line, c_A * k_line, "k--", lw=0.8, label="$c\\,k$, $c = 1.905$")
short = k_line[k_line < 0.11]  # the control's line leaves the picture early
ax.plot(short, c_C * short, "k:", lw=0.8, label="$c_{ctrl}\\,k$, $c_{ctrl} = 13.42$")
ax.set_xlabel("3-space momentum $k$ (units of $|m|$)")
ax.set_ylabel("lowest positive level $\\varepsilon$ (units of $|m|$)")
ax.legend(fontsize=8, loc="lower right")
```

The three bands are drawn with markers joined by lines (`"o-"` circles and a solid line, an `s` followed by two hyphens squares and dashes, `"^:"` triangles and dots; `ms` is the marker size; B's small squares sit inside A's large circles). The straight lines ck and $c_{\mathrm{ctrl}}k$ are drawn in black (`k` for black, followed by two hyphens for the dashed line and by a colon, `"k:"`, for the dotted one); the control's line only up to $k = 0.11$, where it reaches about 1.5 (`k_line[k_line < 0.11]` keeps the momenta below 0.11).

```
save_figure(fig, "brane_band",
            "The lowest positive level of the band sector against the 3-space "
            "momentum $k$ (both in units of $|m|$) at the slice $a_{4,0} = 0$, for "
            "$m = 1$, $L = 3$, no interaction, found by shooting: A (blue circles), "
            "its T3 partner B (orange squares, on top of A) and the control C (aqua "
            "triangles). A and B start with the slope $c = 1.905$ of the brane band "
            "(dashed); the control's zero mode lives at the tip, where the redshift "
            "factor $e^{-Hy}$ is largest, so its level rises with the slope "
            "$c_{ctrl} = 13.42$ (dotted) and soon bends below the first level of "
            "the bulk.")
```

`save_figure` saves Figure 19b.6. What the student should see: the blue circles of A, each with the orange square of B inside, rising close to the dashed line $1.905k$ over the whole range; the control's triangles leaving zero along the steep dotted line and then bending over, staying below the first level of the bulk (the levels above the gap), as the caption says.

In [21], the last check.

```
paths = [output_file(f"{FIGURE_FOLDER}/{name}.png") for name in
         ["19b_1_eight_gammas", "19b_2_gamma_block_map", "19b_3_mean_field_map",
          "19b_4_characteristic_functions", "19b_5_k0_ladders", "19b_6_brane_band"]]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

The list holds the paths of the six figure files; the check requires that all exist, and `all_chec ks_passed` prints the last line, ALL 19 CHECKS PASSED (notebook 19b) (Out [21]).

19.17 Watching T3 in the Rust solver: four universes

What the solver does. The Revision Rust Kohn-Sham solver (Chapter 15; `Revision/kohn_sh am/solver`) solves one instantaneous Kohn-Sham problem at a time with its subcommand `single`: given the bare mass m, the coupling λ, the slice $a_{4,0}$, the particle number N, the tip angle θ and, for a thermal state, the temperature T, it finds every level of every sector by shooting with a counting angle, fills the levels, builds the mean field, mixes old and new densities (Anderson mixing) and repeats until the state reproduces itself; its canonical numerics are 900 Runge-Kutta steps, root tolerance 10^{-13} and self-consistency tolerance 10^{-11} (`Revision/kohn_sham/results/parameters.json`, entry numerics). A `single` run contains no map from one universe to another: each universe is solved on its own. (The solver does contain T3 code elsewhere: its self-test t3_block_map_solver_selftest, in `Revision/kohn_sham/solver/src/runs.rs`, solves two members and compares them; the runs of this chapter do not use it.)

What the agreement of two universes tests. The counting angle is the angle ϕ of the real form of Section 19.3, $a = r\cos\phi$, $b = r\sin\phi$, so that $\tan\phi = b/a$ (`Revision/kohn_sham/solver/src/sh oot.rs`, its header). Write $K = \kappa k$ and $E = \varepsilon - v$. Its equation follows from the real form, line by line:

$$\frac{d\phi}{dy} = \frac{a\,b' - b\,a'}{a^2 + b^2} = \frac{(jE - K)a^2 - Mab - Mab + (K + jE)b^2}{r^2} = jE - K\cos 2\phi - M\sin 2\phi.$$

Rule: the derivative of $\arctan(b/a)$ is $(ab' - ba')/(a^2 + b^2)$; insert $a' = Ma - (K + jE)b$ and $b' = (jE - K)a - Mb$; then $a^2 + b^2 = r^2$, $(a^2 - b^2)/r^2 = \cos^2\phi - \sin^2\phi = \cos 2\phi$ and $2ab/r^2 = 2\sin\phi\cos\phi = \sin 2\phi$. The map of T3 in the real form, $(a, b, j, M) \to (b, a, -j, -M)$, exchanges a and b, so the angle of the image is $\psi = \pi/2 - \phi$. Its derivative is $\psi' = -\phi' = -jE + K\cos 2\phi + M\sin 2\phi$. The equation of the partner problem, with $-j$ and $-M$, gives for ψ, line by line:

$$(-j)E - K\cos 2\psi - (-M)\sin 2\psi = -jE - K\cos(\pi - 2\phi) + M\sin(\pi - 2\phi) = -jE + K\cos 2\phi + M\sin 2\phi.$$

Rule: $\cos(\pi - x) = -\cos x$ and $\sin(\pi - x) = \sin x$. The two right sides are equal: the angle of B obeys the equation of A with ϕ replaced by $\pi/2 - \phi$. The tip condition of the solver starts the angle at $\theta/2$, that is at 0 for A and at $\pi/2 = \pi/2 - 0$ for B. So every Runge-Kutta step for B is the step for A, mirrored: the solver does the same arithmetic for both, and their agreement to the last digits is guaranteed **by construction**. The record says this explicitly (`Revision/pairing/kohn_sham/t3-completion.json`, entry numerical_demonstration; the README of `Revision/pairing/kohn_sham`): the shooting method is covariant under the map. What the agreement does test is the solver's handling of both members: the transformed boundary conditions, the labels of the levels, the filling convention, the self-consistency loop and the Mermin root. It does not test the discretisation. The test that does not depend on the discretisation is the record's demonstration with the independent reference solver of Chapter 16 (Section 19.10): its frames for the two members are not images of each other, so on one grid their levels differ by up to 2.23×10^{-4}, and only after Richardson extrapolation do they agree, to 2.043×10^{-14} (ground) and 3.038×10^{-14} (thermal). The controls, on the other hand, are real tests: nothing in the solver forces C, or D at the same coupling λ, to agree with A, and they do not (D agrees with A at the opposite coupling $-\lambda$, which is again the covariance of the shooting).

The four universes. Notebook 19a solves, always with $|m| = 1$:

name	bare mass	coupling	tip angle	role
A	$+1$	$+\lambda$	0	the canonical state of the record
B	-1	$+\lambda$	π	the T3 partner of A
C	-1	$+\lambda$	0	negative control: the tip is not transformed
D	-1	$-\lambda$	π	wrong partner: the coupling is reversed, as in T1

By T3, B must agree with A in every level, occupation, energy and energy-momentum profile, with the opposite S, Q and M_{eff}; C must differ (Section 19.12); and D, which is the T3 partner of the state of A with the coupling $-\lambda$, must agree with A at $-\lambda$, not at λ.

What is compared, and the tolerance. The solver writes for every state a record with the list of levels (each with its momentum shell n_2, block type j, brane parity, label, level ε, degeneracy g and occupation f), the energy E_{KS}, the chemical potential or Fermi level, the entropy, the four integrals

$2\,\mathrm{Vol}_7 \int e^{6Hy} X\,dy$ of $X = \rho, p_3, p_t, p_0$ and of n, the measured residuals of the conservation law along y, and a table of the profiles $n, S, Q, M_{\mathrm{eff}}, v_v, e_{\mathrm{int}}, \rho, p_3, p_t, p_0$ at the 151 points $y = -3, -2.98, \ldots, 0$. The notebook compares A and B in exactly the way the solver's self-test of the record does: the sorted lists of (ε, g, f), the energies, the integrals and the scalar densities, with the tolerance 10^{-9} that the record fixed before its comparison. It adds the orbital-by-orbital pairing of statement S1 and a point-by-point comparison of every profile column. The differences between A and B that the notebook measures are 6.88×10^{-14} ($N = 8$) and 9.86×10^{-14} ($N = 136$) for the levels at the slice $a_{4,0} = 1$ (Notebook 19a, Out [7]) and, over all the 19 pairs it shares with the record, at most 9.9×10^{-14} for the ground states, 1.0×10^{-13} along the history and 8.1×10^{-13} for the thermal states (Notebook 19a, Out [27]). The largest is the entropy of the thermal state at $T = 0.01$, a number near 42 that the solver adds up level by level from the occupations. The record's own demonstration finds at most 2.179×10^{-13} (ground states) and 3.877×10^{-12} (thermal states) in its 210 states (`Revision/pairing/kohn_sham/reports/t3-rust-demo.json`, printed again in Out [27]). All of these are rounding errors: a computer carries about sixteen significant digits, and the tiny rounding errors of the many arithmetic steps of the shooting and of the self-consistency loop add up. They lie far below the tolerance 10^{-9}, and the paragraph "What the agreement of two universes tests" above explains why the agreement stays at the rounding level by construction.

The margin. The solver keeps, above the highest occupied level, empty levels up to a **margin**; the record uses $0.25 + 2\sigma$ with $\sigma = 0$, 0.1 and 0.3 for $\lambda = 0$, $\pm\lambda_1$, $\pm\lambda_2$, that is the margins 0.25, 0.45, 0.85, for its ground states, and $0.2 + 2\sigma$ for its thermal states, that is 0.4 for the coupling λ_1 used here (`Revision/kohn_sham/solver/src/runs.rs`, functions margin_for and the thermal run). The notebook uses the same margins, so that its runs are the record's runs.

What the runs reproduce. Every run of A is a state of the committed canonical matrix (`Revision/kohn_sham/results/ground/summary.csv`, `emt-integrals.csv`, the profile files, and `Revision/kohn_sham/results/thermo/thermodynamics.csv` for the thermal states), and the notebook checks that it reproduces the recorded numbers. Its runs of A, B and C for $N = 8$ and 136 at λ_1, $a_{4,0} = 1$ repeat the solver's T3 self-test of `Revision/kohn_sham/reports/ks-rust-solver.json` (Section 19.10) number by number. And 19 of its states are states of the record's own demonstration `Revision/pairing/kohn_sham/reports/t3-rust-demo.json` (Section 19.10): there A, B and C equal the plus, image and control members of the table `Revision/pairing/kohn_sham/numerics/results/t3-rust-states.csv`, and D at the coupling λ equals its image member at $-\lambda$ (notebook section 17).

19.18 Example: the universes of mass $+M$ and $-M$ in the Rust solver (Notebook 19a)

Notebook 19a checks the eight gammas and the block map of Γ again, builds the Rust solver with cargo, and runs it 62 times: A, B and C for $N = 8$ and 136 at the slice $a_{4,0} = 1$ (the self-test of the record); A, B and C without interaction for $N = 8$ (the zero modes and the level in the gap); A, B and C at the five slices of the deflating history for $N = 136$ and 688; A, B, C and D for five couplings; and A, B and C at three temperatures. Then it compares the 19 states it shares with the record's demonstration of T3. It needs Rust (cargo 1.91.1 or newer), takes about two minutes (33.6 s in the recorded build on the computer that built this book), writes the solver's raw output (about 2 MB) into a folder that git ignores, draws ten figures and ends with the line ALL 37 CHECKS PASSED (notebook 19a).

19.19 How to run Notebook 19a

Step 1. What this notebook does and what it needs.

Notebook 19a (The Rust Kohn-Sham solver for the universes of mass +M and -M) is the file `Revision /textbook/notebooks/19a_t3_rust_pairs.ipynb` of the repository Dirac_claude. It checks the eight real 16 x 16 gamma matrices of the record, builds from them the chirality matrix Gamma and checks that Gamma is the block map of theorem T3. Then it builds the Rust Kohn-Sham solver of the repository with cargo (about a minute when the program is missing, a second when it is up to date) and solves the Kohn-Sham problem of dirac16complex in the deflating primordial field for the universe of mass +M (bare mass m, coupling lambda, tip angle 0), for its partner of theorem T3 (bare mass -m, the same coupling, tip angle pi), for the negative control with the untransformed tip (bare mass -m, tip angle 0) and for the wrong partner with the reversed coupling (-m, -lambda, tip angle pi). It does this for 8, 136 and 688 particles, at the five instants of the deflating history, for five couplings and at three temperatures (62 runs). It checks that the partners have the same levels, occupations, energies and energy-momentum profiles and the opposite scalar density, that the controls differ, that the +M runs reproduce the committed canonical states, that the solver's own T3 self-test is reproduced number by number, that the runs equal the record's own numerical demonstration of T3 in the 19 states that both solve, and that the free zero modes and the sub-gap level of the control agree with their closed forms, and it draws ten overlay figures. The solver writes its raw output (about 2 MB) into the folder `Revision/kohn_sham/solver/target/textbook_19a`, which git ignores. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the Rust program revision_ks_solver, which is part of the repository and is built on your computer.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download `rustup-init.exe` from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run `rustup-init.exe` again). macOS and Linux: run the command below and

accept the default choice (on Linux first run `sudo apt install build-essential`, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
cargo build --release --manifest-path Revision/kohn_sham/solver/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file `Revision/kohn_sham/solver/target/release/revision_ks_solver` (on Windows with the ending `.exe`). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 19a_t3_rust_pairs.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 19a_t3_rust_pairs.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 19a_t3_rust_pairs.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/19a.captions.json`
- `Revision/textbook/figures/19a_1_level_ladder.png`
- `Revision/textbook/figures/19a_2_level_differences.png`
- `Revision/textbook/figures/19a_3_density_profiles.png`
- `Revision/textbook/figures/19a_4_mass_and_potential.png`
- `Revision/textbook/figures/19a_5_emt_profiles.png`
- `Revision/textbook/figures/19a_6_zero_modes_n8.png`
- `Revision/textbook/figures/19a_7_history_energy.png`
- `Revision/textbook/figures/19a_8_history_agreement.png`
- `Revision/textbook/figures/19a_9_coupling_scan.png`
- `Revision/textbook/figures/19a_10_thermal_states.png`

It changes no other file of the repository except the Rust build folder `target` next to each `Cargo.toml` it builds (inside it the notebook keeps the raw output of its program runs in `Revision/kohn_sham/solver/target/textbook_19a`, which git ignores); running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 19a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 19a_t3_rust_pairs.ipynb
python -m nbconvert --execute --inplace 19a_t3_rust_pairs.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this terminal.

- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build again.
- A cell shows the label with the star for a minute or more: this is normal for the cells that run the history and the coupling scan: they start the Rust program 17 to 27 times, each run takes about a second on a fast computer and up to five seconds on a laptop. Wait until the label shows a number.
- RuntimeError: the solver failed for a state: the error message ends with the last lines the solver printed. The solver and its input files must be the committed versions; get them back and run the notebook again.

```
git checkout -- Revision/kohn_sham Revision/algebra/gammas.json
```

- An AssertionError names a comparison with the record: the line above the error prints the largest difference. Differences in the last two or three digits are rounding effects of another computer and stay far below the tolerance; a larger difference means that the solver or its input files were changed.
- You want the disk space of the solver output back: the folder `Revision/kohn_sham/solver/target/textbook_19a` holds only the raw output of the last run (ignored by git); delete it at any time, the notebook writes it again.

19.20 Notebook 19a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Theorem **T3** of the Revision record says: in the Kohn-Sham model of the fermion
field dirac16complex in the author's deflating primordial field, every
self-consistent state of the universe with the bare mass $+m$, the coupling
$\lambda$ and the tip angle $\theta$ has an exact partner in the universe with the
bare mass $-m$, the **same** coupling $+\lambda$ and the tip angle $\pi - \theta$,
with the same levels, occupations, energies and energy-momentum profiles and the
opposite scalar density. T3 is PROVED by exact algebra (Wolfram 10 of 10 checks,
sympy 13 of 13). This notebook does not prove it again; it **watches it happen**
in the Rust Kohn-Sham solver of the repository, which knows nothing about T3 and
simply solves each universe on its own.

The notebook

- checks the eight real $16 \times 16$ gamma matrices of the record, builds from
```

```
  them the chirality matrix $\Gamma$ and checks that $\Gamma$ is the map of T3;
- builds the Rust program ‘revision_ks_solver‘ with cargo;
- solves four kinds of universes: A (mass $+m$, tip angle $0$; the canonical
  state of the record), B (mass $-m$, coupling $+\lambda$, tip angle $\pi$; the T3
  partner of A), C (mass $-m$, coupling $+\lambda$, tip angle $0$; the **negative
  control** with the untransformed tip) and D (mass $-m$, coupling $-\lambda$, tip
  angle $\pi$; the **wrong partner** with the reversed coupling);
- reproduces, number by number, the solver’s own T3 self-test stored in the
  record ‘Revision/kohn_sham/reports/ks-rust-solver.json‘;
- compares A and B level by level and point by point, for 8, 136 and 688
  particles, at the five instants of the deflating history, for five couplings and
  at three temperatures (62 runs of the solver), and shows that C and D differ;
- checks that every A run reproduces the committed canonical state of the record,
  and that the free zero modes and a level of the control agree with formulas
  derived here by hand;
- draws ten figures that put the universes on top of each other.

It takes about one to two minutes (longer on a laptop).
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 19a (The Rust Kohn-Sham solver for the universes of mass +M and -M) is the file
‘Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb‘ of the repository Dirac_claude. It
checks the eight real 16 x 16 gamma matrices of the record, builds from them the
chirality matrix Gamma and checks that Gamma is the block map of theorem T3. Then it
builds the Rust Kohn-Sham solver of the repository with cargo (about a minute when the
program is missing, a second when it is up to date) and solves the Kohn-Sham problem of
dirac16complex in the deflating primordial field for the universe of mass +M (bare mass
m, coupling lambda, tip angle 0), for its partner of theorem T3 (bare mass -m, the same
coupling, tip angle pi), for the negative control with the untransformed tip (bare mass
-m, tip angle 0) and for the wrong partner with the reversed coupling (-m, -lambda, tip
angle pi). It does this for 8, 136 and 688 particles, at the five instants of the
deflating history, for five couplings and at three temperatures (62 runs). It checks that
the partners have the same levels, occupations, energies and energy-momentum profiles and
the opposite scalar density, that the controls differ, that the +M runs reproduce the
committed canonical states, that the solver’s own T3 self-test is reproduced number by
number, that the runs equal the record’s own numerical demonstration of T3 in the 19
states that both solve, and that the free zero modes and the sub-gap level of the control
agree with their closed forms, and it draws ten overlay figures. The solver writes its
raw output (about 2 MB) into the folder ‘Revision/kohn_sham/solver/target/textbook_19a‘,
which git ignores. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It also needs Rust (the program cargo, version 1.91.1 or newer), because it
runs the Rust program revision_ks_solver, which is part of the repository and is built on
your computer.
```

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home

folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Install Rust and build the Rust program (Rust once per computer, the build once per program).

Windows: download ‘rustup-init.exe‘ from https://rustup.rs, run it and accept the default choices; if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run ‘rustup-init.exe‘ again). macOS and Linux: run the command below and accept the default choice (on Linux first run ‘sudo apt install build-essential‘, which provides the linker that Rust needs).

macOS (zsh) and Linux (bash):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then close the terminal, open a new one, do Step 4 again, and check the version of cargo; it must print 1.91.1 or a newer version:

Windows, macOS and Linux:

```
cargo --version
```

Build the program with the following command, in the repository folder (the same command on all three systems):

Windows, macOS and Linux:

```
cargo build --release --manifest-path Revision/kohn_sham/solver/Cargo.toml
```

The first build takes about 1 minute; later builds reuse the result and take a few seconds. The program is then the file ‘Revision/kohn_sham/solver/target/release/revision_ks_solver‘ (on Windows with the ending ‘.exe‘). The notebook runs the same build command itself before it uses the program (it takes a second when the program is up to date), so the notebook also works if you skip this build; building here first shows any problem with Rust before the notebook starts.

Step 6. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
```

```
    jupyter lab 19a_t3_rust_pairs.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 7. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 19a_t3_rust_pairs.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 19a_t3_rust_pairs.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 8. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/19a.captions.json‘
- ‘Revision/textbook/figures/19a_1_level_ladder.png‘
- ‘Revision/textbook/figures/19a_2_level_differences.png‘
- ‘Revision/textbook/figures/19a_3_density_profiles.png‘
- ‘Revision/textbook/figures/19a_4_mass_and_potential.png‘
- ‘Revision/textbook/figures/19a_5_emt_profiles.png‘
- ‘Revision/textbook/figures/19a_6_zero_modes_n8.png‘
- ‘Revision/textbook/figures/19a_7_history_energy.png‘
- ‘Revision/textbook/figures/19a_8_history_agreement.png‘
- ‘Revision/textbook/figures/19a_9_coupling_scan.png‘
- ‘Revision/textbook/figures/19a_10_thermal_states.png‘

It changes no other file of the repository except the Rust build folder ‘target‘ next to each ‘Cargo.toml‘ it builds (inside it the notebook keeps the raw output of its program runs in ‘Revision/kohn_sham/solver/target/textbook_19a‘, which git ignores); running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 19a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 9. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 19a_t3_rust_pairs.ipynb
  python -m nbconvert --execute --inplace 19a_t3_rust_pairs.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "cargo is not recognized" or "command not found: cargo" or "cargo was not found": open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from this

terminal.
- "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build again.
- A cell shows the label with the star for a minute or more: this is normal for the cells that run the history and the coupling scan: they start the Rust program 17 to 27 times, each run takes about a second on a fast computer and up to five seconds on a laptop. Wait until the label shows a number.
- RuntimeError: the solver failed for a state: the error message ends with the last lines the solver printed. The solver and its input files must be the committed versions; get them back and run the notebook again.

    git checkout -- Revision/kohn_sham Revision/algebra/gammas.json

- An AssertionError names a comparison with the record: the line above the error prints the largest difference. Differences in the last two or three digits are rounding effects of another computer and stay far below the tolerance; a larger difference means that the solver or its input files were changed.
- You want the disk space of the solver output back: the folder ‘Revision/kohn_sham/solver/target/textbook_19a‘ holds only the raw output of the last run (ignored by git); delete it at any time, the notebook writes it again.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 19a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 19a (The Rust Kohn-Sham solver for the universes of mass +M and -M) is the
# file Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb of the repository
# Dirac_claude. It checks the eight real 16 x 16 gamma matrices of the record, builds
# from them the chirality matrix Gamma and checks that Gamma is the block map of theorem
# T3. Then it builds the Rust Kohn-Sham solver of the repository with cargo (about a
# minute when the program is missing, a second when it is up to date) and solves the
# Kohn-Sham problem of dirac16complex in the deflating primordial field for the universe
# of mass +M (bare mass m, coupling lambda, tip angle 0), for its partner of theorem T3
# (bare mass -m, the same coupling, tip angle pi), for the negative control with the
# untransformed tip (bare mass -m, tip angle 0) and for the wrong partner with the
# reversed coupling (-m, -lambda, tip angle pi). It does this for 8, 136 and 688
# particles, at the five instants of the deflating history, for five couplings and at
# three temperatures (62 runs). It checks that the partners have the same levels,
# occupations, energies and energy-momentum profiles and the opposite scalar density,
# that the controls differ, that the +M runs reproduce the committed canonical states,
# that the solver's own T3 self-test is reproduced number by number, that the runs equal
# the record's own numerical demonstration of T3 in the 19 states that both solve, and
# that the free zero modes and the sub-gap level of the control agree with their closed
# forms, and it draws ten overlay figures. The solver writes its raw output (about 2 MB)
```

```
# into the folder Revision/kohn_sham/solver/target/textbook_19a, which git ignores. It
# needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and
# matplotlib; the other packages run Jupyter, the program that shows and runs notebooks.
# It also needs Rust (the program cargo, version 1.91.1 or newer), because it runs the
# Rust program revision_ks_solver, which is part of the repository and is built on your
# computer.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
```

```
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
```

```
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. INSTALL RUST AND BUILD THE RUST PROGRAM (RUST ONCE PER COMPUTER, THE BUILD ONCE
# PER PROGRAM).
#
# Windows: download rustup-init.exe from https://rustup.rs, run it and accept the default
# choices; if it reports that the Visual Studio C++ Build Tools are missing, let it
# install them (or install the workload "Desktop development with C++" from
# https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run rustup-init.exe
# again). macOS and Linux: run the command below and accept the default choice (on Linux
# first run sudo apt install build-essential, which provides the linker that Rust needs).
#
# macOS (zsh) and Linux (bash):
#     curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
#
# Then close the terminal, open a new one, do Step 4 again, and check the version of
# cargo; it must print 1.91.1 or a newer version:
#
# Windows, macOS and Linux:
#     cargo --version
#
# Build the program with the following command, in the repository folder (the same
# command on all three systems):
#
# Windows, macOS and Linux:
#     cargo build --release --manifest-path Revision/kohn_sham/solver/Cargo.toml
#
# The first build takes about 1 minute; later builds reuse the result and take a few
# seconds. The program is then the file
# Revision/kohn_sham/solver/target/release/revision_ks_solver (on Windows with the ending
# .exe). The notebook runs the same build command itself before it uses the program (it
# takes a second when the program is up to date), so the notebook also works if you skip
# this build; building here first shows any problem with Rust before the notebook starts.
#
# STEP 6. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 19a_t3_rust_pairs.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
```

```
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 7. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 19a_t3_rust_pairs.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 19a_t3_rust_pairs.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 8. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/19a.captions.json
# - Revision/textbook/figures/19a_1_level_ladder.png
# - Revision/textbook/figures/19a_2_level_differences.png
# - Revision/textbook/figures/19a_3_density_profiles.png
# - Revision/textbook/figures/19a_4_mass_and_potential.png
# - Revision/textbook/figures/19a_5_emt_profiles.png
# - Revision/textbook/figures/19a_6_zero_modes_n8.png

#
# It changes no other file of the repository except the Rust build folder target next to
# each Cargo.toml it builds (inside it the notebook keeps the raw output of its program
# runs in Revision/kohn_sham/solver/target/textbook_19a, which git ignores); running it
# headless or saving it in JupyterLab also rewrites the notebook file itself. It does not
# use the internet while it runs. The files it writes are the same files that are stored
# in the repository (on another computer a figure may differ in a few bytes, which is
# harmless). To get the stored versions back, run this command in the repository folder
# (it also undoes every change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
```

```
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 37 CHECKS PASSED (notebook 19a)
#
# and the notebook must show 10 figures below the cells that draw them.
#
# STEP 9. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/19a_t3_rust_pairs.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 19a_t3_rust_pairs.ipynb
#     python -m nbconvert --execute --inplace 19a_t3_rust_pairs.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "cargo is not recognized" or "command not found: cargo" or "cargo was not found":
#   open a new terminal after installing Rust, do Step 4 again, and start JupyterLab from
#   this terminal.
# - "linker link.exe not found" (Windows) or "linker cc not found" (Linux): install the
#   C++ Build Tools (Windows) or build-essential (Linux) as described in Step 5 and build
#   again.
# - A cell shows the label with the star for a minute or more: this is normal for the
#   cells that run the history and the coupling scan: they start the Rust program 17 to
#   27 times, each run takes about a second on a fast computer and up to five seconds on
#   a laptop. Wait until the label shows a number.
```

```
# - RuntimeError: the solver failed for a state: the error message ends with the last
#   lines the solver printed. The solver and its input files must be the committed
#   versions; get them back and run the notebook again.
#     git checkout -- Revision/kohn_sham Revision/algebra/gammas.json
# - An AssertionError names a comparison with the record: the line above the error prints
#   the largest difference. Differences in the last two or three digits are rounding
#   effects of another computer and stay far below the tolerance; a larger difference
#   means that the solver or its input files were changed.
# - You want the disk space of the solver output back: the folder
#   Revision/kohn_sham/solver/target/textbook_19a holds only the raw output of the last
#   run (ignored by git); delete it at any time, the notebook writes it again.
#

## 3. The words used in this notebook

- **Coordinates** (the author's names): $x_1, x_2, x_3$ = ordinary 3-space, which
  inflates (scale factor $e^{a_4}\sin^{1/6}z$); $x_4$ = the time; $x_5, x_6, x_7$ =
  the three **extra times**, which **deflate exponentially** (scale factor
  $e^{-a_4}\sin^{1/6}z$); $x_0$ = the hidden space direction, $z = 6Hx_0$ between
  $0$ and $\pi/2$.
- **Hidden coordinate** $y = \ln(\sin z)/(6H)$: it runs from the **tip** $y = -L$
  (the model cuts the hidden direction there, $L = 3$) to the **brane** $y = 0$.
- **Slice** $a_{4,0}$: one instant of the history $a_4 = AHx_4$ ($A = 1$), the value
  of $a_4$ at that instant. The slices are $a_{4,0} = 0, 0.5, 1, 1.5, 2$.
- **Gamma matrices** $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$: the author's eight
  real $16 \times 16$ matrices, one for each coordinate, with
  $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}$ times the unit matrix, where
  $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order
  $x_0, \dots, x_7$. **Chirality** $\Gamma$: their product
  $\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$.
- **Pauli matrices** $\sigma_1, \sigma_2, \sigma_3$: the three $2 \times 2$ matrices
  $\begin{pmatrix}0&1\\1&0\end{pmatrix}$, $\begin{pmatrix}0&-i\\i&0\end{pmatrix}$,
  $\begin{pmatrix}1&0\\0&-1\end{pmatrix}$.
- **Kohn-Sham state**: an approximate state of $N$ identical fermions built from
  one-particle wave functions (**orbitals**) that each solve a one-particle equation
  in a common **effective potential**; the potential depends on the densities of the
  occupied orbitals, so the equations are solved **self-consistently** (repeat until
  nothing changes).
- **Level** $\varepsilon$: an allowed energy of the one-particle equation;
  **occupation** $f$: how many particles sit in an orbital of that level ($0$ to
  $1$); **degeneracy** $g$: how many orbitals share the level. **HOMO** and
  **LUMO**: the highest occupied and the lowest empty level; **Kohn-Sham gap**:
  LUMO minus HOMO.
- **Block type** $j = \pm 1$ and **brane parity** (even or odd): labels of the
  orbitals (explained in section 4).
- **Bare mass** $m$: the mass in the Lagrangian; **effective mass** $M_{eff}(y)$:
  the mass seen by an orbital, $m$ plus the mean-field term.
- **Coupling** $\lambda$: the strength of the self-interaction $U = (\lambda/2)S^2$.
  $\lambda_1$ and $\lambda_2$ are the two calibrated couplings of the record.
- **Densities**: the particle density $n(y)$, the scalar density $S(y)$ and the
  density $Q(y)$; **proper** means per unit of proper 7-volume; the **coordinate
  density** $e^{6Hy}n(y)$ is the density per unit of $y$.
- **Energy-momentum profiles**: the energy density $\rho(y)$ and the pressures
  $p_3(y)$ (3-space), $p_t(y)$ (extra times), $p_0(y)$ (hidden direction).
- **Tip angle** $\theta$: the angle of the boundary condition at the tip.
- **Zero mode**: an orbital with the level $\varepsilon = 0$ at zero momentum.
- **Partner**: the image of a state under the map of theorem T3. **Negative
  control**: a computation that must FAIL to agree; it shows that the agreement is
  not automatic.
- **Relative difference**: $|a - b|/\max(|a|, 1)$; numbers that agree to the last
  digits of a computer have relative differences near $10^{-15}$.
- Status labels: PROVED (exact), COMPUTED (numerical), ASSUMED (a choice),
  HYPOTHESIS, OPEN (not known).
- Units: $H = 1$ and $|m| = 1$; energies, momenta and temperatures in units of
  $|m|$, lengths in units of $1/H$.
```

Text cell:

```
## 4. The physical and mathematical situation

**The geometry.** The Kohn-Sham record works on the background $b_4 = 1$ of the author's
metric of 2026-10-14 (the second function $b_4(x_4)$ of the metric, which multiplies the
extra-time components, is put equal to 1). In the hidden coordinate $y$ this metric is
$ds^2 = e^{2Hy}[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2 +
dx_7^2)] - dx_4^2 + dy^2$. While $a_4$ grows, 3-space inflates by $e^{a_4}$ and the
three extra times deflate by $e^{-a_4}$; the proper 7-volume factor
$e^{3a_4} e^{-3a_4} e^{6Hy} = e^{6Hy}$ does not change, because the deflation of the
extra times exactly compensates the inflation of 3-space. Along the history every
3-space momentum is redshifted: an orbital with momentum $k$ feels
$\kappa(y)\,k$ with $\kappa = e^{-Hy - a_{4,0}}$.

**The Kohn-Sham problem** (record `Revision/kohn_sham/ks-theory.json`). The 16
components of the field split exactly into eight blocks of two components
$\chi(y) = (\chi_1, \chi_2)$, labelled by $j = \pm 1$ and two more signs. In a block
of type $j$ an orbital with 3-momentum $k$ and level $\varepsilon$ solves

$$h_j\chi = \varepsilon\chi,\qquad h_j = j\Big[-i\sigma_1\frac{d}{dy}
+ M_{eff}(y)\,\sigma_2 + \kappa(y)\,k\,\sigma_3\Big] + v_v(y),$$

with the effective mass $M_{eff} = m + \frac{15}{16}\lambda S$ and the potential
$v_v = -\frac{1}{16}\lambda n$ (Hartree plus the exact exchange of the uniform gas;
no correlation).

**Boundary conditions.** At the brane $y = 0$ the $Z_2$ mirror, which is ASSUMED:
even parity $\chi_2(0) = 0$ or odd parity $\chi_1(0) = 0$; both parities are solved
and filled together. At the tip $y = -L$ a chosen condition
$(1 - Q(\theta))\chi(-L) = 0$ with $Q(\theta) = \cos\theta\,\sigma_3 +
\sin\theta\,\sigma_2$: for $\theta = 0$ it says $\chi_2(-L) = 0$, for $\theta = \pi$
it says $\chi_1(-L) = 0$.

**Theorem T3** (PROVED; records `Revision/pairing/kohn_sham/t3-theory.json`,
`wolfram-t3.json`, `python-t3.json`). The map $(\chi, j) \to (\sigma_2\chi, -j)$ at
the same momentum (in 16 components: the chirality matrix $\Gamma$), with the two
brane parities exchanged and $\theta \to \pi - \theta$, sends every self-consistent
Kohn-Sham state with $(m, \lambda, \theta)$ to a self-consistent state with
$(-m, +\lambda, \pi - \theta)$: equal levels with degeneracies, occupations, chemical
potential, entropy, Kohn-Sham energy $E_{KS}$, grand potential and free energy,
equal $n$, $v_v$, $\rho$, $p_3$, $p_t$, $p_0$; opposite $S$, $Q$ and $M_{eff}$. With
$(-m, -\lambda)$ the map fails, and with the untransformed tip it fails too.

**The four universes of this notebook** ($m = 1$):

| name | bare mass | coupling | tip angle | role |
| --- | --- | --- | --- | --- |
| A | $+1$ | $+\lambda$ | $0$ | the canonical state of the record |
| B | $-1$ | $+\lambda$ | $\pi$ | the T3 partner of A |
| C | $-1$ | $+\lambda$ | $0$ | negative control: tip not transformed |
| D | $-1$ | $-\lambda$ | $\pi$ | wrong partner: coupling reversed |

**What is assumed and what is not shown.** The $Z_2$ brane is ASSUMED; the tip is
```

```
a chosen cutoff; the states are instantaneous (adiabatic) mean-field states; the
history $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND (the Kohn-Sham states are not an
admissible source of the $a_4$ equations). T3 maps solutions onto solutions; it
does not create anything: no creation process, rate or amplitude of a pair of
universes follows from it, and nothing here says that the partner exists. Every
number in this notebook is COMPUTED by the solver; the agreement of A and B is a
numerical confirmation of T3, not its proof.
```

Text cell:

```
## 5. The eight real gamma matrices and the map of T3

The map of T3 is built from the author's eight real $16 \times 16$ gamma matrices.
The next cell reads them from the record `Revision/algebra/gammas.json` (a matrix is
a list of 16 rows of 16 numbers; a complex matrix would be stored as a pair of real
and imaginary parts, so a plain list means a real matrix) and checks three things:
(1) every entry is $-1$, $0$ or $+1$, so the matrices are real; (2) the
anticommutation rule $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\mathbf{1}$ for
all 64 pairs; (3) the product $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}
\cdots\gamma^{(x_7)}$ is the diagonal matrix with $-1$ eight times and then $+1$ eight
times, the matrix stored in the record, and anticommutes with every gamma.
```

```

Text cell:

```
The record ‘Revision/kohn_sham/ks-theory.json‘ stores the unitary $16 \times 16$
matrix $V$ whose 16 columns are the basis of the eight blocks (two columns per
block, block $b$ in the columns $2b$ and $2b + 1$), and the label $(j, s_2, s_3)$ of
every block. The entries are written as text: ‘0‘, ‘1‘, ‘-1‘, ‘I‘, ‘-I‘ times
$1/(2\sqrt2)$. The next cell checks that $V$ is unitary, that in every block
$\gamma^{(x_0)}$ acts as $\sigma_3$ and $\gamma^{(x_0)}\gamma^{(x_4)}$ as
$j\sigma_1$, and that $\Gamma$ maps the two columns of block $(j, s_2, s_3)$ onto
the two columns of block $(-j, s_2, s_3)$ times $s_2\sigma_2$. That last statement
is the map $(\chi, j) \to (\sigma_2\chi, -j)$ of T3 (up to the sign $s_2$).
```

In [3]:

```

## 6. Building the solver and a helper that runs it

The next cell builds the Rust program with cargo (the helper ‘rust_program‘ of the
set-up cell; the first build takes about a minute, later builds a second) and
defines the colours of the figures: blue for A, orange for B, aqua for C and yellow
for D, always in this order.
```

In [4]:

```
SOLVER_MANIFEST = "Revision/kohn_sham/solver/Cargo.toml"  # the crate of the solver
program = rust_program(SOLVER_MANIFEST, "revision_ks_solver")  # build it, get path
RUN_FOLDER = REPO / "Revision/kohn_sham/solver/target/textbook_19a"  # git ignores it
RUN_FOLDER.mkdir(parents=True, exist_ok=True)

COLOUR = {"A": "#2a78d6", "B": "#eb6834", "C": "#1baf7a", "D": "#eda100"}
NAME = {"A": "A: $+m$, $+\\lambda$, $\\theta = 0$",
        "B": "B: $-m$, $+\\lambda$, $\\theta = \\pi$ (T3 partner)",
        "C": "C: $-m$, $+\\lambda$, $\\theta = 0$ (control)",
        "D": "D: $-m$, $-\\lambda$, $\\theta = \\pi$ (wrong partner)"}
say("Solver ready, colours defined.")
```

Out [4]:

```
Rust program revision_ks_solver is built and ready.
Solver ready, colours defined.
```

Text cell:

The next cell defines ‘solve‘, which runs the solver once. The subcommand ‘single‘ solves one Kohn-Sham state with the options ‘--m‘ (bare mass), ‘--lambda‘, ‘--a4‘ (the slice), ‘--N‘ (particle number), ‘--tip-theta‘ (tip angle), ‘--margin‘ (how far above the highest occupied level the solver keeps empty levels; the record uses $0.25 + 2\sigma$ with $\sigma = 0$, 0.1, 0.3 for $\lambda = 0$, $\pm\lambda_1$, $\pm\lambda_2$) and optionally ‘--T‘ (temperature). It writes a JSON file (levels, energies, integrals) and, with ‘--profiles‘, a table of the profiles at the 151 points $y = -3, -2.98, \dots, 0$. ‘--root‘ tells it where the repository is (it reads ‘ks-theory.json‘ and the gamma matrices from there). ‘solve‘ returns a dictionary with the JSON record, its levels as a list of tuples $(n_2, j, \text{parity}, \text{label}, \varepsilon, g, f)$ and the profiles as numpy arrays. The four universes are made by ‘universe‘.

## 7. What the record says: the proof counts and the solver's own T3 self-test

The next cell reads the two proof reports of T3 and counts their passing checks
(Wolfram 10, sympy 13). Then it reads the couplings of the record
(‘parameters.json‘) and the solver's check named ‘t3_block_map_solver_selftest‘. That
check solved A, B and C at the slice $a_{4,0} = 1$ with the coupling $\lambda_1$ for
$N = 8$ and $N = 136$ and recorded the energies, the number of levels and the
control's energy in its text; the cell pulls these numbers out with a regular
expression (a pattern that matches text).

## 8. Reproducing the self-test: A, B and C for N = 8 and N = 136

The next cell solves the three universes A, B, C for $N = 8$ and $N = 136$ at the
slice $a_{4,0} = 1$ with the coupling $\lambda_1$ and the record's margin $0.45$
(six runs of the solver). Then it compares, as the self-test does: the sorted lists
of $(\varepsilon, g, f)$ of A and B, the energies $E_{KS}$, the integrals of
$\rho, p_3, p_t, p_0$ over the hidden direction and the scalar densities
($S_A + S_B$ must vanish). It prints each largest difference.

## 10. The two spectra, level by level

T3 does more than say that the sorted lists agree: it says WHICH level goes where.
The orbital of block type $j$ and brane parity $p$ goes to block type $-j$ and the
other parity, at the same momentum shell $n_2$ (the momentum $k = \Delta k
\sqrt{n_2}$) and with the same level. The next cell checks this for $N = 136$: for
every level of A it looks for a level of B in the shell $n_2$, with $-j$ and the
other parity, at the same $\varepsilon$ (within $10^{-9}$), and checks that the
pairing uses every level of B exactly once, with the same degeneracy and occupation.
It also prints, sector by sector, the label of the partner minus the label of the
level. The label is the solver's count of a level inside its sector, counted from
the boundary conditions; A and B have different boundary conditions, so the count
of a partner can differ by one. The map is fixed by the sector and the energy, not
by the label.
```

## 11. The densities and the potentials, point by point

T3 says that the particle density $n(y)$ and the potential $v_v(y)$ of B are those
of A, while the scalar density $S(y)$, the density $Q(y)$ and the effective mass
$M_{eff}(y)$ change sign. The next cell checks this at the 151 points of the
profiles for $N = 8$ and $N = 136$ (relative to the largest value of each column)
and also checks the interaction energy density $e_{int}$, which contains $S$ only as
$S^2$.
```

In [13]:

```
For $N = 8$ the particles sit in the eight zero modes of momentum $k = 0$. Without
interaction ($\lambda = 0$, so $M_{eff} = M = \pm m$ and $v_v = 0$) the block
equation at $k = 0$ is the first-order system $d\chi/dy = N\chi$ with
$N = M\sigma_3 + ij\varepsilon\sigma_1$ (record `ks-theory.json`), and at
$\varepsilon = 0$ it is $d\chi_1/dy = M\chi_1$, $d\chi_2/dy = -M\chi_2$. So:

- A ($M = +m$, even parity $\chi_2(0) = 0$, tip $\chi_2(-L) = 0$): $\chi_2 = 0$ and
  $\chi = (e^{my}, 0)$, largest at the brane;
- B ($M = -m$, odd parity $\chi_1(0) = 0$, tip angle $\pi$: $\chi_1(-L) = 0$):
  $\chi_1 = 0$ and $\chi = (0, e^{my})$, the T3 image $\sigma_2(e^{my}, 0) =
  (0, ie^{my})$ up to the factor $i$, again largest at the brane;
- C ($M = -m$, even parity, tip $\chi_2(-L) = 0$): $\chi = (e^{-my}, 0)$, largest
  at the TIP.

The coordinate density $e^{6Hy}n(y)$ is proportional to $|\chi|^2$, so its value at
the brane divided by its value at the tip is $e^{2mL} = e^6$ for A and B and
$e^{-2mL} = e^{-6}$ for C. The next cell solves the three $N = 8$ universes without
interaction at $a_{4,0} = 1$ (three runs) and checks these two ratios.
```

```

Out [17]:

```
A: brane / tip = 4.034288e+02, closed form 4.034288e+02
B: brane / tip = 4.034288e+02, closed form 4.034288e+02
C: brane / tip = 2.478752e-03, closed form 2.478752e-03
PASS free N = 8: the zero modes of A and B live at the brane, those of C at the tip
```

Text cell:

```
The control C has one more surprise: a level inside the gap $|\varepsilon| < m$.
Take the odd parity ($\chi_1(0) = 0$) with the tip condition $\chi_2(-L) = 0$, at
```

```
$k = 0$ with $M = -m$ and $v_v = 0$. Write $D$ for the derivative $d/dy$. The block
equation $D\chi = N\chi$ reads

$$D\chi_1 = -m\chi_1 + ij\varepsilon\chi_2,\qquad
D\chi_2 = ij\varepsilon\chi_1 + m\chi_2 .$$

Differentiate the second equation: $D^2\chi_2 = ij\varepsilon D\chi_1 + mD\chi_2$.
Insert the first equation: $D^2\chi_2 = ij\varepsilon(-m\chi_1 +
ij\varepsilon\chi_2) + mD\chi_2 = -m(ij\varepsilon\chi_1) - \varepsilon^2\chi_2 +
mD\chi_2$ (because $i^2j^2 = -1$). The second equation says $ij\varepsilon\chi_1 =
D\chi_2 - m\chi_2$; insert it: $D^2\chi_2 = -mD\chi_2 + m^2\chi_2 -
\varepsilon^2\chi_2 + mD\chi_2 = (m^2 - \varepsilon^2)\chi_2$. For
$|\varepsilon| < m$ write $q = \sqrt{m^2 - \varepsilon^2}$; the solution with
$\chi_2(-L) = 0$ is $\chi_2 = \sinh(q(y + L))$, because $D^2\sinh(q(y + L)) =
q^2\sinh(q(y + L))$ and $\sinh 0 = 0$. The brane condition $\chi_1(0) = 0$ is
$D\chi_2(0) - m\chi_2(0) = 0$, that is $q\cosh(qL) = m\sinh(qL)$, or

$$\tanh(qL) = q/m .$$

The function $\tanh(qL) - q/m$ is $0$ at $q = 0$, positive just above $0$ (its slope
there is $L - 1/m = 2$) and negative at $q = m$, so it has a root in $(0, m)$; the
level is $\varepsilon_b = \sqrt{m^2 - q^2} = m/\cosh(qL)$ (since $q/m = \tanh(qL)$
and $1 - \tanh^2 = 1/\cosh^2$). For A ($M = +m$) the same steps give
$q\cosh(qL) = -m\sinh(qL)$, which has no root with $q > 0$: A has no level in the
gap in this sector. The next cell finds $q$ by **bisection** (halve an interval
that contains the root, keep the half where the function changes sign, 200 times)
and checks: the Kohn-Sham gap of the free control C is $\varepsilon_b$; the gaps of
A and B are equal to each other and to the gap of the committed state
‘N8_lam0_a10‘.

## 15. The coupling must keep its sign

T3 pairs $(m, \lambda)$ with $(-m, +\lambda)$. What about $(-m, -\lambda)$, the
parameter change of the classical theorem T1? The next cell solves, for $N = 136$ at
$a_{4,0} = 1$, the five couplings $\lambda = -\lambda_2, -\lambda_1, 0, +\lambda_1,
+\lambda_2$ for all four universes A, B, C, D (with the record's margins $0.85$,
$0.45$, $0.25$). It checks: A reproduces the record at every coupling; B equals A;
D at $\lambda$ equals A at $-\lambda$ (that is T3 applied to the state with
$-\lambda$), so D differs from A whenever $\lambda \ne 0$; C differs from A by $1$
to $3.5$ at every coupling.
```

In [23]:

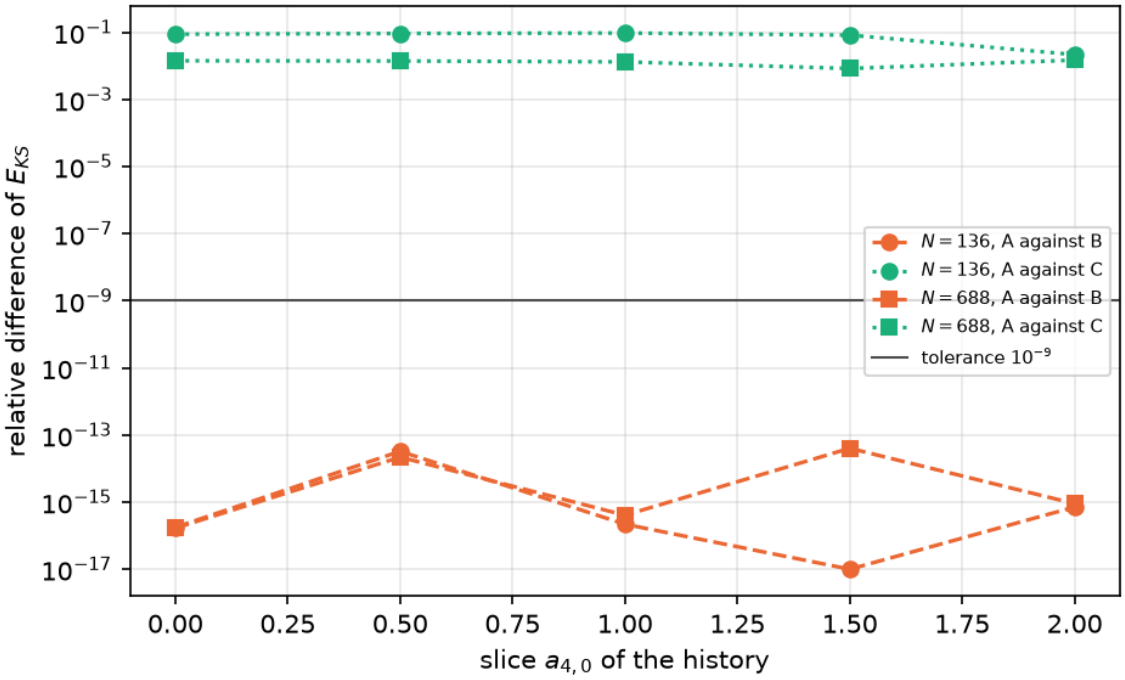

Figure 504: Relative differences of the Kohn-Sham energy between A and its T3 partner B (orange) and between A and the control C (aqua) at the five slices of the history, for $N = 136$ (circles) and $N = 688$ (squares); logarithmic vertical axis, exact zeros drawn at 10^{-17}. The partner agrees to better than 10^{-13} at every slice: T3 holds slice by slice along the deflating history. The control is off by 0.5 to 10 percent. (Notebook 19a, figure 8.)

## 17. The same runs in the record's demonstration of T3

The Revision record has its own numerical demonstration of T3
(‘Revision/pairing/kohn_sham/reports/t3-rust-demo.json‘, 7 checks). With the same
solver it solved the members "plus" (our A), "image" (our B) and "control" (our C)
for all 210 states of the canonical matrix, and it stored their numbers in the table
```

‘Revision/pairing/kohn_sham/numerics/results/t3-rust-states.csv‘, one row per state. The runs of this notebook cover 19 of these states: 7 ground states at the slice $a_{4,0} = 1$ (sections 8, 13 and 15), the other 9 states of the history (section 14) and 3 thermal states (section 16). The next cell reads the report and the table and prints the record’s own largest deviations. Then it checks, state by state: A equals the record’s plus member (E_{KS}); B equals its image member (E_{KS}, μ, the entropy and the four EMT integrals); C equals its control (E_{KS}); and D at the coupling λ equals the record’s image member at $-\lambda$. Last, it measures in each of the three groups the largest deviation between A and B: the levels, E_{KS}, μ, the entropy, the EMT integrals and the ten profile columns (even ones equal, odd ones opposite), each relative as in the cells above.

What this agreement tests. The solver follows the angle ϕ of the real form, $(a, b) = r(\cos\phi, \sin\phi)$. The map of T3, $(a, b, j, M) \to (b, a, -j, -M)$, turns ϕ into $\pi/2 - \phi$, and the equation of the angle of B is the equation of A with ϕ replaced by $\pi/2 - \phi$. So the solver does the same arithmetic for A and B, and their agreement to the last digits is guaranteed by construction: it tests the transformed boundary conditions, the labels, the filling, the self-consistency loop and the Mermin root, not the discretisation. The record’s second demonstration (‘t3-reference-demo.json‘), with the independent finite-difference reference solver, gives the test that does not depend on the discretisation.

      "every figure file of this notebook exists")
all_checks_passed()
```

Out [28]:

```
RESULT runs of the Rust solver in this notebook = 62
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 19a)
```

Text cell:

```
## 19. What this notebook showed

- PROVED in the records and re-checked here exactly: the author's eight gamma
  matrices are real $16 \times 16$ matrices with entries $-1$, $0$, $+1$ that obey
  $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\mathbf{1}$; their product
  $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$ is
  $\mathrm{diag}(-1, \dots, -1, +1, \dots, +1)$ and maps every Kohn-Sham block
  $(j, s_2, s_3)$ onto the block $(-j, s_2, s_3)$ as $s_2\sigma_2$: the map of T3.
- COMPUTED (62 runs of the Rust Kohn-Sham solver, which compare A and B in 19
  states: 7 ground states at $a_{4,0} = 1$, 9 more states of the history and 3
  thermal states; the other runs are the controls C and D): the universe of mass
  $-m$ with the same coupling $+\lambda$ and the transformed tip angle $\pi$ (B) has
  the same Kohn-Sham levels, level by level with the block type and the brane
  parity exchanged, the same occupations, chemical potential, entropy, energy and
  free energy, and the same particle density, potential and energy-momentum
  profiles $\rho$, $p_3$, $p_t$, $p_0$ as the universe of mass $+m$ (A), while its
  scalar density, density $Q$ and effective mass are exactly opposite. The largest
  deviations (section 17) are about $10^{-13}$ for the ground states and the
  history and below $10^{-12}$ for the thermal states: the rounding of the
  computer. This holds for 8, 136 and 688 particles, at every slice of the
  deflating history, for every coupling and at every temperature computed.
- What this agreement tests: the solver's shooting is covariant under the map (the
  angle equation of B is that of A with $\phi \to \pi/2 - \phi$), so the agreement
  to rounding is guaranteed by construction; it tests the solver's handling of the
  transformed boundary conditions, the labels, the filling, the self-consistency
  and the Mermin root. The test that does not depend on the discretisation is the
  record's reference demonstration (`t3-reference-demo.json`).
- COMPUTED: the runs equal the record's own demonstration (`t3-rust-demo.json`,
  table `t3-rust-states.csv`) in the 19 states that both solve: A its plus
  member, B its image member, C its control, D its image at $-\lambda$.
- COMPUTED: the solver's own T3 self-test of the record
  (`ks-rust-solver.json`, check `t3_block_map_solver_selftest`) is reproduced, and
  every A run reproduces the committed canonical state.
- COMPUTED (negative controls): with the untransformed tip (C) the zero modes move
  to the tip, a level appears inside the gap at $\varepsilon_b = m/\cosh(qL)$ with
  $\tanh(qL) = q/m$ (the closed form derived here), and every energy differs; with
  the reversed coupling (D) the energy is that of A at $-\lambda$, not at $\lambda$.
- PROVED elsewhere (records `wolfram-t3.json`, `python-t3.json`, and the
  completion `t3-completion.json`): theorem T3 itself. The runs here demonstrate it
  numerically on the states solved; they are not its proof.
- ASSUMED: the $Z_2$ brane; the tip is a chosen cutoff and T3 needs the transformed
  tip angle; the history is a PRESCRIBED BACKGROUND; mean field without correlation.
- NOT shown: that a universe is created, in pairs or otherwise. T3 maps solutions
  onto solutions; it gives no creation process, rate or amplitude, and it does not
  force the partner to exist.
```

19.21 Line-by-line walk-through of Notebook 19a

The notebook has 28 code cells, In [1] to In [28]; the numbers they print are in Section 19.20 under the labels Out [k].

In [1], the set-up cell. Its first 298 lines are the complete run instructions of Section 19.19 as comment lines, followed by a line of dashes. The code after the title THE SET-UP is the set-up code of Notebook 19b, explained line by line in Section 19.16, with three differences: the name is `NOTEBOOK_ID = "19a"`, and, because this notebook runs a Rust program, the imports contain two more lines and the cell defines one more function.

```
import shutil  # finds the program cargo
import subprocess  # runs cargo and the Rust programs
```

`shutil` can find a program on the computer, here cargo, the build tool of Rust; `subprocess` can run a program and collect what it prints.

```
def rust_program(manifest, binary):
    """Build the Rust program binary of the crate whose Cargo.toml is manifest (a
    repository path) with "cargo build --release" (about a second when it is up to date;
    minutes the first time) and return the path of the program."""
    if shutil.which("cargo") is None:
        raise FileNotFoundError(
            "cargo was not found: install Rust from https://rustup.rs, open a new "
            "terminal, activate the environment and start JupyterLab again")
    crate = (REPO / manifest).parent  # the folder that holds Cargo.toml
    completed = subprocess.run(
        ["cargo", "build", "--release", "--manifest-path", str(REPO / manifest),
         "--target-dir", str(crate / "target")],
        capture_output=True, text=True, encoding="utf-8", errors="replace")
    if completed.returncode != 0:  # show the end of cargo's error message
        print(completed.stderr[-3000:])
        raise RuntimeError(f"cargo build failed for {manifest}")
    for file_name in (binary, binary + ".exe"):  # Linux and macOS; Windows
        path = crate / "target" / "release" / file_name
        if path.is_file():
            say(f"Rust program {binary} is built and ready.")
            return path
    raise FileNotFoundError(f"cargo built {manifest} but {binary} is missing")
```

`rust_program` builds a Rust program and returns where it is. `shutil.which("cargo")` looks for cargo; if it is not found (`is None`), the function stops with a message that says how to install Rust. A **crate** is a Rust package; `crate` is the folder that holds its file `Cargo.toml` (`.parent` removes the last part of a path). `subprocess.run([...])` runs cargo with the arguments in the list, exactly as if the release build command for this manifest, with the build folder `target` next to `Cargo.toml`, were typed into a terminal; `capture_output=True` keeps cargo's messages instead of printing them, and `text=True` with `encoding="utf-8"` reads them as text (`errors="replace"` replaces a character that cannot be read instead of stopping). The **return code** of a program is 0 when it succeeded; otherwise the function prints the last 3000 characters of cargo's error messages (`[-3000:]` takes the end of a string) and stops. The `for` loop tries the program's name without and with the

ending `.exe` (Linux and macOS have no ending, Windows has `.exe`) and returns the first one that exists, after printing that the program is ready.

In [2], the eight gammas and Γ.

```
import csv  # reads the tables (CSV files) of the record
import math  # pi, exp, tanh and cosh of single numbers
import re  # regular expressions: reads numbers out of the record's text

import numpy as np  # arrays of numbers
```

`csv`, `math` and `numpy` as in Notebook 19b; `re` finds patterns in text (**regular expressions**), used in In [6] to read numbers out of a sentence of the record.

```
GAMMAS = "Revision/algebra/gammas.json"  # the record of the gamma matrices
ALGEBRA = "Revision/algebra/reports/wolfram-algebra.json"  # its check report
fixture = json.loads(repository_file(GAMMAS).read_text(encoding="utf-8"))
stored_real = all(isinstance(g, list) for g in fixture["gamma"])  # no complex part
gamma = [np.array(g, dtype=float) for g in fixture["gamma"]]  # gamma[k] is xk
eta = np.array(fixture["eta"], dtype=float)  # +1 +1 +1 +1 -1 -1 -1 -1 (x0, ..., x7)
entries = sorted({float(x) for g in gamma for x in g.flat})  # all values used
say(f"{len(gamma)} matrices of size {gamma[0].shape}; their entries: {entries}")
```

The same reading as In [2] of Notebook 19b, but with the matrices as arrays of decimal numbers (`dtype=float`); whole numbers up to 2^{53} are stored exactly in this format, so the products below are still exact. `entries` lists the values that occur; Out [2] prints −1.0, 0.0, 1.0.

```
worst = 0.0  # largest violation of the anticommutation rule
for a in range(8):
    for b in range(8):
        anti = gamma[a] @ gamma[b] + gamma[b] @ gamma[a]
        rule = 2.0 * eta[a] * (a == b) * np.eye(16)  # 2 eta^ab times the unit
        worst = max(worst, float(np.max(np.abs(anti - rule))))
Gamma = gamma[0]  # gamma^(x0) first ...
for a in range(1, 8):
    Gamma = Gamma @ gamma[a]  # ... times gamma^(x1), gamma^(x2), ..., gamma^(x7)
diagonal = np.diag([-1.0] * 8 + [1.0] * 8)
anticommutes = all(np.array_equal(Gamma @ g, -(g @ Gamma)) for g in gamma)
```

The anticommutation rule for all 64 pairs and the chirality Γ in the author's order, exactly as In [4] and In [5] of Notebook 19b (Section 19.16).

```
check(stored_real and entries == [-1.0, 0.0, 1.0] and worst == 0.0,
      "the eight gamma matrices are real and obey g^a g^b + g^b g^a = 2 eta^ab",
      record=f"{ALGEBRA}, checks reality and Clifford_relation")
check(np.array_equal(Gamma, diagonal) and anticommutes
      and np.array_equal(Gamma, np.array(fixture["Gamma"], dtype=float)),
      "Gamma = g^(x0) g^(x1) ... g^(x7) = diag(-1 (8 times), +1 (8 times))",
      record=f"{ALGEBRA}, check Gamma_diag")
```

Two checks (Out [2]), reproducing the checks reality, Clifford_relation and Gamma_diag of `wolfram-algebra.json`.

In [3], Γ is the block map of T3.

```
KS_THEORY = "Revision/kohn_sham/ks-theory.json"
ks = json.loads(repository_file(KS_THEORY).read_text(encoding="utf-8"))
ENTRY = {"0": 0.0, "1": 1.0, "-1": -1.0, "I": 1j, "-I": -1j}  # the record's text
V = np.array([[ENTRY[x] for x in row]
              for row in ks["blockBasis"]["unnormalisedColumns2Sqrt2V"]])
V = V / (2.0 * math.sqrt(2.0))  # the record stores 2 sqrt(2) V
labels = [tuple(int(x) for x in label) for label in ks["blockBasis"]["labels"]]
sig1 = np.array([[0, 1], [1, 0]], dtype=complex)  # Pauli matrix sigma1
sig2 = np.array([[0, -1j], [1j, 0]])  # Pauli matrix sigma2
sig3 = np.array([[1, 0], [0, -1]], dtype=complex)  # Pauli matrix sigma3
unitary = float(np.max(np.abs(V.conj().T @ V - np.eye(16))))
worst_map, worst_form = 0.0, 0.0
for b, (j, s2, s3) in enumerate(labels):
    p = labels.index((-j, s2, s3))  # the partner block
    Vb, Vp = V[:, 2 * b:2 * b + 2], V[:, 2 * p:2 * p + 2]  # their two columns
    worst_map = max(worst_map, float(np.max(np.abs(Gamma @ Vb - Vp @ (s2 * sig2)))))
    g0 = Vb.conj().T @ gamma[0] @ Vb  # gamma^(x0) inside block b
    g04 = Vb.conj().T @ gamma[0] @ gamma[4] @ Vb  # gamma^(x0) gamma^(x4) there
    worst_form = max(worst_form, float(np.max(np.abs(g0 - sig3))),
                     float(np.max(np.abs(g04 - j * sig1))))
```

These lines are In [5] of Notebook 19b (the second half), with the Pauli matrices called `sig1`, `sig2`, `sig3`: the block basis V read from the record, its unitarity, and for every block the deviation of ΓV_b from $V_p\, s_2\sigma_2$ and of the block forms of $\gamma^{(x_0)}$ and $\gamma^{(x_0)}\gamma^{(x_4)}$ from σ_3 and $j\sigma_1$.

```
    if b < 4:
        say(f"block {b} {labels[b]} <-> block {p} {labels[p]}: matrix "
            f"{s2:+d} sigma2")
say(f"largest deviations: unitarity {unitary:.1e}, block map {worst_map:.1e}, "
    f"block forms {worst_form:.1e}")
check(unitary < 1e-12 and worst_map < 1e-12 and worst_form < 1e-12,
      "Gamma maps block (j, s2, s3) onto block (-j, s2, s3) as s2 sigma2",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.Gamma_is_the_block_map")
```

For the four blocks of type $j = +1$ (`b < 4`) the loop also prints which block is the partner and the matrix $s_2\sigma_2$ between them. Out [3] shows block 0 $(1,1,1)$ with block 4 $(-1,1,1)$ and block 1 $(1,1,-1)$ with block 5, both with $+\sigma_2$; block 2 $(1,-1,1)$ with block 6 and block 3 $(1,-1,-1)$ with block 7, both with $-\sigma_2$; then the deviations (1.1×10^{-16}, exactly 0, 1.1×10^{-16}) and the PASS line.

In [4], the solver is built.

```
SOLVER_MANIFEST = "Revision/kohn_sham/solver/Cargo.toml"  # the crate of the solver
program = rust_program(SOLVER_MANIFEST, "revision_ks_solver")  # build it, get path
RUN_FOLDER = REPO / "Revision/kohn_sham/solver/target/textbook_19a"  # git ignores it
RUN_FOLDER.mkdir(parents=True, exist_ok=True)
```

`rust_program` (In [1]) builds the solver, which takes a second when it is up to date, and returns the path of the program, `program`. `RUN_FOLDER` is a folder inside the solver's build folder `target`, which git ignores, so the raw outputs of the 62 runs never enter the record; `mkdir` creates it.

```
COLOUR = {"A": "#2a78d6", "B": "#eb6834", "C": "#1baf7a", "D": "#eda100"}
NAME = {"A": "A: $+m$, $+\\lambda$, $\\theta = 0$",
        "B": "B: $-m$, $+\\lambda$, $\\theta = \\pi$ (T3 partner)",
        "C": "C: $-m$, $+\\lambda$, $\\theta = 0$ (control)",
        "D": "D: $-m$, $-\\lambda$, $\\theta = \\pi$ (wrong partner)"}
say("Solver ready, colours defined.")
```

Every universe keeps one colour in all ten figures, blue A, orange B, aqua C, yellow D, and one legend text, `NAME`. Out [4] shows the two printed lines.

In [5], the helpers `solve` and `universe`.

```
TIP = {"A": 0.0, "B": math.pi, "C": 0.0, "D": math.pi}  # tip angle of each kind
MASS = {"A": 1.0, "B": -1.0, "C": -1.0, "D": -1.0}  # bare mass of each kind
SIGN = {"A": 1.0, "B": 1.0, "C": 1.0, "D": -1.0}  # D reverses the coupling

def read_profile(path):
    """A profile table as a dictionary: column name -> numpy array (151 values)."""
    data = np.genfromtxt(path, delimiter=",", names=True)
    return {name: data[name] for name in data.dtype.names}
```

The three dictionaries are the table of Section 19.17: the tip angle, the bare mass and the sign of the coupling of each universe. `read_profile` reads a profile table: `np.genfromtxt` reads a CSV file of numbers whose first line holds the column names (`names=True`), and the dictionary comprehension makes one numpy array of 151 values per column (`data.dtype.names` is the list of the column names).

```
def solve(label, m, lam, a4, N, theta, margin, T=None):
    """Run "revision_ks_solver single" for one state and return its results."""
    out = RUN_FOLDER / f"{label}.json"  # the solver's record of this state
    table = RUN_FOLDER / f"{label}.csv"  # its profiles
    command = [str(program), "single", "--root", str(REPO), "--m", repr(m),
               "--lambda", repr(lam), "--a4", repr(a4), "--N", repr(float(N)),
               "--tip-theta", repr(theta), "--margin", repr(margin),
               "--out", str(out), "--profiles", str(table)]
    if T is not None:
        command += ["--T", repr(T)]  # a thermal (Mermin) state
```

`solve` runs the solver once. The two output files are named after the `label`. `command` is the command line as a list: the program, its subcommand `single` (solve one state), and pairs of an option and its value: the options named root (where the repository is: the solver reads `ks-theory.json` and the gammas from there), m, lambda, a4 (the slice), N, tip-theta, margin, out (the JSON record of the state) and profiles (the CSV table), each written with two hyphens in front, as the code shows. `repr(x)` writes a number with all its digits, so the solver receives exactly the value of the notebook. For a thermal state the option T with the temperature is appended (`+=` appends a list).

```
    done = subprocess.run(command, capture_output=True, text=True,
                          encoding="utf-8", errors="replace")
    last = (done.stdout.strip().split("\n") or [""])[-1]  # SUCCESS or FAILURE
    if done.returncode != 0 or last != "SUCCESS":
        raise RuntimeError(f"the solver failed for {label}: {done.stderr[-400:]}")
    state = json.loads(out.read_text(encoding="utf-8"))
    state["levels"] = [tuple(level) for level in
                       state["levels_n2_j_parity_label_eps_deg_f"]]
    state["profile"] = read_profile(table)
    return state
```

`subprocess.run` runs the solver and keeps its printed text. The solver's last printed line is SUCCESS or FAILURE; `last` takes it (`.strip()` removes blank space at the ends, `.split("\n")` cuts the text into lines, `[-1]` takes the last one). If the return code is not 0 or the last line is not SUCCESS, the notebook stops with the end of the solver's error text. Otherwise the solver's JSON record is read into the dictionary `state`; its list of levels, each a list $(n_2, j, \text{parity}, \text{label}, \varepsilon, g, f)$, is stored again as tuples under the shorter key `levels`, and the profile table under `profile`.

```
def universe(kind, lam, a4, N, margin, T=None):
    """Solve universe A, B, C or D with the coupling lam (D uses -lam)."""
    label = f"{kind}_N{N}_lam{lam:+.4g}_a{a4:g}" + ("" if T is None else f"_T{T:g}")
    return solve(label, MASS[kind], SIGN[kind] * lam, a4, N, TIP[kind], margin, T)

say("solve and universe defined; outputs go to the folder "
    "Revision/kohn_sham/solver/target/textbook_19a")
```

`universe` solves one of the four universes: it makes a label such as `A_N136_lam+0.0009298_a1` (`:+.4g` writes the coupling with its sign and four significant digits, `:g` a short number) and calls `solve` with the bare mass, the signed coupling and the tip angle of that kind. Out [5] prints the line about the output folder.

In [6], what the record says.

```
T3_WOLFRAM = "Revision/pairing/kohn_sham/reports/wolfram-t3.json"
T3_SYMPY = "Revision/pairing/kohn_sham/reports/python-t3.json"
wolfram_t3 = json.loads(repository_file(T3_WOLFRAM).read_text(encoding="utf-8"))
sympy_t3 = json.loads(repository_file(T3_SYMPY).read_text(encoding="utf-8"))
passed_w = sum(c["verdict"] == "PASS" for c in wolfram_t3["checks"])
passed_s = sum(c["verdict"] == "PASS" for c in sympy_t3["checks"])
total_w, total_s = len(wolfram_t3["checks"]), len(sympy_t3["checks"])
say(f"proof of T3: Wolfram {passed_w} of {total_w} checks pass, "
    f"sympy {passed_s} of {total_s}")
check(passed_w == total_w == 10 and passed_s == total_s == 13,
      "the proof records of T3 pass completely (10 and 13 checks)",
      record=f"{T3_WOLFRAM} and {T3_SYMPY}")
```

The two proof reports of T3 are read; `sum(c["verdict"] == "PASS" for c in ...)` counts the checks with the verdict PASS (each `True` counts as 1). The check requires 10 of 10 and 13 of 13 (Out [6]); `a == b == c` in Python means $a = b$ and $b = c$.

```
SOLVER_REPORT = "Revision/kohn_sham/reports/ks-rust-solver.json"
PARAMETERS = "Revision/kohn_sham/results/parameters.json"
SELFTEST = "t3_block_map_solver_selftest"
solver_report = json.loads(repository_file(SOLVER_REPORT).read_text(encoding="utf-8"))
parameters = json.loads(repository_file(PARAMETERS).read_text(encoding="utf-8"))
LAMBDA = {int(entry["N"]): (entry["lambda1"], entry["lambda2"])
          for entry in parameters["couplingCalibration"]["values"]}
for N, (l1, l2) in LAMBDA.items():
    say(f"N = {N:3d}: lambda_1 = {l1}, lambda_2 = {l2}")
selftest = next(c for c in solver_report["checks"] if c["name"] == SELFTEST)
```

The solver's report and the parameter record are read. `LAMBDA` maps each particle number to its pair of couplings (λ_1, λ_2); Out [6] prints the table of Section 19.1 (`:3d` writes a whole number three places wide). `next(c for c in ... if ...)` takes the first check whose name is t3_block_map_solver_selftest.

```
PATTERN = re.compile(r"N = (\d+), lambda = (\S+), a4,0 = 1: E_KS (\S+) vs (\S+); "
                     r"(\d+) levels; .*?untransformed tip b\(-L\) = 0\): "
                     r"E_KS = (\S+) vs")
RECORD = {}  # N -> the recorded numbers of the self-test
for part in selftest["detail"].split(" | "):
    found = PATTERN.search(part)
    RECORD[int(found.group(1))] = {
        "lambda": float(found.group(2)), "E_A": float(found.group(3)),
        "E_B": float(found.group(4)), "levels": int(found.group(5)),
        "E_C": float(found.group(6))}
```

The self-test stores its numbers inside a sentence, one part per particle number, separated by a vertical bar. `PATTERN` is a regular expression that matches such a part: `\d+` matches one or more digits, `\S+` one or more characters that are not blank, `.*?` as few arbitrary characters as possible, `\(` a literal bracket; every pattern in round brackets is a **group** whose matched text `found.group(k)` can be read out. A string written `r"..."` keeps its backslashes. For each part the notebook reads the particle number, the coupling, the energies of A and B, the number of levels and the energy of the control C, and stores them in `RECORD`.

```
for N, entry in RECORD.items():
    E_A, E_B, E_C, count = (entry[key] for key in ("E_A", "E_B", "E_C", "levels"))
    say(f"record, N = {N}: E_KS(A) = {E_A:.12e}, E_KS(B) = {E_B:.12e}, "
        f"{count} levels, control E_KS(C) = {E_C:.10e}")
check(selftest["verdict"] == "PASS" and sorted(RECORD) == [8, 136]
      and all(RECORD[N]["lambda"] == LAMBDA[N][0] for N in RECORD),
      "the record holds the passing self-test for N = 8 and 136 at lambda_1",
      record=f"{SOLVER_REPORT}, check {SELFTEST}")
```

The loop prints the recorded numbers (Out [6]: the numbers of Section 19.10). The check requires the self-test to have passed, to hold exactly the particle numbers 8 and 136, and to have used the coupling λ_1 of each.

In [7], the self-test repeated: six runs.

```
SELF = {}  # (N, kind) -> state
for N in (8, 136):
    for kind in "ABC":
        SELF[(N, kind)] = universe(kind, LAMBDA[N][0], 1.0, N, 0.45)
```

Six runs of the solver: A, B and C (`for kind in "ABC"` takes the three letters one after the other) for $N = 8$ and 136, at the slice $a_{4,0} = 1$, with λ_1 and the margin 0.45. `SELF` stores the six states under the key (N, kind).

```
def sorted_levels(state):
    """The levels as a sorted list of (eps, g, f), as the self-test compares them."""
    return sorted((level[4], level[5], level[6]) for level in state["levels"])

def level_difference(first, second):
    """Largest difference of the sorted (eps, g, f) lists of two states."""
    pairs = zip(sorted_levels(first), sorted_levels(second))
    return max(max(abs(x - y) for x, y in zip(p, q)) for p, q in pairs)
```

`sorted_levels` keeps of each level the triple (ε, g, f) (positions 4, 5, 6 of the tuple) and sorts the triples. `level_difference` pairs the sorted lists of two states entry by entry and returns the largest difference of any ε, g or f.

```
def integral_difference(first, second):
    """Largest relative difference of the four integrated EMT components."""
    a, b = first["emtIntegrals_2Vol7_int_e6Hy"], second["emtIntegrals_2Vol7_int_e6Hy"]
    return max(abs(a[c] - b[c]) / max(abs(a[c]), 1.0) for c in ("rho", "p3", "p_t",
                                                                "p0"))

def scalar_sum(first, second):
    """max|S_A + S_B| / max|S_A| on the 151 profile points."""
    sa, sb = first["profile"]["S"], second["profile"]["S"]
    return float(np.max(np.abs(sa + sb)) / max(np.max(np.abs(sa)), 1e-300))
```

`integral_difference` compares the four integrals $2\,\mathrm{Vol}_7 \int e^{6Hy} X\, dy$ of $X = \rho, p_3, p_t, p_0$, each relative to $\max(|a|, 1)$. `scalar_sum` measures how well $S_B = -S_A$ holds: the largest $|S_A + S_B|$ over the 151 points, divided by the largest $|S_A|$ (the `1e-300` avoids a division by zero).

```
for N in (8, 136):
    A, B, C = SELF[(N, "A")], SELF[(N, "B")], SELF[(N, "C")]
    E_A, E_B, E_C = A["E_KS"], B["E_KS"], C["E_KS"]
    count_A, count_B = len(A["levels"]), len(B["levels"])
    say(f"N = {N}: E_KS(A) = {E_A:.12e}, E_KS(B) = {E_B:.12e}, "
        f"{count_A} and {count_B} levels")
    say(f"    levels (eps, g, f): {level_difference(A, B):.2e}; EMT integrals: "
        f"{integral_difference(A, B):.2e}; |S_A + S_B|/max|S|: "
        f"{scalar_sum(A, B):.2e}; control E_KS(C) = {E_C:.10e}")
```

For each N the energies, the numbers of levels and the three differences are printed (Out [7]). For $N = 8$: $E_{KS}(A) = -9.868426190876 \times 10^{-4}$ and $E_{KS}(B) = -9.868426190868 \times 10^{-4}$, the record's numbers digit for digit; 80 levels each; level difference 6.88×10^{-14}, integrals 8.96×10^{-16}, $|S_A + S_B| / \max|S|$ 1.84×10^{-15}; the control -2.0145243719. For $N = 136$: 32.39294915318 for both, 160 levels, differences 9.86×10^{-14}, 2.19×10^{-16}, 8.38×10^{-16}; the control 29.283751318. The record's self-test reports 6.91×10^{-14} and 9.95×10^{-14} for the level differences of its own runs; differences of this size are rounding, and all of them are ten thousand times below the tolerance.

In [8], the self-test as checks.

```
TOL = 1e-9  # the tolerance of the self-test, fixed in the record
REC = f"{SOLVER_REPORT}, check {SELFTEST}"

def close(a, b, tol=TOL):
    """True when a and b agree within tol relative to max(|a|, 1)."""
    return abs(a - b) <= tol * max(abs(a), 1.0)
```

`TOL` is the record's tolerance 10^{-9}, and `close` compares two numbers relative to $\max(|a|, 1)$: relative for large numbers, absolute for numbers below 1.

```
for N in (8, 136):
    A, B, C = SELF[(N, "A")], SELF[(N, "B")], SELF[(N, "C")]
    rec = RECORD[N]
    check(len(A["levels"]) == len(B["levels"]) == rec["levels"]
          and level_difference(A, B) < TOL and integral_difference(A, B) < TOL
          and scalar_sum(A, B) < TOL and close(A["E_KS"], B["E_KS"]),
          f"N = {N}: A and B have equal levels, energies, EMT integrals, S_B = -S_A",
          record=REC)
    check(close(A["E_KS"], rec["E_A"]) and close(B["E_KS"], rec["E_B"])
          and close(C["E_KS"], rec["E_C"]) and abs(C["E_KS"] - A["E_KS"]) > 1.0,
          f"N = {N}: the energies of A, B and the control C are those of the record",
          record=REC)
```

Two checks per particle number (Out [8]): A and B have the recorded number of levels and agree within the tolerance in levels, integrals, scalar density and energy; and the three energies are the recorded ones, with the control more than 1 away from A.

In [9], A is the canonical state of the record.

```
GROUND = "Revision/kohn_sham/results/ground"

def read_rows(relative):
    """A CSV file of the record as {id: row}."""
    with repository_file(relative).open(encoding="utf-8", newline="") as handle:
        return {row["id"]: row for row in csv.DictReader(handle)}

def homo_lumo(state):
    """The highest occupied (f = 1) and the lowest empty (f = 0) level."""
```

```
    occupied = [lv[4] for lv in state["levels"] if lv[6] > 0.5]
    empty = [lv[4] for lv in state["levels"] if lv[6] < 0.5]
    return max(occupied), min(empty)
```

`read_rows` reads a CSV table of the record into a dictionary from the state name in the column `id` to its row. `homo_lumo` returns the highest occupied level (**HOMO**: occupation above one half) and the lowest empty one (**LUMO**).

```
summary = read_rows(f"{GROUND}/summary.csv")
integrals = read_rows(f"{GROUND}/emt-integrals.csv")
A = SELF[(136, "A")]
homo, lumo = homo_lumo(A)
new = {"E_KS": A["E_KS"], "HOMO": homo, "LUMO": lumo, "KS_gap": lumo - homo}
row = summary["N136_lamp1_a10"]
worst_scalar = max(abs(new[key] - float(row[key])) for key in new)
emt_row = integrals["N136_lamp1_a10"]
new_int = A["emtIntegrals_2Vol7_int_e6Hy"]  # the new integrals
worst_integral = max(abs(new_int[c] - float(emt_row[f"int_{c}"]))
                     / max(abs(float(emt_row[f"int_{c}"])), 1.0)
                     for c in ("rho", "p3", "p_t", "p0", "n"))
```

The record's summary table and integral table are read. For the run A at $N = 136$, λ_1, $a_{4,0} = 1$, the four numbers energy, HOMO, LUMO and the Kohn-Sham gap (LUMO minus HOMO) are compared with the row N136_lamp1_a10 of the summary, and the five integrals (ρ, p_3, p_t, p_0 and n) with the same row of the integral table (columns `int_rho` and so on).

```
committed = read_profile(repository_file(f"{GROUND}/profiles/N136_lamp1_a10.csv"))
worst_profile = max(float(np.max(np.abs(A["profile"][c] - committed[c]))
                          / max(np.max(np.abs(committed[c])), 1e-300))
                    for c in committed)
for key in new:
    say(f"{key:7}: new {new[key]: .15e}   record {float(row[key]): .15e}")
say(f"largest differences: scalars {worst_scalar:.1e}, integrals "
    f"{worst_integral:.1e}, profile columns {worst_profile:.1e}")
```

The committed profile file of the state is read, and every column of the new profile is compared with it at all 151 points, relative to the column's largest value. Out [9] prints the four numbers side by side (`{key:7}` pads the name to seven places, `:  .15e` writes sixteen digits with a blank for the sign): $E_{KS} = 32.39294915318298$, HOMO 0.3258848143646794, LUMO 0.3608587569459729, gap 0.03497394258129349, identical to the record; all three largest differences are exactly 0.

```
same_bytes = ((RUN_FOLDER / "A_N136_lam+0.0009298_a1.csv").read_bytes()
              == repository_file(f"{GROUND}/profiles/N136_lamp1_a10.csv").read_bytes())
report("new profile file byte-identical to the record", same_bytes)
check(worst_scalar < TOL and worst_integral < TOL and worst_profile < TOL,
      "A reproduces the canonical state N136_lamp1_a10 of the record",
      record=f"{GROUND}/summary.csv, emt-integrals.csv and profiles, N136_lamp1_a10")
```

`read_bytes` reads a file as raw bytes; `same_bytes` is true when the new profile file is identical byte for byte to the committed one. On the computer that built this book it is (`True` in Out [9]); on

another computer the last digit of a few numbers may differ, which is why the check itself uses the tolerance.

In [10], the pairing level by level (statement S1).

```
OTHER = {"even": "odd", "odd": "even"}  # the brane parity is exchanged

def level_map(first, second, tol=TOL):
    """Pair every level (n2, j, p, l, eps, g, f) of first with a level of second in
    (n2, -j, other p) at the same eps; return the pairs (None if one is missing)."""
    unused = list(second["levels"])
    pairs = []
    for lv in sorted(first["levels"]):
        match = [w for w in unused if w[0] == lv[0] and w[1] == -lv[1]
                 and w[2] == OTHER[lv[2]] and abs(w[4] - lv[4]) <= tol]
        if not match:
            return None
        best = min(match, key=lambda w: abs(w[4] - lv[4]))
        unused.remove(best)
        pairs.append((lv, best))
    return pairs
```

`level_map` tests statement S1 of T3: for every level of the first state it searches, among the levels of the second state not yet used, one in the same momentum shell (`w[0] == lv[0]`), with the opposite block type, the other brane parity and the same level within the tolerance. If there is none, the pairing fails and the function returns `None`; otherwise it takes the closest one (`min` with `key=` compares by the distance; `lambda w: ...` is a short unnamed function), removes it from the unused list, so that each level of the second state is used once, and records the pair.

```
pairs136 = level_map(SELF[(136, "A")], SELF[(136, "B")])
shifts = {}
for lv, w in pairs136:
    key = f"j = {lv[1]:+d}, {lv[2]:4}"
    shifts.setdefault(key, set()).add(w[3] - lv[3])  # label of B minus label of A
for key in sorted(shifts):
    say(f"A levels with {key}: partner in j = opposite, other parity; label shift "
        f"{sorted(shifts[key])}")
worst = max(abs(lv[4] - w[4]) for lv, w in pairs136)
report("largest |eps_A - eps_B| of the paired levels, N = 136", f"{worst:.2e}")
```

For $N = 136$ every level of A is paired with its level of B. For each sector of A (type and parity) the set of label differences, label of B minus label of A, is collected (`setdefault` starts an empty set for a new key). The **label** is the solver's count of a level inside its sector, counted from the boundary conditions; A and B have different boundary conditions, so the count of a partner can be shifted by one. Out [10] shows: the type $+1$ even levels of A are partnered by type -1 odd levels of B with labels one lower, the type -1 odd levels by labels one higher, the other two sectors with the same labels. The map of T3 is fixed by the sector and the energy, not by the label. The largest level difference of the pairs is 9.86×10^{-14}.

```
check(pairs136 is not None and len(pairs136) == len(SELF[(136, "B")]["levels"])
      and all(lv[5] == w[5] and lv[6] == w[6] for lv, w in pairs136),
      "every level of A has its partner in B with -j and the other brane parity",
      record="Revision/pairing/kohn_sham/t3-theory.json, statement S1")
check(level_map(SELF[(136, "A")], SELF[(136, "C")]) is None,
      "the control C has no such partner levels (the pairing fails)")
```

The first check requires the pairing to exist, to use every level of B, and to pair equal degeneracies and occupations; the second requires the same pairing to FAIL for the control.

In [11], the level ladders (Figure 19a.1).

```
fig, ax = plt.subplots(figsize=(7.0, 4.6))
for x, kind in enumerate("ABC"):
    state = SELF[(136, kind)]
    for lv in state["levels"]:
        if lv[4] > 1.3:
            continue  # only the lower part of the spectrum
        full = lv[6] > 0.5  # occupied?
        ax.plot([x - 0.32, x + 0.32], [lv[4], lv[4]],
                color=COLOUR[kind] if full else "0.7", lw=2.0 if full else 1.0)
    ax.plot([x - 0.42, x + 0.42], [state["mu_or_fermi_level"]] * 2, color="0.2",
            ls="--", lw=1.0)
```

At the horizontal positions 0, 1, 2 the levels of A, B and C below 1.3 are drawn as short horizontal lines (`continue` skips a level above 1.3), in the universe's colour and thicker when occupied, light grey and thinner when empty (`a if condition else b` chooses between two values). A dashed dark line marks the Fermi level that the solver reports (`[value] * 2` is a list holding the value twice, the heights of the two ends of the line).

```
ax.set_xticks([0, 1, 2])
ax.set_xticklabels(["A: $+m$, $\\theta = 0$", "B: $-m$, $\\theta = \\pi$",
                    "C: $-m$, $\\theta = 0$ (control)"])
ax.set_xlim(-0.6, 2.6)
ax.set_ylabel("Kohn-Sham level $\\varepsilon$ (units of $|m|$)")
ax.set_title("$N = 136$, $\\lambda = \\lambda_1$, slice $a_{4,0} = 1$")
ax.grid(axis="x", visible=False)
save_figure(fig, "level_ladder",
            "Level ladders of the three universes A (bare mass $+m$, tip angle 0), B "
            "(bare mass $-m$, the same coupling, tip angle $\\pi$: the T3 partner) "
            "and C (bare mass $-m$, tip angle 0: the control) for $N = 136$ "
            "particles, $\\lambda = \\lambda_1$, slice $a_{4,0} = 1$, all solved "
            "independently by the Rust solver. Each short line is one Kohn-Sham "
            "level (vertical axis, units of $|m|$), coloured when occupied and grey "
            "when empty; the dashed line is the Fermi level. A and B are the same "
            "ladder; C, with the untransformed tip, is a different one.")
```

Labels, limits and title; `save_figure` saves Figure 19a.1. What the student should see: two identical ladders for A and B, occupied up to the dashed Fermi level, which the solver reports at the highest occupied level 0.3259 (the HOMO of In [9]), with the first empty level at 0.3609; a different ladder for the control C, with its levels at other heights.

In [12], the level-by-level differences (Figure 19a.2).

```
FLOOR = 1e-17  # where exact zeros are drawn on the logarithmic axis
eps = {kind: np.array([e for e, g, f in sorted_levels(SELF[(136, kind)])])
       for kind in "ABC"}
index = np.arange(1, len(eps["A"]) + 1)
fig, ax = plt.subplots()
ax.semilogy(index, np.maximum(np.abs(eps["A"] - eps["B"]), FLOOR), "o",
            color=COLOUR["B"], ms=4, label="A against B (T3 partner)")
ax.semilogy(index, np.maximum(np.abs(eps["A"] - eps["C"]), FLOOR), "^",
            color=COLOUR["C"], ms=4, label="A against C (control)")
ax.axhline(TOL, color="0.3", ls="--", lw=1.0, label="tolerance $10^{-9}$")
```

`eps` holds the sorted levels of A, B and C (the tuple `(e, g, f)` is unpacked and only `e` kept); `index` numbers them $1, 2, \ldots, 160$. `semilogy` draws with a **logarithmic** vertical axis (equal steps for each factor of ten). A logarithm of zero does not exist, so `np.maximum(..., FLOOR)` raises every exact zero to 10^{-17}. A dashed horizontal line marks the tolerance.

```
ax.set_xlabel("level number $i$ (levels sorted by energy)")
ax.set_ylabel("$|\\varepsilon_{A,i} - \\varepsilon_{X,i}|$ (units of $|m|$)")
ax.set_title("$N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$: 160 levels")
ax.legend(fontsize=8, loc="center right")
save_figure(fig, "level_differences",
            "Level-by-level differences between universe A and its T3 partner B "
            "(orange circles) and between A and the control C (aqua triangles), "
            "for $N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$; horizontal axis "
            "the number of the level in the sorted list, vertical axis the absolute "
            "difference in units of $|m|$ (logarithmic; exact zeros drawn at "
            "$10^{-17}$). The partner agrees to $10^{-13}$ or better, the rounding "
            "of the computer, far below the tolerance $10^{-9}$ (dashed); the "
            "control differs by $10^{-4}$ to $1$.")
```

Axis labels, title and legend; `save_figure` saves Figure 19a.2.

```
max_partner = float(np.max(np.abs(eps["A"] - eps["B"])))
gaps_control = np.abs(eps["A"] - eps["C"])
report("largest level difference A - B", f"{max_partner:.2e}")
report("smallest and largest level difference A - C",
       f"{gaps_control.min():.2e} and {gaps_control.max():.3g}")
check(max_partner < 1e-12 and 1e-4 < gaps_control.min() and gaps_control.max() < 1,
      "levels: A - B below 1e-12, A - C between 1e-4 and 1 (the caption's ranges)")
```

The numbers behind the picture (Out [12]): A and B differ by at most 9.86×10^{-14}; A and C by between 1.88×10^{-4} and 0.456. The check guards the ranges that the caption states. What the student should see: a band of orange circles between the floor 10^{-17} and about 10^{-13}, far below the dashed tolerance line, and the aqua triangles eight to sixteen powers of ten higher.

In [13], the densities point by point (statements S3 and S4).

```
EVEN = ("n", "v_v", "e_int", "rho", "p3", "p_t", "p0")  # unchanged by the map
ODD = ("S", "Q", "M_eff")  # change sign under the map
```

```
def profile_mismatch(first, second):
    """Largest relative mismatch of the T3 rule (even columns equal, odd opposite)."""
    worst = 0.0
    for column in EVEN + ODD:
        sign = -1.0 if column in ODD else 1.0
        a, b = first["profile"][column], second["profile"][column]
        scale = max(float(np.max(np.abs(a))), 1e-300)
        worst = max(worst, float(np.max(np.abs(b - sign * a))) / scale)
    return worst
```

`EVEN` and `ODD` list the profile columns that T3 keeps and those it reverses (Section 19.9). `profile_mismatch` measures, for every column, the largest deviation of the second state's column from the first state's column times the expected sign, relative to the column's largest value, and returns the worst one.

```
for N in (8, 136):
    mismatch = profile_mismatch(SELF[(N, "A")], SELF[(N, "B")])
    control = profile_mismatch(SELF[(N, "A")], SELF[(N, "C")])
    say(f"N = {N}: T3 rule for B: {mismatch:.2e}; the same rule for C: {control:.3g}")
    check(mismatch < TOL and control > 0.1,
          f"N = {N}: n, v_v, e_int, rho, p3, p_t, p0 equal; S, Q, M_eff opposite",
          record="Revision/pairing/kohn_sham/t3-theory.json, statements S3 and S4")
```

Out [13]: the partner B obeys the rule to 2.78×10^{-15} ($N = 8$) and 5.80×10^{-15} ($N = 136$); the control C violates it by factors of 298 and 4650 (its profiles are many times larger than those of A in some columns). Both checks pass.

In [14], the densities (Figure 19a.3).

```
y = SELF[(136, "A")]["profile"]["y"]  # the 151 points from the tip to the brane
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
STYLE = {"A": dict(lw=2.6), "B": dict(lw=1.6, ls="--"), "C": dict(lw=1.4, ls=":")}
for kind in "ABC":
    prof = SELF[(136, kind)]["profile"]
    left.semilogy(y, prof["n"], color=COLOUR[kind], label=NAME[kind], **STYLE[kind])
    if kind != "C":
        right.plot(y, prof["S"], color=COLOUR[kind], label=NAME[kind],
                   **STYLE[kind])
```

`y` holds the 151 points. `STYLE` gives each universe a line width and style: A thick and solid, B thinner and dashed (so that A shows around it), C dotted; `dict(lw=2.6)` makes a dictionary, and `**STYLE[kind]` passes its entries as named arguments to `plot`. The left axes show the particle density $n(y)$ of the three universes on a logarithmic axis, the right axes the scalar density $S(y)$ of A and B only.

```
left.set_xlabel("hidden coordinate $y$ (tip $-3$, brane $0$)")
left.set_ylabel("proper particle density $n(y)$")
left.legend(fontsize=7, loc="upper right")
```

```
right.set_xlabel("hidden coordinate $y$")
right.set_ylabel("proper scalar density $S(y)$")
right.axhline(0.0, color="0.3", lw=0.8)
right.legend(fontsize=7, loc="lower right")
fig.suptitle("$N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$", fontsize=10)
fig.tight_layout()
save_figure(fig, "density_profiles",
            "Left: the proper particle density $n(y)$ of the universes A (blue), B "
            "(orange, dashed) and C (aqua, dotted) for $N = 136$, "
            "$\\lambda = \\lambda_1$, $a_{4,0} = 1$, against the hidden coordinate $y$ "
            "from the tip $y = -3$ to the brane $y = 0$ (logarithmic vertical axis, "
            "units $|m|^7$). Right: the proper scalar density $S(y)$ of A and B. "
            "The density of B is that of A, and its scalar density is the mirror "
            "image $S_B = -S_A$, as T3 states. The control C has its own densities; "
            "its scalar density, more than ten times larger, is not drawn.")
```

Labels, a zero line on the right, legends and a common title (`suptitle`); `save_figure` saves Figure 19a.3. What the student should see: on the left the density of A falls from about 300 at the tip to about 0.009 at the brane (the record's profile file of N136_lamp1_a10: 298.7 and 0.008849), large at the tip because a proper density is a number per unit proper volume, and the proper volume factor e^{6Hy} is tiny there; the dashed orange line of B lies exactly on the blue line of A; the dotted line of C is different. On the right S_A is negative between the ends and zero at both ends (the tip condition $b(-L) = 0$ and either brane condition make $2ab$ vanish there), and S_B is its mirror image, positive.

```
size = {kind: float(np.max(np.abs(SELF[(136, kind)]["profile"]["S"])))
        for kind in "AC"}
factor = size["C"] / size["A"]  # how much larger the control's scalar density is
report("largest |S| of C divided by largest |S| of A", f"{factor:.1f}")
check(factor > 10.0,
      "the scalar density of the control is more than ten times that of A")
```

The caption says the control's scalar density is more than ten times larger; the cell measures the factor (24.1, Out [14]) and checks it.

In [15], the mass and the potential (Figure 19a.4).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
for kind in "ABC":
    prof = SELF[(136, kind)]["profile"]
    left.plot(y, prof["M_eff"], color=COLOUR[kind], label=NAME[kind], **STYLE[kind])
    right.plot(y, prof["v_v"], color=COLOUR[kind], label=NAME[kind], **STYLE[kind])
left.set_xlabel("hidden coordinate $y$")
left.set_ylabel("effective mass $M_{eff}(y)$ (units of $|m|$)")
left.legend(fontsize=7, loc="center right")
right.set_xlabel("hidden coordinate $y$")
right.set_ylabel("potential $v_v(y)$ (units of $|m|$)")
fig.suptitle("$N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$", fontsize=10)
fig.tight_layout()
```

The self-consistent effective mass $M_{\text{eff}}(y)$ (left) and potential $v_v(y)$ (right) of the three universes, in the same styles.

```
save_figure(fig, "mass_and_potential",
            "Left: the self-consistent effective mass $M_{eff}(y)$ of A (blue), B "
            "(orange, dashed) and C (aqua, dotted) for $N = 136$, "
            "$\\lambda = \\lambda_1$, $a_{4,0} = 1$ (units of $|m|$). Right: the "
            "self-consistent potential $v_v(y)$ (units of $|m|$). B has exactly the "
            "opposite mass of A at every point and the same potential: this is why "
            "the bare mass must change sign while the coupling keeps its sign. The "
            "control C has the mass $-m$ but its own, different mean field.")
```

`save_figure` saves Figure 19a.4. What the student should see: on the left the mass of A near $+1$, with a dip to about 0.97 near $y = -2.4$ where S is most negative ($1 + \frac{15}{16}\lambda_1 S$ with $S \approx -37$ in the record's profile), and the mass of B its exact negative near -1; the control near -1 with its own shape. On the right the potentials of A and B on top of each other, small and negative (about -0.017 at the tip), and the control's different curve.

In [16], the energy-momentum profiles (Figure 19a.5).

```
weight = np.exp(6.0 * y)  # the proper-volume factor e^{6 H y}, H = 1
fig, axes = plt.subplots(2, 2, figsize=(9.0, 6.0), sharex=True)
for ax, column, title in zip(axes.flat, ("rho", "p3", "p_t", "p0"),
                             ("energy density $\\rho$", "pressure $p_3$ (3-space)",
                              "pressure $p_t$ (extra times)",
                              "pressure $p_0$ (hidden direction)")):
    for kind in "ABC":
        prof = SELF[(136, kind)]["profile"]
        ax.plot(y, weight * prof[column], color=COLOUR[kind], label=NAME[kind],
                **STYLE[kind])
    ax.set_title(title, fontsize=9)
    ax.set_ylabel("$e^{6Hy}$ times the component")
for ax in axes[1]:
    ax.set_xlabel("hidden coordinate $y$")
axes[0, 0].legend(fontsize=7, loc="upper left")
fig.tight_layout()
```

`weight` is the volume factor e^{6Hy} at the 151 points; multiplying a proper density by it gives a density per unit of y, so the area under each curve is proportional to the integral over the hidden direction. A grid of 2×2 axes with a common horizontal axis (`sharex=True`) shows ρ, p_3, p_t, p_0 times the weight, one per axes, for the three universes; `zip` runs through the axes, the column names and the titles together. Only the lower row gets the horizontal label (`axes[1]` is the second row), and only the first axes the legend.

```
save_figure(fig, "emt_profiles",
            "The energy-momentum profiles of A (blue), B (orange, dashed) and C "
            "(aqua, dotted) for $N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$: "
            "energy density $\\rho$, pressures $p_3$ (3-space), $p_t$ (the "
            "deflating extra times) and $p_0$ (hidden direction), each times the "
            "volume factor $e^{6Hy}$, against the hidden coordinate $y$ (units "
            "$|m|^8$ with $H = 1$). The four profiles of the partner B coincide "
            "with those of A at every point (T3, statement S4); the control C "
            "differs.")
```

`save_figure` saves Figure 19a.5. What the student should see: in all four panels the dashed orange curve of B exactly on the blue curve of A, and the dotted aqua curve of the control elsewhere; $p_t = e_{\text{int}}$ is much smaller than the other three, because the good sector has no kinetic pressure along the extra times.

```
for N in (8, 136):
    B = SELF[(N, "B")]
    integrated, pointwise = (B["yConservationIntegratedRel"],
                             B["yConservationPointwiseRel"])
    say(f"N = {N}, B: y-conservation, integrated {integrated:.1e}, pointwise "
        f"{pointwise:.1e} (relative)")
    check(integrated < 1e-8 and pointwise < 1e-6,
          f"N = {N}: the partner B obeys p0' + 6H p0 = 3H (p3 + p_t)",
          record=f"{SOLVER_REPORT}, checks emt_y_conservation_integrated, pointwise")
```

The solver measures for every state how well the conservation law $p_0' + 6Hp_0 = 3H(p_3 + p_t)$ of Section 19.4 holds, after integration over y and point by point. For the partner B the residuals are 3.9×10^{-13} and 2.2×10^{-9} ($N = 8$) and 1.7×10^{-12} and 8.4×10^{-11} ($N = 136$) (Out [16]), below the tolerances 10^{-8} and 10^{-6} used here; B is a genuine self-consistent state of its own problem.

In [17], where the zero modes live: three free runs.

```
FREE8 = {kind: universe(kind, 0.0, 1.0, 8, 0.25) for kind in "ABC"}  # lambda = 0
L_TIP, M_BARE = 3.0, 1.0  # the tip distance L and the bare mass |m| of the record

def brane_over_tip(state):
    """Coordinate density e^{6Hy} n(y) at the brane divided by its value at the tip."""
    n = state["profile"]["n"]
    return float(n[-1] * weight[-1] / (n[0] * weight[0]))
```

Three runs without interaction for $N = 8$ at $a_{4,0} = 1$ (margin 0.25): the eight quanta fill the eight zero modes. `brane_over_tip` divides the coordinate density $e^{6Hy}n$ at the last point (the brane, index -1) by its value at the first point (the tip, index 0).

```
expected = {"A": math.exp(2 * M_BARE * L_TIP), "B": math.exp(2 * M_BARE * L_TIP),
            "C": math.exp(-2 * M_BARE * L_TIP)}  # e^{+6}, e^{+6}, e^{-6}
ratio_error = 0.0
for kind in "ABC":
    ratio = brane_over_tip(FREE8[kind])
    ratio_error = max(ratio_error, abs(ratio / expected[kind] - 1.0))
    say(f"{kind}: brane / tip = {ratio:.6e}, closed form {expected[kind]:.6e}")
check(ratio_error < 1e-8,
      "free N = 8: the zero modes of A and B live at the brane, those of C at the tip")
```

The closed forms of Section 19.12: the ratio is $e^{2mL} = e^6$ for A and B and e^{-6} for C. Out [17] prints 403.4288 for A and B and 0.002478752 for C, equal to the closed forms; the check requires a relative agreement better than 10^{-8}.

In [18], the control's level in the gap, by hand.

```
def bound_state_q(m, L):
    """The root q in (0, m) of tanh(q L) - q / m, by bisection."""
    low, high = 0.5 * m, m  # the function is positive at m/2 and negative at m
    for _ in range(200):
        middle = 0.5 * (low + high)
        if math.tanh(middle * L) - middle / m > 0.0:
            low = middle  # the root lies above the middle
        else:
            high = middle  # the root lies below the middle
    return 0.5 * (low + high)
```

`bound_state_q` finds the root of $\tanh(qL) = q/m$ of Section 19.12 by bisection, starting from the interval $(m/2, m)$, where the function changes sign (at $m/2$: $\tanh(1.5) - 0.5 = 0.405 > 0$; at m: $\tanh(3) - 1 < 0$). Each of the 200 steps keeps the half that contains the root.

```
q_root = bound_state_q(M_BARE, L_TIP)
eps_b = M_BARE / math.cosh(q_root * L_TIP)  # the level inside the gap
report("q of the control's sub-gap level", f"{q_root:.12f}")
report("sub-gap level eps_b = m / cosh(q L)", f"{eps_b:.12f}", "|m|")
gap = {}
for kind in "ABC":
    homo, lumo = homo_lumo(FREE8[kind])
    gap[kind] = lumo - homo
    say(f"{kind}: HOMO {homo:.3e}, LUMO {lumo:.12f}, Kohn-Sham gap {gap[kind]:.12f}")
```

The root $q = 0.994901528453$ and the level $\varepsilon_b = m/\cosh(qL) = 0.100851121375$ (Out [18]). Then the Kohn-Sham gaps of the three free runs: in all three the HOMO is the zero modes at 0. For A and B the lowest empty level is 0.170349251323, a level of the brane band at the smallest nonzero momentum shell; for the control it is 0.100851121375: its level inside the gap, lower than its brane band.

```
recorded = float(summary["N8_lam0_a10"]["KS_gap"])
same_level = abs(math.sqrt(M_BARE ** 2 - q_root ** 2) - eps_b) < 1e-12  # two forms
check(abs(gap["C"] - eps_b) < 1e-9 and same_level,
      "the free control has the Kohn-Sham gap m/cosh(qL) of the sub-gap level")
check(close(gap["A"], recorded) and close(gap["B"], gap["A"]),
      "the free A and B have the gap of the committed state N8_lam0_a10",
      record=f"{GROUND}/summary.csv, N8_lam0_a10, column KS_gap")
```

The first check: the control's gap equals ε_b, a number derived by hand, to 10^{-9} (in fact to twelve digits), and the two forms $\sqrt{m^2 - q^2}$ and $m/\cosh(qL)$ agree. The second: A has the gap of the committed state N8_lam0_a10, and B the gap of A.

In [19], the zero modes (Figure 19a.6).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8), sharey=True)
for kind in "ABC":
    left.semilogy(y, weight * FREE8[kind]["profile"]["n"], color=COLOUR[kind],
                  label=NAME[kind], **STYLE[kind])
    right.semilogy(y, weight * SELF[(8, kind)]["profile"]["n"], color=COLOUR[kind],
```

```
                    label=NAME[kind], **STYLE[kind])
top = {kind: float(weight[-1] * FREE8[kind]["profile"]["n"][-1]) for kind in "AC"}
left.semilogy(y, top["A"] * np.exp(2 * M_BARE * y), "k:", lw=0.8)  # e^{2 m y}
left.semilogy(y, top["C"] * np.exp(-2 * M_BARE * y), "k:", lw=0.8)  # e^{-2 m y}
```

Two axes with a common vertical scale (`sharey=True`): on the left the coordinate densities $e^{6Hy}n$ of the free runs, on the right those of the interacting runs of In [7]. `top` holds the brane values of the free A and C, and the two thin black dotted lines are the closed forms e^{2my} and e^{-2my} scaled to these values.

```
left.set_title("$N = 8$, $\\lambda = 0$, $a_{4,0} = 1$", fontsize=10)
right.set_title("$N = 8$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$", fontsize=10)
left.set_ylabel("coordinate density $e^{6Hy}\\,n(y)$")
for ax in (left, right):
    ax.set_xlabel("hidden coordinate $y$ (tip $-3$, brane $0$)")
right.legend(fontsize=7, loc="lower right")
fig.tight_layout()
save_figure(fig, "zero_modes_n8",
            "The coordinate particle density $e^{6Hy}n(y)$ (particles per unit of "
            "$y$; logarithmic vertical axis) of the $N = 8$ universes A (blue), B "
            "(orange, dashed) and C (aqua, dotted) at $a_{4,0} = 1$, against the "
            "hidden coordinate $y$ from the tip $-3$ to the brane $0$. Left: without "
            "interaction; the thin black dotted lines are the closed forms "
            "$e^{2my}$ and $e^{-2my}$. A and B hold their particles in zero modes "
            "at the brane; with the untransformed tip (C) the zero modes sit at the "
            "tip. Right: with the coupling $\\lambda_1$; A and B are unchanged in "
            "shape, the control is reshaped by its strong mean field near the tip.")
```

Titles, labels, legend; `save_figure` saves Figure 19a.6. What the student should see: on the left two straight lines on the logarithmic scale, the rising one of A and B (B dashed on top of A) along e^{2my}, and the falling one of C along e^{-2my}, each covering a factor $e^6 \approx 403$ between tip and brane; on the right A and B unchanged in shape, and the control's line bent near the tip, where its quanta, at a huge proper density, feel a strong mean field.

In [20], T3 along the deflating history: 27 runs.

```
SLICES = [0.0, 0.5, 1.0, 1.5, 2.0]
HIST = {}  # (N, kind, a4) -> state
for N in (136, 688):
    for a4 in SLICES:
        for kind in "ABC":
            if N == 136 and a4 == 1.0:
                HIST[(N, kind, a4)] = SELF[(N, kind)]  # already solved
            else:
                HIST[(N, kind, a4)] = universe(kind, LAMBDA[N][0], a4, N, 0.45)
```

A, B and C at the five slices of the history for $N = 136$ and 688, each with its coupling λ_1: 30 states, of which the three of $N = 136$ at $a_{4,0} = 1$ were solved in In [7] and are reused, so 27 new runs.

```
ok_record, ok_partner, ok_control = True, True, True
partner_rel, control_pct = [], []  # relative differences A - B, percents A - C
```

```
for N in (136, 688):
    for a4 in SLICES:
        A, B, C = (HIST[(N, kind, a4)] for kind in "ABC")
        record_energy = float(summary[f"N{N}_lamp1_a{round(10 * a4):02d}"]["E_KS"])
        ok_record &= close(A["E_KS"], record_energy)
        partner_rel.append(abs(A["E_KS"] - B["E_KS"]) / abs(A["E_KS"]))
        control_pct.append(100.0 * abs(A["E_KS"] - C["E_KS"]) / abs(A["E_KS"]))
        ok_partner &= level_difference(A, B) < TOL and profile_mismatch(A, B) < TOL
        E_A, E_B, E_C = A["E_KS"], B["E_KS"], C["E_KS"]
        say(f"N = {N:3d}, a4,0 = {a4:3.1f}: E_KS A {E_A:.10f}, "
            f"B {E_B:.10f}, C {E_C:.6f}")
```

For each of the ten pairs (particle number, slice): the state name of the record is made from the particle number and ten times the slice written with two digits (`:02d`, so 0.5 gives `a05`), and A must reproduce the recorded energy (`&=` keeps a truth value true only while every test is true); the relative energy difference A minus B and the percentage A minus C are collected; and B must agree with A in levels and in every profile column. The loop prints the three energies (Out [20]):

N	$a_{4,0}$	E_{KS} **of A and B**	E_{KS} **of C**
136	0.0	80.2837009244	73.179866
136	0.5	51.2491613321	46.475561
136	1.0	32.3929491532	29.283751
136	1.5	20.2130306754	18.533932
136	2.0	12.4470595905	12.175574
688	0.0	680.4447575708	670.715818
688	0.5	437.5215029073	431.359438
688	1.0	279.4468465636	275.745397
688	1.5	176.7808903556	175.297541
688	2.0	110.4456550192	112.097612

```
report("largest relative E_KS difference A - B", f"{max(partner_rel):.1e}")
report("relative E_KS difference A - C", f"{min(control_pct):.1f} to "
       f"{max(control_pct):.1f}", "percent")
check(ok_record, "A reproduces the recorded E_KS at all 10 states of the history",
      record=f"{GROUND}/summary.csv, N136_lamp1_a00 to a20, N688_lamp1_a00 to a20")
check(ok_partner and max(partner_rel) < 1e-13,
      "B has the levels, energy and profiles of A at every slice")
check(0.5 < min(control_pct) and max(control_pct) < 10.0,
      "the control C differs from A by 0.5 to 10 percent at every slice")
```

The largest relative difference between A and B along the whole history is 4.0×10^{-14}; the control differs by 0.8 to 9.6 percent. Three checks: A is the record at all ten states; B is A at every slice; C differs at every slice. This is T3 slice by slice, as Section 19.6 predicted.

In [21], the energy along the history (Figure 19a.7).

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 3.8))
MARK = {"A": dict(marker="o", ms=7, lw=2.2), "B": dict(marker="s", ms=4, lw=1.4,
                                                       ls="--"),
        "C": dict(marker="^", ms=6, lw=1.2, ls=":"),
```

```
        "D": dict(marker="D", ms=5, lw=1.4)}
for ax, N in zip(axes, (136, 688)):
    for kind in "ABC":
        ax.plot(SLICES, [HIST[(N, kind, a4)]["E_KS"] for a4 in SLICES],
                color=COLOUR[kind], label=NAME[kind], **MARK[kind])
    ax.set_xlabel("slice $a_{4,0}$ of the history $a_4 = Hx_4$")
    ax.set_ylabel("Kohn-Sham energy $E_{KS}$ (units of $|m|$)")
    ax.set_title(f"$N = {N}$, $\\lambda = \\lambda_1$", fontsize=10)
axes[0].legend(fontsize=7, loc="upper right")
fig.tight_layout()
```

`MARK` gives each universe a marker (circle, square, triangle, diamond), a marker size and a line style, used in this figure and in Figures 19a.9 and 19a.10. The two axes show E_{KS} against the slice for $N = 136$ and $N = 688$.

```
save_figure(fig, "history_energy",
            "The Kohn-Sham energy $E_{KS}$ (units of $|m|$) of A (blue circles), B "
            "(orange squares, dashed) and C (aqua triangles, dotted) at the five "
            "slices $a_{4,0} = 0$ to $2$ of the deflating history, for $N = 136$ "
            "(left) and $N = 688$ (right) at the coupling $\\lambda_1$ of each $N$. "
            "The energy falls because the 3-momenta are redshifted as 3-space "
            "inflates and the extra times deflate; the T3 partner B follows A at "
            "every slice, the control C does not.")
```

`save_figure` saves Figure 19a.7. What the student should see: falling curves, from 80.3 to 12.4 ($N = 136$) and from 680 to 110 ($N = 688$), with B's small squares inside A's circles at every slice and the control's triangles below them (above at the last slice of $N = 688$). The fall is the redshift of Chapter 14: a later slice is the first slice with every 3-momentum multiplied by $e^{-a_{4,0}}$.

In [22], the agreement along the history (Figure 19a.8).

```
fig, ax = plt.subplots()
for N, marker in ((136, "o"), (688, "s")):
    for kind in "BC":
        values = [max(abs(HIST[(N, "A", a4)]["E_KS"] - HIST[(N, kind, a4)]["E_KS"])
                      / abs(HIST[(N, "A", a4)]["E_KS"]), FLOOR) for a4 in SLICES]
        ax.semilogy(SLICES, values, marker=marker, color=COLOUR[kind],
                    ls="--" if kind == "B" else ":",
                    label=f"$N = {N}$, A against {kind}")
ax.axhline(TOL, color="0.3", lw=1.0, label="tolerance $10^{-9}$")
ax.set_xlabel("slice $a_{4,0}$ of the history")
ax.set_ylabel("relative difference of $E_{KS}$")
ax.legend(fontsize=7, loc="center right")
```

For both particle numbers and for B and C, the relative energy difference from A at the five slices, raised to the floor 10^{-17} where it is exactly zero, on a logarithmic axis, with the tolerance line.

```
save_figure(fig, "history_agreement",
            "Relative differences of the Kohn-Sham energy between A and its T3 "
            "partner B (orange) and between A and the control C (aqua) at the five "
```

```
            "slices of the history, for $N = 136$ (circles) and $N = 688$ (squares); "
            "logarithmic vertical axis, exact zeros drawn at $10^{-17}$. The "
            "partner agrees to better than $10^{-13}$ at every slice: T3 holds slice "
            "by slice along the deflating history. The control is off by $0.5$ to "
            "$10$ percent.")
```

`save_figure` saves Figure 19a.8. What the student should see: the orange curves between 10^{-17} and a few times 10^{-14}, far below the tolerance line; the aqua curves between about 8×10^{-3} and 0.1.

In [23], the coupling must keep its sign: 17 runs.

```
l1, l2 = LAMBDA[136]
COUPLINGS = [("lamm2", -l2, 0.85), ("lamm1", -l1, 0.45), ("lam0", 0.0, 0.25),
             ("lamp1", l1, 0.45), ("lamp2", l2, 0.85)]  # tag, lambda, margin
SCAN = {}  # (tag, kind) -> state
for tag, lam, margin in COUPLINGS:
    for kind in "ABCD":
        if tag == "lamp1" and kind in "ABC":
            SCAN[(tag, kind)] = SELF[(136, kind)]  # already solved
        else:
            SCAN[(tag, kind)] = universe(kind, lam, 1.0, 136, margin)
MIRROR = {"lamm2": "lamp2", "lamm1": "lamp1", "lam0": "lam0", "lamp1": "lamm1",
          "lamp2": "lamm2"}  # the tag of -lambda
```

The five couplings $-\lambda_2, -\lambda_1, 0, +\lambda_1, +\lambda_2$ of $N = 136$, each with the record's tag and margin, for all four universes at $a_{4,0} = 1$: 20 states, three reused from In [7], so 17 new runs (D at $+\lambda_1$ is new). `MIRROR` gives for each tag the tag of the opposite coupling.

```
ok_record, ok_partner, ok_mirror, ok_wrong = True, True, True, True
control_gap = []  # |E_C - E_A| at each coupling
for tag, lam, margin in COUPLINGS:
    E = {kind: SCAN[(tag, kind)]["E_KS"] for kind in "ABCD"}
    ok_record &= close(E["A"], float(summary[f"N136_{tag}_a10"]["E_KS"]))
    ok_partner &= close(E["A"], E["B"]) and level_difference(
        SCAN[(tag, "A")], SCAN[(tag, "B")]) < TOL
    ok_mirror &= close(E["D"], SCAN[(MIRROR[tag], "A")]["E_KS"])
    ok_wrong &= (lam == 0.0) or abs(E["D"] - E["A"]) > 1e-4
    control_gap.append(abs(E["C"] - E["A"]))
    E_A, E_B, E_C, E_D = (E[kind] for kind in "ABCD")
    say(f"lambda = {lam:+.4e}: A {E_A:.10f}  B {E_B:.10f}  "
        f"C {E_C:.6f}  D {E_D:.10f}")
```

For every coupling, four things are tested. The truth value `ok_record`: A is the record's state of that tag, one of N136_lamm2_a10 to N136_lamp2_a10. The truth value `ok_partner`: B equals A in energy and levels. The truth value `ok_mirror`: D at λ equals A at $-\lambda$, because D $= (-m, -\lambda, \pi)$ is the T3 partner of $(m, -\lambda, 0)$. The truth value `ok_wrong`: D differs from A by more than 10^{-4} unless $\lambda = 0$ (at $\lambda = 0$, D and B are the same problem). The loop prints the four energies (Out [23]):

λ	**A and B**	**C**	**D**
-0.002789	32.3593734113	34.540794	32.4116192324
-0.0009298	32.3755880337	33.529490	32.3929491532
0	32.3841156874	30.731389	32.3841156874
$+0.0009298$	32.3929491532	29.283751	32.3755880337
$+0.002789$	32.4116192324	28.980584	32.3593734113

Read the D column from the bottom up: it is the A column. The control differs even at $\lambda = 0$, because its tip is wrong.

```
check(ok_record, "A reproduces the recorded E_KS for all five couplings",
      record=f"{GROUND}/summary.csv, N136_lamm2_a10 to N136_lamp2_a10")
check(ok_partner, "B = A for every coupling: the partner keeps +lambda")
check(ok_mirror and ok_wrong,
      "D(lambda) = A(-lambda), so (-m, -lambda) is not the partner for lambda != 0",
      record="Revision/pairing/kohn_sham/reports/python-t3.json, check "
             "T3.mean_field_map (control)")
check(1.0 < min(control_gap) and max(control_gap) < 3.5,
      "the control C differs from A by 1 to 3.5 at every coupling")
```

Four checks (Out [23]); the third is the numerical face of the control of Step 3 (Section 19.8), and the fourth guards the range 1.15 to 3.43 that the caption of Figure 19a.9 states as "1 to 3.5".

In [24], the coupling scan (Figure 19a.9).

```
x = [lam / l1 for tag, lam, margin in COUPLINGS]
E0 = SCAN[("lam0", "A")]["E_KS"]
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
for kind in "ABD":
    left.plot(x, [SCAN[(tag, kind)]["E_KS"] - E0 for tag, lam, margin in COUPLINGS],
              color=COLOUR[kind], label=NAME[kind], **MARK[kind])
left.set_xlabel("coupling $\\lambda/\\lambda_1$")
left.set_ylabel("$E_{KS} - E_{KS}(\\lambda = 0)$ (units of $|m|$)")
left.axhline(0.0, color="0.3", lw=0.8)
low, high = left.get_ylim()
left.set_ylim(low, high + 0.6 * (high - low))  # room for the legend at the top
left.legend(fontsize=7, loc="upper center")
```

The horizontal axis is the coupling in units of λ_1: $-3, -1, 0, 1, 3$ (the tuples of `COUPLINGS` are unpacked into three names, of which only `lam` is used). On the left, the interaction part of the energy, E_{KS} minus the value of A at $\lambda = 0$, for A, B and D. `get_ylim` reads the vertical range that matplotlib chose, and `set_ylim` enlarges it upward by 60 percent so that the legend does not cover the curves.

```
for kind in "AC":
    right.plot(x, [SCAN[(tag, kind)]["E_KS"] for tag, lam, margin in COUPLINGS],
               color=COLOUR[kind], label=NAME[kind], **MARK[kind])
right.set_xlabel("coupling $\\lambda/\\lambda_1$")
right.set_ylabel("$E_{KS}$ (units of $|m|$)")
```

```
right.legend(fontsize=7, loc="upper right")
fig.suptitle("$N = 136$, slice $a_{4,0} = 1$", fontsize=10)
fig.tight_layout()
save_figure(fig, "coupling_scan",
            "Left: the interaction part of the Kohn-Sham energy, $E_{KS}$ minus its "
            "value at $\\lambda = 0$ (units of $|m|$), against the coupling "
            "$\\lambda/\\lambda_1$ for $N = 136$, $a_{4,0} = 1$: universe A (blue), "
            "its T3 partner B with the same coupling (orange, dashed, on top of A) "
            "and D with the reversed coupling (yellow diamonds), which is the "
            "mirror image of A. Right: $E_{KS}$ of A and of the control C (aqua), "
            "which lies $1$ to $3.5$ away from A, above it for negative and below "
            "it for positive couplings. Only $(-m, +\\lambda)$ with the transformed "
            "tip is the partner of $(m, \\lambda)$.")
```

On the right, the energies of A and C. `save_figure` saves Figure 19a.9. What the student should see: on the left A's curve rising from -0.025 at $-3\lambda_1$ through 0 to $+0.027$ at $+3\lambda_1$, B's squares on it, and D's diamonds on the curve reflected about the vertical axis; on the right A's nearly flat curve near 32.4 and the control's falling curve, above A for the negative couplings and below A from $\lambda = 0$ on.

In [25], thermal states: nine runs.

```
THERMO = read_rows("Revision/kohn_sham/results/thermo/thermodynamics.csv")
TEMPS = [0.01, 0.02, 0.05]
WARM = {}  # (T, kind) -> state
ok_record, ok_partner, ok_control = True, True, True
for T in TEMPS:
    for kind in "ABC":
        WARM[(T, kind)] = universe(kind, l1, 1.0, 136, 0.4, T=T)
    A, B, C = (WARM[(T, kind)] for kind in "ABC")
    F = {kind: WARM[(T, kind)]["E_KS"] - T * WARM[(T, kind)]["entropy"]
         for kind in "ABC"}  # free energy F = E - T S
    row = THERMO[f"N136_lamp1_a10_T{round(1000 * T)}"]
```

The record's table of thermal states is read. For the three temperatures $T = 0.01, 0.02, 0.05$ of the record, A, B and C are solved at $N = 136$, λ_1, $a_{4,0} = 1$, with the margin 0.4 and Mermin occupations: nine runs. For each the free energy $F = E_{KS} - TS_{\text{ent}}$ is formed (Exercise 19.7 shows that this equals $\Omega + \mu N$ of Section 19.4), and the record's row is found by its name, which ends in T10, T20 or T50 (a thousand times the temperature).

```
    ok_record &= (close(A["mu_or_fermi_level"], float(row["mu"]))
                  and close(A["E_KS"], float(row["E"]))
                  and close(A["entropy"], float(row["entropy"]))
                  and close(F["A"], float(row["F"])))
    ok_partner &= (close(A["mu_or_fermi_level"], B["mu_or_fermi_level"])
                   and close(A["entropy"], B["entropy"]) and close(F["A"], F["B"])
                   and level_difference(A, B) < TOL)
    ok_control &= 2.5 < F["A"] - F["C"] < 3.5
    mu_A, mu_B, mu_C = (s["mu_or_fermi_level"] for s in (A, B, C))
    F_A, F_B, F_C = (F[kind] for kind in "ABC")
    say(f"T = {T:.2f}: mu A {mu_A:.12f} B {mu_B:.12f} C {mu_C:.6f}; "
        f"F A {F_A:.9f} B {F_B:.9f} C {F_C:.5f}")
```

A must reproduce the record's chemical potential, energy, entropy and free energy; B must have the chemical potential, entropy, free energy and levels (with their occupations) of A; and the control's free energy must lie between 2.5 and 3.5 below that of A (`2.5 < x < 3.5` tests both bounds). Out [25] shows, for example at $T = 0.05$: $\mu = 0.295073925379$ and $F = 27.091045285$ for both A and B, and $\mu = 0.289068$, $F = 24.21400$ for the control.

```
check(ok_record, "A reproduces mu, E, entropy and F of the three thermal states",
      record="Revision/kohn_sham/results/thermo/thermodynamics.csv, "
             "N136_lamp1_a10_T10, T20, T50")
check(ok_partner, "B has the occupations, mu, entropy and F of A at every T",
      record="Revision/pairing/kohn_sham/t3-theory.json, statement S4")
check(ok_control, "the control C has a free energy 2.5 to 3.5 below A at every T")
```

Three checks (Out [25]).

In [26], the thermal states (Figure 19a.10).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(9.0, 3.8))
T = 0.05
DOTS = {"A": dict(marker="o", ms=7, ls="none", mfc="none", mew=1.6),
        "B": dict(marker="x", ms=5, ls="none", mew=1.4),
        "C": dict(marker="^", ms=4, ls="none")}
for kind in "ABC":
    lv = WARM[(T, kind)]["levels"]
    left.plot([v[4] for v in lv], [v[6] for v in lv], color=COLOUR[kind],
              label=NAME[kind], **DOTS[kind])
mu = WARM[(T, "A")]["mu_or_fermi_level"]
grid = np.linspace(-0.3, 1.0, 400)
left.plot(grid, 1.0 / (1.0 + np.exp((grid - mu) / T)), color="0.4", lw=1.0,
          label="Fermi function of A")
```

On the left, at $T = 0.05$, every level is a marker at the height of its occupation: A as open rings (`mfc="none"`: no fill; `mew`: the width of the marker's edge), B as crosses, C as small triangles, without connecting lines (`ls="none"`). The grey curve is the Fermi function $1/(1 + e^{(\varepsilon-\mu)/T})$ of A on 400 points.

```
left.set_xlim(-0.3, 1.0)
left.set_xlabel("level $\\varepsilon$ (units of $|m|$)")
left.set_ylabel("occupation $f$")
left.set_title(f"$T = {T}$", fontsize=10)
left.legend(fontsize=6, loc="lower left")
for kind in "ABC":
    right.plot(TEMPS, [WARM[(t, kind)]["E_KS"] - t * WARM[(t, kind)]["entropy"]
                       for t in TEMPS], color=COLOUR[kind], label=NAME[kind],
               **MARK[kind])
right.set_xlabel("temperature $T$ (units of $|m|$)")
right.set_ylabel("free energy $F = E - TS_{ent}$ (units of $|m|$)")
fig.suptitle("$N = 136$, $\\lambda = \\lambda_1$, $a_{4,0} = 1$", fontsize=10)
fig.tight_layout()
```

The left axes show the levels between -0.3 and 1.0. On the right, the free energy of the three universes against the temperature.

```
save_figure(fig, "thermal_states",
            "Thermal Kohn-Sham states for $N = 136$, $\\lambda = \\lambda_1$, "
            "$a_{4,0} = 1$. Left: the occupation $f$ of every level against its "
            "energy (units of $|m|$) at $T = 0.05$ for A (blue rings), B (orange "
            "crosses) and C (aqua triangles); the grey curve is the Fermi function "
            "of A. Every cross of B sits in a ring of A. Right: the free energy "
            "$F = E - TS_{ent}$ against the temperature $T$ (units of $|m|$); A and "
            "B coincide, the control C lies $2.5$ to $3.5$ lower.")
```

`save_figure` saves Figure 19a.10. What the student should see: on the left the rings of A on the grey Fermi curve, falling from 1 to 0 around $\mu = 0.295$, each with an orange cross inside it, and the control's triangles on its own, shifted curve; on the right the free energy falling with the temperature, A and B on top of each other (32.24, 31.59, 27.09) and the control about 3 lower.

In [27], the same runs in the record's demonstration of T3. The record's numerical demonstration (Section 19.10) solved the members plus, image and control for all 210 states; this cell checks that the runs of this notebook are the record's runs where the two overlap.

```
DEMO = "Revision/pairing/kohn_sham/reports/t3-rust-demo.json"
DEMO_TABLE = "Revision/pairing/kohn_sham/numerics/results/t3-rust-states.csv"
demo = json.loads(repository_file(DEMO).read_text(encoding="utf-8"))
verdict = {c["name"]: c["verdict"] for c in demo["checks"]}
detail = {c["name"]: c["detail"] for c in demo["checks"]}
passed = sum(v == "PASS" for v in verdict.values())
say(f"record: {demo['states']} states, {passed} of {len(verdict)} checks pass")
```

The two names are the report of the demonstration and its table. `json.loads` reads the report into a dictionary; its list `checks` holds one dictionary per check, with the keys `name`, `verdict` and `detail`. The two dictionary comprehensions make the look-ups "name to verdict" and "name to detail text". `passed` counts the verdicts equal to PASS (a comparison is `True` or `False`, and `sum` counts each `True` as 1). The line prints the number of states of the record (its key `states`) and the count: "record: 210 states, 7 of 7 checks pass" (Out [27]).

```
for name in ("t3_equal_ground_states", "t3_equal_thermal_states"):
    worst = re.search(r"worst deviation (\S+),", detail[name]).group(1)
    say(f"record, {name}: worst deviation {worst}")
DEMO_ROWS = read_rows(DEMO_TABLE)
PAIRS, GROUP = {}, {}  # state id -> [A, B, C]; state id -> group of runs
```

The detail text of each of the two equality checks contains the words "worst deviation" followed by a number and a comma; the regular expression finds them, and `group(1)` is the part matched by `(\S+)`, the number (`\S+` means one or more characters that are not spaces). Out [27] prints the record's own worst deviations, 2.179×10^{-13} for the 75 ground states and 3.877×10^{-12} for the 135 thermal states. `read_rows` (In [9]) reads the table into a dictionary from the state id, such as N136_lamp1_a10, to its row. `PAIRS` will hold, for every state of the record that this notebook solved, the three states A, B and C of this notebook, and `GROUP` the group of runs the state belongs to.

```
def add(state_id, group, states):
    """Store the states A, B, C of one state of the record, once."""
```

```
    if state_id not in PAIRS:
        PAIRS[state_id], GROUP[state_id] = states, group
```

`add` stores a state only the first time its id appears. This matters because some runs were reused: the state N136_lamp1_a10 is in `SELF`, in `HIST` (the slice $a_{4,0} = 1$) and in `SCAN` (the coupling $+\lambda_1$), and must be counted once.

```
for N in (8, 136):
    add(f"N{N}_lamp1_a10", "ground", [SELF[(N, kind)] for kind in "ABC"])
add("N8_lam0_a10", "ground", [FREE8[kind] for kind in "ABC"])
for tag, lam, margin in COUPLINGS:
    add(f"N136_{tag}_a10", "ground", [SCAN[(tag, kind)] for kind in "ABC"])
for N in (136, 688):
    for a4 in SLICES:
        add(f"N{N}_lamp1_a{round(10 * a4):02d}", "history",
            [HIST[(N, kind, a4)] for kind in "ABC"])
for T in TEMPS:
    add(f"N136_lamp1_a10_T{round(1000 * T)}", "thermal",
        [WARM[(T, kind)] for kind in "ABC"])
```

The ids are built in the naming scheme of the record (Section 19.1): `round(10 * a4):02d` writes ten times the slice with two digits (0.5 becomes 05), and `round(1000 * T)` writes the temperature in thousandths (0.05 becomes 50). The group "ground" receives the states at the slice $a_{4,0} = 1$ of In [7] (two), In [17] (one, without interaction) and In [23] (four more couplings; $+\lambda_1$ is already stored): 7 states. The group "history" receives the states of In [20] not yet stored: four slices for $N = 136$ and five for $N = 688$, 9 states. The group "thermal" receives the 3 states of In [25]. Together 19 states.

```
def relative(a, b):
    """|a - b| relative to max(|a|, 1), the measure of close()."""
    return abs(a - b) / max(abs(a), 1.0)
```

`relative` measures a difference in the same way as `close` of In [8]: relative to the size of the first number, but never relative to a number smaller than 1.

```
worst_A, worst_B, worst_C = 0.0, 0.0, 0.0
for state_id, (A, B, C) in PAIRS.items():
    row = DEMO_ROWS[state_id]  # the record's row of this state
    worst_A = max(worst_A, relative(A["E_KS"], float(row["E_KS_plus"])))
    image = [(B["E_KS"], row["E_KS_image"]), (B["mu_or_fermi_level"],
             row["mu_image"]), (B["entropy"], row["entropy_image"])]
    image += [(B["emtIntegrals_2Vol7_int_e6Hy"][c], row[f"int_{c}_image"])
              for c in ("rho", "p3", "p_t", "p0")]
    worst_B = max([worst_B] + [relative(x, float(r)) for x, r in image])
    control = float(row["E_KS_control_untransformed_tip"])
    worst_C = max(worst_C, relative(C["E_KS"], control))
```

For every one of the 19 states the loop takes the record's row and compares: the energy of A with the record's plus member (column `E_KS_plus`); seven numbers of B with the record's image member (the energy, the chemical potential or Fermi level, the entropy, which is 0 in a ground state, and the

four energy-momentum integrals, columns `int_rho_image` and so on); and the energy of C with the record's control (column `E_KS_control_untransformed_tip`). The table stores numbers as text, so `float` converts them. `max([worst_B] + [...])` takes the largest of the old worst value and the seven new differences.

```
worst_D = max(relative(SCAN[(tag, "D")]["E_KS"],
                       float(DEMO_ROWS[f"N136_{MIRROR[tag]}_a10"]["E_KS_image"]))
              for tag, lam, margin in COUPLINGS)
say(f"{len(PAIRS)} states of the record solved here; largest relative differences "
    f"from the record: A {worst_A:.1e}, B {worst_B:.1e}, C {worst_C:.1e}, "
    f"D {worst_D:.1e}")
```

D at the coupling λ is the universe $(-m, -\lambda)$ with the tip angle π, which is the image member of the record's state at the coupling $-\lambda$; `MIRROR` (In [23]) gives the tag of $-\lambda$. Out [27] prints the four largest differences: A 4.0×10^{-14}, B 2.8×10^{-13}, C 7.0×10^{-14}, D 0. The record's runs and these runs were made by the same program on the same computer, so most numbers agree to every digit and the others to the rounding of the last digits.

```
def t3_deviation(A, B):
    """Largest deviation of B from A under T3 (levels, E_KS, mu, entropy, EMT
    integrals, profiles with the odd columns reversed)."""
    return max(level_difference(A, B), relative(A["E_KS"], B["E_KS"]),
               relative(A["mu_or_fermi_level"], B["mu_or_fermi_level"]),
               relative(A["entropy"], B["entropy"]), integral_difference(A, B),
               profile_mismatch(A, B))
```

`t3_deviation` combines every comparison of A and B of this notebook into one number: the sorted levels with degeneracies and occupations (`level_difference`, In [7]), the energy, the chemical potential, the entropy, the four energy-momentum integrals (`integral_difference`, In [7]) and the ten profile columns with S, Q, M_{eff} reversed (`profile_mismatch`, In [13]).

```
largest = {}
for group in ("ground", "history", "thermal"):
    ids = [state_id for state_id in PAIRS if GROUP[state_id] == group]
    largest[group] = max(t3_deviation(*PAIRS[state_id][:2]) for state_id in ids)
    say(f"{group}: {len(ids)} pairs A, B; largest T3 deviation "
        f"{largest[group]:.1e}")
```

For each group, `ids` lists its states; `PAIRS[state_id][:2]` is the list `[A, B]` of a state, and the star `*` hands its two entries to `t3_deviation` as its two arguments. Out [27]: ground 7 pairs, largest deviation 9.9×10^{-14}; history 9 pairs, 1.0×10^{-13}; thermal 3 pairs, 8.1×10^{-13} (the entropy of the state N136_lamp1_a10_T10 at $T = 0.01$, a number near 42 that the solver adds up level by level from the occupations; the record's table `Revision/pairing/kohn_sham/numerics/results/t3-rust-states.csv` shows the same deviation, 8.117×10^{-13}, for this state in its column t3_scalars_dev). These are the rounding of the computer, and, as Section 19.17 showed, at the rounding level by construction, because the shooting is covariant under the map.

```
check(passed == len(verdict) == 7 and demo["states"] == 210,
      "the record's T3 demonstration passes 7 of 7 checks in 210 states",
```

```
      record=DEMO)
check(len(PAIRS) == 19 and worst_A < TOL and worst_B < TOL,
      "A and B equal the record's plus and image members in 19 states",
      record=f"{DEMO}, checks t3_equal_ground_states, t3_equal_thermal_states")
check(worst_C < TOL, "C equals the record's control with the untransformed tip",
      record=f"{DEMO}, check negative_control_untransformed_tip")
check(worst_D < TOL, "D at lambda equals the record's image member at -lambda",
      record=f"{DEMO}, check negative_control_lambda_sign")
check(max(largest.values()) < TOL,
      "B equals A under T3 in all 19 pairs (ground, history, thermal)")
```

Five checks, each with the tolerance 10^{-9} of the record: the record's demonstration passes completely; A and B are the record's plus and image members in all 19 states; C is the record's control; D is the record's image at the opposite coupling; and B equals A under T3 in every pair of this notebook. The PASS lines name the report and the check of the record that each comparison reproduces (Out [27]).

In [28], the last check.

```
runs = len({id(state) for state in [*SELF.values(), *FREE8.values(), *HIST.values(),
                                    *SCAN.values(), *WARM.values()]})
report("runs of the Rust solver in this notebook", runs)
names = ["level_ladder", "level_differences", "density_profiles",
         "mass_and_potential", "emt_profiles", "zero_modes_n8", "history_energy",
         "history_agreement", "coupling_scan", "thermal_states"]
paths = [output_file(f"{FIGURE_FOLDER}/19a_{k}_{name}.png")
         for k, name in enumerate(names, 1)]
check(runs == 62 and all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

`id(state)` is a number that identifies one object in the computer's memory; a state that was reused (stored under two keys) has one `id`, so the set of the ids of all stored states counts every run once: $6 + 3 + 27 + 17 + 9 = 62$. The check requires 62 runs and all ten figure files (`enumerate(names, 1)` counts from 1), and the last line is ALL 37 CHECKS PASSED (notebook 19a) (Out [28]). Of the 62 runs, 19 states compare A with its partner B (In [27]); the other runs are the controls C and D.

19.22 What T3 says about pairs of universes, and what it does not

What is proved. For the fermion field dirac16complex in the author's primordial universe, in the Kohn-Sham model of the Revision record: to every self-consistent instantaneous Kohn-Sham state of the universe of mass $+M$ (bare mass m, coupling λ, tip angle θ) the chirality Γ, acting on the blocks as σ_2, assigns a self-consistent Kohn-Sham state of the universe of mass $-M$ with the same coupling and the tip angle $\pi - \theta$, at the same slice of the deflating history, with the same levels, occupations, chemical potential, entropy, Kohn-Sham energy, grand potential, free energy and energy-momentum profiles, and the opposite scalar density; and conversely. Inside the ASSUMED Z2 orbifold, the mirror copy of every state carries $(-m, +\lambda)$. With the completion of the record (statement S6, Section 19.10), at the level of the 16-component expectation rule, every component of the energy-momentum tensor and of the current J^a is the same in the two members, while S

and Q change sign; and the filling convention of the $+M$ member, carried by the map, is the filling convention of the $-M$ member. Status: PROVED (Sections 19.5 to 19.11; `wolfram-t3.json` 10 of 10, `python-t3.json` 13 of 13; the completion `t3-completion.json` with `wolfram-t3-completion.json` 3 of 3 and `python-t3-completion.json` 7 of 7).

What is demonstrated numerically (COMPUTED; demonstrations, not proofs). The record's Rust demonstration (`t3-rust-demo.json`) finds the $-M$ partner equal to the $+M$ state in all 75 ground and 135 Mermin states of the canonical matrix, to 2.179×10^{-13} (ground) and 3.877×10^{-12} (thermal); this agreement is at the rounding level by construction, because the solver's shooting is covariant under the map (Section 19.17), so it tests the solver's handling of the two members, not the discretisation. The record's reference demonstration (`t3-reference-demo.json`) is the discretisation-independent test: on one grid the two members differ by up to 2.23×10^{-4}, after Richardson extrapolation by 2.043×10^{-14} (ground) and 3.038×10^{-14} (thermal), in 18 states; and the $-M$ universes of the two solvers agree to 1.255×10^{-11}. Notebook 19a compares A and B in 19 states (7 ground states at $a_{4,0} = 1$, 9 more states of the history, 3 thermal states; 62 runs with the controls), with the largest deviations 9.9×10^{-14}, 1.0×10^{-13} and 8.1×10^{-13} (Out [27]), and finds every run equal to the record's demonstration. The controls do differ: the untransformed tip changes the density profile by at least 4.750 times its maximum, and the T1 parameters $(-m, -\lambda)$ differ by at least 1.21×10^{-2}.

What is not established (the list of the theorem record `t3-theory.json`, entry not_established, in words):

- **No creation.** T3 maps self-consistent Kohn-Sham states onto self-consistent Kohn-Sham states of a second parameter set. It contains no process in which a universe, or a pair of universes, comes into being, no rate, no probability and no amplitude, and it does not force the partner to exist: a universe of mass $+M$ alone is an equally valid solution. The statement "the big bang creates universes in pairs" is the author's HYPOTHESIS; T3 is compatible with it, in the sense that a partner state with equal energy is always available, but compatibility is not a proof.

- **Instantaneous states only.** T3 holds slice by slice for the instantaneous (adiabatic) states along the PRESCRIBED BACKGROUND history $a_4 = AHx_4$; the time-dependent Kohn-Sham problem along the deflating history is OPEN.

- **An assumed brane and a chosen tip.** The Z2 mirror at the brane is ASSUMED; the tip condition is a choice of the model, and T3 needs its transformed form $\pi - \theta$ (Section 19.12 shows what fails without it).

- **Mean field only.** Hartree plus the exchange of the uniform gas, no correlation, quasi-free states, and the filling convention whose justification is OPEN.

- **Not two independently quantised universes.** The pairing is between two Kohn-Sham problems, (m, λ) and $(-m, +\lambda)$; it is not the T1 pairing $(m, \lambda) \to (-m, -\lambda)$, and it says nothing about two separately quantised universes (that question is the quantum reading Q of Chapter 18).

- **No back-reaction.** The Kohn-Sham energy-momentum tensor is not an admissible source of the a_4 field equations: it depends on x_0, and $p_3 + p_t \neq 2p_0$ (`Revision/field_equations_a4/reports/ks-source-conditions.json`, checks ks_profiles_depend_on_x0

and ks_profiles_violate_algebraic_condition). So T3 says nothing about how the geometry of either universe would respond.

- **Numbers only where they were computed.** The numerical demonstrations show the equalities only on the states they solved, to their stated tolerances. Control states for which a solver found no self-consistent solution (14 states in the Rust demonstration, 3 in the reference demonstration, all with $\lambda < 0$) are reported as such, not as a proof that no such state exists (the completion record `t3-completion.json`, entry not_established).

Matter and antimatter. T3 does not touch the matter-antimatter question. The partner has the same charge density $n(y)$ and the same particle number N, not the opposite ones, and by S6 every component of its current J^a is the same, not the opposite; it also has the same, not the opposite, energy: a T3 pair has twice the charge and twice the energy of one member; nothing cancels. (The pair-level statement with zero total charge belongs to T1 and the classical bilinears, Chapter 18.) Nothing in the Kohn-Sham model contains baryons, a violation of baryon number, a violation of CP, or a departure from equilibrium, the ingredients that an explanation of the observed excess of matter over antimatter would need. Chapter 21 teaches the observations and these conditions from zero and states what the theory of this book does and does not say about them; Chapter 20 collects what the pairing theorems T1, T2, Q and T3 together prove about pairs of universes and what they do not.

19.23 What we proved, what we computed, what we assumed

- PROVED, line by line in this chapter and in the records `Revision/pairing/kohn_sham/reports/wolfram-t3.json` (10 of 10 checks) and `Revision/pairing/kohn_sham/reports/python-t3.json` (13 of 13), theorem record `Revision/pairing/kohn_sham/t3-theory.json`: the chirality Γ maps every block (j, s_2, s_3) onto $(-j, s_2, s_3)$ and acts there as $s_2\sigma_2$ (Section 19.5; also blocks_relation_to_Gamma of `ks-theory-python.json`); $\sigma_2 h_j(M, v)\sigma_2 = h_{-j}(-M, v)$ and $\sigma_2 N_j(M)\sigma_2 = N_{-j}(-M)$ (Section 19.6); the tip angle goes to $\pi - \theta$, the brane parities are exchanged, norm and current are kept (Section 19.7); n, t are even and S, Q odd, and the mean field closes exactly for $(-m, +\lambda)$, not for $(-m, -\lambda)$ (Section 19.8); every self-consistent state has its partner with equal levels, occupations, energies and energy-momentum profiles (Section 19.9): theorem T3 (Section 19.10). Also PROVED, by the completion `Revision/pairing/kohn_sham/t3-completion.json` (`reports/wolfram-t3-completion.json` 3 of 3, `reports/python-t3-completion.json` 7 of 7): the mean-field coefficients read from `ks-theory.json` in both engines, with $M_{\text{eff}} - m = \partial e_{\text{int}}/\partial S$ and $v_v = \partial e_{\text{int}}/\partial n$ (Section 19.8); the filling convention carried onto the partner (Section 19.9); statement S6, $\rho' = -\Gamma\rho\Gamma$, so that every component of the energy-momentum tensor and of the current is unchanged and S, Q change sign (Section 19.10). Also PROVED: $\Gamma B \Gamma = -B$, the reason why T3 differs from T1 (Sections 19.5 and 19.11; check Q.image_krein_metric of `Revision/pairing/reports/python-pairing.json`); the mirror copy inside the assumed orbifold carries $(-m, +\lambda)$ (Section 19.11); the exact zero-momentum spectra, the zero modes, the control's level in the gap $\varepsilon_b = M/\cosh(qL)$ with $\tanh(qL) = q/M$, and the slopes c and c_{ctrl} (Section 19.12; checks T3_exact_k0_spectra, bc_exact_k0_spectra, brane_band_slope).
- COMPUTED: Notebook 19b (19 checks) reproduces the proof checks with sympy, the analytic levels of `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv` to 8.9×10^{-16}, the same levels by shooting to 5.9×10^{-12}, and the slope $c = 1.9051482536$ of the record;

$c_{\mathrm{ctrl}} = 13.4219751976$. The record's demonstrations (Section 19.10): Rust, `Revision/pairing/kohn_sham/reports/t3-rust-demo.json` (210 states, 7 of 7), image equal to plus to 2.179×10^{-13} (ground) and 3.877×10^{-12} (thermal), at the rounding level by construction (the covariance of the shooting, Section 19.17); reference, `Revision/pairing/kohn_sham/reports/t3-reference-demo.json` (18 states, 7 of 7), equal to 2.043×10^{-14} and 3.038×10^{-14} after Richardson extrapolation against 2.23×10^{-4} on a single grid, the discretisation-independent test; controls off by at least 4.750 (untransformed tip) and 1.21×10^{-2} (T1 parameters). Notebook 19a (37 checks, 62 runs of the Rust solver, 19 states with A and B) reproduces the solver's T3 self-test of `Revision/kohn_sham/reports/ks-rust-solver.json` (check t3_block_map_solver_selftest), the committed canonical states and, in its 19 states, the record's demonstration `t3-rust-demo.json`; it finds the partner B equal to A to 9.9×10^{-14} (ground states), 1.0×10^{-13} (history) and 8.1×10^{-13} (thermal states) and 4.0×10^{-14} relative in the energy along the whole history; the control C off by 0.8 to 9.6 percent along the history and by 1.15 to 3.43 across the couplings; the wrong partner D equal to A at the opposite coupling; the control's Kohn-Sham gap equal to $\varepsilon_b = 0.100851121375$ to twelve digits.

- ASSUMED: the good sector; the Z2 mirror at the brane; the cut at $L = 3$ with a chosen tip condition (T3 needs the transformed one); the mean field of Hartree plus uniform-gas exchange without correlation. CONVENTION: the filling of the particle levels.
- PRESCRIBED BACKGROUND: the history $a_4 = AHx_4$, $A = 1$, on the background $b_4 = 1$ of the author's metric of 2026-10-14; the Kohn-Sham states are not an admissible source of the a_4 equations.
- OPEN: the time-dependent Kohn-Sham problem; the justification of the filling convention.
- HYPOTHESIS: that universes are created in pairs. Not proved here, and not provable from these equations, which contain no creation process.

19.24 Exercises

Exercise 19.1 (the conjugation rules). Multiply out the 2×2 matrices to show $\sigma_2\sigma_1\sigma_2 = -\sigma_1$ and $\sigma_2\sigma_3\sigma_2 = -\sigma_3$, without using the anticommutation rule.

Answer. First $\sigma_2\sigma_1 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}$ (row times column: the first row $(0, -i)$ times the first column $(0, 1)$ gives $-i$, times the second column $(1, 0)$ gives 0; the second row $(i, 0)$ gives 0 and i). Then $(\sigma_2\sigma_1)\sigma_2 = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} = \begin{pmatrix} 0 & (-i)(-i) \\ i \cdot i & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} = -\sigma_1$. Likewise $\sigma_2\sigma_3 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}$ and $(\sigma_2\sigma_3)\sigma_2 = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} = \begin{pmatrix} i \cdot i & 0 \\ 0 & i(-i) \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = -\sigma_3$.

Exercise 19.2 (the zero modes in the real form). The zero mode of A is $(a, b) = (e^{My}, 0)$ with $j = +1$, mass M, $k = 0$, $v = 0$, $\varepsilon = 0$. Write down its image under $(a, b, j, M) \to (b, a, -j, -M)$ and verify directly that the image solves the real form of B and obeys B's boundary conditions (odd parity at the brane, tip angle π).

Answer. The image is $(a, b) = (0, e^{My})$ with $j = -1$ and the mass $-M$. The real form with $k = 0$, $v = 0$, $\varepsilon = 0$ is $a' = (-M)a - 0 \cdot b = -Ma$ and $b' = 0 \cdot a - (-M)b = Mb$. For $a = 0$: $a' = 0 = -M \cdot 0$; for $b = e^{My}$: $b' = Me^{My} = Mb$. Both hold. The odd brane condition is $a(0) = 0$: true, since $a = 0$ everywhere. The tip angle π demands $a(-L) = 0$: true. So the image is the zero mode of B, largest at the brane, as Section 19.12 found.

Exercise 19.3 (a tip that needs no transformation). For which tip angles θ is the transformed condition, with $\pi - \theta$, the same condition as the original? What does the condition say in the real form, and why is it unchanged by $(a, b) \to (b, a)$?

Answer. The tip matrix $Q(\theta) = \cos\theta\,\sigma_3 + \sin\theta\,\sigma_2$ repeats with the period 2π, so the two conditions agree when $\pi - \theta = \theta$ up to a multiple of 2π: $\theta = \pi/2$ or $\theta = -\pi/2$. For $\theta = \pi/2$, $Q = \sigma_2$, and $(1 - \sigma_2)\chi = 0$ reads $\chi_1 + i\chi_2 = 0$ in the first row (and $-i\chi_1 + \chi_2 = 0$ in the second, the same equation times $-i$): $\chi_2 = i\chi_1$. With $\chi = (a, ib)$ this is $ib = ia$, that is $b(-L) = a(-L)$, which is unchanged when a and b are exchanged. For $\theta = -\pi/2$ the condition is $b(-L) = -a(-L)$, also unchanged. With such a tip the "control" C would be the partner B; the canonical tip $\theta = 0$ is not of this kind.

Exercise 19.4 (every tip condition kills the current). Let $(1 - Q(\theta))\phi = 0$ and $(1 - Q(\theta))\chi = 0$ at $y = -L$. Show that $\phi^\dagger \sigma_1 \chi = 0$ there, using only $Q^\dagger = Q$ and $\sigma_1 Q = -Q\sigma_1$; prove these two facts first.

Answer. $Q^\dagger = \cos\theta\,\sigma_3^\dagger + \sin\theta\,\sigma_2^\dagger = Q$, because the Pauli matrices are Hermitian and $\cos\theta$, $\sin\theta$ are real. $\sigma_1 Q = \cos\theta\,\sigma_1\sigma_3 + \sin\theta\,\sigma_1\sigma_2 = -\cos\theta\,\sigma_3\sigma_1 - \sin\theta\,\sigma_2\sigma_1 = -Q\sigma_1$, because σ_1 anticommutes with σ_3 and with σ_2. The conditions say $Q\chi = \chi$ and $Q\phi = \phi$. Then, line by line: $\phi^\dagger\sigma_1\chi = \phi^\dagger\sigma_1 Q\chi$ (insert $\chi = Q\chi$) $= -\phi^\dagger Q\sigma_1\chi$ (anticommute) $= -(Q^\dagger\phi)^\dagger\sigma_1\chi$ (since $\phi^\dagger Q = (Q^\dagger\phi)^\dagger$) $= -(Q\phi)^\dagger\sigma_1\chi = -\phi^\dagger\sigma_1\chi$. A number equal to its own negative is 0. So the boundary term of Section 19.3 vanishes at the tip for every θ.

Exercise 19.5 (how wrong is the wrong partner?). In the record's canonical state N136_lamp1_a10 ($\lambda_1 = 0.0009298$) the scalar density at $y = -2.4$ is $S = -37$ (the record's profile file `Revision/kohn_sham/results/ground/profiles/N136_lamp1_a10.csv`, rounded). How far is the mass that the wrong partner $(-m, -\lambda)$ gives to the image density from the mass $-M_{\text{eff}}$ that the image needs at that point?

Answer. By Section 19.8 the wrong partner gives $-M_{\text{eff}} + \frac{15}{8}\lambda S$. The mismatch is $\frac{15}{8}\lambda S = 1.875 \times 0.0009298 \times (-37) = -0.0645$ in units of $|m|$. The right partner gives exactly $-M_{\text{eff}}$; here $M_{\text{eff}} = 1 + \frac{15}{16}\lambda_1 S = 1 - 0.0323 = 0.968$, close to the value 0.9677 of the profile file. So the wrong partner's mass is off by twice the mean-field shift $\frac{15}{16}\lambda S = -0.0323$, which is why Notebook 19a finds D at $+\lambda$ equal to A at $-\lambda$ and different from A at $+\lambda$ (In [23]).

Exercise 19.6 (the two slopes for M = H). Show that for $M = H$ and $Y = e^{HL}$ the slopes of Section 19.12 are $c = 2Y/(Y+1)$ and $c_{\text{ctrl}} = \frac{2}{3}(Y^2+Y+1)/(Y+1)$, that $c_{\text{ctrl}} - c = \frac{2}{3}(Y-1)^2/(Y+1)$, and evaluate the difference for $L = 3$.

Answer. With $M = H$, $2M - H = H$ and $2M/(2M - H) = 2$: $c = 2(1 - e^{-HL})/(1 - e^{-2HL}) = 2(1-Y^{-1})/(1-Y^{-2})$. Multiply the numerator and the denominator by Y^2: $c = 2(Y^2-Y)/(Y^2-1) = 2Y(Y-1)/((Y-1)(Y+1)) = 2Y/(Y+1)$. With $2M + H = 3H$: $c_{\text{ctrl}} = \frac{2}{3}(e^{3HL} - 1)/(e^{2HL} - 1) = \frac{2}{3}(Y^3 - 1)/(Y^2 - 1) = \frac{2}{3}(Y-1)(Y^2 + Y + 1)/((Y-1)(Y+1)) = \frac{2}{3}(Y^2 + Y + 1)/(Y+1)$, using $Y^3 - 1 = (Y-1)(Y^2+Y+1)$. The difference over the common denominator: $\left[\frac{2}{3}(Y^2+Y+1) - 2Y\right]/(Y+1) = \frac{2}{3}(Y^2 - 2Y + 1)/(Y+1) = \frac{2}{3}(Y-1)^2/(Y+1)$, positive for every $L > 0$: the control's band is

always steeper. For $L=3$, $Y=e^3=20.0855$: $\frac{2}{3}\times 19.0855^2/21.0855=\frac{2}{3}\times 364.26/21.0855=11.517$, the difference $13.4220-1.9051$ of Notebook 19b.

Exercise 19.7 (the free energy). With the Fermi occupations $f=1/(1+e^x)$, $x=(\varepsilon-\mu)/T$, show that $F=\Omega+\mu N$ equals $E_{KS}-TS_{\text{ent}}$, with the definitions of Section 19.4.

Answer. Three facts about one level, line by line. (1) $1-f=e^x/(1+e^x)=1/(1+e^{-x})$, so $\ln(1+e^{-x})=-\ln(1-f)$. (2) $\ln f=-\ln(1+e^x)=-x-\ln(1+e^{-x})=-x+\ln(1-f)$, using $1+e^x=e^x(1+e^{-x})$ and fact (1). (3) Hence $f\ln f+(1-f)\ln(1-f)=-xf+f\ln(1-f)+(1-f)\ln(1-f)=-xf+\ln(1-f)$. Summed with the degeneracies: $TS_{\text{ent}}=-T\sum g[-xf+\ln(1-f)]=\sum gf(\varepsilon-\mu)-T\sum g\ln(1-f)=\sum gf\varepsilon-\mu N+T\sum g\ln(1+e^{-x})$, using $Tx=\varepsilon-\mu$, $\sum gf=N$ and fact (1). Write $I=2\,\text{Vol}_7\int e^{6Hy}e_{\text{int}}\,dy$. Then $\Omega=-T\sum g\ln(1+e^{-x})-I=(\sum gf\varepsilon-\mu N-TS_{\text{ent}})-I=E_{KS}-TS_{\text{ent}}-\mu N$, using the line before and $E_{KS}=\sum gf\varepsilon-I$. Adding μN gives $F=E_{KS}-TS_{\text{ent}}$. Notebook 19a computes F in this form (In [25]).

Exercise 19.8 (when does the control have a level in the gap?). Take $M=1$ and the tip at $L=\frac{1}{2}$ instead of $L=3$. Does the control's odd sector still have a level inside the gap?

Answer. The level in the gap is a root q in $(0,M)$ of $u(q)=\tanh(qL)-q/M$ (Section 19.12). Now $u(0)=0$ and $u'(0)=L-1/M=-\frac{1}{2}<0$. The function tanh is concave for $q>0$, so u is concave there, and a concave function that starts at 0 with a negative slope stays below the line $u'(0)q$, hence negative, for all $q>0$: there is no root, and no level inside the gap. At the edge $\varepsilon=M$ ($p=0$) the odd characteristic function of C is $\cosh 0-M\cdot L=1-\frac{1}{2}\neq 0$, so there is no level at the edge either. The control has a level in the gap exactly when $L>1/M$; the record's $L=3$ is such a case.

Exercise 19.9 (Krein signs of the eight blocks). Using the block form $B=js_2$, list the Krein signs of the eight blocks and show that Γ, which moves (j,s_2,s_3) to $(-j,s_2,s_3)$, reverses the Krein sign of every block. How many blocks have the Krein sign $+1$?

Answer. The products js_2 for $(j,s_2)=(1,1),(1,-1),(-1,1),(-1,-1)$ are $+1,-1,-1,+1$, each for $s_3=\pm 1$: the blocks $(1,1,\pm 1)$ and $(-1,-1,\pm 1)$ have the Krein sign $+1$, the blocks $(1,-1,\pm 1)$ and $(-1,1,\pm 1)$ have -1. Four blocks have $+1$ and four -1, eight components each way, in agreement with the eight eigenvalues $+1$ and eight -1 of B. The partner block of (j,s_2,s_3) has the sign $(-j)s_2=-js_2$: reversed, for every block. This is $\Gamma B\Gamma=-B$ written block by block (Section 19.5).

20 Do universes come in pairs? What the equations prove and what they do not

The author asked for a proof "that Universes of masses {+mass, -mass} are created in pairs", for the fermion field dirac16complex and for the commuting field dirac16complex00, and the request for this book speaks of proving that "the big bang creates universes in pairs". This chapter answers the question of its title exactly. It collects what the equations of this book PROVE about pairs of universes (the pairing theorems T1, T2, Q and T3 and the corollary C1), proves the central steps again line by line, follows them through one exact solution, and then states, just as exactly, what the equations do NOT prove: that any universe is created, in pairs or otherwise. No creation process, no rate, no probability and no amplitude follows from these equations. The author's statement that the big bang creates universes in pairs therefore remains what it was, a HYPOTHESIS, and this chapter says precisely what a proof of it would still need.

20.1 What this chapter does, and why

Why the question needs care. A sentence like "the equations prove that universes come in pairs" can mean several very different things. It can mean that for every solution of the equations there is a partner solution (a statement about the set of all solutions); it can mean that whenever one universe exists its partner exists too (a statement about what is realised); or it can mean that some process makes two universes at once out of something else (a statement about dynamics, with a rate or a probability). The first kind of statement can be proved from the field equations of this book, and it is proved. The second and the third cannot be proved from them, because these equations describe fields on a given gravitational background and contain no process that produces a universe. A student who confuses the three would believe that the theory has shown something it has not. This chapter therefore separates them carefully and gives every statement its status.

The answer in brief. Each item carries its status word (defined in Section 20.2).

1. PROVED (theorem T1, the chirality pairing): multiplying a field Ψ by the chirality matrix Γ turns every configuration of the theory with mass m and coupling λ into a configuration of the theory with $(-m, -\lambda)$, solutions into solutions, in every gravitational field, and reverses its energy-momentum tensor, its current and its charge. A T1 pair therefore has zero total energy, momentum, stress and charge at every point.

2. PROVED (theorem T2, the mirror pairing): the gamma matrix of the hidden direction together with the mirror $z \to \pi - z$ across the surface $z = \pi/2$ (an ASSUMED construction) turns a solution with $(-m, \lambda)$ into a solution with (m, λ) with EQUAL, not opposite, energy and charge.

3. PROVED (the quantum reading Q, dirac16complex only): the T1 image is the same quantum system relabelled; two independently quantised universes of masses $+m$ and $-m$ have identical one-particle spectra (the $\lambda = 0$ spectra, in flat 4+4 space or in a general field at a point with frozen coefficients) and energies that add, not cancel.

4. PROVED (theorem T3, the Kohn-Sham level, dirac16complex): every self-consistent instantaneous Kohn-Sham state with (m, λ) has a partner with $(-m, +\lambda)$ and equal energies (ASSUMED Z2 brane, transformed tip condition).

5. PROVED (corollary C1): a T1 pair taken as the only source of the author's metric is a zero source, and in Einstein gravity the author's metric then has no solution at all for $H > 0$.

6. COMPUTED in this chapter (Notebook 20b): one exact universe, a solution of the field equation and of all 64 Einstein equations together, that needs no partner; its T1 partner solves its own field equation but cannot be the source of the author's metric.

7. PROVED (the charge of a pair): a T1 partner carries the opposite charge, so a T1 pair has zero total charge; a T2 mirror copy carries the SAME charge. This does NOT solve the matter-antimatter problem: the theory as built has no baryons, no violation of baryon number, no violation of CP and no computed departure from equilibrium (Section 20.23).

8. NOT ESTABLISHED: that any universe is created; any creation process, rate, probability or amplitude; that a partner must exist.

9. HYPOTHESIS: "the big bang creates universes of masses $+M$ and $-M$ in pairs" (the author's statement).

T1, T2, Q, T3 and C1 are exact **maps between solution sets** and one consequence of them: they say which solutions exist if one solution exists. None of them is a statement that a universe comes into being.

The plan. Section 20.2 defines the words. Section 20.3 reads the request and the hypothesis word by word, and Section 20.4 separates the three questions hidden in it. Sections 20.5 and 20.6 state the pairing theorems and prove them line by line: this chapter gives the complete proofs of T1 and T2 (with the reflected-connection lemma) and the Krein-metric step of Q; the remaining steps of Q, which need the one-particle Hamiltonian of Chapter 10, are proved in Chapter 18, and T3, whose proof needs the Kohn-Sham blocks of Chapter 14, is proved in Chapter 19 (Section 20.6 outlines it). Section 20.7 proves the corollary C1, and Notebook 20a makes every step of it visible (Sections 20.8 to 20.11). Section 20.12 derives one exact universe of the theory, and Notebook 20b builds it and its partners (Sections 20.13 to 20.16). Section 20.17 shows, with the creation of an electron and a positron from light, what a proof of creation contains, and Notebook 20c computes it (Sections 20.18 to 20.21). Section 20.22 says what the conservation laws of this theory allow and forbid, Section 20.23 what pairs have to do with matter and antimatter, Section 20.24 lists what is not established, Section 20.25 what a calculation of creation would require, and Section 20.26 gives the answer to the question of the title. The chapter ends with the ledger "What we proved, what we computed, what we assumed" (Section 20.27) and with exercises and their complete answers (Section 20.28).

The three worked examples. Each is a complete Jupyter notebook; you may run them in any order. None of them needs Rust.

notebook	**what it computes**	**checks**	**figures**
20a	corollary C1 step by step: the spin connection on both patches, a configuration with its T1 partner and its T2 mirror copy, the vacuum equations of Einstein and Einstein-Lovelock gravity	37	7
20b	one exact universe of the coupled equations with the deflating history, its T1 partner, the T1 pair and its T2 mirror copy	25	4

notebook	what it computes	checks	figures
20c	allowed is not the same as happens: the thresholds of electron-positron pair creation, and what the pairing record does not establish	12	4

The records this chapter uses. Every formula and number comes from these Revision records or from the chapter's own notebooks, which reproduce the records where they overlap (each such check prints the record file and the check name).

record	what it holds
`Revision/docs/PAIR_CREATION_PROOFS.md`	the Revision document of the pairing theorems, the corollary C1 and the list of what is not established
`Revision/pairing/pairing-theory.json`	T1, T2 and Q with hypotheses, statements, proofs, and the list `not_established`
`Revision/pairing/reports/wolfram-pairing.json`	the WolframScript verification of T1, T2 and Q (101 checks, all PASS)
`Revision/pairing/reports/python-pairing.json`	the independent sympy verification (66 checks, all PASS)
`Revision/pairing/kohn_sham/t3-theory.json`	theorem T3, its hypotheses and its own list of what it does not establish
`Revision/pairing/kohn_sham/reports/`	`wolfram-t3.json` (10 checks) and `python-t3.json` (13 checks), all PASS
`Revision/field_equations_a4/a4-equations.json`	the Lovelock tensors of the author's metric, the null combination and the vacuum factor
`Revision/field_equations_a4/reports/`	`python-a4-report.json` and `wolfram-a4-report.json`: the field equations for a_4; `ks-source-conditions.json`: the Kohn-Sham states as a source
`Revision/lead_checks/reports/`	the lead's independent checks `einstein-gauss-bonnet-a4.json`, `emt-divergence-and-spin-connection.json` and `charge-conjugation-and-u1.json`
`Revision/algebra/gammas.json`	the author's eight real 16×16 gamma matrices

The counts in the table are those printed by Notebook 20a (In [2]) for the two pairing reports and those of the reports' own summaries for T3; a report is named below by its file name only, for example "`python-pairing.json`, check `gammas.Gamma`". Every check cited in this chapter has the verdict PASS.

Notation. The author's coordinates are $x_0, \ldots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates (scale factor $e^{a_4} \sin^{1/6} z$); x_4 is the time; x_5, x_6, x_7 are the three EXTRA TIMES, time-like, which DEFLATE EXPONENTIALLY (scale factor $e^{-a_4} \sin^{1/6} z$, with a_4 increasing); x_0 is the hidden space direction, with $z = 6Hx_0$ between 0 and $\pi/2$ and $H > 0$ the author's constant. The metric is

$$ds^2 = \cot^2 z\, dx_0^2 + e^{2a_4} \sin^{1/3} z\, (dx_1^2 + dx_2^2 + dx_3^2) - dx_4^2$$
$$- e^{-2a_4} \sin^{1/3} z\, (dx_5^2 + dx_6^2 + dx_7^2),$$

with $a_4 = a_4(x_4)$ and $a_4' = da_4/dx_4$; its signature is (4,4) and $\sqrt{|g|} = \cos z$. This is the author's metric of 2026-10-14 on its background $b_4 = 1$: the metric has a second function $b_4(x_4) > 0$ that multiplies the three extra-time components (Chapter 3). The records of the pairing theorems and the notebooks of this chapter work at $b_4 = 1$; Section 20.7 shows that corollary C1 holds for every b_4. The frame metric is $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$. The gamma matrix of the direction x_a is $\gamma^{(x_a)}$, a real 16×16 matrix, with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab} I_{16}$. The **deflating history** is the linear member $a_4 = AHx_4$ with $A = 1$: 3-space grows like e^{Hx_4} and the extra times shrink like e^{-Hx_4}.

20.2 The words of this chapter

- **Configuration**: a field Ψ given by its 16 components at every point, whether or not it obeys the field equation. A statement that holds for every configuration holds **off shell**; one that holds only for solutions holds **on shell**.
- **Solution**: a configuration that obeys the field equation $\gamma^\mu D_\mu \Psi = (m + \lambda S)\Psi$, where $S = \bar{\Psi}\Psi$ and $\bar{\Psi} = \Psi^\dagger C$.
- **Universe of mass** m (the meaning used by the Revision record): a solution of one of the two fields with mass parameter m and coupling λ in the author's primordial gravitational field. It is NOT the total gravitational mass or energy of that universe.
- **Parameter set** (m, λ): the mass and the coupling of the potential $U(S) = \frac{\lambda}{2} S^2$. The theory with (m, λ) and the theory with $(-m, -\lambda)$ are two DIFFERENT theories: their Lagrangians are different functions of the field.
- **Map between solution sets**: a rule that takes EVERY solution of one theory to a solution of another theory (here: multiply the field by a fixed matrix, possibly together with a change of the coordinate x_0).
- **Partner**: the image of a solution under such a map. **T1 partner**: $\Gamma\Psi$ with $(-m, -\lambda)$ at the same point. **T2 mirror copy**: $\gamma^{(x_0)}\Psi$ placed at the mirror point $\pi - z$, with $(-m, \lambda)$.
- **Pair**: a solution together with one partner. A **T1 pair** has opposite energy-momentum tensors; a **T2 pair** has equal ones.
- **Chirality**: the product of all eight gammas in the record's order, $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)} \ldots \gamma^{(x_7)}$, which equals the diagonal matrix $\mathrm{diag}(-I_8, I_8)$ (eight entries -1, then eight entries $+1$).
- **Charge matrix** $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, which defines the adjoint $\bar{\Psi} = \Psi^\dagger C$; **Krein matrix** $B = -iC\gamma^{(x_4)}$.
- **Energy-momentum tensor** $T_{\mu\nu}$: the source of gravity, 64 numbers at every point. **Energy density** $\rho = -T^{x_4}{}_{x_4}$; **pressure** along a direction μ: $p_\mu = T^\mu{}_\mu$ (no sum); p_3 for 3-space, p_t for the extra times, p_0 for the hidden direction.

- **Current** $J^\mu = -i\bar{\Psi}\gamma^\mu\Psi$; **charge density** $J^{x_4} = \Psi^\dagger B\Psi$; **charge** $Q = \int \cos z\, \Psi^\dagger B\Psi\, d^7x$, the integral over the seven directions other than x_4.
- **Patch, mirror patch, brane**: $0 < z < \pi/2$ is the **patch**; the map $z \to \pi - z$ takes it to the **mirror patch** $\pi/2 < z < \pi$; the surface $z = \pi/2$ between them is the **brane**. Gluing the two patches at the brane is the **Z2 construction**; it is ASSUMED.
- **Einstein-Lovelock equations**: $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu$, with the three Lovelock tensors $E_{(k)}$ (Chapter 12), couplings α_k, the **cosmological constant** Λ and the gravitational coupling κ. **Einstein gravity** is $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$; then $E_{(1)} = G$ is the Einstein tensor. **Einstein-Gauss-Bonnet gravity** is $\alpha_1 = 1$, $\alpha_3 = 0$.
- **Vacuum equations**: the field equations of gravity with zero source, $\sum_k \alpha_k E_{(k)}{}^\mu{}_\nu + \Lambda\delta^\mu_\nu = 0$. A **vacuum** is a solution of them.
- **Null combination** $\rho + p_0$: the energy density plus the pressure along x_0.
- **Corollary**: a statement that follows from a theorem in a few lines.
- **Process**: a solution of a dynamical equation that connects an initial state with a different final state. **Creation** of a universe: a process whose initial state has fewer universes than its final state.
- **Rate, probability, amplitude**: numbers that say how often a process happens; they come from a dynamical theory. An **amplitude** is the complex number whose squared modulus is a probability.
- **Cross section**: for a process in which a particle hits a target (for example a photon a nucleus), the effective area of the target that the particle must hit for the process to happen; the number of processes per unit time is the cross section times the number of incoming particles that cross a unit area per unit time. It is measured in units of area.
- **Bogoliubov coefficient**: in a quantum field on a gravitational field that changes in time, a number that says how much of a wave that oscillates with positive frequency at early times has turned into a wave of negative frequency at late times; its squared modulus is the mean number of particles created in that wave. It is the standard measure of particle creation by a changing background.
- **Vacuum decay**: the quantum transition of a state that has the lowest energy only among its neighbouring states (a **false vacuum**) into a state of still lower energy; its rate per unit volume is computed from the quantum theory.
- **Tunnelling**: a quantum transition through a region that the classical equations forbid (a **barrier**), with a small but nonzero probability; proposals in which a universe appears by tunnelling are of this kind (Section 20.25).
- **Wave function of the universe, path integral**: a wave function of the universe is a quantum state of the geometry together with the matter fields (Section 20.25); a path integral computes an amplitude by adding up one complex number for every history that connects the initial and the final state.
- **Allowed**: not forbidden by any conservation law. Allowed does NOT mean that the process happens, nor how often.

- **Conserved quantity**: a number whose value does not change in time for every solution.
- **Status words.** PROVED: an exact statement with a proof, verified by a named check of a Revision record or by an exact computation of this book's notebooks. COMPUTED: a floating-point result with its measured accuracy. ASSUMED: an assumption on which a result rests. HYPOTHESIS: a scientific conjecture that is not established. OPEN: a question that nobody has answered here.

20.3 The request and the hypothesis, read word by word

The request. The author's request, quoted from `Revision/README.md`: "PROVE that Universes of masses {+mass, -mass} are created in pairs for each case of the dirac16complex and the dirac16complex00 fields." The request for this book repeats it as "proving that the 'big bang' creates universes in pairs".

The hypothesis. We write it as one sentence and give it its status:

Hypothesis P (the author's). The big bang creates universes of masses $+M$ and $-M$ in pairs. Status: HYPOTHESIS.

The Revision record gives its answer to the request in its list of answers to the author of 2026-10-01 (`Revision/README.md`): the pairing theorems T1, T2, Q and T3 are proved, each under its stated hypotheses, and "that universes occur in pairs, or are created, is not proved: no creation process, rate or amplitude follows from these equations". This chapter explains why, word by word.

"A universe of mass M." In the record, M (or m) is the mass parameter of the field in its Lagrangian. A universe of mass m is a solution of the field equation with this parameter, in the author's gravitational field (Section 20.2). The sign of m alone does not say which of two physically different kinds of universe one has: theorem T2 (Section 20.6) shows that the image of a solution with $(-m, \lambda)$ under the reflection of one space-like frame direction is a solution with (m, λ) with the same energy-momentum tensor. So "$+M$" and "$-M$" are labels whose sign is tied to the orientation of a frame.

"Created." A creation is a process (Section 20.2): an equation whose solution starts with fewer universes and ends with more, or, in a quantum theory, a nonzero amplitude for the transition from a state with fewer universes to a state with more. The field equations of this book are equations for a field on a given gravitational background; they contain no term that turns "no universe" into "a universe". We return to this in Sections 20.22 and 20.25.

"In pairs." That the second universe is present together with the first one, and necessarily so. The pairing theorems say that the partner is a solution of the partner theory; they do not say that it is present (Section 20.4).

"The big bang." In cosmology the big bang is the hot, dense early phase from which the observed expansion started; in the classical solutions of Einstein's equations that describe it, the scale factor of space goes to zero at a finite time in the past, and the equations break down there (a **singularity**). What we can prove is narrower: the author's metric has no such moment wherever its history a_4 is regular. We prove it line by line, for any history a_4 that is finite with finite a_4' and a_4'' at the time considered, on the patch $0 < z < \pi/2$; the prescribed deflating history is such a history at every finite time. Whether the equations of this book, solved together, produce a big-bang moment is a different question, and it is not decided (see the end of this paragraph).

$$g_{x_1x_1} = g_{x_2x_2} = g_{x_3x_3} = e^{2a_4} \sin^{1/3} z, \qquad 0 < g_{x_1x_1} < \infty.$$

The exponential of a finite number is finite and positive, and $0 < \sin z < 1$ on the patch, so $\sin^{1/3} z$ is positive and finite.

$$g_{x_4x_4} = -1, \qquad g_{x_5x_5} = g_{x_6x_6} = g_{x_7x_7} = -e^{-2a_4} \sin^{1/3} z, \qquad -\infty < g_{x_5x_5} < 0.$$

The same rule with $-2a_4$ in the exponent.

$$g_{x_0x_0} = \cot^2 z, \qquad 0 < g_{x_0x_0} < \infty,$$

because $\cot z = \cos z / \sin z$ is finite and positive for $0 < z < \pi/2$.

$$\sqrt{|g|} = \cos z > 0.$$

This is the record's volume factor (`python-pairing.json`, check `geometry.brane_degenerate`, which also records that it and $g_{x_0x_0}$ vanish at the brane $z = \pi/2$, the edge of the patch). So at every finite time the metric is finite and non-degenerate at every point of the patch. Its curvature is finite as well: every component $R^{ab}{}_{cd}$ is a Laurent polynomial in $\cot z$ (a sum of powers $\cot^k z$ with whole, possibly negative, k) whose coefficients are polynomials in H, a_4' and a_4'' (`python-a4-report.json`, checks `riemann_entries_laurent` and `mixed_riemann_free_of_warp_and_a4`), and such an expression is finite where $\cot z$ is finite and not zero. For the prescribed deflating history $a_4 = Hx_4$ the three numbers $a_4 = Hx_4$, $a_4' = H$ and $a_4'' = 0$ are finite at every finite time x_4, so the metric and its curvature are finite at every finite time on the patch; and its 3-space scale factor $e^{Hx_4} \sin^{1/6} z$ tends to zero only as $x_4 \to -\infty$, never at a finite time. Status: PROVED for the prescribed deflating history $a_4 = AHx_4$, and for any history whose a_4, a_4' and a_4'' stay finite (derived here from the metric and the two record checks). The degenerate places of the metric are the edges of the patch, not a moment of time: the brane $z = \pi/2$ ($g_{x_0x_0} = 0$ and $\sqrt{|g|} = 0$) and the tip $z \to 0$.

What this proof does NOT show: that the equations of this book exclude a big-bang moment. It assumed that a_4, a_4' and a_4'' are finite, and it says nothing about a history in which one of them becomes infinite at a finite time. The history used in this book is prescribed, not computed: the Kohn-Sham history $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND, because the Kohn-Sham states violate the source conditions of the a_4 equations (`ks-source-conditions.json`, checks `ks_profiles_depend_on_x0` and `ks_history_is_a_prescribed_background`). And when the a_4 equations are solved with a given source, they can break down at a finite time: Chapter 12 integrates the evolution equation of Einstein-Gauss-Bonnet gravity with a given constant source and finds that the rate a_4' reaches a critical value at a finite time $x_4^\star$, where a_4'' becomes infinite and no solution with a smooth a_4' continues. The curvature contains a_4'' (for example the Einstein tensor component $G^{x_1}{}_{x_1} = -3a_4'^2 + a_4'' + 15H^2$, `a4-equations.json`, key `lovelockTensors`, entry `E1`, `x1x1`), so it becomes infinite there too: a singularity at a finite time. In Einstein gravity the record allows every history a_4 that has a continuous second derivative, each with the source that it requires (`a4-equations.json`, key `einstein`, entry `allowedA4`), so a history in which $a_4 \to -\infty$ at a finite time, that is in which the 3-space scale factor goes to zero, is not excluded either. So: the PRESCRIBED history contains no big-bang moment; whether the coupled equations of the fields and of a_4, solved together, contain one is not decided (OPEN).

20.4 Three questions: is it allowed, does it happen, how often?

The sentence "universes are created in pairs" packs three questions of very different kinds into one.

Q1, allowed? Do the conservation laws of the theory permit a transition from a state without universes (or with one) to a state with a pair? This question asks whether something FORBIDS the transition. It is answered by comparing the conserved quantities before and after.

Q2, does it happen? Is there a solution of the dynamical equations (the field equations of both members together with the gravitational field equations) that starts without the pair and ends with it? This is a question about dynamics.

Q3, how often? In a quantum theory: what is the amplitude of the transition, its probability, or the number of pairs made per unit time? Its answer is a number.

Symmetry is not realisation. A pairing theorem says: for every solution with mass $+m$ there is a solution with mass $-m$. It does not say that whenever the first is present, the second is present too. An everyday comparison makes the difference plain. The laws of mechanics do not change when everything is reflected in a mirror, so for every right hand that the laws allow, a left hand is allowed as well. That does not mean that every right hand comes with a left hand, still less that hands are created in right-left pairs. To go from "the partner is allowed" to "the partner is created together with the original" one needs an answer to Q2 or Q3.

What the Revision record answers. The pairing theorems T1, T2, Q and T3 answer none of the three questions directly: they are statements about the SETS of solutions of two theories. Q1 is answered in part in Section 20.22: the conservation laws of the theory forbid a T1 pair with nonzero member charges or momenta from appearing out of zero fields, provided that no charge or momentum flows through the brane $z = \pi/2$ (a no-flux condition that is ASSUMED, not derived). Q2 and Q3 are not answered by any equation of the record: no creation process, rate or amplitude is derived (`pairing-theory.json`, list `not_established`, items "No creation process" and "No rate and no amplitude"). Notebook 20c shows on the creation of electron-positron pairs from light what an answer to Q1, Q2 and Q3 looks like when physics does have it.

20.5 What is proved (1): theorem T1, line by line

Hypotheses (`pairing-theory.json`, theorem T1). (H1) The gravitational field is any vielbein with any spin connection, in particular the canonical one of the author's metric; it is a fixed (test) background, NOT varied, and both members of the pair live in the SAME field. (H2) Ψ has Grassmann components (dirac16complex) or commuting components (dirac16complex00); the map acts at the same point, with no change of coordinates. (H3) The potential is $U(S) = \frac{\lambda}{2}S^2$. (H4) The Lagrangian density, the field equation, the energy-momentum tensor and the current are

$$\mathcal{L}_{m,\lambda}[\Psi] = \sqrt{|g|}\,[K - mS - \tfrac{\lambda}{2}S^2], \qquad K = \tfrac{1}{2}(\bar{\Psi}\gamma^\mu D_\mu\Psi - (D_\mu\bar{\Psi})\gamma^\mu\Psi),$$

$$E_{m,\lambda}[\Psi] = \gamma^\mu D_\mu\Psi - (m + \lambda S)\Psi,$$

$$T_{\mu\nu} = \tfrac{1}{4}\big(\bar\Psi\gamma_\mu D_\nu\Psi + \bar\Psi\gamma_\nu D_\mu\Psi - (D_\mu\bar\Psi)\gamma_\nu\Psi - (D_\nu\bar\Psi)\gamma_\mu\Psi\big) - g_{\mu\nu}\,\frac{\mathcal{L}}{\sqrt{|g|}}, \qquad J^\mu = -i\bar\Psi\gamma^\mu\Psi,$$

with $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$, $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, $\Omega_\mu = \frac{1}{2}\omega_{\mu ab}S^{ab}$, $S^{ab} = \frac{1}{4}[\gamma^{(a)},\gamma^{(b)}]$ and $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ for the diagonal vielbein with the lengths f_μ. (This $T_{\mu\nu}$ is the one of the pairing records; it is minus the tensor of the field-theory record. The pairing records write the current as $J^\mu = \bar\Psi\gamma^\mu\Psi$; this book uses the real current $J^\mu = -i\bar\Psi\gamma^\mu\Psi$ of the field-theory record and of `charge-conjugation-and-u 1.json`, whose x_4 component is $\Psi^\dagger B\Psi$ with the Hermitian matrix B. Every statement below is linear in T and in J, so neither the sign convention of T nor the factor $-i$ of J matters.)

Statement (theorem T1).

- (T1a) $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$ off shell; separately $S[\Gamma\Psi] = S[\Psi]$ and $K[\Gamma\Psi] = -K[\Psi]$.
- (T1b) $E_{-m,-\lambda}[\Gamma\Psi] = -\Gamma E_{m,\lambda}[\Psi]$: Ψ solves the (m,λ) equation exactly when $\Gamma\Psi$ solves the $(-m,-\lambda)$ equation.
- (T1c) $T_{\mu\nu}^{(-m,-\lambda)}[\Gamma\Psi] = -T_{\mu\nu}^{(m,\lambda)}[\Psi]$ and $J^\mu[\Gamma\Psi] = -J^\mu[\Psi]$ at every point, off and on shell.
- (T1d) The pair has $T + T' = 0$, $J + J' = 0$ and $Q + Q' = 0$, as classical bilinears.

Proof, step 1: the chirality anticommutes with every gamma. Take one direction b and move $\gamma^{(b)}$ from the left of Γ to its right:

$$\gamma^{(b)}\Gamma = \gamma^{(b)}\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = (-1)^7\,\gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}\gamma^{(b)} = -\Gamma\gamma^{(b)}.$$

On its way $\gamma^{(b)}$ passes the eight factors of Γ: seven of them belong to other directions and each exchange gives a factor -1 (the Clifford relation $\gamma^{(a)}\gamma^{(b)} = -\gamma^{(b)}\gamma^{(a)}$ for $a \neq b$); one of them is $\gamma^{(b)}$ itself, which commutes with itself.

Step 2: the chirality commutes with C, with every S^{ab} and with every Ω_μ.

$$\Gamma C = \Gamma\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)} = (-1)^4\,\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}\Gamma = C\Gamma.$$

Step 1 was applied four times, once for each factor of C. In the same way $\Gamma S^{ab} = S^{ab}\Gamma$ (two factors, $(-1)^2 = 1$), and therefore $\Gamma\Omega_\mu = \Omega_\mu\Gamma$, because Ω_μ is a sum of numbers times the S^{ab}.

Step 3: the covariant derivative commutes with Γ.

$$D_\mu(\Gamma\Psi) = \partial_\mu(\Gamma\Psi) + \Omega_\mu\Gamma\Psi = \Gamma\partial_\mu\Psi + \Gamma\Omega_\mu\Psi = \Gamma D_\mu\Psi.$$

Γ is a constant matrix, so it comes out of the derivative; step 2 moved it past Ω_μ.

Step 4: the adjoint of the partner. $\Gamma = \mathrm{diag}(-I_8, I_8)$ is real and symmetric, so $\Gamma^\dagger = \Gamma$ and $\Gamma^2 = I_{16}$ (`python-pairing.json`, check `gammas.Gamma`).

$$\overline{\Gamma\Psi} = (\Gamma\Psi)^\dagger C = \Psi^\dagger\Gamma^\dagger C = \Psi^\dagger\Gamma C = \Psi^\dagger C\Gamma = \bar\Psi\Gamma.$$

The rules used, in order: the definition of the adjoint; $(M\Psi)^\dagger = \Psi^\dagger M^\dagger$; $\Gamma^\dagger = \Gamma$; step 2. In the same way $D_\mu(\bar\Psi\Gamma) = \partial_\mu\bar\Psi\,\Gamma - \bar\Psi\Gamma\Omega_\mu = (D_\mu\bar\Psi)\Gamma$.

Step 5: the scalar is unchanged, the kinetic term changes sign.

$$S[\Gamma\Psi] = \bar\Psi\Gamma\,\Gamma\Psi = \bar\Psi\Psi = S[\Psi].$$

Step 4 and $\Gamma^2 = I_{16}$. For the kinetic term, every $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ is a number times one gamma, so by step 1 $\Gamma\gamma^\mu\Gamma = -\gamma^\mu\Gamma\Gamma = -\gamma^\mu$, and with steps 3 and 4

$$\overline{\Gamma\Psi}\,\gamma^\mu D_\mu(\Gamma\Psi) = \bar\Psi\,\Gamma\gamma^\mu\Gamma\,D_\mu\Psi = -\bar\Psi\gamma^\mu D_\mu\Psi, \qquad (D_\mu\overline{\Gamma\Psi})\gamma^\mu\Gamma\Psi = -(D_\mu\bar\Psi)\gamma^\mu\Psi.$$

Both terms of K change sign, so $K[\Gamma\Psi] = -K[\Psi]$.

Step 6: the Lagrangian (T1a).

$$\mathcal{L}_{m,\lambda}[\Gamma\Psi] = \sqrt{|g|}\,[\,-K - mS - \tfrac{\lambda}{2}S^2] = -\sqrt{|g|}\,[K - (-m)S - \tfrac{(-\lambda)}{2}S^2] = -\mathcal{L}_{-m,-\lambda}[\Psi].$$

The first equality inserts step 5; the second takes out the factor -1 and writes $+m = -(-m)$ and $+\lambda = -(-\lambda)$; the third is the definition of $\mathcal{L}$ with the parameters $(-m, -\lambda)$.

Step 7: the field equation (T1b).

$$E_{-m,-\lambda}[\Gamma\Psi] = \gamma^\mu D_\mu(\Gamma\Psi) - (-m - \lambda S)\Gamma\Psi = -\Gamma\gamma^\mu D_\mu\Psi + (m + \lambda S)\Gamma\Psi = -\Gamma E_{m,\lambda}[\Psi].$$

The first equality is the definition of E with the parameters $(-m, -\lambda)$ and $S[\Gamma\Psi] = S$; the second uses step 3 and then step 1 to move Γ to the left; the third takes out $-\Gamma$. Since Γ is invertible, the left side vanishes exactly when $E_{m,\lambda}[\Psi]$ does.

Step 8: the energy-momentum tensor and the current (T1c). Each of the four kinetic terms of $T_{\mu\nu}$ has one gamma between $\bar\Psi$ and Ψ and changes sign exactly as in step 5. The last term changes sign by step 6 with the parameters exchanged, $\mathcal{L}_{-m,-\lambda}[\Gamma\Psi] = -\mathcal{L}_{m,\lambda}[\Psi]$. Hence $T_{\mu\nu}^{(-m,-\lambda)}[\Gamma\Psi] = -T_{\mu\nu}^{(m,\lambda)}[\Psi]$. For the current,

$$J^\mu[\Gamma\Psi] = -i\bar\Psi\Gamma\gamma^\mu\Gamma\Psi = +i\bar\Psi\gamma^\mu\Psi = -J^\mu[\Psi],$$

by step 4 and step 1; integrating its x_4 component gives $Q[\Gamma\Psi] = -Q[\Psi]$.

Step 9: the pair and the statistics (T1d). Adding (T1c) to the quantities of Ψ gives $T + T' = 0$, $J + J' = 0$ and $Q + Q' = 0$. Γ multiplies each component by $+1$ or -1 and never reorders two Grassmann numbers, so steps 1 to 8 hold word for word for anticommuting components. Nothing in the proof used the form of the vielbein or of the connection, so it holds in every gravitational field. QED.

Records. The Wolfram pairing report has 51 checks of T1, in the author's field, in a general diagonal field and in a general field at one point, for both statistics. The sympy pairing report has 23 more, written independently. Examples, one per line:

Notebook 20a reproduces T1 at a point of the deflating history (In [7]) and along the hidden direction (In [9]). The complete proof, with the four matrix lemmas behind steps 1 to 4 checked exactly, is in Chapter 18.

What T1 is and what it is not. It is not a symmetry of ONE theory: it changes the parameters and the sign of the action, and for $\lambda \neq 0$ it pairs (m, λ) with $(-m, -\lambda)$, not $+m$ with $-m$ at the same coupling (for $\lambda = 0$ it pairs $+m$ with $-m$ exactly). Both the mass and the coupling must change sign: the negative controls $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{-m,\lambda}[\Psi] \neq 0$ and $\mathcal{L}_{m,\lambda}[\Gamma\Psi] + \mathcal{L}_{m,\lambda}[\Psi] \neq 0$ are recorded (`python-pairing.json`, check `T1.metric.commuting.negative_controls`). The partner has $\rho' = -\rho$ and $p'_\mu = -p_\mu$, so every equation-of-state ratio $w = p/\rho$ is the same for both members.

20.6 What is proved (2): theorem T2, the quantum reading Q and theorem T3

Theorem T2 (the mirror pairing). Hypotheses (`pairing-theory.json`, theorem T2): n is a space-like frame direction (x_0, x_1, x_2 or x_3); in a general field the frame is reflected, $e' = R_n e$, where R_n is the 8×8 diagonal matrix with -1 in place n (this is the same metric, because $R_n \eta R_n = \eta$), and $\Psi' = \gamma^{(n)}\Psi$ at the same point; in the author's field the reflection of x_0 is the mirror $x_0 \to \pi/(6H) - x_0$, that is $z \to \pi - z$, across the brane, with the ASSUMED Z2 construction; both statistics; $U(S) = \frac{\lambda}{2}S^2$. Statement: $\mathcal{L}_{m,\lambda}[\gamma^{(n)}\Psi; R_n e] = +\mathcal{L}_{-m,\lambda}[\Psi; e]$; $S' = -S$; Ψ solves the $(-m, \lambda)$ equation exactly when its image solves the (m, λ) equation; in the author's field the image carries, at the mirror point, the pulled-back tensor $T' = R_0 T R_0$ and the current $J' = R_0 J$: the energy density and the charge are EQUAL, not opposite.

The proof, derived here line by line. First, the charge matrix obeys $C\gamma^{(n)}C^{-1} = -(\gamma^{(n)})^T$ (Chapter 5), that is $(\gamma^{(n)})^T C = -C\gamma^{(n)}$, so

$$\overline{\gamma^{(n)}\Psi} = \Psi^\dagger (\gamma^{(n)})^T C = -\Psi^\dagger C \gamma^{(n)} = -\bar{\Psi}\gamma^{(n)}.$$

The first equality uses that $\gamma^{(n)}$ is real, so $(\gamma^{(n)})^\dagger = (\gamma^{(n)})^T$; the second is the relation just quoted. Then

$$S[\gamma^{(n)}\Psi] = -\bar{\Psi}\gamma^{(n)}\gamma^{(n)}\Psi = -\eta_{nn}S[\Psi] = -S[\Psi],$$

because $(\gamma^{(n)})^2 = \eta_{nn} I_{16}$ and $\eta_{nn} = +1$ for a space-like n. Second, in the reflected frame the curved gammas are $\gamma'^{\mu} = \gamma^{(\mu)}/f_\mu$ for $\mu \neq n$ and $-\gamma^{(n)}/f_n$ for $\mu = n$. Moving $\gamma^{(n)}$ through them,

$$\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)} = -\eta_{nn}\gamma^{\mu} \quad \text{for every } \mu,$$

because for $\mu \neq n$ one exchange gives -1 and $(\gamma^{(n)})^2 = \eta_{nn}$, and for $\mu = n$ the sign of the reflected frame gives the -1. Third, the covariant derivative of the image in the reflected frame is the image of the covariant derivative, $D'_\mu(\gamma^{(n)}\Psi) = \gamma^{(n)} D_\mu \Psi$ (the reflected-connection lemma). Its proof, line by line ($(\gamma^{(n)})^{-1} = \eta_{nn}\gamma^{(n)}$, because $(\gamma^{(n)})^2 = \eta_{nn} I_{16}$):

1. For $a \neq n$, $\gamma^{(n)}\gamma^{(a)}(\gamma^{(n)})^{-1} = -\gamma^{(a)}$ (one exchange); for $a = n$ it is $+\gamma^{(n)}$. Both cases together: $\gamma^{(n)}\gamma^{(a)}(\gamma^{(n)})^{-1} = -(R_n)^a{}_a\gamma^{(a)}$, since $(R_n)^a{}_a$ is -1 for $a = n$ and $+1$ otherwise.
2. $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$ contains two gammas, and inserting $(\gamma^{(n)})^{-1}\gamma^{(n)} = I_{16}$ between them gives $\gamma^{(n)}S^{ab}(\gamma^{(n)})^{-1} = (-1)^2(R_n)^a{}_a(R_n)^b{}_b S^{ab}$ (no sum), that is, S^{ab} for $a, b \neq n$ and $-S^{ab}$ when exactly one of a, b is n.
3. The reflected frame $e' = R_n e$ is the old frame with one leg reversed, by a constant matrix; its spin connection is therefore $\omega'_{\mu ab} = (R_n)^a{}_a(R_n)^b{}_b\,\omega_{\mu ab}$ (no sum): the components with exactly one index n change sign, the others do not.
4. So in $\Omega'_\mu = \frac{1}{2}\omega'_{\mu ab}S^{ab}$ each term carries the same sign as in line 2: $\Omega'_\mu = \gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1}$.
5. Hence $D'_\mu(\gamma^{(n)}\Psi) = \partial_\mu(\gamma^{(n)}\Psi) + \gamma^{(n)}\Omega_\mu(\gamma^{(n)})^{-1}\gamma^{(n)}\Psi = \gamma^{(n)}(\partial_\mu\Psi + \Omega_\mu\Psi) = \gamma^{(n)}D_\mu\Psi$, because $\gamma^{(n)}$ is a constant matrix. In the same way $D'_\mu(\overline{\gamma^{(n)}\Psi}) = -(D_\mu\bar{\Psi})\gamma^{(n)}$.

Hence

$$\overline{\gamma^{(n)}\Psi}\,\gamma'^{\mu}D'_\mu(\gamma^{(n)}\Psi) = -\bar{\Psi}\,\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)}\,D_\mu\Psi = \eta_{nn}\,\bar{\Psi}\gamma^{\mu}D_\mu\Psi,$$

so $K' = K$ for a space-like n, while $S' = -S$. Inserting both into the Lagrangian,

$$\mathcal{L}_{m,\lambda}[\Psi'; e'] = \sqrt{|g|}\,[K - m(-S) - \tfrac{\lambda}{2}(-S)^2] = \sqrt{|g|}\,[K - (-m)S - \tfrac{\lambda}{2}S^2] = \mathcal{L}_{-m,\lambda}[\Psi; e],$$

where the middle step uses $(-S)^2 = S^2$: the mass changes sign, the coupling does not, and the Lagrangian keeps its sign. The field equation follows in the same way. Multiplying $\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)} = -\eta_{nn}\gamma^{\mu}$ on the left by $(\gamma^{(n)})^{-1} = \eta_{nn}\gamma^{(n)}$ gives $\gamma'^{\mu}\gamma^{(n)} = -\gamma^{(n)}\gamma^{\mu}$ (because $\eta_{nn}^2 = 1$), so, with $S' = -S$ and the lemma,

$$E'_{m,\lambda}[\gamma^{(n)}\Psi] = \gamma'^{\mu}\gamma^{(n)}D_\mu\Psi - (m - \lambda S)\gamma^{(n)}\Psi = -\gamma^{(n)}\big[\gamma^{\mu}D_\mu\Psi - (-m + \lambda S)\Psi\big] = -\gamma^{(n)}E_{-m,\lambda}[\Psi],$$

and since $\gamma^{(n)}$ is invertible, the image solves the (m,λ) equation exactly when Ψ solves the $(-m,\lambda)$ equation. For the current, with the adjoint $\overline{\gamma^{(n)}\Psi} = -\bar{\Psi}\gamma^{(n)}$ found first and $\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)} = -\gamma^{\mu}$ for a space-like n,

$$J'^{\mu} = -i\,\overline{\gamma^{(n)}\Psi}\,\gamma'^{\mu}\gamma^{(n)}\Psi = +i\,\bar{\Psi}\,\gamma^{(n)}\gamma'^{\mu}\gamma^{(n)}\,\Psi = -i\bar{\Psi}\gamma^{\mu}\Psi = J^{\mu};$$

each kinetic term of $T_{\mu\nu}$ is unchanged in the same way (with the lemma for the derivatives), and so is $\mathcal{L}/\sqrt{|g|}$ by the Lagrangian line, so $T'_{\mu\nu} = T_{\mu\nu}$ in the reflected frame. In the author's field the mirror $z \to \pi - z$ leaves every metric component unchanged ($\sin(\pi - z) = \sin z$ and $\cot^2(\pi - z) = \cot^2 z$), and its pulled-back positive vielbein is $R_0 e$; this turns the frame statement into the mirror statement. Status: PROVED; the Z2 construction across the brane is ASSUMED, the metric is degenerate at the brane, and no junction condition there is derived. Records: the Wolfram pairing report has 28 checks of T2 and the sympy pairing report 16; among them:

statement	**report**	**check**
the mirror is an isometry	`wolfram-pairing.json`	`T2_mirror_is_isometry`
the same, independently	`python-pairing.json`	`geometry.mirror_isometry`

Notebooks 20a (In [9] and In [11]) and 20b (In [9]) reproduce them.

The quantum reading Q (dirac16complex only). The quantised field obeys the canonical anticommutator $\{\Psi_A(x), \Psi^{\dagger}_B(y)\} = B_{AB}\,\delta^7(x-y)/\sqrt{|g|}$ on a slice $x_4 = \text{const}$ (Chapter 10). For the T1 image,

$$\{(\Gamma\Psi)_A, (\Gamma\Psi)^{\dagger}_B\} = (\Gamma B \Gamma^{\dagger})_{AB}\,\frac{\delta^7}{\sqrt{|g|}} = -B_{AB}\,\frac{\delta^7}{\sqrt{|g|}},$$

because the anticommutator is linear in each argument and

$$\Gamma B \Gamma = -i\,\Gamma C \gamma^{(x_4)} \Gamma = -i\,C\,\Gamma\gamma^{(x_4)}\Gamma = -i\,C(-\gamma^{(x_4)}) = -B,$$

by step 2 and then step 1 of Section 20.5. The statements (`pairing-theory.json`, theorem Q): (Q1) the T1 image carries the Krein metric $-B$, which is also what its own Lagrangian demands; (Q2) its generators coincide with those of Ψ: Ψ and $\Gamma\Psi$ are ONE quantum system

relabelled, and the T1 identity $T' = -T$ is an identity between operators of that one system; (Q3) an independently quantised $(-m, -\lambda)$ universe has the anticommutator $+B$, cannot be identified with $\Gamma\Psi$, and on the product of the two state spaces the generators ADD, so no cancellation follows; (Q4) the one-particle ($\lambda = 0$) spectra of $+m$ and $-m$ are IDENTICAL (similar matrices, $\Gamma h_m \Gamma = h_{-m}$), in flat 4+4 space or in a general field at a point with frozen coefficients (the coefficients of the equation taken constant, equal to their values at that point); (Q5) the T2 image keeps $+B$ ($\gamma^{(x_0)} B \gamma^{(x_0)\dagger} = +B$): the mirror universe is an ordinary, independently quantisable copy with equal energies. Records: `wolfram-pairing.json`, `Q_Krein_metric_of_images`, `Q_no_identification_of_independent_universes`, `Q_one_particle_maps` (12 Q checks); `python-pairing.json`, `Q.no_cancellation_independent_universes`, `Q.T2_image_keeps_B` (10 Q checks). Status: PROVED. The quantum reading therefore removes the one place where a zero total could have looked like "a pair that costs nothing": for two independent quantum universes the energies do not cancel.

Theorem T3 (the Kohn-Sham level, dirac16complex). At the level of the Kohn-Sham model of Chapters 14 and 15 (instantaneous mean-field states at a fixed slice $a_{4,0}$ of the deflating history, good sector, Hartree plus the exact uniform-gas exchange), the block map of Γ, with the two brane parities exchanged and the tip angle $\theta \to \pi - \theta$, maps every self-consistent Kohn-Sham state with (m, λ, θ) onto one with $(-m, +\lambda, \pi - \theta)$, with equal levels, occupations, Kohn-Sham energy, grand potential and energy-momentum profiles, and $S \to -S$ (`t3-theory.json`; `wolfram-t3.json` 10 of 10 and `python-t3.json` 13 of 13 checks PASS). The Z2 brane is ASSUMED; the tip condition is a choice and must be transformed; in its parameters the map is of the T2 type (equal energies), although its matrix is the chirality of T1. Status: PROVED under these hypotheses. The proof in outline (`t3-theory.json`, key `proof`; the check names below are those of `wolfram-t3.json`, and `python-t3.json` has the same checks with a dot after `T3`; Chapter 19 gives the proof line by line and runs the Rust solver for both members): the 2×2 block form of Γ maps each block Hamiltonian with the effective mass M_{eff} onto the block Hamiltonian of the other block with $-M_{\text{eff}}$ at the same level (check `T3_block_hamiltonian_map`); it turns the tip condition with angle θ into the one with $\pi - \theta$ and exchanges the brane parities (checks `T3_tip_condition_map`, `T3_brane_parities_exchanged`); the densities that enter the energies are even under the map and S is odd, so $M_{\text{eff}} \to -M_{\text{eff}}$ exactly when $(m, \lambda) \to (-m, +\lambda)$ (checks `T3_orbital_densities`, `T3_mean_field_map`); a one-to-one map between the orbitals with equal levels then gives equal occupations, energies and energy-momentum profiles (check `T3_energies_and_emt_profiles_equal`). T3's own list of what it does not establish begins with "No creation process, rate or amplitude" and adds: instantaneous states only (the time-dependent problem is OPEN), the brane ASSUMED, mean-field level only, and no back-reaction.

20.7 Corollary C1, line by line

Hypotheses (`Revision/docs/PAIR_CREATION_PROOFS.md`, section 7). (i) The gravitational field is the author's metric with the Einstein-Lovelock equations $\sum_{k=1}^{3} \alpha_k E_{(k)}{}^{\mu}{}_{\nu} + \Lambda \delta^{\mu}_{\nu} = \kappa T^{\mu}{}_{\nu}$. (ii) The complete source is the sum of the classical energy-momentum tensors of the two members of a T1 pair at the same points of the same patch. (iii) Nothing else sources the metric.

Statement. The source vanishes, so a_4 must solve the vacuum equations. (a) In Einstein gravity they have no real solution for $H > 0$ and any Λ. (b) In Einstein-Lovelock gravity the linear member $a_4 = AHx_4 + a_0$ is a vacuum exactly when the vacuum factor V vanishes, where

$$V = \alpha_1 - 40\alpha_2 H^2 - 8A^2\alpha_2 H^2 + 360\alpha_3 H^4 + 144A^2\alpha_3 H^4 + 72A^4\alpha_3 H^4.$$

Proof of (a), line by line.

1. By hypothesis (ii) the source is $T^{\mu}{}_{\nu}[\Psi; m, \lambda] + T^{\mu}{}_{\nu}[\Gamma\Psi; -m, -\lambda]$.
2. By (T1c) the second term is minus the first, so the source is zero at every point.
3. With $\alpha_1 = 1$ and $\alpha_2 = \alpha_3 = 0$ the field equations become $G^{\mu}{}_{\nu} + \Lambda\delta^{\mu}_{\nu} = 0$.
4. The record gives $G^{x_4}{}_{x_4} = 3a_4'^2 + 21H^2$ and $G^{x_0}{}_{x_0} = -3a_4'^2 + 15H^2$ (`python-a4-report.json`, check `einstein_components`), so two of the equations read $3a_4'^2 + 21H^2 + \Lambda = 0$ and $-3a_4'^2 + 15H^2 + \Lambda = 0$.
5. Subtracting the second from the first removes Λ: $6a_4'^2 + 6H^2 = 0$.
6. For a real function a_4 the left side is at least $6H^2$, which is positive for $H > 0$; line 5 is false, so no real a_4 solves the equations. QED.

Adding the two equations of line 4 instead gives $36H^2 + 2\Lambda = 0$, so a solution would need $\Lambda = -18H^2$ and $a_4'^2 = -H^2$, that is $a_4' = \pm iH$: not a real rate. The other two independent equations, $15H^2 - 3a_4'^2 \pm a_4'' + \Lambda = 0$ for 3-space (+) and the extra times (−), then give $a_4'' = 0$. Records: `wolfram-a4-report.json`, check `einstein_no_vacuum_solution`; `python-a4-report.json`, check `einstein_no_vacuum`; `einstein-gauss-bonnet-a4.json`, check `no_vacuum_for_H_positive`. Notebook 20a, In [12], derives all of this with sympy from the record's components.

What the geometry requires of any source. With a source, the x_4 and x_0 equations read $\sum_k \alpha_k E_{(k)}{}^{x_4}{}_{x_4} + \Lambda = -\kappa\rho$ and $\sum_k \alpha_k E_{(k)}{}^{x_0}{}_{x_0} + \Lambda = \kappa p_0$, because $T^{x_4}{}_{x_4} = -\rho$ and $T^{x_0}{}_{x_0} = p_0$. Subtracting the first from the second:

$$\sum_k \alpha_k \left(E_{(k)}{}^{x_0}{}_{x_0} - E_{(k)}{}^{x_4}{}_{x_4}\right) = \kappa p_0 + \kappa\rho.$$

Λ cancels in the difference. So every source must have the null combination

$$\kappa(\rho + p_0) = -\sum_k \alpha_k \left(E_{(k)}{}^{x_4}{}_{x_4} - E_{(k)}{}^{x_0}{}_{x_0}\right).$$

In Einstein gravity, with the components of line 4,

$$\kappa(\rho + p_0) = -\left(3a_4'^2 + 21H^2 + 3a_4'^2 - 15H^2\right) = -6(a_4'^2 + H^2) \le -6H^2 < 0.$$

The first equality inserts the components; the second collects the terms; the inequality holds because $a_4'^2 \ge 0$ (`python-a4-report.json` and `wolfram-a4-report.json`, check `einstein_null_energy_x0`). A T1 pair supplies $\rho + p_0 = 0$, which is never $\le -6H^2$: this is C1(a) once more, now as a statement about the source.

Proof of (b), line by line. For the linear member $a_4' = AH$ the record writes the right-hand side as $-6(A^2 + 1)H^2 V$ with the vacuum factor V above (`wolfram-a4-report.json` and

`python-a4-report.json`, check `linear_member_vacuum_factor`). A vacuum has $\rho = p_0 = 0$, and $6(A^2+1)H^2 > 0$, so it needs $V = 0$. In Einstein-Gauss-Bonnet gravity ($\alpha_1 = 1$, $\alpha_3 = 0$):

$$V = 1 - 40\alpha_2 H^2 - 8A^2\alpha_2 H^2 = 1 - 8\alpha_2 H^2(A^2+5).$$

The terms with α_3 vanish, and $40 = 8 \cdot 5$ lets us take out $8\alpha_2 H^2$. Setting $V = 0$ and adding $8\alpha_2 H^2(A^2+5)$ to both sides:

$$8\alpha_2 H^2(A^2+5) = 1.$$

Dividing by $8\alpha_2 H^2$ (not zero) and subtracting 5:

$$A^2 = \frac{1}{8\alpha_2 H^2} - 5 = \frac{1 - 40\alpha_2 H^2}{8\alpha_2 H^2}.$$

The last step writes 5 as $40\alpha_2 H^2/(8\alpha_2 H^2)$. The right side is not negative exactly when $0 < \alpha_2 H^2 \leq 1/40$; at $1/40$ the vacuum has $A = 0$, so a_4 is constant and neither 3-space nor the extra times change; the author's deflating history needs $A > 0$. For the author's history $A = 1$: $8\alpha_2 H^2 \cdot 6 = 1$, so

$$\alpha_2 H^2 = \tfrac{1}{48}.$$

The cosmological constant follows from the x_4 equation with $\rho = 0$: $\Lambda = -\sum_k \alpha_k {E_{(k)}}^{x_4}{}_{x_4}$. We need the two components at $a_4' = AH$ with $A = 1$. The Einstein part is ${E_{(1)}}^{x_4}{}_{x_4} = {G}^{x_4}{}_{x_4} = 3a_4'^2 + 21H^2 = 3H^2 + 21H^2 = 24H^2$ (line 4 above with $a_4' = H$). For the Gauss-Bonnet part we use the x_4 equation once more: it says $\kappa\rho = -\sum_k \alpha_k {E_{(k)}}^{x_4}{}_{x_4} - \Lambda$, so the part of $\kappa\rho$ that multiplies α_2 is $-{E_{(2)}}^{x_4}{}_{x_4}$, and the record gives that part as $(36A^4 + 120A^2 + 420)H^4$ (`einstein-gauss-bonnet-a4.json`, check `gauss_bonnet_rho_alpha2`, which compares the record with the classical Gauss-Bonnet formula). Hence ${E_{(2)}}^{x_4}{}_{x_4} = -(36 + 120 + 420)H^4 = -576H^4$ at $A = 1$. Therefore

$$\Lambda = -\Big(24H^2 + \frac{1}{48H^2}(-576H^4)\Big) = -24H^2 + 12H^2 = -12H^2.$$

The first equality inserts $\alpha_2 = 1/(48H^2)$; the second uses $576/48 = 12$. Notebook 20a (In [16]) checks exactly that with these values all four independent vacuum equations hold for $a_4 = Hx_4$ (`python-a4-report.json` and `wolfram-a4-report.json`, check `einstein_gauss_bonnet_vacuum_linear`). With the third coupling, $V = 0$ is linear in $x = \alpha_2 H^2$ and $y = \alpha_3 H^4$ for a fixed slope A; collecting the terms with y on one side,

$$y\,(72A^4 + 144A^2 + 360) = (8A^2 + 40)\,x - 1, \qquad y = \frac{(8A^2+40)x - 1}{72A^4 + 144A^2 + 360},$$

a straight line in the plane of the two couplings; Einstein gravity ($x = y = 0$, $V = 1$) lies on none of these lines.

What C1 says, and what it does not say. PROVED: a T1 pair as the only source of the author's metric is a zero source; in Einstein gravity the metric then has no solution for $H > 0$, whatever

a_4 and Λ. PROVED: in Einstein-Gauss-Bonnet gravity with $\alpha_2 H^2 = 1/48$ and $\Lambda = -12H^2$ the author's deflating history IS a vacuum, so C1(a) depends on Einstein gravity. C1 does not apply to T2 pairs: the mirror copy carries the pulled-back, EQUAL tensor, so the sources add. C1 does not apply to two independently quantised universes (statement Q3). And C1 is not a creation statement: it compares two sources in ONE given geometry and derives no process, rate or amplitude. In Einstein gravity it says the opposite of "a pair makes the universe": a T1 pair alone cannot be the source of the author's metric at all.

With the second function b_4. The records state C1 on the background $b_4 = 1$; C1(a) holds for every $b_4(x_4)$. A zero source has $T^{x_4}{}_{x_0} = 0$, and in Einstein gravity the mixed component of the metric with b_4 is $G^{x_4}{}_{x_0} = \frac{3}{2} H \cot z \, b_4'/b_4$, so the mixed equation forces $b_4' = 0$ (`wolfram-a4-report.json`, check `b4_einstein_offdiagonal_forces_b4_constant`). A constant b_4 is the rescaling $x_{5,6,7} \to \sqrt{b_4}\, x_{5,6,7}$ of the extra times, which changes none of the components used in lines 3 to 6, so the proof of (a) applies unchanged. For the Einstein-Lovelock weights of the author's notebook, $w_1 = 1$, $w_2 = 1/32$, $w_3 = 1/1152$ and the author's $\Lambda = 10$ (in units $H = 1$: $\alpha_k = w_k$, and $\Lambda = -10$ in the convention of this chapter), the record proves that every vacuum of the metric with b_4 has a constant b_4 and $a_4 = \pm H x_4 + \text{const}$ (`Revision/metric_b4/results/vacuum-b4.json`; `wolfram-a4-report.json`, check `b4_author_weights_vacuum`). This is the case (b) of C1: with these weights $V = 1 - 48/32 + 576/1152 = 0$ at $A = 1$, so the author's deflating history is a vacuum of the author's own weights, and a T1 pair as the only source is compatible with it.

20.8 Example: corollary C1 made visible

Notebook 20a turns every line of Sections 20.5 and 20.7 into a computation. It reads the author's gamma matrices, builds C, Γ and the generators S^{ab}, and computes with sympy the canonical spin connection of the author's metric on the patch and on the mirror patch; it reproduces the record's twelve components and $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$, and finds $-3H\gamma^{(x_0)}$ on the mirror patch (a computation of this book, not a record). It then takes an arbitrary configuration of dirac16complex00 at one point of the deflating history, evaluates its 64-component energy-momentum tensor, its current and its field equation, and does the same for its T1 partner and its T2 mirror copy: the T1 pair cancels component by component, the T2 pair does not. Finally it derives the vacuum equations of Einstein and Einstein-Lovelock gravity from the record's Lovelock tensors and draws why Einstein gravity has no vacuum and which couplings do. It prints 37 PASS lines, 25 of which reproduce a named check of a Revision report, and draws seven figures. It needs numpy, sympy and matplotlib, no Rust, and runs in about 30 seconds (its recorded check run on the build computer took 16.1 seconds; the notebook's provenance file, which lies next to it, records every run).

20.9 How to run Notebook 20a

Step 1. What this notebook does and what it needs.

Notebook 20a (Corollary C1: a T1 pair as the only source of the author's metric) is the file `Revision/textbook/notebooks/20a_c1_zero_source.ipynb` of the repository Dirac_claude. It reads the author's gamma matrices and builds the canonical spin connection of the author's metric on the patch and on the mirror patch of the hidden direction; it evaluates the energy-momentum tensor, the current and the field equation of a configuration of dirac16complex00 and of its two partners, the T1 partner Gamma Psi with mass and coupling reversed and the T2 mirror copy across the

Z2 brane, and shows that the T1 pair has zero total source at every point while the T2 pair has twice the source of one member; it then derives with sympy, from the Revision record of the field equations for a4, that the zero source has no solution in Einstein gravity for H greater than 0 and any cosmological constant, and which Einstein-Lovelock couplings admit the linear member a4 = A H x4 as a vacuum. It reproduces the Revision records where they overlap and draws seven teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 20a_c1_zero_source.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 20a_c1_zero_source.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 20a_c1_zero_source.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/20a.captions.json`
- `Revision/textbook/figures/20a_1_t1_pair_tensor.png`
- `Revision/textbook/figures/20a_2_pair_profiles.png`
- `Revision/textbook/figures/20a_3_t2_mirror_tensor.png`
- `Revision/textbook/figures/20a_4_einstein_vacuum_parabolas.png`
- `Revision/textbook/figures/20a_5_null_combination.png`
- `Revision/textbook/figures/20a_6_gauss_bonnet_vacuum.png`
- `Revision/textbook/figures/20a_7_third_order_vacua.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 20a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/20a_c1_zero_source.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 20a_c1_zero_source.ipynb
python -m nbconvert --execute --inplace 20a_c1_zero_source.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads nine files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

20.10 Notebook 20a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/20a_c1_zero_source.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The pairing theorem T1 says that the field $\Gamma\Psi$ with the mass $-m$ and the
coupling $-\lambda$ carries exactly MINUS the energy-momentum tensor and MINUS the
current of the field $\Psi$ with $(m, \lambda)$, at every point of every
gravitational field. The Revision record draws one consequence for gravity, the
corollary **C1**: if such a pair is the ONLY source of the author's metric, the
source is zero, and in Einstein gravity the author's metric then has no solution
at all for $H > 0$. This notebook makes every step of C1 visible:

- it rebuilds the canonical spin connection of the author's metric (on the patch
  $0 < z < \pi/2$ of the hidden direction and on the mirror patch
  $\pi/2 < z < \pi$) and reproduces the record's twelve components and the term
  $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$;
- it evaluates, for a configuration of the commuting field dirac16complex00, the
  energy-momentum tensor (all 64 components), the current and the field equation,
  and the same for its T1 partner $\Gamma\Psi$: the totals vanish at every point
  (two figures);
- it does the same for the T2 mirror copy across the Z2 brane $z = \pi/2$: there
  the tensor is EQUAL (pulled back), so the T2 pair does NOT cancel (two figures);
- it derives with sympy, from the record's components of the Einstein tensor,
  that the vacuum equations (zero source) have no real solution, and draws why
  (two figures);
- it shows which Einstein-Lovelock couplings admit the deflating linear member
  $a_4 = AHx_4$ as a vacuum, so that a T1 pair could live in it (two figures);
- it ends with a precise list of what C1 says and what it does not say.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 20a (Corollary C1: a T1 pair as the only source of the author's metric) is the
file `Revision/textbook/notebooks/20a_c1_zero_source.ipynb` of the repository
Dirac_claude. It reads the author's gamma matrices and builds the canonical spin
connection of the author's metric on the patch and on the mirror patch of the hidden
direction; it evaluates the energy-momentum tensor, the current and the field equation of
a configuration of dirac16complex00 and of its two partners, the T1 partner Gamma Psi
with mass and coupling reversed and the T2 mirror copy across the Z2 brane, and shows
that the T1 pair has zero total source at every point while the T2 pair has twice the
```

source of one member; it then derives with sympy, from the Revision record of the field equations for a4, that the zero source has no solution in Einstein gravity for H greater than 0 and any cosmological constant, and which Einstein-Lovelock couplings admit the linear member a4 = A H x4 as a vacuum. It reproduces the Revision records where they overlap and draws seven teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 20a_c1_zero_source.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 20a_c1_zero_source.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the

name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 20a_c1_zero_source.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/20a.captions.json‘
- ‘Revision/textbook/figures/20a_1_t1_pair_tensor.png‘
- ‘Revision/textbook/figures/20a_2_pair_profiles.png‘
- ‘Revision/textbook/figures/20a_3_t2_mirror_tensor.png‘
- ‘Revision/textbook/figures/20a_4_einstein_vacuum_parabolas.png‘
- ‘Revision/textbook/figures/20a_5_null_combination.png‘
- ‘Revision/textbook/figures/20a_6_gauss_bonnet_vacuum.png‘
- ‘Revision/textbook/figures/20a_7_third_order_vacua.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 20a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/20a_c1_zero_source.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use

  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 20a_c1_zero_source.ipynb
python -m nbconvert --execute --inplace 20a_c1_zero_source.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads nine files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 20a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 20a (Corollary C1: a T1 pair as the only source of the author's metric) is the
# file Revision/textbook/notebooks/20a_c1_zero_source.ipynb of the repository
# Dirac_claude. It reads the author's gamma matrices and builds the canonical spin
# connection of the author's metric on the patch and on the mirror patch of the hidden
# direction; it evaluates the energy-momentum tensor, the current and the field equation
# of a configuration of dirac16complex00 and of its two partners, the T1 partner Gamma
# Psi with mass and coupling reversed and the T2 mirror copy across the Z2 brane, and
# shows that the T1 pair has zero total source at every point while the T2 pair has twice
# the source of one member; it then derives with sympy, from the Revision record of the
# field equations for a4, that the zero source has no solution in Einstein gravity for H
# greater than 0 and any cosmological constant, and which Einstein-Lovelock couplings
# admit the linear member a4 = A H x4 as a vacuum. It reproduces the Revision records
# where they overlap and draws seven teaching figures. It needs a computer with Windows
```

```
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
```

```
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
```

```
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 20a_c1_zero_source.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 20a_c1_zero_source.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 20a_c1_zero_source.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/20a.captions.json
# - Revision/textbook/figures/20a_1_t1_pair_tensor.png
# - Revision/textbook/figures/20a_2_pair_profiles.png
# - Revision/textbook/figures/20a_3_t2_mirror_tensor.png
# - Revision/textbook/figures/20a_4_einstein_vacuum_parabolas.png
# - Revision/textbook/figures/20a_5_null_combination.png
# - Revision/textbook/figures/20a_6_gauss_bonnet_vacuum.png
```

```
# - Revision/textbook/figures/20a_7_third_order_vacua.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 37 CHECKS PASSED (notebook 20a)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/20a_c1_zero_source.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 20a_c1_zero_source.ipynb
#     python -m nbconvert --execute --inplace 20a_c1_zero_source.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
```

```
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file below the folder Revision: the notebook reads nine
#   files of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository made with git clone
#   (a notebook copied alone to another folder cannot find them).
#

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$ (the author's names): $x_1, x_2, x_3$ ordinary
  3-space (inflating), $x_4$ the time, $x_5, x_6, x_7$ the three EXTRA TIMES (they
  deflate exponentially: their scale factor is $e^{-a_4}\sin^{1/6}z$ with $a_4$
  increasing), $x_0$ the hidden space direction with $z = 6Hx_0$. In the code the
  positions 0 to 7 of a list stand for $x_0$ to $x_7$.
- **Patch and mirror patch**: the author's metric is used on $0 < z < \pi/2$ (the
  patch). The map $z \to \pi - z$ carries it onto $\pi/2 < z < \pi$ (the mirror
  patch). The surface $z = \pi/2$ between them is called the **brane**; extending
  the field across it (the Z2 construction) is an ASSUMPTION of the record.
- **Gamma matrices** $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$: the author's real
  $16 \times 16$ matrices with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}
  = 2\eta^{ab}$, $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$.
- **$C$** $= \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$; the adjoint
  is $\bar\Psi = \Psi^\dagger C$. **Chirality** $\Gamma = \gamma^{(x_0)}
  \gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$.
- **Configuration**: a field $\Psi$ given by its 16 complex values and their 8
  first derivatives at a point (its first **jet**). A configuration need not solve
  the field equation; it is **on shell** when it does, **off shell** otherwise.
- **Pair** (in this notebook): a configuration together with a partner.
  **T1 partner**: $\Gamma\Psi$ with $(-m, -\lambda)$, at the same point.
  **T2 mirror copy**: $\gamma^{(x_0)}\Psi$ with $(-m, \lambda)$, placed at the
  mirror point $\pi - z$.
- **Energy-momentum tensor** $T_{\mu\nu}$: the source of gravity, 64 numbers at
```

  each point. **Energy density** ρ, **current** $J^\mu = -i\bar\Psi\gamma^\mu
  \Psi$, **charge density** $J^{x_4} = \Psi^\dagger B\Psi$.
- **Einstein tensor** $G^\mu{}_\nu$; **Lovelock tensors** $E_{(k)}{}^\mu{}_\nu$,
  $k = 1, 2, 3$ ($E_{(1)} = G$); couplings $\alpha_1, \alpha_2, \alpha_3$;
  cosmological constant Λ; gravitational coupling κ.
- **Vacuum equations**: the field equations of gravity with zero source,
  $\sum_k\alpha_kE_{(k)}{}^\mu{}_\nu + \Lambda\delta^\mu_\nu = 0$.
- **Linear member**: $a_4 = AHx_4 + a_0$; for $A > 0$ the extra times deflate as
  e^{-AHx_4} while 3-space inflates as e^{AHx_4}. The author's history is
  $A = 1$.
- **Null combination** $\rho + p_0$: the energy density plus the pressure along
  x_0.
- **Corollary**: a statement that follows from a theorem in a few lines.

Text cell:

```
## 4. The physical and mathematical situation

Both fields of the theory have the Lagrangian density
$\mathcal{L}_{m,\lambda} = \sqrt{|g|}\,[K - mS - \tfrac\lambda2S^2]$ with
$K = \tfrac12(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi)$ and
$S = \bar\Psi\Psi$. The pairing records use the energy-momentum tensor

$$T_{\mu\nu} = \tfrac14\big(\bar\Psi\gamma_\mu D_\nu\Psi + \bar\Psi\gamma_\nu D_\mu
\Psi - (D_\mu\bar\Psi)\gamma_\nu\Psi - (D_\nu\bar\Psi)\gamma_\mu\Psi\big)
- g_{\mu\nu}\,\mathcal{L}/\sqrt{|g|},$$

which is minus the tensor of the field-theory record; every statement below is
linear in $T$, so its sign convention does not matter. With it the energy
density is $\rho = -T_{x_4x_4}$.

**Theorem T1, part (T1c)** (PROVED in the Revision record):
$T^{(-m,-\lambda)}_{\mu\nu}[\Gamma\Psi] = -T^{(m,\lambda)}_{\mu\nu}[\Psi]$ and
$J^\mu[\Gamma\Psi] = -J^\mu[\Psi]$ at every point, off and on shell, in every
gravitational field, for both fields.

**Corollary C1** (PROVED in the record). *Hypotheses:* (i) the gravitational field
is the author's metric with the Einstein-Lovelock equations
$\sum_{k=1}^3\alpha_kE_{(k)}{}^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa
T^\mu{}_\nu$; (ii) the complete source is the sum of the classical tensors of the
two members of a T1 pair at the same points of the same patch; (iii) nothing else
sources the metric. *Statement:* the source vanishes, so $a_4$ must solve the
vacuum equations; (a) in Einstein gravity ($\alpha_1 = 1$, $\alpha_2 = \alpha_3 =
0$) these have no real solution for $H > 0$ and any $\Lambda$; (b) in
Einstein-Lovelock gravity the linear member needs $V = 0$ (the vacuum factor of
section 12).

**Proof of (a), line by line.**

1. By hypothesis (ii) the source is $T^\mu{}_\nu[\Psi; m, \lambda] +
   T^\mu{}_\nu[\Gamma\Psi; -m, -\lambda]$.
2. By (T1c) the second term is minus the first, so the source is $0$.
3. The field equations become $G^\mu{}_\nu + \Lambda\delta^\mu_\nu = 0$.
```

```
4. The record gives $G^{x_4}{}_{x_4} = 3a_4'^2 + 21H^2$ and
   $G^{x_0}{}_{x_0} = -3a_4'^2 + 15H^2$, so two of the equations read
   $3a_4'^2 + 21H^2 + \Lambda = 0$ and $-3a_4'^2 + 15H^2 + \Lambda = 0$.
5. Subtracting the second from the first removes $\Lambda$:
   $6a_4'^2 + 6H^2 = 0$.
6. For a real function $a_4$ the left side is at least $6H^2$, which is positive
   for $H > 0$. Line 5 is false, so no real $a_4$ solves the equations.

Sections 5 to 10 below check lines 1 and 2 numerically, point by point; sections
11 to 14 check lines 3 to 6 and part (b) with sympy.

**Status words.** PROVED: an exact statement with a proof (the record's, or this
notebook's exact computation). COMPUTED: a floating-point result with its error.
ASSUMED: a hypothesis. The Z2 brane and the mirror patch are ASSUMED.
```

```
## 5. The Revision records this notebook reproduces

The next cell defines three helpers: ‘read_json‘ reads a JSON file of the
repository; ‘record_verdict‘ finds a check by its name in a Revision report and
returns its verdict; ‘reproduces‘ is a check that passes only when this notebook's
own result holds AND the named record check has the verdict PASS (it prints the
two lines PASS and reproduces together). Then it reads the sentence of the
record's document that states C1, and the counts of the two pairing reports.
```

## 6. The author's gamma matrices, $C$ and the chirality $\Gamma$

The next cell reads the eight gamma matrices from `gammas.json` (whole numbers,
which `sp.Rational` turns into exact numbers), checks the 64 Clifford relations,
and builds $C$, the chirality $\Gamma$ and the generators
$S^{ab} = \tfrac14[\gamma^{(a)}, \gamma^{(b)}]$. It checks the three facts T1
needs (Lemma 1 of the record): $\Gamma = \mathrm{diag}(-I_8, I_8)$, $\Gamma$
anticommutes with every gamma, and $\Gamma$ commutes with $C$. Finally it makes
floating-point copies (numpy arrays) for the numerical part.
```

## 7. The author's metric and its spin connection, on both patches

The vielbein of the author's diagonal metric (on the background $b_4 = 1$ of the
metric of 2026-10-14) is diagonal, $e^a{}_\mu = E_a\delta^a_\mu$, with the lengths
$E = (s_0\cot z, e^{a_4}s, e^{a_4}s, e^{a_4}s, 1, e^{-a_4}s, e^{-a_4}s, e^{-a_4}s)$
```

```
in the order $x_0, \dots, x_7$, $s = \sin^{1/6}z$. On the patch
$\cot z > 0$ and $s_0 = +1$; on the mirror patch $\cot z < 0$, and its own
positive vielbein has $s_0 = -1$ (the record's construction). The canonical spin
connection is $\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu e_b{}^\nu +
\Gamma^\nu{}_{\mu\lambda}e_b{}^\lambda)$ with the inverse vielbein $e_b{}^\nu =
\delta^\nu_b/E_b$. For $a = b$ the two terms cancel; for $a \neq b$ only the second
survives, and lowering $a$ with $\eta$:

$$\omega_{\mu\,ab} = \eta_{aa}\,\frac{E_a}{E_b}\,\Gamma^a{}_{\mu b}
\qquad (a \neq b).$$

The Christoffel symbols of a diagonal metric are
$\Gamma^a{}_{bc} = (\delta_{ac}\partial_bg_{aa} + \delta_{ab}\partial_cg_{aa} -
\delta_{bc}\partial_ag_{bb})/(2g_{aa})$ (no sum), and $\partial/\partial x_0 =
6H\,\partial/\partial z$ because $z = 6Hx_0$. The next cell computes all
$\omega_{\mu ab}$ with sympy for an arbitrary function $a_4(x_4)$, on both patches;
at a point $a_4$ and $a_4'$ become the numbers `a4_value` and `slope`.
```

## 8. A configuration and its T1 partner at one point

From here on we work with floating-point numbers. The next cell turns the
lengths and the connection into numpy functions (‘sp.lambdify‘) and defines two
helpers. ‘geometry_at(s0, z, a4, a4’, H)‘ returns, at one point, the lengths, the
metric, the eight $\Omega_\mu$ and the curved gammas $\gamma^\mu = \gamma^{(\mu)}/
E_\mu$ and $\gamma_\mu = g_{\mu\mu}\gamma^\mu$. ‘bilinears(at, psi, dpsi, m, lam)‘
evaluates, for the first jet (the value ‘psi‘ and the eight first derivatives
‘dpsi[mu]‘), the quantities of section 4 term by term:
$\bar\Psi = \Psi^\dagger C$, $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$,
$D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, $S$, $K$,
$\mathcal{L}/\sqrt{|g|}$, the 64 components $T_{\mu\nu}$, the current $J^\mu$ and
the field-equation residual $E_{m,\lambda} = \gamma^\mu D_\mu\Psi - (m + \lambda S)
\Psi$ (zero exactly when the configuration solves the field equation).
```

```
The next cell chooses a point on the patch ($z = 0.6$, $a_4 = 0.5$ and
$a_4' = H$: the author's deflating history $A = 1$; units $H = 1$), the mass
$m = 2$ and the coupling $\lambda = 1/2$, and a configuration: 16 complex values
and $8 \times 16$ complex first derivatives drawn by a random-number generator
with a fixed seed (so that every run draws the same numbers). Such a configuration
is in general NOT a solution; T1 is an identity that holds off shell, so it must
hold for it. The partner is $\Gamma\Psi$ (value and derivatives multiplied by
$\Gamma$) with $(-m, -\lambda)$. The cell checks, at this point: the quantities
that must be real are real; $S' = S$, $K' = -K$; every one of the 64 components
of $T + T'$ and the 8 components of $J + J'$ vanish; the field-equation residuals
obey $E_{-m,-\lambda}[\Gamma\Psi] = -\Gamma E_{m,\lambda}[\Psi]$ (so one vanishes
exactly when the other does); and two negative controls (a wrong partner) do NOT
cancel.
```

```
## 9. Along the hidden direction: the T1 partner and the T2 mirror copy

T1 holds at EVERY point. To see it along a line, the next cell uses a field that
varies along the hidden direction, $\Psi(z) = \Psi_0 + \tfrac{3}{10}(\pi/2 - z)^2
\Psi_1$, with the values $\Psi_0$ and the derivatives along $x_1, \dots, x_7$ of
section 8 and a second random spinor $\Psi_1$. Its derivative along $x_0$ is
$\partial_0\Psi = 6H\,d\Psi/dz = -\tfrac{18}{5}H(\pi/2 - z)\Psi_1$; it vanishes at
```

```
the brane like $\pi/2 - z$, which keeps the term
$\tan z\,\gamma^{(x_0)}\partial_0\Psi$ of the field equation finite there (the
factor $\tan z = 1/E_0$ grows without bound at $z = \pi/2$, where
$g_{00} = \cot^2z$ vanishes). The field is not a solution (T1 and T2 hold off
shell). The geometry changes with $z$ through $\sin^{1/6}z$ and $\cot z$. The cell
evaluates three objects:

- the field $\Psi$ with $(m, \lambda)$ on the patch, $0 < z < \pi/2$;
- its T1 partner $\Gamma\Psi$ with $(-m, -\lambda)$ at the same points;
- its T2 mirror copy: by theorem T2 (with $m$ replaced by $-m$), the field
  $\Psi'(\pi - z) = \gamma^{(x_0)}\Psi(z)$ on the mirror patch solves the
  $(-m, \lambda)$ equations if and only if $\Psi$ solves the $(m, \lambda)$
  equations. Its derivatives are $\gamma^{(x_0)}$ times those of $\Psi$, with the
  $x_0$ derivative reversed (the mirror reverses the direction $x_0$).

It computes the energy density $\rho = -T_{x_4x_4}$ and the charge density
$J^{x_4}$ of each, and checks: the T1 partner has $-\rho$ and $-J^{x_4}$; the
mirror copy has, at the mirror point $\pi - z$, the SAME $\rho$ and the SAME
$J^{x_4}$.
```

(Notebook 20a, figure 2.)

```
## 10. The T2 mirror pair does not cancel

Theorem T2 in the author's field says more than equal energy densities: at the
mirror point the whole tensor of the copy is the pulled-back tensor,
$T_{\mu\nu}[\Psi'](\pi - z) = (R_0\,T[\Psi](z)\,R_0)_{\mu\nu}$ with $R_0 =
\mathrm{diag}(-1,1,1,1,1,1,1,1)$: the components with exactly one index $x_0$
change sign (the direction $x_0$ is reversed by the mirror), all others are EQUAL.
Likewise $J'^\mu = (R_0)^\mu{}_\nu J^\nu$, $S' = -S$, and the field-equation
residuals obey $E_{-m,\lambda}[\Psi'] = -\gamma^{(x_0)}E_{m,\lambda}[\Psi]$. The
next cell checks all of this at the point $z = 0.6$ with the full configuration
(including its derivative along $x_0$, which the mirror reverses) and draws the
three tables.
```

## 11. The pair as the only source: Einstein's vacuum equations

By lines 1 and 2 of the proof (checked in sections 8 and 9) a T1 pair as the only
source gives $T = 0$, and the field equations of gravity become the vacuum
equations. The next cell reads the four independent components of the Einstein
tensor $G = E_{(1)}$ from the record `a4-equations.json` (the symbols `ad1` and
`ad2` there are $a_4'$ and $a_4''$), forms the vacuum equations
$G^\mu{}_\mu + \Lambda = 0$ for $\mu = x_0, x_1, x_4, x_5$ (the other diagonal
components repeat these, the off-diagonal ones are identically zero), and lets
sympy solve them for $a_4'$, $a_4''$ and $\Lambda$ WITHOUT assuming that $a_4'$
is real. It also forms the two combinations of the proof: the $x_4$ equation minus
the $x_0$ equation, and their sum.
```

## 12. What the geometry requires and what a pair supplies

Line 5 of the proof is a statement about the source. Write the $x_4$ and $x_0$
equations with a source: $\sum_k\alpha_kE_{(k)}{}^{x_4}{}_{x_4} + \Lambda =
-\kappa\rho$ and $\sum_k\alpha_kE_{(k)}{}^{x_0}{}_{x_0} + \Lambda = \kappa p_0$
(the record's sign convention). Subtracting the first from the second removes
$\Lambda$ and gives the **null combination** the geometry REQUIRES of any source:

$$\kappa(\rho + p_0) = -\sum_k\alpha_k\big(E_{(k)}{}^{x_4}{}_{x_4} -
E_{(k)}{}^{x_0}{}_{x_0}\big).$$
```

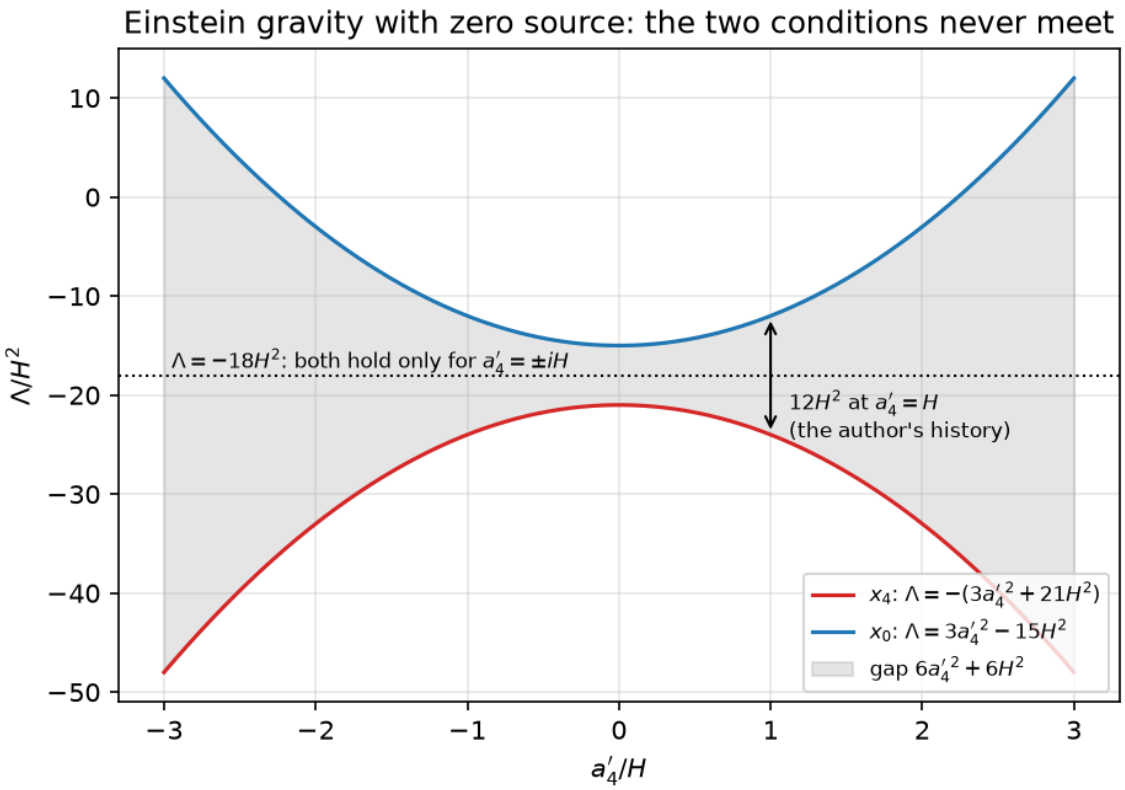

Figure 510: The vacuum equations of Einstein gravity for the author's metric, the situation of a T1 pair as the only source: horizontal axis the rate a_4'/H, vertical axis the cosmological constant Λ/H^2. The x_4 component holds on the red parabola, the x_0 component on the blue one; a vacuum solution would lie on both. They are separated by $6a_4'^2 + 6H^2 \geq 6H^2$ (grey band), $12H^2$ at the author's deflating history $a_4' = H$, so no real rate and no Λ solve both; the only solutions, $a_4' = \pm iH$ with $\Lambda = -18H^2$ (dotted line), are not real. (Notebook 20a, figure 4.)

```
In Einstein gravity this is $-6(a_4'^2 + H^2) < 0$ (the record's
'einstein_null_energy_x0'). For the linear member $a_4' = AH$ the record writes
the right-hand side as $-6(A^2 + 1)H^2V$ with the **vacuum factor**

$$V = \alpha_1 - 40\alpha_2H^2 - 8A^2\alpha_2H^2 + 360\alpha_3H^4 +
144A^2\alpha_3H^4 + 72A^4\alpha_3H^4 .$$

A T1 pair SUPPLIES $\rho + p_0 = 0$; so it can be the only source only where the
requirement is zero, that is where $V = 0$. The next cell reads the record's null
combination and vacuum factor, checks both against the Lovelock components, and
checks the Einstein case.
```

## 13. Einstein-Gauss-Bonnet gravity: when a zero source is allowed

Part (b) of C1. With $\alpha_1 = 1$ and $\alpha_3 = 0$ the vacuum factor is
$V = 1 - 40\alpha_2H^2 - 8A^2\alpha_2H^2 = 1 - 8\alpha_2H^2(A^2 + 5)$. Setting
$V = 0$ and solving for $A^2$, line by line: add $8\alpha_2H^2(A^2 + 5)$ to both
sides, $8\alpha_2H^2(A^2 + 5) = 1$; divide by $8\alpha_2H^2$ (not zero),
```

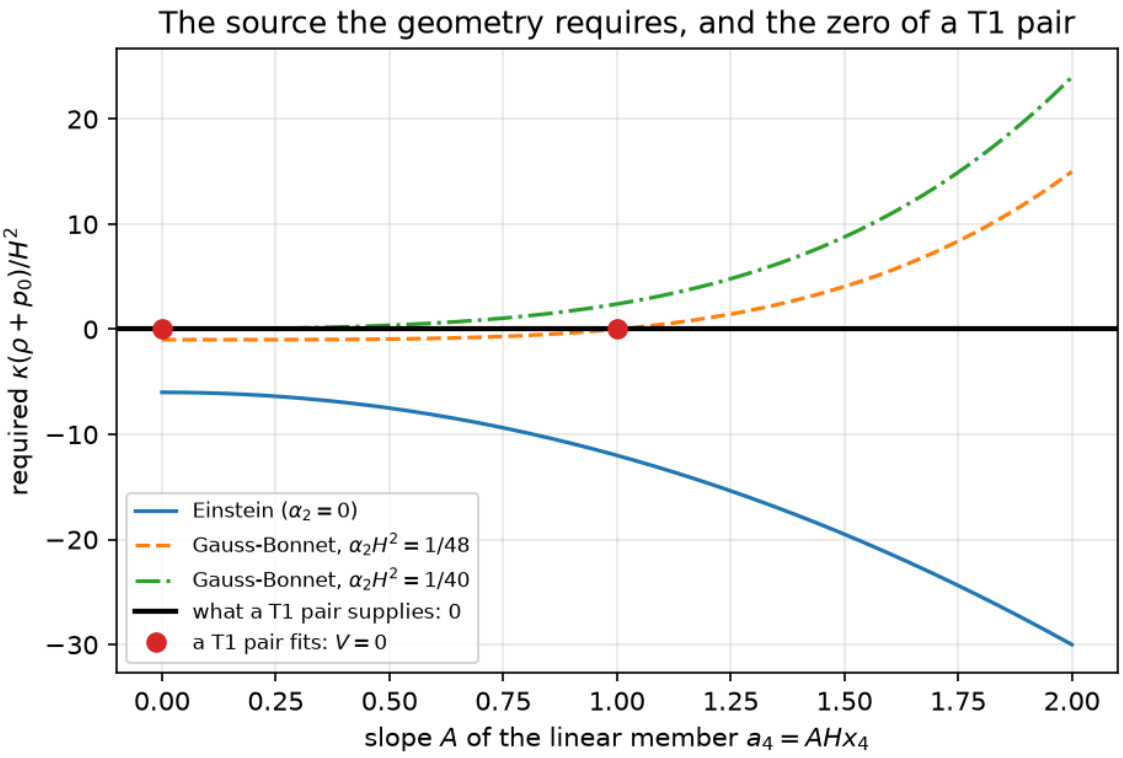

Figure 511: The null combination $\kappa(\rho + p_0)$ (energy density plus the pressure along x_0, times the gravitational coupling; vertical, units H^2) that the field equations require of ANY source of the linear member $a_4 = AHx_4$, against its slope A (horizontal), for Einstein gravity (solid) and two Einstein-Gauss-Bonnet theories with $\alpha_2 H^2 = 1/48$ (dashed) and $1/40$ (dash-dotted). A T1 pair supplies zero (black line). In Einstein gravity the requirement is $-6(A^2 + 1)H^2 < 0$ for every A, so a T1 pair can never be the only source; with the Gauss-Bonnet term the requirement vanishes at one slope (red dots: $A = 1$, the author's history, for $\alpha_2 H^2 = 1/48$, and $A = 0$ for $1/40$). (Notebook 20a, figure 5.)

```
$A^2 + 5 = 1/(8\alpha_2H^2)$; subtract 5,

$$A^2 = \frac{1 - 40\alpha_2H^2}{8\alpha_2H^2},$$

real and not negative exactly when $0 < \alpha_2H^2 \leq 1/40$. Then the $x_4$
equation fixes $\Lambda = -\sum_k\alpha_kE_{(k)}{}^{x_4}{}_{x_4}$. For the author's
history $A = 1$: $8\alpha_2H^2 \cdot 6 = 1$, so $\alpha_2H^2 = 1/48$. The next cell
checks the formula and then checks EXACTLY that with $\alpha_2 = 1/(48H^2)$ and
the resulting $\Lambda$ all four independent components of the vacuum equations
vanish for $a_4 = Hx_4$. In that theory a T1 pair CAN be the only source of the
author's deflating history; C1(a) is a statement about Einstein gravity.
```

## 15. What C1 says, and what it does not say

- **PROVED (record, reproduced here):** the T1 partner $\Gamma\Psi$ with
  $(-m, -\lambda)$ carries minus the energy-momentum tensor and minus the current
  of $\Psi$ at every point, off and on shell; a T1 pair as the ONLY source is a
  zero source; in Einstein gravity the author's metric then has no solution for
  $H > 0$, whatever $a_4$ and $\Lambda$ (the two vacuum conditions never meet).
- **PROVED (record, reproduced here):** in Einstein-Lovelock gravity the linear
  member is a vacuum exactly when $V = 0$; with the Gauss-Bonnet coupling
  $\alpha_2H^2 = 1/48$ and $\Lambda = -12H^2$ the author's history $a_4 = Hx_4$ is
  a vacuum (checked exactly in section 13). So C1(a) depends on Einstein gravity.
- **C1 does not apply to T2 pairs:** the mirror copy carries the pulled-back,
  EQUAL tensor $R_0TR_0$, so the sources add (sections 9 and 10).
- **C1 does not apply to two independently quantised universes** (the record's
  statement Q3): their generators add without cancelling.
- **C1 is not a creation statement.** It concerns the sum of two classical sources
  in ONE given geometry. It derives no process that produces a pair, no rate, no
  amplitude, and it does not say that such a pair, or such a geometry, exists in
  nature. It says the opposite of "a pair creates the universe": in Einstein
  gravity a T1 pair alone cannot be the source of the author's metric at all.
- **ASSUMED:** the classical commuting field dirac16complex00 (for dirac16complex
  the record states the same as identities between Grassmann-algebra elements);
  the Z2 brane and the mirror patch (sections 9 and 10); the units $H = 1$ of the
  numerical examples.
```

Text cell:

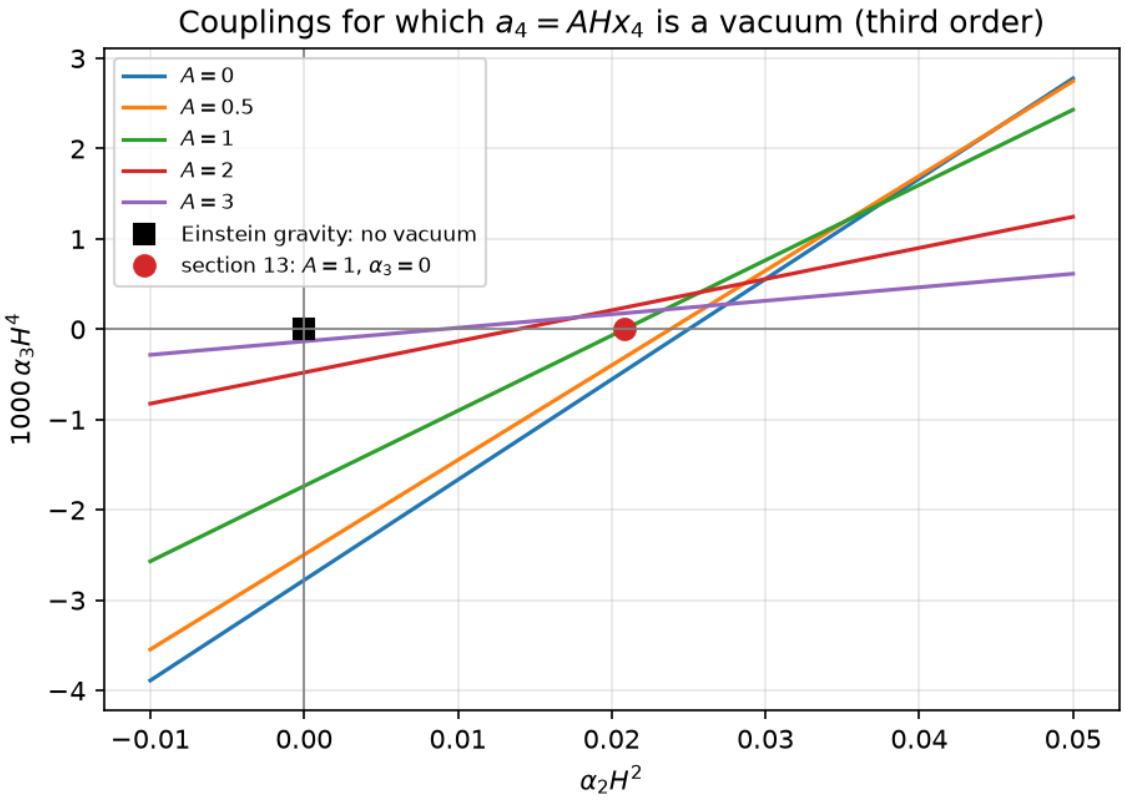

Figure 513: The Einstein-Lovelock couplings for which the linear member $a_4 = AHx_4$ of the author's metric is a vacuum (so that a T1 pair could be its only source): horizontal axis the second-order coupling $\alpha_2 H^2$, vertical axis the third-order coupling times 1000, $1000\,\alpha_3 H^4$ ($\alpha_1 = 1$). For each slope A the condition $V = 0$ is a straight line (coloured, $A = 0$ to 3). Einstein gravity is the origin (black square), where $V = 1$: it lies on no line. The red dot is the Gauss-Bonnet vacuum of the author's history $A = 1$ at $\alpha_2 H^2 = 1/48$. (Notebook 20a, figure 7.)

```
## 16. The last check

The last cell checks that the seven figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [19]:

```
figure_names = ["t1_pair_tensor", "pair_profiles", "t2_mirror_tensor",
                "einstein_vacuum_parabolas", "null_combination",
                "gauss_bonnet_vacuum", "third_order_vacua"]
paths = [output_file(f"{FIGURE_FOLDER}/20a_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

Out [19]:

```
PASS every figure file of this notebook exists
ALL 37 CHECKS PASSED (notebook 20a)
```

Text cell:

```
## 17. What this notebook showed

- The canonical spin connection of the author's metric has the twelve components
  of the record, and $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ on the patch
  ($-3H\gamma^{(x_0)}$ on the mirror patch, with its own positive vielbein).
- For an arbitrary configuration of dirac16complex00 at a point of the deflating
  history, its T1 partner $\Gamma\Psi$ with $(-m, -\lambda)$ has exactly the
  opposite energy-momentum tensor (64 components) and current: the pair's source
  is zero at every point (figures 1 and 2). The wrong partners do not cancel.
- The T2 mirror copy across the brane has the SAME energy density and charge
  density at the mirror point; its tensor is $R_0TR_0$ (figures 2 and 3): mirror
  pairs add, they do not cancel.
- With the pair as the only source, Einstein's equations for the author's metric
  reduce to $6a_4'^2 + 6H^2 = 0$ and $36H^2 + 2\Lambda = 0$; the only solutions
  are $a_4' = \pm iH$, not real (figure 4). The geometry requires
  $\kappa(\rho + p_0) = -6(a_4'^2 + H^2) < 0$ of every source; a T1 pair supplies
  zero (figure 5).
- In Einstein-Gauss-Bonnet gravity the linear member is a vacuum for
  $A^2 = (1 - 40\alpha_2H^2)/(8\alpha_2H^2)$; the author's history $A = 1$ for
  $\alpha_2H^2 = 1/48$, $\Lambda = -12H^2$ (figure 6); with the third coupling the
  vacua of each slope form a straight line that misses Einstein gravity
  (figure 7).
- None of this is a creation process: C1 compares sources in one given geometry.
```

20.11 Line-by-line walk-through of Notebook 20a

The notebook has 19 code cells, In [1] to In [19]. This section explains every line or small group of lines of every one of them, in order: a group of lines is quoted, then explained. Where a later cell

repeats a pattern already explained, we say so and explain only what is new. The markdown cells between the code cells are printed in the complete text above and need no explanation.

In [1], the set-up cell. Every line that starts with `#` is a **comment**, which Python skips. The comment lines at the top of the cell are the complete run instructions of Section 20.9, so that the notebook file carries its own instructions. The code starts after the line that announces THE SET-UP; it is the same in every notebook of this book except for the notebook's name, and it computes no physics.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json`, `os`, `textwrap` and `pathlib` come with Python itself. `from pathlib import Path` takes only the name `Path` out of `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs the Python code), which show a picture file below a cell.

```
NOTEBOOK_ID = "20a"  # this notebook: chapter 20, example a
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a piece of text in quotes) `"20a"`; the figure files and the last printed line are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs each time it is called. The text in triple quotes under the `def` line is its **docstring**: it says what the function does and is not executed.

`Path.cwd()` is the folder in which Jupyter runs the notebook, and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it; `[here, *here.parents]` is a list that starts with `here` and continues with them (the star unpacks one list into another). The `for` loop visits these folders one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains `Revision /textbook/requirements.txt` is the repository, and `return` hands it back. If no folder does, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The first code line calls the function and names its result `REPO`. The second chooses where files are written: `os.environ` holds the **environment variables** of the running program (named texts that it receives from the computer), and `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and `str(REPO)`, the repository folder as text, otherwise. When you run the notebook the variable is not set, so the figures go into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small functions. `repository_file` gives the full path of a file of the repository, for reading a Revision record. `output_file` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder of that file and every missing folder above it, and does nothing if the folder exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a line of the book; `textwrap.fill` breaks the text at blanks and starts every line after the first with four blanks. This is why some long PASS lines of the notebook continue on an indented second line.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to matplotlib's built-in settings, so that the figures are the same on every computer. `plt.rcParams.update({...})` then sets the default size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid (`grid.alpha` 0.3: 30 per cent opaque). The braces make a **dictionary**, a collection of pairs `key:  value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: a name in braces is replaced by its value, so `CAPTION_FILE` is the text `Revision/textbook/figures/20a.captions.json`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty JSON dictionary and a line end into the captions file; `encoding="utf-8"` fixes how the letters are stored and `newline="\n"` stores the same line end on every system.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far: the figures are numbered 1, 2, 3, and a cell that is run twice keeps its number. The file name joins the notebook id, the number and the name, for example `20a_1_t1_pair_tensor.png`. `fig.savefig` writes a PNG file with 150 dots per inch, cuts away the empty margin, and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory; otherwise Jupyter would draw it a second time. The caption is stored, the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys), `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection in square brackets). `check` is the function behind every check of the book: if `condition` is false, `raise AssertionError(...)` stops the notebook with an error that names the check; otherwise the name is appended to `PASSED` and the line PASS followed by the name is printed, and, when `record` is given, a second line that names the Revision record. `record=None` makes that argument optional.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; `(f" {unit}" if unit else "")` adds the unit only when one is given. `all_checks_passed` prints the last line of the notebook, with `len(PASSED)`, the number of checks that passed. The last statement prints the one output line of In [1], Set-up of notebook 20a complete.

In [2], the records and the helper `reproduces`.

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory
```

Two more modules of Python: `contextlib` provides `redirect_stdout`, which sends whatever `print` writes into another place, and `io` provides `StringIO`, a text buffer held in memory.

```
GAMMAS = "Revision/algebra/gammas.json"  # the author's gamma matrices
PROOFS = "Revision/docs/PAIR_CREATION_PROOFS.md"  # the pairing document
PAIR_PY = "Revision/pairing/reports/python-pairing.json"  # sympy pairing record
```

```
PAIR_WL = "Revision/pairing/reports/wolfram-pairing.json"  # Wolfram pairing record
A4_RECORD = "Revision/field_equations_a4/a4-equations.json"  # the a4 equations
A4_PY = "Revision/field_equations_a4/reports/python-a4-report.json"
A4_WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
LEAD_EGB = "Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json"
LEAD_EMT = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
```

Nine short names for the nine files of the repository that the notebook reads: the author's gammas, the Revision document of the pairing proofs, the two pairing reports, the record of the field equations for a_4 with its two reports, and the lead's two independent reports. Names written in capital letters are, by custom, values that the program does not change.

```
def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

def record_verdict(report_file, name):
    """The verdict ("PASS") of the check called name in a report; None if absent."""
    for entry in read_json(report_file)["checks"]:
        if entry["name"] == name:
            return entry["verdict"]
    return None
```

`read_json` reads a file of the repository as text and turns it into Python dictionaries and lists with `json.loads`. Every report holds, under the key `"checks"`, a list whose entries are dictionaries with a `"name"` and a `"verdict"`. `record_verdict` walks through that list and returns the verdict of the check with the given name, or `None` (Python's word for "nothing") if the report has no such check.

```
def reproduces(condition, name, report_file, record_name):
    """A check that also requires the record check record_name to be PASS."""
    found = record_verdict(report_file, record_name) == "PASS"
    lines = io.StringIO()  # a text buffer
    with contextlib.redirect_stdout(lines):  # print() now writes into the buffer
        check(condition and found, name,
              record=f"{report_file}, check {record_name}")
    print(lines.getvalue(), end="")  # both lines with one print call
```

`reproduces` is the check used whenever a result of the notebook reproduces a Revision record. `found` is true only if the named check of the named report has the verdict PASS. The `with` block sends the output of `check` into the buffer `lines`; `check` passes only if the notebook's own `conditio n` holds AND `found` is true, and it prints the PASS line and the line "reproduces" followed by the report and the check. The last line prints both lines at once (`end=""` adds no extra line end). If either condition fails, `check` raises its error inside the `with` block and the notebook stops.

```
proofs = repository_file(PROOFS).read_text(encoding="utf-8")
C1_WORDS = ("a T1 pair taken as the complete classical source of the author's "
            "metric is a zero source, and the Einstein equations then have no "
            "solution for")
say(f"{PROOFS} says: \"{C1_WORDS} H > 0.\"")
check(C1_WORDS in proofs, "the record states the corollary C1")
```

The first line reads the whole Revision document as one text. `C1_WORDS` is the record's sentence of the corollary C1 (two strings written next to each other inside parentheses are joined into one). `say` prints it with the name of the document; `\"` puts a double quote inside a string written with double quotes. The check `C1_WORDS in proofs` is true when the sentence occurs in the document, word for word: the first printed lines of the cell.

```
wolfram_counts = read_json(PAIR_WL)["summary"]  # passed, failed, total
sympy_counts = read_json(PAIR_PY)["counts"]  # pass, fail, pending
passed, total = wolfram_counts["passed"], wolfram_counts["total"]
say(f"pairing reports: Wolfram {passed} of {total} PASS, sympy "
    f"{sympy_counts["pass"]} PASS and {sympy_counts["fail"]} FAIL")
check(wolfram_counts["passed"] == wolfram_counts["total"] == 101
      and sympy_counts["pass"] == 66 and sympy_counts["fail"] == 0,
      "both pairing reports pass every check (101 and 66)")
```

The two pairing reports store their counts under different keys: `"summary"` with `"passed"` and `"total"` (Wolfram) and `"counts"` with `"pass"` and `"fail"` (sympy). `passed, total = a, b` gives two names at once. Inside the braces of an f-string Python 3.12 and newer allow the same kind of quotes as around the string, as in `sympy_counts["pass"]`. The check compares the counts with the numbers of the record (101 Wolfram checks, 66 sympy checks, no failure); `a == b == 101` is true only if both comparisons hold. If a later revision of the record changed these counts, this check would fail and show the change. Output: pairing reports: Wolfram 101 of 101 PASS, sympy 66 PASS and 0 FAIL.

In [3], the gammas, C and the chirality.

```
import itertools  # loops over all combinations of indices

import numpy as np  # floating-point arrays
import sympy as sp  # exact algebra
```

`itertools.product` (used below) runs over all combinations of indices. **numpy**, short `np`, computes with arrays of floating-point numbers (numbers with about 16 significant digits). **sympy**, short `sp`, computes exactly with whole numbers, fractions and symbols.

```
NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # positions 0..7
ETA = [1, 1, 1, 1, -1, -1, -1, -1]  # the frame metric eta, in the order x0..x7
I16 = sp.eye(16)  # the 16 by 16 unit matrix
fixture = read_json(GAMMAS)
gamma = [sp.Matrix([[sp.Rational(x) for x in row] for row in matrix])
         for matrix in fixture["gamma"]]  # gamma[a] = gamma^(x_a), exact
```

Python counts list positions from 0, and position k stands for x_k: position 0 for the hidden direction x_0, position 4 for the time x_4; `NAMES` holds the labels for the figures and `ETA` the diagonal of η in the same order. `sp.eye(16)` is the exact unit matrix I_{16}. The file `gammas.json` stores, under the key `"gamma"`, the eight matrices as lists of rows of whole numbers. The double **list comprehension** `[[... for x in row] for row in matrix]` builds, row by row, a list of lists in which every entry is turned into an exact sympy number by `sp.Rational`; `sp.Matrix` makes a sympy matrix of it; the outer comprehension does this for each of the eight matrices. The record lists the matrices in the order $x_0, \ldots, x_7$, so `gamma[0]` is $\gamma^{(x_0)}$ and `gamma[7]` is $\gamma^{(x_7)}$.

```
clifford = all(gamma[a] * gamma[b] + gamma[b] * gamma[a]
               == (2 * ETA[a] if a == b else 0) * I16
               for a in range(8) for b in range(8))
C = gamma[0] * gamma[1] * gamma[2] * gamma[3]  # C = g^(x0) g^(x1) g^(x2) g^(x3)
reproduces(clifford and C == C.T and C * C == I16
           and all((C * g).T == -(C * g) for g in gamma),
           "Clifford relation; C real symmetric, C^2 = 1, C gamma antisymmetric",
           PAIR_PY, "gammas.C")
```

`*` between sympy matrices is the matrix product. `all(...)` is true when the comparison holds for all 64 pairs (a, b): the anticommutator $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}$ must equal $2\eta_{aa}I_{16}$ when $a = b$ and the zero matrix otherwise (`x if condition else y` chooses one of two values). The next line builds C from the record's definition. The check requires the Clifford relation, $C^T = C$ (`.T` is the transpose; the entries are real, so C is real symmetric), $C^2 = I_{16}$, and that every $C\gamma^{(a)}$ is antisymmetric; it reproduces `python-pairing.json`, check `gammas.C`.

```
chirality = gamma[0]  # the product g^(x0) g^(x1) ... g^(x7), built factor by factor
for a in range(1, 8):
    chirality = chirality * gamma[a]
reproduces(chirality == sp.diag(*([-1] * 8 + [1] * 8)),
           "Gamma = diag(-I8, I8)", PAIR_PY, "gammas.Gamma")
reproduces(all(chirality * g == -g * chirality for g in gamma)
           and chirality * C == C * chirality,
           "Gamma anticommutes with every gamma and commutes with C",
           PAIR_WL, "Gamma_properties")
```

The loop multiplies $\gamma^{(x_0)}$ from the right by $\gamma^{(x_1)}, \ldots, \gamma^{(x_7)}$, in the record's order. `[-1] * 8 + [1] * 8` is the list of eight entries -1 followed by eight entries $+1$, and `sp.diag(*list)` is the diagonal matrix with these entries: the check is $\Gamma = \mathrm{diag}(-I_8, I_8)$. The second check is steps 1 and 2 of Section 20.5: $\Gamma\gamma^{(a)} = -\gamma^{(a)}\Gamma$ for all eight gammas and $\Gamma C = C\Gamma$.

```
S_exact = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
           for a in range(8)]  # the generators S^ab
to_numpy = lambda matrix: np.array(matrix.tolist(), dtype=float)  # noqa: E731
gamma_num = [to_numpy(g) for g in gamma]  # floating-point copies
C_num, Gamma_num = to_numpy(C), to_numpy(chirality)
S_num = [[to_numpy(S_exact[a][b]) for b in range(8)] for a in range(8)]
B_num = -1j * C_num @ gamma_num[4]  # B = -i C gamma^(x4): J^x4 = Psi^dagger B Psi
```

`S_exact[a][b]` is the generator $S^{ab} = \frac{1}{4}[\gamma^{(a)}, \gamma^{(b)}]$, exactly, for all 64 pairs. `lambda matrix: ...` is a one-line function: it turns a sympy matrix into a numpy array of floating-point numbers (`tolist()` gives the list of rows); the comment `noqa: E731` tells a style checker that the one-line form is intended. The next lines make floating-point copies of the gammas, of C, of Γ and of the S^{ab}. In numpy, `@` is the matrix product and `1j` is the imaginary unit i; `B_num` is $B = -iC\gamma^{(x_4)}$ (position 4 is x_4). The cell prints the three PASS lines with their records.

In [4], the spin connection on both patches.

```
H = sp.symbols("H", positive=True)  # the author's constant H > 0
z = sp.symbols("z", real=True)  # the hidden coordinate z = 6 H x0
```

```
x4 = sp.symbols("x4", real=True)  # the time
a4 = sp.Function("a4")(x4)  # the metric function a4(x4), arbitrary
a4_value, slope = sp.symbols("a4_value slope", real=True)  # a4 and a4' at a point
```

`sp.symbols` makes sympy symbols, letters that sympy computes with; `positive=True` and `real=Tru e` tell sympy what kind of number they stand for, which lets it simplify correctly (for example $\sqrt{H^2} = H$). `sp.Function("a4")(x4)` is an unknown function $a_4(x_4)$: sympy can differentiate it without knowing it. The last two symbols will replace a_4 and a_4' at a point.

```
def lengths(s0):
    """The lengths E_a of the diagonal vielbein; s0 = +1 on the patch, -1 on the
    mirror patch (where cot z < 0, so -cot z is the positive length)."""
    s = sp.sin(z) ** sp.Rational(1, 6)  # the warp sin(z)^(1/6) of a length
    return ([s0 * sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
            + [sp.exp(-a4) * s] * 3)  # x0, x1, ..., x7
```

The lengths E_a (written f_a in Sections 20.5 and 20.6) of the diagonal vielbein, in the order $x_0, \ldots, x_7$: $s_0 \cot z$ for the hidden direction, three times $e^{a_4} \sin^{1/6} z$ for the inflating 3-space, 1 for the time, and three times $e^{-a_4} \sin^{1/6} z$ for the DEFLATING extra times (on the background $b_4 = 1$). `**` is the power and `sp.Rational(1, 6)` the exact fraction 1/6. `[x] * 3` is a list of three copies of `x`, and `+` joins lists. On the mirror patch $\cot z$ is negative, so the positive length there is $-\cot z$: the argument `s0` is $+1$ on the patch and -1 on the mirror patch.

```
def d(expr, mu):
    """The partial derivative along the coordinate at position mu."""
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)  # d/dx0 = 6 H d/dz
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7
```

The partial derivative ∂_μ of an expression: along x_4 (position 4) it is `sp.diff(expr, x4)`; along x_0 (position 0) the chain rule gives $\partial/\partial x_0 = (dz/dx_0)\, \partial/\partial z = 6H\, \partial/\partial z$; along the other six directions it is zero, because the metric does not depend on them.

```
def spin_connection(s0):
    """The lengths E_a and omega[mu][a][b] = omega_mu ab at a point (a4 and a4'
    replaced by the symbols a4_value and slope)."""
    E = lengths(s0)
    g = [ETA[a] * E[a] ** 2 for a in range(8)]  # the metric g_aa
    christoffel = {}
    for a, b, c in itertools.product(range(8), repeat=3):
        value = 0  # the formula of the markdown cell, term by term
        if a == c:
            value += d(g[a], b)
        if a == b:
            value += d(g[a], c)
        if b == c:
            value -= d(g[b], a)
        christoffel[a, b, c] = value / (2 * g[a])
```

The diagonal metric is $g_{aa} = \eta_{aa} E_a^2$. `itertools.product(range(8), repeat=3)` runs over all $8^3 = 512$ triples (a, b, c). For each, the loop builds the Christoffel symbol of a diagonal metric term by term, $\Gamma^a{}_{bc} = (\delta_{ac}\partial_b g_{aa} + \delta_{ab}\partial_c g_{aa} - \delta_{bc}\partial_a g_{bb})/(2g_{aa})$: each `if` adds one term exactly when its Kronecker delta is 1, and `+=` and `-=` add to or subtract from `value`. The dictionary `christoffel` stores the result under the key `(a, b, c)`.

```
    omega = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
    for mu, a, b in itertools.product(range(8), repeat=3):
        if a != b:
            value = ETA[a] * E[a] * christoffel[a, mu, b] / E[b]
            value = value.subs(sp.Derivative(a4, x4), slope).subs(a4, a4_value)
            omega[mu][a][b] = sp.simplify(value)
    return [length.subs(a4, a4_value) for length in E], omega
```

`omega` starts as an $8 \times 8 \times 8$ nest of zeros (`_` is a loop name whose value is not used). For $a \neq b$ the component is $\omega_{\mu ab} = \eta_{aa}(E_a/E_b)\Gamma^a{}_{\mu b}$, the formula derived in the markdown cell above the code; for $a = b$ it is zero. `.subs(old, new)` substitutes: first a_4' (sympy's `Derivative(a4, x4)`) by the symbol `slope`, then a_4 by `a4_value`, so that the components become expressions in numbers that can be chosen at a point. `sp.simplify` writes each one in its simplest form. The function returns the lengths (with the same substitution) and the components.

```
E_patch, omega_patch = spin_connection(1)
E_mirror, omega_mirror = spin_connection(-1)
for label, omega in (("patch", omega_patch), ("mirror patch", omega_mirror)):
    count = sum(1 for mu in range(8) for a in range(8) for b in range(a + 1, 8)
                if omega[mu][a][b] != 0)
    say(f"{label}: {count} nonzero components omega_mu ab with a < b")
```

The connection is computed on both patches. For each, `sum(1 for ... if ...)` counts the nonzero components with $a < b$ (the others follow from the antisymmetry $\omega_{\mu ba} = -\omega_{\mu ab}$). Output: 12 on the patch and 12 on the mirror patch.

In [5], the twelve components, $\gamma^\mu \Omega_\mu$ and the mirror isometry.

```
s = sp.sin(z) ** sp.Rational(1, 6)
u, v = sp.exp(a4_value) * s, sp.exp(-a4_value) * s
expected = {}  # (mu, a, b) -> the record's component, on the patch
for i in (1, 2, 3):  # the inflating 3-space directions
    expected[i, i, 4], expected[i, 0, i] = slope * u, -H * u
for t in (5, 6, 7):  # the deflating extra times
    expected[t, 4, t], expected[t, 0, t] = -slope * v, H * v
```

`u` and `v` are the two lengths $e^{a_4} \sin^{1/6} z$ and $e^{-a_4} \sin^{1/6} z$ at a point. The dictionary `expected` holds the record's twelve components: for each inflating direction i, $\omega_{x_i, x_i x_4} = a_4' u$ and $\omega_{x_i, x_0 x_i} = -Hu$; for each deflating extra time t, $\omega_{x_t, x_4 x_t} = -a_4' v$ and $\omega_{x_t, x_0 x_t} = Hv$ (with $a < b$ in the order $x_0, \ldots, x_7$, so the hidden index comes first, and $\omega_{\mu, ba} = -\omega_{\mu, ab}$).

```
def components(omega):
    """The nonzero omega_mu ab with a < b, as a dictionary."""
```

```
    return {(mu, a, b): omega[mu][a][b] for mu in range(8) for a in range(8)
            for b in range(a + 1, 8) if omega[mu][a][b] != 0}

def same_components(found, wanted):
    return set(found) == set(wanted) and all(
        sp.simplify(found[key] - wanted[key]) == 0 for key in wanted)
```

`components` collects the nonzero components with $a < b$ into a dictionary (a **dictionary comprehension**). `same_components` is true when two such dictionaries have the same keys (`set(...)` is the collection of keys without order) and every difference simplifies to zero.

```
reproduces(same_components(components(omega_patch), expected),
           "the twelve spin-connection components of the record (patch)",
           PAIR_PY, "geometry.spin_connection_components")
flipped = {key: (-value if 0 in key[1:] else value)
           for key, value in expected.items()}  # x0 components change sign
reproduces(same_components(components(omega_mirror), flipped),
           "mirror patch: the x0 components change sign, the others do not",
           PAIR_WL, "connection_mirror_patch")
```

The first check compares the patch with the record. On the mirror patch the length $E_0 = -\cot z$ has the opposite sign, so every component with a frame index x_0 changes sign: `flipped` is `expected` with the sign reversed wherever the position 0 occurs among the two frame indices `key[1:]`. The second check compares the mirror patch with it.

```
Omega = {}  # s0 -> the eight matrices Omega_mu
for s0, omega in ((1, omega_patch), (-1, omega_mirror)):
    Omega[s0] = [sum((omega[mu][a][b] * S_exact[a][b] / 2 for a in range(8)
                      for b in range(8) if omega[mu][a][b] != 0), sp.zeros(16))
                 for mu in range(8)]
term = {}  # s0 -> sum over mu of gamma^mu Omega_mu
for s0, E in ((1, E_patch), (-1, E_mirror)):
    term[s0] = sum((gamma[mu] / E[mu] * Omega[s0][mu] for mu in range(8)),
                   sp.zeros(16)).applyfunc(sp.simplify)
```

For each patch, `Omega[s0][mu]` is the matrix $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$; `sum(..., sp.zeros(16))` adds matrices starting from the 16×16 zero matrix. `term[s0]` is $\sum_\mu \gamma^\mu\Omega_\mu$ with $\gamma^\mu = \gamma^{(\mu)}/E_\mu$; `.applyfunc(sp.simplify)` simplifies each of its 256 entries.

```
reproduces(term[1] == 3 * H * gamma[0], "patch: gamma^mu Omega_mu = 3 H gamma^(x0)",
           LEAD_EMT, "gamma_Omega_equals_3H_gamma0")
check(term[-1] == -3 * H * gamma[0], "mirror patch: gamma^mu Omega_mu = -3 H gamma^(x0)")
g_patch = [ETA[a] * E_patch[a] ** 2 for a in range(8)]
reproduces(all(sp.simplify(entry.subs(z, sp.pi - z) - entry) == 0
               for entry in g_patch),
           "z -> pi - z leaves all eight metric components unchanged",
           PAIR_PY, "geometry.mirror_isometry")
```

On the patch the sum is $3H\gamma^{(x_0)}$, the record's spin-connection term, with no a_4 or a_4' left: the terms of the three inflating and the three deflating directions along $\gamma^{(x_4)}$ cancel. On the mirror patch it is $-3H\gamma^{(x_0)}$; this check has no record (a computation of this notebook). The last check substitutes $z \to \pi - z$ into the eight metric components and finds each unchanged: the mirror is an isometry.

In [6], the geometry at a point and the bilinears.

```
point_symbols = (z, a4_value, slope, H)
NUMERIC = {}  # s0 -> (the function of the lengths, the connection pieces)
for s0, E, omega in ((1, E_patch, omega_patch), (-1, E_mirror, omega_mirror)):
    lengths_f = sp.lambdify(point_symbols, E, "numpy")
    pieces = [(mu, a, b, sp.lambdify(point_symbols, omega[mu][a][b], "numpy"))
              for mu in range(8) for a in range(8) for b in range(8)
              if omega[mu][a][b] != 0]
    NUMERIC[s0] = (lengths_f, pieces)
```

`sp.lambdify(symbols, expression, "numpy")` turns a sympy expression into an ordinary Python function of the listed symbols that computes with numpy. For each patch, `lengths_f` computes the eight lengths and `pieces` is a list of the nonzero components (μ, a, b), each with its own function; they are stored under the key $+1$ or -1.

```
def geometry_at(s0, z_value, a4_number, slope_number, H_number=1.0):
    """Lengths, metric, Omega_mu and the curved gammas at one point."""
    lengths_f, pieces = NUMERIC[s0]
    values = (z_value, a4_number, slope_number, H_number)
    E = np.array([float(x) for x in lengths_f(*values)])
    Om = [np.zeros((16, 16)) for _ in range(8)]
    for mu, a, b, f in pieces:  # Omega_mu = (1/2) sum omega_mu ab S^ab
        Om[mu] += float(f(*values)) * S_num[a][b] / 2
    return {"g": np.array(ETA) * E ** 2, "Omega": Om,
            "up": [gamma_num[mu] / E[mu] for mu in range(8)],
            "down": [ETA[mu] * E[mu] * gamma_num[mu] for mu in range(8)]}
```

`geometry_at` evaluates the geometry at one point: the patch (`s0`), z, a_4, a_4' and H (1 unless given). `f(*values)` calls a function with the four numbers as its arguments. It returns a dictionary with the metric $g_{\mu\mu}$, the eight matrices Ω_μ (built from the pieces), the curved gammas with an upper index $\gamma^\mu = \gamma^{(\mu)}/E_\mu$ and with a lower index $\gamma_\mu = g_{\mu\mu}\gamma^\mu = \eta_{\mu\mu}E_\mu\gamma^{(\mu)}$.

```
def bilinears(at, psi, dpsi, m, lam):
    """S, K, L/sqrt|g|, T_mu nu, J^mu, the field-equation residual, and the
    largest imaginary part of a quantity that must be real."""
    bar = psi.conj() @ C_num  # Psibar = Psi^dagger C (a row)
    dbar = [row.conj() @ C_num for row in dpsi]  # d_mu Psibar
    D = [dpsi[mu] + at["Omega"][mu] @ psi for mu in range(8)]  # D_mu Psi
    Dbar = [dbar[mu] - bar @ at["Omega"][mu] for mu in range(8)]  # D_mu Psibar
    S = bar @ psi
    K = 0.5 * sum(bar @ at["up"][mu] @ D[mu] - Dbar[mu] @ at["up"][mu] @ psi
                  for mu in range(8))
    L = K - m * S - lam / 2 * S ** 2  # L / sqrt|g|
```

`bilinears` evaluates, from the first jet of a configuration (the 16 values `psi` and the eight derivative columns `dpsi[mu]`), every quantity of Section 20.5. `psi.conj()` is the complex conjugate of each entry; for a one-dimensional numpy array the product `psi.conj() @ C_num` is the row $\Psi^\dagger C = \bar\Psi$. Then $\partial_\mu\bar\Psi$, $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$ and $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, the scalar S, the kinetic term K and $\mathcal{L}/\sqrt{|g|} = K - mS - \frac{\lambda}{2}S^2$.

```
    T = np.zeros((8, 8), dtype=complex)
    for mu, nu in itertools.product(range(8), repeat=2):
        T[mu, nu] = 0.25 * (bar @ at["down"][mu] @ D[nu]
                            + bar @ at["down"][nu] @ D[mu]
                            - Dbar[mu] @ at["down"][nu] @ psi
                            - Dbar[nu] @ at["down"][mu] @ psi)
        if mu == nu:
            T[mu, nu] -= at["g"][mu] * L
    J = np.array([-1j * bar @ at["up"][mu] @ psi for mu in range(8)])
    residual = sum(at["up"][mu] @ D[mu] for mu in range(8)) - (m + lam * S) * psi
```

The 64 components of $T_{\mu\nu}$, term by term as in the formula of Section 20.5 (the metric is diagonal, so the term $-g_{\mu\nu}\mathcal{L}/\sqrt{|g|}$ appears only for $\mu = \nu$); the eight components of the current $J^\mu = -i\bar\Psi\gamma^\mu\Psi$; and the field-equation residual $E_{m,\lambda} = \gamma^\mu D_\mu\Psi - (m + \lambda S)\Psi$, a column of 16 numbers that is zero exactly when the configuration solves the field equation.

```
    imaginary = max(abs(S.imag), abs(K.imag), np.abs(T.imag).max(),
                    np.abs(J.imag).max())
    return {"S": S.real, "K": K.real, "L": L.real, "T": T.real, "J": J.real,
            "E": residual, "imag": imaginary}
```

S, K, $T_{\mu\nu}$ and J^μ must be real numbers (Chapter 7 proves it); in floating point they come out with tiny imaginary parts of rounding size. `imaginary` is the largest of them, so that the next cell can check it; the function returns the real parts and the residual. The cell prints nothing.

In [7], a configuration and its T1 partner at one point.

```
rng = np.random.default_rng(20261007)  # a fixed seed: the same numbers every run
R0_SIGNS = [-1, 1, 1, 1, 1, 1, 1, 1]  # the mirror reverses the direction x0
psi = rng.normal(size=16) + 1j * rng.normal(size=16)  # the 16 complex values
dpsi = [rng.normal(size=16) + 1j * rng.normal(size=16) for _ in range(8)]
dpsi = dpsi[7:] + dpsi[:7]  # drawn hidden direction last, as before; now x0 first
Z0, A4_0, M0, LAM0 = 0.6, 0.5, 2.0, 0.5  # the point and the parameters (H = 1)
```

`np.random.default_rng(20261007)` is a random-number generator started from a fixed **seed**, so that every run draws the same numbers and the notebook is reproducible. `rng.normal(size=16)` draws 16 numbers from the bell-shaped normal distribution; real part plus i times another 16 such numbers gives 16 random complex values Ψ, and the comprehension draws eight more such columns, the derivatives $\partial_\mu\Psi$. They are drawn in the order in which this notebook drew them before it moved to the author's coordinates, with the hidden direction last; `dpsi[7:] + dpsi[:7]` moves that last column to the front, so that `dpsi[mu]` is $\partial_\mu\Psi$ for x_μ and every number of the notebook stays the same. `R0_SIGNS` is the diagonal of R_0, used later. The point is $z = 0.6$, $a_4 = 0.5$, and the parameters are $m = 2$, $\lambda = 1/2$, in units $H = 1$.

```
at = geometry_at(1, Z0, A4_0, 1.0)  # a4' = 1: the deflating history A = 1
one = bilinears(at, psi, dpsi, M0, LAM0)  # Psi with (m, lambda)
partner = bilinears(at, Gamma_num @ psi, [Gamma_num @ row for row in dpsi],
                    -M0, -LAM0)  # Gamma Psi with (-m, -lambda)
scale = np.abs(one["T"]).max()  # the size of the tensor
report("S of the configuration", f"{one["S"]:.6f}")
report("largest |T_mu nu| of the configuration", f"{scale:.4f}")
```

The geometry at the point on the patch with $a_4' = 1$, the rate of the deflating history. `one` holds the quantities of the configuration with (m, λ); `partner` those of $\Gamma\Psi$ (value and derivatives multiplied by Γ, because $\partial_\mu(\Gamma\Psi) = \Gamma\partial_\mu\Psi$) with $(-m, -\lambda)$. `scale` is the largest modulus of a component of T; every tolerance below is measured relative to it. `:.6f` prints a number with six digits after the point. Output: RESULT S of the configuration = 1.354934 and RESULT largest modulus of $T_{\mu\nu}$ = 26.7625. The configuration is random: it is NOT a solution, and T1 must hold anyway, because it is an off-shell identity.

```
check(max(one["imag"], partner["imag"]) < 1e-12 * scale,
      "S, K, T and J are real numbers (to rounding)")
reproduces(abs(partner["S"] - one["S"]) < 1e-12 and abs(partner["K"] + one["K"])
           < 1e-12, "S' = S and K' = -K", PAIR_PY, "T1.metric.commuting.S_invariant")
reproduces(np.abs(one["T"] + partner["T"]).max() < 1e-12 * scale,
           "T1 pair: all 64 components of T + T' vanish",
           PAIR_PY, "T1.metric.commuting.pair_total_emt_zero")
reproduces(np.abs(one["J"] + partner["J"]).max() < 1e-12 * scale,
           "T1 pair: all 8 components of J + J' vanish",
           PAIR_WL, "T1_current_primordial_commuting")
reproduces(np.abs(partner["E"] + Gamma_num @ one["E"]).max() < 1e-12 * scale,
           "E_(-m,-lambda)[Gamma Psi] = -Gamma E_(m,lambda)[Psi]",
           PAIR_PY, "T1.metric.commuting.euler_lagrange_map")
```

Five checks of theorem T1 at this point, each to 10^{-12} times the size of the tensor, which allows only rounding errors: the imaginary parts are rounding; $S' = S$ and $K' = -K$ (step 5 of Section 20.5); all 64 components of $T + T'$ vanish (T1c); all eight components of $J + J'$ vanish; and the residuals obey $E_{-m,-\lambda}[\Gamma\Psi] = -\Gamma E_{m,\lambda}[\Psi]$ (step 7), so one vanishes exactly when the other does.

```
wrong_1 = bilinears(at, Gamma_num @ psi, [Gamma_num @ row for row in dpsi],
                    -M0, LAM0)  # only the mass reversed
wrong_2 = bilinears(at, Gamma_num @ psi, [Gamma_num @ row for row in dpsi],
                    M0, LAM0)  # nothing reversed
reproduces(min(np.abs(one["T"] + wrong_1["T"]).max(),
               np.abs(one["T"] + wrong_2["T"]).max()) > 1e-3 * scale,
           "negative controls: with (-m, +lambda) or (m, lambda) no cancellation",
           PAIR_PY, "T1.metric.commuting.negative_controls")
```

Two **negative controls**, computations that must FAIL to cancel: the partner $\Gamma\Psi$ with only the mass reversed, and with nothing reversed. In both cases the sum $T + T'$ is far from zero (more than 10^{-3} times the size of the tensor). This shows that the cancellation of the previous check is not an accident of the test: the mass AND the coupling must change sign.

In [8], figure 1: the T1 pair cancels.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.3))
panels = ((one["T"], "$T_{\\mu\\nu}[\\Psi;\\,m,\\lambda]$"),
          (partner["T"], "$T_{\\mu\\nu}[\\Gamma\\Psi;\\,-m,-\\lambda]$"),
          (one["T"] + partner["T"], "sum: the source of the pair"))
```

`plt.subplots(1, 3, ...)` makes a figure with one row of three panels (**axes**), 12 by 4.3 inches. `panels` pairs each table with its title; the titles are written in LaTeX, and inside a Python string a backslash is written twice, so `\\mu` reaches matplotlib as `\mu`.

```
for ax, (values, title) in zip(axes, panels):
    image = ax.imshow(values, cmap="RdBu_r", vmin=-scale, vmax=scale)
    ax.set_xticks(range(8))
    ax.set_xticklabels(NAMES, fontsize=7)
    ax.set_yticks(range(8))
    ax.set_yticklabels(NAMES, fontsize=7)
    ax.grid(False)  # no grid lines across the coloured squares
    ax.set_title(title, fontsize=10)
fig.colorbar(image, ax=list(axes), shrink=0.8, label="value (units $H = 1$)")
```

`zip` walks through the panels and the tables together. `ax.imshow` draws an 8×8 table as coloured squares (a **heat map**): the colour map `RdBu_r` runs from blue (negative) through white (zero) to red (positive), and `vmin=-scale, vmax=scale` uses the same scale in all three panels, so that equal colours mean equal numbers. The tick lines put the labels x_0 to x_7 on both axes; `ax.grid(False)` switches off the grid lines. `fig.colorbar` draws the colour scale beside the panels.

```
save_figure(fig, "t1_pair_tensor",
            "The energy-momentum tensor $T_{\\mu\\nu}$ (rows $\\mu$, columns $\\nu$, "
            ...
            "says, although the configuration is not even a solution.")
```

(The caption string, nine lines, is shown here by its first and last line with `...` between them; it is printed in full in the complete text of the notebook and under the figure. The same is done for every caption below.) `save_figure` saves the figure as `20a_1_t1_pair_tensor.png` and shows it.
What figure 1 shows. Three heat maps of the 64 components $T_{\mu\nu}$ (rows μ, columns ν, from x_0 to x_7; colour scale in units $H = 1$): left the random configuration, middle its T1 partner, right their sum. The student should see that the middle map is the left one with every colour reversed (red becomes blue of the same depth), and that the right map is white everywhere: the source of the T1 pair is zero, component by component, even though the configuration does not solve the field equation. This is theorem T1 (T1c and T1d) at one point of the deflating history.

In [9], along the hidden direction: the T1 partner and the T2 mirror copy.

```
psi_1 = rng.normal(size=16) + 1j * rng.normal(size=16)  # the spinor Psi_1
z_patch = np.linspace(0.05, np.pi / 2 - 0.02, 160)  # points of the patch
rho, charge = {"one": [], "T1": [], "T2": []}, {"one": [], "T1": [], "T2": []}
```

A second random spinor Ψ_1 (the generator continues where it stopped, so the numbers are new but fixed). `np.linspace(a, b, n)` gives n equally spaced numbers from a to b: 160 points of the patch from $z = 0.05$ to just below the brane. `rho` and `charge` are dictionaries of empty lists, one list for each of the three objects.

```
for z_value in z_patch:
    field = psi + 0.3 * (np.pi / 2 - z_value) ** 2 * psi_1  # Psi(z)
    slopes_here = [row.copy() for row in dpsi]  # the derivatives along x1 .. x7
    slopes_here[0] = -3.6 * (np.pi / 2 - z_value) * psi_1  # 6 H dPsi/dz, H = 1
    mirror_slopes = [R0_SIGNS[mu] * (gamma_num[0] @ slopes_here[mu])
                     for mu in range(8)]  # the mirror reverses d/dx0
```

At each point the field is $\Psi(z) = \Psi_0 + \frac{3}{10}(\pi/2 - z)^2\Psi_1$. Its derivatives along $x_1, \ldots, x_7$ are those of In [7] (`row.copy()` makes independent copies); its derivative along x_0 is $6H\, d\Psi/dz = 6 \cdot \frac{3}{10} \cdot 2(\pi/2 - z)(-1)\Psi_1 = -3.6(\pi/2 - z)\Psi_1$ (chain rule, $H = 1$), which vanishes at the brane and keeps the term $\tan z\, \gamma^{(x_0)}\partial_0\Psi$ finite there. The mirror copy has the derivatives $\gamma^{(x_0)}\partial_\mu\Psi$, with the sign of the x_0 derivative reversed, because the mirror $x_0 \to \pi/(6H) - x_0$ reverses that direction.

```
    here = geometry_at(1, z_value, A4_0, 1.0)
    there = geometry_at(-1, np.pi - z_value, A4_0, 1.0)  # the mirror point
    results = {
        "one": bilinears(here, field, slopes_here, M0, LAM0),
        "T1": bilinears(here, Gamma_num @ field,
                        [Gamma_num @ row for row in slopes_here], -M0, -LAM0),
        "T2": bilinears(there, gamma_num[0] @ field, mirror_slopes, -M0, LAM0),
    }
    for key, result in results.items():
        rho[key].append(-result["T"][4, 4])  # rho = -T_x4x4
        charge[key].append(result["J"][4])  # J^x4
```

The geometry at the point z of the patch and at the mirror point $\pi - z$ of the mirror patch. The three objects: the field with (m, λ), its T1 partner with $(-m, -\lambda)$ at the same point, and its T2 mirror copy $\gamma^{(x_0)}\Psi$ with $(-m, \lambda)$ at the mirror point. For each, the energy density $\rho = -T_{x_4x_4}$ (position 4, 4; the notebook computes the tensor $T_{\mu\nu}$ of the pairing records; because $g^{x_4x_4} = -1$, $T^{x_4}{}_{x_4} = g^{x_4x_4}T_{x_4x_4} = -T_{x_4x_4}$, so $-T_{x_4x_4} = +T^{x_4}{}_{x_4}$ in the pairing convention, which is $-T^{x_4}{}_{x_4}$ in the field-theory convention of Section 20.2, that is ρ) and the charge density J^{x_4} are appended to their lists.

```
rho = {key: np.array(values) for key, values in rho.items()}
charge = {key: np.array(values) for key, values in charge.items()}
size = max(np.abs(rho["one"]).max(), np.abs(charge["one"]).max())
check(np.abs(rho["T1"] + rho["one"]).max() < 1e-12 * size
      and np.abs(charge["T1"] + charge["one"]).max() < 1e-12 * size,
      "along z: the T1 partner has -rho and -J^x4 at every point")
check(np.abs(rho["T2"] - rho["one"]).max() < 1e-10 * size
      and np.abs(charge["T2"] - charge["one"]).max() < 1e-10 * size,
      "along z: the T2 copy has the same rho and J^x4 at the mirror point")
```

The dictionary comprehension `{key: np.array(values) for ...}` turns each list into a numpy array, so that whole arrays can be added and compared. `size` is the largest modulus of the field's energy density or charge density along the line; the tolerances are measured relative to it. Two checks at all 160 points: the T1 partner has exactly $-\rho$ and $-J^{x_4}$; the T2 copy has, at the mirror point, the SAME ρ and the SAME J^{x_4}. The second tolerance is 10^{-10} rather than 10^{-12} because the copy is evaluated with a different (mirror-patch) geometry, whose numbers $\sin^{1/6}(\pi - z)$ and

$-\cot(\pi - z)$ agree with those of the patch only up to rounding, and near the brane the factor $\tan z = 1/E_0$ is large and amplifies these rounding differences. The cell prints the two PASS lines.

In [10], figure 2: the profiles across the brane.

```
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.4))
for ax, data, label in ((axes[0], rho, "energy density $\\rho$"),
                        (axes[1], charge, "charge density $J^{x_4}$")):
    ax.plot(z_patch, data["one"], color="tab:blue", label="$\\Psi$, $(m, \\lambda)$")
    ax.plot(z_patch, data["T1"], "--", color="tab:red",
            label="T1 partner $\\Gamma\\Psi$, $(-m, -\\lambda)$")
    ax.plot(z_patch, data["one"] + data["T1"], color="black", linewidth=2.0,
            label="T1 pair: sum")
    ax.plot(np.pi - z_patch, data["T2"], color="tab:green",
            label="T2 copy $\\gamma^{(x_0)}\\Psi$, $(-m, \\lambda)$")
```

Two panels, the energy density on the left and the charge density on the right; the loop draws the same four curves in each. `ax.plot(x, y, ...)` draws a curve through the points; the style string of two minus signs makes it dashed, `color` sets its colour and `label` its name in the legend. The first three curves live on the patch (the field, its T1 partner and their sum); the fourth, the T2 copy, is drawn at its own points $\pi - z$ on the mirror patch.

```
    ax.axvline(np.pi / 2, color="grey", linestyle=":", linewidth=1.5)
    ax.text(np.pi / 2, ax.get_ylim()[1], " brane", va="top", fontsize=8)
    ax.set_xlabel("hidden coordinate $z = 6Hx_0$")
    ax.set_ylabel(label + " (units $H = 1$)")
handles, names = axes[0].get_legend_handles_labels()
fig.legend(handles, names, loc="lower center", ncol=4, fontsize=8.5,
           bbox_to_anchor=(0.5, -0.06))  # one legend below both panels
axes[0].set_title("T1: reversed at the same point; T2: equal at the mirror point",
                  fontsize=9)
axes[1].set_title("the same for the charge density", fontsize=9)
save_figure(fig, "pair_profiles",
            "Left: the energy density $\\rho = -T_{x_4x_4}$, right: the charge "
            ...
            "the brane, with the same sign: T1 pairs cancel, T2 pairs add.")
```

`ax.axvline` draws the dotted vertical line of the brane $z = \pi/2$, and `ax.text` writes the word brane at its top (`ax.get_ylim()[1]` is the upper end of the vertical axis; `va="top"` hangs the text below that height). The axis labels name the quantities and the units. `get_legend_handles_labels` collects the curves and their names from the left panel, and `fig.legend` draws one legend for both panels, in four columns (`ncol=4`), below them (`bbox_to_anchor=(0.5, -0.06)` places its lower centre slightly below the figure). The two titles follow. The call of `save_figure` saves the figure as `20a_2_pair_profiles.png`; its caption string (twelve lines, shown here by its first and last line with `...` between them) is printed in full in the complete text of the notebook and under the figure.
What figure 2 shows. Horizontal axis: the hidden coordinate z from 0 to π, with the brane dotted at $\pi/2$; vertical axis: the energy density (left) and the charge density (right), units $H = 1$. Left of the brane, the blue curve of the field and the red dashed curve of its T1 partner are mirror images of each other in the horizontal axis, and their black sum lies on zero everywhere. Right of the brane, the green curve of the T2 copy is the blue curve reflected in the vertical line of the

brane, with the SAME sign. The student should see the essential difference of the two theorems: T1 partners cancel, T2 partners add.

In [11], the T2 mirror copy does not cancel; figure 3.

```
R0 = np.array(R0_SIGNS, dtype=float)  # the reflection R0 of the x0 direction
mirror_dpsi = [R0[mu] * (gamma_num[0] @ dpsi[mu]) for mu in range(8)]
copy = bilinears(geometry_at(-1, np.pi - Z0, A4_0, 1.0), gamma_num[0] @ psi,
                 mirror_dpsi, -M0, LAM0)  # the T2 copy at the mirror point
pulled_back = np.outer(R0, R0) * one["T"]  # R0 T R0
```

`R0` is the diagonal of $R_0 = \mathrm{diag}(-1, 1, 1, 1, 1, 1, 1, 1)$. The copy of the configuration of In [7] (with its full jet, including the x_0 derivative, which the mirror reverses) is evaluated at the mirror point $\pi - 0.6$. `np.outer(R0, R0)` is the 8×8 table of products $R_{0,\mu} R_{0,\nu}$; multiplying it entry by entry with T gives $(R_0 T R_0)_{\mu\nu}$: the entries with exactly one index x_0 change sign, all others stay.

```
reproduces(np.abs(copy["T"] - pulled_back).max() < 1e-10 * scale,
           "T2 copy: T' = R0 T R0 at the mirror point (64 components)",
           PAIR_PY, "T2.metric.commuting.emt")
reproduces(np.abs(copy["J"] - R0 * one["J"]).max() < 1e-10 * scale,
           "T2 copy: J' = R0 J (the charge density is unchanged)",
           PAIR_PY, "T2.metric.commuting.current")
reproduces(abs(copy["S"] + one["S"]) < 1e-10 * scale, "T2 copy: S' = -S",
           PAIR_PY, "T2.metric.commuting.S_odd")
reproduces(np.abs(copy["E"] + gamma_num[0] @ one["E"]).max() < 1e-10 * scale,
           "T2 copy: E_(-m,lambda)[Psi'] = -gamma^(x0) E_(m,lambda)[Psi]",
           PAIR_PY, "T2.metric.commuting.euler_lagrange_map")
reproduces(np.abs(copy["T"] + one["T"]).max() > 0.1 * scale,
           "T2 pair: the tensors do NOT cancel",
           PAIR_WL, "T2_mirror_energy_momentum_and_current_commuting")
```

Five checks of theorem T2 at the point: the copy's tensor is the pulled-back one, $T' = R_0 T R_0$; its current is $J' = R_0 J$ (so the charge density J^{x_4} is unchanged); its scalar is $S' = -S$; its residual is $-\gamma^{(x_0)}$ times that of the configuration (so it solves the $(-m, \lambda)$ equation on the mirror patch exactly when the configuration solves the (m, λ) equation on the patch); and the sum $T + T'$ is NOT small (more than a tenth of the size of the tensor): a T2 pair has no zero source.

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.3))
panels = ((one["T"], "$T_{\\mu\\nu}[\\Psi]$ at $z$"),
          (copy["T"], "$T_{\\mu\\nu}$ of the T2 copy at $\\pi - z$"),
          (copy["T"] - pulled_back, "copy minus $R_0TR_0$"))
for ax, (values, title) in zip(axes, panels):
    image = ax.imshow(values, cmap="RdBu_r", vmin=-scale, vmax=scale)
    ax.set_xticks(range(8))
    ax.set_xticklabels(NAMES, fontsize=7)
    ax.set_yticks(range(8))
    ax.set_yticklabels(NAMES, fontsize=7)
    ax.grid(False)
    ax.set_title(title, fontsize=10)
fig.colorbar(image, ax=list(axes), shrink=0.8, label="value (units $H = 1$)")
```

```
save_figure(fig, "t2_mirror_tensor",
            "Left: the energy-momentum tensor $T_{\\mu\\nu}$ of the configuration "
            ...
            "the T2 pair has twice the source of one member.")
```

Three new panels: the tensor of the configuration, the tensor of its T2 copy, and the copy minus the pulled-back tensor. The drawing loop is the one of In [8], line for line: a heat map with the same colour scale in each panel, the labels x_0 to x_7 on both axes, no grid, a title; then the common colour bar, and `save_figure` saves `20a_3_t2_mirror_tensor.png`. **What figure 3 shows.** Three heat maps of $T_{\mu\nu}$ (rows and columns x_0 to x_7, units $H = 1$, red positive, blue negative): left the configuration at $z = 0.6$, middle its T2 copy at $\pi - 0.6$, right their difference after the pull-back. The student should see that the left and middle maps are equal except in the last row and the last column, whose off-diagonal entries (one index x_0) have the opposite colour, and that the right map is white. Unlike the T1 partner, the mirror copy carries the SAME energy: a T2 pair has twice the source of one member.

In [12], the T1 pair as the only source: Einstein's vacuum equations.

```
record = read_json(A4_RECORD)
ad1, ad2 = sp.symbols("ad1 ad2")  # a4' and a4'' (complex allowed)
Lam = sp.symbols("Lambda")  # the cosmological constant
alpha2, alpha3, A = sp.symbols("alpha2 alpha3 A", real=True)
KEYS = ["x0x0", "x1x1", "x4x4", "x5x5"]  # the independent diagonal components
```

The record of the field equations for a_4 is read. Its formulas use the names `ad1` and `ad2` for a_4' and a_4''; the notebook makes symbols with the same names and, on purpose, does NOT declare them real, so that sympy may find complex solutions if there are any. `Lam` is Λ; `alpha2`, `alpha3` and `A` are the two higher Lovelock couplings and the slope of the linear member. `KEYS` names the four independent diagonal components (the others repeat these).

```
def lovelock(order, key):
    """The component key of E_(order) from the record, as a sympy expression."""
    text = record["lovelockTensors"][f"E{order}"][key]["input"].replace("^", "**")
    return sp.sympify(text, locals={"ad1": ad1, "ad2": ad2, "H": H})
```

The record stores each component of $E_{(1)}$, $E_{(2)}$ and $E_{(3)}$ as a text in Wolfram's input form, in which a power is written `^`. `.replace("^", "**")` turns it into Python's form, and `sp.sympify` reads the text as a sympy expression; `locals` makes the names in the text mean the notebook's symbols.

```
G = {key: lovelock(1, key) for key in KEYS}  # the Einstein tensor
for key in KEYS:
    say(f"G^{key[:2]}_{key[2:]} = {G[key]}")
vacuum = [G[key] + Lam for key in KEYS]  # zero source
solutions = sp.solve(vacuum, [ad1, ad2, Lam], dict=True)
say(f"all solutions of the vacuum equations: {solutions}")
```

`G` holds the four components of the Einstein tensor $E_{(1)} = G$; the loop prints them (`key[:2]` and `key[2:]` are the first two and the last two letters of the key). Output: $G^{x_0}{}_{x_0} = 15H^2 - 3a_4'^2$,

$G^{x_1}{}_{x_1} = 15H^2 - 3a_4'^2 + a_4''$, $G^{x_4}{}_{x_4} = 21H^2 + 3a_4'^2$, $G^{x_5}{}_{x_5} = 15H^2 - 3a_4'^2 - a_4''$. `vacuum` is the list of the four vacuum equations $G^{\mu}{}_{\mu} + \Lambda = 0$, and `sp.solve` finds ALL solutions for the three unknowns a_4', a_4'', Λ, each as a dictionary. Output: two solutions, $\Lambda = -18H^2$, $a_4'' = 0$ and $a_4' = -iH$ or $+iH$.

```
found = {(s[ad1], s[ad2], s[Lam]) for s in solutions}
reproduces(found == {(sp.I * H, 0, -18 * H ** 2), (-sp.I * H, 0, -18 * H ** 2)},
           "the only solutions have a4' = +i H or -i H: none is real",
           LEAD_EGB, "no_vacuum_for_H_positive")
difference = sp.expand(vacuum[2] - vacuum[0])  # x4 equation minus x0 equation
total = sp.expand(vacuum[2] + vacuum[0])  # x4 equation plus x0 equation
report("x4 equation minus x0 equation", difference)
report("x4 equation plus x0 equation", total)
```

`found` is the set of the solutions as triples; the check requires exactly the two triples $(\pm iH, 0, -18H^2)$ (`sp.I` is sympy's i): no real rate. Then the two combinations of the proof of C1(a): the x_4 equation minus the x_0 equation and their sum, multiplied out by `sp.expand`. Output: $6H^2 + 6a_4'^2$ and $36H^2 + 2\Lambda$, lines 5 and the remark after line 6 of Section 20.7.

```
reproduces(difference == 6 * ad1 ** 2 + 6 * H ** 2
           and total == 36 * H ** 2 + 2 * Lam,
           "6 a4'^2 + 6 H^2 = 0 and 36 H^2 + 2 Lambda = 0 (record's lines)",
           A4_WL, "einstein_no_vacuum_solution")
a_real = sp.symbols("a_real", real=True)  # a real value of a4'
reproduces(sp.solve(difference.subs(ad1, a_real), a_real) == [],
           "for real a4' the difference 6 a4'^2 + 6 H^2 never vanishes",
           A4_PY, "einstein_no_vacuum")
```

The first check compares the two combinations with the record's lines. The second substitutes for a_4' a symbol declared real and asks sympy for the real solutions of $6a_4'^2 + 6H^2 = 0$: the answer is the empty list `[]`, line 6 of the proof.

In [13], figure 4: the two vacuum conditions never meet.

```
slopes = np.linspace(-3.0, 3.0, 601)  # a4'/H
lower = -(3 * slopes ** 2 + 21)  # Lambda/H^2 where the x4 equation holds
upper = 3 * slopes ** 2 - 15  # Lambda/H^2 where the x0 equation holds
check(np.min(upper - lower) >= 6.0 - 1e-12, "the two curves stay 6 H^2 apart or more")
```

601 values of a_4'/H from -3 to 3. Solving the x_4 equation for Λ gives $\Lambda = -(3a_4'^2 + 21H^2)$, a parabola that opens downwards; solving the x_0 equation gives $\Lambda = 3a_4'^2 - 15H^2$, a parabola that opens upwards (in units of H^2). Their vertical distance is $6a_4'^2 + 6H^2 \geq 6H^2$; the check confirms it at all 601 points.

```
fig, ax = plt.subplots(figsize=(7.0, 4.6))
ax.plot(slopes, lower, color="tab:red", label="$x_4$: $\\Lambda = -(3a_4'^2 + 21H^2)$")
ax.plot(slopes, upper, color="tab:blue", label="$x_0$: $\\Lambda = 3a_4'^2 - 15H^2$")
ax.fill_between(slopes, lower, upper, color="grey", alpha=0.2,
                label="gap $6a_4'^2 + 6H^2$")
ax.annotate("", xy=(1.0, -12.0), xytext=(1.0, -24.0),
```

```
            arrowprops={"arrowstyle": "<->", "color": "black"})
ax.text(1.12, -19.3, "$12H^2$ at $a_4' = H$\n(the author's history)", fontsize=8,
        va="top")  # va="top": the text hangs below the given height
ax.axhline(-18.0, color="black", linestyle=":", linewidth=1.0)
ax.text(-2.95, -17.3, "$\\Lambda = -18H^2$: both hold only for $a_4' = \\pm iH$",
        fontsize=8)
ax.set_xlabel("$a_4'/H$")
ax.set_ylabel("$\\Lambda/H^2$")
ax.set_title("Einstein gravity with zero source: the two conditions never meet")
ax.legend(fontsize=8, loc="lower right")
save_figure(fig, "einstein_vacuum_parabolas",
            "The vacuum equations of Einstein gravity for the author's metric, the "
            ...
            "(dotted line), are not real.")
```

The two parabolas are drawn in red and blue; `fill_between` shades the band between them in grey (`alpha=0.2`: 20 per cent opaque). `ax.annotate` with an empty text draws a double arrow at $a_4' = H$ from $\Lambda = -24H^2$ to $-12H^2$, the gap $12H^2$ of the deflating history, and `ax.text` labels it (`\n` starts a new line). `ax.axhline` draws the dotted horizontal line $\Lambda = -18H^2$, the value at which the two equations would hold together if a_4' could be $\pm iH$. **What figure 4 shows.** Horizontal axis: the rate a_4'/H; vertical axis: the cosmological constant Λ/H^2. A vacuum would be a point on both parabolas, and there is none: the grey band between them is never thinner than $6H^2$ and is $12H^2$ thick at the author's history. The student should see at a glance why no choice of the rate and of Λ removes the need for a source in Einstein gravity, and therefore why a T1 pair, whose source is zero, cannot be the only source of the author's metric.

In [14], what the geometry requires and what a pair supplies.

```
couplings = {"alpha1": 1, "alpha2": alpha2, "alpha3": alpha3, "H": H, "ad1": ad1,
             "ad2": ad2, "AA": A}  # alpha1 = 1 throughout
null_text = record["generalSource"]["nullCombinations"]["kappa(rho+p0)"]["input"]
null_required = sp.sympify(null_text.replace("^", "**"), locals=couplings)
V_text = record["linearMember"]["vacuumFactor"]["input"]
V = sp.sympify(V_text.replace("^", "**"), locals=couplings)
```

`couplings` tells `sympify` what the names in the record's texts mean; $\alpha_1 = 1$ throughout (the record writes the slope as `AA`). The record's null combination $\kappa(\rho + p_0)$ for a general source and its vacuum factor V of the linear member are read as sympy expressions.

```
lovelock_sum = {key: lovelock(1, key) + alpha2 * lovelock(2, key)
                + alpha3 * lovelock(3, key) for key in KEYS}
own_null = -(lovelock_sum["x4x4"] - lovelock_sum["x0x0"])
check(sp.expand(own_null - null_required) == 0,
      "the null combination of the record equals -(E^x4_x4 - E^x0_x0)")
```

`lovelock_sum` is $\sum_k \alpha_k E_{(k)}$ for the four components. `own_null` is the notebook's own null combination, $-\sum_k \alpha_k ({E_{(k)}}^{x_4}{}_{x_4} - {E_{(k)}}^{x_0}{}_{x_0})$, derived in Section 20.7; the check finds it equal to the record's.

```
linear = {ad1: A * H, ad2: 0}  # the linear member a4 = A H x4 + a0
reproduces(sp.expand(own_null.subs(linear) + 6 * (A ** 2 + 1) * H ** 2 * V) == 0,
           "linear member: kappa (rho + p0) = -6 (A^2 + 1) H^2 V",
           A4_WL, "linear_member_vacuum_factor")
reproduces(sp.expand(V.subs({alpha2: 0, alpha3: 0})) == 1
           and sp.expand(null_required.subs({alpha2: 0, alpha3: 0})
                         + 6 * ad1 ** 2 + 6 * H ** 2) == 0,
           "Einstein: V = 1 and kappa (rho + p0) = -6 (a4'^2 + H^2)",
           A4_PY, "einstein_null_energy_x0")
reproduces(sp.expand(null_required.subs({alpha2: 0, alpha3: 0})
                     + 6 * ad1 ** 2 + 6 * H ** 2) == 0,
           "the same null combination from the lead's independent Einstein tensor",
           LEAD_EGB, "einstein_null_energy")
```

For the linear member ($a_4' = AH$, $a_4'' = 0$) the null combination equals $-6(A^2+1)H^2V$. In Einstein gravity ($\alpha_2 = \alpha_3 = 0$) $V = 1$ and the null combination is $-6(a_4'^2 + H^2)$, which the record's sympy report and the lead's independent report both state.

In [15], figure 5: the required null combination against the slope.

```
A_axis = np.linspace(0.0, 2.0, 401)
V_numeric = sp.lambdify((A, alpha2, alpha3), V.subs(H, 1), "numpy")
fig, ax = plt.subplots(figsize=(7.0, 4.4))
for x2, style, label in ((0.0, "-", "Einstein ($\\alpha_2 = 0$)"),
                         (1 / 48, "--", "Gauss-Bonnet, $\\alpha_2H^2 = 1/48$"),
                         (1 / 40, "-.", "Gauss-Bonnet, $\\alpha_2H^2 = 1/40$")):
    required = -6 * (A_axis ** 2 + 1) * V_numeric(A_axis, x2, 0.0)
    ax.plot(A_axis, required, style, label=label)
```

401 slopes A from 0 to 2. `V_numeric` is V as a numpy function of A, α_2 and α_3 in units $H = 1$. The loop draws the required $\kappa(\rho + p_0)/H^2 = -6(A^2+1)V$ for three theories: Einstein gravity (solid), Gauss-Bonnet with $\alpha_2 H^2 = 1/48$ (dashed) and with $1/40$ (dash-dotted).

```
ax.axhline(0.0, color="black", linewidth=2.0, label="what a T1 pair supplies: 0")
ax.plot([1.0, 0.0], [0.0, 0.0], "o", color="tab:red", markersize=7,
        label="a T1 pair fits: $V = 0$")
ax.set_xlabel("slope $A$ of the linear member $a_4 = AHx_4$")
ax.set_ylabel("required $\\kappa(\\rho + p_0)/H^2$")
ax.set_title("The source the geometry requires, and the zero of a T1 pair")
ax.legend(fontsize=8, loc="lower left")
save_figure(fig, "null_combination",
            "The null combination $\\kappa(\\rho + p_0)$ (energy density plus the "
            "pressure along $x_0$, times the gravitational coupling; vertical, "
            ...
            "$\\alpha_2H^2 = 1/48$, and $A = 0$ for $1/40$).")
```

The thick black line at zero is what a T1 pair supplies; the two red dots mark where a requirement curve reaches it. **What figure 5 shows.** Horizontal axis: the slope A; vertical axis: the null combination the field equations require of any source, in units H^2. The Einstein curve, $-6(A^2+1)$, stays at or below -6 for every slope, so it never meets the black line: in Einstein gravity a T1 pair

is never the only source. Each Gauss-Bonnet curve reaches zero at exactly one slope: the dashed one crosses it at $A = 1$ (the author's history) for $\alpha_2 H^2 = 1/48$, and the dash-dotted one touches it at $A = 0$ for $1/40$ and is positive at every other slope (there $V = -A^2/5$, so the requirement is $6A^2(A^2+1)/5$). The student should see that C1(a) is a property of Einstein gravity, not of every theory of gravity.

In [16], Einstein-Gauss-Bonnet gravity: when a zero source is allowed.

```
V_gb = sp.expand(V.subs(alpha3, 0))
A_squared = sp.solve(V_gb, A ** 2)[0]
reproduces(sp.simplify(A_squared - (1 - 40 * alpha2 * H ** 2)
                       / (8 * alpha2 * H ** 2)) == 0,
           "Gauss-Bonnet vacuum: A^2 = (1 - 40 alpha2 H^2)/(8 alpha2 H^2)",
           A4_WL, "einstein_gauss_bonnet_vacuum_linear")
```

V with $\alpha_3 = 0$; `sp.solve(V_gb, A ** 2)` solves $V = 0$ for A^2 (sympy treats A^2 as the unknown) and `[0]` takes the one solution. The check compares it with the formula derived line by line in Section 20.7.

```
x2_author = sp.solve(A_squared.subs(H, 1) - 1, alpha2)[0]  # A = 1, H = 1
report("alpha2 H^2 for a vacuum with A = 1", x2_author)
gauss_bonnet = {key: (lovelock(1, key) + alpha2 * lovelock(2, key))
                .subs({ad1: H, ad2: 0, alpha2: x2_author / H ** 2})
                for key in KEYS}
Lam_author = sp.simplify(-gauss_bonnet["x4x4"])  # Lambda from the x4 equation
report("Lambda of that vacuum", Lam_author)
```

Setting $A^2 = 1$ (with $H = 1$) and solving for α_2 gives $1/48$ (Output: RESULT $\alpha_2 H^2$ for a vacuum with $A = 1 = 1/48$). The four components of $E_{(1)} + \alpha_2 E_{(2)}$ are evaluated at $a_4' = H$, $a_4'' = 0$, $\alpha_2 = 1/(48H^2)$; the vacuum x_4 equation $E^{x_4}{}_{x_4} + \Lambda = 0$ gives $\Lambda = -E^{x_4}{}_{x_4}$. Output: RESULT Lambda of that vacuum $= -12H^2$, the value derived by hand in Section 20.7.

```
reproduces(x2_author == sp.Rational(1, 48) and Lam_author == -12 * H ** 2
           and all(sp.simplify(gauss_bonnet[key] + Lam_author) == 0 for key in KEYS),
           "a4 = H x4 solves the Gauss-Bonnet vacuum equations exactly",
           A4_PY, "einstein_gauss_bonnet_vacuum_linear")
zero_off = all(record["lovelockTensors"][f"E{k}"][key]["input"] == "0"
               for k in (1, 2, 3) for key in ("x4x0", "x0x4"))
check(zero_off, "the mixed components x4x0 and x0x4 of E_(1..3) are 0 in the record")
```

The check requires $\alpha_2 H^2 = 1/48$, $\Lambda = -12H^2$, and that ALL FOUR independent vacuum equations vanish exactly for the deflating history. The second check confirms that the record has no mixed component $x_4 x_0$ in any of the three Lovelock tensors, so no further equation remains: in this theory the author's deflating history is a vacuum, and a T1 pair CAN be its only source.

```
Lam_curve = sp.simplify(-(lovelock(1, "x4x4") + alpha2 * lovelock(2, "x4x4"))
                        .subs({ad1: A * H, ad2: 0}).subs(A ** 2, A_squared))
say(f"Lambda along the vacuum curve: {sp.factor(Lam_curve)}")
```

Along the whole family of Gauss-Bonnet vacua the cosmological constant is $\Lambda = -E^{x_4}{}_{x_4}$ at $a_4' = AH$ with A^2 replaced by the vacuum formula; `sp.factor` writes it as a fraction. Output: $3(3840H^4\alpha_2^2 - 192H^2\alpha_2 + 1)/(16\alpha_2)$, that is $720\alpha_2 H^4 - 36H^2 + 3/(16\alpha_2)$; at $\alpha_2 = 1/(48H^2)$ this is $15H^2 - 36H^2 + 9H^2 = -12H^2$.

In [17], figure 6: the Gauss-Bonnet vacua.

```
x_axis = np.linspace(0.004, 1 / 40, 400)  # alpha2 H^2
A_curve = np.sqrt((1 - 40 * x_axis) / (8 * x_axis))
Lam_numeric = sp.lambdify(alpha2, Lam_curve.subs(H, 1), "numpy")
fig, axes = plt.subplots(1, 2, figsize=(12.0, 4.3))
axes[0].plot(x_axis, A_curve, color="tab:purple")
axes[0].plot([1 / 48], [1.0], "o", color="tab:red", markersize=8,
             label="$A = 1$ at $\\alpha_2H^2 = 1/48$")
axes[0].set_ylabel("slope $A$ of the vacuum $a_4 = AHx_4$")
axes[1].plot(x_axis, Lam_numeric(x_axis), color="tab:purple")
axes[1].plot([1 / 48], [-12.0], "o", color="tab:red", markersize=8,
             label="$\\Lambda = -12H^2$ at $\\alpha_2H^2 = 1/48$")
axes[1].set_ylabel("$\\Lambda/H^2$ of that vacuum")
```

The 400 values of the coupling $\alpha_2 H^2$ run from 0.004 to the limit $1/40$. For each of them the array `A_curve` holds the slope of the vacuum, $\sqrt{(1 - 40\alpha_2 H^2)/(8\alpha_2 H^2)}$, computed with the square root `np.sqrt`; it is drawn in the left panel. The right panel shows the cosmological constant of each vacuum, the expression `Lam_curve` of In [16] turned into a numpy function. The red dots mark the author's history.

```
for ax in axes:
    ax.set_xlabel("Gauss-Bonnet coupling $\\alpha_2H^2$")
    ax.axvline(1 / 40, color="grey", linestyle=":")
    ax.legend(fontsize=8)
axes[0].set_title("no vacuum for $\\alpha_2 \\to 0$ (Einstein), $A = 0$ at $1/40$",
                  fontsize=9)
axes[1].set_title("the cosmological constant each vacuum needs", fontsize=9)
save_figure(fig, "gauss_bonnet_vacuum",
            "The vacua of Einstein-Gauss-Bonnet gravity ($\\alpha_1 = 1$, "
            ...
            "$\\alpha_2H^2 = 1/48$ and $\\Lambda = -12H^2$ (checked exactly).")
```

Both panels get the horizontal label, the dotted limit $\alpha_2 H^2 = 1/40$ and a legend. **What figure 6 shows.** Horizontal axis: the Gauss-Bonnet coupling $\alpha_2 H^2$. Left: the slope A of the vacuum; it grows without bound as $\alpha_2 \to 0$, the Einstein limit, which has no vacuum, and falls to $A = 0$ at $1/40$. Right: the cosmological constant Λ/H^2 that the same vacuum needs. The student should see that each coupling between 0 and $1/40$ has exactly one vacuum among the linear members, and that the author's deflating history $A = 1$ is the one at $\alpha_2 H^2 = 1/48$, with $\Lambda = -12H^2$.

In [18], third order: one straight line of vacua per slope; figure 7.

```
y_line = sp.solve(V.subs({alpha2: sp.Symbol("x"), alpha3: sp.Symbol("y"), H: 1}),
                  sp.Symbol("y"))[0]
wanted = ((8 * A ** 2 + 40) * sp.Symbol("x") - 1) / (72 * A ** 4 + 144 * A ** 2 + 360)
check(sp.simplify(y_line - wanted) == 0, "for fixed A the vacua form a straight line")
check(V.subs({alpha2: 0, alpha3: 0}) == 1, "Einstein gravity (origin) has V = 1")
```

$V = 0$ is solved for $y = \alpha_3 H^4$ with $x = \alpha_2 H^2$ (`sp.Symbol("x")` makes one symbol). The check compares the solution with the straight line derived in Section 20.7; the second check confirms that the origin $x = y = 0$, Einstein gravity, has $V = 1$ and is no vacuum.

```
x_plot = np.linspace(-0.01, 0.05, 200)
fig, ax = plt.subplots(figsize=(7.0, 4.6))
for slope_A in (0.0, 0.5, 1.0, 2.0, 3.0):
    line = ((8 * slope_A ** 2 + 40) * x_plot - 1) / (
        72 * slope_A ** 4 + 144 * slope_A ** 2 + 360)
    ax.plot(x_plot, 1000 * line, label=f"$A = {slope_A:g}$")
ax.plot([0.0], [0.0], "s", color="black", markersize=8,
        label="Einstein gravity: no vacuum")
ax.plot([1 / 48], [0.0], "o", color="tab:red", markersize=8,
        label="section 13: $A = 1$, $\\alpha_3 = 0$")
ax.axhline(0.0, color="grey", linewidth=0.8)
ax.axvline(0.0, color="grey", linewidth=0.8)
ax.set_xlabel("$\\alpha_2H^2$")
ax.set_ylabel("$1000\\,\\alpha_3H^4$")
ax.set_title("Couplings for which $a_4 = AHx_4$ is a vacuum (third order)")
ax.legend(fontsize=8, loc="upper left")
save_figure(fig, "third_order_vacua",
            "The Einstein-Lovelock couplings for which the linear member "
            ...
            "author's history $A = 1$ at $\\alpha_2H^2 = 1/48$.")
```

For five slopes the line is drawn, its height multiplied by 1000 so that the small values of $\alpha_3 H^4$ are readable (`{slope_A:g}` prints a number without needless zeros). The black square is the origin, Einstein gravity; the red dot is the Gauss-Bonnet vacuum of In [16] (the legend's "section 13" is the notebook's own section). **What figure 7 shows.** Horizontal axis: $\alpha_2 H^2$; vertical axis: $1000\,\alpha_3 H^4$. For each slope A the couplings for which $a_4 = AHx_4$ is a vacuum form a straight line; the five coloured lines all pass below the origin. The student should see that Einstein gravity, the black square, lies on no line, while every line contains infinitely many theories with a vacuum, among them the red dot of the author's history.

In [19], the last check.

```
figure_names = ["t1_pair_tensor", "pair_profiles", "t2_mirror_tensor",
                "einstein_vacuum_parabolas", "null_combination",
                "gauss_bonnet_vacuum", "third_order_vacua"]
paths = [output_file(f"{FIGURE_FOLDER}/20a_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

`enumerate(list, 1)` pairs each name with its number, starting at 1, so that `paths` lists the seven figure files `20a_1_t1_pair_tensor.png` to `20a_7_third_order_vacua.png`. The check confirms that all exist, and `all_checks_passed()` prints the last line. Output: PASS every figure file of this notebook exists, and ALL 37 CHECKS PASSED (notebook 20a).

20.12 One universe without a partner: an exact solution and its two partners

Why an example. The pairing theorems speak about ALL solutions at once, and so they are easy to misread. One exact solution makes every statement a number that can be checked. We build one **universe** of the commuting field dirac16complex00: a solution of its field equation that is, by itself, the COMPLETE source of the author's metric with the exponentially deflating history $a_4 = Hx_4$ in Einstein gravity. Then we build its T1 partner, the T1 pair and its T2 mirror copy, and ask of each whether it solves its own field equation and whether it can be the source of the author's metric. The answer teaches the lesson of the whole chapter in one example: the universe needs no partner, and the partners exist as solutions of OTHER equations, which nothing in the theory forces anyone to realise.

Status. The universe below and the statements about its partners are COMPUTED by Notebook 20b and derived by hand in this section (exact arithmetic for the field equations and for the two Einstein conditions; floating point, to 10^{-10}, for the 64 components of the Einstein equations at nine points). They are a result of this book, not a Revision record. They rest on PROVED record statements, which are named at each step, and on these ASSUMED inputs: Einstein gravity ($\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$); the background $b_4 = 1$ of the author's metric (the condensate below has $T^{x_4}{}_{x_0} = 0$, and in Einstein gravity such a source forces a constant b_4, which is $b_4 = 1$ after a rescaling of the extra times; Section 20.7); the classical commuting field dirac16complex00 (not the quantised dirac16complex); the sign convention $\sigma_T = +1$ of the record of the field equations for a_4 (it fixes the overall sign of the energy-momentum tensor; Chapter 12); the chosen numbers $A = 1$, $\Lambda = -36H^2$ and $M = -5H$; and, for the mirror copy, the Z2 construction across the brane. Units: $H = \kappa = 1$.

Step 1: the field equation of a condensate. A **condensate** is a field that depends on the time x_4 only, $\Phi = \Phi(x_4)$. Its derivatives along the seven other directions vanish, $\gamma^{x_4} = \gamma^{(x_4)}$ because $g_{x_4x_4} = -1$, and the spin connection enters the field equation only through $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ (`python-a4-report.json`, check `authorT16_gravity_term`; `emt-divergence-and-spin-connection.json`, check `gamma_Omega_equals_3H_gamma0`). So the field equation $\gamma^\mu D_\mu \Phi = (m + \lambda S)\Phi$ becomes

$$\gamma^{(x_4)}\Phi' + 3H\gamma^{(x_0)}\Phi = M\Phi, \qquad M = m + \lambda S,$$

where $\Phi' = d\Phi/dx_4$ and M is the **effective mass**. Subtracting $3H\gamma^{(x_0)}\Phi$ from both sides,

$$\gamma^{(x_4)}\Phi' = \big(M - 3H\gamma^{(x_0)}\big)\Phi.$$

Multiplying from the left by $-\gamma^{(x_4)}$, and using $(-\gamma^{(x_4)})\gamma^{(x_4)} = -\eta^{x_4x_4} I_{16} = I_{16}$ (the Clifford relation with $\eta^{x_4x_4} = -1$),

$$\Phi' = \mathcal{A}\Phi, \qquad \mathcal{A} = -\gamma^{(x_4)}\big(M - 3H\gamma^{(x_0)}\big)$$

(`wolfram-a4-report.json`, check `condensate_equation_x0_consistent`). Chapter 12 derives line by line two facts about $\mathcal{A}$, which we use here: $\mathcal{A}^2 = -(M^2 - 9H^2)I_{16}$, so for $M^2 > 9H^2$ every eigenvalue of $\mathcal{A}$ is $+iw$ or $-iw$ with the **frequency** $w = \sqrt{M^2 - 9H^2}$; and $C\mathcal{A} + \mathcal{A}^T C = 0$, so the density $S = \bar{\Phi}\Phi$ does not change in time (`python-a4-report.json`, check `authorT16_condensate_S_constant`). An eigenvector Φ_0 with $\mathcal{A}\Phi_0 = -iw\Phi_0$ gives the solution $\Phi(x_4) = e^{-iwx_4}\Phi_0$, because its derivative is $-iw\Phi = \mathcal{A}\Phi$.

Step 2: its source. The record proves for a condensate that the diagonal of the kinetic tensor is $K^{x_4}{}_{x_4} = MS$ and zero in the seven other directions (`python-a4-report.json`, check `authorT16_condensate_kinetic_diagonal`), and that the off-diagonal components of its energy-momentum tensor are multiples of 15 **three-gamma bilinears** $\bar{\Phi}\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$ (`wolfram-a4-report.json`, check `condensate_offdiagonal_are_three_gamma_bilinears`). When these 15 numbers vanish, the tensor is diagonal with

$$\rho = mS + \tfrac{\lambda}{2}S^2, \qquad p_3 = p_t = p_0 = p = \tfrac{\lambda}{2}S^2$$

(Chapter 12 derives both lines from $L = MS - mS - \frac{\lambda}{2}S^2 = \frac{\lambda}{2}S^2$). Two combinations will be needed. Adding,

$$\rho + p = mS + \lambda S^2 = (m + \lambda S)S = MS,$$

because $\frac{\lambda}{2}S^2 + \frac{\lambda}{2}S^2 = \lambda S^2$, and then S is taken out. Subtracting,

$$\rho - p = mS,$$

because the two terms $\frac{\lambda}{2}S^2$ cancel.

Step 3: the two Einstein conditions. For the linear member $a_4 = AHx_4$ we have $a_4' = AH$ and $a_4'' = 0$. The record's Einstein tensor (`python-a4-report.json`, check `einstein_components`) then gives $G^{x_4}{}_{x_4} = (3A^2 + 21)H^2$ and $G^{x_1}{}_{x_1} = G^{x_5}{}_{x_5} = G^{x_0}{}_{x_0} = (15 - 3A^2)H^2$. With $T^{x_4}{}_{x_4} = -\rho$ and $T^{x_0}{}_{x_0} = p$, the time equation and the hidden equation are

$$(3A^2 + 21)H^2 + \Lambda = -\kappa\rho, \qquad (15 - 3A^2)H^2 + \Lambda = \kappa p;$$

the equations for x_1, x_2, x_3 and for x_5, x_6, x_7 are the hidden equation again, because their components of G and of T are the same, and every off-diagonal equation reads $0 = 0$ once the 15 three-gamma bilinears vanish. Subtracting the second equation from the first removes Λ:

$$(3A^2 + 21 - 15 + 3A^2)H^2 = -\kappa\rho - \kappa p \quad \Longrightarrow \quad 6(A^2 + 1)H^2 = -\kappa MS,$$

where the last step collects $3A^2 + 3A^2 = 6A^2$ and $21 - 15 = 6$ and uses $\rho + p = MS$. Adding the two equations removes A:

$$(3A^2 + 21 + 15 - 3A^2)H^2 + 2\Lambda = -\kappa\rho + \kappa p \quad \Longrightarrow \quad 36H^2 + 2\Lambda = -\kappa mS,$$

using $-\kappa(\rho - p) = -\kappa mS$. These are the record's two conditions (`python-a4-report.json` and `wolfram-a4-report.json`, check `condensate_einstein_quadratic_U`):

$$\kappa MS = -6(A^2 + 1)H^2, \qquad \kappa mS = -(36H^2 + 2\Lambda).$$

Step 4: the numbers of the universe. We choose $A = 1$ (the author's deflating history: 3-space grows like e^{x_4}, the three extra times shrink like e^{-x_4}), $\Lambda = -36$ and $M = -5$. The choice

$|M| = 5 > 3$ makes the condensate oscillate, with the frequency $w = \sqrt{25 - 9} = 4$. The choice of Λ gives the universe a positive energy density: the time equation says $\kappa\rho = -(24 + \Lambda)$ at $A = 1$, which is positive exactly when $\Lambda < -24$. Line by line:

1. The first condition with $\kappa = 1$: $MS = -6 \cdot 2 = -12$, so $S = -12/M = -12/(-5) = 12/5$.
2. The second condition: $mS = -(36+2\cdot(-36)) = -(36-72) = 36$, so $m = 36/S = 36\cdot 5/12 = 15$.
3. The definition $M = m + \lambda S$ solved for λ: $\lambda = (M - m)/S = (-5 - 15) \cdot 5/12 = -100/12 = -25/3$.
4. The energy density: $\rho = mS + \frac{\lambda}{2}S^2 = 36 + \left(-\frac{25}{6}\right) \cdot \frac{144}{25} = 36 - 24 = 12$.
5. The pressure: $p = \frac{\lambda}{2}S^2 = -24$; the equation of state is $w_{\mathrm{EoS}} = p/\rho = -2$.

Two checks of the arithmetic: $\rho + p = -12 = MS = (-5)(12/5)$, and $\rho - p = 36 = mS = 15 \cdot 12/5$. So the universe has mass $m = +15$ and coupling $\lambda = -25/3$.

Step 5: the condensate itself. It remains to find a spinor Φ_0 with $\mathcal{A}\Phi_0 = -4i\Phi_0$, all 15 three-gamma bilinears zero, and $S = 12/5$. The record's recipe (`wolfram-a4-report.json`, check `condensate_diagonal_witness_exact`): take the eigenvector v_1 of $\mathcal{A}$ with the eigenvalue $-iw$ on which the three products $\gamma^{(x_1)}\gamma^{(x_5)}$, $\gamma^{(x_2)}\gamma^{(x_6)}$ and $\gamma^{(x_3)}\gamma^{(x_7)}$ all have the value -1, the eigenvector v_2 with the same eigenvalue on which they all have the value $+1$, the number $c = \overline{v_1^\dagger C v_2}$ (the bar over a number is its complex conjugate), and the family $\Phi_0(t) = v_1 + t\,c\,v_2$ with a real parameter t. Chapter 12 shows that every member of the family has all 15 bilinears zero and the density $S(t) = 2t\,|v_1^\dagger C v_2|^2$, which is linear in t. Notebook 20b solves $S(t) = 12/5$ exactly and finds $t = 15/512$; by the formula for $S(t)$ this means $|v_1^\dagger C v_2|^2 = (12/5)/(2t) = (12/5)(256/15) = 1024/25$, the value Chapter 12 finds at $M = -5$. The universe is

$$\Phi(x_4) = e^{-4ix_4}\,\Phi_0(15/512),$$

and its **charge density** is $J^{x_4} = \Phi^\dagger B \Phi = -3$, the same at every time because $|e^{-4ix_4}|^2 = 1$ (COMPUTED exactly, Notebook 20b, In [5]). The universe solves its field equation exactly at every time, and its energy-momentum tensor solves all 64 Einstein equations of the author's metric with $a_4 = Hx_4$ and $\Lambda = -36H^2$, at every point checked (Notebook 20b, In [5] and In [6]). It is a complete universe of this theory, and nothing in it refers to a partner. This is the record's sentence made concrete: "a single universe with mass $+m$ is an equally valid solution without its partner" (`Revision/docs/PAIR_CREATION_PROOFS.md`, section 11.3).

Step 6: the T1 partner $\Gamma\Phi$. By theorem T1 the field $\Gamma\Phi$ solves the field equation with $(-m, -\lambda) = (-15, 25/3)$. We check the pieces by hand. Its density is $S' = S = 12/5$ (step 5 of Section 20.5), so its effective mass is

$$M' = -m + (-\lambda)S' = -(m + \lambda S) = -M = 5.$$

Its matrix is $\mathcal{A}' = -\gamma^{(x_4)}(M' - 3H\gamma^{(x_0)}) = -\gamma^{(x_4)}(-M - 3H\gamma^{(x_0)})$. We show that it equals $\Gamma\mathcal{A}\Gamma$, line by line:

$$\Gamma\mathcal{A}\Gamma = -\Gamma\gamma^{(x_4)}(M - 3H\gamma^{(x_0)})\Gamma = -\Gamma\gamma^{(x_4)}\Gamma\,\Gamma(M - 3H\gamma^{(x_0)})\Gamma,$$

by inserting $\Gamma\Gamma = I_{16}$ in the middle;

$$= -(-\gamma^{(x_4)})(M + 3H\gamma^{(x_0)}) = \gamma^{(x_4)}(M + 3H\gamma^{(x_0)}),$$

because $\Gamma\gamma^{(a)}\Gamma = -\gamma^{(a)}\Gamma\Gamma = -\gamma^{(a)}$ for every gamma (step 1 of Section 20.5) and $\Gamma M\Gamma = M$ for the number M;

$$= -\gamma^{(x_4)}(-M - 3H\gamma^{(x_0)}) = \mathcal{A}',$$

by taking out the factor -1. Two matrices related by $\mathcal{A}' = \Gamma\mathcal{A}\Gamma^{-1}$ are called **similar**; they have the same eigenvalues, because $\mathcal{A}v = \mu v$ gives $\mathcal{A}'(\Gamma v) = \Gamma\mathcal{A}v = \mu\,\Gamma v$. So the partner oscillates with the SAME frequency $w = 4$: the opposite sign of its energy is not an opposite frequency. (The record proves the same kind of statement for the one-particle Hamiltonians, $\Gamma h_m\Gamma = h_{-m}$: `wolfram-pairing.json`, check `Q_one_particle_maps`.) By (T1c) its tensor is $T' = -T$: $\rho' = -12$, $p' = +24$, and its charge density is $+3$.

Step 7: the partner alone is not a source of the author's metric. In Section 20.7 we derived what Einstein gravity requires of every source of the author's metric, for every a_4:

$$\kappa(\rho + p_0) = -6(a_4'^2 + H^2) \le -6H^2.$$

The universe supplies $\kappa(\rho + p_0) = 12 - 24 = -12$, which meets the requirement exactly when $a_4'^2 + 1 = 2$, that is $a_4' = \pm H$: the deflating history $+H$ (and its mirror choice $-H$; the equations do not select the sign, Chapter 12). The partner supplies $\kappa(\rho' + p_0') = -12 + 24 = +12$, which is larger than $-6H^2$, the largest value the requirement can take. So no real rate a_4' and no Λ make the partner alone a source of the author's metric. The partner's tensor does not depend on a_4 (the condensate does not feel the deflation, step 1), so this holds for every member of the author's family $a_4(x_4)$, not only for the linear one. The partner is a solution of ITS field equation in the author's geometry, as T1 says, but it cannot produce that geometry. (Status: PROVED here by hand from the record's null combination, `python-a4-report.json`, check `einstein_null_energy_x0`; checked by Notebook 20b, In [7].)

Step 8: the T1 pair. With the universe and its partner as the only source, the source is $T + T' = 0$ (T1d), and the Einstein residual is $G^\mu{}_\nu + \Lambda\delta^\mu_\nu$. At $a_4' = H$ and $\Lambda = -36H^2$ it is

$$\begin{aligned} G^\mu{}_\nu + \Lambda\delta^\mu_\nu &= \mathrm{diag}(12, 12, 12, 24, 12, 12, 12, 12)H^2 - 36H^2\,\delta^\mu_\nu \\ &= \mathrm{diag}(-24, -24, -24, -12, -24, -24, -24, -24)H^2 \neq 0, \end{aligned}$$

where the first matrix is G (step 3 with $A = 1$: $15 - 3 = 12$ and $3 + 21 = 24$). This is corollary C1 on the example: the pair does not solve the equations that the universe alone solves.

Step 9: the T2 mirror copy. By theorem T2 (Section 20.6, with m replaced by $-m$) the field $\Phi''(\pi - z) = \gamma^{(x_0)}\Phi(z)$ on the mirror patch solves the field equation with $(-m, \lambda) = (-15, -25/3)$

there. For the condensate, which does not depend on z, the copy is simply $\gamma^{(x_0)}\Phi(x_4)$. Its density is $S'' = -S$ (Section 20.6), so its effective mass is

$$M'' = -m + \lambda S'' = -m - \lambda S = -M = 5.$$

On the mirror patch the spin-connection term is $-3H\gamma^{(x_0)}$ (computed by Notebook 20a, In [5]; there the positive length of the hidden direction is $-\cot z$). We check the copy's field equation by hand. Multiply the universe's equation $\gamma^{(x_4)}\Phi' + 3H\gamma^{(x_0)}\Phi = M\Phi$ from the left by $-\gamma^{(x_0)}$:

$$-\gamma^{(x_0)}\gamma^{(x_4)}\Phi' - 3H\gamma^{(x_0)}\gamma^{(x_0)}\Phi = -M\gamma^{(x_0)}\Phi.$$

In the first term use $-\gamma^{(x_0)}\gamma^{(x_4)} = \gamma^{(x_4)}\gamma^{(x_0)}$ (the Clifford relation for the two different directions x_4 and x_0) and $\gamma^{(x_0)}\Phi' = (\gamma^{(x_0)}\Phi)'$ (a constant matrix comes out of the derivative); in the second term group the factors as $(-3H\gamma^{(x_0)})(\gamma^{(x_0)}\Phi)$; on the right write $-M = M''$:

$$\gamma^{(x_4)}\big(\gamma^{(x_0)}\Phi\big)' + \big(-3H\gamma^{(x_0)}\big)\big(\gamma^{(x_0)}\Phi\big) = M''\big(\gamma^{(x_0)}\Phi\big),$$

which is exactly the condensate equation on the mirror patch for the field $\gamma^{(x_0)}\Phi$ with the effective mass $M'' = -M$. (Status: PROVED here by hand; checked exactly by Notebook 20b, In [9].) Its tensor is the pulled-back one, $R_0 T R_0$, which for the diagonal tensor of a condensate is T itself: the SAME energy density 12 and pressure -24. Its charge density is $(\gamma^{(x_0)}\Phi)^\dagger B(\gamma^{(x_0)}\Phi) = \Phi^\dagger\gamma^{(x_0)}B\gamma^{(x_0)}\Phi = \Phi^\dagger B\Phi = -3$, the SAME as the universe's, because $\gamma^{(x_0)}$ is real and symmetric and $\gamma^{(x_0)}B\gamma^{(x_0)\dagger} = +B$ (`python-pairing.json`, check `Q.T2_image_keeps_B`). The mirror is an isometry, so the Einstein tensor is the same on both patches, and the copy alone solves all 64 Einstein equations on the mirror patch. The universe on the patch and its copy on the mirror patch together fill the Z2-doubled geometry with twice the energy and twice the charge, not zero. Whether the two halves can be joined at the brane (a junction condition, a brane tension) is not derived anywhere in the record: OPEN; the Z2 construction is ASSUMED.

The bookkeeping. In units $H = \kappa = 1$:

object	m	λ	ρ	p	J^{x_4}	S	**alone a source?**
universe	15	$-25/3$	12	-24	-3	12/5	yes
T1 partner	-15	25/3	-12	24	3	12/5	no
T1 pair	both	both	0	0	0	24/5	no (C1)
T2 copy	-15	$-25/3$	12	-24	-3	$-12/5$	yes (mirror)
T2 pair	both	both	24	-48	-6	0	each half

The objects are the universe Φ, its T1 partner $\Gamma\Phi$ and its T2 copy $\gamma^{(x_0)}\Phi$. The last column says whether the object alone is a source of the author's metric in Einstein gravity: the universe with $a_4 = \pm Hx_4$ and $\Lambda = -36H^2$ on the patch; its T1 partner for no a_4 and no Λ; the T2 copy on the mirror patch. The universe and its T1 partner live on the patch, the T2 copy on the mirror patch. The row of the T1 pair adds the two members at the same point; the row of the T2 pair adds the two members each at its own point (so its ρ is a total of two halves, not a density at one point).

What the example shows, and what it does not. It shows: (1) a universe of this theory can be a complete solution of the coupled equations with no partner at all; (2) its T1 partner exists as a solution of a DIFFERENT field equation (mass -15, coupling $25/3$), with the same frequency and the opposite energy and charge, and it cannot be the source of the author's metric in Einstein gravity; (3) the T1 pair has zero energy and charge and therefore cannot be that source either (C1); (4) the T2 copy is an ordinary solution with the same energy and charge on the mirror patch. It does NOT show that the partner or the copy is created, or must exist; it derives no process, rate or amplitude; it says nothing about the quantised field dirac16complex; and it does not address the stability of the condensate (OPEN).

20.13 Example: one universe and its two partners, computed

Notebook 20b builds the universe of Section 20.12 with exact arithmetic and the author's eight gamma matrices, checks its field equation exactly at every time, evaluates its complete energy-momentum tensor at nine points of the author's metric (three values of the hidden coordinate times three times x_4) and checks all 64 Einstein equations there; then it does the same for the T1 partner, the T1 pair and the T2 mirror copy. It prints 25 PASS lines, 14 of which reproduce a named check of a Revision report, and draws four figures. It needs numpy, sympy and matplotlib, no Rust, and runs in about 30 seconds (its recorded check run on the build computer took 18.7 seconds).

20.14 How to run Notebook 20b

Step 1. What this notebook does and what it needs.

Notebook 20b (One universe and its two partners: an exact case study) is the file `Revision/textbook/notebooks/20b_one_universe_partners.ipynb` of the repository Dirac_claude. It builds, with exact arithmetic and the author's gamma matrices, one exact solution of the coupled equations: a homogeneous condensate of dirac16complex00 that is by itself the complete source of the author's metric with the exponentially deflating history a4 = H x4 in Einstein gravity. It then builds its T1 partner Gamma Phi with mass and coupling reversed, the T1 pair, and its T2 mirror copy across the Z2 brane, checks the field equation of each exactly and the Einstein equations of each numerically at many points, and shows: the universe needs no partner; the T1 partner solves its own field equation but cannot be the source of any member of the author's family in Einstein gravity; the T1 pair cannot either (corollary C1); the T2 copy is a solution with equal energy on the mirror patch. It reproduces the Revision records where they overlap and draws four teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at

the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 20b_one_universe_partners.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 20b_one_universe_partners.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 20b_one_universe_partners.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/20b.captions.json`

- `Revision/textbook/figures/20b_1_einstein_residuals.png`
- `Revision/textbook/figures/20b_2_null_requirement.png`
- `Revision/textbook/figures/20b_3_bookkeeping.png`
- `Revision/textbook/figures/20b_4_partner_in_time.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 25 CHECKS PASSED (notebook 20b)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/20b_one_universe_partners.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 20b_one_universe_partners.ipynb
python -m nbconvert --execute --inplace 20b_one_universe_partners.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads seven files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

20.15 Notebook 20b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/20b_one_universe_partners.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The pairing theorems are statements about ALL solutions at once. This notebook
follows them through ONE exact solution, so that every statement becomes a
number. The solution (the **universe** of this notebook) is a homogeneous
condensate $\Phi(x_4)$ of the commuting field dirac16complex00 that is the
COMPLETE source of the author's metric with the exponentially deflating history
$a_4 = Hx_4$ in Einstein gravity: the field equation (16 components) and the
Einstein equations (64 components) hold together. Then the notebook builds

- the **T1 partner** $\Gamma\Phi$ with the mass and the coupling reversed: it
  solves its own field equation, has the same frequency, the opposite energy
```

```
  density and charge density, and is NOT a source of the author's metric;
- the **T1 pair** (universe plus T1 partner) as the only source: its source is
  zero, and the Einstein equations fail (corollary C1);
- the **T2 mirror copy** $\gamma^{(x_0)}\Phi$ with the mass reversed and the same
  coupling, placed on the mirror patch across the Z2 brane: it solves the coupled
  equations there, with the SAME energy density and charge density.

It checks every field equation exactly (sympy), every energy-momentum tensor and
every Einstein equation numerically at many points (rounding $10^{-10}$), and
draws four teaching figures. The lesson is in section 13: a universe is a complete
solution without any partner; the theorems pair solutions, they do not create
them.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 20b (One universe and its two partners: an exact case study) is the file
‘Revision/textbook/notebooks/20b_one_universe_partners.ipynb‘ of the repository
Dirac_claude. It builds, with exact arithmetic and the author's gamma matrices, one exact
solution of the coupled equations: a homogeneous condensate of dirac16complex00 that is
by itself the complete source of the author's metric with the exponentially deflating
history a4 = H x4 in Einstein gravity. It then builds its T1 partner Gamma Phi with mass
and coupling reversed, the T1 pair, and its T2 mirror copy across the Z2 brane, checks
the field equation of each exactly and the Einstein equations of each numerically at many
points, and shows: the universe needs no partner; the T1 partner solves its own field
equation but cannot be the source of any member of the author's family in Einstein
gravity; the T1 pair cannot either (corollary C1); the T2 copy is a solution with equal
energy on the mirror patch. It reproduces the Revision records where they overlap and
draws four teaching figures. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:
```

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
```

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 20b_one_universe_partners.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 20b_one_universe_partners.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 20b_one_universe_partners.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/20b.captions.json‘
- ‘Revision/textbook/figures/20b_1_einstein_residuals.png‘
- ‘Revision/textbook/figures/20b_2_null_requirement.png‘
- ‘Revision/textbook/figures/20b_3_bookkeeping.png‘
- ‘Revision/textbook/figures/20b_4_partner_in_time.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 25 CHECKS PASSED (notebook 20b)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/20b_one_universe_partners.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 20b_one_universe_partners.ipynb
  python -m nbconvert --execute --inplace 20b_one_universe_partners.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads seven files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 20b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 20b (One universe and its two partners: an exact case study) is the file
# Revision/textbook/notebooks/20b_one_universe_partners.ipynb of the repository
# Dirac_claude. It builds, with exact arithmetic and the author's gamma matrices, one
# exact solution of the coupled equations: a homogeneous condensate of dirac16complex00
# that is by itself the complete source of the author's metric with the exponentially
# deflating history a4 = H x4 in Einstein gravity. It then builds its T1 partner Gamma
# Phi with mass and coupling reversed, the T1 pair, and its T2 mirror copy across the Z2
# brane, checks the field equation of each exactly and the Einstein equations of each
# numerically at many points, and shows: the universe needs no partner; the T1 partner
# solves its own field equation but cannot be the source of any member of the author's
# family in Einstein gravity; the T1 pair cannot either (corollary C1); the T2 copy is a
# solution with equal energy on the mirror patch. It reproduces the Revision records
# where they overlap and draws four teaching figures. It needs a computer with Windows
# 11, macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
```

```
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
```

```
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 20b_one_universe_partners.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
```

```
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 20b_one_universe_partners.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 20b_one_universe_partners.ipynb (in the same folder, without running the cells again)
# to read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/20b.captions.json
# - Revision/textbook/figures/20b_1_einstein_residuals.png
# - Revision/textbook/figures/20b_2_null_requirement.png
# - Revision/textbook/figures/20b_3_bookkeeping.png
# - Revision/textbook/figures/20b_4_partner_in_time.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 25 CHECKS PASSED (notebook 20b)
#
# and the notebook must show 4 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/20b_one_universe_partners.ipynb inside the folder
```

```
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 20b_one_universe_partners.ipynb
#     python -m nbconvert --execute --inplace 20b_one_universe_partners.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.

```
## 3. The words used in this notebook
```

- **Coordinates** $x_0, \dots, x_7$ (the author's names): x_1, x_2, x_3 ordinary 3-space (inflating), x_4 the time, x_5, x_6, x_7 the three EXTRA TIMES (deflating exponentially: scale factor $e^{-a_4}\sin^{1/6}z$), x_0 the hidden direction with $z = 6Hx_0$; the **patch** $0 < z < \pi/2$, the **mirror patch** $\pi/2 < z < \pi$, the **brane** $z = \pi/2$ between them (the Z2 construction across it is ASSUMED). In the code positions 0 to 7 stand for x_0 to x_7.
- **Gamma matrices** $\gamma^{(a)}$, $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, **chirality** $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-I_8, I_8)$, $B = -iC\gamma^{(x_4)}$.
- **Spinor** Φ: 16 complex numbers (here functions of x_4); $\bar\Phi = \Phi^\dagger C$; **density** $S = \bar\Phi\Phi$; **charge density** $J^{x_4} = \Phi^\dagger B\Phi$.
- **Mass** m, **coupling** λ, potential $U = \tfrac\lambda2S^2$, **effective mass** $M = m + \lambda S$.
- **Condensate**: a solution that depends on the time x_4 only. **Frequency** w: $\Phi \propto e^{-iwx_4}$.
- **Energy-momentum tensor** $T^\mu{}_\nu$ in the sign convention of the record of the field equations ($\sigma_T = +1$): energy density $\rho = -T^{x_4}{}_{x_4}$, pressures $p_\mu = T^\mu{}_\mu$ (no sum).
- **Einstein equations** $G^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu$; the **residual** $R^\mu{}_\nu = G^\mu{}_\nu + \Lambda\delta^\mu_\nu - \kappa T^\mu{}_\nu$ is zero exactly when they hold.
- **Linear member** $a_4 = AHx_4$: $A = 1$ is the author's deflating history.
- **Null combination** $\rho + p_0$; **units** $H = \kappa = 1$.

Text cell:

```
## 4. The physical and mathematical situation

**The coupled equations.** The field: $\gamma^\mu D_\mu\Phi = (m + \lambda S)\Phi$.
For a condensate only the $x_4$ derivative survives, and with the spin-connection
term $\sum_\mu\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ of the record the equation
becomes $\Phi' = \mathcal{A}\Phi$ with $\mathcal{A} = -\gamma^{(x_4)}(M -
3H\gamma^{(x_0)})$ (the record's 'condensate_equation_x0_consistent'). Gravity: the
record gives, for the linear member and a condensate with all 15 three-gamma
bilinears zero, $\rho = mS + \tfrac\lambda2S^2$, $p_3 = p_t = p_0 = \tfrac\lambda2
S^2$, and the Einstein equations reduce to two conditions:

$$\kappa MS = -6(A^2 + 1)H^2,\qquad \kappa mS = -(36H^2 + 2\Lambda).$$

**The theorems used (PROVED in the Revision record).** T1: $\Gamma\Phi$ solves the
$(-m, -\lambda)$ field equation, $T \to -T$, $J \to -J$. T2: $\gamma^{(x_0)}\Phi$
placed at the mirror point solves the $(-m, \lambda)$ field equation on the mirror
patch, with the pulled-back (equal) $T$ and $J$. C1: a T1 pair as the only source
is a zero source and has no Einstein solution. The record's null combination:
in Einstein gravity every source of the author's metric must have
$\kappa(\rho + p_0) = -6(a_4'^2 + H^2) < 0$.

**What is new here (COMPUTED in this notebook, not a Revision record).** The
explicit universe and its partners, and the conclusions of sections 10 to 12.

**ASSUMED:** Einstein gravity; the sign convention $\sigma_T = +1$; the classical
commuting field dirac16complex00 (not the quantised dirac16complex); the chosen
```

```
numbers $A = 1$, $\Lambda = -36H^2$, $M = -5H$; the Z2 construction across the
brane (section 12).
```

Text cell:

```
## 5. The Revision records this notebook reproduces

The next cell defines the helpers ‘read_json‘ (reads a JSON file of the
repository), ‘record_verdict‘ (the verdict of a named check in a report) and
‘reproduces‘ (a check that passes only when this notebook’s own result holds AND
the named record check is PASS). It then reads one sentence of the record’s list of
what the pairing theorems do NOT establish; section 13 shows it on the example.
```

## 6. The gamma matrices and the spin connection on both patches

The next cell reads the author's gammas (exact whole numbers), builds $C$,
$\Gamma$, $B$ and $S^{ab}$, and computes the canonical spin connection of the
author's metric exactly as Notebook 20a does: lengths $E = (s_0\cot z, e^{a_4}s,
e^{a_4}s, e^{a_4}s, 1, e^{-a_4}s, e^{-a_4}s, e^{-a_4}s)$ with $s = \sin^{1/6}z$,
$s_0 = +1$ on the patch and $-1$ on the mirror patch, Christoffel symbols of the
diagonal metric, and $\omega_{\mu ab} = \eta_{aa}(E_a/E_b)\Gamma^a{}_{\mu b}$ for
$a \neq b$. It checks the record's $\sum_\mu\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$
on the patch and finds $-3H\gamma^{(x_0)}$ on the mirror patch.
```

## 7. Choosing the universe: the two Einstein conditions

We fix the geometry first: $H = \kappa = 1$, the author's deflating history
$A = 1$ ($a_4 = Hx_4$; the extra times shrink as $e^{-x_4}$), and the cosmological
constant $\Lambda = -36H^2$, chosen so that the universe has a positive energy
density. We choose the effective mass $M = m + \lambda S = -5H$ (then the
condensate oscillates, because $|M| > 3H$, with $w = \sqrt{M^2 - 9H^2} = 4H$). The
two conditions then fix everything, line by line:

1. $\kappa MS = -6(A^2 + 1)H^2 = -12$, so $S = -12/M = 12/5$;
2. $\kappa mS = -(36 + 2\Lambda) = 36$, so $m = 36/S = 15$;
3. $M = m + \lambda S$, so $\lambda = (M - m)/S = -20/(12/5) = -25/3$;
4. $\rho = mS + \tfrac\lambda2S^2 = 36 - 24 = 12$ and $p = \tfrac\lambda2S^2 = -24$.

The next cell checks the two conditions against the record (it rebuilds them from
the record's Einstein tensor) and solves them with sympy.
```

## 8. Building the universe: the condensate $\Phi(x_4)$

The record's recipe for a condensate whose 15 three-gamma bilinears vanish (they
must, for the off-diagonal Einstein equations), at $M = -5$, $H = 1$, $w = 4$: the
spinor $v_1$ with $\mathcal{A}v_1 = -iwv_1$ and $\gamma^{(x_1)}\gamma^{(x_5)} =
\gamma^{(x_2)}\gamma^{(x_6)} = \gamma^{(x_3)}\gamma^{(x_7)} = -1$ on it, the
spinor $v_2$ with the same frequency and the value $+1$, and $c =
\overline{v_1^\dagger Cv_2}$; each is the null space of a stacked matrix. The
family $\Phi_0(t) = v_1 + t\,c\,v_2$ keeps all 15 bilinears zero for every real
$t$ and has $S(t) = 2t|v_1^\dagger Cv_2|^2$, so $t$ is fixed by $S = 12/5$. The
universe is $\Phi(x_4) = e^{-iwx_4}\Phi_0$. The next cell builds it, checks the 15
bilinears and $S$, checks that $S$ is constant ($C\mathcal{A} + \mathcal{A}^TC =
0$), checks the 16 components of the field equation $\gamma^{(x_4)}\Phi' +
3H\gamma^{(x_0)}\Phi = (m + \lambda S)\Phi$ EXACTLY at every time $x_4$, and
computes the charge density $J^{x_4} = \Phi^\dagger B\Phi$.
```

9. The universe alone solves the Einstein equations

The next cell turns the geometry into numpy functions and evaluates the complete energy-momentum tensor of a configuration from its first jet, as in Notebook 20a: the value Φ and the derivatives (here only $\partial_4\Phi = -iw\Phi$; the condensate does not depend on the other coordinates). From the pairing records' tensor $T_{\mu\nu}$ it forms the mixed tensor of this notebook's convention, $T^\mu{}_\nu = -g^{\mu\mu}T_{\mu\nu}$ (the two conventions differ by a sign), and the Einstein residual $R^\mu{}_\nu = G^\mu{}_\nu + \Lambda\delta^\mu_\nu - \kappa T^\mu{}_\nu$ with G from the record at $a_4' = H$. It does this at nine points: $z = 0.3, 0.8, 1.3$ on the patch and the times $x_4 = 0, 0.7, 2$ (where $a_4 = x_4$). All 64 components of the residual must vanish at every point.

## 10. The T1 partner $\Gamma\Phi$

By T1 the partner $\Gamma\Phi$ solves the field equation with $(-m, -\lambda) =
(-15, 25/3)$. Its density is $S' = S$ (the scalar is unchanged), so its effective
mass is $M' = -m - \lambda S = -M = 5$. Its matrix $\mathcal{A}' =
-\gamma^{(x_4)}(M' - 3H\gamma^{(x_0)})$ equals $\Gamma\mathcal{A}\Gamma$, so it
has the SAME eigenvalues $\pm iw$: the partner oscillates with the same frequency
(similar matrices have equal spectra; the record proves the same for the
one-particle Hamiltonians, $\Gamma h_m\Gamma = h_{-m}$). Its tensor is $T' = -T$
and its charge density is $-J^{x_4}$. The next cell checks all of this exactly
where possible, and numerically for the tensor.

Can the partner ALONE be the source of the author's metric? The record's null
combination says that every source must have $\kappa(\rho + p_0) =
-6(a_4'^2 + H^2)$, which is at most $-6H^2$. The universe has $\kappa(\rho + p_0)
= 12 - 24 = -12$, which fits $a_4' = \pm H$. The partner has $\rho' + p_0' =
-(\rho + p_0) = +12$: positive, so it fits NO rate $a_4'$ and no $\Lambda$, in
Einstein gravity. (Its tensor does not depend on $a_4$, so this holds for every
member of the author's family.)
```

## 12. The T2 mirror copy across the brane

By T2 (with $m \to -m$) the field $\Phi'(\pi - z) = \gamma^{(x_0)}\Phi(z)$ on the
mirror patch solves the $(-m, \lambda) = (-15, -25/3)$ field equation there. For
the condensate $\Phi$ does not depend on $z$, so the copy is simply
$\gamma^{(x_0)}\Phi(x_4)$. Its density is $S' = -S$, so its effective mass is
$M' = -m + \lambda S' = -M$. On the mirror patch the spin-connection term is
$-3H\gamma^{(x_0)}$ (section 6). Its tensor is the pulled-back one, $R_0TR_0$,
which for the diagonal $T$ of the condensate is $T$ itself: the SAME energy
density $12$ and pressure $-24$. Its charge density is $+J^{x_4}$ (the record:
$\gamma^{(x_0)}B\gamma^{(x_0)\dagger} = +B$). Because the mirror is an isometry, the
Einstein tensor is the same on both patches. So the copy is a complete solution
of the coupled equations on the mirror patch: together with the universe it
fills the Z2-doubled geometry, with twice the energy, NOT zero. Whether the two
halves can be joined at the brane (a junction condition, a brane tension) is not
derived in the record (OPEN); the Z2 construction is ASSUMED.
```

In [9]:

```

Out [13]:

```
Figure 20b.4 saved as Revision/textbook/figures/20b_4_partner_in_time.png
```

Text cell:

```
**What this example shows (COMPUTED here, exact for the field equations, to
$10^{-10}$ for the Einstein equations):**

1. A universe needs no partner. The condensate $\Phi$ with $m = 15$,
   $\lambda = -25/3$ is by itself a complete solution of the coupled equations
   with the deflating history $a_4 = Hx_4$. The record's sentence "a single
   universe with mass $+m$ is an equally valid solution without its partner" is
   here a solution one can write down.
2. The T1 partner exists as a solution of ITS field equation (mass $-15$,
   coupling $25/3$), with the same frequency and opposite energy and charge. It is
```

```
   not a source of the author's metric in Einstein gravity, for any rate and any
   $\Lambda$, because its $\rho + p_0$ is positive.
3. The T1 pair has zero energy and zero charge, and therefore (C1) it cannot be the
   source of the author's metric in Einstein gravity.
4. The T2 mirror copy (mass $-15$, coupling $-25/3$) is a solution on the mirror
   patch with the SAME energy density and charge density. The Z2-doubled geometry
   with the universe on one side and its copy on the other solves the bulk
   equations on both patches; the brane itself is ASSUMED and its junction is not
   derived (OPEN).

**What it does not show:** that the partner or the copy is created, or that it
must exist; any process, rate or amplitude; anything about the quantised field
dirac16complex (the condensate is a classical solution of dirac16complex00); the
stability of the condensate.
```

Text cell:

```
## 14. The last check

The last cell checks that the four figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [14]:

```
figure_names = ["einstein_residuals", "null_requirement", "bookkeeping",
                "partner_in_time"]
paths = [output_file(f"{FIGURE_FOLDER}/20b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

Out [14]:

```
PASS every figure file of this notebook exists
ALL 25 CHECKS PASSED (notebook 20b)
```

Text cell:

```
## 15. What this notebook showed

- With $A = 1$, $\Lambda = -36H^2$ and $M = -5H$ the record's two Einstein
  conditions give $S = 12/5$, $m = 15$, $\lambda = -25/3$, $\rho = 12$,
  $p = -24$; the record's recipe gives an exact condensate with these numbers
  and the charge density $J^{x_4} = -3$, which solves its field equation exactly
  and, alone, all 64 Einstein equations (figure 1).
- Its T1 partner $\Gamma\Phi$ solves the $(-15, 25/3)$ field equation with the
  same frequency $w = 4H$ (figure 4) and has $\rho' = -12$, $p' = 24$,
  $J' = +3$; with $\kappa(\rho' + p_0') = +12 > -6$ it is the source of no member
```

```
  of the author's family in Einstein gravity (figure 2).
- The T1 pair has zero energy, pressure and charge, and its Einstein residual is
  $G + \Lambda \neq 0$: corollary C1 on an example (figures 1 and 3).
- The T2 mirror copy $\gamma^{(x_0)}\Phi$ with $(-15, -25/3)$ solves the coupled
  equations on the mirror patch with the same $\rho = 12$ and $J^{x_4} = -3$; the
  T2 pair has $\rho = 24$ and $J^{x_4} = -6$ (figure 3).
- The equations pair solutions; they neither require nor create the partner.
```

20.16 Line-by-line walk-through of Notebook 20b

The notebook has 14 code cells, In [1] to In [14]. As in Section 20.11, each group of lines is quoted and then explained; lines that repeat a pattern of Notebook 20a are quoted as well, with a short reminder.

In [1], the set-up cell. It is word for word the set-up cell of Notebook 20a, explained line by line in Section 20.11, with two differences: its comment lines at the top hold the run instructions of Notebook 20b (Section 20.14), and one line names the notebook:

```
NOTEBOOK_ID = "20b"  # this notebook: chapter 20, example b
```

So the figures are saved as `20b_1_...` to `20b_4_...`, the captions in `20b.captions.json`, and the last line will read ALL 25 CHECKS PASSED (notebook 20b). Output: Set-up of notebook 20b complete.

In [2], the records and the helper `reproduces`.

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory

GAMMAS = "Revision/algebra/gammas.json"  # the author's gamma matrices
A4_RECORD = "Revision/field_equations_a4/a4-equations.json"  # the a4 equations
A4_PY = "Revision/field_equations_a4/reports/python-a4-report.json"
A4_WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
PAIR_PY = "Revision/pairing/reports/python-pairing.json"
PAIR_WL = "Revision/pairing/reports/wolfram-pairing.json"
PROOFS = "Revision/docs/PAIR_CREATION_PROOFS.md"
```

The two modules `contextlib` and `io` and the names of the seven files of the repository that the notebook reads: the author's gammas, the record of the field equations for a_4 with its two reports, the two pairing reports and the Revision document of the pairing proofs.

```
def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

def record_verdict(report_file, name):
    """The verdict ("PASS") of the check called name in a report; None if absent."""
    for entry in read_json(report_file)["checks"]:
```

```
        if entry["name"] == name:
            return entry["verdict"]
    return None

def reproduces(condition, name, report_file, record_name):
    """A check that also requires the record check record_name to be PASS."""
    found = record_verdict(report_file, record_name) == "PASS"
    lines = io.StringIO()  # a text buffer
    with contextlib.redirect_stdout(lines):  # print() now writes into the buffer
        check(condition and found, name,
              record=f"{report_file}, check {record_name}")
    print(lines.getvalue(), end="")  # both lines with one print call
```

The three helpers of Notebook 20a, In [2], line for line: `read_json` reads a JSON record; `record_verdict` returns the verdict of a named check of a report (or `None`); `reproduces` passes only when the notebook's own condition holds AND the named record check has the verdict PASS, and then prints the PASS line together with the line that names the record (Section 20.11 explains every line).

```
NO_NECESSITY = ("a single universe with mass $+m$ is an equally valid solution "
                "without its partner")
proofs = repository_file(PROOFS).read_text(encoding="utf-8")
say(f"{PROOFS} says: \"... a single universe with mass +m is an equally valid "
    "solution without its partner.\"")
check(NO_NECESSITY in proofs, "the record states that no partner is required")
```

`NO_NECESSITY` is a sentence of the record's answer to the request (two strings in parentheses are joined into one). The document is read as one text; `say` prints the sentence; the check confirms that it occurs in the document word for word. Output: the quoted sentence and PASS the record states that no partner is required.

In [3], the gammas, C, Γ, B and the spin connection on both patches.

```
import itertools  # loops over all combinations of indices

chirality = gamma[0]  # Gamma = g^(x0) g^(x1) ... g^(x7), factor by factor
for a in range(1, 8):
    chirality = chirality * gamma[a]
B = -sp.I * C * gamma[4]  # the Krein matrix B = -i C gamma^(x4)
S_exact = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
           for a in range(8)]
```

The same objects as in Notebook 20a, In [3], built the same way: the labels, the diagonal of η, the exact unit matrix I_{16} and the exact 16×16 zero matrix `Z16` (`sp.zeros(16, 16)`; two names are assigned at once), the eight exact gammas read from `gammas.json` (here the reading and the conversion are written in one comprehension), C, the chirality Γ (called `chirality`) multiplied factor by factor in the record's order, the Krein matrix $B = -iC\gamma^{(x_4)}$ (`sp.I` is the exact imaginary unit; position 4 is x_4), and the 64 generators S^{ab}.

```
H = sp.symbols("H", positive=True)
z = sp.symbols("z", real=True)
x4 = sp.symbols("x4", real=True)
a4 = sp.Function("a4")(x4)
a4_value, slope = sp.symbols("a4_value slope", real=True)

def d(expr, mu):
    """The partial derivative along the coordinate at position mu."""
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)  # d/dx0 = 6 H d/dz
    return sp.Integer(0)
```

The symbols $H > 0$, z, x_4, the unknown function $a_4(x_4)$, the two symbols that replace a_4 and a_4' at a point, and the partial derivative `d(expr, mu)` with $\partial/\partial x_0 = 6H\,\partial/\partial z$ (Notebook 20a, In [4]).

```
def spin_connection(s0):
    """The lengths E_a and omega[mu][a][b] = omega_mu ab (s0 = +1 patch, -1 mirror)."""
    s = sp.sin(z) ** sp.Rational(1, 6)
    E = [s0 * sp.cot(z)] + [sp.exp(a4) * s] * 3 + [sp.Integer(1)]
    E = E + [sp.exp(-a4) * s] * 3  # x0, x1, ..., x7
    g = [ETA[a] * E[a] ** 2 for a in range(8)]
    christoffel = {}
    for a, b, c in itertools.product(range(8), repeat=3):
        value = 0
        if a == c:
            value += d(g[a], b)
        if a == b:
            value += d(g[a], c)
        if b == c:
            value -= d(g[b], a)
        christoffel[a, b, c] = value / (2 * g[a])
    omega = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
    for mu, a, b in itertools.product(range(8), repeat=3):
        if a != b:
            value = ETA[a] * E[a] * christoffel[a, mu, b] / E[b]
            value = value.subs(sp.Derivative(a4, x4), slope).subs(a4, a4_value)
            omega[mu][a][b] = sp.simplify(value)
    return [length.subs(a4, a4_value) for length in E], omega
```

The canonical spin connection on the patch (`s0 = 1`) or on the mirror patch (`s0 = -1`), exactly as in Notebook 20a, In [4]: the lengths E_a ($s_0 \cot z$, three inflating $e^{a_4} \sin^{1/6} z$, the time 1, three

DEFLATING $e^{-a_4}\sin^{1/6} z$), the diagonal metric $g_{aa} = \eta_{aa}E_a^2$, the Christoffel symbols term by term, and $\omega_{\mu ab} = \eta_{aa}(E_a/E_b)\Gamma^a{}_{\mu b}$ for $a \neq b$ with a_4 and a_4' replaced by the point symbols. The only difference from 20a is that the list of lengths is built inside the function in two lines (the first five lengths, then `E + [sp.exp(-a4) * s] * 3` appends the three of the extra times).

```
CONNECTION = {s0: spin_connection(s0) for s0 in (1, -1)}
gravity_term = {}  # s0 -> sum over mu of gamma^mu Omega_mu
for s0, (E, omega) in CONNECTION.items():
    Omega = [sum((omega[mu][a][b] * S_exact[a][b] / 2 for a in range(8)
                  for b in range(8) if omega[mu][a][b] != 0), Z16)
             for mu in range(8)]
    gravity_term[s0] = sum((gamma[mu] / E[mu] * Omega[mu] for mu in range(8)),
                           Z16).applyfunc(sp.simplify)
reproduces(gravity_term[1] == 3 * H * gamma[0],
           "patch: gamma^mu Omega_mu = 3 H gamma^(x0)", A4_PY, "authorT16_gravity_term")
check(gravity_term[-1] == -3 * H * gamma[0],
      "mirror patch: gamma^mu Omega_mu = -3 H gamma^(x0)")
```

`{s0: spin_connection(s0) for s0 in (1, -1)}` computes the connection on both patches and stores the pair (lengths, components) under the key $+1$ or -1; `.items()` walks through the keys and values of a dictionary. For each patch, `Omega` holds the eight matrices $\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu ab}S^{ab}$, and `gravity_term[s0]` is $\sum_\mu \gamma^\mu\Omega_\mu$ with $\gamma^\mu = \gamma^{(\mu)}/E_\mu$, simplified entry by entry. The checks: $3H\gamma^{(x_0)}$ on the patch (the record's term, `python-a4-report.json`, check `authorT16_gravity_term`) and $-3H\gamma^{(x_0)}$ on the mirror patch (a computation of this book). Output: two PASS lines.

In [4], choosing the universe: the two Einstein conditions.

```
record = read_json(A4_RECORD)
ad1, ad2 = sp.symbols("ad1 ad2", real=True)  # a4' and a4''
A, Lam, kappa = sp.symbols("A Lambda kappa", real=True)
m, lam, S_sym = sp.symbols("m lambda S", real=True)
```

The record of the field equations for a_4 is read. The symbols: a_4' and a_4'' under the record's names `ad1` and `ad2` (here declared real), the slope A, Λ (`Lam`), κ, the mass m, the coupling λ (`lam`; the word `lambda` is reserved in Python) and the density S (`S_sym`, a symbol, to keep it apart from numbers).

```
def einstein(key):
    """The component key of the Einstein tensor E_(1) from the record."""
    text = record["lovelockTensors"]["E1"][key]["input"].replace("^", "**")
    return sp.sympify(text, locals={"ad1": ad1, "ad2": ad2, "H": H})
```

`einstein(key)` reads one component of the Einstein tensor $E_{(1)} = G$ from the record's text in Wolfram's input form and turns it into a sympy expression (`^` becomes `**`; `locals` binds the names `ad1`, `ad2` and `H` to the notebook's symbols), as `lovelock` did in Notebook 20a, In [12].

```
G = {key: einstein(key) for key in ("x1x1", "x4x4", "x5x5", "x0x0")}
LINEAR = {ad1: A * H, ad2: 0}  # the linear member a4 = A H x4
```

```
rho_c, p_c = m * S_sym + lam * S_sym ** 2 / 2, lam * S_sym ** 2 / 2  # condensate
time_eq = G["x4x4"].subs(LINEAR) + Lam + kappa * rho_c  # = 0
hidden_eq = G["x0x0"].subs(LINEAR) + Lam - kappa * p_c  # = 0
first = sp.expand(time_eq - hidden_eq)  # kappa (m + lambda S) S + 6 (A^2 + 1) H^2
second = sp.expand(time_eq + hidden_eq)  # kappa m S + 36 H^2 + 2 Lambda
```

`G` holds the four independent diagonal components. `LINEAR` is the substitution of the linear member, $a_4' = AH$ and $a_4'' = 0$. `rho_c` and `p_c` are the condensate's $\rho = mS + \frac{\lambda}{2}S^2$ and $p = \frac{\lambda}{2}S^2$ (step 2 of Section 20.12). `time_eq` is the time equation written as "left side minus right side", ${G^{x_4}}_{x_4} + \Lambda + \kappa\rho = 0$, and `hidden_eq` the hidden equation, ${G^{x_0}}_{x_0} + \Lambda - \kappa p = 0$. `first` is their difference and `second` their sum, multiplied out by `sp.expand`: exactly the two combinations of step 3.

```
reproduces(sp.expand(first - (kappa * (m + lam * S_sym) * S_sym
                              + 6 * (A ** 2 + 1) * H ** 2)) == 0
           and sp.expand(second - (kappa * m * S_sym + 36 * H ** 2 + 2 * Lam)) == 0,
           "Einstein: kappa M S = -6 (A^2 + 1) H^2, kappa m S = -(36 H^2 + 2 Lambda)",
           A4_PY, "condensate_einstein_quadratic_U")
```

The check compares the two combinations with $\kappa(m + \lambda S)S + 6(A^2 + 1)H^2$ and $\kappa m S + 36H^2 + 2\Lambda$; each difference must expand to zero. It reproduces the record's two conditions (`python-a4-report .json`, check `condensate_einstein_quadratic_U`).

```
CHOICE = {H: 1, kappa: 1, A: 1, Lam: -36}  # the geometry of this notebook
M_VALUE = -5  # the effective mass M = m + lambda S
S_value = sp.solve(first.subs(CHOICE).subs(lam, (M_VALUE - m) / S_sym), S_sym)[0]
m_value = sp.solve(second.subs(CHOICE).subs(S_sym, S_value), m)[0]
lam_value = (M_VALUE - m_value) / S_value
rho_value = rho_c.subs({m: m_value, lam: lam_value, S_sym: S_value})
p_value = p_c.subs({lam: lam_value, S_sym: S_value})
```

`CHOICE` fixes the geometry of the notebook: $H = \kappa = 1$, $A = 1$, $\Lambda = -36$; `M_VALUE` is the effective mass $M = -5$. Then the four lines of step 4, done by sympy: in `first`, λ is replaced by $(M - m)/S$ (this is $M = m + \lambda S$ solved for λ), and `sp.solve(..., S_sym)` solves for S (`[0]` takes the one solution); in `second`, S is replaced by its value and the equation is solved for m; then λ, ρ and p follow by substitution.

```
for label, value in (("S", S_value), ("m", m_value), ("lambda", lam_value),
                     ("rho", rho_value), ("p", p_value)):
    report(label, value)
check((S_value, m_value, lam_value, rho_value, p_value)
      == (sp.Rational(12, 5), 15, sp.Rational(-25, 3), 12, -24),
      "the universe: S = 12/5, m = 15, lambda = -25/3, rho = 12, p = -24")
```

The loop prints the five numbers as RESULT lines, and the check compares them with the exact values of step 4. Output: RESULT S = 12/5, m = 15, lambda = -25/3, rho = 12, p = -24, and the PASS line.

In [5], building the universe.

```
w = sp.sqrt(M_VALUE ** 2 - 9)  # the frequency, H = 1
A_matrix = -gamma[4] * (M_VALUE * I16 - 3 * gamma[0])  # Phi' = A Phi
spaces = []
for sign in (-1, 1):  # the value of g^(x1)g^(x5) = g^(x2)g^(x6) = g^(x3)g^(x7)
    stack = sp.Matrix.vstack(A_matrix + sp.I * w * I16,
                             gamma[1] * gamma[5] - sign * I16,
                             gamma[2] * gamma[6] - sign * I16,
                             gamma[3] * gamma[7] - sign * I16)
    spaces.append(stack.nullspace())  # every solution of stack * v = 0
v1, v2 = spaces[0][0], spaces[1][0]
```

`w` is the frequency $\sqrt{M^2-9} = 4$ (exactly; `sp.sqrt` of 16). `A_matrix` is $\mathcal{A} = -\gamma^{(x_4)}(M - 3\gamma^{(x_0)})$ with $H = 1$. For each of the two values ∓ 1 (`sign`), `sp.Matrix.vstack` stacks four 16×16 matrices on top of each other into one 64×16 matrix: $\mathcal{A} + iwI_{16}$ and the three matrices $\gamma^{(x_1)}\gamma^{(x_5)} - \text{sign}\, I_{16}$, $\gamma^{(x_2)}\gamma^{(x_6)} - \text{sign}\, I_{16}$, $\gamma^{(x_3)}\gamma^{(x_7)} - \text{sign}\, I_{16}$. A column v with `stack * v = 0` satisfies all four conditions at once: $\mathcal{A}v = -iwv$ and each of the three products has the value `sign` on v. `stack.nullspace()` returns a list of columns that span all such v (the **null space**). `v1` is the first column for the value -1, `v2` the first for $+1$.

```
c = sp.conjugate(sp.expand((v1.H * C * v2)[0]))  # c = conj(v1^dagger C v2)
t = sp.symbols("t", real=True)
family = (v1 + t * c * v2).applyfunc(sp.expand)  # Phi_0(t)
```

`v1.H` is the **conjugate transpose** $v_1^\dagger$ (a row), so `(v1.H * C * v2)[0]` is the number $v_1^\dagger C v_2$, and `sp.conjugate` gives $c = \overline{v_1^\dagger C v_2}$. `t` is a real symbol and `family` the column $\Phi_0(t) = v_1 + t\, c\, v_2$, multiplied out entry by entry.

```
def bilinear(phi, matrix):
    """phibar matrix phi = phi^dagger C matrix phi (exact)."""
    return sp.expand((phi.H * C * matrix * phi)[0])

t_value = sp.solve(bilinear(family, I16) - S_value, t)[0]
phi0 = family.subs(t, t_value).applyfunc(sp.expand)  # the universe at x4 = 0
report("t", t_value)
```

`bilinear(phi, matrix)` is $\bar{\phi}\, M \phi = \phi^\dagger C M \phi$, exact. The equation $S(t) = 12/5$ is solved for t, the universe at $x_4 = 0$, `phi0`, is the family at that t, and the value is printed. Output: RESULT t = 15/512.

```
NEEDED = sorted({tuple(sorted((i, 4, 0))) for i in (1, 2, 3, 5, 6, 7)}
                | {tuple(sorted((i, j, 4))) for i in (1, 2, 3) for j in (5, 6, 7)})
zero_15 = all(bilinear(family, gamma[a] * gamma[b] * gamma[e]) == 0
              for a, b, e in NEEDED)  # for every real t, so also for t_value
reproduces([len(space) for space in spaces] == [1, 1] and zero_15
           and bilinear(phi0, I16) == S_value,
           "the universe: 15 three-gamma bilinears 0 and S = 12/5",
           A4_WL, "condensate_diagonal_witness_exact")
```

NEEDED lists the 15 index triples of the three-gamma bilinears that must vanish: the six triples $\{i, x_4, x_0\}$ with i one of $x_1, x_2, x_3, x_5, x_6, x_7$ (positions 1, 2, 3, 5, 6, 7 together with 4 and 0), and the nine triples $\{i, j, x_4\}$ with i in 3-space and j an extra time. Each triple is sorted, the braces `{...}` make a **set** (a collection without repetitions), `|` joins two sets, and `sorted` puts the triples in a fixed order. `zero_15` is true when all 15 bilinears of the family vanish for the SYMBOL t, so for every real t, in particular for 15/512. The check requires the two null spaces to be one-dimensional, the 15 zeros, and $S = 12/5$ for `phi0`; it reproduces the record's witness (`wolfram-a4-report.json`, check `condensate_diagonal_witness_exact`).

```
reproduces((C * A_matrix + A_matrix.T * C).applyfunc(sp.expand) == Z16,
           "C A + A^T C = 0: S stays 12/5 at every time", A4_PY,
           "authorT16_condensate_S_constant")
Phi = phi0 * sp.exp(-sp.I * w * x4)  # the universe Phi(x4)
```

The check $C\mathcal{A} + \mathcal{A}^T C = 0$ (`.T` is the transpose) shows that S stays 12/5 at every time (step 1). `Phi` is the universe $\Phi(x_4) = \Phi_0 e^{-iwx_4}$, a column of 16 exact functions of x_4.

```
def field_residual(field, term, mass, coupling, density):
    """gamma^(x4) field' + term field - (mass + coupling density) field."""
    return (gamma[4] * sp.diff(field, x4) + term * field
            - (mass + coupling * density) * field).applyfunc(sp.simplify)
```

`field_residual` returns $\gamma^{(x_4)}\Phi' + (\text{term})\Phi - (\text{mass} + \text{coupling} \cdot \text{density})\Phi$ for a field that depends on x_4 only: the left side minus the right side of the condensate equation, with the spin-connection term `term` given as an argument (so that the same function serves on the mirror patch). `sp.diff( field, x4)` differentiates each entry, and `.applyfunc(sp.simplify)` simplifies each entry of the result.

```
universe_ok = field_residual(Phi, gravity_term[1].subs(H, 1), m_value, lam_value,
                             S_value) == sp.zeros(16, 1)
reproduces(universe_ok, "the universe solves its field equation (16 components)",
           A4_WL, "condensate_equation_x0_consistent")
charge_value = sp.simplify((phi0.H * B * phi0)[0])  # J^x4, constant in time
report("charge density J^x4 of the universe", charge_value)
```

The universe's residual with the patch term $3\gamma^{(x_0)}$ (`gravity_term[1].subs(H, 1)`), $m = 15$, $\lambda = -25/3$ and $S = 12/5$ must be the zero column, at every time x_4 (the time is a symbol). The last lines compute the charge density $\Phi_0^\dagger B \Phi_0$ exactly; the factor e^{-iwx_4} drops out of it. Output: RESULT t = 15/512, three PASS lines with their records, and RESULT charge density J^x4 of the universe = -3.

In [6], the universe alone solves the Einstein equations.

```
point_symbols = (z, a4_value, slope, H)
S_num = [[np.array(S_exact[a][b].tolist(), dtype=float) for b in range(8)]
         for a in range(8)]
gamma_num = [np.array(g.tolist(), dtype=float) for g in gamma]
C_num = np.array(C.tolist(), dtype=float)
```

```
Gamma_num = np.array(chirality.tolist(), dtype=float)
B_num = np.array(B.tolist(), dtype=complex)
NUMERIC = {}
for s0, (E, omega) in CONNECTION.items():
    pieces = [(mu, a, b, sp.lambdify(point_symbols, omega[mu][a][b], "numpy"))
              for mu in range(8) for a in range(8) for b in range(8)
              if omega[mu][a][b] != 0]
    NUMERIC[s0] = (sp.lambdify(point_symbols, E, "numpy"), pieces)
```

The floating-point copies of the generators, the gammas, C, Γ and B (`dtype=complex` because B is imaginary), and, for both patches, the numpy functions of the lengths and of the nonzero connection components (`sp.lambdify`, as in Notebook 20a, In [6]).

```
def geometry_at(s0, z_value, a4_number, slope_number):
    """Metric, Omega_mu and curved gammas at one point (H = 1)."""
    lengths_f, pieces = NUMERIC[s0]
    values = (z_value, a4_number, slope_number, 1.0)
    E = np.array([float(x) for x in lengths_f(*values)])
    Om = [np.zeros((16, 16)) for _ in range(8)]
    for mu, a, b, f in pieces:
        Om[mu] += float(f(*values)) * S_num[a][b] / 2
    return {"g": np.array(ETA) * E ** 2, "Omega": Om,
            "up": [gamma_num[mu] / E[mu] for mu in range(8)],
            "down": [ETA[mu] * E[mu] * gamma_num[mu] for mu in range(8)]}
```

`geometry_at` is the function of Notebook 20a, In [6], with $H = 1$ fixed: it returns the metric, the eight Ω_μ and the curved gammas with upper and lower index at one point.

```
def mixed_tensor(at, psi, dpsi, mass, coupling):
    """T^mu_nu (convention sigma_T = +1) and K^mu_mu of a first jet."""
    bar = psi.conj() @ C_num
    dbar = [row.conj() @ C_num for row in dpsi]
    D = [dpsi[mu] + at["Omega"][mu] @ psi for mu in range(8)]
    Dbar = [dbar[mu] - bar @ at["Omega"][mu] for mu in range(8)]
    S = (bar @ psi).real
    kinetic = [0.5 * (bar @ at["up"][mu] @ D[mu] - Dbar[mu] @ at["up"][mu] @ psi)
               for mu in range(8)]  # K^mu_mu, no sum
    L = sum(kinetic).real - mass * S - coupling * S ** 2 / 2
```

`mixed_tensor` evaluates the energy-momentum tensor of a first jet, as `bilinears` did in Notebook 20a: $\bar\Phi = \Phi^\dagger C$, $\partial_\mu\bar\Phi$, the covariant derivatives, the real density S, and the eight diagonal kinetic terms $K^\mu{}_\mu = \frac{1}{2}(\bar\Phi\gamma^\mu D_\mu\Phi - (D_\mu\bar\Phi)\gamma^\mu\Phi)$, one for each μ with no sum, kept in the list `kinetic`. Their sum is the kinetic term K, and `L` is $\mathcal{L}/\sqrt{|g|} = K - mS - \frac{\lambda}{2}S^2$ (`.real` drops an imaginary part of rounding size).

```
    T = np.zeros((8, 8))
    for mu, nu in itertools.product(range(8), repeat=2):
        low = 0.25 * (bar @ at["down"][mu] @ D[nu] + bar @ at["down"][nu] @ D[mu]
                      - Dbar[mu] @ at["down"][nu] @ psi
```

```
                    - Dbar[nu] @ at["down"][mu] @ psi).real
        if mu == nu:
            low -= at["g"][mu] * L  # the pairing records' T_mu nu
        T[mu, nu] = -low / at["g"][mu]  # T^mu_nu = -g^(mu mu) T_mu nu
    return T, np.array([k.real for k in kinetic])
```

For each of the 64 pairs (μ, ν), `low` is the tensor $T_{\mu\nu}$ of the pairing records (four kinetic terms, and $-g_{\mu\mu}\mathcal{L}/\sqrt{|g|}$ on the diagonal). The notebook needs the mixed tensor $T^{\mu}{}_{\nu}$ in the convention of the record of the field equations, which is minus the pairing records' tensor (Section 20.5): raising the first index with the diagonal metric, $T^{\mu}{}_{\nu} = g^{\mu\mu}T_{\mu\nu}$ with $g^{\mu\mu} = 1/g_{\mu\mu}$, and changing the sign gives `T[mu, nu] = -low / at["g"][mu]`. The function returns $T^{\mu}{}_{\nu}$ and the eight diagonal kinetic terms.

```
G_numeric = np.diag([float(G[k].subs({ad1: 1, ad2: 0, H: 1})) for k in
                     ("x0x0", "x1x1", "x1x1", "x1x1", "x4x4", "x5x5", "x5x5",
                      "x5x5")])  # G^mu_nu at a4' = H, H = 1, in the order x0..x7
LAMBDA = -36.0
phi0_num = np.array([complex(entry) for entry in phi0])
W = float(w)
POINTS = [(zv, xv) for zv in (0.3, 0.8, 1.3) for xv in (0.0, 0.7, 2.0)]
```

`G_numeric` is the diagonal matrix of $G^{\mu}{}_{\nu}$ at $a_4' = H = 1$, $a_4'' = 0$, in the order $x_0, \ldots, x_7$ (components 1 to 3 equal $G^{x_1}{}_{x_1}$, 5 to 7 equal $G^{x_5}{}_{x_5}$): $\mathrm{diag}(12, 12, 12, 12, 24, 12, 12, 12)$. `LAMBDA` is $\Lambda = -36$, `phi0_num` the universe at $x_4 = 0$ as 16 complex floating-point numbers, `W` the frequency 4.0, and `POINTS` the nine points: $z = 0.3, 0.8, 1.3$ combined with $x_4 = 0, 0.7, 2$.

```
def universe_jet(x_value, matrix=None):
    """Value and derivatives of matrix Phi at the time x_value."""
    value = phi0_num * np.exp(-1j * W * x_value)
    if matrix is not None:
        value = matrix @ value
    jet = [np.zeros(16, dtype=complex) for _ in range(8)]
    jet[4] = -1j * W * value  # d Phi / d x4 = -i w Phi
    return value, jet
```

`universe_jet(x, matrix)` returns the first jet of the universe (or of `matrix` times the universe) at the time x: the value $\Phi_0 e^{-iwx}$ and eight derivative columns, all zero except the one along x_4, $-iw\Phi$. `matrix=None` makes the argument optional; `is not None` tests whether it was given.

```
worst_residual, worst_kinetic = 0.0, 0.0
for z_value, x_value in POINTS:
    at = geometry_at(1, z_value, x_value, 1.0)  # a4 = x4, a4' = 1
    T, kinetic = mixed_tensor(at, *universe_jet(x_value), float(m_value),
                              float(lam_value))
    residual = G_numeric + LAMBDA * np.eye(8) - T  # kappa = 1
    worst_residual = max(worst_residual, np.abs(residual).max())
    wanted = np.zeros(8)
    wanted[4] = M_VALUE * float(S_value)  # K^x4_x4 = M S, all others 0
    worst_kinetic = max(worst_kinetic, np.abs(kinetic - wanted).max())
```

At each of the nine points: the geometry on the patch with $a_4 = x_4$ (the history $a_4 = Hx_4$ with $H = 1$) and $a_4' = 1$; the tensor and the kinetic terms of the universe (`*universe_jet(x_value)` unpacks the pair (value, jet) into two arguments); the Einstein residual $G + \Lambda - \kappa T$ with $\kappa = 1$; and the largest deviation of the kinetic terms from the record's values ${K^{x_4}}_{x_4} = MS = -12$ and zero otherwise. `worst_residual` and `worst_kinetic` keep the largest values over all points.

```
T_universe = T  # the tensor at the last point (it is the same at every point)
report("rho of the universe", f"{-T_universe[4, 4]:.10f}")
report("p of the universe", f"{T_universe[1, 1]:.10f}")
reproduces(worst_kinetic < 1e-10, "K^x4_x4 = M S and K^mu_mu = 0 otherwise (9 points)",
           A4_PY, "authorT16_condensate_kinetic_diagonal")
check(worst_residual < 1e-10,
      "the universe ALONE solves all 64 Einstein equations (9 points)")
```

The tensor at the last point is kept as `T_universe` (it is the same at every point: the condensate has constant ρ and p). The RESULT lines print $\rho = -{T^{x_4}}_{x_4}$ and $p = {T^{x_1}}_{x_1}$ with ten decimals (`:.10f`). Output: RESULT rho of the universe = 12.0000000000, RESULT p of the universe = -24.0000000000, PASS for the kinetic terms (reproducing `python-a4-report.json`, check `authorT16_condensate_kinetic_diagonal`), and PASS the universe ALONE solves all 64 Einstein equations (9 points): every one of the 9×64 residuals is below 10^{-10}.

In [7], the T1 partner $\Gamma\Phi$.

```
partner = chirality * Phi  # Gamma Phi
partner_ok = field_residual(partner, gravity_term[1].subs(H, 1), -m_value,
                            -lam_value, S_value) == sp.zeros(16, 1)
reproduces(partner_ok and bilinear(chirality * phi0, I16) == S_value,
           "Gamma Phi solves the (-m, -lambda) field equation; S' = S",
           PAIR_PY, "T1.metric.commuting.euler_lagrange_map")
```

`partner` is $\Gamma\Phi$, exact. Its residual with the patch term, the parameters $(-m, -\lambda)$ and the density S must vanish at every time, and its density must equal S: step 6 of Section 20.12, reproducing `python-pairing.json`, check `T1.metric.commuting.euler_lagrange_map`.

```
A_partner = -gamma[4] * (-M_VALUE * I16 - 3 * gamma[0])  # M' = -M
same_spectrum = (chirality * A_matrix * chirality == A_partner
                 and (A_partner * A_partner + w ** 2 * I16) == Z16)
reproduces(same_spectrum, "A' = Gamma A Gamma: the partner has the same frequency",
           PAIR_WL, "Q_one_particle_maps")
```

`A_partner` is $\mathcal{A}' = -\gamma^{(x_4)}(-M - 3\gamma^{(x_0)})$. The check requires $\Gamma\mathcal{A}\Gamma = \mathcal{A}'$, the similarity derived by hand in step 6, and $\mathcal{A}'^2 + w^2 I_{16} = 0$, so that every eigenvalue of the partner's matrix is $\pm iw$: the same frequency.

```
partner_charge = sp.simplify(((chirality * phi0).H * B * (chirality * phi0))[0])
reproduces(partner_charge == -charge_value, "the partner's charge density is -J^x4",
           PAIR_PY, "T1.metric.commuting.current")
```

The partner's charge density $(\Gamma\Phi_0)^\dagger B(\Gamma\Phi_0)$, exact, must be $-(-3) = +3$ (`python-pairing.json`, check `T1.metric.commuting.current`).

```
worst_sum, worst_partner = 0.0, 0.0
for z_value, x_value in POINTS:
    at = geometry_at(1, z_value, x_value, 1.0)
    T_one, _ = mixed_tensor(at, *universe_jet(x_value), float(m_value),
                            float(lam_value))
    T_two, _ = mixed_tensor(at, *universe_jet(x_value, Gamma_num),
                            -float(m_value), -float(lam_value))
    worst_sum = max(worst_sum, np.abs(T_one + T_two).max())
    residual = G_numeric + LAMBDA * np.eye(8) - T_two
    worst_partner = max(worst_partner, np.abs(residual - 2 * T_one).max())
T_partner = T_two
reproduces(worst_sum < 1e-10, "T' = -T at all 9 points (64 components each)",
           PAIR_PY, "T1.metric.commuting.emt")
check(worst_partner < 1e-10 and np.abs(2 * T_one).max() > 1.0,
      "partner alone: the Einstein residual is 2 kappa T, not zero")
```

At the nine points: the tensor of the universe (`T_one`) and of the partner (`T_two`, the jet of $\Gamma\Phi$ with $(-m, -\lambda)$; `_` receives the kinetic terms, which are not needed). `worst_sum` is the largest component of $T + T'$, and `worst_partner` the largest deviation of the partner's Einstein residual from $2T$: with the partner as the only source the residual is $G + \Lambda - T' = (G + \Lambda - T) + 2T = 2T$, because the universe makes $G + \Lambda - T$ vanish and $T' = -T$. The checks: $T' = -T$ to 10^{-10} at all points (`python-pairing.json`, check `T1.metric.commuting.emt`), and the partner's residual is $2T$, whose largest entry is larger than 1, so NOT zero.

```
null_universe = -T_universe[4, 4] + T_universe[0, 0]  # kappa (rho + p0)
null_partner = -T_partner[4, 4] + T_partner[0, 0]
report("kappa (rho + p0) of the universe", f"{null_universe:.10f}")
report("kappa (rho + p0) of the partner", f"{null_partner:.10f}")
```

The null combination $\kappa(\rho + p_0) = -T^{x_4}{}_{x_4} + T^{x_0}{}_{x_0}$ of the universe and of the partner, printed with ten decimals. Output: -12.0000000000 and 12.0000000000.

```
rate = sp.symbols("rate", real=True)  # a real value of a4'/H
required = sp.expand(-(einstein("x4x4") - einstein("x0x0")).subs(
    {ad1: rate, ad2: 0, H: 1}))  # the requirement -6 (a4'^2 + 1)
universe_null = rho_value + p_value  # exact: 12 - 24 = -12
partner_null = -(rho_value + p_value)  # exact: T' = -T gives +12
check(abs(null_universe - float(universe_null)) < 1e-10
      and abs(null_partner - float(partner_null)) < 1e-10,
      "kappa (rho + p0): universe -12, partner +12 (numbers = exact values)")
reproduces(required == -6 * rate ** 2 - 6
           and sorted(sp.solve(required - universe_null, rate)) == [-1, 1]
           and sp.solve(required - partner_null, rate) == [],
           "the universe fits a4' = +-H; the partner fits no real rate",
           A4_PY, "einstein_null_energy_x0")
```

`rate` is a real symbol for a_4'/H, and `required` is the requirement $-(G^{x_4}{}_{x_4} - G^{x_0}{}_{x_0}) = -6(a_4'^2 + 1)$ with $H = 1$, computed from the record's components. `universe_null` and `partner_null` are the

exact values -12 and $+12$. The first check compares the floating-point values with the exact ones. The second requires the requirement to be $-6\,\mathrm{rate}^2 - 6$, the universe's value to be met exactly at the two real rates -1 and $+1$, and the partner's value at no real rate (`sp.solve` returns the empty list `[]`): step 7 of Section 20.12, reproducing `python-a4-report.json`, check `einstein_null_energy_x0`. Output of the cell: six PASS lines (five of them with their records) and the two RESULT lines.

In [8], the T1 pair as the only source.

```
worst_pair = 0.0
for z_value, x_value in POINTS:
    at = geometry_at(1, z_value, x_value, 1.0)
    T_one, _ = mixed_tensor(at, *universe_jet(x_value), float(m_value),
                            float(lam_value))
    T_two, _ = mixed_tensor(at, *universe_jet(x_value, Gamma_num),
                            -float(m_value), -float(lam_value))
    residual = G_numeric + LAMBDA * np.eye(8) - (T_one + T_two)
    expected = np.diag([-24.0, -24, -24, -24, -12, -24, -24, -24])
    worst_pair = max(worst_pair, np.abs(residual - expected).max())
check(worst_pair < 1e-10,
      "T1 pair alone: residual = G + Lambda = diag(-24, ..., -12, ...), not zero")
```

At the nine points the residual with the T1 pair as the only source, $G+\Lambda-(T+T')$, must equal the matrix $\mathrm{diag}(-24,-24,-24,-24,-12,-24,-24,-24)$ of step 8 (`np.diag` makes a diagonal matrix from a list). Output: PASS T1 pair alone: residual = G + Lambda = diag(-24, ..., -12, ...), not zero. This is corollary C1 on the example.

In [9], the T2 mirror copy across the brane.

```
copy = gamma[0] * Phi  # gamma^(x0) Phi on the mirror patch
copy_ok = field_residual(copy, gravity_term[-1].subs(H, 1), -m_value, lam_value,
                         -S_value) == sp.zeros(16, 1)
reproduces(copy_ok and bilinear(gamma[0] * phi0, I16) == -S_value,
           "the mirror copy solves the (-m, lambda) equation there; S' = -S",
           PAIR_PY, "T2.metric.commuting.euler_lagrange_map")
copy_charge = sp.simplify(((gamma[0] * phi0).H * B * (gamma[0] * phi0))[0])
reproduces(copy_charge == charge_value, "the copy's charge density is +J^x4",
           PAIR_PY, "Q.T2_image_keeps_B")
```

`copy` is $\gamma^{(x_0)}\Phi$ (position 0 is x_0). Its residual is computed with the MIRROR-patch term $-3\gamma^{(x_0)}$ (`gravity_term[-1]`), the parameters $(-m,\lambda)$ and the density $-S$; it must vanish at every time, and its density must be $-S$: step 9 of Section 20.12, reproducing `python-pairing.json`, check `T2.metric.commuting.euler_lagrange_map`. The copy's charge density, exact, must equal the universe's -3 (`python-pairing.json`, check `Q.T2_image_keeps_B`).

```
worst_copy, worst_pull = 0.0, 0.0
R0 = np.diag([-1.0, 1, 1, 1, 1, 1, 1, 1])  # the reflection of x0
for z_value, x_value in POINTS:
    there = geometry_at(-1, np.pi - z_value, x_value, 1.0)  # the mirror point
    T_copy, _ = mixed_tensor(there, *universe_jet(x_value, gamma_num[0]),
```

```
                            -float(m_value), float(lam_value))
    T_one, _ = mixed_tensor(geometry_at(1, z_value, x_value, 1.0),
                            *universe_jet(x_value), float(m_value), float(lam_value))
    worst_pull = max(worst_pull, np.abs(T_copy - R0 @ T_one @ R0).max())
    residual = G_numeric + LAMBDA * np.eye(8) - T_copy
    worst_copy = max(worst_copy, np.abs(residual).max())
T_mirror = T_copy
```

`R0` is the diagonal matrix $R_0 = \mathrm{diag}(-1, 1, 1, 1, 1, 1, 1, 1)$. At each of the nine points, `there` is the geometry at the mirror point $\pi - z$ of the mirror patch (`s0 = -1`), and `T_copy` the tensor of the copy there, with $(-m, \lambda)$. `T_one` is the universe's tensor at the original point. `worst_pull` is the largest deviation of the copy's tensor from the pulled-back tensor $R_0 T R_0$ (`@` is the matrix product), and `worst_copy` the largest Einstein residual of the copy alone on the mirror patch. The last value of `T_copy` is kept as `T_mirror`.

```
reproduces(worst_pull < 1e-10, "the copy's tensor is R0 T R0 = T at 9 mirror points",
           PAIR_PY, "T2.metric.commuting.emt")
check(worst_copy < 1e-10,
      "the mirror copy ALONE solves the 64 Einstein equations on the mirror patch")
```

The checks: the copy's tensor is $R_0 T R_0$, which equals T because T is diagonal (`python-pairing.json`, check `T2.metric.commuting.emt`), and the copy ALONE solves all 64 Einstein equations on the mirror patch. Output: four PASS lines, three with their records.

In [10], figure 1: the Einstein residuals of the four sources.

```
tables = [
    ("universe $\\Phi$ alone", G_numeric + LAMBDA * np.eye(8) - T_universe),
    ("T1 partner $\\Gamma\\Phi$ alone", G_numeric + LAMBDA * np.eye(8) - T_partner),
    ("T1 pair (C1)", G_numeric + LAMBDA * np.eye(8) - T_universe - T_partner),
    ("T2 copy alone (mirror patch)", G_numeric + LAMBDA * np.eye(8) - T_mirror),
]
```

`tables` is a list of four pairs (title, residual): the universe alone, the T1 partner alone, the T1 pair, and the T2 copy alone (on the mirror patch). Each residual is $G + \Lambda - T$ for the source named.

```
fig, axes = plt.subplots(1, 4, figsize=(14.0, 4.0))
for ax, (title, values) in zip(axes, tables):
    image = ax.imshow(values, cmap="RdBu_r", vmin=-48, vmax=48)
    for mu in range(8):
        if abs(values[mu, mu]) > 1e-6:
            ink = "white" if abs(values[mu, mu]) > 30 else "black"  # readable
            ax.text(mu, mu, f"{values[mu, mu]:.0f}", ha="center", va="center",
                    fontsize=6.5, color=ink)
    ax.set_xticks(range(8))
    ax.set_xticklabels(NAMES, fontsize=6.5)
    ax.set_yticks(range(8))
    ax.set_yticklabels(NAMES, fontsize=6.5)
    ax.grid(False)
    ax.set_title(title, fontsize=9)
fig.colorbar(image, ax=list(axes), shrink=0.75, label="residual (units $H^2$)")
```

One row of four panels, 14 by 4 inches. Each residual is drawn as a heat map with the colour scale from -48 to 48 (`vmin`, `vmax`), the same in all panels. The inner loop writes the value of every nonzero diagonal entry into its square (`f"{...:.0f}"` prints it without decimals; `ha` and `va` centre the text), in white on dark squares (modulus above 30) and in black otherwise, so that it can be read. The labels, the switched-off grid, the titles and one common colour bar follow, as in Notebook 20a, In [8].

```
save_figure(fig, "einstein_residuals",
            "The residual $G^\\mu{}_\\nu + \\Lambda\\delta^\\mu_\\nu - \\kappa "
...
            "equations there.")
```

`save_figure` saves `20b_1_einstein_residuals.png` and shows it (the eleven-line caption is shown here by its first and last lines). **What figure 1 shows.** Four 8×8 tables of the residual $G^\mu{}_\nu + \Lambda\delta^\mu_\nu - \kappa T^\mu{}_\nu$ (rows μ, columns ν, x_0 to x_7; colour scale in units H^2, white means zero), for the author's metric with $a_4 = Hx_4$ and $\Lambda = -36H^2$. The universe alone gives a white table: it solves all 64 equations. The T1 partner alone gives $2\kappa T$, with -48 on the diagonal except -24 at x_4. The T1 pair gives $G + \Lambda$, with -24 on the diagonal except -12 at x_4. The T2 copy alone on the mirror patch gives a white table again. The student should see that only the universe and its mirror copy solve the equations; the T1 partner and the T1 pair do not.

In [11], figure 2: what Einstein gravity requires and what each source supplies.

```
rates = np.linspace(-2.5, 2.5, 501)
fig, ax = plt.subplots(figsize=(7.0, 4.6))
ax.plot(rates, -6 * (rates ** 2 + 1), color="black", linewidth=2.0,
        label="required: $-6(a_4'^2 + H^2)$")
```

501 rates a_4'/H from -2.5 to 2.5, and the requirement $-6(a_4'^2 + H^2)$ drawn as a thick black curve.

```
supplied = (("universe $\\Phi$", null_universe, "tab:blue", "-"),
            ("T1 partner $\\Gamma\\Phi$", null_partner, "tab:red", "-"),
            ("T1 pair", null_universe + null_partner, "tab:purple", "--"),
            ("T2 copy", -T_mirror[4, 4] + T_mirror[0, 0], "tab:green", ":"))
for label, value, colour, style in supplied:
    ax.axhline(value, color=colour, linestyle=style, linewidth=1.6,
               label=f"{label} supplies {value:+.0f}")
ax.plot([-1.0, 1.0], [-12.0, -12.0], "o", color="tab:blue", markersize=8,
        label="solutions: $a_4' = \\pm H$")
```

`supplied` lists four (label, value, colour, line style) entries: the universe's -12, the partner's $+12$, the pair's 0 and the copy's $-T^{x_4}{}_{x_4} + T^{x_0}{}_{x_0} = -12$. Each is drawn as a horizontal line (`ax.axhline`); the label prints the value with its sign (`:+.0f`). Two blue dots mark the two places where the universe's line meets the curve, $a_4' = \pm H$.

```
ax.set_xlabel("rate $a_4'/H$ of the metric function")
ax.set_ylabel("$\\kappa(\\rho + p_0)/H^2$")
ax.set_ylim(-45, 18)
ax.set_title("What Einstein gravity requires, and what each source supplies")
ax.legend(fontsize=7.5, loc="lower center", ncol=2)
```

The axis labels, the vertical range from -45 to 18 (`set_ylim`), the title and a legend in two columns below the curve.

```
save_figure(fig, "null_requirement",
            "The null combination $\\kappa(\\rho + p_0)$ (energy density plus the "
            "pressure along $x_0$; vertical, units $H^2$) that Einstein gravity "
...
            "nowhere.")
```

What figure 2 shows. Horizontal axis: the rate a_4'/H; vertical axis: the null combination $\kappa(\rho+p_0)$ in units H^2. The black parabola is what Einstein gravity requires of every source; its highest point is -6, at $a_4'=0$. The blue line of the universe (-12) meets it at $a_4'=\pm H$; the green dotted line of the T2 copy lies on top of the blue one. The red line of the T1 partner ($+12$) and the purple dashed line of the T1 pair (0) lie above the parabola's highest point and meet it nowhere. The student should see in one picture why the partner and the pair cannot be the source of the author's metric for any rate, while the universe and its mirror copy can.

In [12], figure 3: the bookkeeping.

```
rho_u, p_u = -T_universe[4, 4], T_universe[1, 1]
rho_m, p_m = -T_mirror[4, 4], T_mirror[1, 1]
J_u = float(charge_value)
rows = {
    "universe": (rho_u, p_u, J_u, float(S_value)),
    "T1 partner": (-T_partner[4, 4], T_partner[1, 1], float(partner_charge),
                   float(S_value)),
    "T1 pair": (rho_u - T_partner[4, 4], p_u + T_partner[1, 1],
                J_u + float(partner_charge), 2 * float(S_value)),
    "T2 copy": (rho_m, p_m, float(copy_charge), -float(S_value)),
    "T2 pair": (rho_u + rho_m, p_u + p_m, J_u + float(copy_charge), 0.0),
}
```

The numbers of the table of Section 20.12: ρ and p of the universe and of the copy, the universe's charge density as a floating-point number, and the dictionary `rows`, which holds for each of the five objects the four numbers (ρ, p, J^{x_4}, S). The T1 pair adds the universe and the partner at the same point; the T2 pair adds the universe and the copy, each at its own point; the T2 pair's S is $S+(-S)=0$.

```
for name, (r, p, j, s) in rows.items():
    say(f"{name:11s}: rho = {r:+7.2f}, p = {p:+7.2f}, J^x4 = {j:+6.2f}, "
        f"S = {s:+5.2f}")
check(abs(rows["T1 pair"][0]) < 1e-10 and abs(rows["T1 pair"][2]) < 1e-12
      and abs(rows["T2 pair"][0] - 24) < 1e-9 and abs(rows["T2 pair"][2] + 6) < 1e-12,
      "T1 pair: rho = 0 and J = 0; T2 pair: rho = 24 and J = -6")
```

The loop prints one line per object; in the f-string, `{name:11s}` pads the name to 11 characters and `{r:+7.2f}` prints a number with its sign, two decimals, in a field of 7 characters, so that the columns line up. Output: the five lines of the table (universe $+12$, -24, -3, $+2.40$; T1 partner -12, $+24$, $+3$, $+2.40$; T1 pair 0, 0, 0, $+4.80$; T2 copy $+12$, -24, -3, -2.40; T2 pair $+24$, -48, -6, 0). The check: the T1 pair has $\rho=0$ and $J^{x_4}=0$, the T2 pair $\rho=24$ and $J^{x_4}=-6$.

```
quantities = ["$\\rho$", "$p$", "$J^{x_4}$", "$S$"]
fig, ax = plt.subplots(figsize=(9.0, 5.0))
width = 0.16
colours = ["tab:blue", "tab:red", "tab:purple", "tab:green", "tab:olive"]
for k, (name, values) in enumerate(rows.items()):
    positions = np.arange(4) + (k - 2) * width
    ax.bar(positions, values, width=width, color=colours[k], label=name)
    for x_value, value in zip(positions, values):
        if abs(value) < 1e-9:  # a bar of height zero: write 0 so it is seen
            ax.text(x_value, 1.0, "0", ha="center", fontsize=8,
                    color=colours[k], fontweight="bold")
```

A grouped bar chart: four groups (the quantities ρ, p, J^{x_4}, S), five bars in each (the objects). `np.arange(4)` is $0, 1, 2, 3$, the centres of the groups; the bar of object k is shifted by $(k-2)$ times the width 0.16, so the five bars stand side by side. `enumerate` numbers the objects $k = 0, \ldots, 4$. A bar of height zero cannot be seen, so the inner loop writes a bold 0 in its place.

```
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(range(4))
ax.set_xticklabels(quantities)
ax.set_ylabel("value (units $H = \\kappa = 1$)")
ax.set_title("The bookkeeping of one universe and its partners")
ax.legend(fontsize=8, ncol=5, loc="upper center", bbox_to_anchor=(0.5, -0.08))
ax.set_ylim(-52, 30)
save_figure(fig, "bookkeeping",
...
            "charge of the universe.")
```

A thin line at zero, the names of the quantities under the groups, the label, the title, a legend in five columns below the chart, and the vertical range. **What figure 3 shows.** Groups of bars for ρ, p, J^{x_4} and S (units $H = \kappa = 1$). The red bars of the T1 partner are the blue bars of the universe reversed in ρ, p and J^{x_4} and equal in S, so the T1 pair (purple) is zero in the first three groups. The green bars of the T2 copy equal the blue ones in ρ, p and J^{x_4} and are reversed in S, so the T2 pair (olive) has twice the energy, twice the pressure and twice the charge. The student should see the difference between the two theorems as two different patterns of bars: T1 cancels, T2 adds.

In [13], figure 4: the partner in time.

```
times = np.linspace(0.0, 3.0, 601)
phi_t = np.outer(np.exp(-1j * W * times), phi0_num)  # rows: times, columns: A
partner_t = phi_t @ Gamma_num.T  # Gamma Phi at every time
```

601 times from 0 to 3. `np.outer(a, b)` is the table of all products $a_i b_j$: here row i is the universe $\Phi_0 e^{-iwx_4}$ at the i-th time. `partner_t` is $\Gamma\Phi$ at every time: multiplying each row by Γ^T from the right is the same as multiplying each column vector by Γ from the left.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(12.0, 4.4))
for index, colour in ((0, "tab:blue"), (8, "tab:orange")):
    left.plot(times, phi_t[:, index].real, color=colour, linewidth=4.0,
```

```
            alpha=0.35, label=f"universe, component {index + 1}")
    left.plot(times, partner_t[:, index].real, "--", color=colour,
            label=f"partner, component {index + 1}")  # drawn on top
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("real part")
left.set_title("same oscillation, the first half of the components reversed",
               fontsize=9)
left.legend(fontsize=7.5, loc="lower left", ncol=2)
left.set_ylim(-2.2, 1.7)
```

The left panel: the real parts of components 1 and 9 (positions 0 and 8) of the universe as thick pale lines (`linewidth=4.0`, `alpha=0.35`), and of the partner as dashed lines drawn on top. Component 1 lies in the half where $\Gamma = -1$, component 9 in the half where $\Gamma = +1$. Labels, title, legend and the vertical range follow.

```
eig_u = np.linalg.eigvals(np.array(A_matrix.tolist(), dtype=float))
eig_p = np.linalg.eigvals(np.array(A_partner.tolist(), dtype=float))
right.plot(eig_u.real, eig_u.imag, "o", markersize=11, markerfacecolor="none",
           color="tab:blue", label="universe: eigenvalues of $\\mathcal{A}$")
right.plot(eig_p.real, eig_p.imag, "x", markersize=9, color="tab:red",
           label="partner: eigenvalues of $\\mathcal{A}'$")
right.set_xlim(-1.5, 1.5)
right.set_ylim(-5.5, 5.5)
right.set_xlabel("real part")
right.set_ylabel("imaginary part (units $H$)")
right.set_title("equal spectra: $\\pm 4i$, eight times each", fontsize=9)
right.legend(fontsize=8, loc="center right")
```

The right panel: `np.linalg.eigvals` computes the 16 eigenvalues of $\mathcal{A}$ and of $\mathcal{A}'$ in floating point; they are drawn in the complex plane (real part horizontal, imaginary part vertical), the universe's as open circles (`markerfacecolor="none"`), the partner's as crosses.

```
check(np.allclose(np.sort(eig_u.imag), np.sort(eig_p.imag), atol=1e-12)
      and np.abs(eig_u.real).max() < 1e-12,
      "both spectra are +-4i, eight times each (numerically)")
```

The check: sorted by their imaginary parts, the two lists of eigenvalues agree to 10^{-12} (`np.allclose`), and their real parts are zero to 10^{-12}.

```
save_figure(fig, "partner_in_time",
            "Left: the real parts of components 1 and 9 of the universe "
...
            "the opposite energy density.")
```

What figure 4 shows. Left: the real parts of components 1 and 9 of the universe (thick pale) and of its T1 partner (dashed) against the time x_4 in units $1/H$. Component 1 of the partner is the universe's component 1 with the opposite sign; component 9 is the same; both oscillate with the period $2\pi/4 \approx 1.57$. Right: the eigenvalues of $\mathcal{A}$ (circles) and of $\mathcal{A}' = \Gamma\mathcal{A}\Gamma$ (crosses) in the complex plane: all lie at $+4i$ and $-4i$, eight times each, and the crosses sit inside the circles. The student

should see that the partner has the same frequency as the universe, although its energy density is the opposite: a negative energy density here is not a negative frequency.

In [14], the last check.

```
figure_names = ["einstein_residuals", "null_requirement", "bookkeeping",
                "partner_in_time"]
paths = [output_file(f"{FIGURE_FOLDER}/20b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

As in Notebook 20a, In [19]: the four figure files `20b_1_einstein_residuals.png` to `20b_4_partner_in_time.png` must exist, and `all_checks_passed()` prints the last line. Output: PASS every figure file of this notebook exists, and ALL 25 CHECKS PASSED (notebook 20b).

20.17 Allowed is not the same as happens: an electron and a positron made from light

Why a lesson from ordinary physics. To judge whether the equations of this book prove that universes are created, we must know what a proof of creation contains when physics does have one. The creation of an electron and a positron (its **antiparticle**: the same mass, the opposite electric charge) from light is understood completely. It shows the three questions of Section 20.4 answered one after the other, and it shows that the answer to the first (allowed?) is computed from conservation laws alone, while the answers to the second and the third (does it happen? how often?) need a dynamical theory.

Words and the standard physics we use. We use ordinary space with three directions and one time, units in which the speed of light is 1, and energies, momenta and masses measured in units of the electron mass m. A body of mass μ with the **momentum** $\vec{p} = (p_1, p_2, p_3)$, a vector of length $|\vec{p}| = \sqrt{p_1^2 + p_2^2 + p_3^2}$, has the energy $E = \sqrt{\mu^2 + |\vec{p}|^2}$ (the energy-momentum relation of special relativity). A **photon**, a particle of light, has $\mu = 0$, so $E = |\vec{p}|$. For a collection of bodies the total energy E_{tot} and the total momentum $\vec{p}_{\text{tot}}$ are sums over the bodies, and the **invariant mass** μ of the collection is defined by

$$\mu^2 = E_{\text{tot}}^2 - |\vec{p}_{\text{tot}}|^2.$$

For a single body it is its mass. ASSUMED (standard physics, not derived in this book): the energy-momentum relation, and the conservation of the total energy, the total momentum and the total electric charge of an isolated system in every process. Since μ^2 is built from conserved totals, it is conserved too. A **threshold** is the smallest energy at which a process is allowed.

The rule of every threshold. A process from a state A to a state B is forbidden if some conserved quantity has different values in A and in B. So $\mu_A = \mu_B$ is NECESSARY. The lemma below says that a final state of bodies with masses $\mu_1, \mu_2, \ldots$ has $\mu_B \geq \mu_1 + \mu_2 + \cdots$, so the initial state must bring at least the sum of the final masses as invariant mass. This is a necessary condition only.

Lemma (two bodies have at least the sum of their masses). Two bodies with masses $\mu_1, \mu_2 \geq 0$ and momenta $\vec{p}_1, \vec{p}_2$ have together $(E_1 + E_2)^2 - |\vec{p}_1 + \vec{p}_2|^2 \geq (\mu_1 + \mu_2)^2$.

Proof, line by line. Write $a = |\vec{p}_1|$ and $b = |\vec{p}_2|$.

1. Multiplying out, $(E_1 + E_2)^2 - |\vec{p}_1 + \vec{p}_2|^2 = (E_1^2 - a^2) + (E_2^2 - b^2) + 2(E_1E_2 - \vec{p}_1 \cdot \vec{p}_2)$, because $|\vec{p}_1 + \vec{p}_2|^2 = a^2 + b^2 + 2\vec{p}_1 \cdot \vec{p}_2$ (the **dot product** $\vec{p}_1 \cdot \vec{p}_2 = p_{1,1}p_{2,1} + p_{1,2}p_{2,2} + p_{1,3}p_{2,3}$).
2. The energy-momentum relation $E_i^2 - |\vec{p}_i|^2 = \mu_i^2$ turns this into $\mu_1^2 + \mu_2^2 + 2(E_1E_2 - \vec{p}_1 \cdot \vec{p}_2)$.
3. The dot product is at most the product of the lengths, $\vec{p}_1 \cdot \vec{p}_2 = ab\cos\theta \leq ab$ (θ is the angle between the vectors). So it is enough to show $E_1E_2 \geq \mu_1\mu_2 + ab$.
4. Both sides of that inequality are not negative, so we may compare their squares: $E_1^2E_2^2 - (\mu_1\mu_2 + ab)^2 = (\mu_1^2 + a^2)(\mu_2^2 + b^2) - (\mu_1\mu_2 + ab)^2$.
5. Multiplying out, $(\mu_1^2 + a^2)(\mu_2^2 + b^2) = \mu_1^2\mu_2^2 + \mu_1^2b^2 + \mu_2^2a^2 + a^2b^2$ and $(\mu_1\mu_2 + ab)^2 = \mu_1^2\mu_2^2 + 2\mu_1\mu_2ab + a^2b^2$; the terms $\mu_1^2\mu_2^2$ and a^2b^2 cancel in the difference, and what remains is $\mu_1^2b^2 - 2\mu_1\mu_2ab + \mu_2^2a^2 = (\mu_1b - \mu_2a)^2 \geq 0$, a square.
6. Hence $E_1E_2 - \vec{p}_1 \cdot \vec{p}_2 \geq \mu_1\mu_2$, and line 2 is at least $\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 = (\mu_1 + \mu_2)^2$. QED.

Equality needs equality in lines 3 and 5: parallel momenta and $\mu_1 b = \mu_2 a$, that is $b/\mu_2 = a/\mu_1$: the two bodies move with the same velocity. Applied twice, the lemma gives the same for three bodies, $\mu \geq \mu_1 + \mu_2 + \mu_3$ (first combine two of them into one collection of invariant mass at least $\mu_1 + \mu_2$, then add the third).

Proposition 1 (one photon can never make a pair). A single photon in empty space cannot turn into an electron and a positron. *Proof.* Before: one photon, $\mu_A^2 = E^2 - |\vec{p}|^2 = 0$. After: two bodies of mass m, so $\mu_B \geq 2m > 0$ by the lemma. Conservation needs $\mu_A = \mu_B$, so $0 \geq 2m$, which is false. QED. Charge does not forbid the process ($-1 + 1 = 0$, the photon's charge), and energy alone does not either (the photon may have any energy): the COMBINATION of energy and momentum forbids it.

Proposition 2 (a photon on a nucleus). A photon of energy E_γ that hits a **nucleus** (the heavy centre of an atom) of mass M at rest can make an electron-positron pair, the nucleus remaining in the final state, only if $E_\gamma \geq 2m(1 + m/M)$. *Proof, line by line.*

1. Before: the total energy is $E_\gamma + M$ and the total momentum is the photon's, of length E_γ, so $\mu_A^2 = (E_\gamma + M)^2 - E_\gamma^2 = M^2 + 2E_\gamma M$ (multiply out; E_γ^2 cancels).
2. After: by the lemma applied twice, $\mu_B \geq m + m + M = 2m + M$.
3. Conservation, $\mu_A = \mu_B$, therefore needs $M^2 + 2E_\gamma M \geq (2m + M)^2 = M^2 + 4mM + 4m^2$.
4. Subtract M^2 from both sides and divide by $2M > 0$: $E_\gamma \geq 2m + 2m^2/M = 2m(1 + m/M)$. QED.

Conversely, at and above this energy the conservation laws allow the process: at exactly the threshold the three final bodies move together with the common velocity $v = |\vec{p}_{\text{tot}}|/E_{\text{tot}}$ (the equality case of the lemma), and each carries the share μ_i/μ of the total momentum. For $M = 4m$:

$E_\gamma = 2m(1+1/4) = 5m/2$; the totals are $|\vec{p}_{\rm tot}| = 5m/2$ and $E_{\rm tot} = 5m/2 + 4m = 13m/2$; $\mu = 6m$; the electron and the positron carry the momentum $(1/6)(5m/2) = 5m/12$ each and the energy $\sqrt{m^2 + 25m^2/144} = 13m/12$ each; the nucleus carries $(4/6)(5m/2) = 5m/3$ and $\sqrt{16m^2 + 25m^2/9} = 13m/3$. The momenta add up to $5m/12 + 5m/12 + 5m/3 = 30m/12 = 5m/2$ and the energies to $13m/12 + 13m/12 + 52m/12 = 78m/12 = 13m/2$: exactly the initial totals (COMPUTED exactly, Notebook 20c, In [5]). For a heavy nucleus the threshold approaches the two **rest energies** $2m$: for $M = 1000m$ it is $1001m/500 = 2.002m$, and for $M = 1836m$ (about the mass of a proton) $1837m/918 \approx 2.001089m$. The nucleus takes up the momentum but almost no energy.

Proposition 3 (two photons). Two photons of energies E_a and E_b that meet at the angle θ between their directions can make a pair only if $E_a E_b \geq 2m^2/(1-\cos\theta)$. *Proof.* $\mu^2 = (E_a+E_b)^2 - |\vec{p}_a+\vec{p}_b|^2 = E_a^2 + 2E_aE_b + E_b^2 - (E_a^2 + E_b^2 + 2E_aE_b\cos\theta) = 2E_aE_b(1-\cos\theta)$, using $|\vec{p}_a| = E_a$, $|\vec{p}_b| = E_b$ and $\vec{p}_a \cdot \vec{p}_b = E_aE_b\cos\theta$; the lemma requires $\mu \geq 2m$, that is $\mu^2 \geq 4m^2$, and dividing by $2(1-\cos\theta) > 0$ gives the claim. QED. Head on ($\theta = 180$ degrees, $\cos\theta = -1$) this is $E_aE_b \geq m^2$; photons moving in the same direction ($\theta = 0$, $\mu = 0$) can never make a pair.

Status. The lemma and Propositions 1 to 3 are PROVED here from the ASSUMED standard physics above, and Notebook 20c checks them with sympy and on random samples. They answer Q1 completely: below the threshold the process is forbidden, at and above it allowed. They say NOTHING about Q2 and Q3. That pairs are really made above the threshold, and how often, was computed from **quantum electrodynamics**, the quantum theory of electrons and light, by Bethe and Heitler (H. Bethe and W. Heitler, Proc. R. Soc. Lond. A 146, 83 (1934)) for a photon on a nucleus, and by Breit and Wheeler (G. Breit and J. A. Wheeler, Phys. Rev. 46, 1087 (1934)) for two photons. This book quotes these works; it does not compute their results.

Three lessons for universes.

1. Conservation laws are NECESSARY conditions. They can rule a process out (Proposition 1); they never rule a process in.

2. Whether an allowed process happens, and how often, is computed from the DYNAMICS, here an interaction between light and the electron field. Without it the photon could not hand its energy to the pair.

3. The electron and the positron are two quanta of ONE field, the electron field, whose total charge is $-1 + 1 = 0$, and that field interacts with light. The two universes of a T1 pair are configurations of two DIFFERENT theories, with parameters (m, λ) and $(-m, -\lambda)$, and no term of any Lagrangian of the Revision record couples them. Section 20.22 draws the consequence for their charges.

The comparison, item by item (the right column is the subject of Sections 20.22 to 20.25):

question	electron and positron from light	universes of masses $+m$ and $-m$
Q1: conserved quantities	energy, momentum, charge	the U(1) charge of each universe (local law PROVED; its total is constant only under the ASSUMED no-flux condition at the brane $z = \pi/2$); the momenta of each universe along $x_1, x_2, x_3, x_5, x_6, x_7$ and its rotation quantities (derived, Section 20.22 (d')); the energy of a universe is not conserved in the deflating metric
Q1: an interaction that lets energy or charge pass	light couples to electrons	none in the theory
Q2: the dynamics of creation	quantum electrodynamics	none derived
Q3: rate, probability, amplitude	computed in 1934 (quoted)	none

20.18 Example: the threshold of pair creation, computed

Notebook 20c proves the lemma's key line with sympy and tests the lemma on 20000 random pairs of bodies, shows on 5000 random electron-positron states that one photon can never make a pair, derives the threshold $2m(1 + m/M)$ on a nucleus with an exact final state at the threshold, and the allowed region for two photons. At the end it reads, from the Revision record of the pairing theorems, which of the three questions those theorems answer for universes, and the U(1) record of one universe. It prints 12 PASS lines, one of which reproduces a named check of a Revision report, and draws four figures. It needs numpy, sympy and matplotlib, no Rust, and runs in about 15 seconds (its recorded check run on the build computer, which was busy with other work at the time, took 28.1 seconds).

20.19 How to run Notebook 20c

Step 1. What this notebook does and what it needs.

Notebook 20c (Allowed is not the same as happens: the threshold of pair creation) is the file `Revision/textbook/notebooks/20c_allowed_not_happens.ipynb` of the repository Dirac_claude. It computes, from the relativistic relation between energy, momentum and mass and the conservation of energy and momentum, when the creation of an electron and a positron from light is allowed: it proves with sympy that the invariant mass of two bodies is at least the sum of their masses and tests it on 20000 random pairs, shows that a single photon can never make a pair, derives the threshold photon energy 2m(1 + m/M) on a nucleus of mass M with an exact final state at the threshold, and the allowed region for two photons at any angle. It then reads from the Revision record what the pairing theorems do not establish (no creation process, no rate, no amplitude), and draws four teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python

3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 20c_allowed_not_happens.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 20c_allowed_not_happens.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 20c_allowed_not_happens.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/20c.captions.json`
- `Revision/textbook/figures/20c_1_invariant_mass_inequality.png`
- `Revision/textbook/figures/20c_2_nucleus_threshold.png`
- `Revision/textbook/figures/20c_3_allowed_photon_energies.png`
- `Revision/textbook/figures/20c_4_two_photon_regions.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS every figure file of this notebook exists
ALL 12 CHECKS PASSED (notebook 20c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/20c_allowed_not_happens.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.

- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 20c_allowed_not_happens.ipynb
python -m nbconvert --execute --inplace 20c_allowed_not_happens.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads two files of the repository; it must be opened inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

20.20 Notebook 20c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/20c_allowed_not_happens.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The request behind this chapter speaks of universes "created in pairs". Before we
can say what the equations of this book do and do not prove about that, we must be
clear what a proof of creation would contain. This notebook works it out on the
```

```
one example of pair creation that physics understands completely: an electron and
a positron (its antiparticle) made from light. It separates three questions:

- **Q1, allowed?** Do the conservation laws (energy, momentum, charge) permit the
  process? This is answered here completely, by algebra and by computation.
- **Q2, does it happen?** Is there a dynamical law that turns the initial state
  into the final one? For light this is quantum electrodynamics, which this
  notebook does NOT compute.
- **Q3, how often?** A number: a rate, a probability, a cross section. Again a
  result of the dynamics, not of the conservation laws.

It computes: the invariant mass and the inequality behind every threshold (proved
with sympy, tested on 20000 random pairs); why one photon can never make a pair;
the threshold photon energy on a nucleus, with an exact final state at the
threshold; and the allowed region for two photons. At the end it reads, from the
Revision record of the pairing theorems, which of the three questions those
theorems answer for universes: none of Q2 and Q3.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 20c (Allowed is not the same as happens: the threshold of pair creation) is the
file ‘Revision/textbook/notebooks/20c_allowed_not_happens.ipynb‘ of the repository
Dirac_claude. It computes, from the relativistic relation between energy, momentum and
mass and the conservation of energy and momentum, when the creation of an electron and a
positron from light is allowed: it proves with sympy that the invariant mass of two
bodies is at least the sum of their masses and tests it on 20000 random pairs, shows that
a single photon can never make a pair, derives the threshold photon energy 2m(1 + m/M) on
a nucleus of mass M with an exact final state at the threshold, and the allowed region
for two photons at any angle. It then reads from the Revision record what the pairing
theorems do not establish (no creation process, no rate, no amplitude), and draws four
teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".
```

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 20c_allowed_not_happens.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 20c_allowed_not_happens.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 20c_allowed_not_happens.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/20c.captions.json‘
- ‘Revision/textbook/figures/20c_1_invariant_mass_inequality.png‘
- ‘Revision/textbook/figures/20c_2_nucleus_threshold.png‘
- ‘Revision/textbook/figures/20c_3_allowed_photon_energies.png‘
- ‘Revision/textbook/figures/20c_4_two_photon_regions.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS every figure file of this notebook exists
    ALL 12 CHECKS PASSED (notebook 20c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/20c_allowed_not_happens.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 20c_allowed_not_happens.ipynb
      python -m nbconvert --execute --inplace 20c_allowed_not_happens.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads two files of the repository; it must be opened inside the folder

Revision/textbook/notebooks of a complete copy of the repository made with git clone (a notebook copied alone to another folder cannot find them).

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 20c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 20c (Allowed is not the same as happens: the threshold of pair creation) is
# the file Revision/textbook/notebooks/20c_allowed_not_happens.ipynb of the repository
# Dirac_claude. It computes, from the relativistic relation between energy, momentum and
# mass and the conservation of energy and momentum, when the creation of an electron and
# a positron from light is allowed: it proves with sympy that the invariant mass of two
# bodies is at least the sum of their masses and tests it on 20000 random pairs, shows
# that a single photon can never make a pair, derives the threshold photon energy 2m(1 +
# m/M) on a nucleus of mass M with an exact final state at the threshold, and the allowed
# region for two photons at any angle. It then reads from the Revision record what the
# pairing theorems do not establish (no creation process, no rate, no amplitude), and
# draws four teaching figures. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
```

```
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
```

```
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 20c_allowed_not_happens.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
```

```
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 20c_allowed_not_happens.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 20c_allowed_not_happens.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/20c.captions.json
# - Revision/textbook/figures/20c_1_invariant_mass_inequality.png
# - Revision/textbook/figures/20c_2_nucleus_threshold.png
# - Revision/textbook/figures/20c_3_allowed_photon_energies.png
# - Revision/textbook/figures/20c_4_two_photon_regions.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS every figure file of this notebook exists
#     ALL 12 CHECKS PASSED (notebook 20c)
#
# and the notebook must show 4 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
```

```
#   Revision/textbook/notebooks/20c_allowed_not_happens.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 20c_allowed_not_happens.ipynb
#     python -m nbconvert --execute --inplace 20c_allowed_not_happens.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file below the folder Revision: the notebook reads two
#   files of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository made with git clone
#   (a notebook copied alone to another folder cannot find them).
#

## 3. The words used in this notebook

- **Units**: the speed of light is 1, and energies, momenta and masses are
  measured in units of the electron mass $m$ (so $m = 1$ in the code).
- **Momentum** $\vec p = (p_1, p_2, p_3)$, a vector; its length is $|\vec p| =
  \sqrt{p_1^2 + p_2^2 + p_3^2}$. **Energy** $E$ of a body of mass $\mu$:
  $E = \sqrt{\mu^2 + |\vec p|^2}$ (the energy-momentum relation of special
  relativity). A **photon** (light) has $\mu = 0$, so $E = |\vec p|$.
- **Electron, positron**: two particles of the same mass $m$ and opposite
  electric charge $-1$ and $+1$. **Nucleus**: the heavy centre of an atom, mass
  $M$.
- **Conservation law**: a quantity whose total is the same before and after any
  process (here the total energy, the total momentum and the total charge).
- **Invariant mass** $\mu$ of a collection of bodies: $\mu^2 = E_{\rm tot}^2 -
  |\vec p_{\rm tot}|^2$, computed from the totals. Because the totals are
  conserved, so is $\mu$. For one body $\mu$ is its mass.
- **Threshold**: the smallest energy at which a process is allowed.
- **Allowed** (in this notebook): not forbidden by any conservation law. Allowed
  does not mean that the process happens, nor how often.
- **Rate, cross section, amplitude**: numbers that say how often a process
  happens; they come from a dynamical theory.
- **Lemma, proposition**: a proved statement (a lemma is a step towards others).
```

Text cell:

```
## 4. The physical and mathematical situation

**ASSUMED (standard physics of special relativity):** each body has $E^2 =
\mu^2 + |\vec p|^2$; the total energy and the total momentum of an isolated system
do not change; nor does its total electric charge. Everything else is derived and
computed here.

**The rule of every threshold.** A process A $\to$ B is forbidden if any conserved
quantity has different values in A and in B. Since $\mu^2$ is built from conserved
totals, $\mu_A = \mu_B$ is NECESSARY. The lemma of section 5 says that a final
state made of bodies with masses $\mu_1, \mu_2, \dots$ always has $\mu_B \geq \mu_1
+ \mu_2 + \cdots$. So the initial state must bring at least that much invariant
mass:

$$\mu_A \;\geq\; \text{(sum of the final masses)}.$$

This is a necessary condition only. Whether the process then happens, and how
often, is decided by the dynamics.
```

Text cell:

```
## 5. The lemma: two bodies have at least the sum of their masses

**Lemma.** Two bodies with masses $\mu_1, \mu_2 \geq 0$, momenta $\vec p_1,
\vec p_2$ and energies $E_i = \sqrt{\mu_i^2 + |\vec p_i|^2}$ have together
$(E_1 + E_2)^2 - |\vec p_1 + \vec p_2|^2 \geq (\mu_1 + \mu_2)^2$.
```

```
*Proof, line by line.* Write $a = |\vec p_1|$, $b = |\vec p_2|$.

1. Multiply out the squares: $(E_1 + E_2)^2 - |\vec p_1 + \vec p_2|^2 =
   (E_1^2 - a^2) + (E_2^2 - b^2) + 2(E_1E_2 - \vec p_1\cdot\vec p_2)$.
2. Use $E_i^2 - |\vec p_i|^2 = \mu_i^2$: this is $\mu_1^2 + \mu_2^2 +
   2(E_1E_2 - \vec p_1\cdot\vec p_2)$.
3. The dot product is at most the product of the lengths, $\vec p_1\cdot\vec p_2
   \leq ab$, so it suffices to show $E_1E_2 \geq \mu_1\mu_2 + ab$.
4. Both sides are not negative, so compare their squares:
   $E_1^2E_2^2 - (\mu_1\mu_2 + ab)^2 = (\mu_1^2 + a^2)(\mu_2^2 + b^2) -
   (\mu_1\mu_2 + ab)^2$.
5. Multiplying out, the terms $\mu_1^2\mu_2^2$ and $a^2b^2$ cancel and what remains
   is $\mu_1^2b^2 + \mu_2^2a^2 - 2\mu_1\mu_2ab = (\mu_1b - \mu_2a)^2 \geq 0$.
6. Hence $E_1E_2 - \vec p_1\cdot\vec p_2 \geq \mu_1\mu_2$, and line 2 is at least
   $\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 = (\mu_1 + \mu_2)^2$. QED.

The next cell checks line 5 with sympy, then tests the lemma on 20000 random
pairs of bodies (random masses between 0 and 3, random momenta, fixed seed).
```

## 6. One photon can never make a pair

**Proposition.** A single photon in empty space cannot turn into an electron and
a positron. *Proof.* Before: one photon, $\mu_A^2 = E^2 - |\vec p|^2 = 0$. After:
two bodies of mass $m$, so by the lemma $\mu_B \geq 2m > 0$. The invariant mass is
conserved, so $0 \geq 2m$, which is false. QED.

Charge does not forbid it ($-1 + 1 = 0$, the photon's charge), and energy alone
does not either (the photon may have any energy): the COMBINATION of energy and
momentum forbids it. The next cell checks the statement on 5000 random final
states: none has invariant mass zero; the smallest is $2m$.
```

Figure 518: The invariant mass $\mu = \sqrt{E_{\mathrm{tot}}^2 - |\vec{p}_{\mathrm{tot}}|^2}$ of 20000 random pairs of bodies (vertical) against the sum of their masses $\mu_1 + \mu_2$ (horizontal), both in units of the electron mass m; masses between 0 and 3, random momenta, fixed seed. Every point lies on or above the black diagonal $\mu = \mu_1 + \mu_2$, as the lemma proves: a final state of bodies with given masses needs at least the sum of those masses as invariant mass, which is the origin of every threshold. (Notebook 20c, figure 1.)

In [4]:

```
pair_momenta = rng.normal(size=(2, 5000, 3)) * 3.0  # electron and positron
pair_energies = np.sqrt(1.0 + np.sum(pair_momenta ** 2, axis=-1))  # m = 1

PASS every electron-positron state has mu >= 2 m > 0
```

Text cell:

```
## 7. A photon on a nucleus: the threshold

A photon of energy $E_\gamma$ hits a nucleus of mass $M$ at rest; the final state
is an electron, a positron and the nucleus. Line by line:

1. Before: total energy $E_\gamma + M$, total momentum of length $E_\gamma$ (the
   photon's), so $\mu_A^2 = (E_\gamma + M)^2 - E_\gamma^2 = M^2 + 2E_\gamma M$.
2. After: by the lemma (applied twice) $\mu_B \geq m + m + M$.
3. Conservation, $\mu_A = \mu_B$, therefore needs $M^2 + 2E_\gamma M \geq
   (2m + M)^2 = M^2 + 4mM + 4m^2$.
4. Subtract $M^2$ and divide by $2M$: $E_\gamma \geq 2m + 2m^2/M =
   2m(1 + m/M)$.

At exactly the threshold the three final bodies move together with the common
velocity $v = p_{\rm tot}/E_{\rm tot}$ (the equality case of the lemma). For
$M = 4m$: $E_\gamma = 5m/2$, $p_{\rm tot} = 5m/2$, $E_{\rm tot} = 13m/2$,
$\mu = 6m$, and each body carries the share $\mu_i/\mu$ of the momentum: $5m/12$
for the electron and for the positron, $5m/3$ for the nucleus. The next cell
solves line 3 with sympy, checks this final state EXACTLY (energies and momenta
add up to the initial ones), and computes the threshold for three nuclei: $M =
4m$ (helium-like), $1000m$ and $1836m$ (about a proton).
```

In [5]:

```

## 8. Two photons

Two photons of energies $E_a$ and $E_b$ meet at the angle $\theta$ between their
directions. Line by line: $\mu^2 = (E_a + E_b)^2 - |\vec p_a + \vec p_b|^2$;
multiplying out with $|\vec p_a| = E_a$, $|\vec p_b| = E_b$ and $\vec p_a\cdot\vec
p_b = E_aE_b\cos\theta$ gives $\mu^2 = 2E_aE_b(1 - \cos\theta)$. The lemma requires
$\mu \geq 2m$, so the pair is allowed exactly when
```

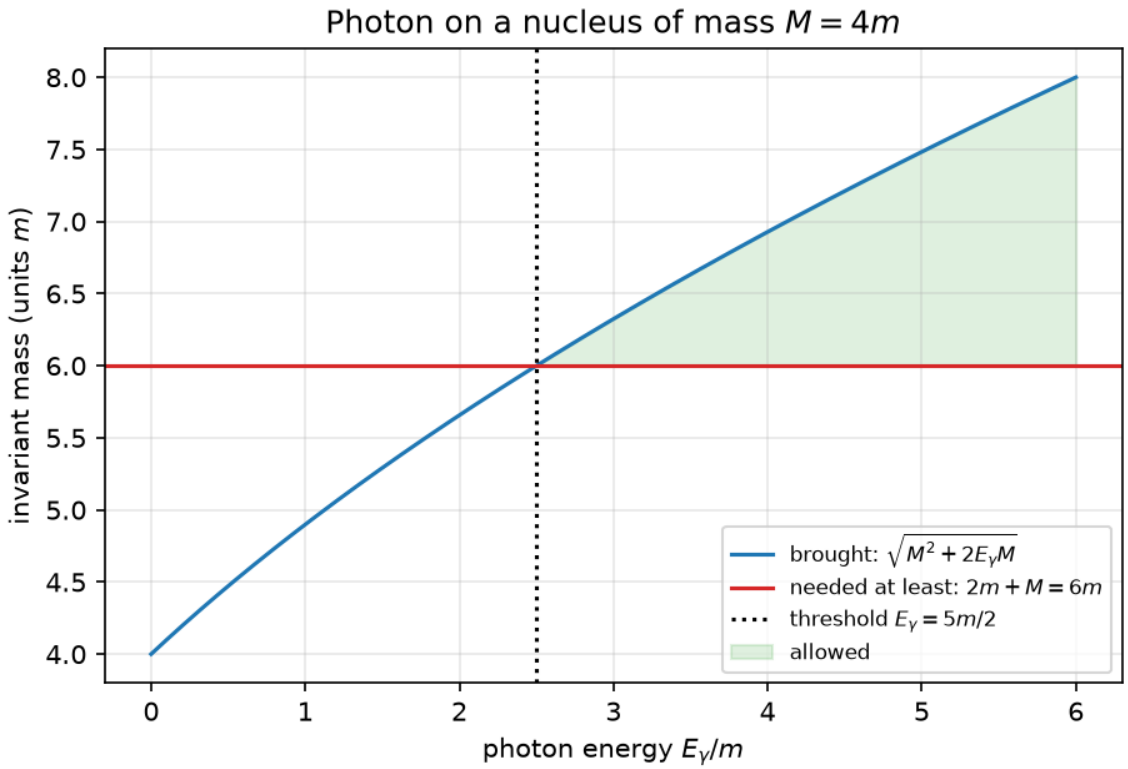

Figure 520: For a photon hitting a nucleus of mass $M = 4m$ at rest: the invariant mass the initial state brings, $\sqrt{M^2 + 2E_\gamma M}$ (blue), and the smallest invariant mass the final state of electron, positron and nucleus needs, $2m + M = 6m$ (red), against the photon energy E_γ (horizontal; all in units of the electron mass m). Conservation of energy and momentum allows the pair only where the blue curve is at or above the red line (green), from the threshold $E_\gamma = 5m/2$ (dotted) on. (Notebook 20c, figure 3.)

```
$$E_aE_b \;\geq\; \frac{2m^2}{1 - \cos\theta}.$$

Head on ($\theta = 180$ degrees, $\cos\theta = -1$) this is $E_aE_b \geq m^2$; for
photons moving in the same direction ($\theta = 0$) never. The next cell checks
the formula with sympy and draws the allowed regions for three angles.

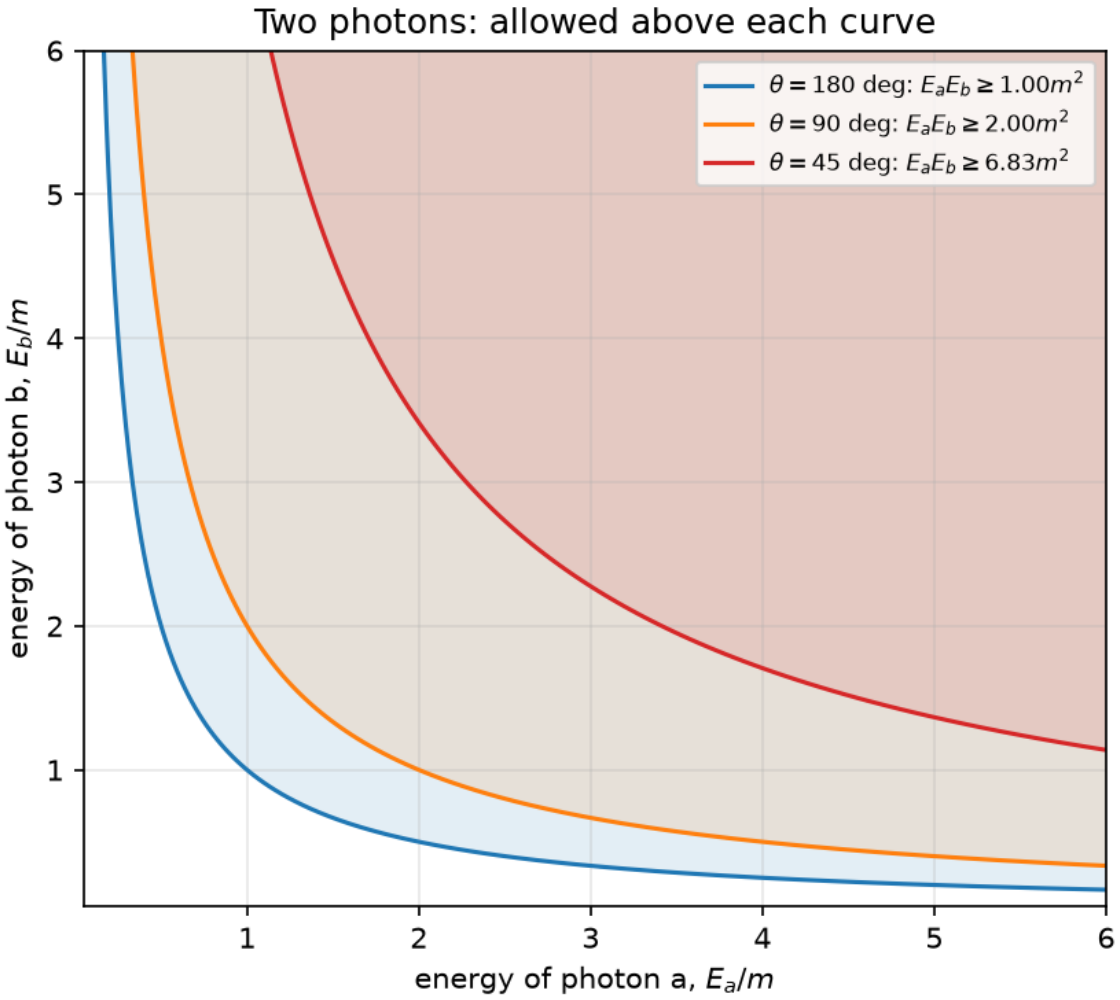

Figure 521: Two photons of energies E_a and E_b (horizontal and vertical, units of the electron mass m) meeting at the angle θ: an electron-positron pair is allowed above the curve $E_aE_b = 2m^2/(1-\cos\theta)$ (shaded), drawn for head-on photons, $\theta = 180$ degrees (blue, $E_aE_b \geq m^2$), for 90 degrees (orange, $2m^2$) and 45 degrees (red, about $6.83m^2$). The smaller the angle, the more energy is needed; photons moving in the same direction can never make a pair. (Notebook 20c, figure 4.)

9. What the conservation laws cannot say, and what this means for universes

Sections 5 to 8 answered Q1 completely for light: below a threshold the process is forbidden, above it allowed. They say NOTHING about Q2 and Q3. That pairs are really made above the threshold, and how often, was computed from quantum electrodynamics, the dynamical theory of electrons and light, by Bethe and Heitler (H. Bethe and W. Heitler, Proc. R. Soc. Lond. A 146, 83 (1934)) for a photon on a nucleus and by Breit and Wheeler (G. Breit and J. A. Wheeler, Phys. Rev. 46, 1087 (1934)) for two photons. This notebook quotes these works; it does not compute their results.

For universes of masses $+m$ and $-m$ the theory of this book supplies:

- **Q1, conserved quantities.** Light: energy, momentum and charge. Universes: the U(1) charge of each universe obeys an exact local conservation law (PROVED in the record); its total is constant only if no charge flows through the brane $z = \pi/2$ (the no-flux condition, ASSUMED: the record does not derive it, and on the homogeneous solutions of chapter 18 charge does flow through the brane). The momenta along the six directions on which the metric does not depend (x_1, x_2, x_3, x_5, x_6, x_7) obey local laws too, separately for each universe (derived from the record's on-shell law $\nabla_\mu T^\mu{}_\nu = 0$ and the symmetry of T; ASSUMED: the boundary terms vanish); the energy of a universe is NOT a conserved quantity, because the deflating metric depends on the time x_4 (for a homogeneous source the record's identity is $d\rho/dx_4 = -3a_4'(p_3 - p_t)$).
- **Q1, interaction.** Light couples to electrons. No term of any Lagrangian of the record couples two universes.
- **Q2, the dynamics of creation.** Light: quantum electrodynamics. Universes: none; no creation process is derived.
- **Q3, rate and amplitude.** Light: computed in 1934. Universes: none; no rate, probability or amplitude.

One consequence can be drawn in two lines from the record's conservation law (status: derived here; ASSUMED: the boundary terms vanish, e.g. periodic coordinates and no flux through the brane $z = \pi/2$, a condition that the record does not derive). Each universe obeys its own field equation and nothing couples the two, so under these conditions the charge Q_+ of the first universe is conserved on its own. If both fields were zero at some time, Q_+ would be zero at every time. A T1 pair whose members carry the charges Q and $-Q$ with $Q \neq 0$ can therefore not evolve out of zero fields in the theory as built: the zero TOTAL charge of a T1 pair does not make its appearance allowed, because the separate charges are conserved too (under the no-flux condition).

The next cell reads the record's own list of what the pairing theorems do not establish and checks that it names the missing answers to Q2 and Q3.

In [9]:

```
theory = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                    .read_text(encoding="utf-8"))
missing = theory["not_established"]  # the record's list
say(f"the record lists {len(missing)} things the pairing theorems do not establish;")
```

all_checks_passed()
```

Out [10]:

```
PASS every figure file of this notebook exists
ALL 12 CHECKS PASSED (notebook 20c)
```

Text cell:

```
## 11. What this notebook showed

- The invariant mass of two bodies is at least the sum of their masses (PROVED
  with sympy, and true for 20000 random pairs); this is the origin of every
  threshold (figure 1).
- One photon can never make an electron-positron pair; on a nucleus of mass $M$
  the photon needs at least $2m(1 + m/M)$: $2.5m$ for $M = 4m$, $2.00109m$ for
  $M = 1836m$, with an exact final state at the threshold (figures 2 and 3); two
  photons need $E_aE_b \geq 2m^2/(1 - \cos\theta)$ (figure 4).
- These are answers to Q1 only (allowed or forbidden). That the process happens,
  and how often, needs a dynamical theory (quantum electrodynamics, quoted, not
  computed).
- For universes the record has local conservation laws but no interaction
  between universes, no creation process, no rate and no amplitude: Q2 and Q3 are
  not answered, and with separately conserved charges (ASSUMED: no flux through
  the brane) a T1 pair with nonzero charges cannot evolve out of zero fields in
  the theory as built.
```

20.21 Line-by-line walk-through of Notebook 20c

The notebook has 10 code cells, In [1] to In [10].

In [1], the set-up cell. It is word for word the set-up cell of Notebook 20a, explained line by line in Section 20.11, except that its comment lines hold the run instructions of Notebook 20c (Section 20.19) and one line names the notebook:

```
NOTEBOOK_ID = "20c"  # this notebook: chapter 20, example c
```

Output: Set-up of notebook 20c complete.

In [2], the lemma.

```
import numpy as np  # arrays and random numbers
import sympy as sp  # exact algebra

mu1, mu2, a, b = sp.symbols("mu1 mu2 a b", nonnegative=True)
E1_sq, E2_sq = mu1 ** 2 + a ** 2, mu2 ** 2 + b ** 2  # E_i^2 = mu_i^2 + |p_i|^2
line5 = sp.expand(E1_sq * E2_sq - (mu1 * mu2 + a * b) ** 2)
check(sp.expand(line5 - (mu1 * b - mu2 * a) ** 2) == 0,
      "line 5: E1^2 E2^2 - (mu1 mu2 + a b)^2 = (mu1 b - mu2 a)^2")
```

numpy and sympy are loaded. The four symbols μ_1, μ_2, a, b are declared not negative (`nonnegative=True`), as in the lemma. `E1_sq` and `E2_sq` are $E_1^2 = \mu_1^2 + a^2$ and $E_2^2 = \mu_2^2 + b^2$. `line5` is $E_1^2E_2^2 - (\mu_1\mu_2 + ab)^2$, multiplied out; the check confirms that it equals $(\mu_1 b - \mu_2 a)^2$, line 5 of the proof, exactly.

```
def invariant_mass(energies, momenta):
    """mu = sqrt(E_tot^2 - |p_tot|^2) of a collection of bodies."""
```

```
    E_total = np.sum(energies, axis=0)
    p_total = np.sum(momenta, axis=0)
    return np.sqrt(np.maximum(E_total ** 2 - np.sum(p_total ** 2, axis=-1), 0.0))
```

`invariant_mass` computes $\mu = \sqrt{E_{\text{tot}}^2 - |\vec{p}_{\text{tot}}|^2}$ for many collections at once. The energies form an array with one row per body; `np.sum(..., axis=0)` adds the rows, so `E_total` holds the total energy of each collection. The momenta form an array with one row per body and three numbers per momentum; `axis=0` again adds over the bodies. `np.sum(p_total ** 2, axis=-1)` adds the squares of the three components (the last axis) and gives $|\vec{p}_{\text{tot}}|^2$. `np.maximum(..., 0.0)` replaces a tiny negative rounding error by 0 before the square root.

```
rng = np.random.default_rng(20261007)  # fixed seed: the same numbers every run
count = 20000
masses = rng.uniform(0.0, 3.0, size=(2, count))  # mu1, mu2
momenta = rng.normal(size=(2, count, 3)) * rng.uniform(0.0, 4.0, size=(2, count, 1))
energies = np.sqrt(masses ** 2 + np.sum(momenta ** 2, axis=-1))
mu_total = invariant_mass(energies, momenta)
margin = mu_total - masses.sum(axis=0)  # must never be negative
report("smallest margin mu_total - (mu1 + mu2) in 20000 pairs",
       f"{margin.min():.2e}")
check(margin.min() > -1e-12, "the lemma holds for all 20000 random pairs")
```

A random-number generator with a fixed seed. `masses` is a 2×20000 array of masses drawn uniformly between 0 and 3. `momenta` is a $2 \times 20000 \times 3$ array: normal random vectors, each multiplied by a random length factor between 0 and 4 (the last axis of size 1 multiplies all three components of a vector by the same number). `energies` is $\sqrt{\mu^2 + |\vec{p}|^2}$ for each body. `margin` is the invariant mass of each pair minus the sum of its two masses; the lemma says it is never negative. Output: RESULT smallest margin mu_total - (mu1 + mu2) in 20000 pairs = 2.34e-04, and PASS the lemma holds for all 20000 random pairs (the check allows -10^{-12} for rounding).

In [3], figure 1: the lemma on 20000 pairs.

```
fig, ax = plt.subplots(figsize=(6.4, 5.0))
ax.plot(masses.sum(axis=0), mu_total, ".", markersize=1.5, alpha=0.4,
        color="tab:blue", label="20000 random pairs")
ax.plot([0, 6], [0, 6], color="black", linewidth=1.5,
        label="$\\mu = \\mu_1 + \\mu_2$")
ax.set_xlabel("sum of the masses $\\mu_1 + \\mu_2$ (units $m$)")
ax.set_ylabel("invariant mass of the pair $\\mu$ (units $m$)")
ax.set_xlim(0, 6)
ax.set_ylim(0, 16)
ax.set_title("Two bodies have at least the sum of their masses")
ax.legend(fontsize=8, loc="upper left", markerscale=6)
```

A scatter plot: each pair is a dot (marker `"."`, size 1.5, 40 per cent opaque) at the sum of its masses (horizontal) and its invariant mass (vertical); the black line is the diagonal $\mu = \mu_1 + \mu_2$. The axis ranges, the title and a legend (`markerscale=6` enlarges the dot in the legend) follow.

```
save_figure(fig, "invariant_mass_inequality",
            "The invariant mass "
```

```
...
            "of every threshold.")
```

What figure 1 shows. Horizontal axis: the sum of the two masses $\mu_1 + \mu_2$; vertical axis: the invariant mass μ of the pair; both in units of the electron mass m. Every one of the 20000 dots lies on or above the black diagonal, and the dots crowd towards it from above. The student should see the lemma as a picture: a collection of bodies never has less invariant mass than the sum of its masses, which is why every creation process has a threshold.

In [4], one photon can never make a pair.

```
pair_momenta = rng.normal(size=(2, 5000, 3)) * 3.0  # electron and positron
pair_energies = np.sqrt(1.0 + np.sum(pair_momenta ** 2, axis=-1))  # m = 1
pair_mu = invariant_mass(pair_energies, pair_momenta)
report("smallest invariant mass of 5000 electron-positron states",
       f"{pair_mu.min():.4f}")
check(pair_mu.min() >= 2.0 - 1e-12, "every electron-positron state has mu >= 2 m > 0")
```

5000 random electron-positron states: the two momenta are normal random vectors times 3, and the energies are $\sqrt{1 + |\vec{p}|^2}$ because $m = 1$. The smallest invariant mass is printed with four decimals and must be at least $2m$; a single photon has invariant mass 0, so no state of the list can be reached from one photon. Output: RESULT smallest invariant mass of 5000 electron-positron states = 2.0003, and the PASS line.

In [5], a photon on a nucleus: the threshold.

```
E_gamma, M_nuc, m_e = sp.symbols("E_gamma M m", positive=True)
mu_initial_sq = (E_gamma + M_nuc) ** 2 - E_gamma ** 2  # line 1
threshold = sp.solve(sp.Eq(mu_initial_sq, (2 * m_e + M_nuc) ** 2), E_gamma)[0]
say(f"threshold photon energy: {sp.factor(threshold)}")
check(sp.simplify(threshold - 2 * m_e * (1 + m_e / M_nuc)) == 0,
      "E_threshold = 2 m (1 + m/M)")
```

The positive symbols E_γ, M and m. `mu_initial_sq` is line 1 of the proof of Proposition 2, $\mu_A^2 = (E_\gamma + M)^2 - E_\gamma^2$. `sp.Eq(a, b)` is the equation $a = b$; solving $\mu_A^2 = (2m + M)^2$ for E_γ gives the threshold, and `sp.factor` prints it as a product. Output: threshold photon energy: $2m$(M + m)/M. The check compares it with $2m(1 + m/M)$.

```
M4 = 4  # the nucleus of mass 4 m, with m = 1
E_th = threshold.subs({m_e: 1, M_nuc: M4})  # 5/2
p_total, E_total = E_th, E_th + M4  # the initial totals
mu_final = sp.Integer(2 + M4)  # 6 m
shares = [1, 1, M4]  # electron, positron, nucleus masses
p_parts = [sp.Rational(mass) * p_total / mu_final for mass in shares]
E_parts = [sp.sqrt(mass ** 2 + p ** 2) for mass, p in zip(shares, p_parts)]
say(f"final state at threshold: momenta {p_parts}, energies {E_parts}")
check(sum(p_parts) == p_total and sp.simplify(sum(E_parts) - E_total) == 0
      and E_th == sp.Rational(5, 2),
      "M = 4 m: the threshold state conserves energy and momentum exactly")
```

The exact final state at the threshold for $M = 4m$ (with $m = 1$): the threshold $E_\gamma = 5/2$; the initial totals $|\vec{p}_{\text{tot}}| = 5/2$ and $E_{\text{tot}} = 13/2$; the final invariant mass $\mu = 6$; the masses of the electron, the positron and the nucleus; each momentum the share μ_i/μ of the total; each energy $\sqrt{\mu_i^2 + p_i^2}$ (`zip` pairs each mass with its momentum). Output: momenta [5/12, 5/12, 5/3], energies [13/12, 13/12, 13/3]. The check requires the momenta to add up to 5/2 and the energies to 13/2 exactly, and the threshold to be 5/2.

```
for M_value in (4, 1000, 1836):
    value = threshold.subs({m_e: 1, M_nuc: M_value})
    report(f"threshold for M = {M_value} m", f"{sp.nsimplify(value)} = "
           f"{float(value):.6f} m")
check(threshold.subs({m_e: 1, M_nuc: 1836}) == 2 + sp.Rational(2, 1836),
      "M = 1836 m: the threshold is 2 m + 2 m/1836, just above 2 m")
```

The threshold for $M = 4m$, $1000m$ and $1836m$, printed as an exact fraction (`sp.nsimplify`) and with six decimals. Output: $5/2 = 2.500000$ m, $1001/500 = 2.002000$ m, $1837/918 = 2.001089$ m. The last check confirms exactly that for $M = 1836m$ the threshold is $2m + 2m/1836$, just above the two rest energies.

In [6], figure 2: the threshold against the mass of the nucleus.

```
M_axis = np.logspace(-0.5, 4, 400)  # M/m from about 0.3 to 10000
fig, ax = plt.subplots(figsize=(7.0, 4.4))
ax.semilogx(M_axis, 2 * (1 + 1 / M_axis), color="tab:blue",
            label="threshold $2m(1 + m/M)$")
ax.axhline(2.0, color="black", linestyle=":", label="the two rest energies $2m$")
for M_value, marker in ((4, "o"), (1000, "s"), (1836, "^")):
    ax.plot([M_value], [2 * (1 + 1 / M_value)], marker, color="tab:red",
            markersize=7, label=f"$M = {M_value}m$: {2 * (1 + 1 / M_value):.5f}$m$")
ax.fill_between(M_axis, 2 * (1 + 1 / M_axis), 9.0, color="tab:green", alpha=0.12,
                label="allowed (not forbidden)")
ax.set_ylim(1.5, 9.0)
ax.set_xlabel("mass of the nucleus $M/m$")
ax.set_ylabel("photon energy $E_\\gamma/m$")
ax.set_title("Pair creation on a nucleus: the threshold")
ax.legend(fontsize=8, loc="upper right")
```

400 masses M/m spaced evenly on a logarithmic scale from $10^{-0.5} \approx 0.3$ to 10^4 (`np.logspace`). `ax.semilogx` draws the threshold $2(1 + 1/M)$ with a logarithmic horizontal axis. The dotted line is the two rest energies $2m$; the three red markers are the thresholds for $M = 4m$, $1000m$ and $1836m$, labelled with five decimals; `fill_between` shades the allowed region above the curve in light green. The vertical range, the labels, the title and the legend follow.

```
save_figure(fig, "nucleus_threshold",
            "The smallest photon energy $E_\\gamma$ (vertical, units of the "
...
            "often the process happens above the threshold.")
```

What figure 2 shows. Horizontal axis: the mass of the nucleus M/m (logarithmic); vertical axis: the photon energy E_γ/m. The blue curve is the threshold $2m(1 + m/M)$; above it (green) the

process is allowed by the conservation laws, below it forbidden. A light nucleus needs much more than the two rest energies; for a heavy nucleus the curve approaches the dotted line $2m$. The student should also see what the picture does NOT say: nothing about how often the process happens in the green region.

In [7], figure 3: what the initial state brings and what the final state needs.

```
E_axis = np.linspace(0.0, 6.0, 601)
brought = np.sqrt(M4 ** 2 + 2 * E_axis * M4)  # mu_A for M = 4 m
crossing = E_axis[np.argmin(np.abs(brought - (2 + M4)))]
report("crossing of the two curves (M = 4 m)", f"{crossing:.2f} m")
check(abs(crossing - 2.5) < 0.01, "the curves cross at E_gamma = 2.5 m")
```

601 photon energies from 0 to 6. `brought` is the invariant mass of the initial state, $\sqrt{M^2 + 2E_\gamma M}$ with $M = 4$. `np.argmin(np.abs(brought - 6))` is the position of the photon energy at which `brought` is closest to the needed $2m + M = 6$; `crossing` is that energy. Output: RESULT crossing of the two curves (M = 4 m) = 2.50 m, and the PASS line (to 0.01, the spacing of the grid).

```
fig, ax = plt.subplots(figsize=(7.0, 4.4))
ax.plot(E_axis, brought, color="tab:blue", label="brought: $\\sqrt{M^2 + 2E_\\gamma M}$")
ax.axhline(2 + M4, color="tab:red", label="needed at least: $2m + M = 6m$")
ax.axvline(2.5, color="black", linestyle=":", label="threshold $E_\\gamma = 5m/2$")
ax.fill_between(E_axis, 2 + M4, brought, where=brought >= 2 + M4,
                color="tab:green", alpha=0.15, label="allowed")
ax.set_xlabel("photon energy $E_\\gamma/m$")
ax.set_ylabel("invariant mass (units $m$)")
ax.set_title("Photon on a nucleus of mass $M = 4m$")
ax.legend(fontsize=8, loc="lower right")
```

The rising blue curve of what the initial state brings, the red horizontal line of what the final state needs at least, the dotted vertical line of the threshold, and the green shading where the first is at or above the second (`where=` restricts the shading). Labels, title and legend follow.

```
save_figure(fig, "allowed_photon_energies",
            "For a photon hitting a nucleus of mass $M = 4m$ at rest: the invariant "
...
            "$E_\\gamma = 5m/2$ (dotted) on.")
```

What figure 3 shows. Horizontal axis: the photon energy E_γ/m; vertical axis: invariant mass in units m; nucleus $M = 4m$. The blue curve (brought) rises with the photon energy and crosses the red line (needed, $6m$) at $E_\gamma = 5m/2$, the dotted threshold. The student should see the threshold as the meeting point of two curves: to the left the process is forbidden, to the right allowed.

In [8], figure 4: two photons.

```
Ea, Eb, theta = sp.symbols("E_a E_b theta", positive=True)
pa = sp.Matrix([Ea, 0, 0])  # photon a along the first axis
pb = sp.Matrix([Eb * sp.cos(theta), Eb * sp.sin(theta), 0])  # photon b at angle
mu_sq = sp.simplify((Ea + Eb) ** 2 - (pa + pb).dot(pa + pb))
```

```
check(sp.simplify(mu_sq - 2 * Ea * Eb * (1 - sp.cos(theta))) == 0,
      "two photons: mu^2 = 2 E_a E_b (1 - cos theta)")
check(sp.simplify(mu_sq.subs(theta, sp.pi) - 4 * Ea * Eb) == 0
      and mu_sq.subs(theta, 0) == 0,
      "head on mu^2 = 4 E_a E_b; same direction mu^2 = 0 (never allowed)")
```

The positive symbols E_a, E_b, θ. Photon a moves along the first axis, $\vec{p}_a = (E_a, 0, 0)$; photon b at the angle θ, $\vec{p}_b = (E_b \cos\theta, E_b \sin\theta, 0)$ (its length is E_b). `mu_sq` is $\mu^2 = (E_a + E_b)^2 - |\vec{p}_a + \vec{p}_b|^2$ (`.dot` is the dot product). The first check confirms $\mu^2 = 2E_aE_b(1 - \cos\theta)$, the proof of Proposition 3; the second the two special cases: head on ($\theta = \pi$, 180 degrees) $\mu^2 = 4E_aE_b$, and in the same direction ($\theta = 0$) $\mu^2 = 0$.

```
grid = np.linspace(0.05, 6.0, 300)
EA, EB = np.meshgrid(grid, grid)
fig, ax = plt.subplots(figsize=(6.4, 5.4))
for degrees, colour in ((180, "tab:blue"), (90, "tab:orange"), (45, "tab:red")):
    bound = 2.0 / (1 - np.cos(np.radians(degrees)))  # E_a E_b >= bound (m = 1)
    ax.contourf(EA, EB, (EA * EB >= bound).astype(float), levels=[0.5, 1.5],
                colors=[colour], alpha=0.12)
    ax.contour(EA, EB, EA * EB, levels=[bound], colors=[colour])
    ax.plot([], [], color=colour,
            label=f"$\\theta = {degrees}$ deg: $E_aE_b \\geq {bound:.2f}m^2$")
ax.set_xlabel("energy of photon a, $E_a/m$")
ax.set_ylabel("energy of photon b, $E_b/m$")
ax.set_title("Two photons: allowed above each curve")
ax.legend(fontsize=8, loc="upper right")
```

A grid of 300 by 300 energy pairs from 0.05 to 6 (`np.meshgrid` makes the two tables `EA` and `EB` of all combinations). For three angles, 180, 90 and 45 degrees (`np.radians` turns degrees into radians), `bound` is $2/(1 - \cos\theta)$, the threshold of E_aE_b with $m = 1$. `contourf` shades, in the colour of the angle, the region where $E_aE_b \geq$ `bound` (the comparison gives `True` or `False`, `.astype(float)` turns it into 1 or 0, and the level band from 0.5 to 1.5 selects the ones); `contour` draws its boundary curve $E_aE_b =$ `bound`. `ax.plot([], [], ...)` draws nothing but adds an entry with the colour and the bound (two decimals) to the legend. Labels, title and legend follow.

```
save_figure(fig, "two_photon_regions",
            "Two photons of energies $E_a$ and $E_b$ (horizontal and vertical, "
...
            "direction can never make a pair.")
```

What figure 4 shows. Horizontal axis: the energy of photon a; vertical axis: the energy of photon b; both in units m. Above each curve the pair is allowed: for head-on photons above $E_aE_b = m^2$ (blue), for 90 degrees above $2m^2$ (orange), for 45 degrees above about $6.83m^2$ (red). The student should see that the smaller the angle between the photons, the more energy is needed, and that photons moving in the same direction can never make a pair.

In [9], what the record says about universes.

```
theory = json.loads(repository_file("Revision/pairing/pairing-theory.json")
                    .read_text(encoding="utf-8"))
```

```
missing = theory["not_established"]  # the record's list
say(f"the record lists {len(missing)} things the pairing theorems do not establish;")
for item in missing[:3]:
    say("- " + item.split(":")[0] + ": " + item.split(":")[1].split(";")[0].strip())
```

The record `pairing-theory.json` is read, and its list `not_established` is taken (`missing`). The first line prints how many items the list has; the loop prints the first three items shortened: `item.split(":")[0]` is the text before the first colon (the item's title), and `item.split(":")[1].split(";")[0].strip()` the text after it up to the first semicolon, without blanks at the ends. Output: the record lists 9 things the pairing theorems do not establish, followed by the three items No creation process, No rate and no amplitude, and No dynamical necessity, each with its first clause.

```
starts = [item.split(":")[0] for item in missing]
check({"No creation process", "No rate and no amplitude",
       "No dynamical necessity"} <= set(starts),
      "the record states: no creation process, no rate or amplitude, no necessity")
```

`starts` is the list of the titles of all nine items. `set(starts)` makes a set of them, and `a <= b` for two sets is true when every element of `a` is in `b`. The check requires the three titles to be in the record's list.

```
u1 = json.loads(repository_file(
    "Revision/lead_checks/reports/charge-conjugation-and-u1.json")
    .read_text(encoding="utf-8"))
verdicts = {entry["name"]: entry["verdict"] for entry in u1["checks"]}
check(verdicts.get("u1_noether_matrix_identity") == "PASS",
      "the record proves the local U(1) conservation law of one universe",
      record="Revision/lead_checks/reports/charge-conjugation-and-u1.json, check "
             "u1_noether_matrix_identity")
```

The lead's report on charge conjugation and the U(1) charge is read, `verdicts` maps each check name to its verdict (`.get(name)` returns `None` if the name is absent), and the check requires `u1_noether_matrix_identity` to have the verdict PASS: the record's proof of the LOCAL conservation law $\partial_\mu(\cos z\, J^\mu) = 0$ of the charge of one universe on shell (the total charge is constant only when, in addition, no charge flows through the brane, Section 20.22 (a)). Output: two PASS lines, the second with the line naming the record.

In [10], the last check.

```
figure_names = ["invariant_mass_inequality", "nucleus_threshold",
                "allowed_photon_energies", "two_photon_regions"]
paths = [output_file(f"{FIGURE_FOLDER}/20c_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths),
      "every figure file of this notebook exists")
all_checks_passed()
```

As in Notebook 20a, In [19]: the four figure files must exist, and `all_checks_passed()` prints the last line. Output: PASS every figure file of this notebook exists, and ALL 12 CHECKS PASSED (notebook 20c).

20.22 What the conservation laws of this theory allow and forbid

Section 20.17 answered question Q1 (allowed?) for light from conservation laws alone. This section does the same for universes, with the conservation laws that the Revision record proves.

When a conservation law forbids. A **conserved quantity** is a number computed from the state of a system that does not change in time for every solution. It forbids a transition from a state A to a state B exactly when its values in A and in B differ. A system may have several conserved quantities, and each forbids on its own: the conservation laws allow a transition only when EVERY conserved quantity has the same value in A and in B. The **empty state** of the classical theory is the configuration in which every field is zero everywhere; all its bilinears, and hence all its conserved quantities, are zero.

(a) The charge of one universe: an exact local law, and a total that is constant only without a flow through the brane. The Lagrangian of Section 20.5 does not change when the field is multiplied by a constant phase, $\Psi \to e^{i\alpha}\Psi$ with a real number α: then $\Psi^\dagger \to e^{-i\alpha}\Psi^\dagger$, so $\bar\Psi \to e^{-i\alpha}\bar\Psi$; every term of $\mathcal{L}$ contains as many factors $\bar\Psi$ as factors Ψ (one of each in K and in mS, two of each in $\frac{\lambda}{2}S^2$; the constant phase comes out of every derivative), so the phases cancel in pairs. Such a symmetry is called a **U(1) symmetry**, and by Noether's theorem it has a conserved current, here $J^\mu = -i\bar\Psi\gamma^\mu\Psi$ (Chapter 21 derives it). The record proves the conservation law directly, for both statistics and in the author's metric: the divergence $\partial_\mu(\sqrt{|g|}\,J^\mu)$ equals, for every configuration, $\sqrt{|g|}$ times a sum of two bilinears, each of which contains the left side E of the field equation or the left side $\bar E$ of its adjoint; so on shell ($E = 0$, $\bar E = 0$)

$$\partial_\mu(\cos z\, J^\mu) = 0.$$

The records of this law:

field	report	check
dirac16complex (Grassmann)	`wolfram-field-theory.json`	`current_conservation_identity_G`
dirac16complex00 (commuting)	`wolfram-field-theory.json`	`current_conservation_identity_C`
dirac16complex (Grassmann)	`python-field-theory.json`	`grassmann_current_conservation`
dirac16complex00 (commuting)	`python-field-theory.json`	`commuting_current_conservation`
both, reduced to a 16×16 matrix identity	`charge-conjugation-and-u1.json`	`u1_noether_matrix_identity`

From it we find WHEN the charge $Q = \int \cos z\, J^{x_4}\, d^7x$ is constant in time, line by line:

1. Write the sum over μ as the x_4 term plus the seven others: $\partial_4(\cos z\, J^{x_4}) = -\sum_{i\neq 4} \partial_i(\cos z\, J^{x_i})$.
2. Integrate both sides over the seven coordinates other than x_4, on a slice $x_4 = \text{const}$; on the left the derivative with respect to x_4 may be taken out of the integral over the other coordinates: $\frac{dQ}{dx_4} = -\sum_{i\neq 4} \int \partial_i(\cos z\, J^{x_i})\, d^7x$.

3. Each term on the right is, by the fundamental theorem of calculus in the variable x_i, the difference of the values of $\cos z\, J^{x_i}$ at the two ends of the range of x_i, integrated over the six remaining coordinates.

4. ASSUMED: these **boundary terms** vanish. This is so, for example, when each of the coordinates $x_1, x_2, x_3, x_5, x_6, x_7$ is periodic, so that its two ends are the same place, and when no current flows through the two ends of the hidden direction. Then $dQ/dx_4 = 0$. At the tip $z = 0$ the flux density $\cos z\, J^{x_0}$ vanishes for the exact solutions of Sections 18.21 and 21.18 (it contains the factor $\sin z$). At the brane $z = \pi/2$ it does NOT vanish in general: for the homogeneous solutions of Section 18.21, $\cos z\, J^{x_0} = \sin z\, q_0$ with the frame current $q_0 = -i\bar{\Psi}\gamma^{(x_0)}\Psi$, which on the solution of Notebook 18c runs from -0.3454 to 0.3454, so the charge of a patch of coordinate volume V_6 in the six directions changes at the rate $dQ/dx_4 = -V_6\, q_0$; Section 21.18 shows another exact solution whose charge changes by what flows out through the brane. The **no-flux condition** at the brane is therefore a real restriction, and no equation of the Revision record derives it (it would be part of the junction condition at the brane, which is OPEN).

Status: the local law is PROVED (records above): no process creates or destroys charge at any point inside the patch; charge can only flow from one place to another. The constancy of the integrated charge holds only under the boundary conditions of line 4, which are ASSUMED; at the brane this no-flux condition is not derived and fails on the exact solutions just cited, so whether the total charge of a universe is conserved is OPEN. Under the no-flux condition no net charge can be generated inside one universe.

(b) Two universes do not interact. A T1 pair consists of two fields: Ψ_+ of the theory (m, λ) and Ψ_- of the theory $(-m, -\lambda)$. Their joint Lagrangian is the sum $\mathcal{L}_{m,\lambda}[\Psi_+] + \mathcal{L}_{-m,-\lambda}[\Psi_-]$: no term of any Lagrangian of the Revision record contains both fields. The field equation of Ψ_+ is obtained by varying Ψ_+ alone; the second term does not contain Ψ_+ and contributes nothing, so Ψ_+ obeys the equation of a single universe whatever Ψ_- does, and the same holds for Ψ_-. Applying (a) to each field separately, under the no-flux condition of (a) (ASSUMED): the charge Q_+ of Ψ_+ and the charge Q_- of Ψ_- are EACH conserved, not only their sum.

(c) What the separate conservation forbids. Line by line:

1. Suppose that at some time $x_4 = t_0$ both fields are zero everywhere (the empty state).

2. Then $J_+^{x_4} = 0$ everywhere at t_0, so $Q_+(t_0) = 0$.

3. By (b), Q_+ is conserved (under the ASSUMED no-flux condition at the brane), so $Q_+(x_4) = 0$ at every time.

4. The members of a T1 pair have opposite charges, $Q_- = -Q_+$ (T1c).

5. Hence a T1 pair whose members carry the charges Q and $-Q$ with $Q \neq 0$ cannot evolve out of zero fields in the theory as built.

The zero TOTAL charge of a T1 pair does not make its appearance allowed, because the separate charges are conserved too (under the no-flux condition). Example: the universe of Section 20.12 has the constant charge density $J^{x_4} = -3$ and $\cos z > 0$ on the patch, so its charge over any region

of the patch is negative, not zero; neither it nor its T1 pair can evolve out of zero fields. (This universe is homogeneous and its J^{x_4} does not change, so by the law $dJ^{x_4}/dx_4 = -6Hq_0$ of Section 18.21 its frame current q_0 is zero: nothing flows through its brane. And for every homogeneous field (f) below gives the same conclusion without any boundary condition.) Status: derived here in five lines from the PROVED local law (a), with the ASSUMED boundary conditions of (a), including the no-flux condition at the brane; for fields that are not homogeneous the argument needs that condition; it is a consequence of the record's identity, not a record of its own (Notebook 20c, section 9, states it in the same words).

(d) The energy of a universe is not conserved in the deflating metric. The metric depends on the time x_4 through a_4, so the energy of one universe is not a conserved quantity. The local law $\nabla_\mu T^\mu{}_\nu = 0$ holds on shell (Chapter 9; `python-field-theory.json`, check `commuting_emt_conservation_on_shell`), and for a homogeneous diagonal source its x_4 component reads $-d\rho/dx_4 - 3a_4'(p_3 - p_t) = 0$ (`emt-divergence-and-spin-connection.json`, check `divergence_x4_component`). Adding $d\rho/dx_4$ to both sides,

$$\frac{d\rho}{dx_4} = -3a_4' \, (p_3 - p_t) :$$

the energy density changes whenever the pressure of 3-space and that of the extra times differ, and energy is exchanged between the inflating 3-space and the deflating extra times. (For the universe of Section 20.12 $p_3 = p_t$, and its ρ is constant.) So the energy is not conserved.

(d') The momenta of a universe: exact local laws, and totals that are constant only without a flow through the brane. The metric does not depend on the six coordinates $x_1, x_2, x_3, x_5, x_6, x_7$: shifting one of them by a constant, $x_i \to x_i + c$, leaves every metric component unchanged. Such a change of coordinates that leaves the metric unchanged is a **symmetry of the metric** (an **isometry**). For each of these six directions the x_i component of the local law gives a conserved **momentum**, line by line:

1. The divergence of a tensor $T^\mu{}_\nu$ is $\nabla_\mu T^\mu{}_\nu = \partial_\mu T^\mu{}_\nu + \Gamma^\mu{}_{\mu\lambda} T^\lambda{}_\nu - \Gamma^\lambda{}_{\mu\nu} T^\mu{}_\lambda$, with the Christoffel symbols $\Gamma^\lambda{}_{\mu\nu} = \frac{1}{2} g^{\lambda\sigma}(\partial_\mu g_{\sigma\nu} + \partial_\nu g_{\sigma\mu} - \partial_\sigma g_{\mu\nu})$ of Chapter 3 (they are not the chirality matrix): the covariant derivative of Chapter 3 adds one Christoffel term for the upper index and subtracts one for the lower index.

2. For the diagonal metric of this book the contracted symbol is $\Gamma^\mu{}_{\mu\lambda} = \frac{1}{2} \sum_\mu \partial_\lambda g_{\mu\mu}/g_{\mu\mu}$ (in the definition with λ and μ contracted, the first and third terms cancel), which is $\partial_\lambda \ln \sqrt{|g|}$, because $|g|$ is the absolute value of the product of the eight $g_{\mu\mu}$ and the logarithm of a product is the sum of the logarithms. So the first two terms of line 1 together are $\frac{1}{\sqrt{|g|}} \partial_\mu (\sqrt{|g|}\, T^\mu{}_\nu)$ (the product rule, read backwards).

3. In the last term, lowering the index gives $\Gamma^\lambda{}_{\mu\nu} T^\mu{}_\lambda = T^{\mu\sigma} \, \frac{1}{2}(\partial_\mu g_{\sigma\nu} + \partial_\nu g_{\sigma\mu} - \partial_\sigma g_{\mu\nu})$. The tensor is symmetric, $T^{\mu\sigma} = T^{\sigma\mu}$ (`python-field-theory.json`, checks `commuting_emt_symmetric` and `grassmann_emt_symmetric`), so exchanging the names μ and σ in the first term shows that it cancels the third; what remains is $\frac{1}{2} T^{\mu\sigma} \partial_\nu g_{\sigma\mu}$.

4. For $\nu = x_i$ with i one of $1, 2, 3, 5, 6, 7$ every $\partial_{x_i} g_{\sigma\mu}$ is zero. On shell the divergence vanishes, $\nabla_\mu T^\mu{}_\nu = 0$, so we are left with $\partial_\mu(\cos z \, T^\mu{}_{x_i}) = 0$, because $\sqrt{|g|} = \cos z$. The records of the on-shell law are the two checks `commuting_emt_conservation_on_shell` and `grassmann_emt_conservation_on_shell` of the report `python-field-theory.json`.

5. This has the form of the charge law of (a) with J^μ replaced by $T^\mu{}_{x_i}$, so the four lines of (a) give that $P_i = \int \cos z \, T^{x_4}{}_{x_i} \, d^7x$ is constant in time, with the same ASSUMED boundary conditions.

The same holds for the rotations of 3-space (in the planes of x_1, x_2, x_3, where the three metric components are equal) and for the rotations of the three extra times among themselves: they too leave the metric unchanged and give local laws of the same form, whose totals are constant under the same ASSUMED boundary conditions. Because the two universes do not couple (b), each of these is conserved SEPARATELY for each universe under these conditions, exactly like the charges; and the T1 partner has $T' = -T$, so its momenta are $-P_i$. Like the charges, the separately conserved momenta therefore forbid a T1 pair whose members have nonzero momenta from appearing out of zero fields (the five lines of (c) with Q replaced by P_i). Status: derived here from the PROVED local law and the PROVED symmetry of T, with the boundary terms ASSUMED to vanish (at the brane this is a no-flux condition like that of (a), not derived). Energy is the one quantity that the deflating metric removes from the list: because the metric depends on x_4, it has no local law of this form. The charges and the momenta (and the rotation quantities) keep exact local laws, and their totals are constant under the ASSUMED no-flux condition at the brane.

(e) The totals of the two kinds of pair. A T1 pair has $T + T' = 0$ and $Q_+ + Q_- = 0$: its totals are those of the empty state, so the conservation of the TOTALS does not forbid its appearance; (c) shows that the separate charges do (under the ASSUMED no-flux condition), unless $Q_+ = 0$. A T2 pair has the total charge $2Q_+$ (the copy carries the SAME charge): under the same condition already its total forbids its appearance from zero fields unless $Q_+ = 0$. (Without that condition the charge of the glued pair of patches changes at twice the rate of one patch: Section 18.21.)

(f) A classical condensate cannot grow out of zero. The zero field solves every field equation of this book, because every term of the field equation contains Ψ. For a condensate the field equation is the ordinary differential equation $\Phi' = -\gamma^{(x_4)}(m + \lambda S - 3H\gamma^{(x_0)})\Phi$ (Section 20.12, step 1), whose right side is a polynomial in the real and imaginary parts of the 16 components that vanishes at $\Phi = 0$. The uniqueness theorem for ordinary differential equations with such a smooth right side (the theorem of Picard and Lindelöf, quoted without proof in Chapter 2) says that near every time only one solution has a given value at that time. The zero function is a solution with the value zero. So a condensate that is zero at one time t_0 is zero on a small interval around t_0. Suppose it were not zero at some later time t_2. Let t^* be the least upper bound of the times s (the smallest number that none of them exceeds) such that the condensate is zero at every time from t_0 to s. Because the solution is continuous, it is zero at t^* itself, so $t^* \neq t_2$ and hence $t^* < t_2$; by the theorem, applied at t^*, it is zero on a small interval beyond t^*, which contradicts the choice of t^*. The same argument runs backwards in time. So the condensate is zero at every time. For the full field equation in 4+4 dimensions, whose initial-value problem is not well posed in the extra-time directions (Chapter 8), no such uniqueness theorem is proved in this book: OPEN.

Summary of Q1 for universes. The totals of a T1 pair are those of the empty state; the separate conservation of each member's charge and momenta, which holds because nothing couples the two universes and under the ASSUMED no-flux condition at the brane, forbids the appearance of a T1 pair with charged members, or with members of nonzero momentum, out of zero fields; under the same condition a T2 pair is forbidden already by its total charge unless it is neutral. Two things could change this, and the record contains neither: an interaction between the two universes, which could leave the totals as the only conserved charges, and a flow through the brane, which the record neither excludes nor describes (both OPEN). And even where the conservation laws allow

something, that is not a creation (Section 20.17, lesson 1).

20.23 Pairs of universes, matter and antimatter

The request for this book also speaks of matter-antimatter mysteries. Chapter 21 teaches that subject from zero; this section states exactly what the pairing theorems contribute to it, and what they do not.

Words. Matter is what stars, planets and we are made of: protons, neutrons and electrons. Their **antiparticles** (antiprotons, antineutrons, positrons) have the same masses and opposite charges and make up **antimatter**. The **baryon number** counts protons and neutrons minus antiprotons and antineutrons. Observations show that the universe we see contains matter and almost no antimatter; Chapter 21 gives the observations and the numbers. To produce such an excess from a state without one, three conditions must hold, as Sakharov stated in 1967 (A. D. Sakharov, JETP Lett. 5, 24 (1967)): (1) some process violates the baryon number; (2) it violates the symmetries C (charge conjugation) and CP (charge conjugation combined with a reflection of space); (3) it happens out of thermal equilibrium.

What is PROVED in this theory.

1. The U(1) charge of one universe obeys an exact LOCAL conservation law (Section 20.22 (a)): no process creates or destroys it at any point inside the patch. Its total is constant only under the no-flux condition at the brane $z = \pi/2$, which is ASSUMED, not proved (OPEN; the homogeneous solutions of Section 18.21 have a patch charge that changes at the rate $-V_6 q_0$); under that condition no net charge of this kind can be generated inside one universe.

2. The pair-level statement: by (T1c) a T1 partner carries the OPPOSITE charge, $J^\mu[\Gamma\Psi] = -J^\mu[\Psi]$, so a T1 pair of universes of masses $+m$ and $-m$ has zero total charge; a T2 mirror copy carries the SAME charge (Section 20.6). Example: the universe of Section 20.12 has $J^{x_4} = -3$, its T1 partner $+3$, its mirror copy -3.

3. Charge conjugation is a MATRIX (rule of this book, from the lead's record `charge-conjugation-and-u1.json`, 12 checks, all PASS; Chapters 5 and 21 derive it step by step). The author's gammas are real, so for a REAL field plain complex conjugation is the identity and is NOT charge conjugation. Solving exactly for every matrix that maps solutions to solutions gives two charge-conjugation matrices: $\mathcal{C}_+ = C$, with $\mathcal{C}_+^{-1}\gamma^{(a)}\mathcal{C}_+ = -(\gamma^{(a)})^T$, which keeps the mass; and $\mathcal{C}_- = \Gamma C$, with $\mathcal{C}_-^{-1}\gamma^{(a)}\mathcal{C}_- = +(\gamma^{(a)})^T$, which reverses the mass (checks `charge_conjugation_matrix_plus` and `charge_conjugation_matrix_minus`). For real commuting fields the current vanishes identically and $\mathcal{C}_+$ acts as the identity; the nontrivial real matrix map is Γ with $(m, \lambda) \to (-m, -\lambda)$, which reverses the current and the kinetic term: theorem T1 (check `real_fields_charge_conjugation`). For the quantised Grassmann field the conjugation that preserves the canonical anticommutator is $\Psi \to \Gamma\Psi^{\dagger T}$, and it reverses the mass (check `quantum_charge_conjugation_unitary_type`).

The universe/anti-universe class of ideas. That our universe might have a partner universe in which the roles of matter and antimatter are exchanged, so that the pair as a whole is neutral, is an old class of ideas. A published example of the class, built differently from anything in this book, is the CPT-symmetric universe of L. Boyle, K. Finn and N. Turok, Phys. Rev. Lett. 121, 251301

(2018); nothing in this chapter is taken from that work, and nothing in this chapter is attributed to it. Item 2 above shows that the T1 pairs of this theory have the bookkeeping of such a pair: opposite charges, zero total. Every scenario that would use this to explain the observed excess of matter in our universe is a HYPOTHESIS, and Section 20.22 (c) shows a first obstacle inside the theory as built: since each universe's charge is conserved on its own under the ASSUMED no-flux condition at the brane, a T1 pair with charged members cannot evolve out of zero fields under that condition; its charges can only be assumed as initial data.

What the theory as built does NOT do. It does NOT solve the matter-antimatter problem. Precisely:

- it contains no baryons (no protons, neutrons or other particles of the Standard Model of particle physics) and no baryon number;
- its only charge is the U(1) charge, which obeys an exact local conservation law, so no process at any point of the patch violates a baryon-like number (Sakharov's condition 1 fails there: PROVED); the total charge of a universe could change only by a flow through the brane $z = \pi/2$, which the ASSUMED no-flux condition excludes and which the record does not describe as a process (OPEN);
- condition 2 (C and CP violation) fails exactly for the commuting field dirac16complex00: its same-mass charge conjugation $\mathcal{C}_+ = C$ is an exact symmetry of its Lagrangian that reverses the charge, so by Proposition 2 of Section 21.5 a C-symmetric start can develop no average charge asymmetry (PROVED; Chapter 21); for the quantised field dirac16complex the only conjugation that keeps the canonical anticommutator, Γ, reverses the mass, and no rates in which C or CP violation could act are computed (NOT COMPUTED);
- no departure from thermal equilibrium of any baryon-number-violating process is computed (condition 3 is not addressed; the deflating history is time-dependent, but no rate is computed in it);
- no asymmetry, no number for it, and no comparison with observation is derived.

What would be needed (OPEN; every item a task, not a result): a charge that can play the role of the baryon number; an interaction that violates it; C and CP violation in that interaction; a departure from equilibrium along a computed history; a calculation of the resulting asymmetry and its comparison with observation; and, for the pair scenario, either an interaction between the universes that leaves only the total charge conserved or a theory of the initial data. Chapter 21 develops the conditions and the scorecard in detail.

20.24 What is not established

The following are NOT established by any equation of this book or of the Revision record. The items 1 to 9 are the record's own list: the nine items of `pairing-theory.json`, key `not_established`, in their order. The list of `PAIR_CREATION_PROOFS.md`, section 11.2, has ten items: its items 1 to 8 are items 1 to 8 here, its item 10 is item 9 here, and its item 9 adds that dirac16complex00 is a classical field, for which no quantum statement is made (the quantum reading Q of Section 20.6 is for dirac16complex only). The sympy checker of the record keeps a third list, which states the points

of items 1 to 9 here in twelve sentences (`python-pairing.json`, key `not_established`; Notebook 00c prints it). The items 10 to 13 are added by this chapter.

1. **No creation process.** The theorems map solutions to solutions and quantities to quantities; nothing produces a universe, a pair of universes or a change of the number of universes; no initial state, vacuum decay or tunnelling process is derived.

2. **No rate and no amplitude.** No transition amplitude, probability, cross section, rate or Bogoliubov coefficient for creating universes of masses $\{+m, -m\}$ is computed or implied; no wave function of the universe and no path integral is part of the theorems.

3. **No dynamical necessity.** Nothing forces the partner to exist or to be realised; a single universe with mass $+m$ is an equally valid solution without its partner (Section 20.12 builds one).

4. **T1 is not a symmetry of one theory.** It changes the parameters and the sign of the action; for $\lambda \neq 0$ it pairs (m, λ) with $(-m, -\lambda)$, not $+m$ with $-m$ at the same coupling. The pure pairing $(m, \lambda) \to (-m, \lambda)$ is T2, at EQUAL energy-momentum.

5. **The zero total holds for classical bilinears only.** The vanishing total energy-momentum and charge of a T1 pair holds for classical bilinears and as an operator identity within ONE quantum system; two independently quantised universes have generators that add without cancelling (statement Q3).

6. **Test fields.** The gravitational field is fixed and the same for both members; corollary C1 is the only statement about back-reaction, it concerns the sum of two classical sources in one geometry, and its part (a) depends on Einstein gravity (Einstein-Gauss-Bonnet gravity admits the deflating history as a vacuum, Section 20.7).

7. **The Z2 brane.** The mirror across $z = \pi/2$ uses the ASSUMED Z2 construction; the metric is degenerate there; no junction condition, brane tension or matching of the field across the brane is derived.

8. **Quantum positivity.** A positive-norm Fock space for either universe is not established by the pairing theorems.

9. **The Kohn-Sham level.** T3 holds for instantaneous mean-field Kohn-Sham states with the ASSUMED brane and the transformed tip condition; the time-dependent problem is OPEN, correlation is not included, and the Kohn-Sham history $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND (the Kohn-Sham states violate the source conditions of the a_4 equations: `ks-source-conditions.json`, check `ks_profiles_violate_algebraic_condition`).

10. **No big bang in the equations.** For the PRESCRIBED deflating history $a_4 = AHx_4$ (and for any history whose a_4, a_4' and a_4'' stay finite) the author's metric and its curvature are finite at every finite time on the patch (Section 20.3), and T1 holds at every time, so no moment is singled out. The history is prescribed, not computed; whether the coupled equations of the fields and of a_4 contain a big-bang moment is not decided (OPEN), and with a given source the a_4 equations of Einstein-Gauss-Bonnet gravity can break down at a finite time (Chapter 12; Section 20.3).

11. **No value of the mass.** m, λ, H and κ are free parameters; no relation between H and m is derived.

12. **No solution of the matter-antimatter problem** (Section 20.23).

13. **No uniqueness for the full 4+4 field equation.** Whether a classical field that vanishes at one time vanishes at all times is proved here only for condensates (Section 20.22 (f)).

20.25 What a calculation of creation would require

Questions Q2 and Q3 can be attacked in two ways. Both are OPEN; this section lists what each would need, so that a student can see where the missing work lies (Chapter 22 collects the open problems).

The classical route (Q2). One would need a solution of the coupled system, the field equations of both members together with the Einstein-Lovelock equations whose source is the total energy-momentum tensor, so that the metric is COMPUTED rather than prescribed, which starts without the pair and ends with it. Section 20.22 shows the obstacles: under the ASSUMED no-flux condition at the brane $z = \pi/2$ (not derived; it fails on the homogeneous solutions of Section 18.21) the separate conservation of the two charges forbids a charged pair from zero fields, and a condensate cannot grow out of zero at all (this needs no boundary condition). So a classical solution can at most describe how a pair that is already present evolves: the pair would have to be in the initial data (and then it is not created), or the solution would have to start at a singular moment with a rule for what emerges from it (and such a rule is an initial condition, not a derivation), or the equations would have to be changed.

The quantum route (Q3). By analogy with Section 20.17, one level up:

1. **A space of states with different numbers of universes**, containing a state with no universe and states with one universe or with a pair. In quantum cosmology the corresponding object is a wave function of the geometry together with the matter fields, which obeys the Wheeler-DeWitt equation (B. S. DeWitt, Phys. Rev. 160, 1113 (1967)); proposals of this kind include those of Hartle and Hawking (J. B. Hartle and S. W. Hawking, Phys. Rev. D 28, 2960 (1983)) and of Vilenkin (A. Vilenkin, Phys. Lett. B 117, 25 (1982)). Nothing of this kind exists in this book, which quantises only the matter field in a prescribed geometry (Chapter 10).

2. **A probability interpretation.** Probabilities need a positive inner product. The canonical state space of dirac16complex is a Krein space with an indefinite inner product, and a positive Fock space is known only in the good sector without extra-time momentum (Chapter 10).

3. **A dynamics that connects the states:** an interaction, or a time-dependent background, whose matrix element between the empty state and the pair state is not zero. Nothing in the theory couples two universes. For a pair whose members carry the charges $\pm Q$ with $Q \neq 0$, the interaction would also have to break the separate conservation of the two charges while keeping their sum (Section 20.22; a flow through the brane, which the record does not describe, is the other open possibility).

4. **The amplitude and what follows from it:** the amplitude $\langle \text{pair}|\, U\, |\text{empty}\rangle$ of the evolution operator U, the probability $|\langle \text{pair}|U|\text{empty}\rangle|^2$, and a rate.

5. **The stability question.** A theory with quanta of negative energy that interact with quanta of positive energy can make the empty state unstable, because pairs of zero total energy can

then be produced without limit (J. M. Cline, S. Jeon and G. D. Moore, Phys. Rev. D 70, 043543 (2004)). A calculation of the creation of T1 pairs, whose members have opposite energies, would have to face this question.

6. **Numbers.** The mass m, the constant H, the gravitational coupling κ and the coupling λ would have to be fixed; the theory as built fixes none of them.

That a universe of zero total energy might appear without violating energy conservation was proposed long ago (E. P. Tryon, Nature 246, 396 (1973)); a zero total has never, by itself, produced a rate: that is always a separate calculation.

The photon analogy, completed.

ingredient	**photon on a nucleus**	**a T1 pair of universes**
the totals allow it?	yes, above the threshold (Proposition 2)	yes: all totals of the pair are zero
an interaction that lets energy or charge pass	light couples to the electron field	none: each universe's charge obeys its own local law and, under the ASSUMED no-flux condition at the brane, is conserved on its own, which forbids a charged pair from zero fields
dynamics connecting the initial and the final state	quantum electrodynamics	none in the theory
a computed probability	the Bethe-Heitler cross section (quoted)	none (OPEN)

The first line is where the pairing theorems stand. The last three lines are the missing steps, and the second shows that a coupling between universes would be needed before any rate could be computed.

20.26 The answer to the question of the title

Do universes come in pairs? For each of the two fields, dirac16complex and dirac16complex00, the equations of this book PROVE: to every solution with mass m the explicit map Γ assigns a solution with mass $-m$ and coupling $-\lambda$, with the opposite energy-momentum tensor and charge, in every gravitational field (T1); the map $\gamma^{(x_0)}$ with the ASSUMED Z2 mirror assigns a solution with mass $-m$ and the same coupling, with the SAME energy-momentum and charge, in the author's primordial field (T2); for dirac16complex at the Kohn-Sham level the block map of Γ with the transformed boundary conditions assigns to every self-consistent instantaneous state with (m, λ) one with $(-m, +\lambda)$ at equal energies (T3); at the quantum level the T1 partner is the same quantum system relabelled, and two independently quantised universes have identical one-particle spectra (the $\lambda = 0$ spectra, in flat 4+4 space or in a general field at a point with frozen coefficients) and energies that add (Q); and a T1 pair as the only source of the author's metric is a zero source, which in Einstein gravity admits no solution for $H > 0$ (C1). These are exact maps between solution sets, with their stated hypotheses.

The equations do NOT prove that universes come in pairs: a single universe with mass $+m$ is an equally valid solution without its partner, and Section 20.12 builds one, exactly. They do NOT prove that any universe is created, in pairs or otherwise: they contain no creation process, no rate, no probability and no amplitude, and in the theory as built, under the ASSUMED no-flux condition at the brane $z = \pi/2$ (not derived; it fails on the homogeneous solutions of Section 18.21), the separate conservation of each universe's charge forbids a charged T1 pair from appearing out of zero fields; without that condition this is OPEN for fields that are not homogeneous (Section 20.22 (c) and (f)). They do NOT solve the matter-antimatter problem.

Hypothesis P ("the big bang creates universes of masses $+M$ and $-M$ in pairs") therefore remains what it was: a HYPOTHESIS. Sections 20.22 to 20.25 say precisely what a proof of it would still need.

20.27 What we proved, what we computed, what we assumed

statement	status	where verified
T1: $\mathcal{L}_{m,\lambda}[\Gamma\Psi] = -\mathcal{L}_{-m,-\lambda}[\Psi]$; solutions to solutions; $T \to -T$, $J \to -J$; the pair has zero total source and charge (classical bilinears; every gravitational field; both fields)	PROVED	`wolfram-pairing.json` (51 T1 checks), `python-pairing.json` (23 T1 checks); Section 20.5; Notebook 20a, In [7] and In [9]; Notebook 20b, In [7]
T2: $\gamma^{(n)}$ with a frame reflection of character -1: $(m, \lambda) \to (-m, \lambda)$, $\mathcal{L} \to +\mathcal{L}$; in the author's field the mirror copy has the pulled-back, EQUAL tensor and charge	PROVED; the Z2 construction ASSUMED	`wolfram-pairing.json` (28 T2 checks), `python-pairing.json` (16 T2 checks); Section 20.6; Notebook 20a, In [9] and In [11]; Notebook 20b, In [9]
Q: the T1 image carries $-B$ and is the same quantum system; independent universes do not cancel; equal one-particle spectra ($\lambda = 0$; flat 4+4 space, or a general field at a point with frozen coefficients); the T2 image keeps $+B$	PROVED	`wolfram-pairing.json` (12 Q checks), `python-pairing.json` (10 Q checks); Section 20.6
T3: Kohn-Sham states with (m, λ, θ) and $(-m, +\lambda, \pi - \theta)$ have equal levels, energies and energy-momentum profiles	PROVED; brane ASSUMED, tip transformed, instantaneous mean-field states	`wolfram-t3.json` (10 checks), `python-t3.json` (13 checks); Section 20.6; Chapter 19

statement	status	where verified
C1(a): a T1 pair as the only source; Einstein gravity has no real solution for $H > 0$; the only solutions are $a_4' = \pm iH$, $\Lambda = -18H^2$	PROVED	`wolfram-a4-report.json`, check `einstein_no_vacuum_solution`; `python-a4-report.json`, check `einstein_no_vacuum`; `einstein-gauss-bonnet-a4.json`, check `no_vacuum_for_H_positive`; Section 20.7; Notebook 20a, In [12]
every source of the author's metric needs $\kappa(\rho + p_0) = -6(a_4'^2 + H^2)$ in Einstein gravity	PROVED	both a4 reports, check `einstein_null_energy_x0`; Notebook 20a, In [14]
C1(b): the linear member is a vacuum exactly when $V = 0$; with $\alpha_2 H^2 = 1/48$ and $\Lambda = -12H^2$ the deflating history is a Gauss-Bonnet vacuum	PROVED	both a4 reports, checks `linear_member_vacuum_factor` and `einstein_gauss_bonnet_vacuum_linear`; exact check in Notebook 20a, In [16]
$\sum_\mu \gamma^\mu \Omega_\mu = -3H\gamma^{(x_0)}$ on the mirror patch	COMPUTED exactly (a result of this book, not a record)	Notebook 20a, In [5]; Notebook 20b, In [3]
the author's metric and its curvature are finite and non-degenerate at every finite time on the patch for the prescribed history $a_4 = AHx_4$ (and any history with finite a_4, a_4', a_4''): no big-bang moment in the prescribed history	PROVED for the prescribed history; for computed histories OPEN (with a given source the a_4 equations can break down at a finite time, Chapter 12)	Section 20.3, from `python-pairing.json`, check `geometry.brane_degenerate`, and `python-a4-report.json`, check `riemann_entries_laurent`
the universe $m = 15$, $\lambda = -25/3$, $A = 1$, $\Lambda = -36H^2$: $S = 12/5$, $\rho = 12$, $p = -24$, $J^{x_4} = -3$, frequency $4H$, a complete solution without a partner	COMPUTED (exact for the field equation; Einstein equations to 10^{-10} at nine points); a result of this book	Section 20.12; Notebook 20b, In [4] to In [6]
its T1 partner solves its own equation with the same frequency but is the source of no member of the author's family in Einstein gravity	PROVED here by hand (record's null combination); checked numerically	Section 20.12, steps 6 and 7; Notebook 20b, In [7]
its T2 mirror copy solves the coupled equations on the mirror patch with equal ρ and J^{x_4}	PROVED here by hand; checked	Section 20.12, step 9; Notebook 20b, In [9]

statement	status	where verified
the charge of one universe obeys an exact local law; its total is constant under the no-flux condition at the brane; then a T1 pair with charged members cannot evolve out of zero fields	the local law PROVED; the no-flux condition ASSUMED (not derived; it fails on the homogeneous solutions of Section 18.21, OPEN); the consequence derived here	`charge-conjugation-and-u1.json`, check `u1_noether_matrix_identity`; both field-theory reports; Section 20.22
$d\rho/dx_4 = -3a_4'(p_3 - p_t)$: the energy of one universe is not conserved	PROVED	`emt-divergence-and-spin-connection.json`, check `divergence_x4_component`; Section 20.22 (d)
the momenta $P_i = \int \cos z\, T^{x_4}{}_{x_i}\, d^7x$ $(i = 1, 2, 3, 5, 6, 7)$ of each universe are conserved separately; a T1 pair whose members have nonzero momenta cannot evolve out of zero fields	derived here from the PROVED local law and the PROVED symmetry of T; boundary terms ASSUMED to vanish	`python-field-theory.json`, checks `commuting_emt_conservation_on_shell`, `grassmann_emt_conservation_on_shell`, `commuting_emt_symmetric` and `grassmann_emt_symmetric`; Section 20.22 (d')
a condensate that vanishes at one time vanishes always	PROVED here with the quoted uniqueness theorem for ODEs	Section 20.22 (f)
the threshold lemma; one photon makes no pair; $E_\gamma \geq 2m(1 + m/M)$; $E_a E_b \geq 2m^2/(1 - \cos\theta)$	PROVED here from ASSUMED special relativity	Section 20.17; Notebook 20c, In [2] to In [8]
the rates of pair creation by light	quoted from the literature (Bethe-Heitler, Breit-Wheeler), not computed	Section 20.17
a T1 pair has zero total charge; a T2 copy has the same charge	PROVED	(T1c) in Section 20.5 and the statement of T2 in Section 20.6 ($J' = R_0 J$)
the two charge-conjugation matrices $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$; for real fields the nontrivial real map is Γ (T1)	PROVED	`charge-conjugation-and-u1.json` (12 checks); Chapters 5 and 21
a partner universe explains the matter excess of our universe	HYPOTHESIS	Section 20.23
the theory solves the matter-antimatter problem	NOT ESTABLISHED: no baryons, no baryon-number violation, no CP violation, no departure from equilibrium computed	Section 20.23
a creation process, rate, probability or amplitude for universes	NOT ESTABLISHED (OPEN)	`pairing-theory.json`, key `not_established`; Sections 20.24 and 20.25
Hypothesis P: "the big bang creates universes of masses $+M$ and $-M$ in pairs"	HYPOTHESIS	Sections 20.3 and 20.26

statement	status	where verified
C1(a) for every second function $b_4(x_4)$ of the metric of 2026-10-14 (a zero source forces b_4 constant); for the author's Einstein-Lovelock weights every vacuum has b_4 constant and $a_4 = \pm Hx_4 + \text{const}$	PROVED	`wolfram-a4-report.json`, checks `b4_einstein_offdiagonal_forces_b4_constant` and `b4_author_weights_vacuum`; `Revision/metric_b4/results/vacuum-b4.json`; Section 20.7
Einstein gravity in the example; the background $b_4 = 1$ of the pairing records and of the notebooks; the sign convention $\sigma_T = +1$; the classical field dirac16complex00 in the examples; the units $H = \kappa = 1$; the Z2 brane and the mirror patch	ASSUMED	Sections 20.12 and 20.6
the junction at the brane; the stability of the condensate; uniqueness for the full 4+4 field equation; a coupling between universes; whether the coupled equations of the fields and of a_4 contain a big-bang moment	OPEN	Sections 20.3, 20.12, 20.22 and 20.25

20.28 Exercises

Exercise 20.1 (the chirality commutes with the generators). Show, using only step 1 of Section 20.5 ($\Gamma\gamma^{(b)} = -\gamma^{(b)}\Gamma$ for every b), that $\Gamma S^{ab} = S^{ab}\Gamma$ for $a \neq b$, where $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$.

Answer. Take the first product: $\Gamma\gamma^{(a)}\gamma^{(b)} = -\gamma^{(a)}\Gamma\gamma^{(b)}$ (step 1 for the direction a) $= +\gamma^{(a)}\gamma^{(b)}\Gamma$ (step 1 for the direction b). In the same way $\Gamma\gamma^{(b)}\gamma^{(a)} = \gamma^{(b)}\gamma^{(a)}\Gamma$. Subtracting the second line from the first and multiplying by $\frac{1}{4}$: $\Gamma S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})\Gamma = S^{ab}\Gamma$. The two signs $(-1)(-1) = +1$ are the reason: S^{ab} contains two gammas.

Exercise 20.2 (a time-like reflection gives a T1-type map). In Section 20.6 the reflection of a space-like direction n gave $S' = -\eta_{nn}S$ and $K' = \eta_{nn}K$. Take the time direction $n = x_4$ ($\eta_{nn} = -1$) and compute $\mathcal{L}_{m,\lambda}[\gamma^{(x_4)}\Psi; R_4 e]$ in terms of $\mathcal{L}$ of Ψ.

Answer. With $\eta_{nn} = -1$: $S' = -(-1)S = S$ and $K' = (-1)K = -K$. Insert into the Lagrangian: $\mathcal{L}_{m,\lambda}[\Psi'; e'] = \sqrt{|g|}\,[K' - mS' - \frac{\lambda}{2}S'^2] = \sqrt{|g|}\,[-K - mS - \frac{\lambda}{2}S^2]$. Take out -1 and write $m = -(-m)$, $\lambda = -(-\lambda)$: $= -\sqrt{|g|}\,[K - (-m)S - \frac{(-\lambda)}{2}S^2] = -\mathcal{L}_{-m,-\lambda}[\Psi; e]$. This is a T1-type map, $(m, \lambda) \to (-m, -\lambda)$ with $\mathcal{L} \to -\mathcal{L}$, as the table of the eight reflections in `PAIR_CREATION_PROOFS.md` (section 5.5) records for x_4, x_5, x_6, x_7.

Exercise 20.3 (another universe and its partner). Repeat steps 4 and 7 of Section 20.12 with

$A = 1$, $\Lambda = -30H^2$ and $M = -5H$ (units $H = \kappa = 1$). Find S, m, λ, ρ, p and the equation of state p/ρ, and decide whether the T1 partner can be the source of the author's metric.

Answer. First condition: $MS = -12$, so $S = 12/5$ (as before; it does not involve Λ). Second: $mS = -(36 + 2(-30)) = -(36 - 60) = 24$, so $m = 24 \cdot 5/12 = 10$. Then $\lambda = (M - m)/S = (-5 - 10) \cdot 5/12 = -75/12 = -25/4$. $\rho = mS + \frac{\lambda}{2}S^2 = 24 + (-\frac{25}{8}) \cdot \frac{144}{25} = 24 - 18 = 6$, and $p = \frac{\lambda}{2}S^2 = -18$, so $p/\rho = -3$. (These are the numbers of the third example of Chapter 12.) Check: $\rho + p = -12 = MS$ and $\rho - p = 24 = mS$. The partner has $\rho' = -6$, $p' = 18$, so $\kappa(\rho' + p'_0) = -6 + 18 = +12 > -6$: it meets the requirement $-6(a_4'^2 + 1)$ at no real rate, and it cannot be the source of any member of the author's family in Einstein gravity. (The partner's null combination is minus the universe's, $-(\rho + p) = -MS = +12$, whatever Λ is: the result does not depend on the choice of Λ.)

Exercise 20.4 (a Gauss-Bonnet vacuum with a faster deflation). In Einstein-Gauss-Bonnet gravity ($\alpha_1 = 1$, $\alpha_3 = 0$), find the coupling $\alpha_2 H^2$ for which the linear member with $A = 2$ (3-space grows like e^{2Hx_4}, the extra times shrink like e^{-2Hx_4}) is a vacuum, and the cosmological constant it needs.

Answer. From Section 20.7, $V = 1 - 8\alpha_2 H^2(A^2 + 5) = 1 - 8\alpha_2 H^2 \cdot 9 = 1 - 72\alpha_2 H^2$, which vanishes for $\alpha_2 H^2 = 1/72$; this lies in the allowed range $0 < \alpha_2 H^2 \le 1/40$. The cosmological constant is $\Lambda = -(E_{(1)}{}^{x_4}{}_{x_4} + \alpha_2 E_{(2)}{}^{x_4}{}_{x_4})$. At $a'_4 = 2H$: $E_{(1)}{}^{x_4}{}_{x_4} = 3a_4'^2 + 21H^2 = 12H^2 + 21H^2 = 33H^2$, and $E_{(2)}{}^{x_4}{}_{x_4} = -(36A^4 + 120A^2 + 420)H^4 = -(576 + 480 + 420)H^4 = -1476H^4$ (Section 20.7). So $\Lambda = -(33H^2 - 1476H^2/72) = -(33 - 20.5)H^2 = -12.5H^2 = -\frac{25}{2}H^2$. Check with the curve printed by Notebook 20a, In [16], $\Lambda = 720\alpha_2 H^4 - 36H^2 + 3/(16\alpha_2)$: with $\alpha_2 = 1/(72H^2)$ this is $10H^2 - 36H^2 + 13.5H^2 = -12.5H^2$.

Exercise 20.5 (a threshold with an exact final state). A photon hits a nucleus of mass $M = 2m$ at rest and makes an electron-positron pair. Find the threshold energy and the momenta and energies of the three final bodies at the threshold, and check that the totals are conserved.

Answer. $E_\gamma = 2m(1 + m/M) = 2m(1 + 1/2) = 3m$. The initial totals: $|\vec{p}_{\text{tot}}| = 3m$, $E_{\text{tot}} = 3m + 2m = 5m$, so $\mu^2 = 25m^2 - 9m^2 = 16m^2$ and $\mu = 4m = m + m + 2m$, the sum of the final masses, as at a threshold. Each body carries the share μ_i/μ of the momentum: the electron and the positron $(1/4)(3m) = 3m/4$ each, with the energy $\sqrt{m^2 + 9m^2/16} = 5m/4$ each; the nucleus $(2/4)(3m) = 3m/2$, with the energy $\sqrt{4m^2 + 9m^2/4} = 5m/2$. Totals: momenta $3m/4 + 3m/4 + 3m/2 = 3m$, energies $5m/4 + 5m/4 + 5m/2 = 5m$, the initial ones. All three move with the velocity $(3m/4)/(5m/4) = (3m/2)/(5m/2) = 3/5$, the equality case of the lemma.

Exercise 20.6 (two photons at a right angle). One photon has the energy $E_a = 4m$. What is the smallest energy of a second photon that meets it at 90 degrees and can make an electron-positron pair with it? And if the second photon moves head on?

Answer. At $\theta = 90$ degrees, $\cos\theta = 0$, and Proposition 3 needs $E_a E_b \ge 2m^2$, so $E_b \ge 2m^2/(4m) = m/2$. Head on, $\cos\theta = -1$, and the condition is $E_a E_b \ge 2m^2/2 = m^2$, so $E_b \ge m/4$.

Exercise 20.7 (the charge density of the partner). Using $J^\mu = -i\bar{\Psi}\gamma^\mu\Psi$, $\bar{\Psi} = \Psi^\dagger C$ and $\gamma^{x_4} = \gamma^{(x_4)}$, show that $J^{x_4} = \Psi^\dagger B \Psi$ with $B = -iC\gamma^{(x_4)}$, and that $J^{x_4}[\Gamma\Psi] = -J^{x_4}[\Psi]$. Then explain in two sentences why the zero total charge of a T1 pair does not allow it to appear out of zero fields.

Answer. $J^{x_4} = -i\Psi^\dagger C\gamma^{(x_4)}\Psi = \Psi^\dagger(-iC\gamma^{(x_4)})\Psi = \Psi^\dagger B\Psi$, by inserting the definitions and moving the number $-i$ next to the matrices. For the partner, $(\Gamma\Psi)^\dagger B(\Gamma\Psi) = \Psi^\dagger \Gamma B \Gamma \Psi$ because $\Gamma^\dagger = \Gamma$,

and $\Gamma B\Gamma = -i\,\Gamma C\gamma^{(x_4)}\Gamma = -i\,C\,\Gamma\gamma^{(x_4)}\Gamma = -i\,C(-\gamma^{(x_4)}) = -B$ (step 2, $\Gamma C = C\Gamma$, then step 1 of Section 20.5); so $J^{x_4}[\Gamma\Psi] = -\Psi^\dagger B\Psi = -J^{x_4}[\Psi]$. The two universes of the pair are two different fields with no coupling, so under the ASSUMED no-flux condition at the brane the charge of each is conserved on its own (Section 20.22 (b)); starting from zero fields each charge then stays zero, so a pair whose members carry the charges Q and $-Q$ with $Q \neq 0$ can never be reached, although the total is zero.

21 Matter and antimatter from zero: what this theory explains and what it does not

The world we see is made of matter, and almost no antimatter. Why that is so is one of the open questions of physics. This chapter explains the question from zero, with the observations, the three conditions that Andrei Sakharov found for any answer, and small worked models of each condition. Then it asks, condition by condition, what the theory of this book says. On the way it derives, line by line, the facts of the theory that matter for the question: that charge conjugation in this theory is made by a **matrix** (with the intertwiner condition of the Revision record as the definition, there are exactly two such matrices), that the charge of the field obeys an **exact local conservation law** in the author's metric while the three extra times deflate (its total is constant only if no charge flows through the edge $z = \pi/2$ of the hidden direction, a condition that is assumed, not derived), how the **quantised** field can be conjugated, and what a pair of solutions of masses $+m$ and $-m$ carries. The chapter ends with a scorecard and with a precise list of what the theory as built does not do.

21.1 What this chapter does, and the answer first

The request that this book answers ends with the words "this theory solves matter anti-matter mysteries". The honest answer comes first, because every later section supports it.

The answer. The theory as built does **not** solve the matter-antimatter problem. The reasons, each of which this chapter proves or documents:

- The theory contains no baryons (no protons, neutrons or quarks), so it cannot say anything about the baryon number of the observed universe.
- The only number of the theory that could play the role of "matter minus antimatter" is the **U(1) charge** Q of its field. It obeys an **exact local conservation law**: in the author's metric, for every history $a_4(x_4)$, in particular the one in which ordinary space inflates and the three extra times x_5, x_6, x_7 deflate exponentially, the charge of a region changes only by what flows through its boundary (PROVED, Sections 21.16 and 21.17). So no process described by these equations makes a net charge at any point inside the patch $0 < z < \pi/2$ of one universe, that is, off the brane: Sakharov's first condition fails there. The total charge of a universe is constant only if no charge flows through the brane $z = \pi/2$, the edge of the hidden direction; this **no-flux condition** is ASSUMED, not derived (OPEN), and Section 21.18 shows an exact solution whose charge changes by exactly what flows out through the brane.
- For the commuting field dirac16complex00 the same-mass charge conjugation is an exact symmetry that reverses the charge (PROVED, Sections 21.10 and 21.31), so Sakharov's second

condition fails for it as well (PROVED, Section 21.31). For the quantised field dirac16complex no violation of C or CP in reaction rates is built into the theory or computed (NOT COMPUTED). No departure from thermal equilibrium is computed (NOT COMPUTED); the Kohn-Sham history of this book is a prescribed background (Section 21.31).

What the theory does provide, exactly.

- Charge conjugation is a matrix. The author's gamma matrices are real, so for a real field plain complex conjugation changes nothing at all. Solving exactly for every matrix that obeys the intertwiner condition $M(\gamma^a)^* = s\,\gamma^a M$ (the record's definition, Section 21.8; other matrices, e.g. $P_- C$ for $V = 0$, can also map solutions to solutions) gives exactly two, up to a factor: $\mathcal{C}_+ = C$, which keeps the mass, and $\mathcal{C}_- = \Gamma C$, which reverses it (PROVED, Sections 21.8 to 21.10; Notebook 21a).
- For a real field the current vanishes, $\mathcal{C}_+$ acts as the identity, and, among the matrices that obey this condition, the only nontrivial real matrix map is Γ, which reverses the mass (PROVED, Section 21.10).
- For the quantised anticommuting field dirac16complex the only charge-conjugation matrix that keeps the canonical anticommutator gives $\Psi \to \Gamma\Psi^{\dagger T}$, and it reverses the mass (PROVED, Sections 21.25 and 21.26; Notebook 21c).
- **Pair level.** The chirality partner $\Gamma\Psi$ of a solution with the parameters (m, λ) is a solution with $(-m, -\lambda)$ and carries exactly the opposite current, so the pair has total charge zero as classical bilinears (PROVED, theorem T1 of the Revision record; Section 21.19; Notebook 21b). This is a **map between two sets of solutions**. It does not create anything: a single universe of mass $+m$ is an equally valid solution without its partner, and no creation process, rate or amplitude follows from these equations (Chapter 20). The idea that a universe and an anti-universe together carry zero charge belongs to a class of ideas in the literature; any scenario in which our universe is one member of such a pair is a HYPOTHESIS (Section 21.37).

The plan. Sections 21.3 to 21.6 explain the problem from zero: particles and antiparticles, the conserved numbers, the observed excess of matter, and Sakharov's three conditions, each derived in plain words with a small model. Section 21.7 sets out the theory of this book. Sections 21.8 to 21.15 derive the charge-conjugation matrices and place Notebook 21a, which solves for them exactly from the Revision gammas. Sections 21.16 to 21.23 derive the exact local conservation law of the charge, the charge balance through the brane and the pair-level bookkeeping, with Notebook 21b. Sections 21.24 to 21.30 treat the reflections, the chirality and the quantised field, with Notebook 21c. Sections 21.31 to 21.36 apply Sakharov's conditions to the theory and place Notebook 21d, which computes the toy models and draws the scorecard. Section 21.37 says what would be needed; Section 21.38 lists every statement with its status; Sections 21.39 and 21.40 hold the exercises and their answers.

Labels. As everywhere in this book: PROVED means exact, with the Revision verifier file and check name, or with a complete derivation given here and an exact check in a notebook; COMPUTED means numerical, with the cell that computes it and its accuracy; ASSUMED marks an input, a convention or a quoted fact of physics; HYPOTHESIS marks a claim that nothing in the Revision record derives; OPEN marks a question that has not been answered; NOT COMPUTED marks something that no computation of the record addresses.

21.2 The words and symbols of this chapter

Each word is defined in plain terms here; the later sections make the definitions precise with formulas.

- **Matter, antimatter.** In cosmology "matter" means the protons and neutrons of atoms, which carry almost all of their mass. **Antimatter** is made of antiparticles.
- **Antiparticle.** For every known particle there is a particle with the same mass and the opposite values of all its charges: the positron e^+ for the electron e^-, the antiproton $\bar{p}$ for the proton p. A bar over a letter marks an antiparticle.
- **Quark.** A constituent of protons and neutrons. The up quark u has electric charge $+2/3$ and the down quark d has $-1/3$, in units of the proton charge.
- **Baryon, baryon number $\mathcal{B}$.** A baryon is made of three quarks, for example the proton $p = uud$ and the neutron $n = udd$. Every quark has $\mathcal{B} = 1/3$ and every antiquark $-1/3$. (Notebook 21d writes the baryon number with the plain letter B; in this chapter's prose the calligraphic $\mathcal{B}$ is used, because the plain B is the Krein matrix below.)
- **Meson.** A quark and an antiquark, such as the pions $\pi^+ = u\bar{d}$, $\pi^- = d\bar{u}$ and π^0; $\mathcal{B} = 0$.
- **Lepton number** L: $+1$ for the electron and its neutrino ν_e, -1 for the positron and the antineutrino $\bar{\nu}_e$, 0 for quarks and photons. It is not the Lagrangian $\mathcal{L}$.
- **Electric charge** Q_{el}, in units of the proton charge. (Notebook 21d prints it as Q in its bookkeeping; in this chapter Q alone is the U(1) charge of the field, defined in Section 21.7.)
- **Conserved number.** A number whose total before any process equals its total after it.
- **Baryon-to-photon ratio** η_B: the number of baryons minus antibaryons per photon of the microwave background (Section 21.4). The letter η with two indices, η_{ab} or η^{ab}, is the frame metric; $\eta(K)$ without a subscript is the efficiency of the rate model of Section 21.6.
- **C, P, T, CP.** Charge conjugation C exchanges particles and antiparticles; parity P reflects space; time reversal T reverses the time; CP is C followed by P. A theory **violates** C (or CP) when a process and its image do not happen at the same rate.
- **Thermal equilibrium, temperature** T, **chemical potential** μ, **Fermi-Dirac occupation** f: Section 21.5. (The letter T also names the energy-momentum tensor in Chapter 9; in this chapter it is a temperature or the name of time reversal.)
- **Rate** K: a number of events per unit time.
- **Coordinates** $x_0, \ldots, x_7$, in the author's order: x_1, x_2, x_3 ordinary 3-space (inflating); x_4 the time; x_5, x_6, x_7 the three **extra times**, time-like, which **deflate exponentially**; x_0 the **hidden** space direction, with the angle $z = 6Hx_0$ between 0 and $\pi/2$ (the **patch**). The end $z = \pi/2$ is called the **brane**.
- **Gamma matrices** $\gamma^{(x0)}, \ldots, \gamma^{(x7)}$: the author's eight real 16×16 matrices; **charge matrix** C, **chirality** Γ, **Krein matrix** B, **generators** S^{ab}: Section 21.7.

- **Spinor field** Ψ: at every point a column of 16 numbers, the **components** $\Psi_1, \ldots, \Psi_{16}$. **Commuting** components are ordinary complex numbers (the field dirac16complex00); **anticommuting** (Grassmann) components obey $\Psi_r \Psi_c = -\Psi_c \Psi_r$ (the field dirac16complex). In Sections 21.10 and 21.15 the number $\epsilon = +1$ or -1 marks the two cases; in Sections 21.5, 21.6 and 21.36 the same letter ϵ is the baryon number made per decay, as in Notebook 21d.

- **Complex conjugate** z^*, **transpose** M^T, **conjugate transpose** $M^\dagger = (M^*)^T$; **symmetric** $M^T = M$; **antisymmetric** $M^T = -M$; **Hermitian** $M^\dagger = M$. A matrix or column is **real** when all its entries are real.

- **Dirac adjoint** $\bar\Psi = \Psi^\dagger C$; **scalar** $S = \bar\Psi\Psi$; **current** $J^\mu = -i\bar\Psi\gamma^\mu\Psi$; **charge density** $J^{(x4)} = \Psi^\dagger B \Psi$; **charge** $Q = \int \cos z \, \Psi^\dagger B \Psi \, d^7x$ (Section 21.7).

- **Charge-conjugation matrix** $\mathcal{C}$: a constant matrix for which $M = \mathcal{C}C$ obeys the **intertwiner condition** $M(\gamma^a)^* = s\,\gamma^a M$ with one sign s for all eight a (the definition of the Revision record, Section 21.8). Then $\Psi^c = \mathcal{C}\bar\Psi^T$ solves the field equation of the same form whenever Ψ does; the converse is not true in general (Section 21.8). The two that exist, up to a factor, are $\mathcal{C}_+$ and $\mathcal{C}_-$.

- **Majorana (reality) condition**: the requirement $\Psi^c = \Psi$.

- **Bilinear**: a number $\Psi^\dagger K \Psi = \sum_{r,c} \Psi_r^* K_{rc} \Psi_c$ with a fixed matrix K.

- **Noether's theorem**: a continuous symmetry of the Lagrangian gives a current whose divergence vanishes on every solution (Section 21.16).

- **Chirality partner**: $\Gamma\Psi$. **Theorem T1** of the Revision record: it solves the field equations with $(m, \lambda) \to (-m, -\lambda)$ and carries the opposite current (Section 21.19).

- **Canonical anticommutator, Krein form, Krein inertia, positive representation**: Section 21.25.

- **Majorana-type term**: a term $\Psi^T M \Psi$ built from Ψ twice, without $\Psi^\dagger$ (Section 21.32).

- **Status labels**: PROVED, COMPUTED, ASSUMED, HYPOTHESIS, OPEN, NOT COMPUTED (Section 21.1).

21.3 Particles, antiparticles and conserved numbers

Antiparticles. In 1928 Dirac wrote down the equation of the electron. Its solutions come with negative as well as positive energies, and Dirac concluded that a particle with the mass of the electron and the opposite electric charge must exist. That particle, the positron, was found in cosmic rays in 1932 (C. D. Anderson, Phys. Rev. 43, 491 (1933)). Since then every known particle has been found to have an antiparticle with the same mass and opposite charges. A few neutral particles, such as the photon, are their own antiparticles.

Annihilation and particle pair creation. An electron and a positron that meet can annihilate into photons. Conversely, a photon of enough energy that passes near a nucleus (which takes up momentum) can turn into an electron and a positron. This is the **pair creation of particles**, an observed process of ordinary physics, in which the total electric charge stays the same because the

two members carry opposite charges. It must not be confused with the question whether universes are created in pairs, which Chapter 20 treats and which no equation of this book answers.

The conserved numbers. Three numbers are counted in every process: the electric charge Q_{el}, the baryon number $\mathcal{B}$ and the lepton number L (Section 21.2). The values for a particle made of quarks follow from its quark content by addition, with an antiquark counted with the opposite sign. Line by line for the particles of the next example:

- proton $p = uud$: $\mathcal{B} = \frac{1}{3} + \frac{1}{3} + \frac{1}{3} = 1$ and $Q_{\text{el}} = \frac{2}{3} + \frac{2}{3} - \frac{1}{3} = 1$ (add the numbers of the three quarks);
- neutron $n = udd$: $\mathcal{B} = 1$ and $Q_{\text{el}} = \frac{2}{3} - \frac{1}{3} - \frac{1}{3} = 0$ (the same rule);
- antiproton $\bar{p} = \bar{u}\bar{u}\bar{d}$: $\mathcal{B} = -1$ and $Q_{\text{el}} = -1$ (every sign reversed);
- pion $\pi^+ = u\bar{d}$: $\mathcal{B} = \frac{1}{3} - \frac{1}{3} = 0$ and $Q_{\text{el}} = \frac{2}{3} - (-\frac{1}{3}) = 1$ (the antiquark $\bar{d}$ counts with the opposite sign of d);
- pion $\pi^- = d\bar{u}$: $\mathcal{B} = 0$ and $Q_{\text{el}} = -\frac{1}{3} - \frac{2}{3} = -1$;
- neutral pion π^0: $\mathcal{B} = 0$ and $Q_{\text{el}} = 0$ (Notebook 21d writes it as $u\bar{u}$; the physical π^0 is a mixture of $u\bar{u}$ and $d\bar{d}$, which have the same numbers).

The electron has $(\mathcal{B}, L, Q_{\text{el}}) = (0, 1, -1)$, the positron $(0, -1, 1)$, the antineutrino $(0, -1, 0)$ and the photon $(0, 0, 0)$.

Worked example: bookkeeping. A number is conserved in a process if its total before equals its total after. For four processes (the totals are sums over the particles on each side):

process	$\mathcal{B}$ **before, after**	L **before, after**	Q_{el} **before, after**	**observed?**
neutron decay $n \to p\, e^- \bar{\nu}_e$	1, $1 + 0 + 0 = 1$	0, $0 + 1 - 1 = 0$	0, $1 - 1 + 0 = 0$	yes
annihilation $p\,\bar{p} \to \pi^+\pi^-\pi^0$	$1 - 1 = 0$, 0	0, 0	$1 - 1 = 0$, $1 - 1 + 0 = 0$	yes
pair creation $\gamma\, p \to p\, e^- e^+$	1, 1	0, $1 - 1 = 0$	1, $1 - 1 + 1 = 1$	yes
proton decay $p \to e^+\pi^0$	1, 0	0, -1	1, $1 + 0 = 1$	never seen

The three observed processes conserve all three numbers. Proton decay would change $\mathcal{B}$ by $0-1 = -1$ and L by $-1-0 = -1$; it would keep Q_{el} and the difference $\mathcal{B}-L$ (before $1-0 = 1$, after $0-(-1) = 1$). It has been searched for and never observed. Notebook 21d computes this table with exact fractions (In [3]) and draws it (figure 21d.1).

The matter-antimatter problem is the question why the universe contains baryons but essentially no antibaryons.

21.4 What is observed: the baryon-to-photon ratio, and no antimatter domains

This section quotes observations. Nothing in it is computed by this book, and no notebook of this chapter uses a measured number; every number here is ASSUMED (quoted) from the literature named with it.

The definition. The universe is filled with the photons of the **cosmic microwave background**, the thermal radiation left over from the hot early universe, today at the temperature 2.7255 K (D. J. Fixsen, Astrophys. J. 707, 916 (2009)). After the first seconds of the universe the number of baryons and the number of these photons in a volume that expands with the universe both stay constant, so their ratio is a fixed number of our universe, the **baryon-to-photon ratio**

$$\eta_B = \frac{n_b - n_{\bar{b}}}{n_\gamma},$$

where n_b, $n_{\bar{b}}$ and n_γ are the numbers of baryons, antibaryons and photons per unit volume. Today $n_{\bar{b}}$ is negligible.

Its value. It is measured in two independent ways. The pattern of hot and cold spots in the microwave background depends on the density of baryons; the Planck satellite's 2018 analysis gives the baryon density parameter $\Omega_b h^2 = 0.0224 \pm 0.0001$ (Planck Collaboration, "Planck 2018 results. VI. Cosmological parameters", Astron. Astrophys. 641, A6 (2020)). The abundances of the light nuclei made in the first minutes (big-bang nucleosynthesis) depend on η_B as well, and the two determinations agree (R. H. Cyburt, B. D. Fields, K. A. Olive and T.-H. Yeh, Rev. Mod. Phys. 88, 015004 (2016)). Converted with the photon density of a black body at 2.7255 K and the mass of the proton (a standard conversion, quoted and not derived here), the Planck value corresponds to

$$\eta_B \approx 6.1 \times 10^{-10} :$$

about six baryons for every ten billion photons, or $1/\eta_B \approx 1.6 \times 10^9$ photons per baryon (the reciprocal of the quoted value, rounded).

Why this is a problem. Run the expansion backwards. When the thermal energy was far above the rest energy of a proton, baryons, antibaryons and photons were all abundant and turned into each other all the time. Had the early universe held exactly as many baryons as antibaryons, almost all of them would have annihilated as it cooled, leaving far less matter than we see (L. Canetti, M. Drewes and M. Shaposhnikov, New J. Phys. 14, 095012 (2012)). The baryons of today are the remnant of a tiny excess of baryons over antibaryons, about one part in 10^9. One could put this excess into the initial state by hand; the standard view, reviewed in the article just cited, is that physical processes should **generate** it from a symmetric start. Explaining how is the matter-antimatter problem, also called **baryogenesis**.

No antimatter domains. Could the universe be symmetric as a whole, with some regions of matter and others of antimatter? Wherever such regions touch, particles and antiparticles annihilate and make gamma rays. Cohen, De Rujula and Glashow showed that the gamma rays from the boundaries would exceed the observed diffuse gamma-ray background unless our region of matter is essentially the whole visible universe (A. G. Cohen, A. De Rujula and S. L. Glashow, Astrophys. J. 495, 539 (1998)). A patchwork universe is therefore excluded.

statement	status	source
$\Omega_b h^2 = 0.0224 \pm 0.0001$	ASSUMED (quoted observation)	Planck Collaboration, Astron. Astrophys. 641, A6 (2020)
$\eta_B \approx 6.1 \times 10^{-10}$, agreement with nucleosynthesis	ASSUMED (quoted)	the same; Cyburt et al., Rev. Mod. Phys. 88, 015004 (2016)
no domains of antimatter in the visible universe	ASSUMED (quoted)	Cohen, De Rujula and Glashow, Astrophys. J. 495, 539 (1998)
a value of η_B from the theory of this book	NOT COMPUTED	nothing in the Revision record computes it

21.5 Sakharov's three conditions, derived in plain words

In 1967 Andrei Sakharov named three ingredients that any process which makes the baryon excess from a symmetric start must contain (A. D. Sakharov, JETP Lett. 5, 24 (1967)). Each follows from a short argument. Throughout, the system is the whole universe; it starts with $\mathcal{B} = 0$ and without any asymmetry, and we ask what is needed for $\mathcal{B} \neq 0$ later. The arguments are general; the small models that illustrate them are ASSUMED toy models, not part of the theory of this book, and Notebook 21d computes each of them.

Condition 1: the baryon number must change.

Proposition 1. If every process conserves $\mathcal{B}$, then $\mathcal{B}(t) = \mathcal{B}(0)$ at every time t.

Proof. Conservation means $d\mathcal{B}/dt = 0$ at every time. A function of one variable whose derivative is zero everywhere on an interval is constant there (the mean value theorem of calculus: $\mathcal{B}(t) - \mathcal{B}(0) = t\,\mathcal{B}'(\tau)$ for some τ between 0 and t, and $\mathcal{B}'(\tau) = 0$). □

Starting from $\mathcal{B} = 0$, the universe would keep $\mathcal{B} = 0$ for ever. So some process must change $\mathcal{B}$.

Condition 2: C and CP must be violated. A transformation is a **symmetry of the dynamics** if it turns every possible history of the system into another possible history that runs in the same direction of time.

Proposition 2. Let $\mathcal{S}$ be a symmetry of the dynamics that reverses $\mathcal{B}$: if the history h has the baryon number $\mathcal{B}[h](t)$ at the time t, its image $\mathcal{S}h$ has $-\mathcal{B}[h](t)$. Let the initial state be an ensemble, a list of possible starting configurations c with probabilities $p(c)$, in which every configuration and its image are equally likely, $p(\mathcal{S}c) = p(c)$. Then the average baryon number is zero at every time.

Proof, line by line. Let h_c be the history that starts from c.

$$\langle \mathcal{B}(t) \rangle = \sum_c p(c)\, \mathcal{B}[h_c](t)$$

(the definition of the average over the ensemble)

$$= \sum_c p(\mathcal{S}c)\, \mathcal{B}[h_{\mathcal{S}c}](t)$$

(the map $c \to \mathcal{S}c$ is one to one, so summing over all c is the same as summing over all $\mathcal{S}c$)

$$= \sum_c p(c)\, \mathcal{B}[\mathcal{S}h_c](t)$$

(the probabilities are equal by assumption, and the history that starts from $\mathcal{S}c$ is $\mathcal{S}h_c$ because $\mathcal{S}$ is a symmetry of the dynamics)

$$= \sum_c p(c)\, \big(- \mathcal{B}[h_c](t)\big) = -\langle \mathcal{B}(t) \rangle$$

($\mathcal{S}$ reverses $\mathcal{B}$). A number equal to minus itself is zero. □

Apply this with $\mathcal{S} = \mathrm{C}$: a start without asymmetry holds particles and antiparticles in equal numbers, so it is C-symmetric, and if C were a symmetry of the dynamics no average asymmetry could develop. Apply it with $\mathcal{S} = \mathrm{CP}$: a start that is the same in every direction is also symmetric under the reflection P, which does not change $\mathcal{B}$; so CP reverses $\mathcal{B}$ as well, and if CP were a symmetry no asymmetry could develop. Hence **both C and CP must be violated**.

A decay model for conditions 1 and 2. A heavy toy particle X decays in two ways: with probability r into a channel of baryon number $\mathcal{B}_1$, with probability $1 - r$ into a channel of baryon number $\mathcal{B}_2$. Its antiparticle $\bar{X}$ decays into the antichannels, of baryon numbers $-\mathcal{B}_1$ and $-\mathcal{B}_2$, with probabilities $\bar{r}$ and $1 - \bar{r}$. (In ordinary quantum field theory the total decay rates of X and $\bar{X}$ are equal; the probabilities r and $\bar{r}$ can differ only if C and CP are violated. This is quoted, ASSUMED.) Start with N particles and N antiparticles. Line by line:

$$\text{one } X \text{ makes on average } r\mathcal{B}_1 + (1-r)\mathcal{B}_2$$

(each channel's baryon number times its probability, summed: the average of a quantity that takes two values);

$$\text{one } \bar{X} \text{ makes on average } \; -\bar{r}\mathcal{B}_1 - (1-\bar{r})\mathcal{B}_2$$

(the same rule with the antichannels);

$$N\big[r\mathcal{B}_1 + (1-r)\mathcal{B}_2 - \bar{r}\mathcal{B}_1 - (1-\bar{r})\mathcal{B}_2\big]$$

(the total of N particles and N antiparticles is N times the sum of the two averages);

$$= N\big[(r-\bar{r})\mathcal{B}_1 + (-r+\bar{r})\mathcal{B}_2\big] = N\,(r-\bar{r})(\mathcal{B}_1 - \mathcal{B}_2)$$

(collect the terms with $\mathcal{B}_1$ and with $\mathcal{B}_2$: in the second, $\mathcal{B}_2 - r\mathcal{B}_2 - \mathcal{B}_2 + \bar{r}\mathcal{B}_2 = -(r-\bar{r})\mathcal{B}_2$; then factor out $r - \bar{r}$). The net baryon number is a **product**. It vanishes if $\mathcal{B}_1 = \mathcal{B}_2$ (then X carries a conserved baryon number: condition 1 fails) or if $r = \bar{r}$ (particle and antiparticle behave alike: condition 2 fails). Example: $X \to qq$ with $\mathcal{B}_1 = \frac{2}{3}$ and $X \to \bar{q}\bar{\ell}$ (an antiquark and an antilepton) with $\mathcal{B}_2 = -\frac{1}{3}$, and $r = 0.6$, $\bar{r} = 0.5$: per pair ($N = 1$) the net baryon number is $(0.6 - 0.5)(\frac{2}{3} + \frac{1}{3}) = 0.1 \times 1 = \frac{1}{10}$ (Notebook 21d, In [5], exact; figure 21d.2 shows it for all r and $\bar{r}$).

Condition 3: a departure from thermal equilibrium. In **thermal equilibrium** at temperature T, a system's reactions run forwards and backwards equally often, and each quantum state of energy E holds a fermion with the **Fermi-Dirac** probability $f(E) = 1/(e^{(E-\mu)/T}+1)$ (Boltzmann's constant set to 1). Here μ, the **chemical potential**, belongs to a conserved number; it is quoted from statistical physics (ASSUMED) that the equilibrium state depends only on the energy and on the conserved numbers. A particle of baryon number $+1$ sees $+\mu$ and its antiparticle, which has the same mass and hence the same energy, sees $-\mu$:

$$f_+ = \frac{1}{e^{(E-\mu)/T}+1}, \qquad f_- = \frac{1}{e^{(E+\mu)/T}+1}.$$

The surplus of particles per state, line by line:

$$f_+ - f_- = \frac{\left(e^{(E+\mu)/T}+1\right) - \left(e^{(E-\mu)/T}+1\right)}{\left(e^{(E-\mu)/T}+1\right)\left(e^{(E+\mu)/T}+1\right)}$$

(the two fractions brought to their common denominator, the product of the two denominators);

$$= \frac{e^{(E+\mu)/T} - e^{(E-\mu)/T}}{e^{2E/T} + e^{(E-\mu)/T} + e^{(E+\mu)/T} + 1}$$

(the two 1s of the numerator cancel; the denominator is multiplied out, with $e^{(E-\mu)/T}e^{(E+\mu)/T} = e^{2E/T}$ because exponents add);

$$= \frac{e^{\mu/T} - e^{-\mu/T}}{e^{E/T} + e^{-\mu/T} + e^{\mu/T} + e^{-E/T}}$$

(numerator and denominator divided by $e^{E/T}$, using $e^u/e^v = e^{u-v}$);

$$= \frac{2\sinh(\mu/T)}{2\cosh(E/T) + 2\cosh(\mu/T)} = \frac{\sinh(\mu/T)}{\cosh(E/T) + \cosh(\mu/T)}$$

(the definitions $\sinh u = (e^u - e^{-u})/2$ and $\cosh u = (e^u + e^{-u})/2$, then the factor 2 cancelled). If reactions that change $\mathcal{B}$ run back and forth in equilibrium, $\mathcal{B}$ is not a conserved number and has no chemical potential: $\mu = 0$, so $\sinh 0 = 0$ and $f_+ = f_-$ at **every** energy. No asymmetry. An asymmetry can only be made while the universe is **out of equilibrium**, for example in decays that happen too late for the inverse processes to keep up.

Worked example. For a state with $E = 2T$ and $\mu = 0$, both occupations are $1/(e^2+1) = 0.119203$. A chemical potential $\mu = 0.1T$ would give $f_+ = 1/(e^{1.9}+1) = 0.130108$ and $f_- = 1/(e^{2.1}+1) = 0.109097$, a surplus of 0.021012 particles per state (Notebook 21d, In [7], where sympy also checks the formula exactly; figure 21d.3 draws the surplus against E/T).

21.6 Condition 3 in a rate model: decays out of equilibrium

How far from equilibrium must the decays be? A small ASSUMED model answers this in closed form. A toy universe cools; the time t is measured in units of its cooling time. Let $n(t)$ be the

number of heavy pairs X, $\bar{X}$ (in units of their starting number) and $n_{eq}(t) = e^{-t}$ the number that equilibrium would hold (heavy particles become rare as the temperature falls). Decays and inverse decays pull n towards n_{eq} at the rate K; every net decay of a pair makes ϵ baryons (the number of Section 21.5); inverse decays, which need X particles in equilibrium, erase the asymmetry a at the rate Kn_{eq}:

$$\frac{dn}{dt} = -K(n - n_{eq}), \qquad \frac{da}{dt} = \epsilon K(n - n_{eq}) - Kn_{eq}\, a, \qquad n(0) = 1, \quad a(0) = 0.$$

Solving it exactly, line by line (for $K \neq 1$).

Line 1. Write $n = n_{eq} + \Delta$. Then $dn/dt = dn_{eq}/dt + d\Delta/dt = -e^{-t} + d\Delta/dt$ (the derivative of a sum, and $de^{-t}/dt = -e^{-t}$). The first equation says $dn/dt = -K\Delta$, so $d\Delta/dt = -K\Delta + e^{-t}$, with $\Delta(0) = n(0) - n_{eq}(0) = 1 - 1 = 0$.

Line 2. The function $\Delta(t) = (e^{-t} - e^{-Kt})/(K-1)$ solves it. Check: its derivative is $(-e^{-t} + Ke^{-Kt})/(K-1)$ (chain rule for each exponential), and $-K\Delta + e^{-t} = \big(-Ke^{-t} + Ke^{-Kt} + (K-1)e^{-t}\big)/(K-1) = (-e^{-t} + Ke^{-Kt})/(K-1)$ (common denominator, then $-K + K - 1 = -1$): the two agree, and $\Delta(0) = (1-1)/(K-1) = 0$.

Line 3. Let $W(t) = K(1 - e^{-t})$, so that $dW/dt = Ke^{-t} = Kn_{eq}$ and $W(0) = 0$. By the product rule, $d(a\, e^{W})/dt = (da/dt + Kn_{eq}\, a)\, e^{W}$, and the second equation turns this into $\epsilon K\Delta\, e^{W}$. Integrating from 0 to t (fundamental theorem of calculus, with $a(0) = 0$) gives $a(t)e^{W(t)} = \epsilon \int_0^t K\Delta(s) e^{W(s)} ds$, that is

$$a(t) = \epsilon \int_0^t K\Delta(s)\, e^{W(s) - W(t)}\, ds.$$

Line 4. As $t \to \infty$, $W(t) \to K$, and $W(s) - K = -Ke^{-s}$. The final asymmetry is $a(\infty) = \epsilon\, \eta(K)$ with the **efficiency**

$$\eta(K) = \int_0^\infty K\Delta(s)\, e^{-Ke^{-s}}\, ds.$$

Line 5. Substitute $y = e^{-s}$: then $ds = -dy/y$, the limits $s = 0$ and $s = \infty$ become $y = 1$ and $y = 0$, and $\Delta = (y - y^K)/(K-1)$. Turning the limits round removes the minus sign:

$$\eta(K) = \frac{K}{K-1} \int_0^1 \frac{y - y^K}{y}\, e^{-Ky}\, dy = \frac{K}{K-1} \int_0^1 (1 - y^{K-1}) e^{-Ky}\, dy.$$

Line 6. The first part is $\int_0^1 e^{-Ky} dy = (1 - e^{-K})/K$. In the second substitute $u = Ky$ ($dy = du/K$, limits 0 and K): $\int_0^1 y^{K-1} e^{-Ky} dy = \int_0^K (u/K)^{K-1} e^{-u} du/K = K^{-K}\gamma(K, K)$, where $\gamma(s, x) = \int_0^x u^{s-1} e^{-u} du$ is the **lower incomplete gamma function**. Hence

$$\eta(K) = \frac{K}{K-1}\Big(\frac{1 - e^{-K}}{K} - K^{-K}\gamma(K, K)\Big).$$

What it says. For slow decays (small K) the decays happen late, when n_{eq} is already tiny, so the erasing term $Kn_{eq}a$ is ineffective and almost the whole ϵ survives. For fast decays (large K)

n stays close to n_{eq} and the inverse decays erase almost everything: $K^{-K}\gamma(K,K)$ and e^{-K} are exponentially small, so $\eta(K) = 1/(K-1)$ up to exponentially small terms. Two controls: with $\epsilon = 0$ (no C and CP violation) the second equation keeps $a = 0$ for ever; without the erasing term $da/dt = \epsilon K(n - n_{eq}) = -\epsilon\, dn/dt$, so $a(\infty) = \epsilon\big(n(0) - n(\infty)\big) = \epsilon$. Notebook 21d checks lines 1 to 3 with sympy, evaluates $\eta(K)$ with mpmath, integrates the two equations with the Runge-Kutta method of Chapter 2 and finds $\eta = 0.9955325865$, 0.4110164748 and 0.0344827586 for $K = 0.1$, 3 and 30, with the integration agreeing to 10^{-7} (In [9] and In [10]; figures 21d.4 and 21d.5). For $K = 30$ the value is $1/29$, the fast-decay limit.

21.7 The theory of this book: two fields, one phase symmetry

This section collects what the rest of the chapter needs. Every formula is from the Revision record; the chapters named derive them in full.

The metric. The author's metric is diagonal. With the abbreviations $s = \sin^{1/3} z$ and $z = 6Hx_0$, its entries in the order $x_0, \ldots, x_7$ are

$$g = \mathrm{diag}\big(\cot^2 z,\ e^{2a_4}s,\ e^{2a_4}s,\ e^{2a_4}s,\ -1,\ -e^{-2a_4}s,\ -e^{-2a_4}s,\ -e^{-2a_4}s\big).$$

Its **scale factors** $f_a = \sqrt{|g_{aa}|}$ are $f_0 = \cot z$ (the hidden direction), $f_1 = f_2 = f_3 = e^{a_4}\sin^{1/6} z$ (ordinary space), $f_4 = 1$ (the time) and $f_5 = f_6 = f_7 = e^{-a_4}\sin^{1/6} z$ (the extra times). This is the author's metric of 2026-10-14 on its background $b_4 = 1$: the metric has a second function $b_4(x_4) > 0$, and with it $f_5 = f_6 = f_7 = e^{-a_4} b_4^{1/2} \sin^{1/6} z$ (Chapter 3). The records and the notebooks of this chapter work at $b_4 = 1$; Section 21.7 says what a changing b_4 changes in the charge. When a_4 grows with the time, ordinary space inflates and the three extra times deflate exponentially. The volume factor is $\sqrt{|\det g|} = f_0 f_1 \cdots f_7 = e^{3a_4}e^{-3a_4}\sin z \cot z = \cos z$: the inflation of space and the deflation of the extra times cancel, and a_4 drops out (Chapter 12; record check `sqrt_abs_det_g_is_cos_z` of `Revision/field_equations_a4/reports/wolfram-a4-report.json`). This one fact will be the reason why the local conservation law of the charge has no time-derivative terms (Section 21.17).

The gammas. The Revision record `Revision/algebra/gammas.json` holds the author's eight real 16×16 gamma matrices $\gamma^{(x0)}, \ldots, \gamma^{(x7)}$, rebuilt in Revision code from the author's formulas. Every entry is -1, 0 or $+1$, and each row and column holds one nonzero entry (a **signed permutation matrix**). They obey the **Clifford relation**

$$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}\,1, \qquad \eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1),$$

and the **symmetry pattern** $(\gamma^a)^T = \eta_{aa}\gamma^a$: the four space-like gammas (x_0, x_1, x_2, x_3) are symmetric, the four time-like ones antisymmetric. Two consequences used again and again: different gammas **anticommute**, $\gamma^a\gamma^b = -\gamma^b\gamma^a$ for $a \neq b$, and $\gamma^a\gamma^a = \eta^{aa}1$. Notebook 21a checks all of this exactly (In [3]).

The four matrices built from them (Chapters 4 and 5):

- the **charge matrix** $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$, the product of the four space-like gammas (the author's sigma16);
- the **chirality** $\Gamma = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\cdots\gamma^{(x7)}$, the product of all eight; it is diagonal, with the entries -1 in the first eight places and $+1$ in the last eight, written $\Gamma = \mathrm{diag}(-1_8, 1_8)$;
- the **Krein matrix** $B = -iC\gamma^{(x4)}$;
- the 28 **generators** $S^{ab} = \frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$ of the rotations and boosts, which for $a \neq b$ equal $\frac{1}{2}\gamma^a\gamma^b$.

Three rules for moving gammas, each derived from the Clifford relation.

(R1) Γ anticommutes with every gamma. Moving γ^b from the left of Γ to its right passes the seven factors γ^a with $a \neq b$, each of which costs a sign, and the factor γ^b itself, which costs none: the total sign is $(-1)^7 = -1$.

(R2) Γ commutes with every product of an even number of gammas, in particular with C and with every S^{ab} (each factor costs a sign by (R1), and an even number of signs multiply to $+1$). Also $\Gamma\Gamma = 1$ and $\Gamma^T = \Gamma$, because Γ is diagonal with entries ± 1.

(R3) $C^T = C$, $CC = 1$ and $C\gamma^a C = -(\gamma^a)^T$ for every a. Derivation, line by line. First

$$C^T = (\gamma^{(x3)})^T(\gamma^{(x2)})^T(\gamma^{(x1)})^T(\gamma^{(x0)})^T = \gamma^{(x3)}\gamma^{(x2)}\gamma^{(x1)}\gamma^{(x0)}$$

(the transpose of a product is the product of the transposes in reverse order; space-like gammas are symmetric). Reversing the order of four different anticommuting factors takes $3 + 2 + 1 = 6$ exchanges, so $C^T = (-1)^6 C = C$. Then

$$CC = CC^T = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}\gamma^{(x3)}\gamma^{(x2)}\gamma^{(x1)}\gamma^{(x0)} = 1$$

(each neighbouring pair $\gamma\gamma$ of a space-like gamma is $+1$; remove them from the inside out). Next, $\gamma^a C = -C\gamma^a$ when a is space-like (passing through C costs three signs for the other three factors and none for γ^a itself) and $\gamma^a C = +C\gamma^a$ when a is time-like (four signs). With the symmetry pattern, $(C\gamma^a)^T = (\gamma^a)^T C^T = \eta_{aa}\gamma^a C = -C\gamma^a$ in both cases: every $C\gamma^a$ is **antisymmetric**. Writing this as $(\gamma^a)^T C = -C\gamma^a$ and multiplying from the right by C (with $CC = 1$) gives $(\gamma^a)^T = -C\gamma^a C$.

The record checks these facts exactly (`Revision/algebra/reports/python-algebra.json` and `Revision/lead_checks/reports/charge-conjugation-and-u1.json`, check `representation_real`; Notebook 21a, In [5]).

The two fields. dirac16complex is a field Ψ with 16 complex **anticommuting** (Grassmann) components, quantised canonically (Chapter 10). dirac16complex00 is a field with 16 complex **commuting** components, a classical field. Both transform as Pin(4,4) spinors and are coupled to gravity through the vielbein (the scale factors) and the canonical spin connection Ω_μ (Chapter 6). The Revision record (`Revision/theory/field-theory.json`, formula `Lagrangian`) gives the same Lagrangian density for both:

$$\mathcal{L} = \cos z \left[\tfrac{1}{2}\sum_\mu \left(\bar\Psi\gamma^\mu D_\mu\Psi - (D_\mu\bar\Psi)\gamma^\mu\Psi\right) - mS - U(S)\right], \qquad \bar\Psi = \Psi^\dagger C, \quad S = \bar\Psi\Psi,$$

with the curved gammas $\gamma^\mu = \gamma^{(\mu)}/f_\mu$ (no sum), $D_\mu\Psi = \partial_\mu\Psi + \Omega_\mu\Psi$, $D_\mu\bar\Psi = \partial_\mu\bar\Psi - \bar\Psi\Omega_\mu$, the mass m and the self-interaction $U(S) = \frac{\lambda}{2}S^2$ with the coupling λ. Its Euler-Lagrange equation (Chapter 7) is the **field equation**

$$\gamma^\mu D_\mu\Psi = V\Psi, \qquad V = m + U'(S),$$

which in the author's metric reads (record formula `field_equation`)

$$e^{-a_4}\sin^{-1/6} z\sum_{i=1}^{3}\gamma^{(xi)}\partial_i\Psi + \gamma^{(x4)}\partial_4\Psi + e^{a_4}\sin^{-1/6} z\sum_{t=5}^{7}\gamma^{(xt)}\partial_t\Psi + \tan z\,\gamma^{(x0)}\partial_0\Psi + 3H\gamma^{(x0)}\Psi = V\Psi.$$

The term $3H\gamma^{(x0)}\Psi$ is $\gamma^\mu\Omega_\mu\Psi$, the spin connection contracted with the gammas (record formula `gammaOmega_total`; Chapter 8). **Every matrix in this equation is real**: the gammas, the scale factors, $\tan z$, $3H$, and every entry of every Ω_μ (lead check `spinor_connection_real`); V is real because $S = \Psi^\dagger C\Psi$ is real (Chapter 7).

The phase symmetry and its current. Multiplying every component by one phase, $\Psi \to e^{i\alpha}\Psi$, multiplies $\Psi^\dagger$ by $e^{-i\alpha}$, so every bilinear $\Psi^\dagger X\Psi$, hence $\mathcal{L}$, is unchanged. The group of these phases is called **U(1)**. Its current and charge (record formula `current`) are

$$J^\mu = -i\bar\Psi\gamma^\mu\Psi, \qquad J^{(x4)} = \Psi^\dagger B\Psi, \qquad Q = \int \cos z\,\Psi^\dagger B\Psi\,dx_0\,dx_1\,dx_2\,dx_3\,dx_5\,dx_6\,dx_7.$$

(The time component: $J^{x4} = -i\Psi^\dagger C\gamma^{(x4)}\Psi = \Psi^\dagger B\Psi$, because $f_4 = 1$.) Section 21.17 proves the local conservation law behind Q: Q does not change in time when no charge flows through the boundary of the slice, and Section 21.18 shows that at the brane $z = \pi/2$ this is a real condition.

With a changing b_4. In the author's metric with a second function $b_4(x_4)$ the volume factor is $\sqrt{|g|} = b_4^{3/2}\cos z$ (`Revision/theory/reports/wolfram-field-theory-b4.json`, check `sqrt_det_g`), so the charge becomes $Q = \int b_4^{3/2}\cos z\,\Psi^\dagger B\Psi\,dx_0\,dx_1\,dx_2\,dx_3\,dx_5\,dx_6\,dx_7$; the extra-time derivatives carry the factor $e^{a_4}b_4^{-1/2}\sin^{-1/6} z$, and $\gamma^\mu\Omega_\mu$ gains the term $\frac{3}{4}(b_4'/b_4)\gamma^{(x4)}$ (Chapter 7). Every matrix of the field equation stays real (`Revision/theory/reports/python-field-theory-b4.json`, check `spinor_connection_real_b4`), and the matrix identity behind the conservation law holds for every b_4 (same report, check `u1_noether_matrix_identity_b4`). So the statements of this chapter about the conjugation matrices and the local conservation law do not depend on b_4; the notebooks and the exact solutions of this chapter are computed at $b_4 = 1$.

21.8 Charge conjugation is a matrix: the condition on the matrix

The question. An antiparticle has the same mass and the opposite charge. In a field theory the step from a solution to its "antiparticle solution" is made by a map called **charge conjugation**: it turns every solution of the field equation into a solution whose charge density has the opposite sign. In Dirac's theory of the electron, whose gamma matrices are complex, this map combines the complex conjugate Ψ^* with a fixed matrix. In the author's theory the gammas are real. Take a **real** field, one whose components are real numbers, so that $\Psi^* = \Psi$. On such a field, complex conjugation does nothing: it is the identity map, and a map that changes nothing cannot exchange matter and antimatter. Whatever charge conjugation is in this theory, it must be made by a **matrix**. This section derives a condition on the matrix that is enough for it to do its job and makes that condition the definition, as the Revision record does; the next section finds every matrix that obeys this condition.

The wish. We look for a constant 16×16 matrix $\mathcal{C}$ such that, whenever Ψ solves the field equation, the column

$$\Psi^c = \mathcal{C}\,\bar{\Psi}^T$$

solves the field equation of the same form, either with the same V (**same mass**) or with $-V$ (**mass reversed**).

From the wish to an equation for a matrix, line by line.

$$\bar{\Psi}^T = (\Psi^\dagger C)^T = C^T(\Psi^\dagger)^T = C\Psi^*$$

(the definition of $\bar{\Psi}$; the rule $(XY)^T = Y^T X^T$; the transpose of the row $\Psi^\dagger$ is the column Ψ^*, and $C^T = C$ by (R3)). So $\Psi^c = \mathcal{C}C\Psi^*$. Write $M = \mathcal{C}C$; then $\Psi^c = M\Psi^*$, and because $CC = 1$, $\mathcal{C} = MC$.

Step 1 (conjugate the equation). The complex conjugate of a product is the product of the conjugates, a real factor is its own conjugate, and the derivative of the conjugate is the conjugate of the derivative (the coordinates are real). All matrices of $\gamma^\mu D_\mu$ and the number V are real (Section 21.7). So $\gamma^\mu D_\mu \Psi^* = V\Psi^*$: **the column Ψ^* solves the same equation.**

Step 2 (multiply by M from the left). $M\gamma^\mu D_\mu \Psi^* = V\,M\Psi^*$ (a number V may stand on either side of a matrix).

Step 3 (the condition). Suppose that, with one sign $s = +1$ or $s = -1$ for all eight directions,

$$M\gamma^a = s\,\gamma^a M \qquad (a = x0, \ldots, x7).$$

Then $M\gamma^\mu = s\,\gamma^\mu M$ (the scale factor $1/f_\mu$ is a number). M commutes with every product of two gammas: $M\gamma^a\gamma^b = s\,\gamma^a M\gamma^b = s^2\gamma^a\gamma^b M = \gamma^a\gamma^b M$ (the condition used twice, then $s^2 = 1$). The spin connection is a combination of such products, so $M\Omega_\mu = \Omega_\mu M$; a constant matrix commutes with a derivative; hence $MD_\mu = D_\mu M$.

Step 4 (the new field). With step 3, $M\gamma^\mu D_\mu \Psi^* = s\,\gamma^\mu M D_\mu \Psi^* = s\,\gamma^\mu D_\mu (M\Psi^*)$, and step 2 becomes $s\,\gamma^\mu D_\mu (M\Psi^*) = V\,(M\Psi^*)$. Multiplying by s and using $s^2 = 1$:

$$\gamma^\mu D_\mu(M\Psi^*) = s\,V\,(M\Psi^*).$$

The new field $M\Psi^*$ solves the equation with V when $s=+1$ and with $-V$ when $s=-1$. Since the gammas are real, $(\gamma^a)^* = \gamma^a$, and the condition can be written $M(\gamma^a)^* = s\,\gamma^a M$, the form in which the Revision record solves it. (For $V = m + \lambda S$, which depends on the field, Section 21.10 shows that for commuting components both matrices found below keep S; then $sV = sm + s\lambda S$, so the new field solves the equation with (m, λ) when $s=+1$ and with $(-m, -\lambda)$ when $s=-1$. For a free field, $\lambda = 0$, only the mass matters.)

Definition. A **charge-conjugation matrix** is a constant 16×16 matrix $\mathcal{C}$ for which the matrix $M = \mathcal{C}C$ obeys the **intertwiner condition**

$$M(\gamma^a)^* = s\,\gamma^a M \qquad (a = x0, \ldots, x7),$$

with one sign s ($+1$ or -1) for all eight directions; it is called **same mass** when $s=+1$ and **mass reversed** when $s=-1$. This is the definition of the Revision record: its checks `intertwiners_same_mass` and `intertwiners_reversed_mass` solve exactly this condition. Steps 1 to 4 prove that every charge-conjugation matrix fulfils the wish: for every solution Ψ, the column $\Psi^c = M\Psi^*$ solves the field equation with sV.

Why the definition is the condition and not the wish. The condition is enough for the wish, but the converse is not true in general: a matrix can turn every solution into a solution without obeying the condition. An example, line by line, for $V=0$ (mass 0 and no self-interaction, a case that the field equation allows), with the chiral projectors $P_\pm = \frac{1}{2}(1 \pm \Gamma)$ and $M = P_-$, that is $\mathcal{C} = P_- C$:

1. P_- is a combination of 1 and of Γ, so by (R2) it commutes with every product of two gammas, hence with every Ω_μ; as a constant matrix it commutes with every derivative. So $P_- D_\mu = D_\mu P_-$.
2. By (R1), $\gamma^a P_- = \frac{1}{2}(\gamma^a - \gamma^a\Gamma) = \frac{1}{2}(\gamma^a + \Gamma\gamma^a) = P_+\gamma^a$, and in the same way $P_-\gamma^a = \gamma^a P_+$. Multiplying by the scale factors gives $\gamma^\mu P_- = P_+\gamma^\mu$.
3. For every solution Ψ: $\gamma^\mu D_\mu(P_-\Psi^*) = P_+\gamma^\mu D_\mu\Psi^* = P_+(V\Psi^*) = 0$ (lines 1 and 2, then Step 1, then $V=0$).

So $P_-\Psi^*$ solves the equation with $V=0$, which is also $-V$: the matrix P_-C fulfils the wish. It does not obey the condition, for either sign: if $P_-\gamma^a = s\,\gamma^a P_-$ held, then with line 2 $\gamma^a P_+ = s\,\gamma^a P_-$; multiplying from the left by $\eta_{aa}\gamma^a$ (and $\eta_{aa}\gamma^a\gamma^a = 1$) gives $P_+ = s\,P_-$, and multiplying from the right by P_+ gives $P_+ = 0$, because $P_+P_+ = P_+$ and $P_-P_+ = \frac{1}{4}(1 - \Gamma\Gamma) = 0$. But $P_+ = \mathrm{diag}(0, 1_8)$ is not zero. (Section 5.28 gives the same example.) So with the wish as the definition, the count "exactly two" of Theorem CC would be false for $V=0$; with the condition as the definition, it is proved below. For $V \neq 0$ this book does not study whether some matrix outside the condition fulfils the wish in the author's metric (OPEN); nothing in this chapter depends on that question, because the Revision record and this chapter use the condition.

21.9 The two charge-conjugation matrices

Theorem CC.

- (a) The matrices M with $M(\gamma^a)^* = +\gamma^a M$ for all eight a are exactly the multiples of 1; the matrices with $M(\gamma^a)^* = -\gamma^a M$ for all a are exactly the multiples of Γ.
- (b) Hence, with the intertwiner condition as the definition (Section 21.8), there are exactly two charge-conjugation matrices, up to a factor: $\mathcal{C}_+ = C$ (same mass), with $\Psi^c = \mathcal{C}_+ \bar{\Psi}^T = \Psi^*$, and $\mathcal{C}_- = \Gamma C$ (mass reversed), with $\Psi^c = \mathcal{C}_- \bar{\Psi}^T = \Gamma\Psi^*$.
- (c) $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$ and $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$ for every a; both are real and symmetric. Conversely, the only matrices X with $\gamma^a X = \zeta X(\gamma^a)^T$ for all a are the multiples of C ($\zeta = -1$) and of ΓC ($\zeta = +1$).

Proof of (a). The gammas are real, so the conditions read $M\gamma^a = \pm\gamma^a M$. For the sign $+$, M commutes with all eight gammas. The 16 components carry an **irreducible** representation of the group Pin(4,4), which the gammas generate (Chapter 5); by Schur's lemma, a matrix that commutes with every matrix of an irreducible representation is a multiple of 1 (record check `pin_commutant_dimension_1` of `Revision/algebra/reports/python-algebra.json`, which solves these equations exactly and finds a space of dimension 1). For the sign $-$, M anticommutes with every gamma; then ΓM commutes with every gamma:

$$\gamma^a(\Gamma M) = -\Gamma\gamma^a M = -\Gamma(-M\gamma^a) = (\Gamma M)\gamma^a$$

(first (R1), then the condition read as $\gamma^a M = -M\gamma^a$, then the two signs multiplied). So $\Gamma M = c\,1$ for a number c, and multiplying from the left by Γ (with $\Gamma\Gamma = 1$) gives $M = c\,\Gamma$. Conversely 1 commutes and Γ anticommutes with every gamma (R1), so both are solutions. □

Why each equation halves the freedom. A 16×16 matrix has 256 entries. Take only the first condition, $M\gamma^{(x1)} = \gamma^{(x1)}M$. The matrix $\gamma^{(x1)}$ is real and symmetric with $\gamma^{(x1)}\gamma^{(x1)} = 1$, so its eigenvalues are $+1$ and -1 (if $\gamma u = cu$ then $u = \gamma\gamma u = c^2 u$, so $c^2 = 1$); its trace is zero (its nonzero entries lie outside the diagonal blocks, figure 21a.1), so each eigenvalue occurs 8 times. If M commutes with $\gamma^{(x1)}$ and $\gamma^{(x1)}u = cu$, then $\gamma^{(x1)}(Mu) = M\gamma^{(x1)}u = c\,Mu$: M maps each eigenspace into itself. In a basis of eigenvectors, M is then made of two free 8×8 blocks: $64 + 64 = 128$ free entries, half of 256. (For $M\gamma^{(x1)} = -\gamma^{(x1)}M$, M maps each eigenspace into the other one, again $64 + 64 = 128$.) Notebook 21a computes the whole sequence exactly: imposing the conditions for the first k gammas leaves $256/2^k$ free numbers, $256, 128, 64, \ldots, 2, 1$ (In [7], figure 21a.2). With all eight only one direction is left: the multiples of 1 or of Γ, as part (a) says.

Proof of (b). $\mathcal{C} = MC$ (Section 21.8). $M = 1$ gives $\mathcal{C}_+ = C$ and $\Psi^c = \Psi^*$; $M = \Gamma$ gives $\mathcal{C}_- = \Gamma C$ and $\Psi^c = \Gamma\Psi^*$. □

Proof of (c). For $\mathcal{C}_+ = C$: $C^{-1} = C$, so $C^{-1}\gamma^a C = C\gamma^a C = -(\gamma^a)^T$ by (R3). For $\mathcal{C}_-$: the inverse of a product is the product of the inverses in reverse order, $\mathcal{C}_-^{-1} = C^{-1}\Gamma^{-1} = C\Gamma$, and

$$\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = C\Gamma\gamma^a\Gamma C = C(-\gamma^a\Gamma)\Gamma C = -C\gamma^a C = +(\gamma^a)^T$$

(first (R1), then $\Gamma\Gamma = 1$, then (R3)). Both are products of real matrices, hence real. $C^T = C$ is (R3); $(\Gamma C)^T = C^T\Gamma^T = C\Gamma = \Gamma C$ by the transpose rule, (R3), (R2). For the converse: by (R3) the equation $\gamma^a X = \zeta X(\gamma^a)^T$ reads $\gamma^a X = -\zeta XC\gamma^a C$; multiplying from the right by C gives $\gamma^a(XC) = -\zeta(XC)\gamma^a$, so by part (a) XC is a multiple of 1 when $\zeta = -1$ and of Γ when $\zeta = +1$; multiplying from the right by C gives $X = c\,C$ or $X = c\,\Gamma C$. □

The shape of the two matrices. $\Gamma = \mathrm{diag}(-1_8, 1_8)$, so ΓC is C with the signs of its first eight rows reversed; both have their entries only in the two diagonal 8×8 blocks (figure 21a.3).

21.10 The reality conditions, the bilinears and real fields

The reality (Majorana) conditions. A field equal to its own conjugate obeys $\Psi = M\Psi^*$. Is that a sensible requirement? Conjugating it gives $\Psi^* = M^*\Psi$, and inserting this back gives $\Psi = MM^*\Psi$. If $MM^* = 1$, this is automatically true and the condition is **consistent**; otherwise it forces further restrictions. For $M = 1$: $MM^* = 1$, and the condition $\Psi = \Psi^*$ says the field is real. For $M = \Gamma$: $\Gamma\Gamma^* = \Gamma\Gamma = 1$, and the condition $\Psi = \Gamma\Psi^*$ says, component by component, $\Psi_r = -\Psi_r^*$ for $r = 1, \ldots, 8$ (purely imaginary components, where $\Gamma = -1$) and $\Psi_r = \Psi_r^*$ for $r = 9, \ldots, 16$ (real components). Both conditions are consistent (lead check `majorana_conditions_consistent`; Notebook 21a, In [10], figure 21a.4).

How a bilinear changes, line by line. For a fixed matrix K the bilinear $\Psi^\dagger K\Psi = \sum_{r,c} \Psi_r^* K_{rc} \Psi_c$ is one number. Replace Ψ by $\Psi' = M\Psi^*$ with a real matrix M. Exchanging two components costs the factor $\epsilon = +1$ for commuting and $\epsilon = -1$ for anticommuting components (the conjugated components Ψ_r^* count as further anticommuting numbers).

Line 1. $(\Psi')^\dagger = (M\Psi^*)^\dagger = (\Psi^*)^\dagger M^\dagger = \Psi^T M^\dagger$ (the rule $(XY)^\dagger = Y^\dagger X^\dagger$; conjugating twice gives the number back). So $\Psi'^\dagger K \Psi' = \Psi^T M^\dagger K M \Psi^* = \sum_{r,c} \Psi_r \, (M^\dagger K M)_{rc} \, \Psi_c^*$.

Line 2. Exchange the factors Ψ_r and Ψ_c^*, which costs ϵ: $\sum_{r,c} \epsilon \, \Psi_c^* (M^\dagger K M)_{rc} \Psi_r$.

Line 3. Rename the summation letters, $r \leftrightarrow c$: $\sum_{r,c} \Psi_r^* \, \epsilon (M^\dagger K M)_{cr} \, \Psi_c = \Psi^\dagger K' \Psi$ with

$$K' = \epsilon \, (M^\dagger K M)^T .$$

If $K' = +K$ the bilinear is kept; if $K' = -K$ it is reversed.

The scalar and the currents. S has $K = C$, the current J^a has $K = -iC\gamma^a$. Both maps are real and symmetric, $M^\dagger = M$.

- $\mathcal{C}_+$ $(M = 1)$, scalar: $K' = \epsilon C^T = \epsilon C$ (R3). So $S \to \epsilon S$.
- $\mathcal{C}_+$, currents: $K' = \epsilon(-iC\gamma^a)^T = \epsilon(-i)(C\gamma^a)^T = \epsilon(-i)(-C\gamma^a) = -\epsilon K$ (the number $-i$ is not changed by a transpose; $C\gamma^a$ is antisymmetric, (R3)). So $J^a \to -\epsilon J^a$.
- $\mathcal{C}_-$ $(M = \Gamma)$, scalar: $\Gamma C \Gamma = C \Gamma \Gamma = C$ (R2), so $K' = \epsilon C$ and $S \to \epsilon S$.
- $\mathcal{C}_-$, currents: $\Gamma(-iC\gamma^a)\Gamma = -iC\Gamma\gamma^a\Gamma = -iC(-\gamma^a) = iC\gamma^a$ (R2, R1, $\Gamma\Gamma = 1$), and its transpose is $i(C\gamma^a)^T = -iC\gamma^a = K$. So $K' = \epsilon K$ and $J^a \to \epsilon J^a$.

map	**components**	S **becomes**	**every** J^a **becomes**
$\mathcal{C}_+$ $(M = 1)$	commuting $(\epsilon = +1)$	$+S$	$-J^a$
$\mathcal{C}_+$ $(M = 1)$	anticommuting $(\epsilon = -1)$	$-S$	$+J^a$
$\mathcal{C}_-$ $(M = \Gamma)$	commuting $(\epsilon = +1)$	$+S$	$+J^a$
$\mathcal{C}_-$ $(M = \Gamma)$	anticommuting $(\epsilon = -1)$	$-S$	$-J^a$

This is the table that the Revision record measured (lead check `bilinears_under_charge_conjugation`; Notebook 21a, In [14], compares with the record's own table). For the commuting field dirac16complex00, $\mathcal{C}_+$ keeps the mass and the scalar and reverses every current, in particular the charge density: it is the antiparticle map of this field. $\mathcal{C}_-$ reverses the mass and keeps the charge. The anticommuting rows are statements about classical Grassmann components; the quantised field is decided by the operator computation of Section 21.26. (The record's detail text adds in parentheses that normal ordering adds no sign: it subtracts the vacuum value, a number, so a bilinear that changes as $X \to sX + c$ has the normal-ordered form changing as $:X: \to s \; :X:$; the record makes no Fock-space computation for this. Its earlier remark that normal ordering supplies one more sign was withdrawn on 2026-10-08. Section 21.26 confirms the corrected text for the charge with explicit operators: the same-mass candidate counts the charge $Q - 16$, the charge shifted by a constant and not reversed, in agreement with the operator computation of Section 5.34.)

A check with numbers (Notebook 21a, In [17]): for one fixed complex column Ψ the notebook finds $S = +6.0205$ and $J^{(x4)} = +6.4970$; for Ψ^*, $S = +6.0205$ and $J^{(x4)} = -6.4970$; for $\Gamma\Psi^*$, $S = +6.0205$ and $J^{(x4)} = +6.4970$.

All 256 bilinears. Every 16×16 matrix is a combination of the 256 products $\Gamma_A = \gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ ($a_1 < \cdots < a_k$ in the order $x_0, \ldots, x_7$, $k = 0, \ldots, 8$, with $\Gamma_\emptyset = 1$), so the bilinears $\bar{\Psi}\Gamma_A\Psi = \Psi^\dagger C\Gamma_A\Psi$ are a complete list. The number k of gammas is the **degree**. For $\mathcal{C}_+$ with commuting components, $K' = (C\Gamma_A)^T$, and line by line:

$$(C\Gamma_A)^T = \Gamma_A^T C^T = (\gamma^{a_k})^T \cdots (\gamma^{a_1})^T\, C$$

(the transpose of a product reverses the order; $C^T = C$);

$$= (-C\gamma^{a_k}C)\cdots(-C\gamma^{a_1}C)\, C = (-1)^k C\gamma^{a_k}\cdots\gamma^{a_1} C\, C$$

(R3 for each factor; the inner pairs $CC = 1$ cancel);

$$= (-1)^k(-1)^{k(k-1)/2}\, C\gamma^{a_1}\cdots\gamma^{a_k} = (-1)^{k(k+1)/2}\, C\Gamma_A$$

($CC = 1$ at the end; reversing the order of k different anticommuting factors takes $k(k-1)/2$ exchanges, each costing a sign; and $k + k(k-1)/2 = k(k+1)/2$). So under $\mathcal{C}_+$ a commuting bilinear of degree k gets the sign $(-1)^{k(k+1)/2}$: $+, -, -, +, +, -, -, +, +$ for $k = 0, \ldots, 8$. For $\mathcal{C}_-$ the extra factor is $\Gamma C\Gamma_A\Gamma = C\,\Gamma\Gamma_A\Gamma = (-1)^k C\Gamma_A$ (R2, then R1 once for each of the k factors), so the sign is $(-1)^k(-1)^{k(k+1)/2} = (-1)^{k(k-1)/2}$ (the exponents differ by $2k$, an even number). Anticommuting components multiply every sign by $\epsilon = -1$. Notebook 21a computes the sign of all 256 bilinears in the four cases and finds exactly these rules (In [15], figure 21a.6).

Real fields. For a field with real commuting components three facts hold.

- (F1) **The currents vanish.** $J^a = -i\Psi^T A\Psi$ with the antisymmetric $A = C\gamma^a$ (R3). For every column u of real numbers and every antisymmetric A, the number $u^T Au$ equals its own transpose, $u^T Au = (u^T Au)^T = u^T A^T u = -u^T Au$ (a number is its own transpose; the transpose of a product reverses the order; $A^T = -A$), and a number equal to minus itself is zero. A real field carries no current and no U(1) charge.
- (F2) $\mathcal{C}_+$ **acts as the identity.** $\Psi^c = \Psi^* = \Psi$: a real field is its own same-mass conjugate.
- (F3) **The real matrix Γ reverses the mass.** The map $\Psi \to \Gamma\Psi$ (no conjugation) takes real fields to real fields. It keeps the scalar, $(\Gamma\Psi)^T C(\Gamma\Psi) = \Psi^T\Gamma^T C\Gamma\Psi = \Psi^T C\Psi$ (R2), and it reverses every kinetic matrix, $\Gamma^T C\gamma^a\Gamma = C\Gamma\gamma^a\Gamma = -C\gamma^a$ (R2, R1). In the field equation, Γ commutes with Ω_μ (an even matrix, R2) and with every derivative, and anticommutes with every γ^μ, so $\gamma^\mu D_\mu(\Gamma\Psi) = -\Gamma\gamma^\mu D_\mu\Psi = -V\,\Gamma\Psi$: with S unchanged, $\Gamma\Psi$ solves the equation with $(m, \lambda) \to (-m, -\lambda)$. This is theorem T1 of the Revision record (Section 21.19).

By Theorem CC, every real matrix that obeys the intertwiner condition of Section 21.8 is a multiple of 1 or of Γ. So for real fields, among the matrices that obey this condition, the only nontrivial matrix map is Γ, and it reverses the mass (lead check `real_fields_charge_conjugation`; Notebook 21a, In [18] and In [19], figure 21a.7). A real field has no charge to reverse (F1); what Γ exchanges is the sign of the mass. Plain complex conjugation, which is the identity on a real field, is never a matter-antimatter map for it.

21.11 The conjugations acting on an exact solution in the author's metric

Theorem CC is general. Here it is watched at work on an **exact solution of the field equation in the author's curved metric**, valid for every history $a_4(x_4)$, in particular the one in which the three extra times deflate exponentially.

The solution. The Revision record (`Revision/theory/field-theory.json`, formula `exact_solutions`, item (i)) states: for $U = 0$,

$$\Psi = \sin^{\alpha} z \,\Big(\cosh(kx_4)\, 1 + \frac{\sinh(kx_4)}{k} M_m \Big) \chi,$$

$$M_m = -m\gamma^{(x4)} + b\,\gamma^{(x4)}\gamma^{(x0)}, \qquad b = 3H(2\alpha+1), \qquad k^2 = b^2 - m^2,$$

with a constant column χ and any number α. It depends only on x_4 and z. **Why it solves the equation**, line by line:

Step 1. $M_m^2 = m^2\gamma^{(x4)}\gamma^{(x4)} - mb\big(\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)} + \gamma^{(x4)}\gamma^{(x0)}\gamma^{(x4)}\big) + b^2\gamma^{(x4)}\gamma^{(x0)}\gamma^{(x4)}\gamma^{(x0)}$ (the square multiplied out, keeping the order of the matrices).

Step 2. $\gamma^{(x4)}\gamma^{(x4)} = -1$ (x_4 is time-like) and $\gamma^{(x0)}\gamma^{(x0)} = +1$; $\gamma^{(x4)}\gamma^{(x0)}\gamma^{(x4)} = -\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)} = \gamma^{(x0)}$ (anticommute the last two, then $\gamma^{(x4)}\gamma^{(x4)} = -1$). So the bracket is $-\gamma^{(x0)} + \gamma^{(x0)} = 0$, and the last term is $b^2\gamma^{(x4)}(\gamma^{(x0)}\gamma^{(x4)})\gamma^{(x0)} = -b^2\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)}\gamma^{(x0)} = b^2$. Hence $M_m^2 = -m^2 + b^2 = k^2$ (times 1).

Step 3. Let $U(x_4) = \cosh(kx_4) + \sinh(kx_4)M_m/k$. Its derivative is $k\sinh(kx_4) + \cosh(kx_4)M_m$ (chain rule), and $M_m U = \cosh(kx_4)M_m + \sinh(kx_4)M_m^2/k = \cosh(kx_4)M_m + k\sinh(kx_4)$ (step 2): so $dU/dx_4 = M_m U$, and $\partial_4\Psi = M_m\Psi$ ($\sin^{\alpha} z$ and χ do not depend on x_4).

Step 4. The derivatives along $x_1, x_2, x_3, x_5, x_6, x_7$ vanish, so the factors $e^{\mp a_4}$ of the field equation multiply zero: **the solution holds for every history** a_4. With $\partial_0 = 6H\,\partial_z$ (chain rule, $z = 6Hx_0$) the equation becomes

$$E_m[\Psi] \equiv \gamma^{(x4)}\partial_4\Psi + 6H\tan z\,\gamma^{(x0)}\partial_z\Psi + 3H\gamma^{(x0)}\Psi - m\Psi = 0.$$

Step 5. $\gamma^{(x4)}\partial_4\Psi = \gamma^{(x4)}M_m\Psi = \big(-m\gamma^{(x4)}\gamma^{(x4)} + b\gamma^{(x4)}\gamma^{(x4)}\gamma^{(x0)}\big)\Psi = (m - b\gamma^{(x0)})\Psi$ (step 3, then $\gamma^{(x4)}\gamma^{(x4)} = -1$).

Step 6. $\partial_z \sin^{\alpha} z = \alpha \sin^{\alpha-1} z \cos z$, so $\partial_z\Psi = \alpha\cot z\,\Psi$ and $6H\tan z\,\gamma^{(x0)}\partial_z\Psi = 6H\alpha\,\gamma^{(x0)}\Psi$ ($\tan z \cot z = 1$).

Step 7. Adding: $E_m[\Psi] = \big(m - b\gamma^{(x0)} + 6H\alpha\gamma^{(x0)} + 3H\gamma^{(x0)} - m\big)\Psi = \big(3H(2\alpha+1) - b\big)\gamma^{(x0)}\Psi = 0$, because $b = 3H(2\alpha+1)$.

The record checks this exactly (check `exact_solution_family_x4_x0` of `Revision/theory/reports/python-field-theory.json`), and Notebook 21a checks it again with sympy (In [11]).

The numbers chosen. $H = 1/6$ (so $z = x_0$), $\alpha = 1$ and $m = 2$. Then $b = 3 \cdot \frac{1}{6} \cdot 3 = \frac{3}{2}$ and $k^2 = \frac{9}{4} - 4 = -\frac{7}{4} < 0$. So $k = iw$ with $w = \sqrt{7}/2$ is imaginary; with $\cosh(iwx_4) = \cos(wx_4)$ and $\sinh(iwx_4)/(iw) = \sin(wx_4)/w$ the solution oscillates in time, and $U = \cos(wx_4) + \sin(wx_4)M_m/w$ is a **real** matrix.

The two conjugates. Since U and $\sin z$ are real, $\Psi^* = \sin z\, U\chi^*$: the same formula with the column χ^*, so Ψ^* solves the equation with the **same** mass $+2$. For the other, $\Gamma M_m \Gamma = -m\Gamma\gamma^{(x4)}\Gamma + b\Gamma\gamma^{(x4)}\gamma^{(x0)}\Gamma = m\gamma^{(x4)} + b\gamma^{(x4)}\gamma^{(x0)} = M_{-m}$ (R1 for the single gamma, R2 for the pair), and k^2 is the same for $\pm m$; so $\Gamma U_m \Gamma = U_{-m}$ and $\Gamma\Psi^* = \sin z\, U_{-m}(\Gamma\chi^*)$: the solution formula with the mass -2. $\Gamma\Psi^*$ **solves the equation with the reversed mass** -2**.** The negative controls fail: $E_{-2}[\Psi^*] = E_{+2}[\Psi^*] + 4\Psi^* = 4\Psi^*$ (the last term of E_m changes by $-(-2)\Psi^* + 2\Psi^*$), so its size is four times the size of Ψ^*, about 10; the notebook measures at least 9.67 along the time (In [13]). By the table of Section 21.10, Ψ^* carries the charge density $-J^{(x4)}$ and $\Gamma\Psi^*$ carries $+J^{(x4)}$ (figure 21a.5).

21.12 Example: Notebook 21a solves for every charge-conjugation matrix

Notebook 21a turns Sections 21.7 to 21.11 into exact computations on the author's gammas. It reads the gammas from `Revision/algebra/gammas.json` and the lead report `Revision/lead_checks/reports/charge-conjugation-and-u1.json`; it checks the eight real gammas and draws them; it builds C, Γ, B and the S^{ab}; it writes the conditions $M(\gamma^a)^* = s\gamma^a M$ as two systems of 2048 linear equations for the 256 entries of M and solves them exactly over the rational numbers; it watches each equation halve the solution space; it builds $\mathcal{C}_+$ and $\mathcal{C}_-$, checks their transposition rules and solves the transposition equations; it checks the two reality conditions; it reads the field equation and the exact solution from the field-theory record word for word and applies both conjugations to the solution; it computes the signs of all 256 bilinears; and it treats real fields. Nine of its checks reproduce checks of the lead report, two reproduce the field-theory record. It runs in about 30 seconds; the times measured on the build computer, which depend on how busy that computer is, are recorded in the notebook's provenance file `Revision/textbook/notebooks/21a_conjugation_matrices.PROVENANCE.md`. It needs no Rust, prints 27 PASS lines and draws seven figures.

21.13 How to run Notebook 21a

Step 1. What this notebook does and what it needs.

Notebook 21a (Charge conjugation is a matrix: calC_+ = C and calC_- = Gamma C) is the file `Revision/textbook/notebooks/21a_conjugation_matrices.ipynb` of the repository Dirac_claude. It checks that the eight gamma matrices of the Revision record are real 16 by 16 matrices that obey the Clifford relation of signature (4,4), solves exactly the linear equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (conj is the complex conjugate; s = +1 keeps the mass, s = -1 reverses it) and finds two one-dimensional solution spaces spanned by 1 and by the chirality Gamma, watches each of the eight equations halve the solution space, builds the charge-conjugation matrices calC_+ = C and calC_- = Gamma C with their transposition rules and reality conditions, applies both conjugations to an exact solution of the field equation in the author's curved metric (valid for every history a4, the deflating one included), tabulates how all 256 bilinears change sign for commuting and for anticommuting components, and shows that for a REAL field calC_+ is the identity while the real matrix Gamma reverses the mass. Seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 21a_conjugation_matrices.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21a_conjugation_matrices.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 21a_conjugation_matrices.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/21a.captions.json`
- `Revision/textbook/figures/21a_1_eight_gammas.png`
- `Revision/textbook/figures/21a_2_halving_solutions.png`
- `Revision/textbook/figures/21a_3_conjugation_matrices.png`
- `Revision/textbook/figures/21a_4_reality_conditions.png`
- `Revision/textbook/figures/21a_5_curved_solution_images.png`
- `Revision/textbook/figures/21a_6_bilinear_signs.png`
- `Revision/textbook/figures/21a_7_real_fields.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the seven figure files of notebook 21a exist
ALL 27 CHECKS PASSED (notebook 21a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/21a_conjugation_matrices.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 21a_conjugation_matrices.ipynb
python -m nbconvert --execute --inplace 21a_conjugation_matrices.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder `Revision/algebra`, `Revision/theory` or `Revision/lead_checks`: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder `Revision/textbook/notebooks`.

21.14 Notebook 21a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/21a_conjugation_matrices.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

**Charge conjugation is a matrix.** In this theory every particle field $\Psi$ is a
column of 16 numbers, and the field equation contains eight $16 \times 16$ gamma
matrices. The author's gamma matrices are *real*: every entry is $-1$, $0$ or
$+1$. For a *real* field ($\Psi^* = \Psi$) plain complex conjugation changes
nothing at all: it is the identity map, and it cannot turn matter into
antimatter. Charge conjugation must therefore be built with a **matrix**
$\mathcal{C}$:

$$\Psi^c = \mathcal{C}\,\bar\Psi^T = \mathcal{C}\,C\,\Psi^* ,$$

where $\bar\Psi = \Psi^\dagger C$ is the Dirac adjoint and $C$ the charge matrix
(the author's sigma16). This notebook finds, exactly, every matrix that obeys the
intertwiner condition of Section 4 (the definition of a charge-conjugation matrix
used by the Revision record). It

1. checks that the Revision record holds **eight real $16 \times 16$ gamma
   matrices** that obey the Clifford relation of signature (4,4), and draws them;
2. solves the linear equations $M(\gamma^a)^* = s\,\gamma^a M$
   ($a = x0, \dots, x7$) for all $16 \times 16$ matrices $M = \mathcal{C}C$: for
   $s = +1$ (same mass) the solutions are the multiples of $1$, for $s = -1$ (mass
   reversed) the multiples of the chirality $\Gamma$; it also shows how each of
   the eight equations halves the space of solutions;
3. builds the two charge-conjugation matrices $\mathcal{C}_+ = C$ and
   $\mathcal{C}_- = \Gamma C$, checks their transposition rules and their reality
   (Majorana) conditions;
4. applies both conjugations to an **exact solution of the field equation in the
   author's curved metric** and shows which mass each image solves the equation
   with;
5. computes how all 256 bilinears $\bar\Psi\,\Gamma_A\Psi$ change sign, for
   commuting and for anticommuting components;
6. treats **real fields**: the current vanishes, $\mathcal{C}_+$ is the identity,
   and, among the matrices that obey the intertwiner condition, the nontrivial
   real map is the matrix $\Gamma$ with the mass reversed.

Nine checks reproduce checks of the Revision record
`Revision/lead_checks/reports/charge-conjugation-and-u1.json`; two more read the
field equation and its exact solution from the Revision field-theory record
`Revision/theory/field-theory.json` and reproduce the check
exact_solution_family_x4_x0 of `Revision/theory/reports/python-field-theory.json`.
Seven teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 21a (Charge conjugation is a matrix: calC_+ = C and calC_- = Gamma C) is the
file ‘Revision/textbook/notebooks/21a_conjugation_matrices.ipynb‘ of the repository
Dirac_claude. It checks that the eight gamma matrices of the Revision record are real 16
by 16 matrices that obey the Clifford relation of signature (4,4), solves exactly the
linear equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (conj is the
complex conjugate; s = +1 keeps the mass, s = -1 reverses it) and finds two
one-dimensional solution spaces spanned by 1 and by the chirality Gamma, watches each of
the eight equations halve the solution space, builds the charge-conjugation matrices
calC_+ = C and calC_- = Gamma C with their transposition rules and reality conditions,
applies both conjugations to an exact solution of the field equation in the author’s
curved metric (valid for every history a4, the deflating one included), tabulates how all
256 bilinears change sign for commuting and for anticommuting components, and shows that
for a REAL field calC_+ is the identity while the real matrix Gamma reverses the mass.
Seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
```

```
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 21a_conjugation_matrices.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step

"What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 21a_conjugation_matrices.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 21a_conjugation_matrices.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/21a.captions.json‘
- ‘Revision/textbook/figures/21a_1_eight_gammas.png‘
- ‘Revision/textbook/figures/21a_2_halving_solutions.png‘
- ‘Revision/textbook/figures/21a_3_conjugation_matrices.png‘
- ‘Revision/textbook/figures/21a_4_reality_conditions.png‘
- ‘Revision/textbook/figures/21a_5_curved_solution_images.png‘
- ‘Revision/textbook/figures/21a_6_bilinear_signs.png‘
- ‘Revision/textbook/figures/21a_7_real_fields.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the seven figure files of notebook 21a exist
ALL 27 CHECKS PASSED (notebook 21a)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/21a_conjugation_matrices.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 21a_conjugation_matrices.ipynb
      python -m nbconvert --execute --inplace 21a_conjugation_matrices.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file in the folder ‘Revision/algebra‘, ‘Revision/theory‘ or ‘Revision/lead_checks‘: the notebook was opened outside the repository, or the repository is incomplete; clone the repository again and open the notebook from its folder ‘Revision/textbook/notebooks‘.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 21a (the complete instructions)
```

```
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 21a (Charge conjugation is a matrix: calC_+ = C and calC_- = Gamma C) is the
# file Revision/textbook/notebooks/21a_conjugation_matrices.ipynb of the repository
# Dirac_claude. It checks that the eight gamma matrices of the Revision record are real
# 16 by 16 matrices that obey the Clifford relation of signature (4,4), solves exactly
# the linear equations M conj(gamma^a) = s gamma^a M for all 16 by 16 matrices M (conj is
# the complex conjugate; s = +1 keeps the mass, s = -1 reverses it) and finds two
# one-dimensional solution spaces spanned by 1 and by the chirality Gamma, watches each
# of the eight equations halve the solution space, builds the charge-conjugation matrices
# calC_+ = C and calC_- = Gamma C with their transposition rules and reality conditions,
# applies both conjugations to an exact solution of the field equation in the author's
# curved metric (valid for every history a4, the deflating one included), tabulates how
# all 256 bilinears change sign for commuting and for anticommuting components, and shows
# that for a REAL field calC_+ is the identity while the real matrix Gamma reverses the
# mass. Seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
```

```
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
```

```
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 21a_conjugation_matrices.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 21a_conjugation_matrices.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
```

```
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 21a_conjugation_matrices.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/21a.captions.json
# - Revision/textbook/figures/21a_1_eight_gammas.png
# - Revision/textbook/figures/21a_2_halving_solutions.png
# - Revision/textbook/figures/21a_3_conjugation_matrices.png
# - Revision/textbook/figures/21a_4_reality_conditions.png
# - Revision/textbook/figures/21a_5_curved_solution_images.png
# - Revision/textbook/figures/21a_6_bilinear_signs.png
# - Revision/textbook/figures/21a_7_real_fields.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the seven figure files of notebook 21a exist
#     ALL 27 CHECKS PASSED (notebook 21a)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/21a_conjugation_matrices.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
```

```
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 21a_conjugation_matrices.ipynb
#     python -m nbconvert --execute --inplace 21a_conjugation_matrices.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file in the folder Revision/algebra, Revision/theory or
#   Revision/lead_checks: the notebook was opened outside the repository, or the
#   repository is incomplete; clone the repository again and open the notebook from its
#   folder Revision/textbook/notebooks.
#
# ------------------------------------------------------------------------------------

```

Text cell:

```
## 3. The words used in this notebook

- **Matrix**: a rectangular table of numbers; a $16 \times 16$ matrix has 16 rows
  and 16 columns. The product $AB$ of two matrices has the entry $\sum_k A_{rk}
  B_{kc}$ in row $r$ and column $c$. The **identity** $1$ has ones on the diagonal
  and zeros elsewhere: $1A = A1 = A$.
- **Real, complex conjugate**: $z^* = a - ib$ for $z = a + ib$; a matrix or a
```

```
  column is *real* when all its entries are real, so that $M^* = M$.
- **Transpose** $M^T$: rows and columns exchanged, $(M^T)_{rc} = M_{cr}$;
  **symmetric**: $M^T = M$; **antisymmetric**: $M^T = -M$; **conjugate
  transpose** $M^\dagger = (M^*)^T$; **Hermitian**: $M^\dagger = M$.
- **Spinor field** $\Psi$: at every point a column of 16 numbers (components).
  The author's coordinates are $x1, x2, x3$ (ordinary space), $x4$ (the time),
  $x5, x6, x7$ (the three extra times, which deflate exponentially) and $x0$ (the
  hidden direction).
- **Gamma matrices** $\gamma^{(x0)}, \dots, \gamma^{(x7)}$: eight fixed
  $16 \times 16$ matrices with the **Clifford relation** $\gamma^a\gamma^b +
  \gamma^b\gamma^a = 2\eta^{ab}\,1$, where $\eta = \mathrm{diag}(+1, +1, +1, +1, -1,
  -1, -1, -1)$ in the order $x0, \dots, x7$ (**signature (4,4)**: four plus signs,
  four minus signs).
- **Charge matrix** $C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$
  (the product of the four space-like gammas); **Dirac adjoint**
  $\bar\Psi = \Psi^\dagger C$; **chirality** $\Gamma = \gamma^{(x0)}\gamma^{(x1)}
  \cdots\gamma^{(x7)}$ (all eight); **Krein matrix** $B = -iC\gamma^{(x4)}$.
- **Field equation**: $(\gamma^\mu D_\mu - V)\Psi = 0$ with $V = m + U'(S)$ real,
  $m$ the **mass**, $S = \bar\Psi\Psi$ the **scalar**; $D_\mu$ is the derivative
  with the gravitational spin connection.
- **Charge-conjugation matrix** $\mathcal{C}$: a constant matrix for which
  $M = \mathcal{C}C$ obeys the **intertwiner condition**
  $M(\gamma^a)^* = s\,\gamma^a M$ for all eight $a$, with one sign $s$ ($s = +1$
  same mass, $s = -1$ mass reversed); this is the definition of the Revision
  record. Then $\Psi^c = \mathcal{C}\bar\Psi^T$ solves a field equation of the
  same form whenever $\Psi$ does (Section 4); the converse is not true in
  general (Section 4).
- **Solution space, dimension**: all solutions of a set of linear equations form a
  space; its *dimension* is the number of free numbers in the general solution.
- **Bilinear**: $\Psi^\dagger K\Psi = \sum_{r,c}\Psi_r^* K_{rc}\Psi_c$ for a fixed
  matrix $K$; the scalar $S = \Psi^\dagger C\Psi$ and the **current**
  $J^a = -i\bar\Psi\gamma^a\Psi$ are bilinears.
- **Commuting, anticommuting components**: the components of dirac16complex00 are
  ordinary numbers ($\Psi_r\Psi_c = \Psi_c\Psi_r$); those of dirac16complex are
  anticommuting (Grassmann) numbers ($\Psi_r\Psi_c = -\Psi_c\Psi_r$). We write
  $\epsilon = +1$ and $\epsilon = -1$ for the two cases.
- **Majorana (reality) condition**: the requirement $\Psi^c = \Psi$.
```

Text cell:

```
## 4. The physical and mathematical situation

**Why a matrix is needed.** Antimatter is described by the *charge conjugate*
$\Psi^c$ of a field: a field built from $\Psi$ that solves the field equation
again and carries the opposite charge. In Dirac's theory of the electron, whose
gamma matrices are complex, $\Psi^c$ involves the complex conjugate $\Psi^*$
together with a matrix. The author's gammas are real; then for a real field
$\Psi^* = \Psi$, and complex conjugation alone does nothing. The matrix is
essential. We derive a condition on the matrix that is enough for $\Psi^c$ to be
a solution, and then we find all matrices that obey the condition below.

**Deriving the condition on the matrix**, line by line. Let $\Psi$ solve
$\gamma^\mu D_\mu\Psi = V\Psi$ with real $V$. In the author's metric the gammas
```

$\gamma^\mu = e^\mu{}_a\gamma^a$ and the spin connection Ω_μ in
$D_\mu = \partial_\mu + \Omega_\mu$ are real (Revision lead check
spinor_connection_real), so the operator $\gamma^\mu D_\mu$ is real.

1. Take the complex conjugate of the equation. Every real factor stays as it is,
   so $\gamma^\mu D_\mu\Psi^* = V\Psi^*$.
2. Multiply from the left by a constant matrix M:
   $M\gamma^\mu D_\mu\Psi^* = V\,M\Psi^*$.
3. Suppose $M\gamma^a = s\,\gamma^a M$ for every a, with one sign $s = \pm1$.
   The spin connection is a sum of products $\gamma^a\gamma^b$, and
   $M\gamma^a\gamma^b = s\gamma^a M\gamma^b = s^2\gamma^a\gamma^b M =
   \gamma^a\gamma^b M$, so M commutes with Ω_μ and $MD_\mu = D_\mu M$.
4. Hence $M\gamma^\mu D_\mu\Psi^* = s\,\gamma^\mu D_\mu(M\Psi^*)$, and step 2
   becomes $s\,\gamma^\mu D_\mu(M\Psi^*) = V\,(M\Psi^*)$. Multiplying by s (and
   using $s^2 = 1$):
   $$\gamma^\mu D_\mu(M\Psi^*) = s\,V\,(M\Psi^*) .$$
   So $M\Psi^*$ solves the equation with the same V when $s = +1$ and with
   $-V$ (the mass reversed) when $s = -1$.

Because the gammas are real, $(\gamma^a)^* = \gamma^a$ and the condition is
$M(\gamma^a)^* = s\,\gamma^a M$: it is enough that M commutes ($s = +1$) or
anticommutes ($s = -1$) with all eight gammas (the converse fails for $V = 0$,
see below). The textbook form of charge conjugation is
$\Psi^c = \mathcal{C}\bar\Psi^T$; since $\bar\Psi^T = (\Psi^\dagger C)^T =
C^T\Psi^* = C\Psi^*$ (C is symmetric), $\Psi^c = \mathcal{C}C\Psi^*$, so
$M = \mathcal{C}C$ and, because $CC = 1$, $\mathcal{C} = MC$.

The definition. A **charge-conjugation matrix** is a constant matrix
$\mathcal{C}$ for which $M = \mathcal{C}C$ obeys this **intertwiner condition**
$M(\gamma^a)^* = s\,\gamma^a M$ with one sign s for all eight a. This is the
definition of the Revision record: its checks intertwiners_same_mass and
intertwiners_reversed_mass solve exactly this condition. Steps 1 to 4 show that
the condition is enough for $M\Psi^*$ to be a solution. The converse is not true
in general: for $V = 0$ (mass 0, no self-interaction) the chiral projector
$P_- = \frac12(1 - \Gamma)$ also maps every solution to a solution without
obeying the condition for either sign (Notebook 05c). The count below therefore
concerns the matrices that obey the condition.

What to expect. The matrices that commute with all eight gammas are the
multiples of 1, because the 16 components carry an *irreducible*
representation of Pin(4,4). If M anticommutes with every gamma, then ΓM
commutes with every gamma (since Γ anticommutes with every gamma), so
$\Gamma M = c\,1$ and $M = c\,\Gamma$. The notebook solves the 4096 equations
exactly and finds exactly these two families.

Text cell:

5. The eight real gamma matrices of the Revision record

The next cell reads the Revision record ‘Revision/algebra/gammas.json‘, which holds
the author’s eight gamma matrices (rebuilt in Revision code from the author’s
formulas) in the order $x0, \dots, x7$, and the frame metric η. It stores
each gamma as a numpy array of whole numbers, defines a helper for products of

```
gammas, and reads the Revision record of the lead checks, whose verdicts the
notebook will reproduce.
```

In [2]:

```
import itertools  # all subsets of a list (for the 256 products of gammas)

import numpy as np  # arrays of numbers, matrices and linear algebra

fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # the list "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
# gamma["x4"] is gamma^(x4), a 16 x 16 array of whole numbers (int64)
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1

def product(directions):
    """The matrix product gamma^(d1) gamma^(d2) ... in the order of the list."""
    result = I16
    for d in directions:
        result = result @ gamma[d]  # @ is the matrix product
    return result

RECORD = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
lead = json.loads(repository_file(RECORD).read_text(encoding="utf-8"))
LEAD = {c["name"]: c for c in lead["checks"]}  # check name -> its entry

## 6. C, the chirality Gamma, B and the generators S^ab

The next cell builds, from the gammas, the charge matrix $C = \gamma^{(x0)}
\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$, the chirality $\Gamma = \gamma^{(x0)}
\gamma^{(x1)}\cdots\gamma^{(x7)}$, the Krein matrix $B = -iC\gamma^{(x4)}$ (`1j` is
Python's imaginary unit $i$) and the 28 generators $S^{ab} = \tfrac14[\gamma^a,
\gamma^b]$ of the rotations and boosts. It compares $C$ and $\Gamma$ with the
matrices stored in the record and checks: $C$ is real and symmetric with $C^2 =
1$; $\Gamma = \mathrm{diag}(-1, \dots, -1, +1, \dots, +1)$ (eight of each); all
$S^{ab}$ are real (record check representation_real); $B$ is purely imaginary,
Hermitian and $B^2 = 1$ (record check B_imaginary_hermitian).
```

In [5]:

## 7. Every matrix that obeys the condition, solved exactly

Write the unknown matrix $M$ as its 256 entries $M_{rc}$. For one gamma the
condition $M(\gamma^a)^* - s\,\gamma^a M = 0$ is a $16 \times 16$ matrix of
zeros, that is, 256 linear equations in the 256 unknowns; for all eight gammas
2048 equations. (For both signs together: 4096.) Reading the entries of $M$ row
by row as one long column $y$, the product $MG$ becomes $(1 \otimes G^T)\,y$ and
$GM$ becomes $(G \otimes 1)\,y$, where $\otimes$ is the Kronecker product
(`np.kron`): the block matrix whose block $(r, c)$ is the entry $A_{rc}$ times the
whole matrix $B$. The next cell builds the coefficient matrix of these equations
and solves them **exactly**, with rational numbers (sympy's `DomainMatrix` over
the rationals `QQ`), so no rounding can hide or invent a solution.
```

In [6]:

```
import sympy as sp  # exact algebra
from sympy.polys.matrices import DomainMatrix  # exact matrices over the rationals
```

```
def conjugation_system(s, directions=COORDS):

**Each equation halves the solution space.** Imposing the condition for only the
first $k$ gammas ($k = 0, 1, \dots, 8$) leaves more solutions. The next cell
computes the dimension of the solution space for each $k$ exactly, as $256$ minus
the *rank* of the coefficient matrix (the number of independent equations among
them), and plots it. Why halving: a matrix $M$ that commutes with $\gamma^{(x1)}$
maps each of its two eigenspaces (dimension 8 each, eigenvalues $\pm1$) into
itself, which leaves $8 \cdot 8 + 8 \cdot 8 = 128$ free entries of the 256; each
further gamma cuts the freedom in half again, down to $256/2^8 = 1$.
```

## 8. The two charge-conjugation matrices

From $M = 1$ and $M = \Gamma$ we get $\mathcal{C} = MC$:
$$\mathcal{C}_+ = C, \qquad \mathcal{C}_- = \Gamma C .$$
The next cell checks the **transposition rules** that characterise them,
$\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$ and
$\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$ for every $a$, and that
both are real (and symmetric). Then it solves, again exactly, the equations
$\gamma^a X = \zeta X(\gamma^a)^T$ for all $a$ with $\zeta = -1$ and $\zeta = +1$:
their only solutions are the multiples of $C$ and of $\Gamma C$, so these two
matrices are the only ones with such transposition rules.
```

## 9. The two reality (Majorana) conditions

A field that equals its own conjugate, $\Psi^c = \Psi$, satisfies
$\Psi = M\Psi^*$. Applying the condition twice gives $\Psi = M(M\Psi^*)^* =
MM^*\Psi$, so the condition can hold for nonzero fields without contradiction only
if $MM^* = 1$. For $M = 1$ the condition is $\Psi = \Psi^*$: the field is real.
For $M = \Gamma$ it is $\Psi = \Gamma\Psi^*$: the last eight components (where
$\Gamma = +1$) are real and the first eight (where $\Gamma = -1$) are purely
imaginary. The next cell checks $MM^* = 1$ for both (record check
majorana_conditions_consistent), makes one example of each kind from a fixed
complex column $v$ by $\Psi = (v + Mv^*)/2$, checks that each example satisfies
its condition, and draws them.
```

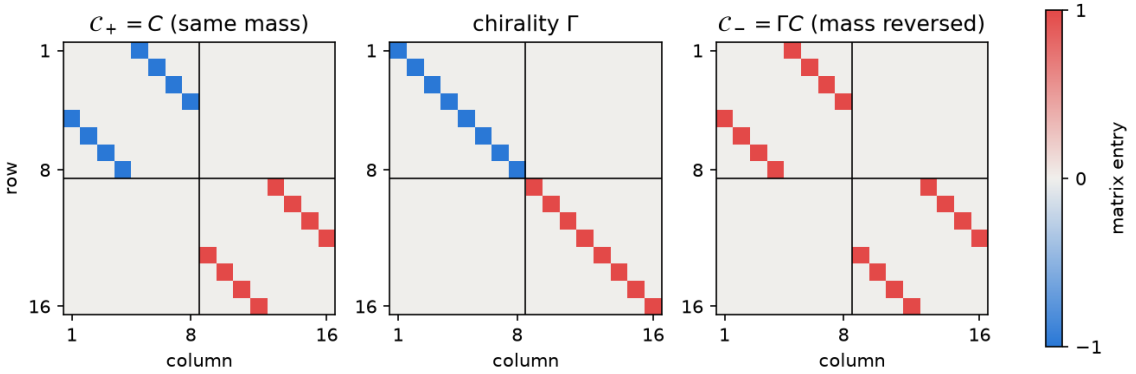

Figure 524: Heat maps of the two charge-conjugation matrices and of the chirality that relates them: $\mathcal{C}_+ = C$ (left, the conjugation that keeps the mass), Γ (middle) and $\mathcal{C}_- = \Gamma C$ (right, the conjugation that reverses the mass); horizontal axis the column, vertical axis the row, colour the entry (red $+1$, blue -1, pale 0). C and ΓC have their entries only in the two diagonal blocks, and they differ only by the sign of the upper half, where $\Gamma = -1$. (Notebook 21a, figure 3.)

## 10. The conjugations acting on an exact solution in the author's metric

The Revision field-theory record (‘Revision/theory/field-theory.json‘, formula
exact_solutions, item (i)) gives an exact solution of the field equation with
$U = 0$ in the author's curved metric:
$$\Psi = \sin^\alpha z\,\Big(\cosh(kx_4)\,1 + \frac{\sinh(kx_4)}{k}\,M_m\Big)\chi,
\quad M_m = -m\gamma^{(x4)} + b\,\gamma^{(x4)}\gamma^{(x0)},\quad b = 3H(2\alpha+1),
```

```
\quad k^2 = b^2 - m^2,$$
with $z = 6Hx_0$ and a constant column $\chi$. It depends only on $x_4$ and $x_0$.
The field equation of the record reads
$$e^{-a_4}\sin^{-1/6}z\,(\gamma^{(x1)}\partial_1 + \gamma^{(x2)}\partial_2 +
\gamma^{(x3)}\partial_3)\Psi + \gamma^{(x4)}\partial_4\Psi + e^{a_4}\sin^{-1/6}z
\,(\gamma^{(x5)}\partial_5 + \gamma^{(x6)}\partial_6 + \gamma^{(x7)}\partial_7)\Psi
+ \tan z\,\gamma^{(x0)}\partial_0\Psi + 3H\gamma^{(x0)}\Psi = m\Psi .$$
The derivatives along $x1, x2, x3, x5, x6, x7$ vanish for this $\Psi$, so the
factors $e^{\mp a_4}$ drop out: the solution holds for **every** history
$a_4(x_4)$, in particular for the one in which the three extra times deflate
exponentially. What remains is
$$E_m[\Psi] = \gamma^{(x4)}\partial_4\Psi + 6H\tan z\,\gamma^{(x0)}\partial_z\Psi
+ 3H\gamma^{(x0)}\Psi - m\Psi = 0 ,$$
where $\partial_0 = 6H\,\partial_z$ by the chain rule ($z = 6Hx_0$).

We take $H = 1/6$ (so that $z = x_0$), $\alpha = 1$ and $m = 2$. Then $b = 3/2$
and $k^2 = 9/4 - 4 = -7/4 < 0$, so $k = i\sqrt7/2$ is imaginary; with
$\cosh(i\theta) = \cos\theta$ and $\sinh(i\theta)/i = \sin\theta$ the solution
oscillates: $\cosh(kx_4) = \cos(wx_4)$ and $\sinh(kx_4)/k = \sin(wx_4)/w$ with
$w = \sqrt7/2$. Both are real functions, so conjugation acts only on $\chi$.

The next cell first reads the two formulas from the Revision record (written there
in Wolfram notation: ‘g[x4]‘ is $\gamma^{(x4)}$, ‘d4‘ is $\partial_4$, ‘al‘ is
$\alpha$, ‘E^a4[x4]‘ is $e^{a_4}$) and checks that they are, word for word, the
formulas written above, so that any later change of the record is caught. Then it
builds $\Psi$ with sympy for a fixed complex $\chi$ and checks, exactly, that
$E_m[\Psi] = 0$ (Revision check exact_solution_family_x4_x0).

```
The next cell forms the two conjugates. Because the matrix $U$ in $\Psi =
\sin z\,U\chi$ is real, $\Psi^* = \sin z\,U\chi^*$ and $\Gamma\Psi^* = \sin z\,
\Gamma U\chi^*$. The general argument of section 4 predicts: $\Psi^*$ solves the
equation with the **same** mass $m = 2$, and $\Gamma\Psi^*$ with the **reversed**
mass $-2$. The cell checks both exactly, and checks the two negative controls:
$\Psi^*$ does not solve the equation with $-2$, and $\Gamma\Psi^*$ does not solve
it with $+2$.
```

In [12]:

```
Psi_conj = Psi.conjugate()  # Psi*: every entry complex-conjugated (x4, z are real)
Psi_gamma_conj = Gamma_s * Psi_conj  # Gamma Psi*

def vanishes(vector):

```

Text cell:

```
The next cell turns the exact expressions into fast numerical functions
(‘sp.lambdify‘) and evaluates them along the time $x_4$ at the fixed angle
$z = \pi/4$. It computes the charge density $J^{(x4)} = \Psi^\dagger B\Psi$ of
$\Psi$, $\Psi^*$ and $\Gamma\Psi^*$ (‘np.einsum("tr,rc,tc->t", ...)‘ forms
$\sum_{r,c}\Psi_r^* B_{rc}\Psi_c$ at every time $t$) and checks the signs of the
table of section 11 below: $\Psi^*$ carries $-J^{(x4)}$, $\Gamma\Psi^*$ carries
$+J^{(x4)}$. It also computes the size of the left-hand side of the field
equation, $|E_{\pm2}[\cdot]|$ (the square root of the sum of the squared moduli of
its 16 components). Where a field solves the equation, $|E|$ is zero up to
rounding (about $10^{-15}$). Where it does not, $|E|$ is far from zero: since
$E_{-2}[\Psi^*] = E_{+2}[\Psi^*] + 4\Psi^*$ and the first term vanishes,
$|E_{-2}[\Psi^*]| = 4|\Psi^*|$, about 10 here (and in the same way
$|E_{+2}[\Gamma\Psi^*]| = 4|\Gamma\Psi^*|$). The cell checks this too. The figure
shows the charge densities on the left and $|E|$ on a logarithmic scale on the
right.

## 11. How the bilinears change: the sign table

Under $\Psi \to M\Psi^*$ a bilinear $\Psi^\dagger K\Psi = \sum_{r,c}\Psi_r^*K_{rc}
```

```
\Psi_c$ becomes $\sum_{r,c}(M\Psi^*)_r^*K_{rc}(M\Psi^*)_c = \sum\Psi_r(M^\dagger
KM)_{rc}\Psi_c^*$ ($M$ is real). To bring this back to the form $\sum\Psi^*_c
(\dots)\Psi_r$ we exchange the two factors $\Psi_r$ and $\Psi_c^*$: for commuting
components this costs nothing, for anticommuting components a sign. Hence the new
bilinear is $\Psi^\dagger K'\Psi$ with
$$K' = \epsilon\,(M^\dagger KM)^T ,\qquad \epsilon = +1 \text{ (commuting)},\
\epsilon = -1 \text{ (anticommuting)} .$$
If $K' = \pm K$, the bilinear keeps or reverses its sign. The next cell computes
this for the scalar $S$ ($K = C$) and the eight currents $J^a$ ($K = -iC\gamma^a$),
for both matrices and both kinds of components, and compares with the signs
measured in the Revision record (check bilinears_under_charge_conjugation).

Text cell:

```
**All 256 bilinears.** Every $16 \times 16$ matrix is a combination of the 256
products $\Gamma_A = \gamma^{a_1}\gamma^{a_2}\cdots\gamma^{a_k}$ ($a_1 < \dots <
a_k$ in the order $x0, \dots, x7$, $k = 0, \dots, 8$; $\Gamma_\emptyset = 1$), so
the bilinears $\bar\Psi\Gamma_A\Psi = \Psi^\dagger C\Gamma_A\Psi$ are a complete
list. The next cell computes the sign of each of them for the four cases. The
result depends only on the number $k$ of gammas (the *degree*): for commuting
components $\mathcal{C}_+$ gives $(-1)^{k(k+1)/2}$ and $\mathcal{C}_-$ gives
$(-1)^{k(k-1)/2}$; anticommuting components add one more factor $-1$.
```

In [15]:

## 12. Real fields

For a **real** field ($\Psi^* = \Psi$) with commuting components:

1. $\mathcal{C}_+$ maps $\Psi$ to $\Psi^c = \Psi^* = \Psi$: it is the identity. A
   real field is its own charge conjugate.
2. Every current vanishes: $J^a = -i\Psi^TC\gamma^a\Psi = 0$, because the matrix
   $C\gamma^a$ is antisymmetric, and $\Psi^TA\Psi = \sum_{r,c}\Psi_rA_{rc}\Psi_c$
   is zero for an antisymmetric $A$ (the terms $(r, c)$ and $(c, r)$ cancel). A
   real field carries no U(1) charge.
3. The real matrix $\Gamma$ maps real fields to real fields, keeps
   $S = \Psi^TC\Psi$ (since $\Gamma^TC\Gamma = C$) and reverses every kinetic
```

```
   matrix ($\Gamma^TC\gamma^a\Gamma = -C\gamma^a$). With $m \to -m$ and
   $\lambda \to -\lambda$ it maps solutions to solutions (theorem T1 of the
   Revision pairing record). For real fields, the matter-antimatter map is the
   **matrix** $\Gamma$ together with the reversed mass.

The next cell checks these statements exactly with sympy, using a real field with
16 symbolic real components $r_1, \dots, r_{16}$ (record check
real_fields_charge_conjugation).
```

In [18]:

```
r = sp.Matrix(sp.symbols("r1:17", real=True))  # a real field with symbolic entries
C_s = sp.Matrix(C.tolist())
antisymmetric = all(np.array_equal((C @ gamma[x]).T, -(C @ gamma[x])) for x in COORDS)

## 13. The Revision record and the figure files

The next cell checks that the Revision record of the lead checks reports all its
checks as passed, and that the nine checks reproduced in this notebook are among
them. (The remaining three are reproduced elsewhere in this chapter's notebooks:
the reality of the spin connection and the U(1) identity concern the local
conservation law of the charge (notebook 21b), and the last check concerns the
quantised field (notebook 21c).) Then it checks
that the seven figure files exist and prints the number of checks that passed.
```

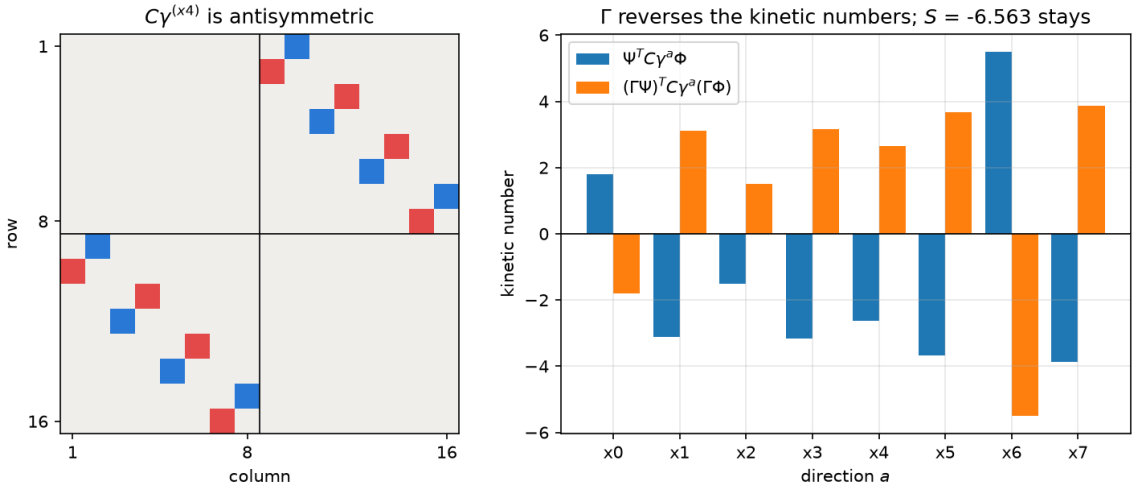

Figure 528: Real fields. Left: heat map of the real matrix $C\gamma^{(x4)}$ (horizontal axis the column, vertical axis the row, red $+1$, blue -1); it is antisymmetric, so $\Psi^T C\gamma^{(x4)}\Psi = 0$ for every real Ψ and a real field carries no current. Right: the eight kinetic numbers $\Psi^T C\gamma^a\Phi$ of two fixed real columns (left bars) and of their images under the real matrix Γ (right bars); horizontal axis the direction a, vertical axis the value (pure numbers). Every kinetic number changes sign while $S = \Psi^T C\Psi$ stays: with the mass reversed, Γ maps real solutions to real solutions. (Notebook 21a, figure 7.)

```

Text cell:

```
## 14. What this notebook showed

- PROVED (exact, whole-number arithmetic): the calculation uses **eight real
  $16 \times 16$ gamma matrices** (signed permutation matrices) that obey the
  Clifford relation of signature (4,4), $\eta = \mathrm{diag}(+1, +1, +1, +1, -1,
  -1, -1, -1)$ in the order $x0, \dots, x7$.
- PROVED (exact rational linear algebra): the only matrices $M$ with
  $M(\gamma^a)^* = s\,\gamma^a M$ for all eight gammas are the multiples of $1$
  ($s = +1$, same mass) and of $\Gamma$ ($s = -1$, mass reversed); each gamma
  equation halves the solution space, $256 \to 128 \to \dots \to 1$.
- PROVED: with the intertwiner condition as the definition (that of the Revision
  record), the two charge-conjugation matrices are $\mathcal{C}_+ = C$ (with
  $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$; $\Psi^c = \Psi^*$) and
  $\mathcal{C}_- = \Gamma C$ (with $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- =
  +(\gamma^a)^T$; $\Psi^c = \Gamma\Psi^*$); both are real, and both reality
  (Majorana) conditions are consistent. The condition is sufficient, not
  necessary: for $V = 0$ the projector $P_-$ also maps every solution to a
  solution (Notebook 05c).
- PROVED (exact, sympy): on the Revision record's exact solution in the author's
  curved metric (valid for every history $a_4$, the deflating one included),
  $\Psi^*$ solves the equation with the same mass and $\Gamma\Psi^*$ the one with
  the reversed mass.
- PROVED: under $\mathcal{C}_+$ commuting components keep $S$ and reverse $J$;
  under $\mathcal{C}_-$ they keep both; anticommuting components reverse every
  sign classically; all 256 bilinears follow the degree rules $(-1)^{k(k+1)/2}$
  and $(-1)^{k(k-1)/2}$.
- PROVED: for a real field $\mathcal{C}_+$ is the identity and $J = 0$ (a real
  field is its own conjugate and has no U(1) charge); among the matrices that obey
  the intertwiner condition, the nontrivial real map is the matrix $\Gamma$ with
  the mass reversed. Plain complex conjugation is never
  the charge conjugation of a real field: charge conjugation is a matrix.
- Reproduced: nine checks of 'Revision/lead_checks/reports/
  charge-conjugation-and-u1.json', the formulas field_equation and exact_solutions
  of 'Revision/theory/field-theory.json' (compared word for word) and the check
  exact_solution_family_x4_x0 of 'Revision/theory/reports/python-field-theory.json'.
```

21.15 Line-by-line walk-through of Notebook 21a

The notebook has 20 code cells, In [1] to In [20]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted, then explained. The printed lines of each cell are shown in Section 21.14 after the label Out; the figures are shown there with their captions.

In [1], the set-up cell. Every line that starts with # is a **comment**, which Python skips. The comment lines at the top of the cell are the complete run instructions of Section 21.13, so that the notebook file carries its own instructions. The code starts after the line that announces THE SET-UP; it is the same in every notebook of this book and computes no physics.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module**, a part of Python or of an installed package, so that the code can use it; the text after `#` on the same line is a comment. `json`, `os`, `textwrap` and `pathlib` come with Python. `from pathlib import Path` takes the single name `Path` out of `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python), which show a picture file below a cell.

```
NOTEBOOK_ID = "21a"  # this notebook: chapter 21, example a
```

A **variable** is a name for a value; this line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"21a"`. The figure files are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**, a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description that Python stores but does not execute. `Path.cwd()` is the folder in which Jupyter runs the notebook, and `.resolve()` writes it as a complete address. `here.parents` is the list of the folders above it, and `[here, *here.parents]` is the list that starts with `here` and continues with them (the star unpacks one list into another). The `for` loop visits these folders one after the other; the indented lines below it run once for each. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If none does, `raise` stops the notebook with a `FileNotFoundError` whose message (two strings written next to each other, which Python joins) says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The function is called and its result named `REPO`. The last line chooses where files are written: `os.environ` holds the **environment variables** of the program (named texts it receives from the computer), and `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and `str(REPO)` (the path written as a string) otherwise. When you run the notebook it is not set, so files go into the repository; the book's checking tool sets it to a scratch folder.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small functions. `repository_file` gives the full path of a repository file, for reading a Revision record. `output_file` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates its folder and any missing folder above it, and does nothing if the folder exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters; `textwrap.fill` breaks the text at blanks and starts every line after the first with four blanks. That is why some printed lines of Section 21.14 continue on an indented second line.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

`matplotlib.rcdefaults()` returns to the built-in settings, so that the figures are the same on every computer. `plt.rcParams.update({...})` sets the size of a figure (7.0 by 4.2 inches), the size of its letters (10 points) and a faint grid (`grid.alpha` 0.3 means 30 per cent opaque). The braces make a **dictionary**: pairs `key: value`, separated by commas. A line that ends inside an open bracket continues on the next line.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: a name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/21a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty JSON dictionary and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored, and `"\n"` is the line-end character.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far (`len` counts the entries of a dictionary): the figures are numbered 1, 2, 3, and a cell run twice keeps its number. The file name joins the notebook id, the number and the name, for example `21a_1_eight_gammas.png`. `fig.savefig` writes the PNG file with 150 dots per inch, cuts away the empty margin and stores no program name, so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory. The caption is stored, the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys), `display(Image(...))` shows the saved picture below the cell (the output `<IPython.core.display.Image object>` in Section 21.14 is the text label of that picture), and the last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (square brackets). `check` is the notebook's test: `if not condition` is true when the condition is false, and then `raise AssertionError(...)` stops the notebook with an error that names the check. Otherwise the name is appended to the list and the line PASS with the name is printed. `record=None` gives the third argument a default value; when a cell passes a record, a second line says which Revision record and check the result reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; `(f" {unit}" if unit else "")` adds the unit only when one is given (an empty string counts as false). `all_checks_passed` prints the last line of the notebook with the number of passed checks. The last statement prints the one line of Out [1].

In [2]: reading the gammas and the lead record.

```
import itertools  # all subsets of a list (for the 256 products of gammas)

import numpy as np  # arrays of numbers, matrices and linear algebra
```

`itertools` comes with Python; its function `combinations` (In [15]) lists all subsets of a given size. `numpy`, imported under the short name `np`, stores numbers in **arrays** (tables of numbers) and does matrix algebra.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
COORDS = fixture["coordinates"]  # the list "x0", ..., "x7"
ETA = dict(zip(COORDS, fixture["eta"]))  # +1 space-like, -1 time-like
```

`read_text` reads the whole Revision record `Revision/algebra/gammas.json` as text, and `json.loads` turns the text into Python objects: here a dictionary, called `fixture`. `fixture["coordinates"]` is the entry stored under the key `"coordinates"`, the list of the eight names `"x0"` to `"x7"`. `zip` pairs each name with the matching entry of `fixture["eta"]`, and `dict` turns the pairs into a dictionary, so that `ETA["x4"]` is -1 and `ETA["x0"]` is $+1$.

```
# gamma["x4"] is gamma^(x4), a 16 x 16 array of whole numbers (int64)
gamma = {x: np.array(m, dtype=np.int64) for x, m in zip(COORDS, fixture["gamma"])}
I16 = np.eye(16, dtype=np.int64)  # the identity matrix 1
```

The braces with `for` inside build a dictionary in one line (a **dictionary comprehension**): for each name `x` and stored matrix `m` (a list of 16 lists of 16 numbers), the entry `gamma[x]` is the numpy array of `m` with whole-number entries (`int64`, 64-bit integers). Whole numbers make every product below exact. `np.eye(16)` is the 16×16 identity matrix.

```
def product(directions):
    """The matrix product gamma^(d1) gamma^(d2) ... in the order of the list."""
    result = I16
    for d in directions:
        result = result @ gamma[d]  # @ is the matrix product
    return result
```

`product(["x0", "x1"])` starts with the identity and multiplies from the right by each listed gamma in turn; `@` is numpy's matrix product.

```
RECORD = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
lead = json.loads(repository_file(RECORD).read_text(encoding="utf-8"))
LEAD = {c["name"]: c for c in lead["checks"]}  # check name -> its entry
```

The lead report of the Revision record is read in the same way. Its entry `"checks"` is a list of checks, each a dictionary with a name, a verdict and a detail text; `LEAD` makes them findable by name.

```
def lead_passed(name):
    """True when the Revision record has the check name with the verdict PASS."""
    return LEAD.get(name, {}).get("verdict") == "PASS"
```

`LEAD.get(name, {})` returns the check's entry, or an empty dictionary if the record has no such check; `.get("verdict")` then returns its verdict or nothing; `==` compares with `"PASS"`. The function is therefore true only when the record holds the named check with the verdict PASS.

```
say(f"coordinates: {' '.join(COORDS)}")
say("eta: " + " ".join(f"{ETA[x]:+d}" for x in COORDS))
say(f"lead record: {lead['summary']['passed']} of {lead['summary']['total']} "
    "checks passed")
```

A string followed by `.join(list)` joins the strings of the list with that string between them; here the string is one blank. In `f"{ETA[x]:+d}"` the format `+d` prints a whole number with its sign. The third line reads the record's summary. Out [2] shows the eight coordinates in the author's order, the signs $+1, +1, +1, +1, -1, -1, -1, -1$, and "lead record: 12 of 12 checks passed".

In [3]: the eight real gammas and the Clifford relation.

```
shapes_ok = len(gamma) == 8 and all(g.shape == (16, 16) for g in gamma.values())
entries_ok = all(set(np.unique(g)) <= {-1, 0, 1} for g in gamma.values())
```

`len(gamma)` counts the entries of the dictionary; `g.shape` is the pair (rows, columns) of an array; `all(...)` is true when the test inside is true for every item. `np.unique(g)` lists the different entries of `g`, `set(...)` makes a set of them, and `<=` asks whether that set lies inside the set $\{-1, 0, 1\}$: every entry is -1, 0 or $+1$, so every gamma is real.

```
# a signed permutation matrix: exactly one nonzero entry in every row and column
permutation_ok = all((np.abs(g).sum(axis=0) == 1).all()
                     and (np.abs(g).sum(axis=1) == 1).all() for g in gamma.values())
check(shapes_ok and entries_ok and permutation_ok,
      "eight real 16 x 16 gamma matrices, entries -1, 0, +1, signed permutations")
```

`np.abs(g)` replaces every entry by its size; `.sum(axis=0)` adds each column and `.sum(axis=1)` each row; `== 1` compares every sum with 1 and `.all()` asks that all comparisons hold. Since the entries are 0 or ± 1, a sum of sizes equal to 1 means exactly one nonzero entry. The check combines the three tests with `and`.

```
clifford_ok = all(
    np.array_equal(gamma[a] @ gamma[b] + gamma[b] @ gamma[a],
                   2 * (ETA[a] if a == b else 0) * I16)
    for a in COORDS for b in COORDS)  # all 64 ordered pairs (a, b)
check(clifford_ok, "Clifford relation gamma^a gamma^b + gamma^b gamma^a = "
      "2 eta^ab 1 for all 64 pairs, signature (4,4)")
```

For each of the $8 \times 8 = 64$ ordered pairs, `np.array_equal` compares the anticommutator with $2\eta^{ab}1$ exactly; `(ETA[a] if a == b else 0)` is η_{aa} on the diagonal and 0 otherwise. Whole-number arithmetic makes this an exact proof of the Clifford relation for the stored matrices.

```
check(all(np.array_equal(gamma[x].T, ETA[x] * gamma[x]) for x in COORDS),
      "symmetry pattern (gamma^a)^T = eta_aa gamma^a")
```

`.T` is the transpose. The check proves the symmetry pattern of Section 21.7. Out [3] shows the three PASS lines.

In [4]: the heat maps of the eight gammas.

```
from matplotlib.colors import LinearSegmentedColormap

# blue for -1, almost white for 0, red for +1
SIGNS = LinearSegmentedColormap.from_list("signs", ["#2a78d6", "#f0efec", "#e34948"])
```

A **colour map** turns numbers into colours. `from_list` makes one that runs through three colours given as hexadecimal codes (red, green and blue amounts): blue at the lowest value, almost white in the middle, red at the highest.

```
def heat_map(ax, matrix, title, row_label=True):
    """Draw a 16 x 16 matrix with entries from -1 to +1 (blue -1, pale 0, red +1).
    Rows and columns are numbered from 1; black lines separate the two halves."""
    image = ax.imshow(matrix, cmap=SIGNS, vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xticks([0, 7, 15], ["1", "8", "16"])
    ax.set_yticks([0, 7, 15], ["1", "8", "16"])
    ax.axhline(7.5, color="black", linewidth=0.8)
    ax.axvline(7.5, color="black", linewidth=0.8)
```

```
    ax.set_xlabel("column")
    if row_label:
        ax.set_ylabel("row")
    ax.grid(False)
    return image
```

`ax` is one panel of a figure. `ax.imshow` draws the matrix as a grid of coloured squares, with -1 (`vmin`) blue and $+1$ (`vmax`) red. Python counts rows and columns from 0, so the tick positions 0, 7 and 15 get the labels 1, 8 and 16. `axhline` and `axvline` draw a horizontal and a vertical line at 7.5, between rows (columns) 8 and 9, which splits the matrix into its four 8×8 blocks. The axis labels are set (the row label only when asked), the grid is switched off, and the drawn image is returned for the colour bar.

```
fig, axes = plt.subplots(2, 4, figsize=(12.0, 6.6))
for k, (ax, x) in enumerate(zip(axes.flat, COORDS)):
    kind = "space-like" if ETA[x] == 1 else "time-like"
    image = heat_map(ax, gamma[x], f"$\\gamma^{{({x})}}$, {kind}",
                     row_label=(k % 4 == 0))
fig.colorbar(image, ax=axes, ticks=[-1, 0, 1], shrink=0.7, label="matrix entry")
```

`plt.subplots(2, 4, ...)` makes a figure with two rows of four panels, 12 by 6.6 inches. `axes.fla t` runs through the panels row by row, `zip` pairs them with the coordinates, and `enumerate` adds the counter `k` = 0, 1, 2, ... The title is LaTeX: in an f-string a doubled brace prints one brace and a doubled backslash prints one backslash, so for `x = "x4"` the title is $\gamma^{(x4)}$ followed by "time-like". `k % 4` is the remainder of k divided by 4, which is 0 for the first panel of each row: only those get a row label. `fig.colorbar` adds one colour bar for all panels.

```
save_figure(fig, "eight_gammas",
            "The eight real $16 \\times 16$ gamma matrices of the Revision record, "
            "in the author's coordinate order $x1, x2, x3$ (ordinary space), $x4$ "
            "(the time), $x5, x6, x7$ (the deflating extra times), $x0$ (the hidden "
            "direction); horizontal axis the column, vertical axis the row, colour "
            "the entry (red $+1$, blue $-1$, pale $0$). Every matrix has exactly one "
            "nonzero entry in each row and column, and only in the two off-diagonal "
            "$8 \\times 8$ blocks: each gamma exchanges the two halves of the "
            "spinor.")
```

Figure 21a.1, saved with the caption written in the following string lines, which Python joins into one string. **What the figure shows.** Eight panels, one per gamma. Each panel has exactly one coloured square in every row and column, and all of them lie in the upper-right and lower-left blocks: every gamma maps the first eight components into the last eight and back. These two halves are the chiral halves, where $\Gamma = -1$ and $\Gamma = +1$; that every gamma exchanges them is the reason why Γ anticommutes with every gamma.

In [5]: C, Γ, B and the generators.

```
C = product(["x0", "x1", "x2", "x3"])  # the charge matrix (the author's sigma16)
Gamma = product(["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"])  # the chirality
B = -1j * (C @ gamma["x4"])  # B = -i C gamma^(x4), a complex matrix
```

The three matrices of Section 21.7. Python writes the imaginary unit i as `1j`, so `-1j * (...)` multiplies every entry by $-i$; `B` is therefore an array of complex numbers.

```
pairs = [(a, b) for i, a in enumerate(COORDS) for b in COORDS[i + 1:]]  # 28 pairs
S_gen = {(a, b): (gamma[a] @ gamma[b] - gamma[b] @ gamma[a]) / 4 for a, b in pairs}
```

`COORDS[i + 1:]` is the part of the list after position `i`, so each pair (a, b) with a before b appears once: $8 \cdot 7/2 = 28$ pairs. `S_gen` stores the generator $S^{ab} = \frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$ for each pair; division by 4 makes the entries decimal numbers (they are 0 and $\pm\frac{1}{2}$).

```
same_as_record = (np.array_equal(C, np.array(fixture["C"]))
                  and np.array_equal(Gamma, np.array(fixture["Gamma"])))
gamma_diag = np.diag(np.concatenate([-np.ones(8), np.ones(8)])).astype(np.int64)
check(same_as_record and np.array_equal(Gamma, gamma_diag),
      "C and Gamma equal the record; Gamma = diag(-1 (8 times), +1 (8 times))")
```

The record also stores C and Γ; the first line compares them with the products just computed. `np.concatenate` joins eight -1 and eight $+1$ into one list, `np.diag` makes the diagonal matrix with that list on its diagonal, and `.astype(np.int64)` turns its entries into whole numbers. The check proves $\Gamma = \mathrm{diag}(-1_8, 1_8)$.

```
check(np.array_equal(C.T, C) and np.array_equal(C @ C, I16)
      and all(np.isrealobj(s) for s in S_gen.values()) and lead_passed(
          "representation_real"),
      "gamma^a, C (symmetric, C^2 = 1) and all 28 S^ab are real",
      record=f"{RECORD}, check representation_real")
```

This proves (R3)'s $C^T = C$ and $CC = 1$, checks that every generator is stored as real numbers (`np.isrealobj` is true for an array without complex entries), and asks that the lead record holds the check `representation_real` with the verdict PASS; the second printed line names that record check.

```
