check(not rho_linear.has(x4) and not p_linear.has(x4),
      "linear member: rho and p are constants")
```

```
check(sp.expand(rho_linear.subs(A, -A) - rho_linear) == 0
      and sp.expand(p_linear.subs(A, -A) - p_linear) == 0,
      "rho and p are even in A: A -> -A is a symmetry (deflation is a choice)")
```

Neither contains x_4, so both are constants; and replacing A by $-A$ changes neither: deflation is a choice of sign.

In [29], the vacuum factor.

```
V = sp.expand(sp.cancel((e44 - e00).subs(LINEAR) / (6 * (A ** 2 + 1) * H ** 2)))
report("vacuum factor V", V)
reproduces(V.is_polynomial(A) and sp.expand(6 * (A ** 2 + 1) * H ** 2 * V
                                            - (e44 - e00).subs(LINEAR)) == 0,
           "e44 - e00 = 6 (A^2 + 1) H^2 V with a polynomial V",
           PY, "linear_member_vacuum_factor")
```

$e_{44} - e_{00} = -\kappa(\rho + p)$ is divided by $6(A^2+1)H^2$; the quotient V is a polynomial in A (no remainder), printed in the RESULT line.

```
V_gauss_bonnet = sp.expand(V.subs({alpha1: 1, alpha3: 0}))
reproduces(sp.expand(V_gauss_bonnet - (1 - 8 * alpha2 * H ** 2 * (A ** 2 + 5))) == 0,
           "Gauss-Bonnet: V = 1 - 8 alpha2 H^2 (A^2 + 5)",
           PY, "einstein_gauss_bonnet_vacuum_linear")
V_any = V.subs(A, ad1 / H)  # the same polynomial with A H -> a4'
check(sp.expand((e00 - e44) + 6 * (ad1 ** 2 + H ** 2) * V_any) == 0,
      "for every a4: kappa (rho + p0) = -6 (a4'^2 + H^2) V(a4')")
```

For Einstein-Gauss-Bonnet gravity $V = 1 - 8\alpha_2 H^2(A^2 + 5)$. Because e_{44} and e_{00} contain no a_4'', the same factorisation holds for every history once AH is replaced by a_4': the last check (Section 12.11).

```
linear_record = equations_json["linearMember"]
same = (sp.expand(parse(linear_record["rho"]["input"], NAMES_RECORD) - rho_linear)
        == 0
        and sp.expand(parse(linear_record["p"]["input"], NAMES_RECORD) - p_linear)
        == 0
        and sp.expand(parse(linear_record["vacuumFactor"]["input"], NAMES_RECORD)
                      - V) == 0)
reproduces(same, "rho, p and V of the linear member equal the record",
           PY, "json_linear_member")
```

ρ, p and V are compared with the record's linear-member formulas.

In [30], the last check.

```
figure_names = ["12a_1_riemann_matrix.png", "12a_2_einstein_components.png",
                "12a_3_lovelock_heat_maps.png", "12a_4_evolution_factor.png",
                "12a_5_no_vacuum_gap.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all five figure files exist")
all_checks_passed()
```

The five figure files must exist, and the last line prints ALL 59 CHECKS PASSED (notebook 12a): 4 checks in In [2], 2 in In [4], 2 in In [5], 5 in In [8], 4 in In [12], 1 in In [14], 10 in In [16], 4 in In [17], 3 in In [18], 3 in In [19], 1 in In [21], 4 in In [22], 2 in In [23], 3 in In [25], 3 in In [26], 3 in In [28], 4 in In [29] and 1 in In [30].

12.17 Example: the source that the linear member requires

The second notebook takes the field equations from the record and asks, for the linear member $a_4 = AHx_4 + a_0$, what source they require, as a function of the slope A, of the cosmological constant and of the Lovelock couplings. It draws the signs of ρ and p, shows that a positive energy density in Einstein gravity comes only with $w < -1$, finds the Gauss-Bonnet and third-order vacua, and writes the two conditions that a homogeneous condensate of dirac16complex00 must meet to be the source. It runs in about 15 seconds, prints 24 PASS lines and draws eight figures.

12.18 How to run Notebook 12b

Step 1. What this notebook does and what it needs.

Notebook 12b (The source that the linear member a4 = A H x4 requires) is the file `Revision /textbook/notebooks/12b_required_source.ipynb` of the repository Dirac_claude. It reads the Lovelock components of the a4 field equations from the Revision record, derives the energy density and the pressure that the exponentially deflating linear member a4 = A H x4 + a0 requires for every slope A, every cosmological constant and every Lovelock coupling, checks the symmetry A to minus A, the null energy condition, the Einstein-Gauss-Bonnet and third-order vacua and the conditions on a homogeneous condensate of dirac16complex00, compares every result with the Revision records, and draws eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 12b_required_source.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12b_required_source.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 12b_required_source.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/12b.captions.json`
- `Revision/textbook/figures/12b_1_einstein_source.png`
- `Revision/textbook/figures/12b_2_source_regions.png`
- `Revision/textbook/figures/12b_3_phantom_w.png`
- `Revision/textbook/figures/12b_4_gauss_bonnet_source.png`
- `Revision/textbook/figures/12b_5_null_energy_map.png`
- `Revision/textbook/figures/12b_6_gauss_bonnet_vacuum.png`
- `Revision/textbook/figures/12b_7_third_order_vacua.png`

- `Revision/textbook/figures/12b_8_condensate_slope.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all eight figure files exist
ALL 24 CHECKS PASSED (notebook 12b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/12b_required_source.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 12b_required_source.ipynb
python -m nbconvert --execute --inplace 12b_required_source.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

12.19 Notebook 12b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/12b_required_source.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The author's metric contains one unknown function, $a_4(x_4)$. Its simplest
choice is the **linear member** $a_4 = AHx_4 + a_0$: 3-space grows like
$e^{AHx_4}$ and the three extra times shrink like $e^{-AHx_4}$ (exponential
deflation for $A > 0$). The field equations then say exactly what source (energy
density $\rho$ and pressure $p$) must be present. This notebook

- reads the Lovelock tensors of the field equations from the Revision record and
  derives from them the required $\kappa\rho$ and $\kappa p$ for every slope $A$,
  cosmological constant $\Lambda$ and Lovelock couplings $\alpha_1, \alpha_2,
  \alpha_3$, and compares them with the record;
- shows that the result does not change when $A$ is replaced by $-A$ (deflation is
  a choice of sign);
- maps, in Einstein gravity, where $\rho$ and $p$ are positive or negative, and
  shows that a positive energy density always comes with $w = p/\rho < -1$;
- shows what the Gauss-Bonnet coupling $\alpha_2$ and the third-order coupling
  $\alpha_3$ change, where the null energy condition holds, and where a vacuum
  (no source at all) exists;
- writes the conditions that a homogeneous condensate of the commuting field
  dirac16complex00 must meet to be the source;
- draws eight teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 12b (The source that the linear member a4 = A H x4 requires) is the file
‘Revision/textbook/notebooks/12b_required_source.ipynb‘ of the repository Dirac_claude.
It reads the Lovelock components of the a4 field equations from the Revision record,
derives the energy density and the pressure that the exponentially deflating linear
member a4 = A H x4 + a0 requires for every slope A, every cosmological constant and every
Lovelock coupling, checks the symmetry A to minus A, the null energy condition, the
Einstein-Gauss-Bonnet and third-order vacua and the conditions on a homogeneous
condensate of dirac16complex00, compares every result with the Revision records, and
draws eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv

Then close the terminal and open a NEW one (a terminal opened before the installation
does not know the new programs), and check the version of Python; it must print 3.12 or a
higher number:

Windows (PowerShell):
```

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 12b_required_source.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its

finished when the last code cell shows a number; this takes about 15 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut

**Step 6. Or run the notebook without a browser (headless).**
```

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12b_required_source.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 12b_required_source.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/12b.captions.json‘
- ‘Revision/textbook/figures/12b_1_einstein_source.png‘
- ‘Revision/textbook/figures/12b_2_source_regions.png‘
- ‘Revision/textbook/figures/12b_3_phantom_w.png‘
- ‘Revision/textbook/figures/12b_4_gauss_bonnet_source.png‘
- ‘Revision/textbook/figures/12b_5_null_energy_map.png‘
- ‘Revision/textbook/figures/12b_6_gauss_bonnet_vacuum.png‘
- ‘Revision/textbook/figures/12b_7_third_order_vacua.png‘
- ‘Revision/textbook/figures/12b_8_condensate_slope.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all eight figure files exist
ALL 24 CHECKS PASSED (notebook 12b)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start

JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/12b_required_source.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 12b_required_source.ipynb
python -m nbconvert --execute --inplace 12b_required_source.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 12b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 12b (The source that the linear member a4 = A H x4 requires) is the file
# Revision/textbook/notebooks/12b_required_source.ipynb of the repository Dirac_claude.
# It reads the Lovelock components of the a4 field equations from the Revision record,
```

```
# derives the energy density and the pressure that the exponentially deflating linear
# member a4 = A H x4 + a0 requires for every slope A, every cosmological constant and
# every Lovelock coupling, checks the symmetry A to minus A, the null energy condition,
# the Einstein-Gauss-Bonnet and third-order vacua and the conditions on a homogeneous
# condensate of dirac16complex00, compares every result with the Revision records, and
# draws eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an
# internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
```

```
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
```

```
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 12b_required_source.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 12b_required_source.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 12b_required_source.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/12b.captions.json
```

```
# - Revision/textbook/figures/12b_1_einstein_source.png
# - Revision/textbook/figures/12b_2_source_regions.png
# - Revision/textbook/figures/12b_3_phantom_w.png
# - Revision/textbook/figures/12b_4_gauss_bonnet_source.png
# - Revision/textbook/figures/12b_5_null_energy_map.png
# - Revision/textbook/figures/12b_6_gauss_bonnet_vacuum.png
# - Revision/textbook/figures/12b_7_third_order_vacua.png
# - Revision/textbook/figures/12b_8_condensate_slope.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all eight figure files exist
#     ALL 24 CHECKS PASSED (notebook 12b)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/12b_required_source.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 12b_required_source.ipynb
#     python -m nbconvert --execute --inplace 12b_required_source.ipynb
```

```
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record
#   of the repository. Run it inside the folder Revision/textbook/notebooks of a complete
#   copy of the repository made with git clone, not on a copy of the notebook file alone.

## 3. The words used in this notebook

- **Linear member**: the choice $a_4 = AHx_4 + a_0$ with constant **slope** $A$, so
  that $a_4' = AH$ and $a_4'' = 0$. $A > 0$: 3-space inflates and the extra times
  $x_5, x_6, x_7$ deflate exponentially; $A < 0$: the opposite; $A = 0$: static.
- **Source**: the matter whose energy-momentum tensor stands on the right-hand side
  of the field equations: energy density $\rho$, pressures $p_3$ (3-space), $p_t$
  (extra times), $p_0$ (hidden direction $x_0$).
- **Required source**: the $\rho$ and $p$ that the field equations demand for a
  given $a_4$; we read them off the equations instead of assuming a kind of matter.
- **Couplings**: $\alpha_1$ (Einstein), $\alpha_2$ (Gauss-Bonnet), $\alpha_3$ (third
  order); **Einstein gravity** is $\alpha_1 = 1$, $\alpha_2 = \alpha_3 = 0$;
  $\Lambda$ is the cosmological constant, $\kappa > 0$ the strength of gravity.
- **Units**: the plots use $H = 1$ and $\kappa = 1$, so $\kappa\rho$, $\kappa p$
  and $\Lambda$ are in units of $H^2$; $\alpha_2 H^2$ and $\alpha_3 H^4$ are pure
  numbers.
- **Equation of state** $w = p/\rho$.
- **Null energy condition** (NEC) along $x_0$: $\rho + p_0 \ge 0$. Ordinary matter
  satisfies it; a source with $w < -1$ and $\rho > 0$ (called *phantom*) violates
```

```
  it.
- **Vacuum**: $\rho = p = 0$, no source at all.
- **Condensate**: a configuration of the field dirac16complex00 that depends only on
  the time $x_4$; $S = \bar\Phi\Phi$ is its scalar density, $m$ the mass, and
  $U = \tfrac{\lambda}{2}S^2$ the self-interaction with strength $\lambda$.
- **Status labels**: PROVED (an exact identity, checked here and in the record),
  ASSUMED (a choice made, not derived), OPEN (not established).
```

Text cell:

```
## 4. The physical and mathematical situation

For a source that does not depend on $x_0$ and has no mixed components, the
Einstein-Lovelock field equations of the author's metric reduce to (the Revision
record `a4-equations.json`):

$$\sum_k \alpha_k E_{(k)}{}^{x_4}{}_{x_4} + \Lambda = -\kappa\rho,\qquad
\sum_k \alpha_k E_{(k)}{}^{x_0}{}_{x_0} + \Lambda = \kappa p_0,$$
$$\sum_k \alpha_k E_{(k)}{}^{x_1}{}_{x_1} + \Lambda = \kappa p_3,\qquad
\sum_k \alpha_k E_{(k)}{}^{x_5}{}_{x_5} + \Lambda = \kappa p_t.$$

For the linear member every component depends only on $A$, $H$ and the couplings,
so the required $\rho$ and $p$ are constants. The equations allow ANY $a_4$; what
they fix is the source that this $a_4$ needs. Whether a real field supplies that
source is a separate question (section 9 of this notebook states what is known for
one case).
```

Text cell:

```
## 5. The Revision records this notebook reproduces

The next cell defines the helpers that read the Revision records: `read_json`
reads a JSON file of the repository, `record_verdict` finds a check by its name in
a report, and `reproduces` is a check that passes only when this notebook's own
result holds AND the record lists the named check with the verdict PASS; it
collects its two printed lines (PASS and reproduces) in a text buffer and prints
them with one call, so that they always stay together in the output.
```

In [2]:

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory

PY = "Revision/field_equations_a4/reports/python-a4-report.json"  # sympy record
WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"  # Wolfram record

## 6. The required source of the linear member

The record stores each Lovelock component as a text in the Wolfram Language
(‘ad1‘ stands for $a_4’$, ‘ad2‘ for $a_4’’$, ‘^‘ for a power). The next cell turns
the four distinct components of $E_{(1)}, E_{(2)}, E_{(3)}$ into sympy expressions,
forms the four left-hand sides, and substitutes the linear member
$a_4’ = AH$, $a_4’’ = 0$. Then it reads off

$$\kappa\rho = -\Big(\sum_k \alpha_k E_{(k)}{}^{x_4}{}_{x_4} + \Lambda\Big),\qquad
\kappa p_0 = \sum_k \alpha_k E_{(k)}{}^{x_0}{}_{x_0} + \Lambda,$$

and the same for $p_3$ and $p_t$.
```

The next cell checks four things. (1) The three pressures are equal,
$p_3 = p_t = p_0 =: p$ (for $a_4'' = 0$ the components $E^{x_1}{}_{x_1}$,
$E^{x_5}{}_{x_5}$, $E^{x_0}{}_{x_0}$ coincide). (2) $\kappa\rho$ and $\kappa p$ equal
the linear-member formulas stored in the record. (3) Both contain $A$ only through
$A^2$: replacing $A$ by $-A$ changes nothing, so the equations accept deflating
extra times ($A > 0$) and inflating ones ($A < 0$) on the same footing. (4) The
Einstein part ($\alpha_1$) of $\kappa\rho$ is $-3H^2(A^2 + 7)$, as the lead's
independent check found.

## 8. The Gauss-Bonnet and the third-order couplings

The coupling $\alpha_2$ multiplies the Gauss-Bonnet tensor $E_{(2)}$. The next
cell extracts the $\alpha_2$ parts of $\kappa\rho$ and $\kappa p$ (the derivatives
with respect to $\alpha_2$) and compares them with the lead's independent
computation from the classical Gauss-Bonnet formula:
$H^4(36A^4 + 120A^2 + 420)$ and $12H^4(A^4 + 14A^2 - 15)$. Then it draws
$\kappa\rho$ and $\kappa p$ for Einstein-Gauss-Bonnet gravity
($\alpha_1 = 1$, $\alpha_3 = 0$, $\Lambda = 0$) for four values of $\alpha_2H^2$,
and checks two facts that the plot shows: at $A = 0$ the energy density is
$\kappa\rho = -21H^2 + 420\alpha_2H^4$ (positive only for $\alpha_2H^2 > 1/20$),
and at $A = \pm 1$ the $\alpha_2$ part of the pressure,
$12H^4(1 + 14 - 15) = 0$, vanishes, so $\kappa p = (15 - 3)H^2 = 12H^2$ for every
$\alpha_2$.
```

In [9]:

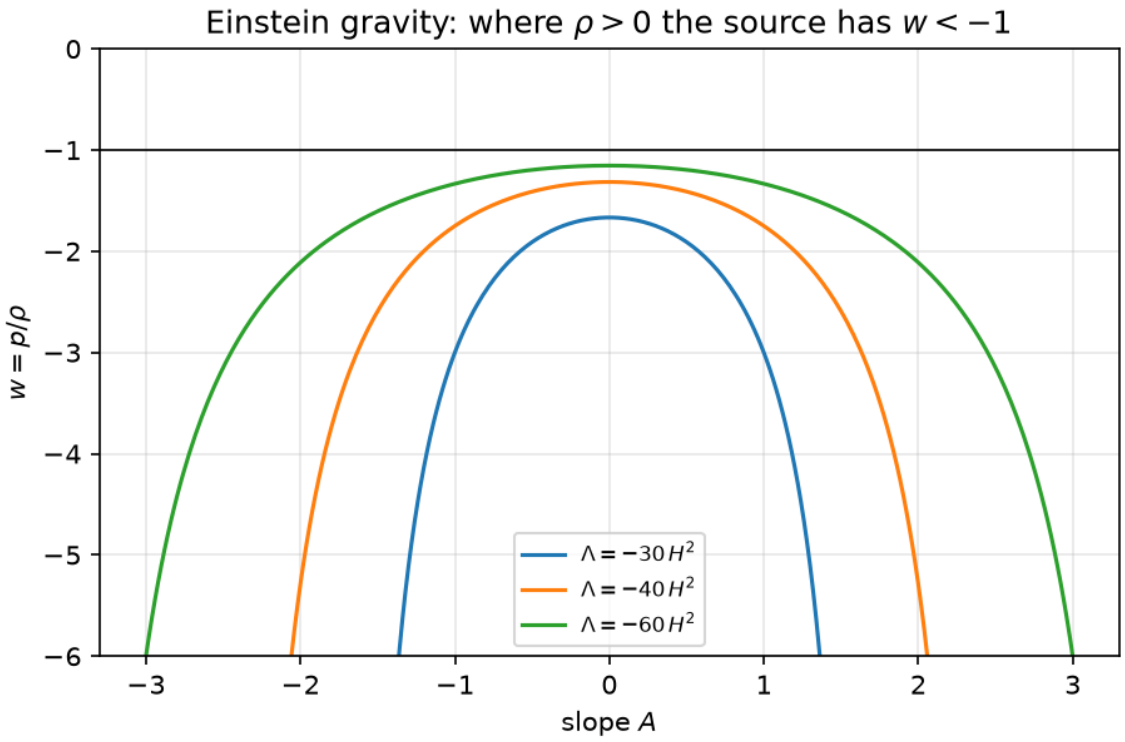

Figure 326: Einstein gravity: the equation of state $w = p/\rho$ that the linear member requires, drawn only where the energy density is positive ($\kappa\rho > H^2$), for $\Lambda = -30H^2$, $-40H^2$ and $-60H^2$, as a function of the slope A. Every curve lies below the line $w = -1$: a positive energy density comes with $w < -1$, because $\kappa(\rho + p) = -6(1 + A^2)H^2$ is negative for every A. (Notebook 12b, figure 3.)

**The null energy condition and the vacuum.** For every coupling the record
factorises

$$\kappa(\rho + p) = -6(A^2 + 1)H^2\,V,\qquad
V = \alpha_1 - 8\alpha_2H^2(A^2 + 5) + \alpha_3H^4(72A^4 + 144A^2 + 360).$$

So the null energy condition $\rho + p \ge 0$ holds exactly where $V \le 0$, and a
vacuum ($\rho = p = 0$) needs $V = 0$ (and then $\Lambda$ chosen so that
$\rho = 0$). The next cell checks the factorisation against the record and draws
the sign of $V$ in the plane of $A$ and $\alpha_2H^2$ (with $\alpha_1 = 1$,
$\alpha_3 = 0$). The boundary $V = 0$ is the curve
$A^2 = (1 - 40\alpha_2H^2)/(8\alpha_2H^2)$, which has real points only for
$0 < \alpha_2H^2 \le 1/40$.

## 9. A homogeneous condensate of dirac16complex00 as the source

The record proves (checks ‘condensate_S_constant‘,
‘condensate_kinetic_tensor_diagonal‘) that a condensate $\Phi(x_4)$ of the commuting
field has constant $S = \bar\Phi\Phi$, energy density $\rho = mS + U(S)$ and equal
pressures $p = SU’(S) - U(S)$ (sign convention $\sigma_T = +1$ of the record), and
that, when its off-diagonal conditions hold (see below), it allows only the
linear member. With $U = \tfrac{\lambda}{2}S^2$ we have
$U’ = \lambda S$, so $\rho = mS + \tfrac{\lambda}{2}S^2$ and $p = \tfrac{\lambda}{2}S^2$.
Setting them equal to the Einstein values and taking the difference and the sum:

$$\kappa mS = -(36H^2 + 2\Lambda),\qquad 6(A^2 + 1)H^2 = -\kappa S(m + \lambda S).$$

The next cell checks this equivalence with sympy, then solves for $A^2$ in units
$H = \kappa = 1$: $S = -(36 + 2\Lambda)/m$ and
$A^2 = 5 + \Lambda/3 - \lambda S^2/6$. For the two worked examples it also prints
the density $S$ and the effective mass $M = m + \lambda S$ that the condensate
must have.
```

```

Text cell:

```
**What is established here, and where it is completed.** The two conditions above
are PROVED consequences of the field equations for a condensate source. The
Revision record has exact condensates with all 15 bilinears zero, but it contains
no check that combines one of them with these Einstein conditions. Notebook 12d of
this chapter does that combination: it builds condensates with all 15 bilinears
zero and exactly the values $(M, S) = (5, -36/5)$ and $(-5, 12/5)$ of the two worked
examples, and checks every field equation exactly (a computation of the textbook,
not a Revision record). With $\Lambda = 0$ the required energy density is
$\kappa\rho = -(21 + 3A^2)H^2 < 0$: such a source has negative energy.
```

Text cell:

```
## 10. The last check

The last cell checks that the eight figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [15]:

```
figure_names = ["einstein_source", "source_regions", "phantom_w",
                "gauss_bonnet_source", "null_energy_map", "gauss_bonnet_vacuum",
                "third_order_vacua", "condensate_slope"]
paths = [output_file(f"{FIGURE_FOLDER}/12b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths), "all eight figure files exist")
all_checks_passed()
```

Out [15]:

```
PASS all eight figure files exist
ALL 24 CHECKS PASSED (notebook 12b)
```

Text cell:

```
## 11. What this notebook showed

- The linear member $a_4 = AHx_4 + a_0$ needs a source with equal pressures
  $p_3 = p_t = p_0 = p$ and constant $\rho$ and $p$, given by the record formulas
  (PROVED).
- $\rho$ and $p$ contain $A$ only as $A^2$: the field equations accept deflating
  extra times ($A > 0$) and inflating ones ($A < 0$) equally; deflation is a choice
  of sign, an initial condition (PROVED).
- Einstein gravity: $\kappa\rho = -(21 + 3A^2)H^2 - \Lambda$,
  $\kappa p = (15 - 3A^2)H^2 + \Lambda$, $\kappa(\rho + p) = -6(1 + A^2)H^2 < 0$;
```

```
  $\rho > 0$ is possible only with $\Lambda < -(21 + 3A^2)H^2$ and then $w < -1$
  (PROVED).
- Gauss-Bonnet and third-order couplings: $\kappa(\rho + p) = -6(A^2 + 1)H^2V$; the
  null energy condition holds where $V \le 0$; vacua exist on $V = 0$, for
  Einstein-Gauss-Bonnet gravity only when $0 < \alpha_2 H^2 \le 1/40$ (PROVED).
- A homogeneous dirac16complex00 condensate as the source needs
  $\kappa mS = -(36H^2 + 2\Lambda)$ and $6(A^2 + 1)H^2 = -\kappa S(m + \lambda S)$
  (PROVED); the two worked examples need $(M, S) = (5, -36/5)$ and $(-5, 12/5)$,
  and Notebook 12d builds condensates that meet them exactly.
```

12.20 Line-by-line walk-through of Notebook 12b

The notebook has 15 code cells, In [1] to In [15].

In [1], the set-up cell. It is the set-up cell of Notebook 12a, word for word, except for two things: the comment lines at the top hold the run instructions of Notebook 12b (Section 12.18), and the line `NOTEBOOK_ID = "12b"` names this notebook. Every line is explained in Section 12.16 under In [1]; the cell prints its one line, Set-up of notebook 12b complete.

In [2], the Revision records. The first lines are those of In [2] of Notebook 12a: the imports of `contextlib` and `io`, the short names `PY`, `WL`, `LEAD` and `EQUATIONS` of four record files, and the three helpers `read_json`, `record_verdict` and `reproduces` (Section 12.16, In [2]). New are the last three lines:

```
record = read_json(EQUATIONS)
title = record["title"]  # the title stored in the record
say(f"read {EQUATIONS}: {title}")
```

The record of the field equations is read once into the dictionary `record`, which the later cells use; its title is printed to show which file was read.

In [3], the required source for every coupling.

```
import numpy as np  # arrays of numbers for the plots
import sympy as sp  # exact algebra with symbols

H = sp.symbols("H", positive=True)  # the constant H of the metric
A = sp.symbols("A", real=True)  # the slope of the linear member
ad1, ad2 = sp.symbols("ad1 ad2", real=True)  # a4' and a4''
alpha1, alpha2, alpha3 = sp.symbols("alpha1 alpha2 alpha3", real=True)
Lam, kappa = sp.symbols("Lam kappa", real=True)  # Lambda and kappa
NAMES = {"ad1": ad1, "ad2": ad2, "H": H, "AA": A, "alpha1": alpha1,
         "alpha2": alpha2, "alpha3": alpha3, "Lam": Lam, "kappa": kappa}
```

The imports and symbols as in Notebook 12a; `NAMES` tells the parser which names of the record mean which symbols (the record calls the slope `AA`).

```
def parse(text):
    return sp.sympify(text.replace("^", "**"), locals=NAMES)
```

parse turns a formula of the record, written in the Wolfram Language, into a sympy expression: the power sign ^ becomes ** and sp.sympify reads the text (docstring left out).

```
ALPHA = {1: alpha1, 2: alpha2, 3: alpha3}
lovelock = record["lovelockTensors"]
side = {key: sum(ALPHA[k] * parse(lovelock[f"E{k}"][key]["input"]) for k in (1, 2, 3))
        for key in ("x1x1", "x4x4", "x5x5", "x0x0")}  # sum_k alpha_k E_(k)
```

For each of the four distinct diagonal components the dictionary comprehension forms $\sum_k \alpha_k E_{(k)}$ from the record's three tensors: side["x4x4"] is e_{44} of Section 12.8, and so on.

```
LINEAR = {ad1: A * H, ad2: 0}  # a4' = A H, a4'' = 0
kappa_rho = sp.expand(-(side["x4x4"] + Lam).subs(LINEAR))
kappa_p3 = sp.expand((side["x1x1"] + Lam).subs(LINEAR))
kappa_pt = sp.expand((side["x5x5"] + Lam).subs(LINEAR))
kappa_p0 = sp.expand((side["x0x0"] + Lam).subs(LINEAR))
say(f"kappa rho = {kappa_rho}")
say(f"kappa p0 = {kappa_p0}")
```

The linear member is substituted, and the four field equations of Section 12.8 are solved for the source: $\kappa\rho = -(e_{44} + \Lambda)$, $\kappa p_3 = e_{11} + \Lambda$, and so on. Out [3] prints $\kappa\rho$ and κp_0: the general formulas of Section 12.12.

In [4], equal pressures and the symmetry A to minus A.

```
reproduces(sp.expand(kappa_p3 - kappa_p0) == 0 and sp.expand(kappa_pt - kappa_p0) == 0,
           "linear member: p3 = pt = p0 = p", PY, "linear_member_equal_pressures")
kappa_p = kappa_p0  # the common pressure, times kappa
```

The three pressures agree for every coupling; the common value is named kappa_p.

```
linear_record = record["linearMember"]
same = (sp.expand(kappa * parse(linear_record["rho"]["input"]) - kappa_rho) == 0
        and sp.expand(kappa * parse(linear_record["p"]["input"]) - kappa_p) == 0)
reproduces(same, "kappa rho and kappa p equal the record", PY, "json_linear_member")
```

The record stores ρ and p themselves (divided by κ); multiplied by kappa they must equal the notebook's $\kappa\rho$ and κp.

```
check(sp.expand(kappa_rho.subs(A, -A) - kappa_rho) == 0
      and sp.expand(kappa_p.subs(A, -A) - kappa_p) == 0,
      "A -> -A leaves rho and p unchanged: deflation is a choice of sign")
reproduces(sp.expand(sp.diff(kappa_rho, alpha1) + 3 * H ** 2 * (A ** 2 + 7)) == 0,
           "the alpha1 part of kappa rho is -3 H^2 (A^2 + 7)",
           LEAD, "einstein_linear_rho_alpha1")
```

Replacing A by $-A$ changes nothing (Section 12.12). The part of $\kappa\rho$ that multiplies α_1 is its derivative with respect to α_1 (the formula is linear in the couplings); it must be $-3H^2(A^2 + 7)$, as the lead's independent computation found.

In [5], Einstein gravity.

```
EINSTEIN = {alpha1: 1, alpha2: 0, alpha3: 0}
rho_e = sp.expand(kappa_rho.subs(EINSTEIN))  # kappa rho in Einstein gravity
p_e = sp.expand(kappa_p.subs(EINSTEIN))  # kappa p in Einstein gravity
report("Einstein: kappa rho", rho_e)
report("Einstein: kappa p", p_e)
```

The Einstein couplings are substituted and $\kappa\rho = -3A^2H^2 - 21H^2 - \Lambda$ and $\kappa p = -3A^2H^2 + 15H^2 + \Lambda$ are printed.

```
same = (sp.expand(kappa * parse(linear_record["rhoEinstein"]["input"]) - rho_e) == 0
        and sp.expand(kappa * parse(linear_record["pEinstein"]["input"]) - p_e) == 0
        and sp.expand(kappa * parse(linear_record["rhoPlusPEinstein"]["input"])
                      - (rho_e + p_e)) == 0)
reproduces(same and sp.expand(rho_e + p_e + 6 * (1 + A ** 2) * H ** 2) == 0,
           "Einstein: kappa (rho + p) = -6 (1 + A^2) H^2 < 0", PY,
           "json_linear_member")
```

The three Einstein formulas of the record (ρ, p, $\rho + p$) are compared, and the sum $\kappa(\rho + p) = -6(1 + A^2)H^2$ is checked.

```
UNITS = {H: 1, Lam: 0, A: 1}
rho_1, p_1 = rho_e.subs(UNITS), p_e.subs(UNITS)
report("Einstein, Lambda = 0, A = 1: kappa rho", rho_1, "H^2")
report("Einstein, Lambda = 0, A = 1: kappa p", p_1, "H^2")
report("Einstein, Lambda = 0, A = 1: w = p/rho", sp.Rational(p_1, rho_1))
check(rho_1 == -24 and p_1 == 12, "A = 1, Lambda = 0: kappa rho = -24, kappa p = 12")
```

The canonical history $A = 1$ without cosmological constant, in units $H = 1$: $\kappa\rho = -24$, $\kappa p = 12$, and the exact fraction `sp.Rational(p_1, rho_1)` $= -1/2$.

In [6], figure 1: the Einstein source against A.

```
rho_f = sp.lambdify((A, Lam), rho_e.subs(H, 1), "numpy")  # numbers from formulas
p_f = sp.lambdify((A, Lam), p_e.subs(H, 1), "numpy")
a_values = np.linspace(-3.0, 3.0, 301)
```

`sp.lambdify` makes numpy functions of A and Λ from the exact formulas with $H = 1$; `a_values` holds 301 slopes from -3 to 3.

```
fig, ax = plt.subplots()
ax.axvspan(0, 3, color="tab:green", alpha=0.08)  # the deflating half, A > 0
ax.plot(a_values, rho_f(a_values, 0.0), label="$\\kappa\\rho/H^2$")
ax.plot(a_values, p_f(a_values, 0.0), label="$\\kappa p/H^2$")
ax.plot(a_values, rho_f(a_values, 0.0) + p_f(a_values, 0.0), ":", color="black",
        label="$\\kappa(\\rho+p)/H^2=-6(1+A^2)$")
ax.axhline(0.0, color="black", linewidth=0.8)
```

`ax.axvspan(0, 3, ...)` shades the vertical strip $0 < A < 3$ in a faint green: the deflating half. The three curves are $\kappa\rho$, κp and their sum (dotted, `":"`) at $\Lambda = 0$; `axhline` draws the zero line.

```
ax.text(1.5, 15, "$A>0$: extra times deflate", ha="center", fontsize=9)
ax.text(-1.5, 15, "$A<0$: extra times inflate", ha="center", fontsize=9)
ax.set_xlabel("slope $A$ of $a_4 = AHx_4 + a_0$")
ax.set_ylabel("required source (units of $H^2/\\kappa$)")
ax.set_title("Einstein gravity, $\\Lambda = 0$: the source of the linear member")
ax.legend(fontsize=8, loc="lower center")
save_figure(fig, "einstein_source",
            ...)
```

`ax.text(x, y, text, ...)` writes a text at the point (x, y) of the plot; the two texts name the halves. Labels, title, legend and `save_figure` as before. **What the figure shows.** Every curve is symmetric about $A = 0$: the deflating half is the mirror image of the inflating half. The energy density is a downward parabola that never rises above $-21H^2/\kappa$; the pressure is positive for $|A| < \sqrt{5}$; their sum lies below zero everywhere.

In [7], figure 2: the signs of rho and p.

```
a_grid, lam_grid = np.meshgrid(np.linspace(-3, 3, 241), np.linspace(-60, 30, 241))
rho_grid = rho_f(a_grid, lam_grid)
p_grid = p_f(a_grid, lam_grid)
region = np.where(rho_grid > 0, 0, np.where(p_grid < 0, 1, 2))  # three regions
```

`np.meshgrid` makes two 241 by 241 arrays that together hold every point of a grid in the plane of A (from -3 to 3) and Λ/H^2 (from -60 to 30); the functions of In [6] evaluate $\kappa\rho$ and κp at all of them at once. `np.where(condition, x, y)` takes `x` where the condition holds and `y` elsewhere; the nested use labels each point 0 ($\rho > 0$), 1 ($\rho \le 0$, $p < 0$) or 2 ($\rho \le 0$, $p \ge 0$).

```
fig, ax = plt.subplots()
colours = matplotlib.colors.ListedColormap(["#f4a582", "#d1e5f0", "#92c5de"])
ax.pcolormesh(a_grid, lam_grid, region, cmap=colours, shading="auto")
ax.plot(a_values, -(21 + 3 * a_values ** 2), color="black",
        label="$\\rho = 0$: $\\Lambda = -(21+3A^2)H^2$")
ax.plot(a_values, 3 * a_values ** 2 - 15, "--", color="black",
        label="$p = 0$: $\\Lambda = (3A^2-15)H^2$")
```

`ListedColormap` makes a colour map of three colours (written as hexadecimal colour codes), one per region, and `ax.pcolormesh` colours the grid with it. The solid curve is the border $\rho = 0$, the dashed one the border $p = 0$ (Section 12.12).

```
ax.text(0, -50, "$\\rho > 0$, $p < 0$: $w < -1$", ha="center")
ax.text(0, -18, "$\\rho < 0$, $p < 0$", ha="center")
ax.text(0, 5, "$\\rho < 0$, $p > 0$", ha="center")
ax.set_xlim(-3, 3)
ax.set_ylim(-60, 30)
ax.set_xlabel("slope $A$")
ax.set_ylabel("$\\Lambda/H^2$")
ax.set_title("Einstein gravity: the signs of the required $\\rho$ and $p$")
ax.legend(fontsize=8, loc="upper center")
save_figure(fig, "source_regions",
            ...)
```

Three texts name the regions; `set_xlim` and `set_ylim` fix the ranges of the axes. **What the figure shows.** Below the solid curve the energy density is positive, but there the pressure is negative and $w < -1$. Above the dashed curve the pressure is positive and the energy density negative. In the band between both are negative. No colour stands for "both positive", and since the two curves never touch, no point is a vacuum.

In [8], figure 3: positive energy forces w below minus 1.

```
w_e = sp.simplify(p_e / rho_e)  # w = p/rho in Einstein gravity
say(f"Einstein: w = p/rho = {w_e}")
check(sp.simplify(w_e + 1 - (rho_e + p_e) / rho_e) == 0,
      "w + 1 = (rho + p)/rho, so rho > 0 and rho + p < 0 give w < -1")
```

The equation of state $w = p/\rho$ is printed, and the identity $w + 1 = (\rho + p)/\rho$ (add $\rho/\rho = 1$ to p/ρ) is checked; with $\rho > 0$ and $\rho + p < 0$ it gives $w + 1 < 0$.

```
fig, ax = plt.subplots()
for lam in (-30.0, -40.0, -60.0):
    rho_values = rho_f(a_values, lam)
    keep = rho_values > 1.0  # where the energy density is clearly positive
    w_values = np.where(keep, p_f(a_values, lam) / np.where(keep, rho_values, 1.0),
                        np.nan)  # nan: not drawn
    ax.plot(a_values, w_values, label=f"$\\Lambda = {lam:.0f}\\,H^2$")
    check(np.nanmax(w_values) < -1.0, f"Lambda = {lam:.0f} H^2: w < -1 where rho > 0")
```

For three cosmological constants the energy density is computed on the 301 slopes; `keep` is an array of true and false values that marks where $\kappa\rho > 1$ (clearly positive). There $w = p/\rho$ is computed; elsewhere `np.nan` (not a number) is stored, which matplotlib does not draw. The inner `np.where(keep, rho_values, 1.0)` avoids a division by a value near zero outside the kept points. `np.nanmax` is the largest value that is not `nan`; it must be below -1.

```
ax.axhline(-1.0, color="black", linewidth=0.8)
ax.set_ylim(-6, 0)
ax.set_xlabel("slope $A$")
ax.set_ylabel("$w = p/\\rho$")
ax.set_title("Einstein gravity: where $\\rho > 0$ the source has $w < -1$")
ax.legend(fontsize=8)
save_figure(fig, "phantom_w",
            ...)
```

The line $w = -1$, the range of the vertical axis, labels, legend and `save_figure`. **What the figure shows.** Each curve is drawn only for slopes small enough that $\kappa\rho > H^2$ (for $\Lambda = -30H^2$ the energy density is positive for $|A| < \sqrt{3}$, from $21 + 3A^2 < 30$), and each lies entirely below $w = -1$: a positive energy density of the author's metric is always phantom.

In [9], figure 4: the Gauss-Bonnet coupling.

```
reproduces(sp.expand(sp.diff(kappa_rho, alpha2)
                     - H ** 4 * (36 * A ** 4 + 120 * A ** 2 + 420)) == 0,
```

```
           "the alpha2 part of kappa rho is H^4 (36 A^4 + 120 A^2 + 420)",
           LEAD, "gauss_bonnet_rho_alpha2")
reproduces(sp.expand(sp.diff(kappa_p, alpha2)
                     - 12 * H ** 4 * (A ** 4 + 14 * A ** 2 - 15)) == 0,
           "the alpha2 part of kappa p is 12 H^4 (A^4 + 14 A^2 - 15)",
           LEAD, "gauss_bonnet_p_alpha2")
```

The parts of $\kappa\rho$ and κp that multiply α_2 are compared with the lead's classical Gauss-Bonnet computation.

```
symbols_numeric = (A, Lam, alpha1, alpha2, alpha3)
rho_l = sp.lambdify(symbols_numeric, kappa_rho.subs(H, 1), "numpy")  # any coupling
p_l = sp.lambdify(symbols_numeric, kappa_p.subs(H, 1), "numpy")
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
for a2 in (0.0, 0.01, 0.025, 0.04):
    label = f"$\\alpha_2H^2 = {a2}$"
    left.plot(a_values, rho_l(a_values, 0, 1, a2, 0), label=label)
    right.plot(a_values, p_l(a_values, 0, 1, a2, 0), label=label)
```

Numpy functions of the slope, Λ and the three couplings. A figure with two panels side by side (`left` and `right`); for four values of $\alpha_2 H^2$, with $\Lambda = 0$, $\alpha_1 = 1$, $\alpha_3 = 0$, the energy density is drawn on the left and the pressure on the right.

```
for ax, name in ((left, "\\kappa\\rho/H^2"), (right, "\\kappa p/H^2")):
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xlabel("slope $A$")
    ax.set_ylabel(f"${name}$")
    ax.legend(fontsize=8)
left.set_title("energy density, $\\Lambda = 0$")
right.set_title("pressure, $\\Lambda = 0$")
save_figure(fig, "gauss_bonnet_source",
            ...)
```

The same zero line, labels and legend for both panels, then titles and `save_figure`.

```
rho_gb_0 = sp.expand(kappa_rho.subs({alpha1: 1, alpha3: 0, Lam: 0, A: 0}))
check(sp.expand(rho_gb_0 - (420 * alpha2 * H ** 4 - 21 * H ** 2)) == 0,
      "Gauss-Bonnet, Lambda = 0, A = 0: kappa rho = (420 alpha2 H^2 - 21) H^2")
p_gb_1 = [sp.expand(kappa_p.subs({alpha1: 1, alpha3: 0, Lam: 0, A: s}))
          for s in (1, -1)]
check(p_gb_1 == [12 * H ** 2, 12 * H ** 2],
      "Gauss-Bonnet, Lambda = 0, A = +1 or -1: kappa p = 12 H^2 for every alpha2")
```

Two facts that the figure shows, checked exactly: at $A = 0$ the energy density is $(420\alpha_2 H^2 - 21)H^2$, and at $A = \pm 1$ the pressure is $12H^2$ whatever α_2 is, because the Gauss-Bonnet part $12H^4(1+14-15)$ vanishes there. (These two PASS lines appear after the figure in Out [9], because they are printed after `save_figure`.) **What the figure shows.** The Gauss-Bonnet term adds $\alpha_2 H^4(36A^4 + 120A^2 + 420) > 0$ to $\kappa\rho$: for $\alpha_2 H^2 = 0.025$ and 0.04 the energy density becomes positive at large $|A|$ without any cosmological constant. All pressure curves cross at $A = \pm 1$.

In [10], figure 5: the null energy condition and the vacuum curve.

```
V = parse(linear_record["vacuumFactor"]["input"])  # the record vacuum factor
reproduces(sp.expand(kappa_rho + kappa_p + 6 * (A ** 2 + 1) * H ** 2 * V) == 0,
           "kappa (rho + p) = -6 (A^2 + 1) H^2 V for every coupling",
           PY, "linear_member_vacuum_factor")
V_gb = sp.expand(V.subs({alpha1: 1, alpha3: 0}))
reproduces(sp.expand(V_gb - (1 - 8 * alpha2 * H ** 2 * (A ** 2 + 5))) == 0,
           "Gauss-Bonnet: V = 1 - 8 alpha2 H^2 (A^2 + 5)",
           PY, "einstein_gauss_bonnet_vacuum_linear")
```

The record's vacuum factor V is read and the factorisation $\kappa(\rho + p) = -6(A^2 + 1)H^2V$ is checked, then its Gauss-Bonnet form.

```
a_grid, g_grid = np.meshgrid(np.linspace(-3, 3, 241), np.linspace(0.0, 0.06, 241))
V_grid = 1 - 8 * g_grid * (a_grid ** 2 + 5)  # V with H = 1
fig, ax = plt.subplots()
ax.pcolormesh(a_grid, g_grid, np.sign(V_grid), cmap="coolwarm", shading="auto",
              vmin=-2, vmax=2)
```

A grid in the plane of A and $\alpha_2 H^2$ (from 0 to 0.06); V on the grid; `np.sign` is $+1$, 0 or -1, and the colour map `coolwarm` with the range -2 to 2 shows the two signs in muted blue and red.

```
g_curve = np.linspace(0.0025, 1 / 40, 200)  # alpha2 H^2 on the vacuum curve
a_curve = np.sqrt((1 - 40 * g_curve) / (8 * g_curve))
ax.plot(a_curve, g_curve, color="black", label="vacuum $V = 0$, $A > 0$ (deflating)")
ax.plot(-a_curve, g_curve, "--", color="black", label="vacuum $V = 0$, $A < 0$")
```

The vacuum curve $A^2 = (1 - 40\alpha_2 H^2)/(8\alpha_2 H^2)$, drawn for $\alpha_2 H^2$ from 0.0025 to 1/40, with its deflating branch $A > 0$ (solid) and the mirror branch (dashed).

```
ax.text(0, 0.006, "$V > 0$: NEC violated", ha="center")
ax.text(0, 0.045, "$V < 0$: NEC holds", ha="center")
ax.set_xlim(-3, 3)
ax.set_xlabel("slope $A$")
ax.set_ylabel("$\\alpha_2 H^2$")
ax.set_title("Einstein-Gauss-Bonnet: the sign of $V$ and the vacuum curve")
ax.legend(fontsize=8, loc="upper right")
save_figure(fig, "null_energy_map",
            ...)
```

Texts naming the two regions (NEC is the null energy condition), labels and `save_figure`. **What the figure shows.** Below the curve $V > 0$ and the required source violates the null energy condition, as in Einstein gravity; above it a sufficiently large Gauss-Bonnet coupling allows a source that satisfies it. On the curve itself a vacuum is possible; the curve reaches $A = 0$ at $\alpha_2 H^2 = 1/40$.

In [11], figure 6: the Gauss-Bonnet vacua.

```
A2_vacuum = (1 - 40 * alpha2 * H ** 2) / (8 * alpha2 * H ** 2)  # A^2 on V = 0
GB = {alpha1: 1, alpha3: 0}
rho_gb = sp.expand(kappa_rho.subs(GB))
```

```
Lam_vacuum = sp.solve(rho_gb, Lam)[0]  # the Lambda that makes rho = 0
Lam_on_curve = sp.simplify(Lam_vacuum.subs(A ** 2, A2_vacuum))
say(f"Lambda of the vacuum: {Lam_on_curve}")
```

A^2 on the vacuum curve; $\kappa\rho$ of Einstein-Gauss-Bonnet gravity; `sp.solve(rho_gb, Lam)` solves $\kappa\rho = 0$ for Λ and returns a list with one solution, of which `[0]` takes the first. Then A^2 is replaced by its value on the curve (sympy also replaces $A^4 = (A^2)^2$) and the result is simplified: $\Lambda = 720H^4\alpha_2 - 36H^2 + 3/(16\alpha_2)$, printed in Out [11].

```
p_on_curve = sp.simplify((kappa_p.subs(GB).subs(Lam, Lam_vacuum)).subs(A ** 2,
                                                                       A2_vacuum))
check(p_on_curve == 0,
      "Gauss-Bonnet vacuum: with V = 0 and Lambda from rho = 0, also p = 0")
at_edge = Lam_on_curve.subs({alpha2: sp.Rational(1, 40), H: 1})
report("vacuum at alpha2 H^2 = 1/40: Lambda/H^2", at_edge)
check(at_edge == sp.Rational(-21, 2), "at alpha2 H^2 = 1/40: A = 0, Lambda = -10.5 H^2")
```

With this Λ and on the curve the pressure vanishes as well: a true vacuum. At the edge $\alpha_2 H^2 = 1/40$ the cosmological constant is exactly $-21/2$ (in units H^2).

```
lam_vac_f = sp.lambdify(alpha2, Lam_on_curve.subs(H, 1), "numpy")
g_curve = np.linspace(0.004, 1 / 40, 200)
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
left.plot(g_curve, np.sqrt((1 - 40 * g_curve) / (8 * g_curve)), label="$A > 0$")
left.plot(g_curve, -np.sqrt((1 - 40 * g_curve) / (8 * g_curve)), "--",
          label="$A < 0$")
left.set_xlabel("$\\alpha_2 H^2$")
left.set_ylabel("slope $A$ of the vacuum")
left.legend(fontsize=8)
right.plot(g_curve, lam_vac_f(g_curve))
right.set_xlabel("$\\alpha_2 H^2$")
right.set_ylabel("$\\Lambda/H^2$ of the vacuum")
fig.suptitle("Einstein-Gauss-Bonnet gravity: the vacuum linear members")
save_figure(fig, "gauss_bonnet_vacuum",
            ...)
```

The two branches $\pm A$ of the vacuum slope on the left and the vacuum's cosmological constant on the right, for $\alpha_2 H^2$ from 0.004 to 1/40. **What the figure shows.** The smaller the Gauss-Bonnet coupling, the faster the vacuum deflates (or inflates) the extra times; at 1/40 the vacuum is static with $\Lambda = -10.5H^2$.

In [12], figure 7: the third-order vacuum lines.

```
V_one = sp.expand(V.subs({alpha1: 1, H: 1}))  # V with alpha1 = 1, H = 1
alpha3_line = sp.solve(V_one, alpha3)[0]  # alpha3 H^4 on the vacuum line
say(f"vacuum line: alpha3 H^4 = {sp.factor(alpha3_line)}")
check(alpha3_line.subs({A: 1, alpha2: sp.Rational(1, 48)}) == 0,
      "A = 1, alpha2 H^2 = 1/48: the vacuum line passes through alpha3 = 0")
line_f = sp.lambdify((A, alpha2), alpha3_line, "numpy")
```

$V = 0$ is solved for α_3 (with $\alpha_1 = H = 1$): for fixed A the solution is linear in α_2, a straight line, printed in factored form by `sp.factor`. One point is checked: $A = 1$, $\alpha_2 H^2 = 1/48$ gives $\alpha_3 = 0$, because $V = 1 - 8 \cdot \frac{1}{48} \cdot 6 = 0$.

```
g_values = np.linspace(0.0, 0.08, 201)
fig, ax = plt.subplots()
for slope in (0, 1, 2, 3):
    label = "$A = 0$" if slope == 0 else f"$A = \\pm{slope}$"
    ax.plot(g_values, line_f(slope, g_values), label=label)
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("$\\alpha_2 H^2$")
ax.set_ylabel("$\\alpha_3 H^4$")
ax.set_title("Third-order Lovelock gravity: the vacuum lines $V = 0$")
ax.legend(fontsize=8)
save_figure(fig, "third_order_vacua",
            ...)
```

The lines for $A = 0, 1, 2, 3$ (each serves $\pm A$). **What the figure shows.** Each line crosses the axis $\alpha_3 = 0$ at the Gauss-Bonnet vacuum of that slope; with a positive α_3 a vacuum exists at larger α_2.

In [13], a condensate of dirac16complex00 as the source.

```
m, lam, S = sp.symbols("m lam S", real=True)  # mass, coupling lambda, density S
rho_condensate = m * S + lam * S ** 2 / 2  # rho = m S + U, U = (lambda/2) S^2
p_condensate = lam * S ** 2 / 2  # p = S U' - U
```

The mass m, the self-coupling λ (named `lam`) and the density S of a condensate; its energy density $mS + U$ and pressure $SU' - U$ with $U = \frac{\lambda}{2}S^2$, $U' = \lambda S$, so $SU' - U = \lambda S^2 - \frac{\lambda}{2}S^2 = \frac{\lambda}{2}S^2$ (the record's formulas, Section 12.26).

```
condition_rho = sp.expand(kappa * rho_condensate - rho_e)  # = 0
condition_p = sp.expand(kappa * p_condensate - p_e)  # = 0
first = sp.expand(kappa * m * S + 36 * H ** 2 + 2 * Lam)  # kappa m S = -(36 H^2 + 2 L)
second = sp.expand(6 * (A ** 2 + 1) * H ** 2 + kappa * S * (m + lam * S))
reproduces(sp.expand(condition_rho - condition_p - first) == 0
           and sp.expand(condition_rho + condition_p - second) == 0,
           "condensate, Einstein: kappa m S = -(36 H^2 + 2 Lambda) and "
           "6 (A^2 + 1) H^2 = -kappa S (m + lambda S)",
           PY, "condensate_einstein_quadratic_U")
```

The two Einstein equations for this source are `condition_rho = 0` and `condition_p = 0`. Their difference is the first condition and their sum the second; the derivation is written out in Section 12.26.

```
UNIT = {H: 1, kappa: 1}
S_solution = sp.solve(first.subs(UNIT), S)[0]
A2_solution = sp.expand(sp.solve(second.subs(UNIT), A ** 2)[0].subs(S, S_solution))
say(f"S = {S_solution},  A^2 = {A2_solution}")
```

In units $H = \kappa = 1$ the first condition gives $S = -2(\Lambda + 18)/m$, and the second, solved for A^2 with this S, gives A^2 as a function of m, λ and Λ (printed in Out [13]); for $\Lambda = 0$ it is $5 - 216\lambda/m^2$.

```
example_1 = A2_solution.subs({m: 5, lam: 0, Lam: 0})
example_2 = A2_solution.subs({m: -15, lam: sp.Rational(25, 6), Lam: 0})
report("m = 5, lambda = 0, Lambda = 0: A^2", example_1)
report("m = -15, lambda = 25/6, Lambda = 0: A^2", example_2)
check(example_1 == 5 and example_2 == 1, "the two worked examples: A^2 = 5 and A^2 = 1")
```

Two worked examples: $m = 5$, $\lambda = 0$ gives $A^2 = 5$; $m = -15$, $\lambda = 25/6$ gives $A^2 = 5 - 216 \cdot \frac{25}{6}/225 = 5 - 4 = 1$, the slope of the canonical history.

```
effective = []  # the effective mass M = m + lambda S of each example
for mass, coupling in ((5, 0), (-15, sp.Rational(25, 6))):
    S_value = S_solution.subs({m: mass, Lam: 0})  # the density the example needs
    effective.append(mass + coupling * S_value)
    report(f"m = {mass}, lambda = {coupling}: S and M = m + lambda S",
           f"{S_value}, {effective[-1]}")
check(effective == [5, -5], "the examples need M = 5 (S < 0) and M = -5 (S > 0)")
```

For each example the density it needs ($S = -36/5$ and $12/5$) and the effective mass $M = m + \lambda S$ (5 and -5) are printed; `effective[-1]` is the last entry of the list.

In [14], figure 8: the off-diagonal conditions and the slope of a condensate.

```
condensate = record["fields"]["dirac16complex00"]
entries = condensate["offDiagonalKinetic"]
bilinears = sorted({term["bilinear"] for entry in entries for term in entry["terms"]})
report("off-diagonal kinetic components of the condensate", len(entries))
report("distinct three-gamma bilinears", len(bilinears))
reproduces(len(entries) == 42 and len(bilinears) == 15,
           "42 off-diagonal components, multiples of 15 three-gamma bilinears",
           WL, "condensate_offdiagonal_are_three_gamma_bilinears")
```

The record lists every nonzero off-diagonal kinetic component of a condensate, each with the bilinear it multiplies. A **set comprehension** (braces) keeps each bilinear once, `sorted` puts them in order: 42 components, 15 distinct three-gamma bilinears.

```
a2_f = sp.lambdify((m, lam), A2_solution.subs(Lam, 0), "numpy")
fig, ax = plt.subplots()
for mass, upper in ((5, 1.0), (-15, 6.0)):
    lam_values = np.linspace(0.0, upper, 200)
    ax.plot(lam_values, a2_f(mass, lam_values), label=f"$m = {mass}$")
ax.plot([0], [5], "o", color="black")
ax.plot([25 / 6], [1], "s", color="black")
```

A^2 as a numpy function of m and λ at $\Lambda = 0$, drawn against λ for $m = 5$ (up to $\lambda = 1$) and $m = -15$ (up to 6); a circle and a square mark the two worked examples.

```
arrow = {"arrowstyle": "->"}  # a thin arrow from the text to the point
ax.annotate("$m=5$, $\\lambda=0$: $A^2=5$", (0, 5), (0.5, 5.8), fontsize=8,
            arrowprops=arrow)
ax.annotate("$m=-15$, $\\lambda=25/6$: $A^2=1$", (25 / 6, 1), (3.6, 2.6),
            fontsize=8, arrowprops=arrow)
ax.set_ylim(-4.2, 6.6)
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("self-coupling $\\lambda$ (units $H = \\kappa = 1$)")
ax.set_ylabel("$A^2$ required by the condensate")
ax.set_title("A dirac16complex00 condensate as the source, Einstein, $\\Lambda=0$")
ax.legend(fontsize=8)
save_figure(fig, "condensate_slope",
            ...)
```

`ax.annotate(text, point, text_position, ...)` writes a text with an arrow to a point. **What the figure shows.** Both lines fall linearly, $A^2 = 5 - 216\lambda/m^2$, the line of the light mass $m = 5$ much faster; a real slope exists only while $A^2 \geq 0$, that is $\lambda \leq 5m^2/216$.

In [15], the last check.

```
figure_names = ["einstein_source", "source_regions", "phantom_w",
                "gauss_bonnet_source", "null_energy_map", "gauss_bonnet_vacuum",
                "third_order_vacua", "condensate_slope"]
paths = [output_file(f"{FIGURE_FOLDER}/12b_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths), "all eight figure files exist")
all_checks_passed()
```

`enumerate(figure_names, 1)` numbers the names from 1, which gives the eight file names; all must exist. The last line is ALL 24 CHECKS PASSED (notebook 12b): 4 checks in In [4], 2 in In [5], 4 in In [8], 4 in In [9], 2 in In [10], 2 in In [11], 1 in In [12], 3 in In [13], 1 in In [14] and 1 in In [15].

12.21 Solving the evolution equation for a prescribed stress

The idea. If the anisotropic stress $\Delta = p_3 - p_t$ is known as a function of time (or of the state), the evolution equation $a_4'' F(a_4') = \kappa\Delta$ is an **ordinary differential equation** for $a_4(x_4)$, and with the starting values $a_4(0)$ and $a_4'(0)$ it has one solution, which a computer can follow step by step. We prescribe the stress by hand: it is ASSUMED, chosen to see what the equations do. The Revision record constructs no state of either field that produces these stresses, and Section 12.22 recalls why the Kohn-Sham states of the repository are not admissible sources at all.

A first-order system. Write $v = a_4'$. Then

$$\frac{d}{dx_4} a_4 = v, \qquad \frac{d}{dx_4} v = \frac{\kappa\Delta}{F(v)}, \qquad \frac{d}{dx_4}(\kappa\rho) = -3v\,\kappa\Delta.$$

The first line is the definition of v, the second the evolution equation divided by F, the third the conservation law of Section 12.10. The third is not needed for a_4; Notebook 12c integrates it alongside, so that the energy density obtained from conservation can be compared with the one the constraint gives: a numerical test of the Bianchi identity.

The Runge-Kutta method of fourth order (RK4), from Chapter 2: for $dy/dx = f(x,y)$ one step of size h computes $k_1 = f(x,y)$, $k_2 = f(x+h/2, y+hk_1/2)$, $k_3 = f(x+h/2, y+hk_2/2)$, $k_4 = f(x+h, y+hk_3)$ and $y_{\text{new}} = y + \frac{h}{6}(k_1 + 2k_2 + 2k_3 + k_4)$. Its error after a fixed time shrinks like h^4: halving the step divides it by about 16.

No stress. With $\Delta = 0$: $a_4'' = 0$, so $a_4' = AH$ is constant and $a_4 = AHx_4 + a_0$: the linear member.

A pulse of stress (Einstein gravity). We start on the canonical history ($a_4(0) = 0$, $a_4'(0) = H$; units $H = 1$) and prescribe $\kappa\Delta(x_4) = \kappa\Delta_0\, e^{-((x_4 - x_c)/w)^2}$ with centre $x_c = 3$, width $w = 0.5$ and height $\kappa\Delta_0 = 2/(w\sqrt{\pi})$. With $F = 2$:

$$a_4'(x_4) = 1 + \int_0^{x_4} a_4''(s)\, ds = 1 + \frac{\kappa\Delta_0}{2} \int_0^{x_4} e^{-((s-x_c)/w)^2}\, ds$$

(the fundamental theorem of calculus, then $a_4'' = \kappa\Delta/2$)

$$= 1 + \frac{\kappa\Delta_0\, w}{2} \int_{-x_c/w}^{(x_4 - x_c)/w} e^{-t^2}\, dt$$

(substitution $t = (s - x_c)/w$, $ds = w\, dt$; the limits $s = 0$ and $s = x_4$ become $t = -x_c/w$ and $t = (x_4 - x_c)/w$)

$$= 1 + \frac{\kappa\Delta_0\, w\sqrt{\pi}}{4} \Big(\operatorname{erf} \frac{x_4 - x_c}{w} + \operatorname{erf} \frac{x_c}{w} \Big)$$

(the **error function** $\operatorname{erf}(u) = \frac{2}{\sqrt{\pi}} \int_0^u e^{-t^2} dt$ gives $\int_{u_0}^{u_1} e^{-t^2} dt = \frac{\sqrt{\pi}}{2}(\operatorname{erf} u_1 - \operatorname{erf} u_0)$, and erf is odd, $\operatorname{erf}(-u) = -\operatorname{erf} u$)

$$= 1 + \tfrac{1}{2} \Big(\operatorname{erf} \frac{x_4 - x_c}{w} + \operatorname{erf} \frac{x_c}{w} \Big)$$

($\kappa\Delta_0\, w\sqrt{\pi}/4 = 2/4 = 1/2$). At $x_4 = 0$ the bracket is zero and $a_4' = 1$. Long after the pulse $\operatorname{erf}((x_4 - x_c)/w) \to 1$, and $\operatorname{erf}(x_c/w) = \operatorname{erf}(6)$ differs from 1 by less than 10^{-15}, so $a_4' \to 2$: the pulse moves the history from the linear member $A = 1$ to $A = 2$, and the extra times deflate at every time, only faster afterwards. Integrating once more with $\int \operatorname{erf}(t)\, dt = t \operatorname{erf}(t) + e^{-t^2}/\sqrt{\pi}$ gives a_4 exactly (Notebook 12c, In [7]).

A relaxing stress. Now the stress depends on the state: $\kappa\Delta = -2\eta\,(a_4' - H)$ with a constant $\eta > 0$, starting on the faster member $a_4'(0) = 2H$ (units $H = 1$). Then

$$a_4'' = \frac{\kappa\Delta}{2} = -\eta\,(a_4' - 1)$$

(Einstein, $F = 2$). The excess $u = a_4' - 1$ obeys $u' = a_4'' = -\eta u$ with $u(0) = 1$, whose solution is $u = e^{-\eta x_4}$ (the derivative of $e^{-\eta x_4}$ is $-\eta e^{-\eta x_4}$). So

$$a_4' = 1 + e^{-\eta x_4}, \qquad a_4 = x_4 + \frac{1 - e^{-\eta x_4}}{\eta}$$

(integrate from 0, with $a_4(0) = 0$). The rate relaxes from $2H$ to H; the extra times keep deflating, first at the rate $2H$, later at the rate H. The conservation law gives $\kappa\rho' = -3a_4'\kappa\Delta = 6\eta\, a_4'(a_4' - 1) > 0$: the energy density rises. With $\Lambda = 0$ (the value Notebook 12c uses) the constraint gives $\kappa\rho = -3(a_4')^2 - 21H^2$, so $\kappa\rho$ rises from $-33H^2$ (at the rate $2H$, the value of the linear member $A = 2$) towards $-24H^2$ (the value of $A = 1$).

A constant stress in Einstein-Gauss-Bonnet gravity: the equation breaks down. With $\alpha_1 = 1$, $\alpha_3 = 0$ and $H = 1$, $F(v) = 2 - 80\alpha_2 - 48\alpha_2 v^2$. Define $G(v) = (2 - 80\alpha_2)v - 16\alpha_2 v^3$; its derivative is $G'(v) = 2 - 80\alpha_2 - 48\alpha_2 v^2 = F(v)$. Then, along a solution with a constant stress $\kappa\Delta$,

$$\frac{d}{dx_4} G(a_4'(x_4)) = G'(a_4')\, a_4'' = F(a_4')\, a_4'' = \kappa\Delta$$

(chain rule, then the evolution equation), and integrating from 0:

$$G(a_4'(x_4)) = G(a_4'(0)) + \kappa\Delta\, x_4.$$

The right-hand side grows without limit, but G has a largest value at the **critical rate** $v_c = \sqrt{(2 - 80\alpha_2)/(48\alpha_2)}$, where $G' = F = 0$. So the rate reaches v_c at the finite time

$$x_4^\star = \frac{G(v_c) - G(a_4'(0))}{\kappa\Delta},$$

and there $a_4'' = \kappa\Delta/F$ becomes infinite: beyond $x_4^\star$ no solution with a smooth a_4' exists. For $\kappa\Delta = 0.5$ and $a_4'(0) = 1$: $\alpha_2 = 0.005$ gives $v_c = 2.5820$ and $x_4^\star = 2.4682$; $\alpha_2 = 0.01$ gives $v_c = 1.5811$ and $x_4^\star = 0.4498$ (Notebook 12c, In [13]; Exercise 8 repeats the second by hand). In Einstein gravity ($F = 2$) the same stress simply makes the rate grow linearly, $a_4' = 1 + 0.25x_4$, for ever.

12.22 Example: four prescribed histories integrated with RK4

The third notebook programs RK4, tests it, and integrates the evolution equation for the four prescribed stresses of Section 12.21. It compares every numerical history with its exact solution, measures the order of convergence of RK4, compares the energy density from the conservation law with the one from the constraint, and finds the Gauss-Bonnet breakdown at the predicted time. Along every history with the deflating sign the extra times deflate exponentially at every time. At the end it reads the record's verdict on the Kohn-Sham states and recomputes the record's numbers. The record `Revision/field_equations_a4/reports/ks-source-conditions.json` (every one of its checks PASS; Notebook 12c, In [15]) finds that every recorded Kohn-Sham state with a nonzero energy-momentum tensor depends on x_0 and violates $p_3 + p_t = 2p_0$, even after integration over x_0 (check `ks_integrals_violate_algebraic_condition`). Notebook 12c, In [16], recomputes the record's numbers from the Kohn-Sham table `Revision/kohn_sham/results/ground/emt-integrals.csv` and asserts that they equal the record: of the 75 recorded states, 70 have a nonzero energy-momentum tensor; for these the ratio $(\int p_3 + \int p_t)/(2\int p_0)$, which equals 1 for every admissible source, is nowhere closer to 1 than 0.414328, and for $N = 136$ particles and $\lambda = 0$ it is 0.339767, 0.25969 and 0.239714 at the slices $a_{4,0} = 0, 1, 2$ (COMPUTED from the record's table, equal to the record). So the Kohn-Sham history $a_4 = AHx_4$ of Chapters 14 and 15 is a

PRESCRIBED background, not a solution of these equations with the Kohn-Sham source (Chapter 17). The notebook runs in about 15 seconds, prints 30 PASS lines and draws six figures.

12.23 How to run Notebook 12c

Step 1. What this notebook does and what it needs.

Notebook 12c (Integrating the evolution equation of a4 for prescribed sources) is the file `Revision /textbook/notebooks/12c_a4_evolution.ipynb` of the repository Dirac_claude. It integrates the evolution equation of the author's metric, in which the second derivative of a4 times the factor F equals kappa (p3 - p_t), with the fourth-order Runge-Kutta method for prescribed anisotropic stresses p3 - p_t (zero, a pulse that raises the deflation rate, a stress that relaxes it, a constant stress in Einstein-Gauss-Bonnet gravity), with the extra times deflating along every history, compares every history a4(x4) with its exact solution, measures the convergence order, computes the energy density and the pressures that each history requires, checks numerically that the constraint and the conservation law hold along the solutions, and draws six teaching plots of a4, its rate and the scale factors of 3-space and of the deflating extra times. At the end it reads the record on the Kohn-Sham states and recomputes its numbers from the table of their integrated energy-momentum tensors. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 12c_a4_evolution.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12c_a4_evolution.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 12c_a4_evolution.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/12c.captions.json`
- `Revision/textbook/figures/12c_1_linear_member.png`
- `Revision/textbook/figures/12c_2_stress_pulse.png`
- `Revision/textbook/figures/12c_3_required_source.png`
- `Revision/textbook/figures/12c_4_damped_deflation.png`
- `Revision/textbook/figures/12c_5_rk4_convergence.png`
- `Revision/textbook/figures/12c_6_gauss_bonnet_breakdown.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 30 CHECKS PASSED (notebook 12c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/12c_a4_evolution.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 12c_a4_evolution.ipynb
python -m nbconvert --execute --inplace 12c_a4_evolution.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.
- "RuntimeWarning: overflow" or "invalid value" below a cell after you changed a number: a changed coupling or stress drove a4' past the point where F vanishes; the notebook as distributed stops every integration before that point. Undo the change or lower the stress.

12.24 Notebook 12c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/12c_a4_evolution.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field equations for $a_4(x_4)$ contain one equation with the second derivative
$a_4''$, the **evolution equation**

$$a_4''\,F(a_4') = \kappa\,(p_3 - p_t),$$

where $p_3 - p_t$ is the difference between the pressure along 3-space and the
pressure along the extra times (the **anisotropic stress**). If $p_3 - p_t$ is
given as a function of the time $x_4$, this is an ordinary differential equation
for $a_4$, and we can solve it step by step on the computer. This notebook

- takes $F$ and the other Lovelock components from the Revision record;
- writes a fourth-order Runge-Kutta solver (RK4) and tests it;
- integrates the equation for four **prescribed** stresses: zero (the linear
  member), a short pulse that raises the deflation rate of the extra times from
  $a_4' = H$ to $a_4' = 2H$, a stress that relaxes the rate from $2H$ back to $H$,
  and a constant stress in Einstein-Gauss-Bonnet gravity, where the equation
  breaks down at a finite time; along every one of these histories the extra
  times deflate exponentially at all times ($a_4' > 0$);
- compares each numerical history with its exact solution and measures the
  convergence order of RK4;
- computes the energy density and the pressures that each history requires, and
  checks that the constraint and the conservation law hold along the solution;
- draws six plots of $a_4$, its rate $a_4'$, and the scale factors $e^{a_4}$ of
  3-space and $e^{-a_4}$ of the deflating extra times.
```

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 12c (Integrating the evolution equation of a4 for prescribed sources) is the file ‘Revision/textbook/notebooks/12c_a4_evolution.ipynb‘ of the repository Dirac_claude. It integrates the evolution equation of the author’s metric, in which the second derivative of a4 times the factor F equals kappa (p3 - p_t), with the fourth-order Runge-Kutta method for prescribed anisotropic stresses p3 - p_t (zero, a pulse that raises the deflation rate, a stress that relaxes it, a constant stress in Einstein-Gauss-Bonnet gravity), with the extra times deflating along every history, compares every history a4(x4) with its exact solution, measures the convergence order, computes the energy density and the pressures that each history requires, checks numerically that the constraint and the conservation law hold along the solutions, and draws six teaching plots of a4, its rate and the scale factors of 3-space and of the deflating extra times. At the end it reads the record on the Kohn-Sham states and recomputes its numbers from the table of their integrated energy-momentum tensors. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a

higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
```

```
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 12c_a4_evolution.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut

Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12c_a4_evolution.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 12c_a4_evolution.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/12c.captions.json‘
- ‘Revision/textbook/figures/12c_1_linear_member.png‘
- ‘Revision/textbook/figures/12c_2_stress_pulse.png‘
- ‘Revision/textbook/figures/12c_3_required_source.png‘
- ‘Revision/textbook/figures/12c_4_damped_deflation.png‘
- ‘Revision/textbook/figures/12c_5_rk4_convergence.png‘
- ‘Revision/textbook/figures/12c_6_gauss_bonnet_breakdown.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 30 CHECKS PASSED (notebook 12c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel

```
  called python3; with the environment active, run the following command and start
  JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from
  a copy outside the repository. Open the file
  ‘Revision/textbook/notebooks/12c_a4_evolution.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was
  downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with
  ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use
  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick
  "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt
  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not
  active; do Step 4. If the environment is active and the message stays, the programs
  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 12c_a4_evolution.ipynb
      python -m nbconvert --execute --inplace 12c_a4_evolution.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record of
  the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy
  of the repository made with git clone, not on a copy of the notebook file alone.
- "RuntimeWarning: overflow" or "invalid value" below a cell after you changed a number:
  a changed coupling or stress drove a4’ past the point where F vanishes; the notebook as
  distributed stops every integration before that point. Undo the change or lower the
  stress.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).
```

In [1]:

```
# HOW TO RUN NOTEBOOK 12c (the complete instructions)
#
```

```
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 12c (Integrating the evolution equation of a4 for prescribed sources) is the
# file Revision/textbook/notebooks/12c_a4_evolution.ipynb of the repository Dirac_claude.
# It integrates the evolution equation of the author's metric, in which the second
# derivative of a4 times the factor F equals kappa (p3 - p_t), with the fourth-order
# Runge-Kutta method for prescribed anisotropic stresses p3 - p_t (zero, a pulse that
# raises the deflation rate, a stress that relaxes it, a constant stress in
# Einstein-Gauss-Bonnet gravity), with the extra times deflating along every history,
# compares every history a4(x4) with its exact solution, measures the convergence order,
# computes the energy density and the pressures that each history requires, checks
# numerically that the constraint and the conservation law hold along the solutions, and
# draws six teaching plots of a4, its rate and the scale factors of 3-space and of the
# deflating extra times. At the end it reads the record on the Kohn-Sham states and
# recomputes its numbers from the table of their integrated energy-momentum tensors. It
# needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
```

```
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
```

```
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 12c_a4_evolution.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 12c_a4_evolution.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
```

```
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 12c_a4_evolution.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/12c.captions.json
# - Revision/textbook/figures/12c_1_linear_member.png
# - Revision/textbook/figures/12c_2_stress_pulse.png
# - Revision/textbook/figures/12c_3_required_source.png
# - Revision/textbook/figures/12c_4_damped_deflation.png
# - Revision/textbook/figures/12c_5_rk4_convergence.png
# - Revision/textbook/figures/12c_6_gauss_bonnet_breakdown.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 30 CHECKS PASSED (notebook 12c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/12c_a4_evolution.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
```

```
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 12c_a4_evolution.ipynb
#     python -m nbconvert --execute --inplace 12c_a4_evolution.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a4-equations.json: the notebook reads the Revision record
#   of the repository. Run it inside the folder Revision/textbook/notebooks of a complete
#   copy of the repository made with git clone, not on a copy of the notebook file alone.
# - "RuntimeWarning: overflow" or "invalid value" below a cell after you changed a
#   number: a changed coupling or stress drove a4' past the point where F vanishes; the
#   notebook as distributed stops every integration before that point. Undo the change or
#   lower the stress.
#
# ------------------------------------------------------------------------------------------

```

Text cell:

```
## 3. The words used in this notebook

- **Ordinary differential equation (ODE)**: an equation for an unknown function of
  one variable (here $a_4(x_4)$) that contains its derivatives.
- **Initial value problem**: an ODE together with the starting values, here
  $a_4(0) = 0$ and the starting rate $a_4'(0)$.
- **First-order system**: the second-order equation written as two first-order
```

```
  ones, $\frac{d}{dx_4}a_4 = v$ and $\frac{d}{dx_4}v = \kappa(p_3 - p_t)/F(v)$,
  with $v = a_4'$.
- **RK4** (Runge-Kutta of fourth order): a rule that advances the solution by one
  step $h$ using four evaluations of the right-hand side; its error shrinks like
  $h^4$.
- **Convergence order**: the power $q$ in "error $\approx$ constant $\times h^q$";
  halving $h$ divides the error by $2^q$.
- **Anisotropic stress** $\Delta = p_3 - p_t$: the difference of the pressures along
  3-space and along the extra times.
- **Prescribed source**: a source that we choose by hand to see what the equations
  do (status ASSUMED); it is not derived from any field of the theory.
- **Scale factor**: the factor by which lengths along a direction grow:
  $e^{a_4}$ for 3-space and $e^{-a_4}$ for the extra times $x_5, x_6, x_7$ (times
  the common factor $\sin^{1/6} z$, which does not change with $x_4$).
- **Constraint**: the time component of the field equations, which fixes the
  energy density $\rho$ from $a_4'$; **conservation**: $\rho' = -3a_4'(p_3 - p_t)$.
- **Deflation rate**: the rate $a_4'$. While $a_4' > 0$ the scale factor
  $e^{-a_4}$ of the extra times shrinks exponentially, at the momentary rate $a_4'$.
- **Canonical history**: the author's metric leaves the function $a_4(x_4)$ free;
  the author requires only that the extra times deflate ($a_4' > 0$). The linear
  member with the constant rate $a_4' = AH$ and $A = 1$ is the canonical history
  of the Revision record (ASSUMED, a prescribed choice); this notebook also uses
  the faster member $A = 2$.
- **Breakdown**: a point where $F(a_4') = 0$, so that the evolution equation can no
  longer be solved for $a_4''$.
- **Units**: $H = 1$ and $\kappa = 1$: the time $x_4$ is measured in units of
  $1/H$, $a_4'$ in units of $H$, $\kappa\rho$ and the pressures in units of $H^2$.
```

Text cell:

```
## 4. The physical and mathematical situation

For a source that does not depend on $x_0$ and has no mixed components, the
field equations of the author's metric are (Revision record `a4-equations.json`)

$$\kappa\rho = -\Big(\sum_k\alpha_k E_{(k)}{}^{x_4}{}_{x_4}(a_4') + \Lambda\Big),
\qquad \kappa p_0 = \sum_k\alpha_k E_{(k)}{}^{x_0}{}_{x_0}(a_4') + \Lambda,$$
$$a_4''\,F(a_4') = \kappa(p_3 - p_t),\qquad p_3 + p_t = 2p_0.$$

We choose (prescribe) the anisotropic stress $\Delta(x_4) = p_3 - p_t$ and the
starting values $a_4(0)$, $a_4'(0)$. The evolution equation then determines
$a_4(x_4)$; the first equation gives the energy density, the second the hidden
pressure, and $p_3 = p_0 + \Delta/2$, $p_t = p_0 - \Delta/2$. The record proves
that the derivative of the constraint is $3a_4'$ times the evolution equation; so
along a solution the energy density must obey $\rho' = -3a_4'\Delta$, which this
notebook checks numerically.

**Honesty.** Every stress used here is a mathematical test input (ASSUMED). The
Revision record constructs no state of either field that produces it, and it shows
that the Kohn-Sham states of the repository are not admissible sources (section 13
of this notebook reads that record). The histories below show what the equations
do, not what the universe did. In all of them the three extra times $x_5, x_6,
x_7$ deflate exponentially at every time (the rate $a_4'$ stays positive); the
```

```
only exception is the history with $A = -1$ in section 7, the mirror image that the
equations allow, drawn only to show that symmetry.
```

Text cell:

```
## 5. The Revision records and the Lovelock components

The next cell defines the helpers that read the Revision records (as in every
notebook of this chapter; ‘reproduces‘ prints its PASS and reproduces lines with
one call, through a text buffer, so that they stay together) and turns three
entries of ‘a4-equations.json‘ into Python functions of the rate $v = a_4’$ and
the couplings, with $H = 1$:
‘rho_side(v, a1, a2, a3)‘ $= \sum_k\alpha_kE_{(k)}{}^{x_4}{}_{x_4}$,
‘p0_side(v, a1, a2, a3)‘ $= \sum_k\alpha_kE_{(k)}{}^{x_0}{}_{x_0}$ and
‘F_of(v, a1, a2, a3)‘ $= F$. ‘sp.lambdify‘ turns a sympy formula into a fast
numpy function.
```

In [2]:

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory
import math  # the error function erf, for an exact solution

import matplotlib.ticker  # control of the tick labels of an axis
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra, used here only to read the record formulas

## 6. The Runge-Kutta method of fourth order

For a system $\frac{dy}{dx} = f(x, y)$ (here $y$ is a list of numbers) one RK4 step
of size $h$ from $(x, y)$ computes

$$k_1 = f(x, y),\quad k_2 = f(x + \tfrac h2, y + \tfrac h2 k_1),\quad
k_3 = f(x + \tfrac h2, y + \tfrac h2 k_2),\quad k_4 = f(x + h, y + hk_3),$$
$$y_{\text{new}} = y + \tfrac h6(k_1 + 2k_2 + 2k_3 + k_4).$$

The function ‘rk4‘ below repeats this step. Its optional argument ‘stop‘ is a
function of $y$; when it returns True the integration ends (used in section 12 to
stop before $F$ reaches zero). The test integrates $y' = -y$, $y(0) = 1$, from 0
to 1 with 20 steps; the exact value is $y(1) = e^{-1}$, and the RK4 error must be
tiny (below $10^{-7}$).
```

In [4]:

```
def rk4(rhs, y0, h, steps, stop=None):
    """Solve dy/dx = rhs(x, y), y(0) = y0, with at most steps RK4 steps of size h.

## 7. No anisotropic stress: the linear member

The state is $y = (a_4, a_4', \kappa\rho)$. The right-hand side is

$$\frac{d}{dx_4}a_4 = a_4',\qquad \frac{d}{dx_4}a_4' = \frac{\kappa\Delta(x_4)}
{F(a_4')},\qquad \frac{d}{dx_4}(\kappa\rho) = -3a_4'\,\kappa\Delta(x_4).$$

The third line is the conservation law; we integrate it alongside so that we can
later compare the energy density it gives with the one the constraint gives. The
helper `history` builds the right-hand side for a stress function and the
couplings, starts with $\kappa\rho$ from the constraint, and integrates.

With $\Delta = 0$ the equation is $a_4'' = 0$, so $a_4 = a_4'(0)\,x_4$: the linear
member $a_4 = AHx_4$ with $A = a_4'(0)/H$. The next cell integrates it for the
deflating rates $A = 1$ and $A = 2$ and, to show the symmetry $A \to -A$ of the
equations, for the mirror image $A = -1$ (inflating extra times; a departure
from the author's model, drawn only for the comparison), up to $x_4 = 3$, and
compares with the exact straight lines.
```

In [5]:

```

## 8. A pulse of anisotropic stress raises the deflation rate

Now we start on the canonical history, the deflating linear member with $A = 1$
($a_4(0) = 0$, $a_4'(0) = H$), and prescribe a short pulse of stress around the
time $x_c = 3$ with width $w = 0.5$:

$$\kappa\Delta(x_4) = \kappa\Delta_0\,e^{-((x_4 - x_c)/w)^2},\qquad
\kappa\Delta_0 = \frac{2}{w\sqrt\pi}.$$

In Einstein gravity $a_4'' = \kappa\Delta/2$. Integrating once, with
$\int e^{-t^2}dt = \tfrac{\sqrt\pi}{2}\operatorname{erf}(t)$ (erf is the *error
function*; it rises from $-1$ to $1$), and with $H = 1$:
```

```
$$a_4'(x_4) = 1 + \frac{\kappa\Delta_0 w\sqrt\pi}{4}\Big(\operatorname{erf}
\frac{x_4 - x_c}{w} + \operatorname{erf}\frac{x_c}{w}\Big)
= 1 + \frac12\Big(\operatorname{erf}\frac{x_4 - x_c}{w}
+ \operatorname{erf}\frac{x_c}{w}\Big),$$

which rises from 1 to almost exactly 2: after the pulse the history is the
deflating linear member with $A = 2$; the extra times deflate at every time, only
faster after the pulse. Integrating again, with
$\int\operatorname{erf}(t)\,dt = t\operatorname{erf}(t) + e^{-t^2}/\sqrt\pi$, gives
$a_4(x_4)$ exactly. The next cell integrates numerically up to $x_4 = 8$ with
$h = 0.01$ and compares both.
```

## 9. The source the pulse history requires, and the constraint

Along the pulse history the field equations fix the whole source (with
$\Lambda = 0$):

$$\kappa\rho = -(3(a_4')^2 + 21),\quad \kappa p_0 = 15 - 3(a_4')^2,\quad
\kappa p_3 = \kappa p_0 + \tfrac12\kappa\Delta,\quad
\kappa p_t = \kappa p_0 - \tfrac12\kappa\Delta.$$

The third component of our state, $\kappa\rho$ integrated from the conservation law
$\rho' = -3a_4'\Delta$, must agree with the $\kappa\rho$ that the constraint gives
at every time: this is the numerical form of the record's proof that the
derivative of the constraint is $3a_4'$ times the evolution equation. The next
cell defines a small helper that writes the measured disagreement as a power of
ten for the caption, checks the agreement, checks that the source starts on the
values of the linear member $A = 1$ ($\kappa\rho = -(3 + 21) = -24$,
$\kappa p = 15 - 3 = 12$) and ends on those of $A = 2$
($\kappa\rho = -(12 + 21) = -33$, $\kappa p = 15 - 12 = 3$), and draws the four
source components and the size of the disagreement.
```

## 10. A stress that relaxes the deflation rate

A stress can also depend on the state. We start on the faster deflating member
$A = 2$ ($a_4'(0) = 2H$) and prescribe
$\kappa\Delta = -2\eta\,(a_4' - H)$ with a constant $\eta > 0$: a resistance
proportional to the excess of the rate over $H$, like friction. In Einstein
gravity $a_4'' = \kappa\Delta/2 = -\eta(a_4' - H)$; the excess $u = a_4' - H$
obeys $u' = -\eta u$, so $u = He^{-\eta x_4}$ and, with $H = 1$,

$$a_4' = 1 + e^{-\eta x_4},\qquad
```

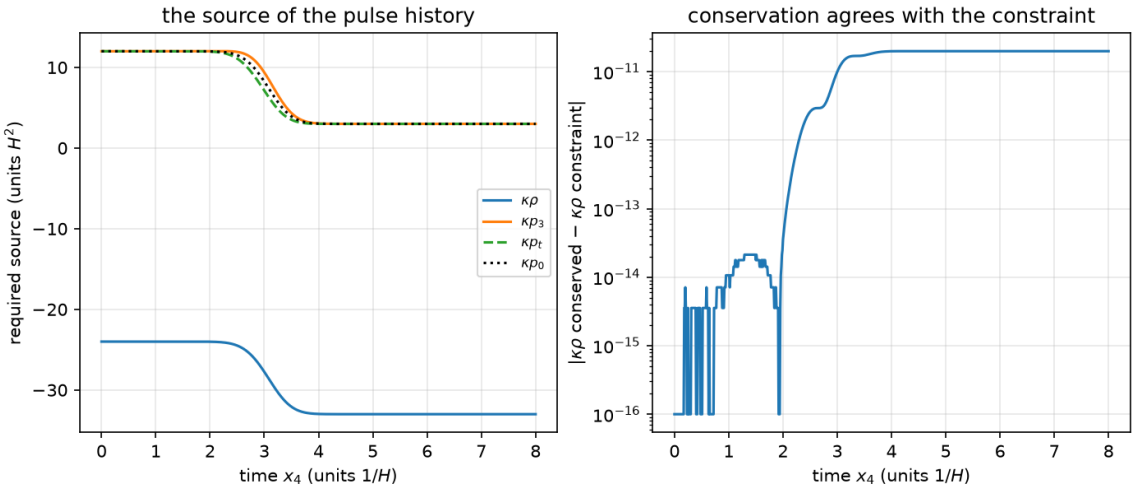

Figure 334: Left: the source that the pulse history requires in Einstein gravity with $\Lambda = 0$, in units of H^2: the energy density $\kappa\rho$, the pressures κp_3 (3-space), κp_t (extra times, dashed) and κp_0 (hidden direction, dotted). During the pulse p_3 and p_t split by the prescribed stress; before it the source is that of the linear member $A = 1$ ($\kappa\rho = -24$, $\kappa p = 12$), after it that of the linear member $A = 2$ ($\kappa\rho = -33$, $\kappa p = 3$). Right: on a logarithmic axis, the difference between the energy density integrated from the conservation law and the one given by the constraint (an exact zero is drawn at 10^{-16}). The two agree to about 2×10^{-11}, the accuracy of the RK4 integration with the step $h = 0.01$. (Notebook 12c, figure 3.)

```
a_4 = x_4 + \frac{1}{\eta}\big(1 - e^{-\eta x_4}\big).$$

The deflation rate relaxes from $2H$ to $H$: the history moves smoothly from the
linear member $A = 2$ to $A = 1$, and the extra-time scale factor $e^{-a_4}$
shrinks exponentially at every time, first at the rate $2H$, later at the rate
$H$. The next cell integrates this for $\eta = 0.25, 0.5, 1$ up to $x_4 = 10$,
compares with the exact solution, and checks the conservation law, which here
reads $\kappa\rho' = -3a_4'\kappa\Delta = 6\eta\,a_4'(a_4' - 1) > 0$: the energy
density rises from $-33$ (the value of $A = 2$) towards $-24$ (the value of
$A = 1$), in units of $H^2/\kappa$.
```

In [10]:

```
damped = {}  # eta -> (x4, solution)

## 11. How fast does RK4 converge?

For the relaxing history the right-hand side depends on the solution itself, so
it is a genuine differential equation and a good test of the method. (For the
pulse the stress depends on $x_4$ alone; RK4 then reduces to Simpson's rule for an
integrand that vanishes smoothly at both ends, and such integrals converge much
faster than $h^4$, which would hide the order.) The next cell integrates the
relaxing history with $\eta = 1$ up to $x_4 = 8$ with the step sizes
$h = 0.4, 0.2, 0.1, 0.05, 0.025$ and measures the error of $a_4(8)$ against the
exact value $8 + (1 - e^{-8})$. If the error behaves like $Ch^4$, halving $h$
divides it by $2^4 = 16$, and the measured order $\log_2(e_h / e_{h/2})$ is close
to 4. The table prints each step, its error and the order; the plot shows the
errors on logarithmic axes, where $Ch^4$ is a straight line of slope 4.
```

## 12. Einstein-Gauss-Bonnet gravity: the evolution equation breaks down

With the Gauss-Bonnet coupling ($\alpha_1 = 1$, $\alpha_3 = 0$, $H = 1$),
$F(a_4') = 2 - 80\alpha_2 - 48\alpha_2(a_4')^2$ decreases as $|a_4'|$ grows and
```

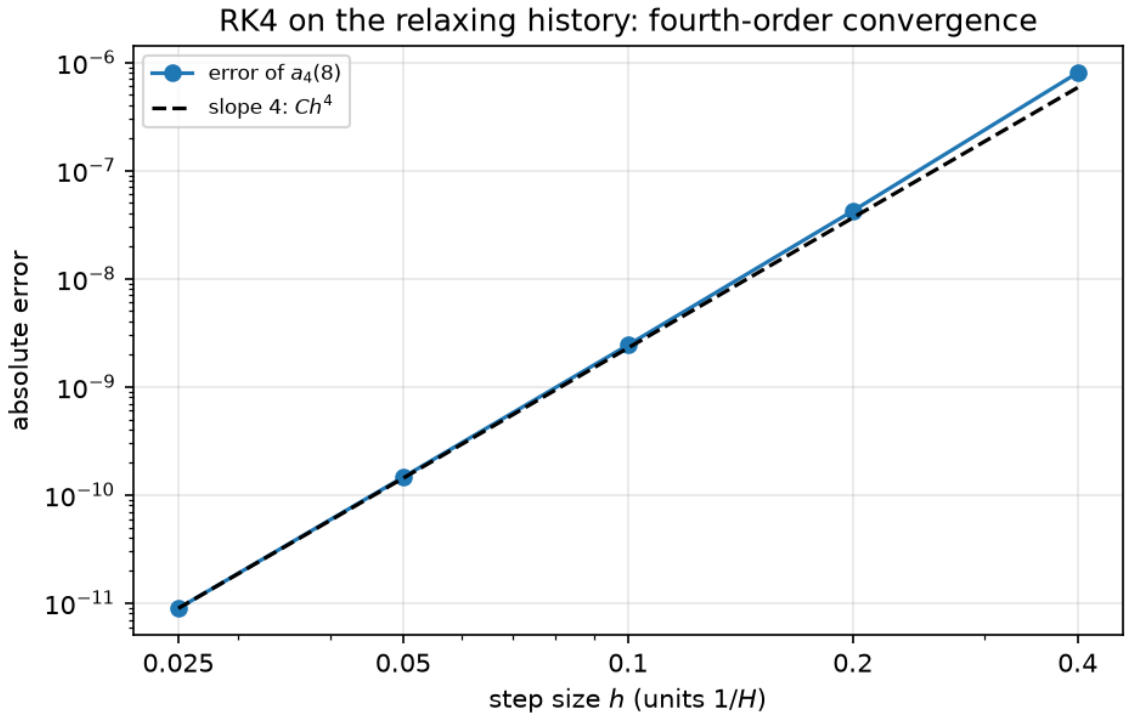

Figure 336: The error of the RK4 value of a_4 at $x_4 = 8$ for the relaxing history with $\eta = 1$ (exact value $8 + 1 - e^{-8}$), for the step sizes $h = 0.4$, 0.2, 0.1, 0.05 and 0.025 (units $1/H$), on logarithmic axes. The points follow the dashed reference line Ch^4 of slope 4: halving the step divides the error by about 16, the fourth-order convergence of the Runge-Kutta method. (Notebook 12c, figure 5.)

```
vanishes at $a_4'_c = \sqrt{(2 - 80\alpha_2)/(48\alpha_2)}$. For a constant stress
$\kappa\Delta$ the equation $F(a_4')\,a_4'' = \kappa\Delta$ can be integrated
once: with $G(v) = (2 - 80\alpha_2)v - 16\alpha_2v^3$ (so that $dG/dv = F$),

$$G(a_4'(x_4)) = G(a_4'(0)) + \kappa\Delta\,x_4 .$$

$G$ has its maximum at $a_4'_c$, so the rate reaches $a_4'_c$ at the finite time
$x_4^{\star} = (G(a_4'_c) - G(a_4'(0)))/(\kappa\Delta)$, with $a_4'' = \kappa\Delta/F$
growing without bound; beyond it the equation has no solution with a smooth
$a_4'$. The next cell starts on the canonical deflating member ($a_4'(0) = H$),
integrates with $\kappa\Delta = 0.5$ and $\alpha_2 = 0.005, 0.01$ (step
$h = 0.001$), stops when $F < 0.05$, and checks the integrated relation and the
breakdown time.

## 13. Which sources are real? The record on the Kohn-Sham states

The stresses above were chosen by hand. The Revision record asks the opposite
question for the only many-particle states it has computed, the Kohn-Sham states
of dirac16complex: can they be the source of the author's metric? The next cell
reads the record's answer, prints how many of its checks passed and checks that
every one did. The answer is no: every nonzero Kohn-Sham state depends on $x_0$
and violates $p_3 + p_t = 2p_0$, so the Kohn-Sham history $a_4 = AHx_4$ is a
prescribed background, not a solution of these equations with that source.
```

In [15]:

```
ks = read_json(KS)
say("record: " + ks["conclusion"])
detail = {entry["name"]: entry["detail"] for entry in ks["checks"]}

Text cell:

```
## 14. The record's numbers, recomputed from the Kohn-Sham table

The record does not only say no; it gives numbers. We recompute them here from
the table `emt-integrals.csv` of the Kohn-Sham record, which holds one row per
recorded ground state: its name (for example `N136_lam0_a10`: $N = 136$
particles, coupling $\lambda = 0$, slice $a_{4,0} = 1$) and the integrals over
the hidden direction, $2\,\mathrm{Vol}_7\int e^{6Hy}\,T\,dy$, of the energy
density and of the three pressures (columns `int_rho`, `int_p3`, `int_p_t`,
`int_p0`). If the source obeyed $p_3 + p_t = 2p_0$ at every point, it would also
obey it after the integration, and the ratio
$$r = \frac{\int p_3 + \int p_t}{2\int p_0}$$
would be exactly 1. The next cell

- counts the states, and those whose four integrals are not all zero (a state
  with a zero energy-momentum tensor is no source at all);
- computes $r$ for every other state, finds the one closest to 1, and prints $r$
  for the history $N = 136$, $\lambda = 0$ at the slices $a_{4,0} = 0, 1, 2$;
- compares every number with the text of the record, which prints them with six
  significant digits (the format `.6g`), so that a change of either is caught.
```

ALL 30 CHECKS PASSED (notebook 12c)
```

Text cell:

```
## 16. What this notebook showed

- With a prescribed anisotropic stress $p_3 - p_t$ the evolution equation
  $a_4''F(a_4') = \kappa(p_3 - p_t)$ is an ordinary differential equation for
  $a_4(x_4)$, which RK4 solves with fourth-order accuracy (COMPUTED, compared with
  exact solutions).
- No stress gives the linear member $a_4 = AHx_4$: 3-space inflates as
  $e^{AHx_4}$ and the extra times deflate as $e^{-AHx_4}$, with a constant
  7-volume (PROVED, and reproduced numerically).
- A pulse of stress can raise the deflation rate from $H$ to $2H$, and a relaxing
  stress can bring it back to $H$; along both histories the extra times deflate
  exponentially at every time (COMPUTED for ASSUMED stresses).
- The energy density that the conservation law gives equals the one that the
  constraint gives along every history, as the record's Bianchi identity requires
  (COMPUTED).
- In Einstein-Gauss-Bonnet gravity a constant stress drives $a_4'$ to the zero of
  $F$ in a finite time, where the evolution equation breaks down (PROVED by the
  integrated relation, COMPUTED numerically).
- None of these stresses is known to come from a field of the theory; the record
  shows that the Kohn-Sham states of the repository are not admissible sources
```

```
  (record ks-source-conditions.json). The notebook recomputes the record's
  numbers from the Kohn-Sham table: the integrated ratio
  $(\int p_3 + \int p_t)/(2\int p_0)$, which must be 1 for an admissible source,
  differs from 1 for every recorded state with a nonzero energy-momentum tensor
  (COMPUTED from the record's table; equal to the record).
```

12.25 Line-by-line walk-through of Notebook 12c

The notebook has 17 code cells, In [1] to In [17].

In [1], the set-up cell. As in Notebook 12a (Section 12.16, In [1]), except that the comments hold the run instructions of Notebook 12c (Section 12.23) and `NOTEBOOK_ID = "12c"`.

In [2], the records and the Lovelock components as functions.

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory
import math  # the error function erf, for an exact solution

import matplotlib.ticker  # control of the tick labels of an axis
import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra, used here only to read the record formulas
```

Besides the modules met before: `math`, Python's module of mathematical functions (it has the error function `math.erf`), and `matplotlib.ticker`, which controls the labels of axis ticks.

```
PY = "Revision/field_equations_a4/reports/python-a4-report.json"  # sympy record
WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"  # Wolfram record
EQUATIONS = "Revision/field_equations_a4/a4-equations.json"  # the equations
KS = "Revision/field_equations_a4/reports/ks-source-conditions.json"
```

Short names of four record files; `KS` is the record on the Kohn-Sham sources. The three helpers `read_json`, `record_verdict` and `reproduces` that follow are those of Notebook 12a, In [2] (Section 12.16).

```
record = read_json(EQUATIONS)
H, ad1, ad2 = sp.symbols("H ad1 ad2", real=True)
a1, a2, a3 = sp.symbols("alpha1 alpha2 alpha3", real=True)
LOCALS = {"H": H, "ad1": ad1, "ad2": ad2, "alpha1": a1, "alpha2": a2, "alpha3": a3}

def from_record(text):
    return sp.sympify(text.replace("^", "**"), locals=LOCALS).subs(H, 1)
```

The record is read; the symbols for H, a_4', a_4'' and the couplings are made (in this notebook the Python names of the couplings are `a1`, `a2`, `a3`, so that the name `alpha2` stays free for a plain number later); `from_record` parses a formula of the record and sets $H = 1$ (docstring left out).

```
lovelock = record["lovelockTensors"]
weights = {1: a1, 2: a2, 3: a3}

def lovelock_sum(component):
    return sum(weights[k] * from_record(lovelock[f"E{k}"][component]["input"])
               for k in (1, 2, 3))

e44 = lovelock_sum("x4x4")  # the time component (constraint)
e00 = lovelock_sum("x0x0")  # the hidden component
F_expr = from_record(record["generalSource"]["evolution_F"]["input"])
```

`lovelock_sum` forms $\sum_k \alpha_k E_{(k)}$ for one component of the record. It gives e_{44} and e_{00} of Section 12.8; F is read directly from the record.

```
rho_side = sp.lambdify((ad1, a1, a2, a3), e44, "numpy")
p0_side = sp.lambdify((ad1, a1, a2, a3), e00, "numpy")
F_of = sp.lambdify((ad1, a1, a2, a3), F_expr, "numpy")
say(f"F(a4') with H = 1: {F_expr}")
EINSTEIN = (1.0, 0.0, 0.0)  # alpha1, alpha2, alpha3 of Einstein gravity
```

Three fast numpy functions of the rate $v = a_4'$ and the couplings: `rho_side` is e_{44} (so $\kappa\rho = -(e_{44}+\Lambda)$), `p0_side` is e_{00} (so $\kappa p_0 = e_{00} + \Lambda$) and `F_of` is F. F is printed. `EINSTEIN` is a **tuple** (a fixed list in round brackets) of the Einstein couplings; `F_of(v, *EINSTEIN)` passes its three numbers as three arguments.

In [3], a test of the functions.

```
rates = np.array([-2.0, -0.5, 0.0, 1.0, 3.0])  # a few values of a4'
ok = (np.allclose(F_of(rates, *EINSTEIN), 2.0)
      and np.allclose(rho_side(rates, *EINSTEIN), 3 * rates ** 2 + 21)
      and np.allclose(p0_side(rates, *EINSTEIN), 15 - 3 * rates ** 2))
reproduces(ok, "Einstein: F = 2, E44 = 3 a4'^2 + 21, E88 = 15 - 3 a4'^2 (H = 1)",
           PY, "einstein_components")
```

At five rates the three functions must give the Einstein values of Section 12.9 (`np.allclose` compares arrays up to rounding).

In [4], the RK4 solver and its test.

```
def rk4(rhs, y0, h, steps, stop=None):
    xs = [0.0]
    ys = [np.array(y0, dtype=float)]
    for n in range(steps):
        x, y = xs[-1], ys[-1]
        k1 = rhs(x, y)
        k2 = rhs(x + h / 2, y + h / 2 * k1)
        k3 = rhs(x + h / 2, y + h / 2 * k2)
        k4 = rhs(x + h, y + h * k3)
```

```
        xs.append((n + 1) * h)  # (n + 1) h avoids adding up rounding errors
        ys.append(y + h / 6 * (k1 + 2 * k2 + 2 * k3 + k4))
        if stop is not None and stop(ys[-1]):
            break
    return np.array(xs), np.array(ys)
```

`rk4` solves $dy/dx =$ `rhs(x, y)` from $x = 0$ with the starting value `y0`, by at most `steps` steps of size `h` (docstring left out). The lists `xs` and `ys` hold the points reached; `[-1]` is the last one. The four lines `k1` to `k4` and the update are the RK4 formulas of Section 12.21, applied to the whole array `y` at once. The new x is computed as $(n + 1)h$ rather than by adding h again and again, which would accumulate rounding errors. If a function `stop` is given and returns true for the new point, `break` ends the loop early. The function returns the points as arrays: `ys[n, 0]` is the first component at step n.

```
x_test, y_test = rk4(lambda x, y: -y, [1.0], 0.05, 20)
error_test = abs(y_test[-1, 0] - math.exp(-1.0))
say(f"y' = -y: RK4 with h = 0.05 gives y(1) = {y_test[-1, 0]:.10f}; "
    f"exact {math.exp(-1.0):.10f}")
check(error_test < 1e-7, "RK4 solves y' = -y to better than 1e-7 with 20 steps")
```

A test with a known answer: $y' = -y$, $y(0) = 1$, whose solution is e^{-x}. `lambda x, y:  -y` is a one-line function without a name. Twenty steps of 0.05 reach $x = 1$; the result 0.3678794611 differs from $e^{-1} = 0.3678794412$ by 2×10^{-8}.

In [5], no stress: the linear member.

```
def history(stress, rate0, h, steps, couplings=EINSTEIN, Lam=0.0, stop=None):
    def rhs(x, y):
        push = stress(x, y)  # kappa (p3 - pt) at this time
        return np.array([y[1], push / F_of(y[1], *couplings), -3.0 * y[1] * push])

    rho0 = -(rho_side(rate0, *couplings) + Lam)  # kappa rho at x4 = 0
    return rk4(rhs, [0.0, rate0, rho0], h, steps, stop)
```

`history` integrates the first-order system of Section 12.21 for a given stress function (docstring left out). Inside it, `rhs` is the right-hand side for the state $y = (a_4, v, \kappa\rho)$: $dy_0/dx = v$, $dy_1/dx = \kappa\Delta/F(v)$, $dy_2/dx = -3v\,\kappa\Delta$. The starting energy density is taken from the constraint, $\kappa\rho = -(e_{44} + \Lambda)$ at the starting rate. The defaults are Einstein gravity and $\Lambda = 0$.

```
def no_stress(x, y):
    return 0.0  # Delta = 0: an isotropic source

linear = {}  # slope A -> (x4, solution)
for slope in (2.0, 1.0, -1.0):  # deflating A = 2, 1 and the mirror image A = -1
    linear[slope] = history(no_stress, slope, 0.01, 300)
    x4, y = linear[slope]
    error = np.max(np.abs(y[:, 0] - slope * x4))  # compare with a4 = A x4
    check(error < 1e-12, f"Delta = 0, A = {slope:g}: a4 = A H x4 exactly")
```

With zero stress, three histories of 300 steps of 0.01 (up to $x_4 = 3$) are integrated, starting at the rates $A = 2$, 1 and -1; `y[:, 0]` is the column of a_4 values, which must equal Ax_4 (the format `:g` prints 2.0 as 2).

```
x4, y = linear[1.0]
report("A = 1, Lambda = 0: kappa rho along the history", f"{y[-1, 2]:.6f}", "H^2")
product = np.exp(3 * y[:, 0]) * np.exp(-3 * y[:, 0])  # e^(3 a4) e^(-3 a4)
check(np.max(np.abs(product - 1.0)) < 1e-12,
      "the 7-volume factor e^(3 a4) e^(-3 a4) stays 1")
```

For $A = 1$ the energy density at the end is -24, the value of Section 12.12, and the 7-volume factor stays 1.

In [6], figure 1: the linear histories and the scale factors.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
for slope, style, words in ((2.0, "-", "deflating"), (1.0, "-.", "deflating"),
                            (-1.0, "--", "mirror image")):
    x4, y = linear[slope]
    left.plot(x4, y[:, 0], style, label=f"$A = {slope:g}$ ({words})")
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("$a_4$")
left.set_title("$\\Delta = 0$: $a_4 = AHx_4$")
left.legend(fontsize=8)
```

Two panels. The left one draws the three histories with three line styles (solid, dash-dotted, dashed).

```
x4, y = linear[1.0]
right.semilogy(x4, np.exp(y[:, 0]), label="3-space $e^{a_4}$ (inflates)")
right.semilogy(x4, np.exp(-y[:, 0]), "--", label="extra times $e^{-a_4}$ (deflate)")
right.semilogy(x4, np.exp(3 * y[:, 0]) * np.exp(-3 * y[:, 0]), ":", color="black",
               label="$e^{3a_4}e^{-3a_4} = 1$")
right.set_xlabel("time $x_4$ (units $1/H$)")
right.set_ylabel("scale factor")
right.set_title("$A = 1$: the scale factors")
right.legend(fontsize=8)
save_figure(fig, "linear_member",
            ...)
```

`semilogy` draws with a logarithmic vertical axis, on which an exponential is a straight line. **What the figure shows.** On the left three straight lines of slopes 2, 1 and -1. On the right e^{a_4} rises and e^{-a_4} falls along straight lines of equal and opposite slope, and the product of their cubes is the flat line 1.

In [7], the pulse.

```
X_C, WIDTH = 3.0, 0.5  # the centre and the width of the pulse
PUSH = 2.0 / (WIDTH * math.sqrt(math.pi))  # kappa Delta_0
RATE_START = 1.0  # a4'(0)/H: the canonical deflating history A = 1
```

```
def pulse(x, y):
    return PUSH * math.exp(-((x - X_C) / WIDTH) ** 2)  # kappa Delta(x4)
```

The constants of the pulse of Section 12.21 and the stress function itself (it ignores the state `y`).

```
def exact_pulse(x):
    scale = PUSH * WIDTH * math.sqrt(math.pi) / 4  # = 1/2
    t, t0 = (x - X_C) / WIDTH, -X_C / WIDTH  # the argument now and at x4 = 0

    def antiderivative(s):  # an antiderivative of erf
        return s * math.erf(s) + math.exp(-s * s) / math.sqrt(math.pi)

    rate = RATE_START + scale * (math.erf(t) + math.erf(X_C / WIDTH))
    a4 = RATE_START * x + scale * (WIDTH * (antiderivative(t) - antiderivative(t0))
                                   + x * math.erf(X_C / WIDTH))
    return a4, rate
```

The exact solution (docstring left out): `rate` is the formula for a_4' derived in Section 12.21; `a4` is its integral from 0, in which $\int_0^x \operatorname{erf}((s - x_c)/w)\, ds = w\,(\text{antiderivative}(t) - \text{antiderivative}(t_0))$ by the same substitution as before.

```
x4_pulse, y_pulse = history(pulse, RATE_START, 0.01, 800)
exact = np.array([exact_pulse(x) for x in x4_pulse])  # columns: a4, a4'
error_a4 = np.max(np.abs(y_pulse[:, 0] - exact[:, 0]))
error_rate = np.max(np.abs(y_pulse[:, 1] - exact[:, 1]))
say(f"largest error: a4 {error_a4:.0e}, a4' {error_rate:.0e}")
check(error_a4 < 1e-8 and error_rate < 1e-8,
      "pulse: RK4 (h = 0.01) agrees with the exact solution to 1e-8")
```

800 steps of 0.01 up to $x_4 = 8$; the exact values at the same points; the largest differences are 9×10^{-11} for a_4 and 10^{-10} for a_4' (COMPUTED).

```
check(np.min(y_pulse[:, 1]) >= 1.0 - 1e-12,
      "the rate a4' never falls below H: the extra times deflate at every time")
report("rate a4'/H after the pulse (x4 = 8)", f"{y_pulse[-1, 1]:.10f}")
check(abs(y_pulse[-1, 1] - 2.0) < 1e-8,
      "after the pulse a4' = 2 H: the deflating linear member A = 2")
```

The rate never falls below 1 (the stress is never negative), and at the end it is 2.0000000000.

In [8], figure 2: the pulse history in four panels.

```
fig, axes = plt.subplots(2, 2, figsize=(10.0, 7.0))
stress_values = np.array([pulse(x, None) for x in x4_pulse])
axes[0, 0].plot(x4_pulse, stress_values)
axes[0, 0].set_ylabel("$\\kappa(p_3 - p_t)$ (units $H^2$)")
axes[0, 0].set_title("the prescribed stress pulse")
```

A 2 by 2 grid of panels; `axes[0, 0]` is the top left one. The stress is evaluated at every time (`None` stands for the unused state) and drawn.

```
every = slice(0, None, 40)  # every 40th point for the exact markers
axes[0, 1].plot(x4_pulse, y_pulse[:, 1], label="RK4")
axes[0, 1].plot(x4_pulse[every], exact[every, 1], "o", markersize=3, label="exact")
axes[0, 1].set_ylabel("$a_4'/H$")
axes[0, 1].set_title("the rate $a_4'$")
axes[0, 1].legend(fontsize=8)
axes[1, 0].plot(x4_pulse, y_pulse[:, 0], label="RK4")
axes[1, 0].plot(x4_pulse[every], exact[every, 0], "o", markersize=3, label="exact")
axes[1, 0].set_ylabel("$a_4$")
axes[1, 0].set_title("$a_4$")
axes[1, 0].legend(fontsize=8)
```

`slice(0, None, 40)` selects every 40th entry of an array. The top right panel draws the RK4 rate as a line and the exact rate as dots; the bottom left one does the same for a_4.

```
axes[1, 1].semilogy(x4_pulse, np.exp(y_pulse[:, 0]), label="3-space $e^{a_4}$")
axes[1, 1].semilogy(x4_pulse, np.exp(-y_pulse[:, 0]), "--",
                    label="extra times $e^{-a_4}$")
axes[1, 1].set_ylabel("scale factor")
axes[1, 1].set_title("the scale factors")
axes[1, 1].legend(fontsize=8)
for ax in axes[1]:
    ax.set_xlabel("time $x_4$ (units $1/H$)")
fig.tight_layout()
save_figure(fig, "stress_pulse",
            ...)
```

The bottom right panel draws both scale factors on a logarithmic axis; `axes[1]` is the bottom row, whose panels get the label of the time axis; `fig.tight_layout()` spaces the panels so that labels do not overlap. **What the figure shows.** The rate climbs from 1 to 2 while the pulse acts and stays there; a_4 bends from slope 1 to slope 2; on the logarithmic axis e^{-a_4} falls along a straight line that becomes twice as steep after the pulse: the extra times deflate at every time.

In [9], figure 3: the required source and the test of conservation.

```
def as_power_of_ten(value):
    mantissa, exponent = f"{value:.0e}".split("e")
    return f"${mantissa} \\times 10^{{{int(exponent)}}}$"
```

A small helper for the caption (docstring left out): the format `.0e` writes a number with one digit, for example `2e-11`; splitting at the letter e gives the digit and the exponent, which are put into mathematics as 2×10^{-11} (a tripled brace in an f-string prints one brace around the value).

```
rate = y_pulse[:, 1]
rho_constraint = -(rho_side(rate, *EINSTEIN) + 0.0)  # kappa rho, Lambda = 0
p0_values = p0_side(rate, *EINSTEIN) + 0.0  # kappa p0
```

```
p3_values = p0_values + stress_values / 2  # kappa p3
pt_values = p0_values - stress_values / 2  # kappa pt
mismatch = np.abs(y_pulse[:, 2] - rho_constraint)  # conservation versus constraint
say(f"largest difference of the two energy densities: {mismatch.max():.0e}")
```

Along the pulse history the four parts of the source follow from the field equations (Section 12.9; the `+ 0.0` is $\Lambda = 0$ written out): $\kappa\rho$ from the constraint, κp_0 from the hidden equation, and p_3, p_t from p_0 and the stress. `mismatch` is the difference between the energy density carried along by the conservation law (the third column of the state) and the constraint's: at most 2×10^{-11}.

```
reproduces(mismatch.max() < 1e-8,
           "the energy density from conservation equals the constraint along x4",
           WL, "constraint_propagation_bianchi")
check(abs(rho_constraint[0] + 24) < 1e-6 and abs(p0_values[0] - 12) < 1e-6,
      "before the pulse: kappa rho = -24, kappa p = 12 (the linear member A = 1)")
check(abs(rho_constraint[-1] + 33) < 1e-6 and abs(p0_values[-1] - 3) < 1e-6,
      "after the pulse: kappa rho = -33, kappa p = 3 (the linear member A = 2)")
```

The agreement is the numerical form of the record's constraint propagation (Section 12.10). The source starts at the values of $A = 1$ and ends at those of $A = 2$: $-(3 \cdot 4 + 21) = -33$ and $15 - 12 = 3$.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
left.plot(x4_pulse, rho_constraint, label="$\\kappa\\rho$")
left.plot(x4_pulse, p3_values, label="$\\kappa p_3$")
left.plot(x4_pulse, pt_values, "--", label="$\\kappa p_t$")
left.plot(x4_pulse, p0_values, ":", color="black", label="$\\kappa p_0$")
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("required source (units $H^2$)")
left.set_title("the source of the pulse history")
left.legend(fontsize=8)
right.semilogy(x4_pulse, np.maximum(mismatch, 1e-16))  # exact zeros at 1e-16
right.set_xlabel("time $x_4$ (units $1/H$)")
right.set_ylabel("$|\\kappa\\rho$ conserved $-$ $\\kappa\\rho$ constraint$|$")
right.set_title("conservation agrees with the constraint")
save_figure(fig, "required_source",
            ...)
```

The four source curves on the left; the mismatch on a logarithmic axis on the right, where a value of exactly zero (whose logarithm does not exist) is drawn at 10^{-16} by `np.maximum`. The caption, passed to `save_figure`, contains the measured mismatch written by `as_power_of_ten`. **What the figure shows.** Outside the pulse all three pressures coincide; during it p_3 and p_t split symmetrically about p_0, and ρ falls from -24 to -33. The mismatch stays at the level of the RK4 error.

In [10], the relaxing stress.

```
damped = {}  # eta -> (x4, solution)
for eta in (0.25, 0.5, 1.0):
    def friction(x, y, eta=eta):
        return -2.0 * eta * (y[1] - 1.0)  # kappa Delta = -2 eta (a4' - H)
```

```
    x4, y = history(friction, 2.0, 0.01, 1000)  # start on A = 2
    damped[eta] = (x4, y)
```

For three values of η the stress $\kappa\Delta = -2\eta(a_4' - 1)$ depends on the state. The argument `eta=eta` stores the current value of η in the function; without it all three functions would use the last value of the loop. Each history has 1000 steps of 0.01, up to $x_4 = 10$.

```
    exact_a4 = x4 + (1.0 / eta) * (1.0 - np.exp(-eta * x4))
    error = np.max(np.abs(y[:, 0] - exact_a4))
    mismatch = np.max(np.abs(y[:, 2] + rho_side(y[:, 1], *EINSTEIN)))
    check(error < 1e-9 and mismatch < 1e-8,
          f"eta = {eta}: a4 = x4 + (1 - e^(-eta x4))/eta, conservation holds")
    check(np.min(y[:, 1]) > 1.0,
          f"eta = {eta}: the rate a4' stays above H (the extra times deflate)")
    report(f"eta = {eta}: rate a4'/H at x4 = 10", f"{y[-1, 1]:.6f}")
```

The exact a_4 of Section 12.21 is compared, and conservation against the constraint as in In [9]. The rate stays above 1 and at $x_4 = 10$ equals $1 + e^{-10\eta}$: 1.082085, 1.006738 and 1.000045.

In [11], figure 4: the relaxing histories.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
x4 = damped[0.25][0]
for slope, style, power in ((2.0, ":", "-2x_4"), (1.0, "-.", "-x_4")):
    left.plot(x4, slope * np.ones_like(x4), style, color="black",
              label=f"linear member $A = {slope:g}$")  # the two linear members
    right.semilogy(x4, np.exp(-slope * x4), style, color="black",
                   label=f"$A = {slope:g}$: $e^{{{power}}}$")
for eta, (x4, y) in damped.items():
    left.plot(x4, y[:, 1], label=f"$\\eta = {eta}$")
    right.semilogy(x4, np.exp(-y[:, 0]), label=f"$\\eta = {eta}$")
```

The two linear members $A = 2$ and $A = 1$ in black (constant rates on the left; e^{-2x_4} and e^{-x_4} on the right, the exponent written into the label by the f-string), then the three relaxing histories: their rates on the left and their extra-time scale factors on the right.

```
left.set_ylim(0.0, 2.3)
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("$a_4'/H$")
left.set_title("the deflation rate relaxes from $2H$ to $H$")
left.legend(fontsize=8)
right.set_xlabel("time $x_4$ (units $1/H$)")
right.set_ylabel("extra-time scale factor $e^{-a_4}$")
right.set_title("the extra times keep deflating")
right.legend(fontsize=8)
save_figure(fig, "damped_deflation",
            ...)
```

Labels and `save_figure`. **What the figure shows.** Each rate falls from 2 towards 1, faster for larger η. On the logarithmic axis each scale factor starts along the steeper black line and ends parallel to the flatter one: the deflation slows down but never stops.

In [12], figure 5: the convergence of RK4.

```
def relaxing_unit(x, y):
    return -2.0 * (y[1] - 1.0)  # kappa Delta = -2 eta (a4' - H) with eta = 1

exact_end = 8.0 + (1.0 - math.exp(-8.0))  # the exact a4(8) for eta = 1
steps_list = [20, 40, 80, 160, 320]  # h = 8/steps = 0.4, 0.2, 0.1, 0.05, 0.025
sizes, errors = [], []
for steps in steps_list:
    x4, y = history(relaxing_unit, 2.0, 8.0 / steps, steps)
    sizes.append(8.0 / steps)
    errors.append(abs(y[-1, 0] - exact_end))
```

The relaxing history with $\eta = 1$ is integrated to $x_4 = 8$ five times, with 20, 40, 80, 160 and 320 steps, and the error of $a_4(8)$ is stored for each step size.

```
orders = [math.log2(errors[i] / errors[i + 1]) for i in range(len(errors) - 1)]
for i, (size, error) in enumerate(zip(sizes, errors)):
    order = f"{orders[i - 1]:.2f}" if i > 0 else "-"
    say(f"h = {size:<6} error of a4(8) = {error:.2e}   measured order {order}")
check(all(3.7 < q < 4.3 for q in orders),
      "RK4 converges with order 4 (measured orders between 3.7 and 4.3)")
```

If the error is Ch^q, then halving h divides it by 2^q, and $q = \log_2(e_h/e_{h/2})$ (`math.log2` is the logarithm to base 2). The table prints each step (`:<6` pads it to six characters), its error with two decimals in powers of ten, and the measured order: 4.24, 4.12, 4.06, 4.03 (COMPUTED). The check requires every order to lie between 3.7 and 4.3.

```
fig, ax = plt.subplots()
ax.loglog(sizes, errors, "o-", label="error of $a_4(8)$")
reference = errors[-1] * (np.array(sizes) / sizes[-1]) ** 4
ax.loglog(sizes, reference, "--", color="black", label="slope 4: $C h^4$")
ax.set_xticks(sizes)  # one tick at each step size used
ax.set_xticklabels([f"{size:g}" for size in sizes])
ax.xaxis.set_minor_formatter(matplotlib.ticker.NullFormatter())  # no extra labels
ax.set_xlabel("step size $h$ (units $1/H$)")
ax.set_ylabel("absolute error")
ax.set_title("RK4 on the relaxing history: fourth-order convergence")
ax.legend(fontsize=8)
save_figure(fig, "rk4_convergence",
            ...)
```

`loglog` uses logarithmic scales on both axes, where Ch^4 is a straight line of slope 4. The reference line passes through the last measured point. The ticks of the horizontal axis are put at the five step sizes; `NullFormatter` removes the labels of the small extra ticks that a logarithmic axis would add.
What the figure shows. The five points lie on the reference line: the method is of fourth order.

In [13], the Gauss-Bonnet breakdown.

```
STRESS, RATE0 = 0.5, 1.0  # kappa Delta and the starting rate a4'(0) = H (A = 1)

def constant_stress(x, y):
    return STRESS
```

A constant stress $\kappa\Delta = 0.5$, starting on the canonical history.

```
breakdown = {}  # alpha2 -> (x4, solution, predicted breakdown time)
for alpha2 in (0.005, 0.01):
    couplings = (1.0, alpha2, 0.0)

    def G(v, alpha2=alpha2):
        return (2 - 80 * alpha2) * v - 16 * alpha2 * v ** 3  # dG/dv = F

    critical = math.sqrt((2 - 80 * alpha2) / (48 * alpha2))  # F(critical) = 0
    x_star = (G(critical) - G(RATE0)) / STRESS  # the breakdown time
```

For two Gauss-Bonnet couplings: the function G of Section 12.21, the critical rate where $F = 0$ and the predicted breakdown time $x_4^\star$.

```
    def near_zero(y, couplings=couplings):
        return F_of(y[1], *couplings) < 0.05  # stop before F reaches zero

    x4, y = history(constant_stress, RATE0, 0.001, 20000, couplings,
                    stop=near_zero)
    breakdown[alpha2] = (x4, y, x_star)
```

`near_zero` tells `rk4` to stop when F falls below 0.05, before the division by F explodes. The integration uses the small step 0.001, because a_4'' grows steeply near the breakdown.

```
    residual = np.max(np.abs(G(y[:, 1]) - G(RATE0) - STRESS * x4))
    check(residual < 1e-6, f"alpha2 = {alpha2}: G(a4') = G(a4'(0)) + kappa Delta x4")
    check(abs(x4[-1] - x_star) < 0.01,
          f"alpha2 = {alpha2}: F reaches 0 near the predicted time x4*")
    report(f"alpha2 = {alpha2}: critical rate, breakdown time x4*",
           f"{critical:.4f} H, {x_star:.4f}/H")
```

Along the numerical history the integrated relation $G(a_4') = G(a_4'(0)) + \kappa\Delta x_4$ must hold, and the integration must stop within 0.01 of $x_4^\star$. The RESULT lines give 2.5820 and 2.4682 for $\alpha_2 = 0.005$, and 1.5811 and 0.4498 for $\alpha_2 = 0.01$.

In [14], figure 6: the breakdown compared with Einstein gravity.

```
x_einstein, y_einstein = history(constant_stress, RATE0, 0.01, 500)
check(np.max(np.abs(y_einstein[:, 1] - (RATE0 + STRESS * x_einstein / 2))) < 1e-12,
      "Einstein: a4' = 1 + 0.25 x4 for the constant stress")
```

In Einstein gravity ($F = 2$) the same stress gives $a_4' = 1 + 0.25x_4$ up to $x_4 = 5$, exactly.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
left.plot(x_einstein, y_einstein[:, 1], color="black", label="Einstein")
right.plot(x_einstein, F_of(y_einstein[:, 1], *EINSTEIN) * np.ones_like(x_einstein),
           color="black", label="Einstein")
for alpha2, (x4, y, x_star) in breakdown.items():
    line = left.plot(x4, y[:, 1], label=f"$\\alpha_2H^2 = {alpha2}$")[0]
    left.axvline(x_star, linestyle="--", color=line.get_color(), linewidth=0.8)
    right.plot(x4, F_of(y[:, 1], 1.0, alpha2, 0.0), color=line.get_color(),
               label=f"$\\alpha_2H^2 = {alpha2}$")
```

The Einstein rate and $F = 2$ in black. `F_of(y_einstein[:, 1], *EINSTEIN)` is already an array with one value 2 per time, because the formula of F still contains the rate in terms multiplied by the couplings $\alpha_2 = \alpha_3 = 0$; multiplying by `np.ones_like(x_einstein)`, an array of ones of the same length, is only a safeguard, as in Notebook 12a, In [24] (Section 12.16): a formula with no rate left in it would give the single number 2. For each Gauss-Bonnet history the rate is drawn; `plot` returns a list of drawn lines, and `[0]` takes the line, whose colour `get_color()` is reused for a dashed vertical line at $x_4^\star$ (`axvline`) and for the curve of F on the right.

```
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("$a_4'/H$")
left.set_title("the rate under a constant stress")
left.legend(fontsize=8)
right.axhline(0.0, color="black", linewidth=0.8)
right.set_xlabel("time $x_4$ (units $1/H$)")
right.set_ylabel("$F(a_4')$")
right.set_title("$F$ along the history")
right.legend(fontsize=8)
save_figure(fig, "gauss_bonnet_breakdown",
            ...)
```

What the figure shows. In Einstein gravity the rate rises along a straight line for ever. With the Gauss-Bonnet coupling it bends upwards ever more steeply and reaches the dashed line, the predicted $x_4^\star$, where F (right) drops to zero: the evolution equation breaks down at a finite time.

In [15], the record on the Kohn-Sham states.

```
ks = read_json(KS)
say("record: " + ks["conclusion"])
detail = {entry["name"]: entry["detail"] for entry in ks["checks"]}
verdicts = [entry["verdict"] for entry in ks["checks"]]
passed = verdicts.count("PASS")  # how many checks of the record passed
say(f"{KS}: {passed} of {len(verdicts)} checks PASS")
check(len(verdicts) > 0 and passed == len(verdicts) == ks["summary"]["checks"]
      and "ks_history_is_a_prescribed_background" in detail,
      "record: no Kohn-Sham state is an admissible source (every check PASS)")
```

The record is read and its conclusion printed. `detail` is made by a **dictionary comprehension**: a dictionary that maps the name of each check of the record to its detail text, which the next cell reads. The verdicts are counted as in Notebook 12a, In [2], and the count is printed with the name of the report. The check requires that the report has checks, that all of them passed, that the

report's own summary counts the same number (a chained comparison `a == b == c` is true when $a = b$ and $b = c$), and that the check stating the prescribed background is present (`in` tests whether a name is a key of the dictionary).

In [16], the record's numbers recomputed from the Kohn-Sham table.

```
import csv  # reads tables of comma-separated values
import re  # regular expressions: find a pattern in a text

TABLE = "Revision/kohn_sham/results/ground/emt-integrals.csv"
with repository_file(TABLE).open(encoding="utf-8", newline="") as handle:
    table = {row["id"]: row for row in csv.DictReader(handle)}
INTEGRALS = ("int_rho", "int_p3", "int_p_t", "int_p0")  # 2 Vol_7 int e^(6Hy) T dy
```

`csv` and `re` come with Python. The `with` block opens the table of the Kohn-Sham record and closes it again at the end of the block. `csv.DictReader` reads the table line by line: its first line holds the names of the columns, and every further line becomes a dictionary from column name to text. `table` maps the name of each state (column `id`) to its row. `INTEGRALS` names the four columns of the integrated energy density and pressures.

```
zero = sorted(name for name, row in table.items()
              if all(float(row[column]) == 0.0 for column in INTEGRALS))
nonzero = [name for name in table if name not in zero]
report("Kohn-Sham states in the table", len(table))
report("states with a nonzero energy-momentum tensor", len(nonzero))
say("states with a zero energy-momentum tensor: " + ", ".join(zero))
```

`zero` lists, in alphabetical order, the states whose four integrals are all exactly zero (`float` turns a text such as `0.000000000000000e0` into the number 0; `all` is true when every one of its values is true); `nonzero` holds the other states. Out [16] reports 75 states, 70 of them with a nonzero energy-momentum tensor, and names the five others: the five slices of the state with $N = 8$ particles and $\lambda = 0$.

```
counted = re.search(r"(\d+) ground-state profiles .*?\((\d+) with a nonzero",
                    detail["ks_profiles_depend_on_x0"])
reproduces(counted is not None
           and counted.groups() == (str(len(table)), str(len(nonzero))),
           f"{len(nonzero)} of the {len(table)} states have a nonzero tensor",
           KS, "ks_profiles_depend_on_x0")
listed = detail["ks_zero_source_states_listed"].rsplit(": ", 1)[-1].split(", ")
reproduces(sorted(listed) == zero,
           "the states with a zero tensor are the ones the record lists",
           KS, "ks_zero_source_states_listed")
```

The record writes its two counts into the detail text of its check `ks_profiles_depend_on_x0`, in the words "75 ground-state profiles ... (70 with a nonzero energy-momentum tensor)". `re.search` looks for a **pattern** in that text: `\d+` matches one or more digits, round brackets around a part of the pattern **capture** what that part matches, `.*?` matches any text up to the next part of the pattern, and `\(` matches a round bracket itself. `counted.groups()` returns the two captured numbers as

texts, which must equal our two counts. The detail text of the check `ks_zero_source_states_listed` ends, after its last colon, with the list of the states whose tensor is zero: `rsplit(":  ", 1)[-1]` takes the text after the last colon and space, and `split(", ")` cuts it at the commas. Both comparisons are made with `reproduces`, so the record's checks must also have the verdict PASS.

```
ratio = {}  # r = (int p3 + int p_t)/(2 int p0) of every nonzero state
for name in nonzero:
    row = table[name]
    if float(row["int_p0"]) != 0.0:
        ratio[name] = ((float(row["int_p3"]) + float(row["int_p_t"]))
                       / (2 * float(row["int_p0"])))
closest = min(ratio, key=lambda name: abs(ratio[name] - 1.0))
report(f"closest to 1: r of {closest}", f"{ratio[closest]:.6g}")
HISTORY = ["N136_lam0_a00", "N136_lam0_a10", "N136_lam0_a20"]  # N = 136, lambda = 0
for name in HISTORY:
    slice_a4 = float(table[name]["a4"])  # the slice a4,0 of this state
    report(f"N = 136, lambda = 0, a4,0 = {slice_a4:g}: r", f"{ratio[name]:.6g}")
```

For every nonzero state with $\int p_0 \neq 0$ the ratio $r = (\int p_3 + \int p_t)/(2 \int p_0)$ is computed. `min(ratio, key=...)` returns the name whose ratio has the smallest distance $|r - 1|$ from 1 (`lambda name: ...` is a small function written in one line). The format `.6g` prints six significant digits, as the record does, and `:g` prints the slice $a_{4,0}$ (column `a4`) without trailing zeros. Out [16] shows the state closest to 1, N688_lamm2_a00, with $r = 0.414328$, and for the history $N = 136$, $\lambda = 0$ the ratios 0.339767, 0.25969 and 0.239714 at $a_{4,0} = 0, 1, 2$: far from the required 1 at every slice.

```
text = detail["ks_integrals_violate_algebraic_condition"]
tolerance = float(ks["tolerance"].split()[-1])  # "relative 1e-06" gives 1e-06
best = re.search(r"closest to 1: (\S+) at (\w+)", text)
reproduces(len(ratio) == len(nonzero) and abs(ratio[closest] - 1.0) > tolerance
           and best is not None
           and best.groups() == (f"{ratio[closest]:.6g}", closest),
           "r differs from 1 for every nonzero state; the closest as recorded",
           KS, "ks_integrals_violate_algebraic_condition")
found = [re.search(name + r": (\S+?)[,\s]", text) for name in HISTORY]
reproduces(all(item is not None and item.group(1) == f"{ratio[name]:.6g}"
               for item, name in zip(found, HISTORY)),
           "r of N = 136, lambda = 0 at a4,0 = 0, 1, 2 equals the record",
           KS, "ks_integrals_violate_algebraic_condition")
```

The record's tolerance is read from its text "relative 1e-06" (`split()` cuts the text at the spaces, `[-1]` takes the last part). The first check requires a ratio for every nonzero state, that even the closest one differs from 1 by more than the tolerance, and that the record names the same closest state with the same six digits (`\S+` matches characters that are not spaces, `\w+` letters, digits and underscores). The second check finds in the record's text, for each state of the history, the number after its name and a colon (`\S+?` takes as few characters as possible, up to the comma or space that `[,\s]` matches) and requires it to be exactly our number printed with six digits; `zip` walks through the two lists side by side. A change of the Kohn-Sham record, or of its checker, that moved any of these numbers would stop the notebook here.

In [17], the last check.

```
figure_names = ["linear_member", "stress_pulse", "required_source",
                "damped_deflation", "rk4_convergence", "gauss_bonnet_breakdown"]
paths = [output_file(f"{FIGURE_FOLDER}/12c_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths), "all six figure files exist")
all_checks_passed()
```

The same pattern as In [15] of Notebook 12b (Section 12.20): `figure_names` lists the short names of the six figures in the order in which they were drawn, `enumerate(figure_names, 1)` numbers them from 1, which gives the six file names `12c_1_linear_member.png` to `12c_6_gauss_bonnet_breakdown.png`, and `output_file` gives the path where each was written. `path.is_file()` is true when the file exists, and `all` requires this of every one of the six. `all_checks_passed()` prints the last line, ALL 30 CHECKS PASSED (notebook 12c): 1 check in In [3], 1 in In [4], 4 in In [5], 3 in In [7], 3 in In [9], 6 in In [10], 1 in In [12], 4 in In [13], 1 in In [14], 1 in In [15], 4 in In [16] and 1 in In [17].

12.26 A condensate of dirac16complex00 as an exact source

The previous examples prescribed the source. Can a field of this theory be the source, exactly? The Revision record proves three facts about the commuting field dirac16complex00 (Chapter 7), and leaves one question open. This section derives what the last notebook needs.

The field and its equation. dirac16complex00 is a column Φ of 16 complex numbers at every point, which transform as a Pin(4,4) spinor. The gamma matrices are the author's eight real 16 by 16 matrices $\gamma^{(x_0)}, \ldots, \gamma^{(x_7)}$ of the record `Revision/algebra/gammas.json` (built from the author's formulas in Chapter 4), which satisfy the Clifford relation $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}$ with $\eta = \mathrm{diag}(+,+,+,+,-,-,-,-)$ (record checks `authorT16_clifford`; Notebook 12d, In [3]). The adjoint is $\bar{\Phi} = \Phi^\dagger C$ with the real symmetric matrix $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, $C^2 = 1$, and $C\gamma^{(a)}$ antisymmetric for every a (record check `authorT16_C_properties`). The density $S = \bar{\Phi}\Phi$ is a real number. With the potential $U = \frac{\lambda}{2}S^2$ the field equation of the record is

$$\gamma^\mu D_\mu \Phi = (m + \lambda S)\,\Phi = M\,\Phi, \qquad D_\mu = \partial_\mu + \Omega_\mu,$$

where $M = m + \lambda S$ is the **effective mass**, $\gamma^\mu = \gamma^{(\mu)}/\sqrt{|g_{\mu\mu}|}$ are the gammas of the curved metric and Ω_μ is the spin connection of Chapter 6. For the author's metric, with the author's gammas, the spin connection enters the equation only through one term (PROVED: sympy record, check `authorT16_gravity_term`; lead's record, check `gamma_Omega_equals_3H_gamma0`; Notebook 12d, In [5]):

$$\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}.$$

The condensate equation. For a condensate, $\Phi = \Phi(x_4)$, only the derivative along x_4 survives, and $\gamma^{x_4} = \gamma^{(x_4)}$ because $g_{44} = -1$. Line by line:

$$\gamma^{(x_4)}\Phi' + 3H\gamma^{(x_0)}\Phi = M\Phi$$

(the field equation for $\Phi(x_4)$, with the spin-connection term inserted)

$$\gamma^{(x_4)}\Phi' = \big(M - 3H\gamma^{(x_0)}\big)\Phi$$

(subtract $3H\gamma^{(x_0)}\Phi$ from both sides)

$$\Phi' = -\gamma^{(x_4)}\big(M - 3H\gamma^{(x_0)}\big)\Phi =: \mathcal{A}\,\Phi$$

(multiply from the left by $-\gamma^{(x_4)}$, since $(-\gamma^{(x_4)})\gamma^{(x_4)} = -\eta^{44} = 1$). The 16 by 16 matrix $\mathcal{A}$ contains neither a_4 nor z: the condensate does not feel the deflation (record check `condensate_equation_x0_consistent`).

Its square. Line by line:

$$\mathcal{A}^2 = \gamma^{(x_4)}\big(M - 3H\gamma^{(x_0)}\big)\gamma^{(x_4)}\big(M - 3H\gamma^{(x_0)}\big)$$

(the two minus signs multiply to plus)

$$= \gamma^{(x_4)}\gamma^{(x_4)}\big(M + 3H\gamma^{(x_0)}\big)\big(M - 3H\gamma^{(x_0)}\big)$$

(move the middle $\gamma^{(x_4)}$ to the left: $\gamma^{(x_0)}\gamma^{(x_4)} = -\gamma^{(x_4)}\gamma^{(x_0)}$ by the Clifford relation, so $(M - 3H\gamma^{(x_0)})\gamma^{(x_4)} = \gamma^{(x_4)}(M + 3H\gamma^{(x_0)})$)

$$= (-1)\big(M^2 - 3HM\gamma^{(x_0)} + 3HM\gamma^{(x_0)} - 9H^2(\gamma^{(x_0)})^2\big) = -\big(M^2 - 9H^2\big)$$

($(\gamma^{(x_4)})^2 = -1$, $(\gamma^{(x_0)})^2 = +1$; the middle terms cancel). So for $M^2 > 9H^2$, with the frequency $w = \sqrt{M^2 - 9H^2}$, the condensate oscillates. If $\mathcal{A}v = \mu v$ for a nonzero vector v, then $\mu^2 v = \mathcal{A}^2 v = -w^2 v$, so every eigenvalue of $\mathcal{A}$ is $+iw$ or $-iw$. Both occur, each 8 times: $\mathcal{A}$ is real, so its characteristic polynomial $\det(\mu - \mathcal{A})$ has real coefficients, and the non-real root iw comes together with its complex conjugate $-iw$, with the same multiplicity; the 16 roots therefore split as $8 + 8$ (Exercise 10 gives a second proof with the trace; Notebook 12d, In [7], counts eight and eight numerically). Every vector u is a sum of eigenvectors of the two kinds, $u = u_- + u_+$ with $u_- = \frac{1}{2}(u + \frac{i}{w}\mathcal{A}u)$ and $u_+ = \frac{1}{2}(u - \frac{i}{w}\mathcal{A}u)$: indeed $\mathcal{A}u_- = \frac{1}{2}(\mathcal{A}u + \frac{i}{w}\mathcal{A}^2 u) = \frac{1}{2}(\mathcal{A}u - iwu) = -iw\,u_-$ (with $\mathcal{A}^2 = -w^2$), and in the same way $\mathcal{A}u_+ = +iw\,u_+$. An eigenvector Φ_0 with $\mathcal{A}\Phi_0 = -iw\Phi_0$ gives the solution $\Phi(x_4) = e^{-iwx_4}\Phi_0$ (its derivative is $-iw\Phi = \mathcal{A}\Phi$). For $M = \pm 5H$, $w = 4H$. The hidden-direction term moves the threshold of oscillation from $|M| = 0$ to $|M| = 3H$ (Notebook 12d, In [6] and figure 1).

The density is constant. Line by line:

$$S' = (\Phi')^\dagger C\Phi + \Phi^\dagger C\Phi' = \Phi^\dagger(\mathcal{A}^T C + C\mathcal{A})\Phi$$

(product rule; $(\mathcal{A}\Phi)^\dagger = \Phi^\dagger\mathcal{A}^\dagger$, and $\mathcal{A}^\dagger = \mathcal{A}^T$ because $\mathcal{A}$ is real). Now $\mathcal{A} = -M\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}$, and $C\gamma^{(a)}$ antisymmetric means $(\gamma^{(a)})^T C = -C\gamma^{(a)}$ (transpose $(C\gamma^{(a)})^T = (\gamma^{(a)})^T C^T$ and $C^T = C$). Hence $(\gamma^{(x_4)})^T C + C\gamma^{(x_4)} = 0$, and

$$(\gamma^{(x_4)}\gamma^{(x_0)})^T C = (\gamma^{(x_0)})^T(\gamma^{(x_4)})^T C = -(\gamma^{(x_0)})^T C\gamma^{(x_4)} = C\gamma^{(x_0)}\gamma^{(x_4)} = -C\gamma^{(x_4)}\gamma^{(x_0)}$$

(transpose of a product reverses the order; the rule above twice; the Clifford relation), so $\mathcal{A}^T C + C\mathcal{A} = 0$ and $S' = 0$ (record check `authorT16_condensate_S_constant`).

Its energy-momentum tensor. The record writes the source as $T^{\mu}{}_{\nu} = \sigma_T\big(-K^{(\mu}{}_{\nu)} + \delta^{\mu}_{\nu} L\big)$ with the kinetic tensor $K^{\mu}{}_{\nu} = \frac{1}{2}\big(\bar{\Phi}\gamma^{\mu} D_{\nu}\Phi - (D_{\nu}\bar{\Phi})\gamma^{\mu}\Phi\big)$, its symmetrised form $K^{(\mu}{}_{\nu)}$, and the on-shell Lagrangian $L = \sum_{\mu} K^{\mu}{}_{\mu} - mS - U$. The overall sign $\sigma_T = +1$ is the record's declared convention and is not fixed by a Revision check: it is ASSUMED. For a condensate the record proves that the diagonal of K is $K^{x_4}{}_{x_4} = MS$ and zero in the seven other directions, and that $K^{x_4}{}_{x_0} = 0$ (check `authorT16_condensate_kinetic_diagonal`). Then, line by line:

$$L = MS - mS - \tfrac{\lambda}{2}S^2 = (m + \lambda S)S - mS - \tfrac{\lambda}{2}S^2 = \tfrac{\lambda}{2}S^2$$

(the definition, $M = m + \lambda S$, and $\lambda S^2 - \frac{\lambda}{2}S^2 = \frac{\lambda}{2}S^2$), and

$$\rho = -T^{x_4}{}_{x_4} = K^{x_4}{}_{x_4} - L = MS - \tfrac{\lambda}{2}S^2 = mS + \tfrac{\lambda}{2}S^2, \qquad p_3 = p_t = p_0 = L = \tfrac{\lambda}{2}S^2.$$

So the condensate supplies exactly what the linear member needs: equal pressures and constant ρ and p. But the 42 nonzero off-diagonal components of K are multiples of 15 **three-gamma bilinears** $\bar{\Phi}\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$: the six with $\{a,b,c\} = \{i, x_4, x_0\}$ (i a 3-space direction or an extra time) and the nine with $\{i, j, x_4\}$ (i in 3-space, j an extra time). The off-diagonal field equations $0 = \kappa T^{\mu}{}_{\nu}$ need all 15 to vanish (Wolfram record, check `condensate_offdiagonal_are_three_gamma_bilinears`). The record shows that condensates with all 15 zero exist (checks `condensate_diagonal_witness_exact` and `authorT16_condensate_witness`), and it proves that such a condensate allows only the linear member (key `theoremLinear` of `Revision/field_equations_a4/a4-equations.json`), under exact hypotheses. *Hypotheses*: Φ is a homogeneous condensate as above (classical, commuting) that solves its field equation and satisfies the off-diagonal conditions (all 15 bilinears zero); a_4 is twice continuously differentiable; the couplings are not all zero, $(\alpha_1, \alpha_2, \alpha_3) \neq (0,0,0)$. *Conclusion*: $a_4 = AHx_4 + a_0$ with real constants A and a_0. *Proof*: the condensate has $p_3 = p_t$, so the evolution equation gives $a_4'' F(a_4') = 0$ at every time. Suppose $a_4'' \neq 0$ at some time. Since a_4'' is continuous, $a_4'' \neq 0$ on a whole interval around it, so $F(a_4') = 0$ there: a_4' takes only values among the roots of F. F is a polynomial in a_4' that is not identically zero when the couplings are not all zero (record check `evolution_F_not_identically_zero`), so it has finitely many roots. A continuous function on an interval that takes only finitely many values is constant there (between two different values it would have to pass through all the values in between). So a_4' is constant on the interval and $a_4'' = 0$ there, a contradiction. Hence $a_4'' = 0$ at every time, $a_4' = AH$ is constant and $a_4 = AHx_4 + a_0$.

The two Einstein conditions. For the linear member the Einstein equations with this source are the time equation and seven equal equations (Section 12.12):

$$(21 + 3A^2)H^2 + \Lambda = -\kappa\rho, \qquad (15 - 3A^2)H^2 + \Lambda = \kappa p.$$

Subtracting the second from the first:

$$(21 + 3A^2 - 15 + 3A^2)H^2 = -\kappa(\rho + p) \;\Rightarrow\; \kappa MS = -6(A^2 + 1)H^2$$

(Λ cancels; $\rho + p = mS + \lambda S^2 = (m + \lambda S)S = MS$). Adding them:

$$(21+3A^2+15-3A^2)H^2+2\Lambda=-\kappa(\rho-p)\ \Rightarrow\ \kappa mS=-(36H^2+2\Lambda)$$

($\rho-p=mS$). These are the record's two conditions (PROVED: check `condensate_einstein_quadratic_U` in both reports; Notebook 12b, In [13], and Notebook 12d, In [13]). The first says that a real slope needs $\kappa MS\le -6H^2$: the density and the effective mass must have opposite signs. Given A, Λ and M they fix $S=-6(A^2+1)H^2/(\kappa M)$, then $m=-(36H^2+2\Lambda)/(\kappa S)$, then $\lambda=(M-m)/S$.

What the record leaves open. The record's document `Revision/docs/DIRAC16COMPLEX00_FIELD_THEORY.md` says: "This record contains no check that combines a witness with the Einstein conditions." Notebook 12d makes that combination. It needs condensates with all 15 bilinears zero AND a density of the required sign and size. It builds them from two eigenvectors v_1, v_2 of $\mathcal{A}$ with the same frequency (the record's recipe; Section 12.30, In [8], explains how they are found) as the family $\Phi_0(t)=v_1+t\,c\,v_2$ with a real parameter t and $c=\overline{v_1^\dagger C v_2}$ (the bar is the complex conjugate). Its density, with $\sigma=v_1^\dagger C v_2$ and the notebook's finding $v_1^\dagger C v_1=v_2^\dagger C v_2=0$:

$$S(t)=v_1^\dagger C v_1+t\,c\,v_1^\dagger C v_2+t\,\bar c\,v_2^\dagger C v_1+t^2|c|^2\,v_2^\dagger C v_2=t\,\bar\sigma\sigma+t\,\sigma\bar\sigma=2t\,|\sigma|^2$$

(expand the product; $c=\bar\sigma$; $v_2^\dagger C v_1=\bar\sigma$ because C is real and symmetric). So every real density, positive or negative, occurs. With the record's $H=\kappa=1$ and $\sigma=-128/25-96i/25$ at $M=-5$: $|\sigma|^2=(128^2+96^2)/625=1024/25$ and $S(t)=2048t/25$ (Notebook 12d, In [9]).

Three exact solutions (units $H=\kappa=1$):

example	A	Λ	M	S	m	λ	(ρ,p)
1	1	0	-5	$12/5$	-15	$25/6$	$(-24,12)$
2	$\sqrt{5}$	0	5	$-36/5$	5	0	$(-36,0)$
3	1	-30	-5	$12/5$	10	$-25/4$	$(6,-18)$

The equations of state $w=p/\rho$ are $-1/2$, 0 and -3. Example 1 by hand: $S=-6(1+1)/(-5)=12/5$; $m=-36/S=-36\cdot 5/12=-15$; $\lambda=(M-m)/S=(-5+15)\cdot 5/12=25/6$; $\rho=mS+\frac{\lambda}{2}S^2=-36+\frac{25}{12}\cdot\frac{144}{25}=-36+12=-24$; $p=12$. Examples 1 and 3 have the canonical history $a_4=Hx_4$: the extra times deflate as e^{-Hx_4}. Notebook 12d checks, exactly and for every time and every value of the hidden coordinate, all 16 components of the field equation and all 64 components of the Einstein equations, for $+A$ and for $-A$ (In [15]).

Status. These three solutions are PROVED for the stated numbers by exact computer algebra, under ASSUMED inputs: Einstein gravity, the sign convention $\sigma_T=+1$, the classical commuting field dirac16complex00 (not the quantised dirac16complex), and the chosen values of Λ, m and λ. They are a computation of this book, not a Revision record. The equations do not select the sign of A: the same condensate solves them with $-A$. With $\Lambda=0$ the energy density is negative; a positive one (example 3) needs $\Lambda<-(21+3A^2)H^2$ and then has $w<-1$. Not shown: whether such a condensate is stable, how it could arise, anything about the quantised field, and anything about the creation of universes.

12.27 Example: three exact solutions of the coupled equations

The last notebook rebuilds, with exact rational and complex-rational arithmetic and the author's eight real gamma matrices, the spin-connection term, the condensate equation and its solution, builds the family of condensates with all 15 three-gamma bilinears zero, computes their complete energy-momentum tensor in the author's metric with an arbitrary $a_4(x_4)$, solves the two Einstein conditions and checks the three exact solutions of Section 12.26 component by component. It runs in about 25 seconds, prints 40 PASS lines and draws six figures.

12.28 How to run Notebook 12d

Step 1. What this notebook does and what it needs.

Notebook 12d (An exact solution: a condensate of dirac16complex00 as the source of the deflating member) is the file `Revision/textbook/notebooks/12d_condensate_solution.ipynb` of the repository Dirac_claude. It builds, with exact arithmetic and the author's gamma matrices, homogeneous condensates of the commuting field dirac16complex00 whose 15 three-gamma bilinears vanish, computes their complete energy-momentum tensor in the author's metric, chooses the mass, the self-coupling and the cosmological constant so that the Einstein equations hold, and checks every component of the field equation of the condensate and of the Einstein equations for the exponentially deflating linear member a4 = H x4 (and a4 = sqrt(5) H x4), at every time x4 and every value of the hidden coordinate. It reproduces the Revision records where they overlap and draws six teaching plots. The combination of a condensate with the Einstein conditions is a computation of this notebook; the Revision record states that it does not contain one. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two

commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 12d_condensate_solution.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 25 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12d_condensate_solution.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 12d_condensate_solution.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/12d.captions.json`
- `Revision/textbook/figures/12d_1_condensate_frequency.png`
- `Revision/textbook/figures/12d_2_three_gamma_bilinears.png`
- `Revision/textbook/figures/12d_3_allowed_sources.png`
- `Revision/textbook/figures/12d_4_tensor_equality.png`
- `Revision/textbook/figures/12d_5_solution_in_time.png`
- `Revision/textbook/figures/12d_6_family_in_lambda.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 40 CHECKS PASSED (notebook 12d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/12d_condensate_solution.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 12d_condensate_solution.ipynb
python -m nbconvert --execute --inplace 12d_condensate_solution.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads the Revision records of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

12.29 Notebook 12d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/12d_condensate_solution.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The other notebooks of this chapter derive the field equations for $a_4(x_4)$ and
the source that a given $a_4$ requires. Here we ask whether a field of the theory
can BE that source, exactly, with the extra times deflating exponentially. The
Revision record proves three things about a homogeneous condensate of the commuting
field dirac16complex00 (a solution $\Phi(x_4)$ that depends on the time only):

1. it can be a source of the author's metric only for the linear member
   $a_4 = AHx_4 + a_0$, and then only if 15 numbers built from it, the three-gamma
   bilinears, are zero;
2. in Einstein gravity it must then meet two conditions that tie its mass $m$,
   its self-coupling $\lambda$ and its density $S$ to $A$ and $\Lambda$;
3. condensates with all 15 bilinears zero exist (exact examples).

The record states that it contains no check that combines 3 with 2. This notebook
does that combination, with exact arithmetic (rational and complex-rational
numbers, never rounded) and the author's gamma matrices. It

- rebuilds the spin-connection term $\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$ and
  the condensate equation, and solves it for every starting spinor;
- builds a one-parameter family of condensates with all 15 bilinears zero and a
  density $S$ of either sign;
- computes their complete energy-momentum tensor (all 64 components) in the
  author's metric with an arbitrary $a_4(x_4)$;
- solves the two Einstein conditions and finds three exact solutions of the
  coupled equations, two of them with the extra times deflating as $e^{-Hx_4}$;
- checks all 16 components of the field equation of the condensate and all 64
  components of the Einstein equations, at every time $x_4$ and every value of
  the hidden coordinate;
- states exactly what this shows and what it does not, and draws six plots.
```

Text cell:

2. How to run this notebook

Step 1. What this notebook does and what it needs.

Notebook 12d (An exact solution: a condensate of dirac16complex00 as the source of the deflating member) is the file ‘Revision/textbook/notebooks/12d_condensate_solution.ipynb‘ of the repository Dirac_claude. It builds, with exact arithmetic and the author’s gamma matrices, homogeneous condensates of the commuting field dirac16complex00 whose 15 three-gamma bilinears vanish, computes their complete energy-momentum tensor in the author’s metric, chooses the mass, the self-coupling and the cosmological constant so that the Einstein equations hold, and checks every component of the field equation of the condensate and of the Einstein equations for the exponentially deflating linear member a4 = H x4 (and a4 = sqrt(5) H x4), at every time x4 and every value of the hidden coordinate. It reproduces the Revision records where they overlap and draws six teaching plots. The combination of a condensate with the Einstein conditions is a computation of this notebook; the Revision record states that it does not contain one. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
```

```
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 12d_condensate_solution.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 25 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 12d_condensate_solution.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 12d_condensate_solution.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/12d.captions.json‘
- ‘Revision/textbook/figures/12d_1_condensate_frequency.png‘
- ‘Revision/textbook/figures/12d_2_three_gamma_bilinears.png‘
- ‘Revision/textbook/figures/12d_3_allowed_sources.png‘
- ‘Revision/textbook/figures/12d_4_tensor_equality.png‘
- ‘Revision/textbook/figures/12d_5_solution_in_time.png‘
- ‘Revision/textbook/figures/12d_6_family_in_lambda.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files exist
ALL 40 CHECKS PASSED (notebook 12d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
    python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/12d_condensate_solution.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
    python -m jupyterlab 12d_condensate_solution.ipynb
    python -m nbconvert --execute --inplace 12d_condensate_solution.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" naming a file below the folder Revision: the notebook reads the Revision records of the repository. Run it inside the folder Revision/textbook/notebooks of a complete copy of the repository made with git clone, not on a copy of the notebook file alone.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 12d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 12d (An exact solution: a condensate of dirac16complex00 as the source of the
# deflating member) is the file Revision/textbook/notebooks/12d_condensate_solution.ipynb
```

```
# of the repository Dirac_claude. It builds, with exact arithmetic and the author's gamma
# matrices, homogeneous condensates of the commuting field dirac16complex00 whose 15
# three-gamma bilinears vanish, computes their complete energy-momentum tensor in the
# author's metric, chooses the mass, the self-coupling and the cosmological constant so
# that the Einstein equations hold, and checks every component of the field equation of
# the condensate and of the Einstein equations for the exponentially deflating linear
# member a4 = H x4 (and a4 = sqrt(5) H x4), at every time x4 and every value of the

# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
```

```
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 12d_condensate_solution.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 25
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 12d_condensate_solution.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 12d_condensate_solution.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
```

```
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/12d.captions.json
# - Revision/textbook/figures/12d_1_condensate_frequency.png
# - Revision/textbook/figures/12d_2_three_gamma_bilinears.png
# - Revision/textbook/figures/12d_3_allowed_sources.png
# - Revision/textbook/figures/12d_4_tensor_equality.png
# - Revision/textbook/figures/12d_5_solution_in_time.png
# - Revision/textbook/figures/12d_6_family_in_lambda.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files exist
#     ALL 40 CHECKS PASSED (notebook 12d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/12d_condensate_solution.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
```

```
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 12d_condensate_solution.ipynb
#     python -m nbconvert --execute --inplace 12d_condensate_solution.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" naming a file below the folder Revision: the notebook reads the
#   Revision records of the repository. Run it inside the folder
#   Revision/textbook/notebooks of a complete copy of the repository made with git clone,
#   not on a copy of the notebook file alone.

## 3. The words used in this notebook

- **Coordinates** $x_0, \dots, x_7$ (the author's names): $x_1, x_2, x_3$ ordinary
  3-space, $x_4$ the time, $x_5, x_6, x_7$ the three extra times (which deflate
  exponentially), $x_0$ the hidden direction with $z = 6Hx_0$ in $(0, \pi/2)$. In the
  code the positions 0 to 7 of a list stand for $x_0$ to $x_7$.
- **Gamma matrices** $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$: the author's eight real
  16 by 16 matrices with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} =
  2\eta^{ab}$, $\eta = \mathrm{diag}(+,+,+,+,-,-,-,-)$ (the Clifford relation).
- **Spinor** $\Phi$: a column of 16 complex numbers (here: functions of $x_4$).
  dirac16complex00 is a field of such spinors whose components are ordinary
  (commuting) complex numbers.
- **Adjoint** $\bar\Phi = \Phi^\dagger C$ with $C = \gamma^{(x_0)}\gamma^{(x_1)}
  \gamma^{(x_2)}\gamma^{(x_3)}$; $\Phi^\dagger$ is the row of complex conjugates.
```

```
- **Density** $S = \bar\Phi\Phi$, a real number. **Bilinear**: a number
  $\bar\Phi X \Phi$ with a 16 by 16 matrix $X$; a **three-gamma bilinear** has
  $X = \gamma^{(a)}\gamma^{(b)}\gamma^{(c)}$ with three different directions.
- **Mass** $m$, **self-coupling** $\lambda$, **potential** $U(S) = \tfrac\lambda2 S^2$
  with $U'(S) = \lambda S$; **effective mass** $M = m + \lambda S$.
- **Spin connection** $\Omega_\mu$: the 16 by 16 matrices that make the derivative
  of a spinor covariant, $D_\mu\Phi = \partial_\mu\Phi + \Omega_\mu\Phi$.
- **Condensate**: a solution that depends on the time $x_4$ only.
- **Frequency** $w$: in $e^{-iwx_4}$, the number of radians per unit of time.
- **Energy-momentum tensor** $T^\mu{}_\nu$: the energy density
  $\rho = -T^{x_4}{}_{x_4}$, the pressures $p_\mu = T^\mu{}_\mu$ (no sum), and the
  mixed components; **sign convention** $\sigma_T = +1$ of the Revision record.
- **Einstein equations** with cosmological constant $\Lambda$ and coupling
  $\kappa$: $G^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu$.
- **Linear member** $a_4 = AHx_4 + a_0$: for $A > 0$ the extra times deflate as
  $e^{-AHx_4}$ while 3-space inflates as $e^{AHx_4}$.
- **Witness**: an explicit example that proves that something exists.
- **Units**: $H = 1$ and $\kappa = 1$ in the examples ($\kappa$ and the size of
  $\Phi$ enter the equations only through $\kappa S$).
```

Text cell:

```
## 4. The physical and mathematical situation

The coupled equations are, for the field (the Euler-Lagrange equation of the
Revision record, with $\gamma^\mu = e_a{}^\mu\gamma^{(a)}$ the gammas of the curved
metric),

$$\gamma^\mu D_\mu\Phi = (m + U'(S))\,\Phi,$$

and for the metric, in Einstein gravity,

$$G^\mu{}_\nu + \Lambda\delta^\mu_\nu = \kappa T^\mu{}_\nu,\qquad
T^\mu{}_\nu = \sigma_T\big(-K^{(\mu}{}_{\nu)} + \delta^\mu_\nu L\big),$$

$$K^\mu{}_\nu = \tfrac12\big(\bar\Phi\gamma^\mu D_\nu\Phi
- (D_\nu\bar\Phi)\gamma^\mu\Phi\big),\qquad
L = \sum_\mu K^\mu{}_\mu - mS - U(S),$$

where $K^{(\mu}{}_{\nu)}$ is the symmetrised kinetic tensor and $L$ the Lagrangian
on shell (the record's formulas; $\sigma_T = +1$). For the linear member the
Einstein tensor is diagonal with $G^{x_4}{}_{x_4} = (21 + 3A^2)H^2$ and all seven
other diagonal entries $(15 - 3A^2)H^2$.

**Status.** Every check below is an exact identity verified by computer algebra
(PROVED for the stated numbers). ASSUMED: Einstein gravity, the sign convention
$\sigma_T = +1$, the classical commuting field dirac16complex00 (not the quantised
dirac16complex), and the values of $\Lambda$, $m$, $\lambda$ chosen below. The
combination of a condensate with the Einstein conditions is new in this notebook;
it is not a Revision record.
```

Text cell:

5. The Revision records this notebook reproduces

The next cell defines the helpers that read the Revision records: ‘read_json‘
reads a JSON file of the repository, ‘record_verdict‘ finds a check by its name in
a report, and ‘reproduces‘ is a check that passes only when this notebook’s own
result holds AND the record lists the named check with the verdict PASS (it
collects its two printed lines in a text buffer and prints them with one call, so
that they always stay together in the output). It then
prints the sentence of the record’s document that this notebook answers.

In [2]:

```
import contextlib  # redirect_stdout: send printed lines into a buffer
import io  # StringIO: a text buffer in memory

GAMMAS = "Revision/algebra/gammas.json"  # the author's gamma matrices
EQUATIONS = "Revision/field_equations_a4/a4-equations.json"  # the a4 equations
PY = "Revision/field_equations_a4/reports/python-a4-report.json"  # sympy record
WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"  # Wolfram record
EMT = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
DOC = "Revision/docs/DIRAC16COMPLEX00_FIELD_THEORY.md"  # the record's document

def read_json(relative):
    """Read a JSON file of the repository (a Revision record)."""
    return json.loads(repository_file(relative).read_text(encoding="utf-8"))

def record_verdict(report_file, name):
    """The verdict of the check name in a report ("PASS"), None if absent."""
    for entry in read_json(report_file)["checks"]:
        if entry["name"] == name:
            return entry["verdict"]
    return None

def reproduces(condition, name, report_file, record_name):
    """A check that also requires the record check record_name to be PASS.  Its
    printed lines (PASS and reproduces) are collected in a text buffer and printed
    by one print call, so that they always stay together in the cell's output."""
    found = record_verdict(report_file, record_name) == "PASS"
    lines = io.StringIO()  # a text buffer
    with contextlib.redirect_stdout(lines):  # print() now writes into the buffer
        check(condition and found, name, record=f"{report_file}, check {record_name}")
    print(lines.getvalue(), end="")  # all lines at once

OPEN_SENTENCE = ("This record contains no check that combines a witness with the "
                 "Einstein conditions")
document = repository_file(DOC).read_text(encoding="utf-8")
say(f"{DOC} says: \"{OPEN_SENTENCE}.\"")
check(OPEN_SENTENCE in document, "the record leaves this combination open")
```

Out [2]:

```
Revision/docs/DIRAC16COMPLEX00_FIELD_THEORY.md says: "This record contains no check that
    combines a witness with the Einstein conditions."
PASS the record leaves this combination open
```

Text cell:

```
## 6. The author's gamma matrices and the matrix $C$

The next cell reads the eight gamma matrices from the Revision record
`gammas.json` (each entry an integer or a fraction written as text, which
`sp.Rational` turns into an exact number), checks the Clifford relation for all 64
pairs, builds $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$,
compares it with the $C$ stored in the record, and checks the three properties the
adjoint needs: $C$ is real and symmetric, $C^2 = 1$, and every $C\gamma^{(a)}$ is
antisymmetric.
```

In [3]:

```
import itertools  # loops over all combinations of indices

import numpy as np  # floating-point arrays, used only for the plots
import sympy as sp  # exact algebra

    authorT16_C_properties
```

Text cell:

```
## 7. The spin connection and the term $3H\gamma^{(x_0)}$

The vielbein of the author's diagonal metric is diagonal: $e^a{}_\mu = E_a
\delta^a_\mu$ with $E_a = \sqrt{|g_{aa}|}$, that is $E = (e^{a_4}s, e^{a_4}s,
e^{a_4}s, 1, e^{-a_4}s, e^{-a_4}s, e^{-a_4}s, \cot z)$ with $s = \sin^{1/6} z$.
The canonical spin connection is
$\omega_\mu{}^a{}_b = e^a{}_\nu(\partial_\mu e_b{}^\nu + \Gamma^\nu{}_{\mu\lambda}
e_b{}^\lambda)$ with the inverse vielbein $e_b{}^\nu = \delta_b^\nu/E_b$. For
$a = b$ the two terms cancel ($E_a\partial_\mu(1/E_a) = -\partial_\mu\ln E_a$ and
$\Gamma^a{}_{\mu a} = \partial_\mu\ln E_a$); for $a \ne b$ only the second survives:

$$\omega_{\mu\,ab} = \eta_{aa}\,\omega_\mu{}^a{}_b
= \eta_{aa}\,\frac{E_a}{E_b}\,\Gamma^a{}_{\mu b}\qquad(a \ne b),$$

and $\Omega_\mu = \tfrac12\sum_{a,b}\omega_{\mu\,ab}S^{ab}$ with
$S^{ab} = \tfrac14[\gamma^{(a)}, \gamma^{(b)}]$. The next cell computes the
Christoffel symbols of the diagonal metric (with $\partial/\partial x_0 =
6H\,\partial/\partial z$), the connection and the eight matrices $\Omega_\mu$ for an
arbitrary function $a_4(x_4)$, writing every function of $z$ through
$\cot z$ (the helper `clean`, as in Notebook 12a).
```

In [4]:

```
H = sp.symbols("H", positive=True)  # the constant H of the metric
z = sp.symbols("z", positive=True)  # z = 6 H x0 in (0, pi/2)

## 8. The condensate equation and its solution for every starting spinor

For $\Phi = \Phi(x_4)$ only the $x_4$ derivative survives, and $\gamma^{x_4} =
\gamma^{(x_4)}$ (because $E_4 = 1$). With the term of section 7 the field equation
becomes $\gamma^{(x_4)}\Phi' + 3H\gamma^{(x_0)}\Phi = M\Phi$, $M = m + U'(S)$.
Multiplying by $\gamma^{(x_4)}$ and using $(\gamma^{(x_4)})^2 = -1$:

$$\Phi' = \mathcal{A}\,\Phi,\qquad \mathcal{A} = -\gamma^{(x_4)}\big(M -
3H\gamma^{(x_0)}\big).$$

The matrix $\mathcal{A}$ contains neither $a_4$ nor $z$: the condensate does not
feel the deflation at all. Squaring, with $(\gamma^{(x_4)})^2 = -1$,
$(\gamma^{(x_0)})^2 = 1$ and $\gamma^{(x_4)}\gamma^{(x_0)} =
-\gamma^{(x_0)}\gamma^{(x_4)}$, the mixed terms cancel and

$$\mathcal{A}^2 = -(M^2 - 9H^2)\cdot 1 .$$

So, for $M^2 > 9H^2$ and $w = \sqrt{M^2 - 9H^2}$, every solution is
$\Phi(x_4) = \cos(wx_4)\,\Phi(0) + \tfrac{\sin(wx_4)}{w}\,\mathcal{A}\Phi(0)$
(differentiate twice: $\Phi'' = -w^2\Phi$, and $\Phi'(0) = \mathcal{A}\Phi(0)$).
The next cell checks the reduction, the square, and $C\mathcal{A} +
\mathcal{A}^TC = 0$, which makes $S$ constant: $S' = \Phi^\dagger(\mathcal{A}^T C
+ C\mathcal{A})\Phi = 0$ (the matrices are real, $M$ is real).

## 9. Condensates whose 15 three-gamma bilinears vanish
```

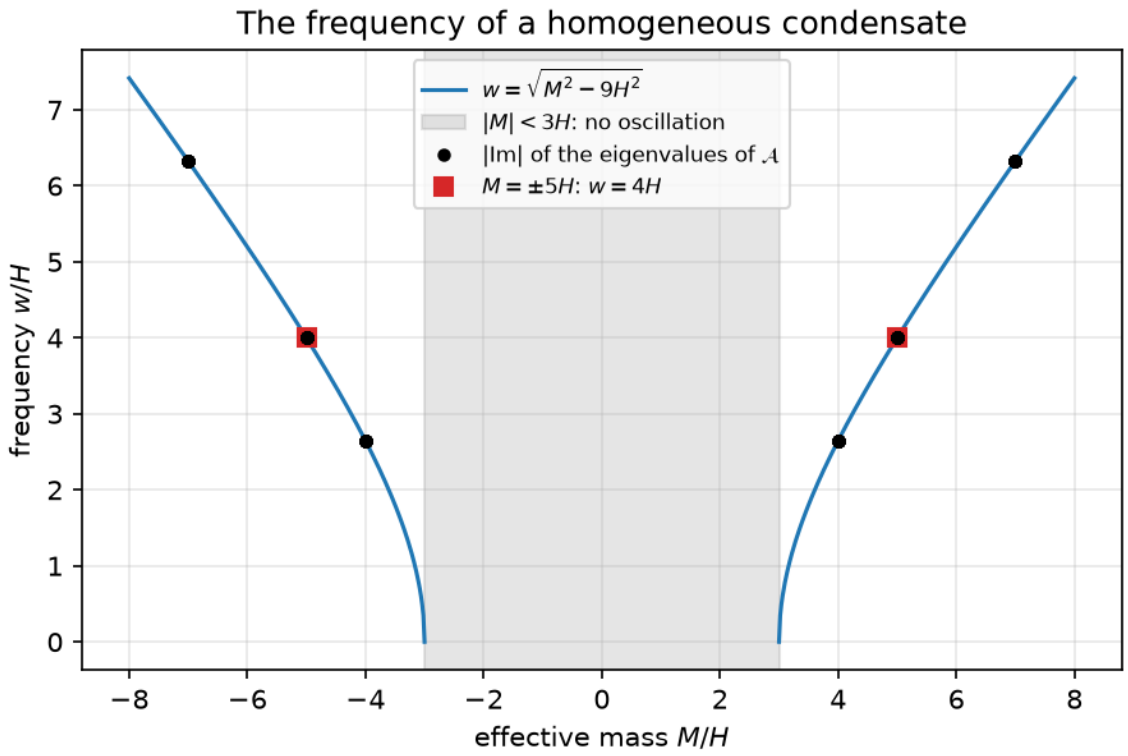

Figure 338: The frequency w of a homogeneous condensate of dirac16complex00 in the author's metric as a function of its effective mass $M = m+\lambda S$, both in units of H: the curve $w = \sqrt{M^2 - 9H^2}$ from $\mathcal{A}^2 = -(M^2 - 9H^2)$, and as black dots the absolute imaginary parts of the 16 eigenvalues of the 16 by 16 matrix $\mathcal{A}$, computed numerically at six masses (each dot stands for all 16 eigenvalues of its mass, eight equal to $+iw$ and eight equal to $-iw$). In the grey band $|M| < 3H$ the eigenvalues are real and the condensate grows or decays instead of oscillating. The red squares mark $M = \pm 5H$, $w = 4H$, the masses used in this notebook. The hidden-direction term $3H\gamma^{(x_0)}$ of the field equation shifts the threshold from 0 to $3H$. (Notebook 12d, figure 1.)

The Revision record shows that the off-diagonal parts of the kinetic tensor of a condensate are multiples of 15 three-gamma bilinears $B_{abc} = \bar\Phi\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}\Phi$: the six with $\{a, b, c\} = \{i, x_4, x_0\}$ (i a 3-space direction or an extra time) and the nine with $\{i, j, x_4\}$ (i in 3-space, j an extra time). The off-diagonal Einstein equations $0 = \kappa T^\mu{}_\nu$ need all 15 to vanish. The record's recipe for such a condensate, at $M = -5$, $H = 1$, $w = 4$: take the spinor v_1 with $\mathcal{A}v_1 = -iwv_1$ and $\gamma^{(x_1)}\gamma^{(x_5)} = \gamma^{(x_2)}\gamma^{(x_6)} = \gamma^{(x_3)}\gamma^{(x_7)} = -1$ on it, the spinor v_2 with the same frequency and the value $+1$, and $c = \overline{v_1^\dagger C v_2}$ (the bar is the complex conjugate). Each is found as the null space (the solutions of a set of linear equations) of a stacked matrix. We extend the recipe to the family

$$\Phi_0(t) = v_1 + t\,c\,v_2\qquad(t \text{ any real number}),$$

and the condensate is $\Phi(x_4) = e^{-iwx_4}\Phi_0(t)$. The next cell builds v_1, v_2 and c, checks that each null space is one-dimensional, that $\Phi_0(t)$ has the frequency w, and that the 15 bilinears vanish for EVERY real t (sympy keeps t as a symbol).

In [8]:

```
t = sp.symbols("t", real=True)  # the free real parameter of the family
TRIPLES = list(itertools.combinations(range(8), 3))  # all 56 sets {a, b, c}

## 10. The complete energy-momentum tensor of the condensate

The next cell computes the kinetic tensor $K^\mu{}_\nu$ for every pair
$(\mu, \nu)$ as a bilinear $\Phi_0^\dagger N^\mu{}_\nu\Phi_0$, with the matrix
$N^\mu{}_\nu = \tfrac12(C\gamma^\mu\mathcal{D}_\nu - \bar{\mathcal{D}}_\nu
```

```
\gamma^\mu)$, where $\mathcal{D}_\nu = \mathcal{A}\delta_{\nu 4} + \Omega_\nu$ acts
on $\Phi$ ($\Phi' = \mathcal{A}\Phi$) and $\bar{\mathcal{D}}_\nu =
\mathcal{A}^TC\delta_{\nu 4} - C\Omega_\nu$ on $\bar\Phi$ (the phase $e^{-iwx_4}$
cancels in every bilinear). It works for the whole family (symbol $t$) and for an
ARBITRARY $a_4(x_4)$ and every $z$, at $H = 1$. Then it symmetrises,
$K^{(\mu}{}_{\nu)} = \tfrac12\big(K^\mu{}_\nu + (g_{\nu\nu}/g_{\mu\mu})
K^\nu{}_\mu\big)$ (lower the upper index, symmetrise, raise it again), and checks
the record's statements: every off-diagonal component vanishes, for every $a_4$,
$a_4'$ and $z$; on the diagonal only $K^{x_4}{}_{x_4} = MS$ survives.
```

With $\sigma_T = +1$ the energy-momentum tensor is $T^\mu{}_\nu = -K^{(\mu}{}_{\nu)} +
\delta^\mu_\nu L$, $L = \sum_\mu K^\mu{}_\mu - mS - U(S) = MS - mS - U$. On shell
$M = m + \lambda S$, so $L = \lambda S^2 - \tfrac\lambda2 S^2 = \tfrac\lambda2 S^2$,
and therefore

$$\rho = -T^{x_4}{}_{x_4} = MS - L = mS + \tfrac\lambda2S^2,\qquad
p_3 = p_t = p_0 = L = \tfrac\lambda2 S^2,$$

with all mixed components zero. The next cell builds this tensor with symbols $m$
and $\lambda$ (and $M = -5 = m + \lambda S$) and checks these formulas.
```

```
## 11. The two Einstein conditions and their solution

For the linear member the Einstein equations with this source are the time
equation $(21 + 3A^2)H^2 + \Lambda = -\kappa\rho$ and the seven equal equations
$(15 - 3A^2)H^2 + \Lambda = \kappa p$ (the mixed ones read $0 = 0$, section 10).
Their difference and their sum give, with $\rho + p = (m + \lambda S)S = MS$ and
$\rho - p = mS$:

$$\kappa MS = -6(A^2 + 1)H^2,\qquad \kappa mS = -(36H^2 + 2\Lambda).$$
```

```
These are the record's two conditions. The first fixes the density: a real slope
$A$ needs $\kappa MS \le -6H^2$, so $S$ and $M$ must have opposite signs (possible
in our family, which has both signs of $S$). The second then fixes $m$, and
$\lambda = (M - m)/S$. The next cell reads the Einstein components from the record
'a4-equations.json', checks this equivalence with sympy, and solves for $S$, $m$
and $\lambda$.
```

(Notebook 12d, figure 3.)

```
## 12. Three exact solutions of the coupled equations

With $H = \kappa = 1$ and the slopes $A = 1$ (the canonical deflating history of
the Revision record) and $A = \sqrt5$:

| example | $A$ | $\Lambda$ | $M$ | $S$ | $m$ | $\lambda$ | $\rho$ | $p$ |
| --- | --- | --- | --- | --- | --- | --- | --- | --- |
| 1 | $1$ | $0$ | $-5$ | $12/5$ | $-15$ | $25/6$ | $-24$ | $12$ |
| 2 | $\sqrt5$ | $0$ | $5$ | $-36/5$ | $5$ | $0$ | $-36$ | $0$ |
| 3 | $1$ | $-30$ | $-5$ | $12/5$ | $10$ | $-25/4$ | $6$ | $-18$ |

(from $S = -6(A^2 + 1)/M$, $m = -(36 + 2\Lambda)/S$, $\lambda = (M - m)/S$,
$\rho = mS + \lambda S^2/2$, $p = \lambda S^2/2$). Examples 1 and 2 are the two
worked examples of Notebook 12b (there $S$ and $A^2$ were found from $m$,
$\lambda$ and $\Lambda$); example 3 has a positive energy density. For each, the
next cell computes the parameter $t$ of the family from $S(t)$, builds
$\Phi_0(t)$ (at $M = +5$ for example 2), and checks EXACTLY:

1. the 16 components of the field equation $\gamma^\mu D_\mu\Phi = (m +
   \lambda S)\Phi$ for $\Phi = e^{-iwx_4}\Phi_0$, with the full $\sum_\mu
   \gamma^\mu\Omega_\mu$ of section 7, an arbitrary $a_4(x_4)$ and every $z$;
2. all 64 components $G^\mu{}_\nu + \Lambda\delta^\mu_\nu - \kappa T^\mu{}_\nu = 0$
   of the Einstein equations for the linear member with this $A$, at every
   $x_4$ and $z$ ($T$ from section 10, $G$ from the record);
3. the same 64 components with $-A$: the equations contain $A$ only as $A^2$.
```

## 13. The solution in time

The next cell draws example 1 as functions of the time $x_4$: on the left the real
parts of three components of $\Phi(x_4) = e^{-4ix_4}\Phi_0$ (they oscillate with
the period $2\pi/4$) and the density $S = 12/5$, which stays constant; on the
right, on a logarithmic axis, the scale factor $e^{a_4} = e^{x_4}$ of 3-space and
$e^{-a_4} = e^{-x_4}$ of the extra times, which deflate exponentially, together
with those of example 2 ($a_4 = \sqrt5\,x_4$).
```

In [18]:

```
sol = solutions["example 1"]

## 14. The whole family for the deflating member $A = 1$

For $A = 1$, $M = -5$ and $S = 12/5$ (the condensate of examples 1 and 3) every
cosmological constant gives a solution: $m = -(36 + 2\Lambda)/S$,
$\lambda = (M - m)/S$, $\kappa\rho = -24 - \Lambda$, $\kappa p = 12 + \Lambda$. The
next cell checks this family against the exact solutions and draws $m$, $\lambda$,
$\kappa\rho$ and $\kappa p$ as functions of $\Lambda$. The energy density is
positive only for $\Lambda < -24H^2$, and then $p < -\rho$: $w < -1$, because
$\kappa(\rho + p) = \kappa MS = -12H^2$ for every $\Lambda$ (the violation of the
null energy condition that Notebook 12a proved for every source of this metric).
```

In [19]:

```
lam_axis = sp.symbols("Lambda_axis", real=True)
S_one = sp.Rational(12, 5)

## 15. What this shows, and what it does not

- **PROVED here (exact):** for each of the three examples the author's metric with
  the linear member ($a_4 = Hx_4$ for examples 1 and 3: the extra times deflate as
  $e^{-Hx_4}$; $a_4 = \sqrt5\,Hx_4$ for example 2) and the condensate
  $\Phi = e^{-iwx_4}\Phi_0$ solve the field equation of dirac16complex00 (16
  components) and the Einstein equations (64 components) at every time and every
  value of the hidden coordinate. So the coupled equations of the theory have exact
  solutions in which a field of the theory drives the exponential deflation of the
  extra times. This answers, for these examples, the combination that the Revision
  record leaves open; it is a computation of this notebook, not a Revision record.
- **ASSUMED:** Einstein gravity ($\alpha_2 = \alpha_3 = 0$); the record's sign
  convention $\sigma_T = +1$ of the energy-momentum tensor (with the opposite sign
  every $\rho$ and $p$ changes sign and the conditions change accordingly); the
  classical commuting field dirac16complex00, not the quantised dirac16complex; the
  chosen values of $\Lambda$, $m$, $\lambda$.
- **The sign of $A$ is not selected:** the same condensate solves the equations
  with $-A$ (inflating extra times); the deflation is the author's choice of sign.
- **Energy:** with $\Lambda = 0$ the energy density is negative (examples 1 and 2);
  a positive energy density needs $\Lambda < -(21 + 3A^2)H^2$ and then has
  $w < -1$ (example 3: $w = -3$).
- **Not shown:** whether such a condensate is stable, how it could arise, any
```

```
  statement about the quantised field, and nothing about the creation of
  universes.
```

Text cell:

```
## 16. The last check

The last cell checks that the six figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [20]:

```
figure_names = ["condensate_frequency", "three_gamma_bilinears", "allowed_sources",
                "tensor_equality", "solution_in_time", "family_in_lambda"]

         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths), "all six figure files exist")
all_checks_passed()
```

Out [20]:

```
PASS all six figure files exist
ALL 40 CHECKS PASSED (notebook 12d)
```

Text cell:

```
## 17. What this notebook showed

- With the author's gammas, the spin connection of the author's metric gives
  $\sum_\mu\gamma^\mu\Omega_\mu = 3H\gamma^{(x_0)}$, and a homogeneous condensate
  obeys $\Phi' = \mathcal{A}\Phi$ with $\mathcal{A}^2 = -(M^2 - 9H^2)$: it
  oscillates with $w = \sqrt{M^2 - 9H^2}$ and keeps $S$ constant, whatever $a_4$
  does (PROVED, reproducing the Revision record).
- The family $\Phi_0(t) = v_1 + t\,c\,v_2$ has all 15 three-gamma bilinears zero for
  every real $t$ and the density $S(t) = 2t|v_1^\dagger Cv_2|^2$ of either sign
  (PROVED); its energy-momentum tensor is diagonal, $\rho = mS + \lambda S^2/2$,
  $p_3 = p_t = p_0 = \lambda S^2/2$, for every $a_4$ (PROVED).
- Three exact solutions of the coupled Einstein and dirac16complex00 equations,
  two with the extra times deflating as $e^{-Hx_4}$: all 16 + 64 components hold
  exactly (PROVED for the stated numbers, under the ASSUMED convention
  $\sigma_T = +1$ and Einstein gravity).
- The equations do not select the sign of $A$; a positive energy density requires
  $\Lambda < -(21 + 3A^2)H^2$ and $w < -1$ (PROVED).
```

12.30 Line-by-line walk-through of Notebook 12d

The notebook has 20 code cells, In [1] to In [20].

In [1], the set-up cell. As in Notebook 12a (Section 12.16, In [1]), except that the comments hold the run instructions of Notebook 12d (Section 12.28) and `NOTEBOOK_ID = "12d"`.

In [2], the records and the open question. After the imports of `contextlib` and `io` the cell names six record files:

```
GAMMAS = "Revision/algebra/gammas.json"  # the author's gamma matrices
EQUATIONS = "Revision/field_equations_a4/a4-equations.json"  # the a4 equations
PY = "Revision/field_equations_a4/reports/python-a4-report.json"  # sympy record
WL = "Revision/field_equations_a4/reports/wolfram-a4-report.json"  # Wolfram record
EMT = "Revision/lead_checks/reports/emt-divergence-and-spin-connection.json"
DOC = "Revision/docs/DIRAC16COMPLEX00_FIELD_THEORY.md"  # the record's document
```

These are the gamma matrices, the equations of gravity, the three reports and the record's document on the field dirac16complex00. Then follow the three helpers of Notebook 12a, In [2], which Section 12.16 explains.

```
OPEN_SENTENCE = ("This record contains no check that combines a witness with the "
                 "Einstein conditions")
document = repository_file(DOC).read_text(encoding="utf-8")
say(f"{DOC} says: \"{OPEN_SENTENCE}.\"")
check(OPEN_SENTENCE in document, "the record leaves this combination open")
```

The sentence of the record's document that states the open question is stored (two strings in brackets are joined into one), the document is read as text, the sentence is printed (`\"` is a quotation mark inside a string), and the check requires the document to contain it. If someone changes the document, this check fails and the notebook must be revised.

In [3], the author's gamma matrices and C.

```
import itertools  # loops over all combinations of indices

import numpy as np  # floating-point arrays, used only for the plots
import sympy as sp  # exact algebra

NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]  # positions 0..7
ETA = [1, 1, 1, 1, -1, -1, -1, -1]  # the frame metric eta, x0..x7
I16, Z16 = sp.eye(16), sp.zeros(16, 16)  # the 16 by 16 unit and zero matrices
```

The imports; the coordinate names; the diagonal of the frame metric η; the exact 16 by 16 unit matrix `sp.eye(16)` and zero matrix.

```
fixture = read_json(GAMMAS)
gamma = [sp.Matrix([[sp.Rational(x) for x in row] for row in matrix])
         for matrix in fixture["gamma"]]  # gamma[a] = gamma^(xa)
```

The record stores the eight gammas as lists of 16 rows of 16 entries, each written as text; `sp.Rational(x)` turns each text into an exact number and `sp.Matrix` makes a matrix. `gamma[0]` is $\gamma^{(x_0)}$, ..., `gamma[7]` is $\gamma^{(x_7)}$: the author's eight real 16 by 16 matrices.

```
clifford = all(gamma[a] * gamma[b] + gamma[b] * gamma[a]
               == 2 * ETA[a] * (1 if a == b else 0) * I16
               for a in range(8) for b in range(8))
reproduces(clifford, "the author's gammas satisfy the Clifford relation",
           PY, "authorT16_clifford")
```

For all 64 pairs: $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)}$ (for sympy matrices `*` is the matrix product) must equal $2\eta^{ab}$ times the unit matrix, that is $2\eta^{aa}$ on the diagonal $a = b$ and 0 otherwise.

```
C = gamma[0] * gamma[1] * gamma[2] * gamma[3]  # C = g^(x0) g^(x1) g^(x2) g^(x3)
stored_C = sp.Matrix([[sp.Rational(x) for x in row] for row in fixture["C"]])
properties = (C == stored_C and C == C.T and C * C == I16
              and all((C * g).T == -(C * g) for g in gamma))
reproduces(properties, "C is the record's C, real symmetric, C^2 = 1, C gamma "
           "antisymmetric", PY, "authorT16_C_properties")
```

C is the product of the four space-like gammas; it must equal the C stored in the record, be symmetric (`C.T` is the transpose), square to 1 and make every $C\gamma^{(a)}$ antisymmetric (Section 12.26).

In [4], the spin connection.

```
H = sp.symbols("H", positive=True)  # the constant H of the metric
z = sp.symbols("z", positive=True)  # z = 6 H x0 in (0, pi/2)
x4 = sp.symbols("x4", real=True)  # the time
a4 = sp.Function("a4")(x4)  # an arbitrary function a4(x4)
cz = sp.symbols("cz", positive=True)  # cot z > 0 on the patch
ad1, ad2 = sp.symbols("ad1 ad2", real=True)  # a4' and a4''
s6 = sp.sin(z) ** sp.Rational(1, 6)  # the warp sin(z)^(1/6) of a length
E = [sp.cot(z)] + [sp.exp(a4) * s6] * 3 + [sp.Integer(1)] + [sp.exp(-a4) * s6] * 3
g = [ETA[a] * E[a] ** 2 for a in range(8)]  # g_aa = eta_aa E_a^2
```

Symbols as in Notebook 12a. `E` lists the eight scale factors $E_a = \sqrt{|g_{aa}|}$ (the diagonal **vielbein** of Chapter 6), and the metric is rebuilt from them as $g_{aa} = \eta_{aa}E_a^2$; a_4 is an arbitrary function, so every result holds for every history.

```
TRIG = {sp.sin(z): 1 / sp.sqrt(1 + cz ** 2), sp.cos(z): cz / sp.sqrt(1 + cz ** 2),
        sp.tan(z): 1 / cz, sp.cot(z): cz}  # every function of z through cot z

def clean(expr):
    expr = expr.subs(sp.Derivative(a4, (x4, 2)), ad2).subs(sp.Derivative(a4, x4), ad1)
    expr = sp.expand_trig(expr).subs(TRIG)
    return sp.expand(sp.cancel(sp.powsimp(sp.expand(expr), force=True)))

def d(expr, mu):
    if mu == 4:
        return sp.diff(expr, x4)
    if mu == 0:
        return 6 * H * sp.diff(expr, z)  # d/dx0 = (dz/dx0) d/dz = 6 H d/dz
    return sp.Integer(0)  # nothing depends on x1, x2, x3, x5, x6, x7
```

The same tools as in Notebook 12a, In [5] and In [7] (docstrings left out): `clean` writes derivatives as `ad1`, `ad2` (the second derivative first) and every function of z through $\cot z$; `d` is the partial derivative.

```
Gamma = [[[sp.Integer(0)] * 8 for _ in range(8)] for _ in range(8)]
for a, b, c in itertools.product(range(8), repeat=3):  # diagonal-metric formula
    value = 0
    if a == c:
        value += d(g[a], b)
    if a == b:
        value += d(g[a], c)
    if b == c:
        value -= d(g[b], a)
    Gamma[a][b][c] = value / (2 * g[a])
S_ab = [[(gamma[a] * gamma[b] - gamma[b] * gamma[a]) / 4 for b in range(8)]
        for a in range(8)]
```

The Christoffel symbols exactly as in Notebook 12a, In [5]; then the 64 matrices $S^{ab} = \frac{1}{4}(\gamma^{(a)}\gamma^{(b)} - \gamma^{(b)}\gamma^{(a)})$, the generators of the spinor transformations (Chapter 5).

```
omega = [[[clean(ETA[a] * E[a] * Gamma[a][mu][b] / E[b]) if a != b else 0
           for b in range(8)] for a in range(8)] for mu in range(8)]
antisymmetric = all(sp.expand(omega[mu][a][b] + omega[mu][b][a]) == 0
                    for mu in range(8) for a in range(8) for b in range(8))
check(antisymmetric, "omega_mu ab = -omega_mu ba (canonical spin connection)")
```

The canonical spin connection of the diagonal vielbein, $\omega_{\mu\,ab} = \eta_{aa}(E_a/E_b)\,\Gamma^a{}_{\mu b}$ for $a \neq b$ and 0 for $a = b$ (the text cell before the cell derives it from the definition). The check confirms that it is antisymmetric in a and b, as a connection of this kind must be.

```
Omega = [sum((omega[mu][a][b] * S_ab[a][b] / 2 for a in range(8) for b in range(8)
              if omega[mu][a][b] != 0), Z16) for mu in range(8)]
for mu in range(8):
    terms = sum(1 for a in range(8) for b in range(8) if omega[mu][a][b] != 0)
    say(f"Omega_{NAMES[mu]}: {terms} nonzero entries omega_mu ab")
```

$\Omega_\mu = \frac{1}{2}\sum_{a,b}\omega_{\mu\,ab}S^{ab}$ for each μ; `sum(..., Z16)` starts the sum at the zero matrix (a sum of matrices must start from a matrix). The loop prints how many $\omega_{\mu\,ab}$ are not zero: four for each 3-space direction and extra time (the pairs with x_4 and with x_0, in both orders), none for x_4 and x_0.

In [5], the term 3H gamma^(x0).

```
gamma_curved = [gamma[mu] / E[mu] for mu in range(8)]  # gamma^mu = gamma^(mu)/E_mu
reproduces(Omega[4] == Z16 and Omega[0] == Z16, "Omega_x4 = Omega_x0 = 0",
           PY, "authorT16_Omega_x0_x4_zero")
```

The curved gammas $\gamma^\mu = \gamma^{(\mu)}/E_\mu$; the spin connection along the time and along x_0 is zero.

```
anticommute = all((gamma_curved[mu] * Omega[mu] + Omega[mu] * gamma_curved[mu])
                  .applyfunc(clean) == Z16 for mu in range(8))
reproduces(anticommute, "{gamma^mu, Omega_mu} = 0 for each mu (no sum)",
           PY, "authorT16_anticommutator_no_sum")
```

For each μ separately $\gamma^\mu\Omega_\mu + \Omega_\mu\gamma^\mu = 0$; `.applyfunc(clean)` applies `clean` to every entry of the matrix. (A line that starts with a dot continues the expression of the line above, inside the brackets.)

```
gravity_term = sum((gamma_curved[mu] * Omega[mu] for mu in range(8)), Z16)
gravity_term = gravity_term.applyfunc(clean)
reproduces(gravity_term == 3 * H * gamma[0], "gamma^mu Omega_mu = 3 H gamma^(x0)",
           PY, "authorT16_gravity_term")
reproduces(gravity_term == 3 * H * gamma[0], "the same, the lead's independent check",
           EMT, "gamma_Omega_equals_3H_gamma0")
```

The sum $\sum_\mu \gamma^\mu\Omega_\mu$ equals $3H\gamma^{(x_0)}$: no a_4 and no z remain, because the time-direction terms of the three inflating and the three deflating directions cancel. Two records confirm it.

In [6], the condensate equation.

```
MM = sp.symbols("M", real=True)  # the effective mass M = m + lambda S

def condensate_matrix(M_value, H_value):
    return -gamma[4] * (M_value * I16 - 3 * H_value * gamma[0])

A_sym = condensate_matrix(MM, H)
```

`condensate_matrix` builds $\mathcal{A} = -\gamma^{(x_4)}(M - 3H\gamma^{(x_0)})$ of Section 12.26 for given M and H (docstring left out); `A_sym` is the matrix with the symbols M and H.

```
reduced = (gamma[4] * A_sym + gravity_term - MM * I16).applyfunc(sp.expand)
reproduces(reduced == Z16 and not A_sym.has(z),
           "gamma^(x4) A + 3 H gamma^(x0) = M: the equation is Phi' = A Phi",
           WL, "condensate_equation_x0_consistent")
check((A_sym * A_sym + (MM ** 2 - 9 * H ** 2) * I16).applyfunc(sp.expand) == Z16,
      "A^2 = -(M^2 - 9 H^2): every condensate oscillates with w = sqrt(M^2 - 9 H^2)")
reproduces((C * A_sym + A_sym.T * C).applyfunc(sp.expand) == Z16,
           "C A + A^T C = 0: S is constant along x4", PY,
           "authorT16_condensate_S_constant")
```

Three facts derived in Section 12.26: inserting $\Phi' = \mathcal{A}\Phi$ into the field equation gives $\gamma^{(x_4)}\mathcal{A} + 3H\gamma^{(x_0)} = M$ (and $\mathcal{A}$ is free of z); $\mathcal{A}^2 = -(M^2 - 9H^2)$; and $C\mathcal{A} + \mathcal{A}^T C = 0$, so S is constant.

In [7], figure 1: the frequency of a condensate.

```
m_axis = np.linspace(-8.0, 8.0, 801)  # M/H
fig, ax = plt.subplots()
```

```
ax.plot(m_axis[m_axis <= -3.0], np.sqrt(m_axis[m_axis <= -3.0] ** 2 - 9.0),
        color="tab:blue", label="$w = \\sqrt{M^2 - 9H^2}$")
ax.plot(m_axis[m_axis >= 3.0], np.sqrt(m_axis[m_axis >= 3.0] ** 2 - 9.0),
        color="tab:blue")
ax.axvspan(-3.0, 3.0, color="grey", alpha=0.2, label="$|M| < 3H$: no oscillation")
```

801 masses from -8 to 8 (units $H = 1$); `m_axis[m_axis <= -3.0]` keeps the entries not above -3 (an array of true and false values used as an index), and the two branches of $w = \sqrt{M^2 - 9}$ are drawn; the grey band marks $|M| < 3$.

```
worst = 0.0  # the largest deviation of a numerical eigenvalue from +-i w
upper = []  # for each mass: how many eigenvalues have a positive imaginary part
for M_value in (-7.0, -5.0, -4.0, 4.0, 5.0, 7.0):
    matrix = np.array(condensate_matrix(M_value, 1).tolist(), dtype=float)
    eigenvalues = np.linalg.eigvals(matrix)
    w_value = np.sqrt(M_value ** 2 - 9.0)
    worst = max(worst, np.max(np.abs(np.abs(eigenvalues.imag) - w_value)),
                np.max(np.abs(eigenvalues.real)))
    upper.append(int(np.sum(eigenvalues.imag > 0)))  # the ones near +i w
    ax.plot([M_value] * 16, np.abs(eigenvalues.imag), "o", color="black",
            markersize=4, zorder=3)  # zorder 3: drawn on top of the red squares
```

For six masses the exact matrix is converted to a floating-point array and its 16 eigenvalues are computed numerically with `np.linalg.eigvals`. `worst` records the largest distance of an imaginary part (in absolute value) from w and the largest real part. `eigenvalues.imag > 0` is an array of true and false values, one for each eigenvalue; `np.sum` counts the true ones (true counts as 1), and `upper.append` stores this count, the number of eigenvalues near $+iw$, for each mass. The absolute imaginary parts are drawn as black dots at the mass (`[M_value] * 16` repeats the mass 16 times; `zorder=3` draws them above the other marks).

```
ax.plot([], [], "o", color="black", markersize=4,
        label="$|\\mathrm{Im}|$ of the eigenvalues of $\\mathcal{A}$")
ax.plot([-5, 5], [4, 4], "s", color="tab:red", markersize=7,
        label="$M = \\pm5H$: $w = 4H$")
ax.set_xlabel("effective mass $M/H$")
ax.set_ylabel("frequency $w/H$")
ax.set_title("The frequency of a homogeneous condensate")
ax.legend(fontsize=8, loc="upper center")
say(f"largest deviation of a numerical eigenvalue from +-i w: {worst:.0e}")
say(f"eigenvalues near +i w, for each of the six masses: {upper}")
check(worst < 1e-9 and upper == [8] * 6,
      "the 16 eigenvalues of A are +i w and -i w, eight of each (six masses)")
save_figure(fig, "condensate_frequency",
            ...)
```

An empty plot with a label gives the dots one legend entry; red squares mark $M = \pm5$, $w = 4$. The largest deviation, 10^{-14}, and the six counts, all 8, are printed; the check requires a deviation below 10^{-9} and the count 8 at every mass (`[8] * 6` is the list of six eights), so eight eigenvalues are near $+iw$ and the other eight near $-iw$. **What the figure shows.** All dots lie on the curve $w = \sqrt{M^2 - 9H^2}$; each dot stands for all 16 eigenvalues of its mass, because the absolute value of

the imaginary part does not distinguish $+iw$ from $-iw$. Inside the grey band there is no oscillation, so the examples use $M = \pm 5H$.

In [8], the family of condensates with the 15 bilinears zero.

```
t = sp.symbols("t", real=True)  # the free real parameter of the family
TRIPLES = list(itertools.combinations(range(8), 3))  # all 56 sets {a, b, c}
NEEDED = sorted({tuple(sorted((i, 4, 0))) for i in (1, 2, 3, 5, 6, 7)}
                | {tuple(sorted((i, j, 4))) for i in (1, 2, 3) for j in (5, 6, 7)})
```

The real parameter t. `itertools.combinations(range(8), 3)` lists the 56 sets of three different positions in increasing order. `NEEDED` is the set (braces) of the 15 triples whose bilinears the field equations need to vanish: $\{i, x_4, x_0\}$ for the six directions i, joined (`|`) with $\{i, j, x_4\}$ for i in 3-space and j an extra time; each triple is sorted, and the whole is sorted into a list.

```
def witness_parts(M_value, H_value):
    w_value = sp.sqrt(M_value ** 2 - 9 * H_value ** 2)
    A_value = condensate_matrix(M_value, H_value)
    spaces = []
    for sign in (-1, 1):  # the eigenvalue of g^(x1)g^(x5) = g^(x2)g^(x6) = ...
        stack = sp.Matrix.vstack(A_value + sp.I * w_value * I16,
                                 gamma[1] * gamma[5] - sign * I16,
                                 gamma[2] * gamma[6] - sign * I16,
                                 gamma[3] * gamma[7] - sign * I16)
        spaces.append(stack.nullspace())  # all solutions of stack * v = 0
    v1, v2 = spaces[0][0], spaces[1][0]
    c = sp.conjugate(sp.expand((v1.H * C * v2)[0]))  # c = conj(v1^dagger C v2)
    return spaces, v1, v2, c, w_value, A_value
```

The record's recipe (docstring left out). `sp.Matrix.vstack` stacks four 16 by 16 matrices into one 64 by 16 matrix; a column v with `stack * v = 0` satisfies four equations at once: $\mathcal{A}v = -iwv$ (`sp.I` is i), and $\gamma^{(x_1)}\gamma^{(x_5)}v = \gamma^{(x_2)}\gamma^{(x_6)}v = \gamma^{(x_3)}\gamma^{(x_7)}v = \pm v$ (each of these products squares to 1, so its eigenvalues are ± 1). `.nullspace()` returns a list of columns that span all solutions, computed exactly. v_1 is the first solution with the sign -1, v_2 with $+1$. `v1.H` is the conjugate transpose $v_1^\dagger$, and `[0]` takes the single entry of the 1 by 1 product; c is its complex conjugate.

```
def bilinear(phi, matrix):
    return sp.expand((phi.H * C * matrix * phi)[0])

def three_gamma(triple):
    a, b, c = triple
    return gamma[a] * gamma[b] * gamma[c]
```

`bilinear` computes $\bar{\Phi}X\Phi = \Phi^\dagger C X \Phi$ for a matrix X; `three_gamma` builds $\gamma^{(a)}\gamma^{(b)}\gamma^{(c)}$ for a triple (docstrings left out).

```
spaces, v1, v2, c, w, A_witness = witness_parts(-5, 1)
phi_t = (v1 + t * c * v2).applyfunc(sp.expand)  # the family Phi_0(t)
```

```
check([len(space) for space in spaces] == [1, 1],
      "the two null spaces are one-dimensional (v1 and v2 are unique)")
report("frequency w at M = -5 H", w, "H")
check((A_witness * phi_t + sp.I * w * phi_t).applyfunc(sp.expand)
      == sp.zeros(16, 1), "A Phi_0(t) = -i w Phi_0(t) for every t")
needed_values = [bilinear(phi_t, three_gamma(triple)) for triple in NEEDED]
check(len(NEEDED) == 15 and all(value == 0 for value in needed_values),
      "the 15 three-gamma bilinears vanish for every real t")
```

The recipe at $M = -5$, $H = 1$, and the family $\Phi_0(t) = v_1 + t\,c\,v_2$ with t kept as a symbol. Each solution space is one-dimensional, so v_1 and v_2 are unique up to a factor; the frequency is $w = 4$; every member of the family is an eigenvector of $\mathcal{A}$ with the eigenvalue $-iw$; and the 15 needed bilinears are zero as expressions in t, so for every real t.

In [9], the density of the family.

```
S_t = bilinear(phi_t, I16)  # S(t) = Phi_0(t)^dagger C Phi_0(t)
cross = sp.expand((v1.H * C * v2)[0])  # v1^dagger C v2
report("v1^dagger C v2", cross)
report("S(t)", S_t)
check(bilinear(v1, I16) == 0 and bilinear(v2, I16) == 0
      and sp.expand(S_t - 2 * t * cross * sp.conjugate(cross)) == 0,
      "S(t) = 2 t |v1^dagger C v2|^2: every real density occurs")
```

The density of the family, the cross term $\sigma = v_1^\dagger C v_2 = -128/25 - 96i/25$, and $S(t) = 2048t/25$; the check confirms $v_1^\dagger C v_1 = v_2^\dagger C v_2 = 0$ and $S(t) = 2t|\sigma|^2$ (derived in Section 12.26).

```
_, u1, u2, c_plus, w_plus, A_plus = witness_parts(5, 1)  # the record's M = +5
phi_plus = (u1 + c_plus * u2).applyfunc(sp.expand)  # t = 1
S_plus = bilinear(phi_plus, I16)
ok_plus = ((A_plus * phi_plus + sp.I * w_plus * phi_plus).applyfunc(sp.expand)
           == sp.zeros(16, 1)
           and all(bilinear(phi_plus, three_gamma(tr)) == 0 for tr in NEEDED)
           and S_plus != 0 and sp.im(S_plus) == 0)
reproduces(ok_plus, "M = +5, H = 1: a witness with S real, not 0, 15 bilinears 0",
           PY, "authorT16_condensate_witness")
```

The recipe repeated at $M = +5$, where the record ran it with the author's gammas, at $t = 1$ (the record's witness; `_` receives the unused first value): it is an eigenvector, its 15 bilinears vanish and its density is a real number different from 0 (`sp.im` is the imaginary part).

In [10], figure 2: all 56 three-gamma bilinears.

```
phi_one = phi_t.subs(t, 1)  # Phi_0(1)
all_values = [bilinear(phi_one, three_gamma(triple)) for triple in TRIPLES]
check(all(sp.im(value) == 0 for value in all_values),
      "all 56 three-gamma bilinears of Phi_0(1) are real numbers")
nonzero = [triple for triple, value in zip(TRIPLES, all_values) if value != 0]
say("nonzero bilinears: " + ", ".join(
    "".join(NAMES[i][1] for i in triple) for triple in nonzero))
check(all(4 not in triple and 0 not in triple for triple in nonzero),
      "every nonzero one avoids x4 and x0")
```

All 56 bilinears of the member $t = 1$ are computed and are real. The nonzero ones are printed as digit strings (`NAMES[i][1]` is the second character of `"x1"`, the digit): 123, 127, 136, 167, 235, 257, 356, 567, all built from 3-space directions and extra times (positions 3 and 7, x_4 and x_0, never occur).

```
labels = ["".join(NAMES[i][1] for i in triple) for triple in TRIPLES]
numbers = np.array([float(value) for value in all_values])
is_needed = np.array([triple in NEEDED for triple in TRIPLES])
fig, ax = plt.subplots(figsize=(11.0, 4.2))
positions = np.arange(len(TRIPLES))
ax.bar(positions[~is_needed], numbers[~is_needed], color="tab:blue",
       label="other bilinears")
ax.plot(positions[is_needed], numbers[is_needed], "x", color="tab:red",
        markersize=8, label="the 15 the field equations need to vanish")
```

Labels, values and a true/false array marking the needed triples. `np.arange(56)` is 0 to 55; `~is_needed` is the opposite array. The other 41 bilinears are drawn as blue bars (`ax.bar`), the 15 needed ones as red crosses.

```
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(positions)
ax.set_xticklabels(labels, rotation=90, fontsize=6.5)
ax.set_xlabel("directions $abc$ of $\\bar\\Phi\\gamma^{(a)}\\gamma^{(b)}"
              "\\gamma^{(c)}\\Phi$ (digits: $x_0$ = 1, ..., $x_7$ = 8)")
ax.set_ylabel("value of the bilinear")
ax.set_title("The 56 three-gamma bilinears of the condensate $\\Phi_0(1)$, "
             "$M = -5H$")
ax.legend(fontsize=8)
save_figure(fig, "three_gamma_bilinears",
            ...)
```

Axis, tick labels turned by 90 degrees, titles and `save_figure`. **What the figure shows.** Every red cross sits on zero; only eight blue bars rise, at triples without x_4 and x_0, which no field equation constrains.

In [11], the complete kinetic tensor.

```
UNIT_H = {H: 1}  # the examples use H = 1
Omega_1 = [matrix.subs(UNIT_H) for matrix in Omega]
gamma_1 = [matrix.subs(UNIT_H) for matrix in gamma_curved]
g_1 = [entry.subs(UNIT_H) for entry in g]
```

The spin connection, the curved gammas and the metric with $H = 1$; a_4 and z stay arbitrary.

```
def D_phi(nu):
    return (A_witness if nu == 4 else Z16) + Omega_1[nu]

def D_phibar(nu):
    return (A_witness.T * C if nu == 4 else Z16) - C * Omega_1[nu]
```

The matrices that give the covariant derivatives (docstrings left out): $D_\nu\Phi = \partial_\nu\Phi + \Omega_\nu\Phi$, with $\partial_4\Phi = \mathcal{A}\Phi$ and no other derivative; and $D_\nu\bar\Phi = \partial_\nu\bar\Phi - \bar\Phi\Omega_\nu = \Phi^\dagger(\mathcal{A}^T C\,\delta_{\nu 4} - C\Omega_\nu)$, because $\partial_4\bar\Phi = (\mathcal{A}\Phi)^\dagger C = \Phi^\dagger\mathcal{A}^T C$.

```
K = [[(phi_t.H * ((C * gamma_1[mu] * D_phi(nu) - D_phibar(nu) * gamma_1[mu]) / 2)
       * phi_t)[0] for nu in range(8)] for mu in range(8)]
K_sym = [[clean((K[mu][nu] + (g_1[nu] / g_1[mu]) * K[nu][mu]) / 2)
          for nu in range(8)] for mu in range(8)]
```

All 64 components $K^\mu{}_\nu = \frac{1}{2}(\bar\Phi\gamma^\mu D_\nu\Phi - (D_\nu\bar\Phi)\gamma^\mu\Phi)$ as bilinears of $\Phi_0(t)$ (the phase e^{-iwx_4} cancels between $\Phi^\dagger$ and Φ). The symmetrised tensor: lower the upper index ($K_{\mu\nu} = g_{\mu\mu}K^\mu{}_\nu$), average with the exchanged component, raise again; this gives $\frac{1}{2}(K^\mu{}_\nu + (g_{\nu\nu}/g_{\mu\mu})K^\nu{}_\mu)$.

```
off_diagonal = all(K_sym[mu][nu] == 0 for mu in range(8) for nu in range(8)
                   if mu != nu)
reproduces(off_diagonal, "every off-diagonal K^(mu nu) vanishes, for every a4, a4', z",
           WL, "condensate_diagonal_witness_exact")
diagonal = [K_sym[mu][mu] for mu in range(8)]
say(f"diagonal of K: {diagonal}")
reproduces(all(diagonal[mu] == 0 for mu in range(8) if mu != 4)
           and sp.expand(diagonal[4] - (-5) * S_t) == 0,
           "K^x4_x4 = M S and every other diagonal entry is 0",
           PY, "authorT16_condensate_kinetic_diagonal")
```

Every off-diagonal component is zero for the whole family, every a_4 and every z; the diagonal is $[0,0,0,-2048t/5,0,0,0,0]$, that is $K^{x_4}{}_{x_4} = MS = -5\cdot 2048t/25$.

In [12], the energy-momentum tensor of the family.

```
m, lam = sp.symbols("m lambda", real=True)  # the mass and the self-coupling

def source_tensor(K_matrix, S_value, m_value, lam_value):
    L_value = (sum(K_matrix[mu][mu] for mu in range(8)) - m_value * S_value
               - lam_value * S_value ** 2 / 2)
    return [[sp.expand(-K_matrix[mu][nu] + (L_value if mu == nu else 0))
             for nu in range(8)] for mu in range(8)]
```

`source_tensor` builds $T^\mu{}_\nu = -K^{(\mu}{}_{\nu)} + \delta^\mu_\nu L$ with $L = \sum_\mu K^\mu{}_\mu - mS - \frac{\lambda}{2}S^2$ ($\sigma_T = +1$; docstring left out).

```
on_shell = {m: -5 - lam * S_t}  # M = m + lambda S = -5
T_family = source_tensor(K_sym, S_t, m, lam)
rho_family = sp.expand(-T_family[4][4].subs(on_shell))
pressures = [sp.expand(T_family[mu][mu].subs(on_shell)) for mu in (1, 5, 0)]
check(sp.expand(rho_family - ((-5 - lam * S_t) * S_t + lam * S_t ** 2 / 2)) == 0
      and all(sp.expand(p - lam * S_t ** 2 / 2) == 0 for p in pressures),
      "rho = m S + (lambda/2) S^2 and p3 = pt = p0 = (lambda/2) S^2 on shell")
```

On shell the mass is fixed by $M = m + \lambda S = -5$. The check confirms $\rho = mS + \frac{\lambda}{2}S^2$ and $p_3 = p_t = p_0 = \frac{\lambda}{2}S^2$ (Section 12.26).

In [13], the two Einstein conditions.

```
A, Lam, kappa = sp.symbols("A Lambda kappa", real=True)
record = read_json(EQUATIONS)
E1 = record["lovelockTensors"]["E1"]  # the Einstein tensor G = E_(1)
LINEAR = {"ad1": A * H, "ad2": 0, "H": H}  # a4' = A H, a4'' = 0

def from_record(key):
    return sp.sympify(E1[key]["input"].replace("^", "**"), locals=LINEAR)
```

Symbols for the slope, Λ and κ; the Einstein tensor of the record. `LINEAR` is used as the dictionary of names for the parser, so that reading a formula already replaces `ad1` by AH and `ad2` by 0 (docstring left out).

```
G_time, G_space = from_record("x4x4"), from_record("x1x1")
G_extra, G_hidden = from_record("x5x5"), from_record("x0x0")
check(sp.expand(G_space - G_hidden) == 0 and sp.expand(G_extra - G_hidden) == 0,
      "linear member: G^x1_x1 = G^x5_x5 = G^x0_x0 (the record's components)")
```

The four Einstein components for the linear member; the seven non-time ones are equal.

```
S_sym, rho_sym, p_sym = sp.symbols("S rho p", real=True)
time_equation = G_time + Lam + kappa * rho_sym  # = 0
space_equation = G_hidden + Lam - kappa * p_sym  # = 0
condensate = {rho_sym: m * S_sym + lam * S_sym ** 2 / 2, p_sym: lam * S_sym ** 2 / 2}
first = sp.expand(kappa * (m + lam * S_sym) * S_sym + 6 * (A ** 2 + 1) * H ** 2)
second = sp.expand(kappa * m * S_sym + 36 * H ** 2 + 2 * Lam)
reproduces(sp.expand((time_equation - space_equation).subs(condensate) - first) == 0
           and sp.expand((time_equation + space_equation).subs(condensate)
                         - second) == 0,
           "Einstein: kappa M S = -6 (A^2 + 1) H^2 and kappa m S = -(36 H^2 + 2 Lambda)",
           PY, "condensate_einstein_quadratic_U")
```

The time equation and the common equation of the other directions, written as expressions that must vanish; with the condensate's ρ and p, their difference and sum are the two conditions of Section 12.26.

```
M_value = sp.symbols("M_value", real=True)
S_needed = sp.solve(kappa * M_value * S_sym + 6 * (A ** 2 + 1) * H ** 2, S_sym)[0]
m_needed = sp.solve(second, m)[0]
say(f"S = {S_needed},  m = {m_needed},  lambda = (M - m)/S")
```

The first condition solved for S and the second for m; λ then follows as $(M - m)/S$.

In [14], figure 3: which condensates can drive a linear member.

```
m_left = np.linspace(-10.0, -0.01, 1000)  # M/H < 0
m_right = np.linspace(0.01, 10.0, 1000)  # M/H > 0
fig, ax = plt.subplots(figsize=(7.0, 5.2))
# grey: kappa M S > -6, where A^2 = -kappa M S/6 - 1 would be negative
ax.fill_between(m_left, -12.0, np.minimum(-6.0 / m_left, 12.0), color="grey",
                alpha=0.25, linewidth=0.0)
ax.fill_between(m_right, np.maximum(-6.0 / m_right, -12.0), 12.0, color="grey",
                alpha=0.25, linewidth=0.0, label="no real slope $A$")
```

Masses on either side of zero (the hyperbolas are not defined at $M = 0$); `figsize=(7.0, 5.2)` makes the figure 7 inches wide and 5.2 high. The comment line states the rule for the grey region: the first condition of Section 12.26, $\kappa MS = -6(A^2 + 1)$ (units $H = 1$), solved for the slope gives $A^2 = -\kappa MS/6 - 1$, and this is negative, so that no real A exists, exactly when $\kappa MS > -6$. A real slope therefore needs $\kappa MS \le -6$. For $M < 0$ this means $\kappa S \ge -6/M$, so the region below the curve $\kappa S = -6/M$ is shaded grey; for $M > 0$ it means $\kappa S \le -6/M$, so the region above is shaded. `np.minimum` and `np.maximum` keep the curves inside the plotted range ± 12.

```
ax.axvspan(-3.0, 3.0, facecolor="none", edgecolor="black", hatch="//",
           linewidth=0.0, label="$|M| < 3H$: no oscillating condensate")
for slope_squared, style in ((0, ":"), (1, "-"), (4, "--"), (5, "-.")):
    level = 6.0 * (slope_squared + 1)
    label = f"$A^2 = {slope_squared}$"
    ax.plot(m_left, -level / m_left, style, color="tab:blue", label=label)
    ax.plot(m_right, -level / m_right, style, color="tab:blue")
```

The hatched band $|M| < 3$, where no condensate oscillates. Then the hyperbolas $\kappa MS = -6(A^2+1)$ for $A^2 = 0, 1, 4, 5$, on both sides.

```
ax.plot([-5], [12 / 5], "o", color="tab:red", markersize=8,
        label="examples 1 and 3: $M = -5H$, $\\kappa S = 12/5$")
ax.plot([5], [-36 / 5], "s", color="tab:green", markersize=8,
        label="example 2: $M = 5H$, $\\kappa S = -36/5$")
ax.set_xlim(-10, 10)
ax.set_ylim(-12, 12)
ax.set_xlabel("effective mass $M/H$")
ax.set_ylabel("$\\kappa S$ (units $H = 1$)")
ax.set_title("Which condensates can drive a linear member (Einstein gravity)")
ax.legend(fontsize=7.5, loc="lower left")
save_figure(fig, "allowed_sources",
            ...)
```

The three examples are marked. **What the figure shows.** Allowed condensates lie in the upper left and lower right quarters, where S and M have opposite signs and outside the grey; the red circle lies on the hyperbola $A^2 = 1$ and the green square on $A^2 = 5$.

In [15], the three exact solutions.

```
EXAMPLES = [  # name, A, Lambda, M (with H = kappa = 1)
    ("example 1", sp.Integer(1), sp.Integer(0), -5),
    ("example 2", sp.sqrt(5), sp.Integer(0), 5),
```

```
    ("example 3", sp.Integer(1), sp.Integer(-30), -5),
]
UNITS = {H: 1, kappa: 1}
solutions = {}  # name -> the numbers of the solution
```

The three examples of Section 12.26 by their slope, cosmological constant and effective mass; $\sqrt{5}$ is kept exact as `sp.sqrt(5)`.

```
for name, slope, cosmological, M_example in EXAMPLES:
    S_value = sp.nsimplify(S_needed.subs(UNITS).subs({M_value: M_example,
                                                      A: slope}))
    m_value = m_needed.subs(UNITS).subs({S_sym: S_value, Lam: cosmological})
    lam_value = (M_example - m_value) / S_value
```

For each example: the density from the first condition (`sp.nsimplify` writes the result in its simplest exact form), the mass from the second, the self-coupling from $\lambda = (M - m)/S$.

```
    spaces_e, v1_e, v2_e, c_e, w_e, A_e = witness_parts(M_example, 1)
    S_of_t = bilinear((v1_e + t * c_e * v2_e).applyfunc(sp.expand), I16)
    t_value = sp.solve(S_of_t - S_value, t)[0]
    phi0 = (v1_e + t_value * c_e * v2_e).applyfunc(sp.expand)
    phi = phi0 * sp.exp(-sp.I * w_e * x4)  # the condensate Phi(x4)
```

The family at this mass; the member whose density is the required one ($S(t)$ is linear in t, so `sp.solve` gives one t: $15/512$ for examples 1 and 3, $-45/512$ for example 2); the condensate $\Phi(x_4) = e^{-iwx_4}\Phi_0$.

```
    # 1. the field equation, with the full spin-connection sum of section 7:
    residual = (gamma[4] * sp.diff(phi, x4) + gravity_term.subs(UNIT_H) * phi
                - (m_value + lam_value * S_value) * phi).applyfunc(sp.simplify)
    field_ok = residual == sp.zeros(16, 1) and bilinear(phi0, I16) == S_value
```

The 16 components of the field equation $\gamma^\mu D_\mu \Phi - (m + \lambda S)\Phi$: the only derivative is along x_4, where $\gamma^{x_4} = \gamma^{(x_4)}$, plus the spin-connection term of In [5] at $H = 1$. Every component must simplify to zero, at every time, and the density must be the required one. (The comment refers to section 7 of the notebook.)

```
    # 2. the Einstein equations, all 64 components, for +A and for -A:
    K_e = K_sym if M_example == -5 else None
    if K_e is None:  # example 2 has its own condensate matrix A (M = +5)
        K_raw = [[(phi0.H * ((C * gamma_1[mu] * ((A_e if nu == 4 else Z16)
                                                 + Omega_1[nu])
                             - ((A_e.T * C if nu == 4 else Z16) - C * Omega_1[nu])
                             * gamma_1[mu]) / 2) * phi0)[0]
                  for nu in range(8)] for mu in range(8)]
        K_e = [[clean((K_raw[mu][nu] + (g_1[nu] / g_1[mu]) * K_raw[nu][mu]) / 2)
                for nu in range(8)] for mu in range(8)]
    else:
        K_e = [[entry.subs(t, t_value) for entry in row] for row in K_e]
    T_e = source_tensor(K_e, S_value, m_value, lam_value)
```

For $M = -5$ the kinetic tensor of In [11] is reused with the found t. For example 2 ($M = +5$) it is computed afresh exactly as in In [11], with the matrix $\mathcal{A}$ of $M = +5$. Then the energy-momentum tensor (with $\kappa = 1$ it is κT).

```
    einstein_ok = {}
    for sign in (1, -1):
        G_diag = [G_hidden] + [G_space] * 3 + [G_time] + [G_extra] * 3
        values = {A: sign * slope, H: 1}
        einstein_ok[sign] = all(
            sp.simplify((G_diag[mu].subs(values) + cosmological if mu == nu else 0)
                        - T_e[mu][nu]) == 0
            for mu in range(8) for nu in range(8))
```

For the slope $+A$ and for $-A$ all 64 components of $G^{\mu}{}_{\nu} + \Lambda\delta^{\mu}_{\nu} - \kappa T^{\mu}{}_{\nu}$ must simplify to zero (off the diagonal the left-hand side is 0, so T must vanish there). Since T contains no x_4 and no z, this holds at every time and every value of the hidden coordinate.

```
    rho_e, p_e = -T_e[4][4], T_e[1][1]
    solutions[name] = {"A": slope, "Lambda": cosmological, "M": M_example,
                       "S": S_value, "m": m_value, "lambda": lam_value, "t": t_value,
                       "rho": rho_e, "p": p_e, "phi0": phi0, "w": w_e, "T": T_e}
    say(f"{name}: A = {slope}, Lambda = {cosmological}, M = {M_example}, "
        f"S = {S_value}, t = {t_value}, m = {m_value}, lambda = {lam_value}, "
        f"rho = {rho_e}, p = {p_e}")
    check(field_ok, f"{name}: the 16 components of the field equation hold exactly")
    check(einstein_ok[1], f"{name}: all 64 Einstein components hold exactly")
    check(einstein_ok[-1], f"{name}: they hold as well with -A (A enters as A^2)")
```

The energy density and pressure are read off, all numbers are stored for the later cells, printed in one line, and the three checks of the example are made. Out [15] shows the table of Section 12.26 and nine PASS lines.

In [16], the numbers compared with the table.

```
table = {"example 1": (sp.Rational(12, 5), -15, sp.Rational(25, 6), -24, 12),
         "example 2": (sp.Rational(-36, 5), 5, 0, -36, 0),
         "example 3": (sp.Rational(12, 5), 10, sp.Rational(-25, 4), 6, -18)}
for name, (S_v, m_v, lam_v, rho_v, p_v) in table.items():
    sol = solutions[name]
    same = (sol["S"] == S_v and sol["m"] == m_v and sol["lambda"] == lam_v
            and sol["rho"] == rho_v and sol["p"] == p_v)
    formula = 5 + sol["Lambda"] / 3 - sol["lambda"] * sol["S"] ** 2 / 6
    check(same and sp.simplify(formula - sol["A"] ** 2) == 0,
          f"{name}: the numbers of the table and A^2 = 5 + Lambda/3 - lambda S^2/6")
    report(f"{name}: w = p/rho", sol["p"] / sol["rho"])
```

The computed numbers must equal the table of Section 12.26, and A^2 must equal Notebook 12b's formula $5 + \Lambda/3 - \lambda S^2/6$ (Exercise 7 derives it). The equations of state are $-1/2$, 0 and -3.

In [17], figure 4: both sides of the Einstein equations for example 3.

```
sol = solutions["example 3"]
G_diag = [G_hidden] + [G_space] * 3 + [G_time] + [G_extra] * 3
left_side = np.array([[float(G_diag[mu].subs({A: 1, H: 1}) + sol["Lambda"])
                       if mu == nu else 0.0 for nu in range(8)] for mu in range(8)])
right_side = np.array([[float(sol["T"][mu][nu]) for nu in range(8)]
                       for mu in range(8)])
check(np.max(np.abs(left_side - right_side)) == 0.0,
      "example 3: the two 8 by 8 tables are equal entry by entry")
```

The two sides as 8 by 8 arrays of numbers; they agree exactly (the difference is 0.0, not merely small, because both come from exact numbers).

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.4))
scale = np.abs(right_side).max()
panels = ((left_side, "$G^\\mu{}_\\nu + \\Lambda\\delta^\\mu_\\nu$"),
          (right_side, "$\\kappa T^\\mu{}_\\nu$ of the condensate"),
          (left_side - right_side, "difference"))
for ax, (values, title) in zip(axes, panels):
    ax.imshow(values, cmap="RdBu_r", vmin=-scale, vmax=scale)
    for mu in range(8):
        value = values[mu, mu]
        ink = "white" if abs(value) > 0.6 * scale else "black"  # readable on dark
        ax.text(mu, mu, f"{value:.0f}", ha="center", va="center", fontsize=7,
                color=ink)
```

Three heat maps with one common scale (left side, right side, difference), drawn as in Notebook 12a, In [20], with the diagonal values written in.

```
    ax.set_xticks(range(8))
    ax.set_xticklabels(NAMES, fontsize=7)
    ax.set_yticks(range(8))
    ax.set_yticklabels(NAMES, fontsize=7)
    ax.grid(False)
    ax.set_title(title, fontsize=9)
fig.suptitle("Example 3 ($A = 1$, $\\Lambda = -3OH^2$): the Einstein equations hold "
             "component by component")
save_figure(fig, "tensor_equality",
            ...)
```

What the figure shows. The two tables are identical: -6 at x_4 (minus the energy density 6) and -18 at the seven other diagonal places, white everywhere else; the difference is white throughout.

In [18], figure 5: the solution in time.

```
sol = solutions["example 1"]
phi_numbers = np.array([complex(entry) for entry in sol["phi0"]])
biggest = np.argsort(-np.abs(phi_numbers), kind="stable")[:3]  # three components
times = np.linspace(0.0, 3.0, 601)  # x4 in units 1/H
```

Φ_0 of example 1 as 16 complex floating-point numbers. `np.argsort` lists the positions in the order of the sorted values; sorting $-|\Phi_0|$ puts the largest first, `kind="stable"` keeps equal values in their

original order (so that every computer chooses the same three), and `[:3]` keeps the first three positions.

```
density = []
for x_value in times:  # S from the numbers, at every time (it must stay 12/5)
    phi_x = phi_numbers * np.exp(-4j * x_value)
    density.append((phi_x.conj() @ np.array(C.tolist(), dtype=float) @ phi_x).real)
density = np.array(density)
check(np.max(np.abs(density - 12 / 5)) < 1e-12,
      "example 1: S(x4) = 12/5 at every time (numerically)")
```

At 601 times the condensate $\Phi = e^{-4ix_4}\Phi_0$ is formed (`4j` is $4i$ in Python), and $S = \Phi^\dagger C \Phi$ is computed with `@`, the matrix product of numpy, and `.conj()`, the complex conjugate. It stays $12/5$ up to rounding.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
for index in sorted(biggest):
    left.plot(times, (phi_numbers[index] * np.exp(-4j * times)).real,
              label=f"Re $\\Phi_{{{index + 1}}}(x_4)$")
left.plot(times, density, color="black", linewidth=2.0,
          label="$S = \\bar\\Phi\\Phi = 12/5$")
left.set_ylim(-1.35, 4.0)  # room for the legend above the curves
left.set_xlabel("time $x_4$ (units $1/H$)")
left.set_ylabel("value")
left.set_title("example 1: the condensate oscillates, $S$ stays constant")
left.legend(fontsize=8, loc="upper center", ncol=2)
```

The real parts of the three largest components (numbered from 1 in the label) and the constant density; `ncol=2` arranges the legend in two columns.

```
for name, style in (("example 1", "-"), ("example 2", "--")):
    slope = float(solutions[name]["A"])
    right.semilogy(times, np.exp(slope * times), style, color="tab:orange",
                   label=f"3-space $e^{{a_4}}$, {name}")
    right.semilogy(times, np.exp(-slope * times), style, color="tab:blue",
                   label=f"extra times $e^{{-a_4}}$, {name}")
right.set_xlabel("time $x_4$ (units $1/H$)")
right.set_ylabel("scale factor")
right.set_title("3-space inflates, the extra times deflate")
right.legend(fontsize=8)
save_figure(fig, "solution_in_time",
            ...)
```

The scale factors of examples 1 and 2 on a logarithmic axis. **What the figure shows.** The components oscillate with the period $2\pi/4 \approx 1.57$ while S stays flat; the extra-time scale factor falls along straight lines of slope -1 (example 1) and $-\sqrt{5}$ (example 2): exponential deflation, driven by the condensate.

In [19], figure 6: the family in the cosmological constant.

```
lam_axis = sp.symbols("Lambda_axis", real=True)
S_one = sp.Rational(12, 5)
m_family = -(36 + 2 * lam_axis) / S_one
lam_family = (-5 - m_family) / S_one
rho_family_line = m_family * S_one + lam_family * S_one ** 2 / 2
p_family_line = lam_family * S_one ** 2 / 2
check(sp.expand(rho_family_line - (-24 - lam_axis)) == 0
      and sp.expand(p_family_line - (12 + lam_axis)) == 0
      and m_family.subs(lam_axis, 0) == solutions["example 1"]["m"]
      and m_family.subs(lam_axis, -30) == solutions["example 3"]["m"],
      "A = 1 family: kappa rho = -24 - Lambda, kappa p = 12 + Lambda")
```

For $A = 1$, $M = -5$, $S = 12/5$ every Λ gives a solution with $m = -(36+2\Lambda)/S$ and $\lambda = (M-m)/S$; then $\kappa\rho = -24 - \Lambda$ and $\kappa p = 12 + \Lambda$, and examples 1 and 3 are members.

```
axis = np.linspace(-45.0, 15.0, 301)
functions = [sp.lambdify(lam_axis, f, "numpy") for f in
             (m_family, lam_family, rho_family_line, p_family_line)]
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
left.plot(axis, functions[0](axis), label="mass $m/H$")
left.plot(axis, functions[1](axis), "--", label="self-coupling $\\lambda$")
right.plot(axis, functions[2](axis), label="$\\kappa\\rho/H^2$")
right.plot(axis, functions[3](axis), "--", label="$\\kappa p/H^2$")
```

The four formulas as numpy functions of Λ, drawn from -45 to 15: parameters on the left, the source on the right.

```
for ax in (left, right):
    ax.axvspan(-45.0, -24.0, color="tab:green", alpha=0.1)
    ax.axhline(0.0, color="black", linewidth=0.8)
    ax.set_xlabel("cosmological constant $\\Lambda/H^2$")
for name, marker in (("example 1", "o"), ("example 3", "s")):
    sol = solutions[name]
    x_value = float(sol["Lambda"])
    left.plot([x_value] * 2, [float(sol["m"]), float(sol["lambda"])], marker,
              color="black")
    right.plot([x_value] * 2, [float(sol["rho"]), float(sol["p"])], marker,
               color="black", label=name)
left.set_title("the condensate's parameters ($A = 1$, $M = -5H$)")
right.set_title("the source it provides")
left.legend(fontsize=8)
right.legend(fontsize=8)
save_figure(fig, "family_in_lambda",
            ...)
```

The green band $\Lambda < -24$ in both panels, the zero lines, and black markers for the two examples. **What the figure shows.** Along the family $\rho + p = -12$ never changes; the energy density becomes positive only in the green band, and there $p < -\rho$: $w < -1$.

In [20], the last check.

```
figure_names = ["condensate_frequency", "three_gamma_bilinears", "allowed_sources",
                "tensor_equality", "solution_in_time", "family_in_lambda"]
paths = [output_file(f"{FIGURE_FOLDER}/12d_{k}_{name}.png")
         for k, name in enumerate(figure_names, 1)]
check(all(path.is_file() for path in paths), "all six figure files exist")
all_checks_passed()
```

As in In [15] of Notebook 12b (Section 12.20): `figure_names` lists the short names of the six figures in the order in which they were drawn, `enumerate(figure_names, 1)` numbers them from 1, which gives the six file names `12d_1_condensate_frequency.png` to `12d_6_family_in_lambda.png`, and `output_file` gives the path where each was written. `path.is_file()` is true when the file exists, and `all` requires this of every one of the six. `all_checks_passed()` prints the last line, ALL 40 CHECKS PASSED (notebook 12d): 1 check in In [2], 2 in In [3], 1 in In [4], 4 in In [5], 3 in In [6], 1 in In [7], 3 in In [8], 2 in In [9], 2 in In [10], 2 in In [11], 1 in In [12], 2 in In [13], 9 in In [15], 3 in In [16], 1 in In [17], 1 in In [18], 1 in In [19] and 1 in In [20].

12.31 What we proved, what we computed, what we assumed

PROVED (exact). The table names, for each statement, the checks of the Revision record that verify it and the notebook cell of this chapter that reproduces them. "Sympy report" and "Wolfram report" are the two reports of the field equations in the folder `Revision/field_equations_a4/reports`; "lead's reports" are `einstein-gauss-bonnet-a4.json` and `emt-divergence-and-spin-connection.json` in `Revision/lead_checks/reports`.

statement	where it is verified
$\sqrt{\lvert\det g\rvert} = \cos z$, independent of a_4: the 7-volume is constant	Wolfram report, `sqrt_abs_det_g_is_cos_z`; Notebook 12a, In [4]
37 nonzero Christoffel symbols; 156 nonzero Riemann components, free of the warp and of e^{a_4}, polynomials in $\cot z$ and $1/\cot z$	Notebook 12a, In [5]; sympy report, `mixed_riemann_free_of_warp_and_a4`, `riemann_entries_laurent`; In [8]
the Einstein tensor is diagonal, isotropic in 3-space and in the extra times, independent of x_0, with the four components of Section 12.6	lead's report, `einstein_off_diagonal_zero`, `einstein_isotropy`, `einstein_x0_independent`; sympy report, `einstein_components`; In [12]
the three Lovelock tensors from the GKD equal the Rust record in all 64 components; $E_{(1)} = G$; each is divergence-free; $P_{(4)} = 0$	sympy report, `P1_equals_gkd_branch_monomials` to `P3_equals_gkd_branch_monomials`, `P1_equals_minus_4_Einstein`, `E1_divergence_free` to `E3_divergence_free`; Wolfram report, `P4_vanishes_pigeonhole`; In [14] to In [19]
$E_{(2)}$ equals the classical Gauss-Bonnet tensor	Notebook 12a, In [18] (every a_4); lead's report, `gauss_bonnet_rho_alpha2`, `gauss_bonnet_p_alpha2` (linear member)
the field equations reduce to the constraint, the evolution equation $a_4'' F(a_4') = \kappa(p_3 - p_t)$, the hidden equation and the conditions $p_3 + p_t = 2p_0$, no x_0 dependence, no mixed components	Wolfram report, `independent_components`; sympy report, `evolution_factorises`, `evolution_F_not_identically_zero`, `algebraic_identity`; In [21] and In [22]

statement	**where it is verified**
the constraint propagates; the source obeys $\rho' = -3a_4'(p_3 - p_t)$	sympy report, `bianchi_x4`, `conservation_components`; Wolfram report, `constraint_propagation_bianchi`; lead's report, `divergence_x4_component`, `divergence_x0_component`; In [23] and In [25]
Einstein gravity: no vacuum for $H > 0$; every source has $\kappa(\rho + p_0) = -6((a_4')^2 + H^2) < 0$	sympy report, `einstein_null_energy_x0`; Wolfram report, `einstein_no_vacuum_solution`; lead's report, `no_vacuum_for_H_positive`; In [26]
the linear member needs $p_3 = p_t = p_0$ and constant ρ, p; A enters only as A^2: the deflation of the extra times is a choice of sign	sympy report, `linear_member_equal_pressures`, `json_linear_member`; Notebook 12a, In [28]; Notebook 12b, In [4]
Einstein gravity: a positive energy density of the linear member needs $\Lambda < -(21 + 3A^2)H^2$ and has $w < -1$	Notebook 12b, In [5] and In [8]
Einstein-Gauss-Bonnet gravity: among the linear members, vacua exist exactly for $0 < \alpha_2 H^2 \leq 1/40$	sympy report, `linear_member_vacuum_factor`, `einstein_gauss_bonnet_vacuum_linear`; Notebook 12b, In [10] and In [11]
with the author's eight real 16 by 16 gammas: $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$; a condensate obeys $\Phi' = \mathcal{A}\Phi$, $\mathcal{A}^2 = -(M^2 - 9H^2)$, with constant S, $\rho = mS + \frac{\lambda}{2}S^2$, $p_3 = p_t = p_0 = \frac{\lambda}{2}S^2$	sympy report, `authorT16_gravity_term`, `authorT16_condensate_S_constant`, `authorT16_condensate_kinetic_diagonal`; lead's report, `gamma_Omega_equals_3H_gamma0`; Notebook 12d, In [5] to In [12]
in Einstein gravity a condensate is a source of the linear member only if $\kappa M S = -6(A^2 + 1)H^2$ and $\kappa m S = -(36H^2 + 2\Lambda)$	sympy and Wolfram reports, `condensate_einstein_quadratic_U`; Notebook 12b, In [13]; Notebook 12d, In [13]
three exact solutions of the coupled equations of Einstein gravity and dirac16complex00, two with the extra times deflating as e^{-Hx_4}: all 16 field-equation components and all 64 Einstein components hold, for $+A$ and $-A$	Notebook 12d, In [15]: a computation of this book, not a Revision record, under the assumptions listed below

COMPUTED (numerical, with measured accuracy; Notebook 12c): RK4 integrations of the evolution equation for prescribed stresses, agreeing with the exact solutions to 9×10^{-11} (pulse, step 0.01) and to better than 10^{-9}, the bound of the check (relaxing stress); measured convergence orders 4.24, 4.12, 4.06, 4.03; the energy density from conservation agrees with the constraint to 2×10^{-11}; the Gauss-Bonnet breakdown is reached at the predicted times $x_4^\star = 2.4682/H$ ($\alpha_2 H^2 = 0.005$) and $0.4498/H$ ($\alpha_2 H^2 = 0.01$) within 0.01; the eigenvalues of $\mathcal{A}$ agree with $\pm iw$ to 10^{-14}, eight of each sign (Notebook 12d, In [7]); the ratio $(\int p_3 + \int p_t)/(2\int p_0)$ of the 70 recorded Kohn-Sham states with a nonzero energy-momentum tensor, recomputed from the record's table `Revision/kohn_sham/results/ground/emt-integrals.csv` and equal to the record, is nowhere closer to the required 1 than 0.414328 (Notebook 12c, In [16]).

ASSUMED: the stresses of Notebook 12c (test inputs; no field of the theory is known to produce

them); Einstein gravity and the sign convention $\sigma_T = +1$ of the energy-momentum tensor in Notebook 12d; the classical commuting field dirac16complex00 (not the quantised dirac16complex) as the source there; the chosen values of Λ, m, λ and of the Lovelock couplings; Lovelock's theorem is quoted from the literature, not proved.

HYPOTHESIS: none is used in this chapter.

OPEN: whether the condensates of Notebook 12d are stable and how they could arise; whether any state of the quantised field dirac16complex is an admissible source (the recorded Kohn-Sham states are not: `Revision/field_equations_a4/reports/ks-source-conditions.json`, every one of its checks PASS, its numbers recomputed in Notebook 12c, In [15] and In [16]); the values of α_2, α_3, Λ and κ in nature. Nothing in this chapter concerns the creation of universes, in pairs or otherwise, or the asymmetry between matter and antimatter: the symmetry $A \to -A$ relates two histories of one metric and is not the pairing of universes of masses $+m$ and $-m$, whose exact statement and limits are the subject of Chapters 18 to 21.

12.32 Exercises

Exercise 1. Compute ${\Gamma^{x_5}}_{x_5x_0}$ and ${\Gamma^{x_0}}_{x_5x_5}$ by hand from the diagonal formula of Section 12.4.

Answer. $g_{55} = -e^{-2a_4}\sin^{1/3} z$, and $\partial_0 g_{55} = 6H\cdot(-e^{-2a_4})\frac{1}{3}\sin^{-2/3} z\cos z = 2H\cot z\ g_{55}$. First symbol ($a = c = x_5$, $b = x_0$, the term with δ_{ac}): ${\Gamma^{x_5}}_{x_5x_0} = \partial_0 g_{55}/(2g_{55}) = H\cot z$. Second ($b = c = x_5$, $a = x_0$, the term with δ_{bc}): ${\Gamma^{x_0}}_{x_5x_5} = -\partial_0 g_{55}/(2g_{00}) = -2H\cot z\, g_{55}/(2\cot^2 z) = -H\tan z\ g_{55} = He^{-2a_4}\sin^{1/3} z\,\tan z = He^{-2a_4}\sin^{4/3} z/\cos z$. Both agree with Out [6] of Notebook 12a.

Exercise 2. Compute the pair curvature $K_{x_5x_6}$ of two extra times by hand.

Answer. With $a = m = x_5$, $b = n = x_6$ the derivative terms vanish (${\Gamma^{x_5}}_{x_6x_6} = {\Gamma^{x_5}}_{x_6x_5} = 0$, because g_{55} does not depend on x_6), and so does the last sum. The remaining sum has $e = x_4$ and $e = x_0$: ${R^{x_5}}_{x_6x_5x_6} = {\Gamma^{x_5}}_{x_5x_4}{\Gamma^{x_4}}_{x_6x_6} + {\Gamma^{x_5}}_{x_5x_0}{\Gamma^{x_0}}_{x_6x_6} = (-a_4')(-a_4' g_{66}) + H\cot z\,(-H\tan z\, g_{66}) = ((a_4')^2 - H^2)g_{66}$ (Section 12.4: ${\Gamma^{x_4}}_{x_6x_6} = -a_4' g_{66}$ and ${\Gamma^{x_0}}_{x_6x_6} = -H\tan z\, g_{66}$). Raising with $g^{66} = 1/g_{66}$: $K_{x_5x_6} = (a_4')^2 - H^2$, the same as for two 3-space directions (the table of Section 12.5).

Exercise 3. Use the rule ${G^h}_h = -\sum_{\text{pairs not containing } h} K$ to compute all diagonal components of the Einstein tensor for the canonical history $a_4 = Hx_4$, and from them the required $\kappa\rho$, κp and w for $\Lambda = 0$.

Answer. With $a_4' = H$, $a_4'' = 0$ the pair curvatures are: two 3-space directions or two extra times 0; 3-space with extra time $-2H^2$; 3-space or extra time with the time H^2; with x_0 $-H^2$; time with x_0 0. Pairs without x_4: $9\cdot(-2H^2) + 6\cdot(-H^2) = -24H^2$, so ${G^{x_4}}_{x_4} = 24H^2$. Pairs without x_0: $9\cdot(-2H^2) + 6\cdot H^2 = -12H^2$, so ${G^{x_0}}_{x_0} = 12H^2$. Pairs without x_1: six mixed pairs ($-12H^2$), five time pairs ($+5H^2$), five with x_0 ($-5H^2$): $-12H^2$, so ${G^{x_1}}_{x_1} = 12H^2$, and the same for an extra time. Then $\kappa\rho = -{G^{x_4}}_{x_4} = -24H^2$, $\kappa p = 12H^2$, $w = 12/(-24) = -1/2$, as in Notebook 12b, In [5]. Check with the formulas: $3H^2 + 21H^2 = 24H^2$ and $15H^2 - 3H^2 = 12H^2$.

Exercise 4. In Einstein gravity, for the canonical history ($A = 1$), which cosmological constant makes the required energy density zero? What are then the pressure and $\rho + p$? Is this a vacuum?

Answer. $\kappa\rho = -24H^2 - \Lambda = 0$ gives $\Lambda = -24H^2$. Then $\kappa p = 12H^2 + \Lambda = -12H^2$ and $\kappa(\rho + p) = -12H^2$, as the formula $-6(1 + A^2)H^2$ says. The pressure is not zero, so this is not a vacuum: a

source with zero energy density and negative pressure is still needed.

Exercise 5. In Einstein-Gauss-Bonnet gravity, find the coupling $\alpha_2 H^2$ for which the canonical history $A = 1$ is a vacuum, and the cosmological constant it needs. Check that the pressure vanishes too.

Answer. $V = 1 - 8\alpha_2 H^2(A^2+5) = 1 - 48\alpha_2 H^2 = 0$ gives $\alpha_2 H^2 = 1/48$ (the point checked in Notebook 12b, In [12]). With $\alpha_1 = 1$, $\alpha_3 = 0$: $\kappa\rho = -(21+3)H^2 + \alpha_2 H^4(36+120+420) - \Lambda = -24H^2 + 576H^2/48 - \Lambda = -12H^2 - \Lambda$, which is zero for $\Lambda = -12H^2$. The pressure: $\kappa p = (15-3)H^2 + 12\alpha_2 H^4(1+14-15) + \Lambda = 12H^2 + 0 - 12H^2 = 0$. (The formula of Notebook 12b, $\Lambda = 720H^4\alpha_2 - 36H^2 + 3/(16\alpha_2)$, gives $15H^2 - 36H^2 + 9H^2 = -12H^2$ as well.)

Exercise 6. Show, for Einstein gravity, that if the constraint holds at every time and the source obeys the conservation law $\rho' = -3a_4'(p_3 - p_t)$, then the evolution equation holds wherever $a_4' \neq 0$.

Answer. Differentiate the constraint $-\kappa\rho = 3(a_4')^2 + 21H^2 + \Lambda$: $-\kappa\rho' = 6a_4'a_4''$. Insert the conservation law on the left: $3a_4'\kappa(p_3 - p_t) = 6a_4'a_4''$. Where $a_4' \neq 0$ divide by $3a_4'$: $\kappa(p_3 - p_t) = 2a_4''$, the evolution equation. (Where $a_4' = 0$ the division is not allowed, and the evolution equation is an independent statement.)

Exercise 7. A condensate with $U = \frac{\lambda}{2}S^2$ is the source of the linear member in Einstein gravity. Derive Notebook 12b's formula $A^2 = 5 + \Lambda/3 - \lambda S^2/6$ (units $H = \kappa = 1$) and check it on example 3 of Section 12.26.

Answer. The two conditions read $MS = -6(A^2+1)$ and $mS = -(36 + 2\Lambda)$. Since $M = m + \lambda S$: $MS = mS + \lambda S^2 = -(36+2\Lambda) + \lambda S^2$. So $-6(A^2+1) = -36 - 2\Lambda + \lambda S^2$, hence $A^2 + 1 = 6 + \Lambda/3 - \lambda S^2/6$ and $A^2 = 5 + \Lambda/3 - \lambda S^2/6$. Example 3: $\Lambda = -30$, $\lambda = -25/4$, $S = 12/5$: $5 - 10 + \frac{25}{4}\cdot\frac{144}{25}\cdot\frac{1}{6} = 5 - 10 + 6 = 1 = A^2$.

Exercise 8. In Einstein-Gauss-Bonnet gravity with $\alpha_2 H^2 = 0.01$, a constant stress $\kappa\Delta = 0.5H^2$ acts from $a_4'(0) = H$. Compute the critical rate and the breakdown time (units $H = 1$).

Answer. $F(v) = 2 - 0.8 - 0.48v^2 = 1.2 - 0.48v^2$ vanishes at $v_c = \sqrt{1.2/0.48} = \sqrt{2.5} \approx 1.5811$. $G(v) = 1.2v - 0.16v^3$: $G(v_c) = 1.2\cdot 1.58114 - 0.16\cdot 3.95285 \approx 1.89737 - 0.63246 = 1.26491$ (using $v_c^3 = 2.5\,v_c$), and $G(1) = 1.2 - 0.16 = 1.04$. So $x_4^\star = (1.26491 - 1.04)/0.5 \approx 0.4498$, the value of Notebook 12c, In [13].

Exercise 9. For the relaxing stress of Section 12.21, by how much does the extra-time scale factor e^{-a_4} end up smaller than on the history $a_4 = x_4$, for $\eta = 0.5$?

Answer. $a_4 - x_4 = (1 - e^{-\eta x_4})/\eta \to 1/\eta = 2$ for large x_4. So $e^{-a_4} = e^{-x_4}e^{-(a_4 - x_4)} \to e^{-x_4}e^{-2}$: the extra times end up smaller by the factor $e^{-2} \approx 0.135$ than on the canonical history, because they deflated faster at first.

Exercise 10. Show that $\mathcal{A} = -\gamma^{(x_4)}(M - 3H\gamma^{(x_0)})$ has the eigenvalues $\pm i\sqrt{M^2 - 9H^2}$ when $M^2 > 9H^2$ and $\pm\sqrt{9H^2 - M^2}$ when $M^2 < 9H^2$. What is the period of the condensate for $M = -5H$?

Answer. If $\mathcal{A}v = \mu v$ for a nonzero v, then $\mathcal{A}^2 v = \mu^2 v$; with $\mathcal{A}^2 = -(M^2 - 9H^2)$ (Section 12.26) this gives $\mu^2 = 9H^2 - M^2$. For $M^2 > 9H^2$ the right-hand side is negative and μ is one of $\pm i\sqrt{M^2 - 9H^2}$; for $M^2 < 9H^2$ it is positive and μ is one of $\pm\sqrt{9H^2 - M^2}$, real: solutions grow or decay. This shows only that no other value occurs; that both signs occur, each 8 times, follows from the **trace** (the sum of the diagonal entries), which equals the sum of the 16 eigenvalues, each counted as often as it occurs.

Write $\mathcal{A} = -M\gamma^{(x_4)} + 3H\gamma^{(x_4)}\gamma^{(x_0)}$. Then $\operatorname{tr}\gamma^{(x_4)} = \operatorname{tr}\big(\gamma^{(x_0)}\gamma^{(x_0)}\gamma^{(x_4)}\big) = \operatorname{tr}\big(\gamma^{(x_0)}\gamma^{(x_4)}\gamma^{(x_0)}\big) = -\operatorname{tr}\big(\gamma^{(x_0)}\gamma^{(x_0)}\gamma^{(x_4)}\big) = -\operatorname{tr}\gamma^{(x_4)}$, so $\operatorname{tr}\gamma^{(x_4)} = 0$ (first $(\gamma^{(x_0)})^2 = 1$; then $\operatorname{tr}(XY) = \operatorname{tr}(YX)$ with $X = \gamma^{(x_0)}$, which moves the first factor to the end; then the Clifford relation $\gamma^{(x_4)}\gamma^{(x_0)} = -\gamma^{(x_0)}\gamma^{(x_4)}$; then $(\gamma^{(x_0)})^2 = 1$ again). In the same way $\operatorname{tr}\big(\gamma^{(x_4)}\gamma^{(x_0)}\big) = \operatorname{tr}\big(\gamma^{(x_0)}\gamma^{(x_4)}\big) = -\operatorname{tr}\big(\gamma^{(x_4)}\gamma^{(x_0)}\big) = 0$. So $\operatorname{tr}\mathcal{A} = 0$. If n_+ eigenvalues equal $+\mu_0$ and n_- equal $-\mu_0$, with $\mu_0 \neq 0$ (here $M^2 \neq 9H^2$), then $n_+ + n_- = 16$ and $\operatorname{tr}\mathcal{A} = (n_+ - n_-)\mu_0 = 0$, hence $n_+ = n_- = 8$. For $M^2 > 9H^2$ this also follows from $\mathcal{A}$ being real (Section 12.26). For $M = -5H$: $w = \sqrt{25-9}\,H = 4H$, and e^{-iwx_4} repeats after $x_4 = 2\pi/w = \pi/(2H) \approx 1.57/H$.

13 Many-body quantum mechanics and DFT from zero

This chapter builds, from zero, the tool with which Chapters 14 to 16 compute the states of many quanta of the field dirac16complex in the author's primordial field: **density functional theory**, DFT for short, in the form of Kohn and Sham. Every idea is first developed for ordinary particles that move slowly (non-relativistic particles), because there every step can be seen and checked by hand. The chapter has five worked examples, Notebooks 13a to 13e, and every number in its text is computed by one of them.

13.1 What this chapter is for

The problem. Chapter 14 asks for the lowest-energy state (the **ground state**) and the first excited state of a fixed number N of dirac16complex quanta that interact with each other inside the author's primordial gravitational field. A quantum state of one particle in ordinary three-dimensional space is a complex-valued function of three variables (its **wave function**, defined in Section 13.2). If we store such a function on a grid with 10 points along each coordinate, we need 10^3 complex numbers. The state of two particles is a function of 6 variables, 10^6 numbers; the state of ten particles a function of 30 variables, 10^{30} numbers, more than every computer on Earth can hold together. Every added particle multiplies the work by 10^3. This growth is called the **exponential wall** of the many-body problem.

The way around it. DFT works with the **density** n of the particles instead of their wave function: the expected number of particles per unit volume at each point of space. The density is a function of three variables, whatever N is. Sections 13.8 to 13.10 prove that the density alone fixes the ground-state energy, and they show how Kohn and Sham turned this fact into equations that a computer can solve: one-particle equations in an effective potential, solved again and again until the potential and the density agree (**self-consistency**). The price is one quantity, the **exchange-correlation energy**, that is not known exactly and must be approximated. We will see exactly where the approximation enters and what it is.

Plan. Sections 13.2 to 13.7 are the quantum mechanics of many identical fermions: one particle, many particles, Slater determinants, creation and annihilation operators with Wick's theorem, the energy of a determinant with its direct and exchange parts, the Hartree-Fock equations, and an exactly solvable model of two electrons on two sites. Sections 13.8 to 13.10 are density functional theory proper: the Hohenberg-Kohn theorem, functional derivatives and the Kohn-Sham equations. Notebook 13c (Sections 13.11 to 13.14) checks all of this with numbers. Sections 13.15 and 13.16 compute the exchange energy of a uniform gas, show that for a contact interaction it is exactly

local, and carry the result over to the 16-component field dirac16complex, reproducing the exchange formulas of the Revision record (Notebook 13b, Sections 13.17 to 13.20). Section 13.21 explains how the self-consistency loop is solved and why it can fail (Notebook 13d, Sections 13.22 to 13.25). Sections 13.26 and 13.27 extend everything to a finite temperature (Mermin's theorem) and to excited states (the Kohn-Sham gap, Janak's theorem and the Delta-SCF method), checked in Notebook 13e (Sections 13.28 to 13.31). Section 13.32 puts all the pieces together in one complete Kohn-Sham calculation, eight fermions in a trap, solved in Notebook 13a (Sections 13.33 to 13.36). Section 13.37 says what of this chapter is used for dirac16complex, Section 13.38 lists what was proved, computed and assumed, and Section 13.39 has exercises with complete answers.

The order of the notebooks. The notebooks are lettered in the order in which they were planned, and the chapter presents them in the order in which their ideas are needed: 13c, 13b, 13d, 13e, and last 13a, the complete calculation, which uses every idea of the others.

Units. In this chapter Planck's constant divided by 2π and the particle mass are set to 1 ($\hbar = m = 1$), so the kinetic-energy operator of one particle on a line is $-\frac{1}{2}\,d^2/dx^2$. Each notebook states its other units (the hopping t of the two-site model, the trap frequency of Notebook 13a). A temperature is measured as an energy (Boltzmann's constant is 1).

Symbols with a local meaning. Several letters mean something else in this chapter than in the rest of the book. (i) x is the position of a particle, or a point of a grid, or (in Section 13.21) the excess of charge on one site; it is never one of the author's spacetime coordinates $x_0, \ldots, x_7$, which appear only in Sections 13.16 and 13.37 and are named there. (ii) Ψ is the wave function of N particles, except in Sections 13.16 and 13.37, where it is the dirac16complex field, as those sections say. (iii) ρ is a density matrix (Section 13.4) or a density operator (Section 13.26), not an energy density. (iv) t is the hopping between two sites, T the temperature and T_s a kinetic energy. (v) S is a one-body quantity $\sum V_{pq} a_p^\dagger a_q$ in Section 13.4, the symmetric two-site state in Section 13.7, the scalar density of dirac16complex in Sections 13.16 to 13.20 and 13.37, and the entropy in Sections 13.26 to 13.31. (vi) U is the repulsion of two electrons on one site in the two-site model, U_{kp} the entries of a unitary matrix, and $U(S)$ the interaction potential of dirac16complex in Section 13.16. (vii) g counts the internal labels of a particle and g_c is the strength of a contact interaction; neither is the metric. (viii) H and $\hat{H}$ are Hamiltonians (energy operators); the author's constant H of the metric appears only in Section 13.37.

13.2 One quantum particle: states, operators and the variational principle

States on a grid. The state of one particle on a line is a complex-valued function $\phi(x)$, its **wave function**. Its squared modulus $|\phi(x)|^2 = \phi^*(x)\,\phi(x)$ (the star means complex conjugate) is the probability per unit length of finding the particle at x, so a physical state is **normalised**: $\int |\phi|^2\,dx = 1$. On a computer the line is replaced by M equally spaced points x_k, $k = 1, \ldots, M$, with the spacing h, and a state becomes a column of M numbers $(\phi_1, \ldots, \phi_M)$; integrals become sums, $\int f\,dx \approx \sum_k f_k\,h$. Two states are compared by their **inner product**

$$\langle \chi | \phi \rangle = \int \chi^*(x)\,\phi(x)\,dx \approx \sum_k \chi_k^*\,\phi_k\,h.$$

It is linear in ϕ, it gives the complex conjugate when the two states are exchanged, $\langle \phi|\chi\rangle = \langle \chi|\phi\rangle^*$, and $\langle \phi|\phi\rangle \geq 0$. Two states with $\langle \chi|\phi\rangle = 0$ are **orthogonal**; a set of normalised, pairwise orthogonal

states is **orthonormal**.

Operators. A measurable quantity is represented by a linear **operator** A: a rule that turns a state into a state, with $A(c_1\phi + c_2\chi) = c_1 A\phi + c_2 A\chi$ for numbers c_1, c_2. On a grid an operator is an $M \times M$ matrix. It is **Hermitian** when $\langle\chi|A\phi\rangle = \langle A\chi|\phi\rangle$ for all states; for a matrix this means that it equals its conjugate transpose, $A^\dagger = A$ (for a real matrix: it is symmetric). The **expectation value** $\langle A\rangle = \langle\phi|A\phi\rangle$ in a normalised state is the average of many measurements. The energy operator of one particle in an external potential $v(x)$ is the **Hamiltonian**

$$h = -\frac{1}{2}\,\frac{d^2}{dx^2} + v(x).$$

On the grid the second derivative is replaced by the **difference formula** $(\phi_{k+1} - 2\phi_k + \phi_{k-1})/h^2$, which follows from the Taylor expansions $\phi_{k\pm1} = \phi_k \pm h\,\phi_k' + \frac{1}{2}h^2\phi_k'' \pm \frac{1}{6}h^3\phi_k''' + O(h^4)$: adding them, the odd powers cancel, and the error is of order h^2. So $-\frac{1}{2}\,d^2/dx^2$ becomes the symmetric matrix with $1/h^2$ on the diagonal and $-1/(2h^2)$ just above and below it. A state with $h\phi = \epsilon\,\phi$ is an **eigenstate** (a stationary state) with the energy ϵ, an **eigenvalue** of h.

Two facts about Hermitian operators, line by line. Let $A\phi = a\,\phi$ with $\phi \neq 0$. Then

$$a\,\langle\phi|\phi\rangle = \langle\phi|A\phi\rangle = \langle A\phi|\phi\rangle = a^*\,\langle\phi|\phi\rangle.$$

The first equality puts $A\phi = a\phi$ into the second slot (linearity); the second is the definition of Hermitian; the third puts $A\phi = a\phi$ into the first slot, where a number comes out complex conjugated. Since $\langle\phi|\phi\rangle > 0$, we may divide by it: $a = a^*$, **the eigenvalues are real**. Next let $A\phi = a\phi$ and $A\chi = b\chi$ with $a \neq b$ (both real by the first fact). Then

$$b\,\langle\phi|\chi\rangle = \langle\phi|A\chi\rangle = \langle A\phi|\chi\rangle = a\,\langle\phi|\chi\rangle,$$

by the same three rules, so $(b-a)\langle\phi|\chi\rangle = 0$, and because $b - a \neq 0$, $\langle\phi|\chi\rangle = 0$: **eigenstates with different eigenvalues are orthogonal**. For a Hermitian matrix one can always choose an orthonormal basis of eigenvectors (the spectral theorem of linear algebra); numpy's function `eigh` returns exactly such a basis, with the eigenvalues in increasing order.

Worked example: two sites. Two grid points ("sites" L and R) and the hopping matrix

$$h = \begin{pmatrix} 0 & -t \\ -t & 0 \end{pmatrix}, \qquad t > 0.$$

The eigenvalues solve $\det(h - \epsilon) = \epsilon^2 - t^2 = 0$, so $\epsilon = \pm t$. For $\epsilon = -t$ the first row of $(h + t)\phi = 0$ reads $t\phi_L - t\phi_R = 0$, so $\phi_L = \phi_R$, and normalised $\phi = (1, 1)/\sqrt{2}$ (the **bonding** orbital, lower energy); for $\epsilon = +t$ we get $(1, -1)/\sqrt{2}$ (antibonding). They are orthogonal: $(1 \cdot 1 + 1 \cdot (-1))/2 = 0$.

The variational principle, line by line. Let $\phi_0, \phi_1, \ldots$ be an orthonormal basis of eigenvectors of a Hermitian H with eigenvalues $E_0 \le E_1 \le \ldots$, and let $\phi = \sum_n c_n\phi_n$ be any normalised state. Then

$$\langle\phi|H\phi\rangle = \sum_{n,m} c_m^* c_n\,\langle\phi_m|H\phi_n\rangle = \sum_{n,m} c_m^* c_n E_n\,\delta_{mn} = \sum_n |c_n|^2 E_n.$$

The first step expands both slots (linearity in the second slot, conjugation in the first); the second uses $H\phi_n = E_n\phi_n$ and orthonormality, $\langle\phi_m|\phi_n\rangle = \delta_{mn}$ (1 if $m = n$, else 0); the third keeps only $m = n$. Since every $E_n \geq E_0$ and $\sum_n |c_n|^2 = \langle\phi|\phi\rangle = 1$,

$$\sum_n |c_n|^2 E_n \;\geq\; E_0 \sum_n |c_n|^2 = E_0,$$

with equality exactly when only the c_n with $E_n = E_0$ are nonzero. So **the ground-state energy is the smallest expectation value of the energy over all normalised states**, and the states that reach it are the ground states. Every method of this chapter is an application of this inequality.

Internal labels. Real particles carry a label besides their position: an electron has a spin with two values, up and down. A particle with g labels has a wave function $\phi(x, \sigma)$ with $\sigma = 1, \ldots, g$. The quanta of dirac16complex in the sector of Chapter 14 have $g = 8$ states for each momentum (Section 13.16).

13.3 Many identical fermions and Slater determinants

The many-particle wave function. N particles are described by one complex function of all their positions and labels, $\Psi(x_1\sigma_1, \ldots, x_N\sigma_N)$. Its squared modulus is the probability density of finding particle 1 at x_1 with label σ_1, particle 2 at x_2 with σ_2, and so on. (In this paragraph the letters $x_1, \ldots, x_N$ are the positions of particles $1, \ldots, N$, not spacetime coordinates.)

Identical particles and the Pauli principle. No experiment can tell two electrons apart, so $|\Psi|^2$ must not change when two particles are exchanged. Nature realises this in two ways: for **bosons** Ψ itself is unchanged, for **fermions** it changes sign:

$$\Psi(\ldots, x_i\sigma_i, \ldots, x_j\sigma_j, \ldots) = -\,\Psi(\ldots, x_j\sigma_j, \ldots, x_i\sigma_i, \ldots) \qquad \text{(fermions)}.$$

Electrons, protons and neutrons are fermions, and so are the quanta of dirac16complex, whose components are anticommuting (Grassmann) numbers (Chapter 7). That a field describes fermions is an ASSUMED property of the field: it is built into dirac16complex by the choice of Grassmann components. Put $x_i\sigma_i = x_j\sigma_j$ in the rule above: then $\Psi = -\Psi$ at such points, so $\Psi = 0$ there. **Two identical fermions are never found at the same place with the same label** (the Pauli principle).

The many-body Hamiltonian. For N particles in an external potential v with a pair interaction w,

$$\hat{H} = \sum_{i=1}^{N} \Big[-\frac{1}{2}\frac{\partial^2}{\partial x_i^2} + v(x_i) \Big] + \sum_{i<j} w(x_i, x_j) = \hat{T} + \hat{V} + \hat{W}.$$

Only $\hat{V}$ distinguishes one system from another: all atoms with N electrons share the same kinetic energy $\hat{T}$ and interaction $\hat{W}$. This observation is the seed of DFT.

The density. The density is the expected number of particles per unit length at x,

$$n(x) = N \sum_{\sigma} \int |\Psi(x\sigma, x_2\sigma_2, \ldots, x_N\sigma_N)|^2 \, dx_2 \cdots dx_N$$

(the sum over σ also includes the sums over $\sigma_2, \ldots, \sigma_N$). The factor N appears because any of the N identical particles may be the one at x, and antisymmetry makes all N choices give the same integral; so $\int n \, dx = N$. The external energy needs only the density: $\langle \Psi | \hat{V} \Psi \rangle = \int v(x) \, n(x) \, dx$, because each of the N terms $v(x_i)$ gives the same integral.

Slater determinants for two particles. Take two orthonormal one-particle states ϕ_a, ϕ_b (**orbitals**; we write r for the position and label of one particle together). The product $\phi_a(r_1)\phi_b(r_2)$ is not antisymmetric, but

$$\Phi(r_1, r_2) = \frac{1}{\sqrt{2}} \big[\phi_a(r_1)\phi_b(r_2) - \phi_b(r_1)\phi_a(r_2) \big] = \frac{1}{\sqrt{2}} \det \begin{pmatrix} \phi_a(r_1) & \phi_b(r_1) \\ \phi_a(r_2) & \phi_b(r_2) \end{pmatrix}$$

is: exchanging r_1 and r_2 exchanges the two rows of the determinant, which changes its sign. If $\phi_a = \phi_b$ the two columns are equal and $\Phi = 0$: two fermions cannot occupy the same orbital. The norm follows line by line:

$$\begin{aligned} \iint |\Phi|^2 &= \tfrac{1}{2} \iint \big[|\phi_a(r_1)|^2 |\phi_b(r_2)|^2 + |\phi_b(r_1)|^2 |\phi_a(r_2)|^2 \big] - \tfrac{1}{2} \iint 2 \operatorname{Re}\big[\phi_a^*(r_1)\phi_b(r_1) \, \phi_b^*(r_2)\phi_a(r_2) \big] \\ &= \tfrac{1}{2} \, (1 \cdot 1 + 1 \cdot 1) - \operatorname{Re}\big[\langle \phi_a | \phi_b \rangle \langle \phi_b | \phi_a \rangle \big] = 1 - 0 = 1. \end{aligned}$$

The first line multiplies out $|u - v|^2 = |u|^2 + |v|^2 - 2 \operatorname{Re}(u^* v)$; the second integrates each factor separately (the integral of a product of a function of r_1 and a function of r_2 is the product of the integrals), uses the normalisation of ϕ_a and ϕ_b, and uses their orthogonality, $\langle \phi_a | \phi_b \rangle = 0$.

N particles, line by line. For N orthonormal orbitals $\phi_1, \ldots, \phi_N$ the **Slater determinant** is $\Phi = \det[\phi_a(r_i)]/\sqrt{N!}$, the determinant of the $N \times N$ table whose row i holds the values of all orbitals at the position (and label) r_i of particle i: the entry in row i and column a is $\phi_a(r_i)$. The Leibniz formula of Section 1.20 writes it as a sum over the $N!$ permutations σ of $1, \ldots, N$, each term taking from row i the entry in column $\sigma(i)$:

$$\Phi(r_1, \ldots, r_N) = \frac{1}{\sqrt{N!}} \sum_{\sigma} \operatorname{sign}(\sigma) \, \phi_{\sigma(1)}(r_1) \, \phi_{\sigma(2)}(r_2) \cdots \phi_{\sigma(N)}(r_N).$$

For $N = 2$ the two permutations give back the formula above. Three properties follow from the rules of determinants of Section 1.20. (i) **Antisymmetry**: exchanging the particles i and j exchanges the rows i and j of the table, which changes the sign of the determinant (rule 3). (ii) **Pauli**: if two orbitals are equal, $\phi_a = \phi_b$ with $a \neq b$, the columns a and b of the table are equal; the transposed table then has two equal rows, so its determinant is 0 (rule 4), and the determinant of the table is the same number (rule 2): $\Phi = 0$. (iii) **The norm.** Here and below $\int dr$ means the integral over the position together with the sum over the label, and $\int d^N r$ the same for all N particles. Writing $|\Phi|^2 = \Phi^* \Phi$ with one Leibniz sum over σ for Φ^* and another over τ for Φ:

$$\int |\Phi|^2 \, d^N r = \frac{1}{N!} \sum_\sigma \sum_\tau \operatorname{sign}(\sigma) \operatorname{sign}(\tau) \int \prod_{i=1}^{N} \phi^*_{\sigma(i)}(r_i) \, \phi_{\tau(i)}(r_i) \, d^N r$$
$$= \frac{1}{N!} \sum_\sigma \sum_\tau \operatorname{sign}(\sigma) \operatorname{sign}(\tau) \prod_{i=1}^{N} \langle \phi_{\sigma(i)} | \phi_{\tau(i)} \rangle$$
$$= \frac{1}{N!} \sum_\sigma \sum_\tau \operatorname{sign}(\sigma) \operatorname{sign}(\tau) \prod_{i=1}^{N} \delta_{\sigma(i)\tau(i)}$$
$$= \frac{1}{N!} \sum_\sigma \operatorname{sign}(\sigma)^2 = \frac{N!}{N!} = 1.$$

The first line multiplies the two sums term by term (the complex conjugate of a product is the product of the conjugates, and the signs are real) and collects the two factors that belong to particle i; the second integrates each particle's variable separately (the integral of a product of functions of different variables is the product of the integrals), and each factor is an inner product of two orbitals; the third uses orthonormality; the fourth notes that the product of the Kronecker deltas is 1 exactly when $\tau(i) = \sigma(i)$ for every i, that is $\tau = \sigma$, and 0 otherwise, so only the $N!$ terms with $\tau = \sigma$ survive, each with $\operatorname{sign}(\sigma)^2 = 1$. (iv) **The density.** By the definition of the density, with the variable of particle 1 set to r and the other $N-1$ variables integrated, the same steps give

$$n(r) = N \int |\Phi(r, r_2, \ldots, r_N)|^2 \, dr_2 \cdots dr_N = \frac{N}{N!} \sum_\sigma \sum_\tau \operatorname{sign}(\sigma) \operatorname{sign}(\tau) \, \phi^*_{\sigma(1)}(r) \, \phi_{\tau(1)}(r) \prod_{i=2}^{N} \delta_{\sigma(i)\tau(i)}$$
$$= \frac{1}{(N-1)!} \sum_\sigma |\phi_{\sigma(1)}(r)|^2 = \frac{1}{(N-1)!} \sum_{a=1}^{N} (N-1)! \, |\phi_a(r)|^2 = \sum_{a=1}^{N} |\phi_a(r)|^2.$$

The first line inserts the two Leibniz sums and integrates over $r_2, \ldots, r_N$ as in the norm; the factor of particle 1 is not integrated. In the second line, the deltas for $i = 2, \ldots, N$ force $\tau(i) = \sigma(i)$ for these places, and then also $\tau(1) = \sigma(1)$, because a permutation uses every number once and only one number is left for place 1; so again only $\tau = \sigma$ survives, with $\operatorname{sign}(\sigma)^2 = 1$, and $N/N! = 1/(N-1)!$. Next, the permutations with $\sigma(1) = a$ are the $(N-1)!$ orderings of the other $N-1$ numbers on the places $2, \ldots, N$, so each orbital a appears $(N-1)!$ times; the factorials cancel. So **the density of a Slater determinant is the sum of the orbital densities** (here $n(r)$ is the density at the position and label r; summed over the label it is the density $n(x)$ defined above, so $\int n \, dr = N$ by the norm of each orbital). For two particles the same computation reads $n(r) = 2 \int |\Phi(r, r_2)|^2 \, dr_2 = |\phi_a(r)|^2 \cdot 1 + |\phi_b(r)|^2 \cdot 1 - 2 \operatorname{Re}[\phi^*_a(r) \phi_b(r) \langle \phi_b | \phi_a \rangle] = |\phi_a(r)|^2 + |\phi_b(r)|^2$ (multiply out as above, integrate over r_2 only, use orthonormality). A Slater determinant is the state of N **independent** fermions; a general antisymmetric state is a sum of many determinants. Kohn-Sham theory (Section 13.10) rests on the fact that a single determinant can nevertheless carry the exact density.

Worked example (Notebook 13c, In [2]). Let space be three points $r = 0, 1, 2$ (no label), with the orthonormal orbitals $\phi_0 = (1, 0, 0)$ and $\phi_1 = (0, 1, 1)/\sqrt{2}$. Then $\Phi(0, 1) = [\phi_0(0)\phi_1(1) - \phi_1(0)\phi_0(1)]/\sqrt{2} = [1 \cdot \frac{1}{\sqrt{2}} - 0]/\sqrt{2} = \frac{1}{2}$, and $\Phi(1, 2) = [0 \cdot \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}} \cdot 0]/\sqrt{2} = 0$. The nine values are $\pm\frac{1}{2}$ (four of them) and 0 (five of them, among them the three diagonal values), so $\sum |\Phi|^2 = 4 \cdot \frac{1}{4} = 1$, and the density is $n(r) = 2 \sum_{r_2} |\Phi(r, r_2)|^2 = (1, \frac{1}{2}, \frac{1}{2}) = \phi_0^2 + \phi_1^2$. Figure 13c.1 draws this table and a determinant of two fermions in a box.

13.4 Creation and annihilation operators and Wick's theorem

Determinants are long to write. **Second quantisation** labels a determinant only by which orbitals it uses. It is the same formalism that Chapter 10 uses for the quantised dirac16complex field, here in its simplest form.

Occupation numbers. Fix an orthonormal basis of M orbitals $\phi_0, \dots, \phi_{M-1}$. A determinant built from some of them is fixed, up to its sign, by the **occupation numbers** $n_p \in \{0, 1\}$, $n_p = 1$ when ϕ_p is used. We write it $|n_0 n_1 \cdots n_{M-1}\rangle$ and fix the sign by listing the occupied orbitals in increasing order of p as the columns of the determinant. The state without any particle is the **vacuum** $|0\rangle$. With $M = 4$ orbitals there are $2^4 = 16$ such states; numbering them $s = 0, \dots, 15$, the occupation n_p is the binary digit (bit) p of s, so for example $s = 5 = 1 + 4$ occupies the orbitals 0 and 2.

The operators. The **creation operator** $a_p^\dagger$ adds a particle in orbital p, the **annihilation operator** a_p removes one:

$$
\begin{aligned}
a_p^\dagger \,|\cdots n_p \cdots\rangle &= (-1)^{\nu_p}\,(1 - n_p)\,|\cdots n_p{+}1 \cdots\rangle, \\
a_p \,|\cdots n_p \cdots\rangle &= (-1)^{\nu_p}\,n_p\,|\cdots n_p{-}1 \cdots\rangle, \qquad \nu_p = \sum_{q<p} n_q .
\end{aligned}
$$

The factor $1 - n_p$ makes $a_p^\dagger$ give zero on an occupied orbital (Pauli), the factor n_p makes a_p give zero on an empty one, and the sign $(-1)^{\nu_p}$ is the sign that a determinant picks up when the column of orbital p is moved past the ν_p occupied columns in front of it (each exchange of two columns changes the sign). On the 16 states of four orbitals each a_p is a 16×16 matrix of zeros and ± 1, and $a_p^\dagger$ is its transpose (Figure 13c.2 draws two of them).

The anticommutation relations. With the **anticommutator** $\{A, B\} = AB + BA$,

$$
\{a_p, a_q^\dagger\} = \delta_{pq}, \qquad \{a_p, a_q\} = 0, \qquad \{a_p^\dagger, a_q^\dagger\} = 0.
$$

Proof for $p = q$, on a state with $n_p = 0$: $a_p^\dagger$ creates the particle with the sign $(-1)^{\nu_p}$, and a_p removes it again with the same sign (the orbitals before p are unchanged), so $a_p a_p^\dagger$ gives the state back with the sign $(-1)^{2\nu_p} = +1$; and $a_p^\dagger a_p$ gives 0 because a_p acts on an empty orbital. The sum is 1. On a state with $n_p = 1$ the two roles are exchanged, and the sum is again 1. For $p < q$: whichever of the two operators acts on orbital p changes n_p, which changes ν_q by one and so flips the sign factor of the operator acting on q; the two orders therefore give the same state with opposite signs, and their sum vanishes. In particular $a_p^\dagger a_p^\dagger = 0$: the Pauli principle once more. The **number operator** $\hat{n}_p = a_p^\dagger a_p$ gives n_p, and $\hat{N} = \sum_p \hat{n}_p$ counts the particles of a state.

Operators of the many-body theory. A one-body operator, one copy $A(i)$ of a one-particle operator A for each particle, becomes $\hat{A} = \sum_{p,q} A_{pq}\, a_p^\dagger a_q$ with $A_{pq} = \langle \phi_p | A \phi_q \rangle$: applied to a determinant, $\sum_i A(i)$ replaces one occupied orbital ϕ_q at a time by $A\phi_q = \sum_p \phi_p A_{pq}$, and "remove q, put p, with the weight A_{pq}" is what $A_{pq}\, a_p^\dagger a_q$ does, sign included. The pair interaction is

$$
\hat{W} = \frac{1}{2} \sum_{p,q,r,s} w_{pqrs}\, a_p^\dagger a_q^\dagger a_s a_r, \qquad w_{pqrs} = \iint \phi_p^*(r)\, \phi_q^*(r')\, w(r, r')\, \phi_r(r)\, \phi_s(r')\, dr\, dr',
$$

where $\int dr$ includes the sum over the label. The operator removes an occupied pair (r, s) and puts

(p,q) in its place; the factor $\frac{1}{2}$ compensates for counting each pair twice, and the reversed order $a_s a_r$ makes the direct term come with a plus sign.

Expectation values in a determinant. Let $|\Phi\rangle$ occupy the set O of basis orbitals, and write $[p \in O]$ for 1 if p is occupied and 0 otherwise. Then

$$\langle\Phi|a_p^\dagger a_q|\Phi\rangle = \delta_{pq}\,[p \in O].$$

Reason: a_q removes q, and $a_p^\dagger$ must put back the same orbital to return to $|\Phi\rangle$, because states with different occupations are orthogonal; for $p = q$ the operator is $\hat{n}_p$, which gives $[p \in O]$. For four operators the pair removed must be the pair put back, $\{p,q\} = \{r,s\}$ with $p \neq q$:

$$\langle\Phi|a_p^\dagger a_q^\dagger a_s a_r|\Phi\rangle = [p \in O]\,[q \in O]\,(\delta_{pr}\delta_{qs} - \delta_{ps}\delta_{qr}).$$

If $p = r$ and $q = s$ the operator is $a_p^\dagger a_q^\dagger a_q a_p = a_p^\dagger \hat{n}_q a_p = \hat{n}_q \hat{n}_p$ (for $q \neq p$, $\hat{n}_q$ commutes with a_p and $a_p^\dagger$, because moving a_p past the pair $a_q^\dagger a_q$ costs two sign changes), which gives $[p \in O][q \in O]$; if $p = s$ and $q = r$, one exchange $a_q a_p = -a_p a_q$ gives the minus sign. Both formulas are summarised by the **one-body density matrix** $\rho = \sum_{a\in O} |\phi_a\rangle\langle\phi_a|$, whose matrix elements are $\rho_{qp} = \langle a_p^\dagger a_q\rangle$:

$$\langle a_p^\dagger a_q\rangle = \rho_{qp}, \qquad \langle a_p^\dagger a_q^\dagger a_s a_r\rangle = \rho_{rp}\,\rho_{sq} - \rho_{sp}\,\rho_{rq}.$$

This is **Wick's theorem** for a determinant: every expectation value is a sum of products of the density matrix. For a determinant ρ is a projector: $\rho^2 = \rho$ (applying "project on the occupied orbitals" twice is the same as once), and $\operatorname{Tr}\rho = N$.

Every basis. If new orbitals are made from the old ones by a unitary matrix U ($U^\dagger U = 1$), $\phi'_p = \sum_k \phi_k U_{kp}$, then a determinant is linear in each of its columns, so the creation operator of ϕ'_p is $a'^\dagger_p = \sum_k U_{kp}\, a_k^\dagger$, and its adjoint is $a'_p = \sum_k U^*_{kp}\, a_k$. Expectation values are linear in the operator, so

$$\langle a'^\dagger_p a'_q\rangle = \sum_{k,l} U_{kp}\, U^*_{lq}\, \langle a_k^\dagger a_l\rangle = \sum_{k,l} U^*_{lq}\, \rho_{lk}\, U_{kp} = (U^\dagger \rho\, U)_{qp},$$

which is the matrix element of the same ρ between the new orbitals. Call this matrix $\rho' = U^\dagger \rho\, U$, so that $\langle a'^\dagger_p a'_q\rangle = \rho'_{qp}$. The four-operator formula transforms in the same way; line by line:

$$\begin{aligned}
\langle a'^\dagger_p a'^\dagger_q a'_s a'_r\rangle &= \sum_{k,l,m,n} U_{kp}\, U_{lq}\, U^*_{ms}\, U^*_{nr}\, \langle a_k^\dagger a_l^\dagger a_m a_n\rangle \\
&= \sum_{k,l,m,n} U_{kp}\, U_{lq}\, U^*_{ms}\, U^*_{nr}\, (\rho_{nk}\,\rho_{ml} - \rho_{mk}\,\rho_{nl}) \\
&= \Big(\sum_{n,k} U^*_{nr}\,\rho_{nk}\,U_{kp}\Big)\Big(\sum_{m,l} U^*_{ms}\,\rho_{ml}\,U_{lq}\Big) \\
&\qquad - \Big(\sum_{m,k} U^*_{ms}\,\rho_{mk}\,U_{kp}\Big)\Big(\sum_{n,l} U^*_{nr}\,\rho_{nl}\,U_{lq}\Big) \\
&= \rho'_{rp}\,\rho'_{sq} - \rho'_{sp}\,\rho'_{rq}.
\end{aligned}$$

The first line inserts the four expansions $a'^\dagger_p = \sum_k U_{kp}\, a^\dagger_k$, $a'^\dagger_q = \sum_l U_{lq}\, a^\dagger_l$, $a'_s = \sum_m U^*_{ms}\, a_m$, $a'_r = \sum_n U^*_{nr}\, a_n$, multiplies out, and uses the linearity of expectation values; the second is the four-operator formula above with p, q, s, r renamed k, l, m, n; the third (written on two rows) splits each of the two products into two independent sums (each sum collects the factors that carry its two summation letters); the fourth recognises each sum as an element of the matrix product $U^\dagger \rho\, U$, for example $\sum_{n,k} U^*_{nr}\, \rho_{nk}\, U_{kp} = (U^\dagger \rho\, U)_{rp}$ because $(U^\dagger)_{rn} = U^*_{nr}$. The result is Wick's formula again, now with the density matrix ρ' of the new basis. So Wick's theorem holds in every orthonormal basis.

A thermal ensemble. Wick's theorem also holds for a **thermal ensemble** of non-interacting fermions, the statistical mixture of states that describes them at a temperature $T > 0$ (Section 13.26), with occupations f_a between 0 and 1 in place of 0 and 1. Section 13.26 shows two facts about it: in the basis of the orbitals ϕ_a of the non-interacting Hamiltonian, the ensemble is a mixture of the occupation-number states $|n_0 n_1 \cdots\rangle$ (they are the eigenstates of $\hat{H} - \mu\hat{N}$, so the Gibbs state, a function of this operator, gives each of them a probability, its Gibbs weight); and in this mixture orbital a is occupied with the Fermi-Dirac probability f_a, independently of the other orbitals. An expectation value in a mixture is the average, with these probabilities, of the expectation values in its states (Section 13.26), and each state is a determinant of basis orbitals. So the two determinant formulas above give, in this basis, line by line:

$$\begin{aligned}
\langle a^\dagger_p a_q\rangle &= \delta_{pq}\,\langle \hat{n}_p\rangle = \delta_{pq}\, f_p, \\
\langle a^\dagger_p a^\dagger_q a_s a_r\rangle &= \langle \hat{n}_p\, \hat{n}_q\rangle\, (\delta_{pr}\delta_{qs} - \delta_{ps}\delta_{qr}) \\
&= f_p\, f_q\, (\delta_{pr}\delta_{qs} - \delta_{ps}\delta_{qr}) \\
&= \rho_{rp}\,\rho_{sq} - \rho_{sp}\,\rho_{rq}, \qquad \rho = \mathrm{diag}(f_0, f_1, \dots).
\end{aligned}$$

The first line averages $\delta_{pq}[p \in O]$; the average of $[p \in O]$ is the probability that orbital p is occupied, f_p. So $\rho_{qp} = \delta_{pq} f_p$: the density matrix is diagonal, with the occupations on its diagonal. The second line averages $[p \in O]\,[q \in O]$, the value of $\hat{n}_p \hat{n}_q$ in each occupation-number state; this average is the probability that both p and q are occupied. The third line uses the independence: for $p \neq q$ that probability is the product $f_p f_q$. (For $p = q$ the bracket $\delta_{pr}\delta_{ps} - \delta_{ps}\delta_{pr}$ is 0, so this case needs nothing.) Independence is needed here because the four-operator formula is a product of two density-matrix elements, and the average of a product of two occupations is in general not the product of their averages; for independent occupations it is. The fourth line inserts $\rho_{rp} = \delta_{pr} f_p$, $\rho_{sq} = \delta_{qs} f_q$, $\rho_{sp} = \delta_{ps} f_p$ and $\rho_{rq} = \delta_{qr} f_q$: the two products are $f_p f_q\, \delta_{pr}\delta_{qs}$ and $f_p f_q\, \delta_{ps}\delta_{qr}$. The basis change above then carries Wick's theorem for the thermal ensemble to every orthonormal basis, with $\rho' = U^\dagger\, \mathrm{diag}(f_0, f_1, \dots)\, U$. Notebook 13c checks all $16 + 256$ two- and four-operator values in a randomly rotated basis, for a determinant and for a thermal ensemble (In [6] and In [7]).

The normal-ordered square of a one-body quantity. The interaction of the dirac16complex Kohn-Sham model (Section 13.16) is the square of a one-body quantity $S = \sum_{p,q} V_{pq}\, a^\dagger_p a_q$ with a Hermitian matrix V (the **vertex**). Its **normal-ordered square** puts all creation operators to the left: $:S^2: = \sum V_{pq} V_{rs}\, a^\dagger_p a^\dagger_r a_s a_q$. Line by line:

$$\begin{aligned}\langle{:}S^2{:}\rangle &= \sum_{p,q,r,s} V_{pq}V_{rs}\,\langle a_p^\dagger a_r^\dagger a_s a_q\rangle \\ &= \sum_{p,q,r,s} V_{pq}V_{rs}\,(\rho_{qp}\,\rho_{sr} - \rho_{sp}\,\rho_{qr}) \\ &= \Big(\sum_{p,q} V_{pq}\rho_{qp}\Big)\Big(\sum_{r,s} V_{rs}\rho_{sr}\Big) - \sum_{p,q,r,s} V_{pq}\,\rho_{qr}\,V_{rs}\,\rho_{sp} \\ &= (\mathrm{Tr}\,V\rho)^2 - \mathrm{Tr}(V\rho\,V\rho).\end{aligned}$$

The first line uses the linearity of expectation values; the second is Wick's four-operator formula with the indices renamed (its q, s, r are here r, s, q); the third splits the first product into two independent sums and reorders the factors of the second; the fourth recognises the sums as traces of matrix products ($\mathrm{Tr}\,AB = \sum_{p,q} A_{pq}B_{qp}$). The first term is a **Hartree** (direct) term, the second an **exchange** term. PROVED here, and recorded in the Revision record as the check hf_wick_contraction of `Revision/kohn_sham/reports/ks-theory-python.json` (brute force on a two-mode state; Notebook 13b, In [21], checks that its verdict is PASS); Notebook 13c (In [8]) checks it on four orbitals with a random Hermitian vertex.

13.5 The energy of a determinant: direct and exchange terms

The formula. The Hamiltonian in second quantisation is $\hat{H} = \sum h_{pq}\,a_p^\dagger a_q + \frac{1}{2}\sum w_{pqrs}\,a_p^\dagger a_q^\dagger a_s a_r$ with $h = -\frac{1}{2}\,d^2/dx^2 + v$. For the determinant of the basis orbitals in O, line by line:

$$\begin{aligned}\langle\Phi|\hat{H}|\Phi\rangle &= \sum_{p,q} h_{pq}\,\delta_{pq}[p\in O] + \tfrac{1}{2}\sum_{p,q,r,s} w_{pqrs}\,[p\in O][q\in O]\,(\delta_{pr}\delta_{qs} - \delta_{ps}\delta_{qr}) \\ &= \sum_{a\in O} h_{aa} + \tfrac{1}{2}\sum_{a,b\in O}(w_{abab} - w_{abba}).\end{aligned}$$

The first line inserts the two expectation values of Section 13.4; the second carries out the sums over the Kronecker deltas (δ_{pr} sets $r = p$, and so on) and renames p, q as a, b. Notebook 13c (In [10]) checks this formula for random one-body and two-body integrals.

Direct and exchange in space. Writing out the integrals and using $\sum_{a\in O}\phi_a(r)\phi_a^*(r') = \rho(r, r')$ (the density matrix in space, whose diagonal is the density n):

$$\begin{aligned}E_H &= \tfrac{1}{2}\sum_{a,b} w_{abab} = \tfrac{1}{2}\iint n(r)\,w(r,r')\,n(r')\,dr\,dr', \\ E_x &= -\tfrac{1}{2}\sum_{a,b} w_{abba} = -\tfrac{1}{2}\iint |\rho(r,r')|^2\,w(r,r')\,dr\,dr'.\end{aligned}$$

E_H is the **Hartree energy**: the classical energy of the cloud n with itself. E_x is the **exchange energy** (the Fock term); it has no classical analogue, it comes from the antisymmetry of Φ, and for a repulsive w it lowers the energy. Three remarks. (1) **No self-interaction.** In E_H the terms $a = b$ describe a particle repelling its own cloud, which is unphysical; in E_x the terms $a = b$ are the same numbers with a minus sign, so they cancel. (2) **Exchange acts only between equal labels.** If every orbital has a definite label, $\rho(x\sigma, x'\sigma') = 0$ for $\sigma \neq \sigma'$, so for a label-independent

w the exchange term couples only particles with the same label. (3) **Double counting.** Adding orbital energies counts every pair twice (Section 13.6).

The contact interaction. Let the particles interact only when they are at the same point, with the strength g_c and independently of their labels: $w(x\sigma, x'\sigma') = g_c\,\delta(x - x')$, where δ is Dirac's delta function ($\int f(x')\,\delta(x - x')\,dx' = f(x)$). For orbitals of definite label, with the label densities $n_\sigma(x) = \rho(x\sigma, x\sigma)$, line by line:

$$\begin{aligned} E_x &= -\tfrac{1}{2}\sum_{\sigma,\sigma'}\iint |\rho(x\sigma, x'\sigma')|^2\, g_c\,\delta(x - x')\,dx\,dx' \\ &= -\tfrac{g_c}{2}\sum_{\sigma,\sigma'}\int |\rho(x\sigma, x\sigma')|^2\,dx \\ &= -\tfrac{g_c}{2}\int \sum_{\sigma} n_\sigma(x)^2\,dx. \end{aligned}$$

The first line writes the space-and-label integral as a sum over both labels and integrals over both positions; the second does the x' integral with the delta function; the third keeps only $\sigma' = \sigma$ (the other terms vanish for orbitals of definite label) and uses $\rho(x\sigma, x\sigma) = n_\sigma(x)$. In the same way $E_H = \frac{g_c}{2}\int n^2\,dx$. Two facts follow. **First, the exchange energy of a contact interaction is exactly local**: an integral over one point of a function of the densities at that point, although the general exchange integral involves two points. **Second**, if all g labels are equally occupied, $n_\sigma = n/g$, then $\sum_\sigma n_\sigma^2 = g\,(n/g)^2 = n^2/g$, and

$$E_x = -\frac{1}{g}\,E_H \qquad \text{(contact interaction, } g \text{ equally occupied labels).}$$

For $g = 2$: $E_H + E_x = \frac{g_c}{2}\int [(n_\uparrow + n_\downarrow)^2 - n_\uparrow^2 - n_\downarrow^2]dx = g_c\int n_\uparrow n_\downarrow\,dx$. Two fermions with the same label never meet (Pauli), so only opposite labels feel a contact force, and exchange removes exactly the unphysical same-label part of E_H. For a single label ($g = 1$) the contact interaction cancels completely. PROVED here; Notebook 13b checks it for the uniform gas, for a non-uniform determinant and with label-mixing orbitals (In [6], In [12], In [13]).

13.6 The Hartree and Hartree-Fock equations

The **Hartree-Fock approximation** takes the best single determinant: it minimises $\langle\Phi|\hat{H}|\Phi\rangle$ over all choices of N orthonormal orbitals. By the variational principle (Section 13.2) its energy E_{HF} is an upper bound on the true ground-state energy E_0.

Minimising with side conditions: Lagrange multipliers. To minimise a function $f(y_1, \ldots, y_m)$ of m real variables under a side condition $c(y) = c_0$, look at a small step dy that keeps the condition: it changes c by $dc = \sum_i (\partial c/\partial y_i)\,dy_i = 0$. At a minimum the change $df = \sum_i (\partial f/\partial y_i)\,dy_i$ must vanish for every such step (otherwise the step or the opposite step would lower f). Write the gradient of f as $\partial f/\partial y_i = \lambda\,\partial c/\partial y_i + r_i$, where λ is chosen so that the rest r is perpendicular to the gradient of c, $\sum_i r_i\,\partial c/\partial y_i = 0$. Then the step $dy_i = \epsilon\,r_i$ keeps the condition, and

$$0 = df = \epsilon\sum_i (\lambda\,\partial c/\partial y_i + r_i)\,r_i = \epsilon\sum_i r_i^2,$$

where the first equality is the condition for a minimum, the second inserts the split gradient, and the third uses the perpendicularity of r. So every $r_i = 0$: **at a constrained minimum,** $\partial f/\partial y_i = \lambda\,\partial c/\partial y_i$ **for every** i. The number λ is a **Lagrange multiplier**; with several conditions one takes one multiplier for each. (That a first-order step can be completed to a step that keeps the condition exactly is the implicit function theorem of analysis, used here without proof.) Differentiating the minimum value $f^*(c_0)$ by the chain rule shows that $df^*/dc_0 = \lambda$: the multiplier is the rate at which the constrained minimum changes with the condition.

The Hartree-Fock equations, line by line. The unknowns are the N occupied orbitals $\phi_1, \dots, \phi_N$; in this paragraph every sum over b and c runs over them, and $\int dr$ includes the sum over the label. The energy to be minimised is (Section 13.5)

$$E = \sum_c h_{cc} + \tfrac{1}{2}\sum_{c,b} (w_{cbcb} - w_{cbbc}), \qquad h_{cc} = \int \phi_c^*(r)\,(h\phi_c)(r)\,dr,$$

with, by the definition of w_{pqrs} in Section 13.4,

$$w_{cbcb} = \iint \phi_c^*(r)\,\phi_b^*(r')\,w(r,r')\,\phi_c(r)\,\phi_b(r')\,dr\,dr',$$
$$w_{cbbc} = \iint \phi_c^*(r)\,\phi_b^*(r')\,w(r,r')\,\phi_b(r)\,\phi_c(r')\,dr\,dr'.$$

The side conditions and their multipliers. The conditions are $\langle\phi_c|\phi_b\rangle = \delta_{cb}$. Since $\langle\phi_b|\phi_c\rangle = \langle\phi_c|\phi_b\rangle^*$, the independent real conditions are $\langle\phi_c|\phi_c\rangle = 1$ and, for $c < b$, $\operatorname{Re} X = 0$ and $\operatorname{Im} X = 0$ with $X = \langle\phi_c|\phi_b\rangle$. Give each a real multiplier, λ_c and α, β. With $\operatorname{Re} X = (X + X^*)/2$ and $\operatorname{Im} X = (X - X^*)/(2i)$ one has $\alpha \operatorname{Re} X + \beta \operatorname{Im} X = \Lambda_{bc} X + \Lambda_{bc}^* X^*$ with $\Lambda_{bc} = (\alpha - i\beta)/2$; so, putting $\Lambda_{cc} = \lambda_c$ and $\Lambda_{cb} = \Lambda_{bc}^*$, the multipliers form a **Hermitian** matrix Λ, and the function to be made stationary is

$$\mathcal{L} = E - \sum_{c,b} \Lambda_{bc}\big(\langle\phi_c|\phi_b\rangle - \delta_{cb}\big).$$

$\mathcal{L}$ is real for any orbitals, orthonormal or not. In E, h_{cc} is real because h is Hermitian; $w_{cbcb} = \iint |\phi_c(r)|^2\,w(r,r')\,|\phi_b(r')|^2\,dr\,dr'$ is real because the interaction w is real; and w_{cbbc} equals its own complex conjugate after the integration variables are renamed ($r \leftrightarrow r'$), because w is real and symmetric, $w(r',r) = w(r,r')$, as every interaction of this chapter. The complex conjugate of the multiplier sum is $\sum_{c,b} \Lambda_{bc}^* \langle\phi_b|\phi_c\rangle = \sum_{c,b} \Lambda_{cb} \langle\phi_b|\phi_c\rangle$, the same sum with the names b and c exchanged. By the Lagrange rule above, at a constrained minimum $\partial\mathcal{L}/\partial y_i = 0$ for every real variable y_i (here: the real and imaginary parts of the orbital values; on a grid these are finitely many numbers), so the first-order change of $\mathcal{L}$ vanishes for **every** small change of the orbitals.

Changing one orbital. Change ϕ_a by $\varepsilon\zeta$, where ζ is any function and ε a small real number; then ϕ_a^* changes by $\varepsilon\zeta^*$. Each term of $\mathcal{L}$ is a sum of products in which ϕ_a and ϕ_a^* appear as factors, so to first order in ε the change of $\mathcal{L}$ is $\varepsilon(A + B)$ with $A = \int \zeta^*(r)\,G_a(r)\,dr$, where G_a collects what multiplies the change of ϕ_a^*, and $B = \int \zeta(r)\,K_a(r)\,dr$, where K_a collects what multiplies the change of ϕ_a. Since $\mathcal{L}$ is real for every ζ, $A + B$ is real; with $i\zeta$ in place of ζ, A becomes $-iA$ and B becomes iB, so $i(B - A)$ is real as well. Writing $A = a_1 + ia_2$ and $B = b_1 + ib_2$, the first statement says $a_2 + b_2 = 0$ and the second $b_1 - a_1 = 0$: $B = A^*$, and the change is $\varepsilon(A + A^*) = 2\varepsilon \operatorname{Re} \int \zeta^* G_a\,dr$. It

must vanish for every ζ; for $\zeta = G_a$ it is $2\varepsilon \int |G_a|^2\, dr$, which vanishes only if $G_a(r) = 0$ at every point. So **the minimum requires $G_a = 0$, and G_a is found by changing ϕ_a^* alone** while ϕ_a and all other orbitals are kept fixed. (This is the precise meaning of "varying ϕ^* as if it were independent of ϕ". Section 13.9 calls $G_a(r)$ the **functional derivative** of $\mathcal{L}$ with respect to $\phi_a^*(r)$; here it was found directly as the coefficient of the first-order change.)

The four parts of G_a. Replace ϕ_a^* by $\phi_a^* + \varepsilon\zeta^*$ and keep everything else. The one-body part:

$$\delta\Big(\sum_c h_{cc}\Big) = \varepsilon \int \zeta^*(r)\,(h\phi_a)(r)\,dr,$$

because only the term $c = a$ contains ϕ_a^*, as its first factor. The direct part:

$$\begin{aligned}\delta\Big(\tfrac{1}{2}\sum_{c,b} w_{cbcb}\Big) &= \tfrac{\varepsilon}{2}\sum_b \iint \zeta^*(r)\,\phi_b^*(r')\,w(r,r')\,\phi_a(r)\,\phi_b(r')\,dr\,dr' \\ &\quad + \tfrac{\varepsilon}{2}\sum_c \iint \phi_c^*(r)\,\zeta^*(r')\,w(r,r')\,\phi_c(r)\,\phi_a(r')\,dr\,dr' \\ &= \tfrac{\varepsilon}{2}\int \zeta^*(r)\,v_H(r)\,\phi_a(r)\,dr + \tfrac{\varepsilon}{2}\int \zeta^*(r)\,v_H(r)\,\phi_a(r)\,dr = \varepsilon\int \zeta^*(r)\,v_H(r)\,\phi_a(r)\,dr.\end{aligned}$$

The first line collects the terms with $c = a$, where ϕ_a^* is the first factor (variable r), and the second those with $b = a$, where it is the second factor (variable r'); the term $c = b = a$ contains ϕ_a^* twice and contributes to both lines, one change each, as the product rule says. In the third line, the first part uses $\sum_b \phi_b^*(r')\phi_b(r') = n(r')$ and the **Hartree potential** $v_H(r) = \int w(r,r')\,n(r')\,dr'$; the second part becomes the same after renaming the two integration variables ($r \leftrightarrow r'$) and using $w(r',r) = w(r,r')$. The two halves add up: the factor $\frac{1}{2}$ is cancelled. The exchange part, in the same way:

$$\begin{aligned}\delta\Big(-\tfrac{1}{2}\sum_{c,b} w_{cbbc}\Big) &= -\tfrac{\varepsilon}{2}\sum_b \iint \zeta^*(r)\,\phi_b^*(r')\,w(r,r')\,\phi_b(r)\,\phi_a(r')\,dr\,dr' \\ &\quad - \tfrac{\varepsilon}{2}\sum_c \iint \phi_c^*(r)\,\zeta^*(r')\,w(r,r')\,\phi_a(r)\,\phi_c(r')\,dr\,dr' \\ &= -\varepsilon\int \zeta^*(r)\Big[\int \rho(r,r')\,w(r,r')\,\phi_a(r')\,dr'\Big]dr.\end{aligned}$$

The first two lines are again the terms $c = a$ and $b = a$; in the first, $\sum_b \phi_b(r)\phi_b^*(r') = \rho(r,r')$ is the density matrix in space (Section 13.5); the second becomes the same after renaming $r \leftrightarrow r'$ and using the symmetry of w, and the two halves add up. The multiplier part:

$$\delta\Big(-\sum_{c,b}\Lambda_{bc}\,\langle\phi_c|\phi_b\rangle\Big) = -\varepsilon\sum_b \Lambda_{ba}\int \zeta^*(r)\,\phi_b(r)\,dr,$$

because $\langle\phi_c|\phi_b\rangle = \int \phi_c^*\phi_b\,dr$ contains ϕ_a^* only for $c = a$, and the numbers δ_{cb} do not change. Adding the four parts, $G_a(r) = (h\phi_a)(r) + v_H(r)\,\phi_a(r) - \int \rho(r,r')\,w(r,r')\,\phi_a(r')\,dr' - \sum_b \Lambda_{ba}\,\phi_b(r)$, and $G_a = 0$ is

$$\hat{F}\phi_a = \sum_b \Lambda_{ba}\,\phi_b, \qquad (\hat{F}\phi)(r) = h\phi(r) + v_H(r)\,\phi(r) - \int \rho(r,r')\,w(r,r')\,\phi(r')\,dr',$$

with the Hartree potential $v_H(r) = \int w(r,r')\,n(r')\,dr'$ found above. $\hat{F}$ is the **Fock operator**. It depends on the occupied orbitals only through ρ, which does not change when the occupied orbitals are mixed among themselves by a unitary matrix; such a mixing can make the Hermitian matrix Λ diagonal, which gives the **canonical Hartree-Fock equations** $\hat{F}\phi_a = \epsilon_a\phi_a$. They look like one-particle equations, but $\hat{F}$ contains the unknown orbitals: they are **nonlinear** and are solved by iteration, starting from a guess and repeating until nothing changes any more (**self-consistency**, Section 13.21). For the ground state one occupies the N orbitals with the lowest ϵ_a (the **aufbau** rule, German for "building up"). The older **Hartree approximation** keeps v_H and drops the exchange integral, and with it the cancellation of the self-interaction.

Double counting. Summing the orbital energies over the occupied orbitals,

$$\sum_{a\in O}\epsilon_a = \sum_a \langle\phi_a|\hat{F}\phi_a\rangle = \sum_a h_{aa} + \sum_{a,b}(w_{abab} - w_{abba}) = \sum_a h_{aa} + 2E_H + 2E_x,$$

where the first step uses $\hat{F}\phi_a = \epsilon_a\phi_a$ and normalisation, the second inserts the definition of $\hat{F}$, and the third the definitions of E_H and E_x of Section 13.5. Comparing with the energy of the determinant,

$$E_{HF} = \sum_{a\in O}\epsilon_a - E_H - E_x.$$

Koopmans' theorem. Removing the particle of orbital a while the other orbitals are kept unchanged lowers the energy by $h_{aa} + \sum_b(w_{abab} - w_{abba}) = \langle\phi_a|\hat{F}\phi_a\rangle = \epsilon_a$: the orbital energy is the energy of that particle in the unrelaxed determinant. The Kohn-Sham analogue, Janak's theorem, is proved in Section 13.27.

13.7 Two electrons on two sites: exact and Hartree-Fock

The smallest system in which the interaction matters: two sites L and R with one orbital each, the hopping t of Section 13.2 between them, a repulsion $U > 0$ when both electrons sit on the same site, and two electrons with opposite labels. In second quantisation, with the four orbitals L up, R up, L down, R down (numbers 0, 1, 2, 3) and site energies $-\Delta/2$ on L and $+\Delta/2$ on R,

$$\hat{H} = -t\sum_\sigma (a^\dagger_{L\sigma}a_{R\sigma} + a^\dagger_{R\sigma}a_{L\sigma}) + U(\hat{n}_{L\uparrow}\hat{n}_{L\downarrow} + \hat{n}_{R\uparrow}\hat{n}_{R\downarrow}) - \tfrac{\Delta}{2}\hat{n}_L + \tfrac{\Delta}{2}\hat{n}_R,$$

with $\hat{n}_L = \hat{n}_{L\uparrow} + \hat{n}_{L\downarrow}$. In this section $\Delta = 0$.

Exact solution. Two electrons with opposite labels can be both on L (state LL), both on R (RR), or one on each, in the symmetric combination S of "up on L, down on R" and "up on R, down on L"; the antisymmetric combination has energy 0 and plays no role. Hopping one electron turns LL into either of the two mixed states, which gives the matrix element $-\sqrt{2}\,t$ between LL and S (two

terms $-t$, and the normalisation $1/\sqrt{2}$ of S), and likewise between RR and S; the repulsion gives U on LL and RR and 0 on S. In the basis (LL, RR, S)

$$\hat{H} = \begin{pmatrix} U & 0 & -\sqrt{2}\,t \\ 0 & U & -\sqrt{2}\,t \\ -\sqrt{2}\,t & -\sqrt{2}\,t & 0 \end{pmatrix}.$$

The combination $(LL - RR)/\sqrt{2}$ is decoupled, with the energy U. The combination $D = (LL + RR)/\sqrt{2}$ couples to S with the element $\frac{1}{\sqrt{2}}(-\sqrt{2}\,t - \sqrt{2}\,t) = -2t$, which leaves the 2×2 matrix $\begin{pmatrix} U & -2t \\ -2t & 0 \end{pmatrix}$. Its eigenvalues solve $\epsilon(\epsilon - U) - 4t^2 = 0$, so

$$E_0 = \tfrac{1}{2}(U - \sqrt{U^2 + 16t^2}),$$

the lower root (it is negative, because $\sqrt{U^2 + 16t^2} > U$, so it is below the energies 0 and U of the other states). For $t = 1$, $U = 2$: $E_0 = \frac{1}{2}(2 - \sqrt{20}) = -1.236068$ (Notebook 13c, In [11]).

The energy of every determinant. A determinant for two electrons of opposite labels uses one up orbital and one down orbital. Take the up orbital with the values $(\cos\alpha, \sin\alpha)$ on (L, R) and the down orbital $(\cos\beta, \sin\beta)$, $0 \le \alpha, \beta \le \pi/2$ (real positive values give the lowest hopping energy). The hopping energy of an orbital (c_L, c_R) is $-2t\,c_L c_R$, which is $-2t\cos\alpha\sin\alpha = -t\sin 2\alpha$ for the up orbital. The repulsion is a contact interaction on each site, so by Section 13.5 its Hartree plus exchange energy is U times the product of the up and down densities on each site. Writing $c_\alpha = \cos 2\alpha$ and $s_\alpha = \sin 2\alpha$ (and the same for β), line by line:

$$\begin{aligned} E(\alpha,\beta) &= -t\,(s_\alpha + s_\beta) + U(\cos^2\alpha\,\cos^2\beta + \sin^2\alpha\,\sin^2\beta) \\ &= -t\,(s_\alpha + s_\beta) + \tfrac{U}{4}\big[(1 + c_\alpha)(1 + c_\beta) + (1 - c_\alpha)(1 - c_\beta)\big] \\ &= -t\,(s_\alpha + s_\beta) + \tfrac{U}{2}(1 + c_\alpha c_\beta). \end{aligned}$$

The first line adds the two hopping energies and $U(n_{L\uparrow}n_{L\downarrow} + n_{R\uparrow}n_{R\downarrow})$; the second uses $\cos^2\alpha = \frac{1}{2}(1 + \cos 2\alpha)$ and $\sin^2\alpha = \frac{1}{2}(1 - \cos 2\alpha)$; the third multiplies out (the terms $\pm c_\alpha$, $\pm c_\beta$ cancel). Notebook 13c (In [12]) checks this formula against the expectation value of the Hamiltonian matrix.

The best determinant. Restricted Hartree-Fock puts both electrons into the bonding orbital, $\alpha = \beta = \pi/4$: $s = 1$, $c = 0$, so $E_{RHF} = -2t + U/2$. Is there a better determinant? Since $(c_\alpha + c_\beta)^2 \ge 0$, we have $c_\alpha c_\beta \ge -\frac{1}{2}(c_\alpha^2 + c_\beta^2)$, and with $1 - c^2 = s^2$:

$$E \;\ge\; -t\,(s_\alpha + s_\beta) + \tfrac{U}{2}\Big(1 - \tfrac{c_\alpha^2 + c_\beta^2}{2}\Big) = \Big(-t\,s_\alpha + \tfrac{U}{4}s_\alpha^2\Big) + \Big(-t\,s_\beta + \tfrac{U}{4}s_\beta^2\Big).$$

Each bracket is a parabola in one number $s \in [0,1]$; its derivative $-t + \frac{U}{2}s$ vanishes at $s = 2t/U$. For $U \le 2t$ this lies at or beyond 1, so the smallest value on $[0,1]$ is at $s = 1$, $-t + U/4$, and the minimum over all determinants is $E_{HF} = -2t + U/2$, the restricted one. For $U > 2t$ the smallest value is at $s = 2t/U$: $-t \cdot \frac{2t}{U} + \frac{U}{4} \cdot \frac{4t^2}{U^2} = -\frac{t^2}{U}$, so $E_{HF} = -2t^2/U$. Equality holds in the inequality for $\beta = \pi/2 - \alpha$ ($c_\beta = -c_\alpha$, $s_\beta = s_\alpha$): the **unrestricted** determinant puts the up electron mostly on one site and the down electron mostly on the other. It breaks the left-right symmetry of each

label but keeps the total density $(1,1)$. Figure 13c.6 shows the energy landscape $E(\alpha,\beta)$ at $U=4t$, with the restricted point as a saddle.

Correlation. For $t=1$, $U=2$: $E_{HF}=-1$, and $E_c = E_0 - E_{HF} = -0.236068$ is the **correlation energy**, the energy that no single determinant can capture (it is never positive, by the variational principle). Its meaning is visible in the **double occupancy**, the probability that both electrons sit on the same site: $\frac{1}{2}$ in the restricted determinant for every U, but only 0.276393 in the exact ground state at $U=2t$ (Notebook 13c, In [11]). The exact electrons avoid each other and keep each label shared equally between the sites; a single determinant cannot do both. Yet the density is the same, $(1,1)$, in the exact state and in the Hartree-Fock state. A theory that works with the density alone must therefore contain somewhere the information that turns the density $(1,1)$ into -1.236068 rather than -1. In DFT that information is the exchange-correlation energy.

13.8 The density decides everything: the Hohenberg-Kohn theorem

We now leave wave functions behind. Fix the particle number N and the interaction $\hat{W}$, and regard the external potential v as the only thing that distinguishes one system from another.

Theorem (Hohenberg and Kohn, 1964). Let v and v' be two external potentials whose Hamiltonians $\hat{H}=\hat{T}+\hat{W}+\hat{V}$ and $\hat{H}'=\hat{T}+\hat{W}+\hat{V}'$ have non-degenerate ground states Ψ and Ψ' (non-degenerate: no other state has the same lowest energy). If $v-v'$ is not a constant, the ground-state densities n and n' differ. So the ground-state density determines the potential up to a constant, hence the Hamiltonian, hence every property of the system.

Proof, line by line. First, $\Psi \neq \Psi'$. If they were equal, subtracting the two Schroedinger equations $\hat{H}\Psi = E_0\Psi$ and $\hat{H}'\Psi = E_0'\Psi$ would give $(\hat{V}-\hat{V}')\Psi = (E_0-E_0')\Psi$, that is $\sum_i [v(x_i)-v'(x_i)] = E_0-E_0'$ wherever $\Psi \neq 0$, which forces $v-v'$ to be a constant (this step ASSUMES that Ψ does not vanish on a whole region, which holds for the potentials of physics). Now suppose, to reach a contradiction, that $n=n'$. Because Ψ is the only ground state of $\hat{H}$ and $\Psi' \neq \Psi$, the variational principle holds with a strict inequality:

$$E_0 < \langle \Psi' | \hat{H} \Psi' \rangle = \langle \Psi' | \hat{H}' \Psi' \rangle + \langle \Psi' | (\hat{V}-\hat{V}')\Psi' \rangle = E_0' + \int (v-v')\, n'\, dx.$$

The first step is the strict variational principle; the second writes $\hat{H} = \hat{H}' + (\hat{V}-\hat{V}')$; the third uses $\hat{H}'\Psi' = E_0'\Psi'$ and the rule that an external energy needs only the density (Section 13.3). Exchanging the roles of the two systems gives in the same way

$$E_0' < E_0 + \int (v'-v)\, n\, dx.$$

Adding the two inequalities and using $n=n'$, the two integrals cancel and we get $E_0 + E_0' < E_0 + E_0'$, which is false. Hence $n \neq n'$. $\square$

The universal functional (constrained search). For every density n that comes from some antisymmetric N-particle wave function define

$$F[n] = \min_{\Psi \to n} \langle \Psi | \hat{T} + \hat{W} | \Psi \rangle,$$

the smallest kinetic-plus-interaction energy among all wave functions with the density n (the arrow means "has the density"). F is **universal**: it does not depend on v. (We ASSUME that the minimum is attained.) **The variational principle for the density** then reads

$$E_0 = \min_n \Big(F[n] + \int v\, n\, dx \Big).$$

Proof: the variational principle over wave functions is $E_0 = \min_\Psi \langle \Psi | \hat{T} + \hat{W} + \hat{V} | \Psi \rangle$. Organise the minimisation in two steps, first over all Ψ with a given density n, then over n. In the first step $\langle \Psi | \hat{V} | \Psi \rangle = \int v\, n\, dx$ is the same for all these Ψ, so the inner minimum is $F[n] + \int v\, n\, dx$; the outer minimum over n is then the minimum over all Ψ, which is E_0. $\square$

These statements say that the energy is a functional of the density alone and that minimising it over densities gives the exact ground-state energy and density. They do not say what $F[n]$ is: finding good approximations to it is the work of DFT. On two sites the theorem can be seen at work: Notebook 13c (In [16], Figure 13c.7) shows that the exact density n_L on the left site rises strictly with the site-energy difference Δ, so each density belongs to exactly one Δ.

13.9 Functionals and functional derivatives

A **functional** assigns a number to a whole function: $F[n]$ takes the function $n(x)$ and returns one number. Examples: $\int n\, dx$, $\int n^2\, dx$, the Hartree energy $E_H[n]$.

Definition. Change n by a small amount $\epsilon\, \eta(x)$, where η is any fixed function and ϵ a small number. If

$$F[n + \epsilon\eta] = F[n] + \epsilon \int \frac{\delta F}{\delta n(x)}\, \eta(x)\, dx + O(\epsilon^2)$$

for every η, the function $\delta F / \delta n(x)$ is the **functional derivative** of F at n. On a grid with spacing h, F is an ordinary function of the numbers n_k, and $\delta F / \delta n(x_k) = (\partial F / \partial n_k)/h$: the functional derivative is the gradient, divided by the length that belongs to one point.

Examples, line by line. (i) For $A[n] = \int n^2\, dx$: $A[n + \epsilon\eta] = \int (n^2 + 2\epsilon\, n\eta + \epsilon^2 \eta^2)\, dx$ (multiply out the square), so the part of first order in ϵ is $\epsilon \int 2n\, \eta\, dx$ and $\delta A / \delta n = 2n$. (ii) For $G[n] = \int f(n(x))\, dx$ with a differentiable function f: Taylor's formula $f(n + \epsilon\eta) = f(n) + \epsilon f'(n)\, \eta + O(\epsilon^2)$ gives $\delta G / \delta n = f'(n)$. (iii) For $E_H = \frac{1}{2} \int\int n(x)\, w(x, x')\, n(x')\, dx\, dx'$, the first-order change is $\frac{\epsilon}{2} \int\int [\eta(x)\, w\, n(x') + n(x)\, w\, \eta(x')]$; renaming $x \leftrightarrow x'$ in the second term and using $w(x, x') = w(x', x)$ makes the two terms equal, so $\delta E_H / \delta n(x) = \int w(x, x')\, n(x')\, dx' = v_H(x)$, the Hartree potential. (iv) $\delta \int v\, n\, dx / \delta n = v$. Notebook 13a (In [15]) tests the definition directly on a grid: it changes the density by $\pm\epsilon\eta$ and compares the difference quotient with $\int (\delta F / \delta n)\, \eta\, dx$.

Minimising with a fixed particle number. To minimise $E[n]$ over densities with $\int n\, dx = N$, take a Lagrange multiplier μ (Section 13.6) and require $\delta E / \delta n(x) = \mu$ at every point where $n > 0$. The multiplier is the **chemical potential**: $\mu = dE_0 / dN$, the change of the lowest energy per added particle (where this derivative exists), by the meaning of a multiplier shown in Section 13.6.

13.10 The Kohn-Sham equations

The universal functional $F[n]$ contains the kinetic energy, the hardest part to write as an explicit formula of n (Notebook 13a shows the crude attempt, the Thomas-Fermi approximation). Kohn and Sham (1965) avoided the problem: compute the kinetic energy **exactly**, but for a fictitious system of non-interacting particles that has the same density.

The non-interacting reference system. For non-interacting particles the constrained search defines

$$T_s[n] = \min_{\Phi \to n} \langle \Phi | \hat{T} | \Phi \rangle,$$

the smallest kinetic energy of a non-interacting state with the density n; its minimiser is a single Slater determinant of orbitals ϕ_a with $n = \sum_a |\phi_a|^2$. The Kohn-Sham scheme ASSUMES that the density of interest is the ground-state density of some non-interacting system in some potential v_s (**non-interacting v-representability**). This is an assumption, not a theorem; on two sites it holds (Notebook 13c, In [16], finds the potential exactly).

Splitting the functional. Write

$$F[n] = T_s[n] + E_H[n] + E_{xc}[n],$$

which **defines** the **exchange-correlation energy** $E_{xc} = F - T_s - E_H$. It collects everything the easy pieces miss: the exchange energy of Section 13.5, the correlation energy of Section 13.7, and the difference between the true kinetic energy and T_s. Nothing has been approximated yet.

The equations. Minimise $E[n] = T_s[n] + \int v\, n\, dx + E_H[n] + E_{xc}[n]$ by varying the orbitals of the determinant, with Lagrange multipliers ϵ_a for their normalisation. Since $n = \sum_a |\phi_a|^2$, a change of ϕ_a^* at the point x changes n at x by $\phi_a(x)$ times that change; so every density functional $G[n]$ contributes $(\delta G/\delta n)\, \phi_a$ (chain rule), and the kinetic term contributes $-\frac{1}{2}\, \phi_a''$. Setting the derivative to zero gives the **Kohn-Sham equations**

$$\Big[-\frac{1}{2}\, \frac{d^2}{dx^2} + v_s(x) \Big] \phi_a = \epsilon_a\, \phi_a, \qquad n(x) = \sum_{a \in O} |\phi_a(x)|^2,$$

$$v_s = v + v_H + v_{xc}, \qquad v_{xc}(x) = \frac{\delta E_{xc}}{\delta n(x)},$$

with the N lowest orbitals occupied. The **Kohn-Sham potential** v_s is local: a multiplication by a function, simpler than the Fock operator. If E_{xc} were known exactly, these one-particle equations would give the exact ground-state density and energy of the interacting system.

Total energy, line by line. Multiply the equation of orbital a by ϕ_a^*, integrate and sum over the occupied orbitals:

$$\sum_{a \in O} \epsilon_a = \sum_a \int \phi_a^* \Big(-\frac{1}{2} \phi_a'' \Big) dx + \int v_s\, n\, dx = T_s + \int v_s\, n\, dx.$$

The first step uses normalisation, $\int |\phi_a|^2 = 1$, on the right and $\sum_a |\phi_a|^2 = n$ in the potential term; the second is the definition of T_s for the minimising determinant. Solving for T_s and inserting it into $E = T_s + \int v\, n + E_H + E_{xc}$, with $v_s = v + v_H + v_{xc}$ and $\int v_H\, n\, dx = 2E_H$:

$$E_0 = \sum_{a \in O} \epsilon_a - E_H[n] + E_{xc}[n] - \int v_{xc}\, n\, dx,$$

the Kohn-Sham analogue of the double-counting formula of Section 13.6.

Self-consistency. v_s depends on n, n on the orbitals, and the orbitals on v_s. The equations are solved by the loop: (1) guess a density; (2) build v_s; (3) solve the one-particle equations and occupy the N lowest orbitals; (4) form the new density; (5) if it equals the old one within a tolerance, stop; otherwise mix old and new (Section 13.21) and go back to (2).

What the orbitals mean. The Kohn-Sham orbitals and levels belong to the fictitious non-interacting system; only the density and the total energy are guaranteed to be physical. The levels are nevertheless useful: each is the derivative of the energy with respect to the occupation of its own orbital (Janak's theorem, Section 13.27).

The exact Kohn-Sham potential on two sites. Give the two sites the energies $\mp\Delta_s/2$ and put two non-interacting electrons into the lowest orbital of $\begin{pmatrix} -\Delta_s/2 & -t \\ -t & \Delta_s/2 \end{pmatrix}$. Section 13.21 derives that the lowest eigenvector of $\begin{pmatrix} a & -t \\ -t & b \end{pmatrix}$ has $|c_L|^2 = \frac{1}{2}(1 + (b-a)/\sqrt{(b-a)^2 + 4t^2})$; here $b - a = \Delta_s$, so with $x = n_L - 1 = 2|c_L|^2 - 1$, line by line:

$$\begin{aligned} x &= \frac{\Delta_s}{\sqrt{\Delta_s^2 + 4t^2}} \\ x^2\,(\Delta_s^2 + 4t^2) &= \Delta_s^2 \\ \Delta_s^2\,(1 - x^2) &= 4t^2 x^2 \\ \Delta_s &= \frac{2t\,x}{\sqrt{1 - x^2}}. \end{aligned}$$

The second line squares the first and multiplies by the denominator; the third collects the terms with Δ_s^2; the fourth takes the square root, with the sign of x (which is the sign of Δ_s by the first line). So for every exact density n_L between 0 and 2 there is exactly one Kohn-Sham site-energy difference Δ_s, and $\Delta_s - \Delta$ is the exact Hartree-exchange-correlation potential difference between the sites. Notebook 13c (In [16] to In [18], Figure 13c.8) computes it and splits it into a Hartree-exchange part and a correlation part.

13.11 Example: determinants, operators and the two-site model

Notebook 13c turns Sections 13.3 to 13.10 into numbers that can be checked: the three-point determinant of Section 13.3, the operator matrices and Wick's theorem of Section 13.4 (with the identity for $:S^2:$ that the Revision Kohn-Sham theory uses), the energy formula of Section 13.5, the exact and Hartree-Fock solutions of the two-site model of Section 13.7, and the Hohenberg-Kohn

map and the exact Kohn-Sham potential of Sections 13.8 and 13.10. Everything in it is exact finite-dimensional mathematics: it is PROVED by the derivations above and checked by the notebook to rounding. It ends with the line ALL 33 CHECKS PASSED (notebook 13c) and draws eight figures.

13.12 How to run Notebook 13c

Step 1. What this notebook does and what it needs.

Notebook 13c (Slater determinants, second quantization and the two-site model) is the file `Revision/textbook/notebooks/13c_two_site_model.ipynb` of the repository Dirac_claude. It evaluates Slater determinants of two fermions (on three points and in a box), builds the creation and annihilation operators of four orbitals as 16 x 16 matrices and checks their anticommutation relations, Wick's theorem for a determinant and for a thermal ensemble, the normal-ordered square of a one-body vertex and the energy formula of a determinant; it then solves the two-site model with two electrons exactly and in restricted and unrestricted Hartree-Fock (energies, correlation energy, double occupancy, the Hartree-Fock energy landscape), and shows the Hohenberg-Kohn map from the site-energy difference to the density and its exact Kohn-Sham inversion, with eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13c_two_site_model.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13c_two_site_model.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 13c_two_site_model.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/13c.captions.json`
- `Revision/textbook/figures/13c_1_slater_determinants.png`
- `Revision/textbook/figures/13c_2_operator_matrices.png`
- `Revision/textbook/figures/13c_3_density_matrices.png`
- `Revision/textbook/figures/13c_4_two_site_energies.png`
- `Revision/textbook/figures/13c_5_double_occupancy.png`
- `Revision/textbook/figures/13c_6_hf_landscape.png`
- `Revision/textbook/figures/13c_7_density_map.png`
- `Revision/textbook/figures/13c_8_ks_inversion.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13c_8_ks_inversion.png exists
ALL 33 CHECKS PASSED (notebook 13c)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/13c_two_site_model.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 13c_two_site_model.ipynb
python -m nbconvert --execute --inplace 13c_two_site_model.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

13.13 Notebook 13c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/13c_two_site_model.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook turns the first half of many-body quantum mechanics into numbers that
can be checked. It

- evaluates the Slater determinant of two fermions on three points (every value,
  the normalisation and the density) and draws a two-fermion determinant in a box;
- builds the creation and annihilation operators of four orbitals as $16 \times 16$
  matrices and checks the anticommutation relations;
- checks Wick's theorem (every expectation value of a determinant is made of its
  density matrix) for a determinant and for a thermal ensemble, and the formula for
  the normal-ordered square of a one-body vertex that the Revision Kohn-Sham theory
  uses;
- checks the energy formula of a determinant (direct minus exchange terms);
- solves the model of two electrons on two sites exactly, and in restricted and
  unrestricted Hartree-Fock, and compares energies, correlation energy and double
  occupancy for all strengths of the repulsion;
- shows the Hohenberg-Kohn theorem at work on two sites (the density determines the
  site-energy difference) and finds the exact Kohn-Sham potential by inverting the
  density;
- draws eight teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 13c (Slater determinants, second quantization and the two-site model) is the
file `Revision/textbook/notebooks/13c_two_site_model.ipynb` of the repository
Dirac_claude. It evaluates Slater determinants of two fermions (on three points and in a
box), builds the creation and annihilation operators of four orbitals as 16 x 16 matrices
and checks their anticommutation relations, Wick's theorem for a determinant and for a
thermal ensemble, the normal-ordered square of a one-body vertex and the energy formula
of a determinant; it then solves the two-site model with two electrons exactly and in
```

restricted and unrestricted Hartree-Fock (energies, correlation energy, double occupancy, the Hartree-Fock energy landscape), and shows the Hohenberg-Kohn map from the site-energy difference to the density and its exact Kohn-Sham inversion, with eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
```

```
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 13c_two_site_model.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 13c_two_site_model.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp]

Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 13c_two_site_model.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/13c.captions.json‘
- ‘Revision/textbook/figures/13c_1_slater_determinants.png‘
- ‘Revision/textbook/figures/13c_2_operator_matrices.png‘
- ‘Revision/textbook/figures/13c_3_density_matrices.png‘
- ‘Revision/textbook/figures/13c_4_two_site_energies.png‘
- ‘Revision/textbook/figures/13c_5_double_occupancy.png‘
- ‘Revision/textbook/figures/13c_6_hf_landscape.png‘
- ‘Revision/textbook/figures/13c_7_density_map.png‘
- ‘Revision/textbook/figures/13c_8_ks_inversion.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13c_8_ks_inversion.png exists
ALL 33 CHECKS PASSED (notebook 13c)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/13c_two_site_model.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use

  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 13c_two_site_model.ipynb
python -m nbconvert --execute --inplace 13c_two_site_model.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 13c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 13c (Slater determinants, second quantization and the two-site model) is the
# file Revision/textbook/notebooks/13c_two_site_model.ipynb of the repository
# Dirac_claude. It evaluates Slater determinants of two fermions (on three points and in
# a box), builds the creation and annihilation operators of four orbitals as 16 x 16
# matrices and checks their anticommutation relations, Wick's theorem for a determinant
# and for a thermal ensemble, the normal-ordered square of a one-body vertex and the
# energy formula of a determinant; it then solves the two-site model with two electrons
# exactly and in restricted and unrestricted Hartree-Fock (energies, correlation energy,
# double occupancy, the Hartree-Fock energy landscape), and shows the Hohenberg-Kohn map
# from the site-energy difference to the density and its exact Kohn-Sham inversion, with
# eight teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy and matplotlib; the other packages run Jupyter, the program that shows
# and runs notebooks. It does not need Rust.
```

```
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
```

```
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
```

```
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 13c_two_site_model.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 13c_two_site_model.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 13c_two_site_model.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/13c.captions.json
# - Revision/textbook/figures/13c_1_slater_determinants.png
# - Revision/textbook/figures/13c_2_operator_matrices.png
# - Revision/textbook/figures/13c_3_density_matrices.png
# - Revision/textbook/figures/13c_4_two_site_energies.png
# - Revision/textbook/figures/13c_5_double_occupancy.png
# - Revision/textbook/figures/13c_6_hf_landscape.png
# - Revision/textbook/figures/13c_7_density_map.png
# - Revision/textbook/figures/13c_8_ks_inversion.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
```

```
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 13c_8_ks_inversion.png exists
#     ALL 33 CHECKS PASSED (notebook 13c)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/13c_two_site_model.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 13c_two_site_model.ipynb
#     python -m nbconvert --execute --inplace 13c_two_site_model.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Orbital**: a one-particle state; here either a function on a few points or one
  of a finite list of basis states.
- **Slater determinant**: the antisymmetric state of $N$ fermions built from $N$
  orthonormal orbitals, $\Phi = \det[\phi_a(x_i)]/\sqrt{N!}$.
- **Antisymmetric**: changing sign when two particles are exchanged.
- **Occupation-number state** $|n_0 n_1 n_2 n_3\rangle$: the determinant that uses
  the orbitals $p$ with $n_p = 1$; there are $2^4 = 16$ of them for four orbitals.
- **Creation operator** $a_p^\dagger$, **annihilation operator** $a_p$: add or
  remove a fermion in orbital $p$, with the sign $(-1)^{\nu_p}$, where $\nu_p$ is the
  number of occupied orbitals before $p$; on the 16 occupation-number states they
  are $16 \times 16$ matrices.
- **Anticommutator** $\{A, B\} = AB + BA$.
- **Density matrix** $\rho_{qp} = \langle a_p^\dagger a_q\rangle$; for a determinant
  its eigenvalues are 0 and 1, for a thermal ensemble the occupation probabilities.
- **Wick's theorem**: $\langle a_p^\dagger a_q^\dagger a_s a_r\rangle =
  \rho_{rp}\rho_{sq} - \rho_{sp}\rho_{rq}$ for determinants and thermal ensembles of
  non-interacting fermions.
- **Two-site model**: two places L and R, one orbital each, two labels (up, down);
  hopping $t$ between the sites, repulsion $U$ when both electrons sit on the same
  site.
- **Hartree-Fock (HF)**: the best single determinant; **restricted** (both labels in
  the same orbital) or **unrestricted** (each label its own orbital).
- **Correlation energy**: the exact ground-state energy minus the Hartree-Fock
  energy (never positive).
- **Double occupancy**: the probability that both electrons sit on the same site.
- **Hohenberg-Kohn theorem**: the ground-state density determines the external
  potential (up to a constant); **Kohn-Sham inversion**: finding the potential of
  NON-interacting electrons that gives the same density.
```

Text cell:

```
## 4. The physical and mathematical situation

**Determinants.** For fermion 1 at the position $r_1$ and fermion 2 at $r_2$, in
the orthonormal orbitals $\phi_a$, $\phi_b$,
$\Phi(r_1, r_2) = [\phi_a(r_1)\phi_b(r_2) - \phi_b(r_1)\phi_a(r_2)]/\sqrt2$. It is
antisymmetric, vanishes when $r_1 = r_2$, is normalised, and its density is
$|\phi_a|^2 + |\phi_b|^2$. (The letters $r_1$, $r_2$ name the positions of the two
particles; they are not coordinates of spacetime.)

**Operators.** With four orbitals the occupation-number states are the 16 numbers
$0, \dots, 15$ written in binary: bit $p$ of the number is $n_p$. The matrix of
$a_p$ maps a state with $n_p = 1$ to the state with $n_p = 0$, times
$(-1)^{\nu_p}$; $a_p^\dagger$ is its transpose. The anticommutation relations
$\{a_p, a_q^\dagger\} = \delta_{pq}$, $\{a_p, a_q\} = 0$ follow.

**The two-site model.** The four orbitals are L up, R up, L down, R down (numbers 0,
1, 2, 3). With site energies $-\Delta/2$ (L) and $+\Delta/2$ (R),

$$\hat H = -t\sum_{\sigma}(a_{L\sigma}^\dagger a_{R\sigma} + a_{R\sigma}^\dagger
a_{L\sigma}) + U(\hat n_{L\uparrow}\hat n_{L\downarrow} + \hat n_{R\uparrow}\hat
n_{R\downarrow}) - \tfrac{\Delta}{2}\hat n_L + \tfrac{\Delta}{2}\hat n_R .$$

For $\Delta = 0$ the exact ground-state energy of two electrons with opposite labels
is $E_0 = \tfrac12(U - \sqrt{U^2 + 16t^2})$.

**Hartree-Fock.** A determinant with the up orbital $(\cos\alpha, \sin\alpha)$ and
the down orbital $(\cos\beta, \sin\beta)$ on (L, R) has the energy
$E(\alpha, \beta) = -t(\sin 2\alpha + \sin 2\beta) + \tfrac{U}{2}(1 + \cos 2\alpha
\cos 2\beta)$ (hopping energy of each orbital, plus $U$ times the double
occupancy). Restricted HF ($\alpha = \beta = \pi/4$) gives $-2t + U/2$; the
minimum over all $\alpha, \beta$ is $-2t + U/2$ for $U \le 2t$ and $-2t^2/U$ for
$U > 2t$ (unrestricted).

**Units.** All energies are in units of the hopping $t$ ($t = 1$).

**Status.** Exact finite-dimensional mathematics (PROVED: every statement follows
from the definitions; this notebook checks each one to rounding). No Revision number
is reproduced; the Wick identity for the normal-ordered square is the one of the
Revision check hf_wick_contraction.

## 7. Wick's theorem for a determinant and for a thermal ensemble

The next cell mixes the four orbitals with a random unitary $4 \times 4$ matrix $U$
```

(from the QR factorisation of a random complex matrix with a fixed seed), builds the new creation operators $a_p'^\dagger = \sum_k U_{kp}a_k^\dagger$, and the determinant $|\Phi\rangle = a_0'^\dagger a_1'^\dagger|0\rangle$ that occupies the new orbitals 0 and 1. Its density matrix is $\rho = \sum_{a = 0, 1} U_{:,a}U_{:,a}^\dagger$. It then checks $\langle a_p^\dagger a_q\rangle = \rho_{qp}$ and all 256 four-operator expectation values against Wick's formula.

In [6]:

```
rng = np.random.default_rng(12345)  # fixed seed: the same numbers every run
U_mix = np.linalg.qr(rng.normal(size=(M, M)) + 1j * rng.normal(size=(M, M)))[0]

## 10. Hartree-Fock: restricted and unrestricted

The next cell first checks the energy formula $E(\alpha, \beta)$ of section 4
against the Fock-space expectation value of the determinant
$(\cos\alpha\,a_{L\uparrow}^\dagger + \sin\alpha\,a_{R\uparrow}^\dagger)
(\cos\beta\,a_{L\downarrow}^\dagger + \sin\beta\,a_{R\downarrow}^\dagger)|0\rangle$
at a few angles, then minimises $E(\alpha, \beta)$ on a fine grid of angles for many
values of $U$. With $\beta = \pi/2 - \alpha$ and $s = \sin 2\alpha$ the energy is
$-2ts + \tfrac{U}{2}s^2$ (a parabola in $s \in [0, 1]$), whose minimum gives the
closed forms checked below.
```

## 11. The Hohenberg-Kohn map and the exact Kohn-Sham potential on two sites

Give the sites the energies $\mp\Delta/2$. For every $\Delta$ the exact ground state
has a density $n_L$ on the left site ($n_R = 2 - n_L$). The Hohenberg-Kohn theorem
says that different $\Delta$ give different $n_L$: the map $\Delta \to n_L$ is
one-to-one, so $n_L$ determines $\Delta$. The next cell computes $n_L(\Delta)$ for
$U = 0, 2, 4$ and checks that it strictly increases.

Kohn and Sham ask: which site-energy difference $\Delta_s$ makes NON-interacting
electrons have the same $n_L$? For two non-interacting electrons in the lowest
orbital of $\begin{pmatrix}-\Delta_s/2 & -t\\ -t & \Delta_s/2\end{pmatrix}$,
$n_L - 1 = \Delta_s/\sqrt{\Delta_s^2 + 4t^2}$, which inverts to
$\Delta_s = 2t\,(n_L - 1)/\sqrt{1 - (n_L - 1)^2}$. The difference $\Delta_s -
\Delta$ is the exact Hartree-exchange-correlation potential difference between the
sites.
```

In [16]:

```
deltas = np.linspace(-4.0, 4.0, 81)
density_maps = {U: np.array([two_site(1.0, U, d)[2] for d in deltas])
```

(Notebook 13c, figure 7.)

Out [17]:

```
Figure 13c.7 saved as Revision/textbook/figures/13c_7_density_map.png
```

Text cell:

```
For comparison the next cell also computes the potential of the mean-field
(Hartree plus exchange, restricted) approximation, in which each electron feels $U$
times the density of the other label on each site: its site-energy difference is
$\Delta - U(n_L - 1)$, with $n_L$ solved self-consistently (by bisection on the
equation $n_L - 1 = G(n_L - 1)$ with $G(x) = (\Delta - Ux)/\sqrt{(\Delta - Ux)^2 +
4t^2}$; the left side minus the right side increases with $x$, so the root is
unique).

Then it splits the screening $\Delta_s - \Delta$ of the exact Kohn-Sham potential,
AT THE EXACT DENSITY $n_L$, into two parts: the Hartree-exchange part
```

```
$\Delta_{Hx} = -U(n_L - 1)$ (the mean-field formula evaluated with the exact
density) and the rest, the correlation part
$\Delta_c = \Delta_s - \Delta - \Delta_{Hx}$. It checks, for $U = 2t$ and $4t$,
that $\Delta_c$ has the sign opposite to $\Delta$ for every $\Delta \ne 0$
(correlation screens further, in the same direction as Hartree and exchange), and
that the self-consistent mean field screens less than the exact Kohn-Sham
potential. Finally it draws the curves.
```

```
## 13. What this notebook showed

- A Slater determinant is antisymmetric, vanishes when two fermions meet, is
  normalised, and its density is the sum of its orbital densities.
- Creation and annihilation operators are ordinary matrices on the occupation-number
  states; their anticommutation relations hold exactly.
- Wick's theorem holds for determinants and for thermal ensembles of non-interacting
  fermions; in particular $\langle :S^2:\rangle = (\mathrm{Tr}\,V\rho)^2 -
  \mathrm{Tr}(V\rho V\rho)$, the Hartree-minus-exchange identity that the Revision
  Kohn-Sham theory uses with the vertex $C$.
- The energy of a determinant is the one-body energy plus the direct minus the
  exchange terms.
- For two electrons on two sites: $E_0 = \tfrac12(U - \sqrt{U^2 + 16t^2})$, the best
  determinant gives $-2t + U/2$ ($U \le 2t$) or $-2t^2/U$ ($U > 2t$, unrestricted,
  symmetry broken), and the correlation energy is what no determinant captures. At
  $U = 2t$: $E_0 = -1.236068\,t$, $E_{HF} = -t$, double occupancy 0.276393 versus
  1/2.
- The density determines the site-energy difference (Hohenberg-Kohn on two sites),
  and the exact Kohn-Sham potential exists and screens the true one. At the exact
  density its screening is the Hartree-exchange part $-U(n_L - 1)$ plus a
  correlation part of the same sign; the self-consistent mean field, which leaves
  out correlation, screens less.
```

13.14 Line-by-line walk-through of Notebook 13c

The notebook has nineteen code cells, In [1] to In [19]. This section explains every line of every one of them. Each code cell is preceded in the notebook by a text cell that says what it does; the numbers it prints are in Section 13.13.

In [1], the set-up cell. Apart from its comment lines and the notebook's name, it is the same in every notebook of the book; the notebooks 13b, 13d, 13e and 13a of this chapter have exactly this code with their own name, and their walk-throughs refer back to this paragraph. Its first part repeats the complete run instructions of Section 13.12 as **comment lines**: every line that starts with `#` is skipped by Python, and the lines are there so that the notebook file carries its own instructions. The code starts after the comment line THE SET-UP, which stands between two lines of `=` signs; the comment lines inside the code (which say, for example, why `REPO` is never printed) are left out below, because the text explains the same things.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux

import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell

NOTEBOOK_ID = "13c"  # this notebook: chapter 13, example c
```

`import` loads a **module** (a part of Python or of a package) so that the code can use it; the text after `#` on each line says what it is for. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system. `import matplotlib.pyplot as plt` loads the drawing functions under the short name `plt`. The last line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"13c"`; the figure files are named after it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

(The docstring, the text in triple quotes under the `def` line that says what the function does, is left out here.) `def` defines a **function**, a named piece of code that runs when it is called. `Path.cwd()` is the folder in which the notebook runs and `.resolve()` writes it as a complete address. The list `[here, *here.parents]` holds this folder, its parent folder, the parent of that, and so on up to the top of the disk; the `for` loop takes them one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that holds `Revision/textbook/requirements.txt` is the repository, and `return` hands it back; if none does, `raise` stops the notebook with an error message that says what to do.

```
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))

def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path

def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`REPO` is the repository folder; it is never printed, because it differs from computer to computer while the printed output of a notebook must be the same everywhere. `os.environ.get(name, default)` reads an **environment variable** (a named text that a program receives from the computer) or returns the default; when you run the notebook the variable is not set, so `OUTPUT_ROOT` is the repository, and the book's checking tool sets it to a scratch folder so that a check never changes the repository; the three comment lines before it (they start with `#` and are not executed) say the same. `repository_file` gives the full path of a repository file for reading (a Revision record); `output_file` gives the full path at which to write a file, after creating its folder (`mkdir` with `parents=True` makes missing parent folders too, and `exist_ok=True` makes it do nothing if the folder exists). `say` prints a text in lines of at most 89 characters (the width of a page of the book); continuation lines start with four blanks.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})

FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

`matplotlib.rcdefaults()` returns to the built-in plotting settings, so that the figures are the same on every computer, and `plt.rcParams.update` sets the figure size (7.0 by 4.2 inches), the letter size (10 points) and a faint grid. The braces `{...}` make a **dictionary**: pairs of a key and a value. A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/13c.captions.json"`. The last line, after two comment lines that describe it, writes an empty dictionary `{}` into the captions file; `newline="\n"` stores the same line end on every operating system.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`save_figure` (shown without its docstring; its three comment lines explain the options of `savefig`) numbers the figures 1, 2, 3, ... in the order in which they are saved (`setdefault` returns the number already stored for this name, or stores one more than the count so far), saves the figure as a PNG file with 150 dots per inch, cut to its content (`bbox_inches="tight"`) and without the program's name in the file (so that two runs write the same bytes), closes it, records its caption in the captions file (`json.dumps` turns the dictionary into JSON text), shows the saved picture below the cell, and prints where it was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")

def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`PASSED` is an empty **list** (an ordered collection, in square brackets). `check` is the function behind every check: if the statement `condition` is false (`False`), `raise AssertionError(...)` stops the

notebook with an error that names the check; if it is true, the name is appended to `PASSED` and the line PASS name is printed, followed by a line naming the Revision record and its check when the argument `record` is given. (Python's own `assert` statement is not used, because Python started with the option that optimises the code skips it.) `report` prints a key number as a line that starts with RESULT. `all_checks_passed` prints the last line of the notebook with the number of checks that passed. The last statement prints the one output line of In [1].

In [2], the determinant on three points.

```
import itertools  # loops over all combinations of indices

import numpy as np  # arrays, matrices and linear algebra

phi0 = np.array([1.0, 0.0, 0.0])
phi1 = np.array([0.0, 1.0, 1.0]) / np.sqrt(2.0)
# Phi[r1, r2] = (phi0(r1) phi1(r2) - phi1(r1) phi0(r2)) / sqrt(2)
Phi = (np.outer(phi0, phi1) - np.outer(phi1, phi0)) / np.sqrt(2.0)
```

`itertools` is a module of Python that makes all combinations of indices; `numpy`, called `np`, holds arrays and matrices. `np.array([...])` makes an **array** (a list of numbers that supports arithmetic), so `phi0` and `phi1` are the two orbitals of Section 13.3; dividing an array by $\sqrt{2}$ divides every entry. `np.outer(u, w)` is the 3×3 table with the entries $u_{r_1} w_{r_2}$; so `Phi` is the table of $\Phi(r_1, r_2)$, row r_1 and column r_2, exactly the formula in the comment line.

```
for r1 in range(3):
    say("Phi(%d, r2) for r2 = 0, 1, 2: %s" % (r1, np.array2string(
        Phi[r1], precision=6, floatmode="fixed", suppress_small=True)))
density_3 = 2.0 * np.sum(Phi ** 2, axis=1)  # n(r) = N sum_r2 |Phi(r, r2)|^2
```

The loop prints the three rows of the table. `"...  %d ...  %s" % (r1, text)` puts the number `r1` in place of `%d` and the text in place of `%s`; `np.array2string` writes a row as text with 6 digits after the point (`precision=6`, and `floatmode="fixed"` always prints all six), and `suppress_small=True` prints numbers that are very close to zero as zeros instead of in powers-of-ten notation. `Phi ** 2` squares every entry, and `np.sum(..., axis=1)` adds along each row (over r_2); times $N = 2$ this is the density $n(r)$ of Section 13.3.

```
check(abs(Phi[0, 1] - 0.5) < 1e-15 and abs(Phi[1, 2]) < 1e-15,
      "Phi(0,1) = 1/2 and Phi(1,2) = 0")
check(np.allclose(Phi, -Phi.T, atol=1e-15) and np.allclose(np.diag(Phi), 0.0),
      "Phi is antisymmetric and zero on the diagonal (Pauli)")
check(abs(np.sum(Phi ** 2) - 1.0) < 1e-15
      and np.allclose(density_3, [1.0, 0.5, 0.5], atol=1e-15)
      and np.allclose(density_3, phi0 ** 2 + phi1 ** 2, atol=1e-15),
      "Phi is normalised and its density is (1, 1/2, 1/2) = phi0^2 + phi1^2")
```

Three checks. `Phi[0, 1]` is the entry in row 0 and column 1, and `1e-15` means 10^{-15}: the first check compares the two values worked out by hand in Section 13.3. `Phi.T` is the transposed table (rows and columns exchanged), so `Phi` equal to `-Phi.T` is antisymmetry; `np.allclose(a, b, atol=...)` is true when every entry of `a` differs from the entry of `b` by less than the given amount; `np.diag(`

`Phi)` is the diagonal. The third check adds all nine squares (the normalisation) and compares the density with $(1, \frac{1}{2}, \frac{1}{2})$ and with $\phi_0^2 + \phi_1^2$.

In [3], two determinants as pictures.

```
x_box = np.linspace(0.0, 1.0, 101)
chi1 = np.sqrt(2.0) * np.sin(np.pi * x_box)
chi2 = np.sqrt(2.0) * np.sin(2.0 * np.pi * x_box)
Phi_box = (np.outer(chi1, chi2) - np.outer(chi2, chi1)) / np.sqrt(2.0)
```

`np.linspace(0.0, 1.0, 101)` is 101 equally spaced positions from 0 to 1. `chi1` and `chi2` are the two lowest orbitals of a particle in the box $0 < x < 1$ ($\sqrt{2}\sin(\pi x)$ and $\sqrt{2}\sin(2\pi x)$, normalised and orthogonal), and `Phi_box` their determinant on the 101×101 grid of positions of the two fermions.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
image = left.imshow(Phi, origin="lower", cmap="coolwarm", vmin=-0.6, vmax=0.6)
for r1, r2 in itertools.product(range(3), repeat=2):  # write every value in
    left.text(r2, r1, f"{Phi[r1, r2]:+.2f}", ha="center", va="center")
```

`plt.subplots(1, 2, ...)` makes a figure with two pairs of axes side by side, named `left` and `right`. `imshow` draws a table as a **heat map**: each entry is a coloured square, here red for positive and blue for negative (`cmap="coolwarm"`, the colour scale from -0.6 to 0.6), with row 0 at the bottom (`origin="lower"`). `itertools.product(range(3), repeat=2)` gives all nine pairs (r_1, r_2), and `left.text` writes each value, with its sign and two decimals (`:+.2f`), in the middle of its square.

```
left.set_xticks([0, 1, 2])
left.set_yticks([0, 1, 2])
left.set_xlabel("position $r_2$ of fermion 2")
left.set_ylabel("position $r_1$ of fermion 1")
left.set_title("three points")
```

`set_xticks` and `set_yticks` put tick marks only at the three points 0, 1, 2; `set_xlabel`, `set_ylabel` and `set_title` write the axis labels and the title of the left panel. Text between two dollar signs is drawn by matplotlib as a formula, so the text r_2 between dollar signs in the label appears as r_2.

```
image = right.imshow(Phi_box, origin="lower", extent=(0, 1, 0, 1),
                     cmap="coolwarm")
right.plot([0, 1], [0, 1], "k--", lw=0.8)
right.set_xlabel("position $r_2$ of fermion 2")
right.set_ylabel("position $r_1$ of fermion 1")
right.set_title("two fermions in a box")
fig.colorbar(image, ax=right, shrink=0.85)
save_figure(fig, "slater_determinants",
```

The right panel draws the 101×101 table `Phi_box` as a heat map; `extent=(0, 1, 0, 1)` stretches it over the square $0 \le r_1, r_2 \le 1$, so that the axes show positions instead of table indices, and without `vmin` and `vmax` the colour scale runs over the table's own range. The line with `right.pl`

`ot([0, 1], [0, 1], ...)` draws the straight line from $(0, 0)$ to $(1, 1)$, the diagonal $r_1 = r_2$: in its style string the letter k means black and the two hyphens that follow it a dashed line, and `lw=0.8` is the line width in points. `fig.colorbar(image, ax=right, shrink=0.85)` adds the colour scale of the right panel, 85 per cent as tall as the panel. The call `save_figure(fig, "slater_determi nants",` saves Figure 13c.1; the lines that follow it in the cell are the text of the caption, which the book prints under the figure. The last lines check that the box determinant is antisymmetric as well:

```
check(np.allclose(Phi_box, -Phi_box.T, atol=1e-14), "the box determinant is "
      "antisymmetric")
```

(Python joins two strings written next to each other into one.)

What Figure 13c.1 shows. On the left, the nine values of the three-point determinant: $+0.50$ in row $r_1 = 0$ at $r_2 = 1, 2$, -0.50 in column $r_2 = 0$ at $r_1 = 1, 2$, and 0 everywhere else, in particular on the diagonal. Reflecting the table in its diagonal changes every sign: that is antisymmetry. On the right, the box determinant is positive (red, up to about $+2.2$) where fermion 1 is to the right of fermion 2 ($r_1 > r_2$, above the dashed diagonal), negative (blue) in the mirror-image region, and exactly zero along the diagonal: two fermions with the same label are never found at the same place.

In [4], creation and annihilation operators as matrices.

```
M = 4  # orbitals
DIM = 2 ** M  # occupation-number states

def bit(state, p):
    """The occupation n_p (0 or 1) of orbital p in the state number state."""
    return (state >> p) & 1
```

In Python `**` means "to the power", so `DIM` is $2^4 = 16$. The function `bit` returns the occupation n_p of orbital p in the state with the number `state`: the operator written with two greater-than signs shifts the binary digits of the number `state` by `p` places to the right, and `& 1` keeps the last binary digit. For example, for the state 5 (binary 0101) and $p = 2$ the shift gives binary 01, whose last digit is 1: orbital 2 is occupied.

```
a = []  # a[p] is the 16 x 16 matrix of the annihilation operator a_p
for p in range(M):
    matrix = np.zeros((DIM, DIM))
    for state in range(DIM):
        if bit(state, p) == 1:
            nu = sum(bit(state, q) for q in range(p))  # occupied before p
            matrix[state ^ (1 << p), state] = (-1) ** nu
    a.append(matrix)
a_dag = [matrix.T for matrix in a]  # creation operators: the transposes
```

For each orbital p the cell starts from a 16×16 matrix of zeros and goes through the 16 states. Where orbital p is occupied, it counts the occupied orbitals before p (ν_p of Section 13.4). The row index is `state ^ (...)`, where the parentheses hold the number 1 shifted p binary places to the left (the operator written with two less-than signs), which is 2^p; the operator `^` is the "exclusive or"

of the binary digits, so the row index is `state` with bit p switched off: the number of the state after the removal. The entry in that row and in the column of the old state is $(-1)^{\nu_p}$: the matrix of a_p maps the old state to the new one with the sign of Section 13.4. `a.append` adds the matrix to the list. The creation operators are the transposes (`.T`), because the matrices are real.

```
identity = np.eye(DIM)
worst = 0.0
for p, q in itertools.product(range(M), repeat=2):
    worst = max(worst,
                np.abs(a[p] @ a_dag[q] + a_dag[q] @ a[p] - (p == q) * identity).max(),
                np.abs(a[p] @ a[q] + a[q] @ a[p]).max(),
                np.abs(a_dag[p] @ a_dag[q] + a_dag[q] @ a_dag[p]).max())
check(worst == 0.0, "{a_p, a_q^dag} = delta_pq and {a_p, a_q} = 0 exactly")
```

`np.eye(DIM)` is the 16×16 unit matrix and `@` is the matrix product. For all 16 pairs (p, q) the loop computes the three anticommutators of Section 13.4 minus their required values (`(p == q)` is 1 when $p = q$ and 0 otherwise) and keeps the largest entry of any of them in `worst`. The check requires it to be exactly 0: the matrices hold only 0 and ± 1, so there is no rounding at all.

```
number = sum(a_dag[p] @ a[p] for p in range(M))  # the particle-number operator
check(np.array_equal(np.diag(number), [bin(s).count("1") for s in range(DIM)]),
      "the number operator counts the occupied orbitals of every state")
```

`number` is $\hat{N} = \sum_p a_p^\dagger a_p$. Its diagonal must hold, for every state s, the number of ones in the binary form of s (`bin(s)` writes s in binary, `.count("1")` counts its ones).

In [5], the operator matrices as heat maps.

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.2))
for ax, p in zip(axes, (1, 3)):
    image = ax.imshow(a_dag[p], cmap="coolwarm", vmin=-1, vmax=1)
    ax.set_title(f"creation operator $a_{p}^\\dagger$")
    ax.set_xlabel("state number before (column)")
    ax.set_ylabel("state number after (row)")
fig.colorbar(image, ax=axes, shrink=0.8)
save_figure(fig, "operator_matrices",
```

`plt.subplots(1, 2, ...)` makes two panels, kept together in `axes`. `zip(axes, (1, 3))` pairs the first panel with orbital 1 and the second with orbital 3, and the loop draws `a_dag[p]`, the 16×16 matrix of $a_p^\dagger$, as a heat map with the colour scale fixed from -1 (blue) through 0 (grey) to $+1$ (red). Without `origin="lower"`, `imshow` puts row 0 at the top, as a matrix is printed. In the title the f-string puts the value of `p` in place of `{p}`, and the doubled backslash is one backslash in the text, so matplotlib draws $a_1^\dagger$ and $a_3^\dagger$. The axis labels say that a column is the state before the operator acts and a row the state after it. `fig.colorbar(image, ax=axes, shrink=0.8)` draws one colour scale for both panels. `save_figure` saves Figure 13c.2 (the lines after it are the caption).

What Figure 13c.2 shows. Every column holds at most one coloured square, so each operator sends a state to exactly one other state or to zero. In the left panel ($a_1^\dagger$) the squares sit in the columns 0, 1, 4, 5, 8, 9, 12, 13, the states in which orbital 1 is empty, and in the rows two higher

(bit 1 switched on, which adds $2^1 = 2$ to the state number); the columns 0, 4, 8, 12 (orbital 0 empty) carry $+1$ and the columns 1, 5, 9, 13 (orbital 0 occupied) carry -1, the sign $(-1)^{\nu_1}$. In the right panel ($a_3^\dagger$) the columns 0 to 7 go to the rows 8 to 15, with the sign $+1$ or -1 according to whether an even or an odd number of the orbitals 0, 1, 2 is occupied. The columns 8 to 15 are empty: there orbital 3 is already occupied, and the Pauli principle gives zero.

In [6], Wick's theorem for a determinant.

```
rng = np.random.default_rng(12345)  # fixed seed: the same numbers every run
U_mix = np.linalg.qr(rng.normal(size=(M, M)) + 1j * rng.normal(size=(M, M)))[0]
a_dag_new = [sum(U_mix[k, p] * a_dag[k] for k in range(M)) for p in range(M)]
```

`np.random.default_rng(12345)` makes a generator of random numbers with a fixed starting value (**seed**), so every run draws the same numbers. `rng.normal(size=(M, M))` is a 4×4 table of random numbers, `1j` is the imaginary unit i, so the argument is a random complex matrix; `np.linalg.qr(...)[0]` is the first factor of its **QR factorisation**, a unitary matrix U (its columns are orthonormal). `a_dag_new[p]` is $a_p'^\dagger = \sum_k U_{kp}\, a_k^\dagger$, the creation operator of the new orbital p (Section 13.4).

```
vacuum = np.zeros(DIM)
vacuum[0] = 1.0  # state number 0: no fermion at all
Phi_state = a_dag_new[0] @ a_dag_new[1] @ vacuum
rho_det = sum(np.outer(U_mix[:, k], U_mix[:, k].conj()) for k in (0, 1))
```

The vacuum is the column with 1 in place 0 (the state number 0 has no fermion). `Phi_state` is $a_0'^\dagger a_1'^\dagger |0\rangle$, the determinant of the new orbitals 0 and 1, and `rho_det` is its density matrix $\rho = \sum_{a=0,1} U_{:,a} U_{:,a}^\dagger$ (`U_mix[:, k]` is column k, `.conj()` the complex conjugate, and `np.outer` the column times the conjugated row).

```
def wick_errors(expect, rho):
    """Largest errors of <a+_p a_q> = rho_qp and of the four-operator formula."""
    two = max(abs(expect(a_dag[p] @ a[q]) - rho[q, p])
              for p, q in itertools.product(range(M), repeat=2))
    four = max(abs(expect(a_dag[p] @ a_dag[q] @ a[s] @ a[r])
                   - (rho[r, p] * rho[s, q] - rho[s, p] * rho[r, q]))
               for p, q, r, s in itertools.product(range(M), repeat=4))
    return two, four

def in_determinant(operator):
    """<Phi| operator |Phi> for the determinant Phi_state."""
    return np.vdot(Phi_state, operator @ Phi_state)
```

`wick_errors` takes a rule `expect` that turns an operator into its expectation value, and a density matrix `rho`; it returns the largest error of the two-operator formula over the 16 pairs (p, q) and of the four-operator formula over the $4^4 = 256$ combinations (p, q, r, s), both written exactly as in Section 13.4. `in_determinant` is such a rule for the determinant: `np.vdot(u, w)` is $\sum_k u_k^* w_k$, the inner product.

```
check(abs(np.vdot(Phi_state, Phi_state) - 1.0) < 1e-14, "the determinant is "
      "normalised")
two, four = wick_errors(in_determinant, rho_det)  # the largest errors (rounding)
check(two < 1e-14 and four < 1e-14,
      "Wick's theorem holds for the determinant (all 16 + 256 values, to 1e-14)")
check(np.allclose(rho_det @ rho_det, rho_det, atol=1e-14)
      and abs(np.trace(rho_det).real - 2.0) < 1e-14,
      "the density matrix of a determinant obeys rho^2 = rho, Tr rho = 2")
```

Three checks: the determinant has norm 1; all 272 Wick values agree to 10^{-14} (only rounding remains); and $\rho^2 = \rho$ with trace 2 (`np.trace` is the sum of the diagonal, `.real` its real part).

In [7], Wick's theorem for a thermal ensemble.

```
energies = np.array([-1.0, -0.3, 0.4, 1.2])  # orbital energies (units of t)
MU, TEMPERATURE = 0.0, 0.5
H0 = sum(energies[p] * a_dag_new[p] @ a_dag_new[p].conj().T for p in range(M))
K = H0 - MU * number  # H0 - mu N, a Hermitian 16 x 16 matrix
```

Four orbital energies, the chemical potential $\mu = 0$ and the temperature $T = 0.5$. `a_dag_new[p].conj().T` is the conjugate transpose of $a'^{\dagger}_p$, which is a'_p; so `H0` is $\hat{H}_0 = \sum_p \epsilon_p \, a'^{\dagger}_p a'_p$, non-interacting fermions in the mixed orbitals, and `K` is $\hat{H}_0 - \mu\hat{N}$.

```
k_values, k_vectors = np.linalg.eigh(K)
weights = np.exp(-(k_values - k_values.min()) / TEMPERATURE)  # shifted: no overflow
gibbs = (k_vectors * (weights / weights.sum())) @ k_vectors.conj().T
f = 1.0 / (np.exp((energies - MU) / TEMPERATURE) + 1.0)  # Fermi-Dirac
rho_thermal = sum(f[p] * np.outer(U_mix[:, p], U_mix[:, p].conj()) for p in range(M))
```

`np.linalg.eigh` returns the eigenvalues and the orthonormal eigenvectors (as columns) of the Hermitian matrix `K`. The Gibbs weights $e^{-k_i/T}$ are computed after subtracting the smallest eigenvalue, which multiplies every weight by the same number and so cancels after dividing by their sum, but keeps the exponentials from becoming too large for the computer. `k_vectors * (weights / weights.sum())` multiplies each eigenvector column by its normalised weight, and the product with the conjugate transpose gives the density operator $e^{-(\hat{H}_0 - \mu\hat{N})/T}/Z = \sum_i p_i \, u_i u_i^{\dagger}$ (a function of a matrix defined through its eigenvalues, Section 13.26). `f` are the Fermi-Dirac occupations $1/(e^{(\epsilon_p - \mu)/T} + 1)$ and `rho_thermal` the density matrix $\sum_p f_p \, U_{:,p} U^{\dagger}_{:,p}$.

```
two, four = wick_errors(lambda operator: np.trace(gibbs @ operator), rho_thermal)
check(two < 1e-13 and four < 1e-13,
      "Wick's theorem holds for the thermal ensemble of non-interacting fermions "
      "(to 1e-13)")
```

`lambda operator: ...` is a function without a name; here it is the rule "expectation value in the ensemble", $\mathrm{Tr}(\hat{\rho}\, A)$. The check requires all 272 Wick values to agree to 10^{-13}.

In [8], the normal-ordered square of a vertex.

```
raw = rng.normal(size=(M, M)) + 1j * rng.normal(size=(M, M))
V = (raw + raw.conj().T) / 2.0  # a random Hermitian vertex
S_square = sum(V[p, q] * V[r, s] * a_dag[p] @ a_dag[r] @ a[s] @ a[q]
               for p, q, r, s in itertools.product(range(M), repeat=4))
```

A random complex matrix plus its conjugate transpose, halved, is Hermitian: that is the vertex V. `S_square` is the 16×16 matrix of $:S^2: = \sum V_{pq} V_{rs}\, a_p^\dagger a_r^\dagger a_s a_q$, summed over all 256 index combinations.

```
for label, expect, rho in (("determinant", in_determinant, rho_det),
                           ("thermal", lambda o: np.trace(gibbs @ o), rho_thermal)):
    lhs = expect(S_square)
    rhs = np.trace(V @ rho) ** 2 - np.trace(V @ rho @ V @ rho)
    say(f"{label}: <:S^2:> = {lhs.real:.10f}, Hartree - exchange = {rhs.real:.10f}")
    check(abs(lhs - rhs) < 1e-12,
          f"<:S^2:> = (Tr V rho)^2 - Tr(V rho V rho) in the {label} state",
          record="Revision/kohn_sham/reports/ks-theory-python.json, check "
                 "hf_wick_contraction")
```

For the determinant and for the thermal ensemble, `lhs` is the expectation value of $:S^2:$ computed from the matrices and `rhs` the formula $(\mathrm{Tr}\, V\rho)^2 - \mathrm{Tr}(V\rho V\rho)$ of Section 13.4. The printed values agree to all ten printed decimals, -1.0717850309 and -1.9027816067, and each check names the Revision check hf_wick_contraction whose identity it reproduces.

In [9], the density matrices.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
image = left.imshow(np.abs(rho_det), cmap="viridis", vmin=0.0)
left.set_title("$|\\rho_{qp}|$ of the determinant")
left.set_xticks(range(M))
left.set_yticks(range(M))
left.set_xlabel("$p$")
left.set_ylabel("$q$")
fig.colorbar(image, ax=left, shrink=0.85)
```

The left panel is a heat map of `np.abs(rho_det)`, the sizes $|\rho_{qp}|$ of the 16 complex entries of the determinant's density matrix, on the colour scale viridis (dark blue for small, yellow for large values) starting at 0 (`vmin=0.0`); the column is p and the row is q. The tick marks are put at the four orbital numbers (`range(M)` is $0, 1, 2, 3$), and the colour scale is added beside the panel.

```
occupations_det = np.sort(np.linalg.eigvalsh(rho_det))[::-1]
occupations_th = np.sort(np.linalg.eigvalsh(rho_thermal))[::-1]
positions = np.arange(M)
right.bar(positions - 0.2, occupations_det, width=0.4, label="determinant")
right.bar(positions + 0.2, occupations_th, width=0.4, label="thermal, $T = 0.5$")
right.set_xticks(positions)
right.set_xlabel("eigenvalue number")
right.set_ylabel("occupation (eigenvalue of $\\rho$)")
right.legend()
save_figure(fig, "density_matrices",
```

`np.linalg.eigvalsh` computes the eigenvalues of a Hermitian matrix (real numbers, in increasing order); `np.sort(...)[::-1]` sorts them and reverses the order (the slice `[::-1]` steps backwards through an array), so the largest comes first. `positions` is $0, 1, 2, 3$. `right.bar(x, heights, width=0.4, ...)` draws a bar of the given height at each position x; shifting the two sets of bars by ∓ 0.2 puts them side by side. The `label` of each set appears in the legend (`right.legend()`). `save_figure` saves Figure 13c.3, and the check

```
check(np.allclose(occupations_det, [1, 1, 0, 0], atol=1e-14)
      and np.allclose(occupations_th, np.sort(f)[::-1], atol=1e-14),
      "the occupations are 1, 1, 0, 0 and the Fermi-Dirac numbers")
```

requires the eigenvalues to be exactly $1, 1, 0, 0$ for the determinant and the Fermi-Dirac numbers f_p for the ensemble.

What Figure 13c.3 shows. On the left, all 16 entries of the determinant's density matrix are nonzero (between about 0.08 and 0.85): in the randomly mixed basis the two occupied orbitals are spread over all four basis orbitals, so ρ does not look like a projector. Its eigenvalues on the right are nevertheless exactly 1, 1, 0, 0 (blue bars): the determinant occupies two orbitals completely and the others not at all. The thermal ensemble (orange bars) has the four Fermi-Dirac numbers, about 0.88, 0.65, 0.31 and 0.08 for the levels -1, -0.3, 0.4, 1.2 at $T = 0.5$: every level is partly occupied, the lower ones more.

In [10], the energy of a determinant.

```
chi = np.linalg.qr(rng.normal(size=(6, M)))[0]  # four orthonormal orbitals on 6 points
W_raw = rng.normal(size=(6, 6))
W_pair = (W_raw + W_raw.T) / 2.0  # a symmetric interaction W(x, x')
h_raw = rng.normal(size=(M, M))
h_one = (h_raw + h_raw.T) / 2.0  # a symmetric one-body matrix
# w[p,q,r,s] = sum_{x,x'} chi_p(x) chi_q(x') W(x,x') chi_r(x) chi_s(x')
w = np.einsum("xp,yq,xy,xr,ys->pqrs", chi, chi, W_pair, chi, chi)
```

The QR factorisation of a random 6×4 table gives four orthonormal real orbitals on six points. A random table plus its transpose, halved, is symmetric: a pair interaction $W(x, x')$ with the symmetry of a real interaction, and a one-body matrix h_{pq}. `np.einsum` computes a sum of products written as a pattern: here, for every (p, q, r, s), the sum over the points x and y of $\chi_p(x)\chi_q(y)W(x, y)\chi_r(x)\chi_s(y)$, which is the two-body integral w_{pqrs} of Section 13.4 on the six points.

```
H_many = sum(h_one[p, q] * a_dag[p] @ a[q] for p, q in itertools.product(range(M),
                                                                        repeat=2))
H_many = H_many + 0.5 * sum(w[p, q, r, s] * a_dag[p] @ a_dag[q] @ a[s] @ a[r]
                            for p, q, r, s in itertools.product(range(M), repeat=4))
basis_det = a_dag[0] @ a_dag[1] @ vacuum  # occupies the basis orbitals 0 and 1
direct = basis_det @ H_many @ basis_det
formula = sum(h_one[k, k] for k in (0, 1)) + 0.5 * sum(
    w[k, l, k, l] - w[k, l, l, k] for k in (0, 1) for l in (0, 1))
```

`H_many` is the 16×16 matrix of $\hat{H} = \sum h_{pq} a_p^\dagger a_q + \frac{1}{2} \sum w_{pqrs} a_p^\dagger a_q^\dagger a_s a_r$, built in two statements (the one-body part, then the two-body part added to it). `basis_det` is the column of the state

$a_0^\dagger a_1^\dagger|0\rangle$; since all matrices here are real, `basis_det @ H_many @ basis_det` (row times matrix times column) is the expectation value `direct` of $\hat{H}$ in this determinant of the basis orbitals 0 and 1. `formula` is $\sum_a h_{aa} + \frac{1}{2}\sum_{a,b}(w_{abab} - w_{abba})$ of Section 13.5, with the sums over $a, b \in \{0, 1\}$ written as generator expressions.

```
say(f"<Phi|H|Phi> = {direct:.10f};  sum h_aa + (1/2) sum (w_abab - w_abba) = "
    f"{formula:.10f}")
check(abs(direct - formula) < 1e-12,
      "the energy of a determinant is one-body + direct - exchange")
```

The cell prints both numbers with ten decimals, -1.5322375649 and -1.5322375649, and checks that they agree to 10^{-12}.

In [11], the exact two-site model.

```
n_op = [a_dag[p] @ a[p] for p in range(M)]  # occupation operators
DOUBLE = n_op[0] @ n_op[2] + n_op[1] @ n_op[3]  # both electrons on one site
# The states with exactly one up (orbital 0 or 1) and one down (2 or 3) electron:
SECTOR = [s for s in range(DIM) if bit(s, 0) + bit(s, 1) == 1
          and bit(s, 2) + bit(s, 3) == 1]
```

With the orbitals numbered L up (0), R up (1), L down (2), R down (3), `DOUBLE` is $\hat{n}_{L\uparrow}\hat{n}_{L\downarrow} + \hat{n}_{R\uparrow}\hat{n}_{R\downarrow}$. The **list comprehension** `[s for s in range(DIM) if ...]` collects the state numbers with exactly one up and one down electron; it prints as $[5, 6, 9, 10]$: in binary 0101 (L up and L down: both on L), 0110 (R up, L down), 1001 (L up, R down) and 1010 (both on R).

```
def two_site(t, U, delta=0.0):
    """Ground-state energy, double occupancy and n_L of the two-site model."""
    H = -t * (a_dag[0] @ a[1] + a_dag[1] @ a[0] + a_dag[2] @ a[3] + a_dag[3] @ a[2])
    H = H + U * DOUBLE - 0.5 * delta * (n_op[0] + n_op[2]) \
        + 0.5 * delta * (n_op[1] + n_op[3])
    block = H[np.ix_(SECTOR, SECTOR)]  # the 4 x 4 block of the sector
    values, vectors = np.linalg.eigh(block)
    ground = vectors[:, 0]
    occupancy = ground @ DOUBLE[np.ix_(SECTOR, SECTOR)] @ ground
    n_left = ground @ (n_op[0] + n_op[2])[np.ix_(SECTOR, SECTOR)] @ ground
    return values[0], occupancy, n_left
```

The function builds the Hamiltonian of Section 13.7 term by term (the backslash at the end of a line continues the statement on the next line): hopping of each label between L and R, the repulsion U on doubly occupied sites, and the site energies $-\Delta/2$ on L and $+\Delta/2$ on R. `np.ix_(SECTOR, SECTOR)` selects the rows and columns of the four states of the sector, so `block` is a 4×4 matrix. Its lowest eigenvalue `values[0]` is the ground-state energy and the first column of `vectors` the ground state; the expectation values of `DOUBLE` and of $\hat{n}_L$ in it are the double occupancy and the density on L. The function returns the three numbers.

```
say(f"the sector holds the states {SECTOR}")
for U in (2.0, 4.0):
```

```
    E0, occupancy, n_left = two_site(1.0, U)
    report(f"U = {U:.0f}: exact E_0", f"{E0:.6f}")
    report(f"U = {U:.0f}: exact double occupancy", f"{occupancy:.6f}")
    check(abs(E0 - 0.5 * (U - np.sqrt(U ** 2 + 16.0))) < 1e-12
          and abs(n_left - 1.0) < 1e-12,
          f"U = {U:.0f}: E_0 = (U - sqrt(U^2 + 16 t^2))/2 and n_L = 1")
```

For $t = 1$ and $U = 2$ and 4 the cell prints the exact energy and double occupancy and checks the closed form $E_0 = \frac{1}{2}(U - \sqrt{U^2 + 16t^2})$ of Section 13.7 and the symmetric density $n_L = 1$. The results are $E_0 = -1.236068$ with double occupancy 0.276393 at $U = 2$, and -0.828427 with 0.146447 at $U = 4$.

In [12], Hartree-Fock, restricted and unrestricted.

```
def hf_energy(alpha, beta, U, t=1.0):
    """E(alpha, beta) of the determinant with up (cos a, sin a), down (cos b, sin b)."""
    return (-t * (np.sin(2 * alpha) + np.sin(2 * beta))
            + 0.5 * U * (1.0 + np.cos(2 * alpha) * np.cos(2 * beta)))
```

The formula $E(\alpha, \beta) = -t(\sin 2\alpha + \sin 2\beta) + \frac{U}{2}(1 + \cos 2\alpha \cos 2\beta)$ of Section 13.7.

```
H_test = -(a_dag[0] @ a[1] + a_dag[1] @ a[0] + a_dag[2] @ a[3] + a_dag[3] @ a[2]) \
    + 3.0 * DOUBLE  # t = 1, U = 3
worst = 0.0
for alpha, beta in ((0.3, 1.1), (0.7, 0.2), (np.pi / 4, np.pi / 4)):
    det = (np.cos(alpha) * a_dag[0] + np.sin(alpha) * a_dag[1]) @ (
        np.cos(beta) * a_dag[2] + np.sin(beta) * a_dag[3]) @ vacuum
    worst = max(worst, abs(det @ H_test @ det - hf_energy(alpha, beta, 3.0)))
check(worst < 1e-12, "the Hartree-Fock energy formula equals <Phi|H|Phi>")
```

For $t = 1$, $U = 3$ and three pairs of angles the cell builds the determinant $(\cos\alpha\, a^\dagger_{L\uparrow} + \sin\alpha\, a^\dagger_{R\uparrow})(\cos\beta\, a^\dagger_{L\downarrow} + \sin\beta\, a^\dagger_{R\downarrow})|0\rangle$ from the operator matrices and checks that its energy equals the formula.

```
angles = np.linspace(0.0, np.pi / 2, 1001)
A, B = np.meshgrid(angles, angles, indexing="ij")
U_values = np.linspace(0.0, 8.0, 33)
E_exact = np.array([two_site(1.0, U)[0] for U in U_values])
D_exact = np.array([two_site(1.0, U)[1] for U in U_values])
E_rhf = -2.0 + 0.5 * U_values  # restricted: alpha = beta = pi/4
E_uhf = np.array([hf_energy(A, B, U).min() for U in U_values])  # grid minimum
```

1001 angles from 0 to $\pi/2$; `np.meshgrid` makes the two 1001×1001 tables `A` and `B` of all pairs (α, β). For 33 repulsions $U = 0, 0.25, \ldots, 8$ the cell computes the exact energy and double occupancy, the restricted energy $-2t + U/2$, and the smallest value of $E(\alpha, \beta)$ over the whole grid of angles (`.min()`).

```
U_safe = np.where(U_values > 2.0, U_values, 1.0)  # avoids dividing by U = 0
E_closed = np.where(U_values <= 2.0, -2.0 + 0.5 * U_values, -2.0 / U_safe)
```

```
check(np.max(np.abs(E_uhf - E_closed)) < 1e-5,
      "the minimum over all determinants is -2t + U/2 (U <= 2t) and -2t^2/U")
check(np.all(E_exact <= E_uhf + 1e-12) and np.all(E_uhf <= E_rhf + 1e-12),
      "variational order: exact <= unrestricted HF <= restricted HF")
```

`np.where(condition, a, b)` takes `a` where the condition holds and `b` elsewhere. `E_closed` is the closed form of Section 13.7, $-2t + U/2$ for $U \le 2t$ and $-2t^2/U$ beyond; `U_safe` replaces the values $U \le 2$ (where the second formula is not used) by 1, so that no division by zero occurs. The first check compares the grid minimum with the closed form (the grid of angles allows an error below 10^{-5}); the second checks the variational order exact $\le$ unrestricted $\le$ restricted at every U (`np.all` is true when every entry is true).

```
E_c = E_exact - E_closed  # correlation energy
report("U = 2: correlation energy E_0 - E_HF", f"{E_c[8]:.6f}")
fine_U = np.linspace(2.0, 8.0, 60001)  # closed forms on a fine grid of U > 2t
fine_c = 0.5 * (fine_U - np.sqrt(fine_U ** 2 + 16.0)) + 2.0 / fine_U
report("U of the largest correlation energy (in size)",
       f"{fine_U[np.argmin(fine_c)]:.3f}")
```

The correlation energy at the entry 8, $U = 8 \cdot 0.25 = 2$, is -0.236068. On a fine grid of U beyond $2t$ the cell evaluates $E_0 - E_{HF} = \frac{1}{2}(U - \sqrt{U^2 + 16}) + 2/U$, and `np.argmin` finds the place of its most negative value: the correlation energy is largest in size at $U = 3.335\,t$.

In [13], the energies.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(U_values, E_rhf, "--", label="restricted HF $-2t + U/2$")
left.plot(U_values, E_closed, "-.", label="unrestricted HF")
left.plot(U_values, E_exact, color="black", lw=2.0, label="exact $E_0$")
left.axvline(2.0, color="gray", lw=0.8)
left.set_xlabel("repulsion $U/t$")
left.set_ylabel("ground-state energy ($t$)")
left.legend(fontsize=8)
```

`left.plot(x, y, style, label=...)` draws the points (x, y) joined by a line: the restricted energy $-2t + U/2$ dashed (the style string of two hyphens), the best determinant's energy in closed form dash-dotted (`"-."`), and the exact energy as a thick black line (`lw=2.0`). `axvline(2.0, ...)` draws a thin grey vertical line at $U = 2t$, where restricted and unrestricted Hartree-Fock separate. The axis labels give the units: U is divided by t, and the energies are in units of t. `legend(fontsize=8)` lists the three labels in small letters.

```
right.plot(U_values, E_c, "o-", ms=3, color="black")
right.set_xlabel("repulsion $U/t$")
right.set_ylabel("correlation energy $E_0 - E_{HF}$ ($t$)")
fig.subplots_adjust(wspace=0.32)  # room between the panels for the axis label
fig.suptitle("Two electrons on two sites: exact versus Hartree-Fock")
save_figure(fig, "two_site_energies",
```

The right panel draws the correlation energy at the 33 values of U as dots joined by a line (`"o-"`; `ms=3` is the size of the dots in points). `fig.subplots_adjust(wspace=0.32)` widens the gap between

the panels so that the label of the right vertical axis does not touch the left panel, and `fig.suptitle` writes one title above both panels. `save_figure` saves Figure 13c.4. Its caption is not a fixed text: one of its lines is an f-string with the expression `fine_U[np.argmin(fine_c)]:.1f` in braces, which writes the computed place of the largest correlation energy, rounded to one decimal (3.3), into the caption.

What Figure 13c.4 shows. On the left, all three energies start at $-2t$ for $U = 0$ (both electrons in the bonding orbital, no repulsion). The restricted energy rises along the straight line $-2t + U/2$; the best determinant follows it up to $U = 2t$ and then bends away towards 0 as $-2t^2/U$; the exact energy lies below both at every $U > 0$ and also approaches 0 for large U. On the right, the correlation energy is zero at $U = 0$, falls to its most negative value, about $-0.337\,t$, near $U = 3.3t$, and then rises slowly towards zero: at large U the electrons sit on different sites anyway, and the unrestricted determinant describes that well.

In [14], the double occupancy.

```
D_uhf = np.where(U_values <= 2.0, 0.5, 2.0 / U_safe ** 2)
```

The unrestricted double occupancy is $\frac{1}{2}(1 + c_\alpha c_\beta)$ with $c_\beta = -c_\alpha$ and $s_\alpha = 2t/U$, that is $\frac{1}{2}(1 - c_\alpha^2) = \frac{1}{2}s_\alpha^2 = 2t^2/U^2$ for $U > 2t$, and $\frac{1}{2}$ below (the formula $E(\alpha, \beta)$ of Section 13.7 is U times this number plus the hopping energy).

```
fig, ax = plt.subplots()
ax.plot(U_values, 0.5 * np.ones_like(U_values), "--", label="restricted HF: 1/2")
ax.plot(U_values, D_uhf, "-.", label="unrestricted HF: $2t^2/U^2$ for $U > 2t$")
ax.plot(U_values, D_exact, color="black", lw=2.0, label="exact")
ax.set_xlabel("repulsion $U/t$")
ax.set_ylabel("double occupancy")
ax.set_title("How often both electrons sit on the same site")
ax.legend()
save_figure(fig, "double_occupancy",
```

One panel with three curves against U/t: the restricted value $\frac{1}{2}$ (`np.ones_like(U_values)` is an array of ones as long as `U_values`, so `0.5 * np.ones_like(U_values)` is the constant $\frac{1}{2}$ at every U) dashed, the unrestricted value dash-dotted, and the exact double occupancy as a thick black line; then the axis labels, the title, the legend, and `save_figure` for Figure 13c.5. The cell then checks

```
check(abs(D_exact[8] - 0.276393) < 1e-6 and abs(D_exact[16] - 0.146447) < 1e-6,
      "exact double occupancy 0.276393 at U = 2t and 0.146447 at U = 4t")
check(np.all(np.diff(D_exact) < 0), "the exact double occupancy falls as U grows")
```

the two worked values (entries 8 and 16 are $U = 2$ and $U = 4$) and that the exact double occupancy falls at every step of U (`np.diff` gives the differences of neighbouring entries).

What Figure 13c.5 shows. All three curves start at $\frac{1}{2}$ for $U = 0$. The exact double occupancy falls smoothly from the start: the exact electrons begin to avoid each other at any repulsion, while each label stays shared equally between the sites. The restricted determinant stays at $\frac{1}{2}$ for every U. The unrestricted one stays at $\frac{1}{2}$ up to $U = 2t$, then drops steeply as $2t^2/U^2$, crosses the exact curve near $U = 3.3t$ and lies below it beyond: by breaking the left-right symmetry it overshoots.

In [15], the Hartree-Fock energy landscape.

```
E_map = hf_energy(A, B, 4.0)
index = np.unravel_index(np.argmin(E_map), E_map.shape)
```

`E_map` is $E(\alpha, \beta)$ at $U = 4t$ on the whole grid of angles; `np.argmin` finds the position of its smallest value in the table read as one long list, and `np.unravel_index` turns that position back into a row and a column, the pair `index`.

```
fig, ax = plt.subplots(figsize=(6.0, 5.0))
contours = ax.contourf(A, B, E_map, levels=30, cmap="viridis")
fig.colorbar(contours, ax=ax, label="$E(\\alpha, \\beta)$ ($t$)")
ax.plot([np.pi / 4], [np.pi / 4], "wx", ms=10, label="restricted (saddle)")
ax.plot([angles[index[0]], angles[index[1]]], [angles[index[1]], angles[index[0]]],
        "r*", ms=12, label="unrestricted minima")
```

`ax.contourf(A, B, E_map, levels=30, ...)` colours the plane of the angles (α, β) in 30 bands of equal energy (a **contour map**: each band joins the points with nearly the same value), and the colour scale is labelled with the energy and its unit t. The style `"wx"` draws a white cross (w white, x cross) at the restricted point $(\pi/4, \pi/4)$, and `"r*"` red stars at the grid minimum $(\alpha, \beta) =$ `(angles[index[0]], angles[index[1]])` and at its mirror image with the two angles exchanged (the two lists hold the horizontal and the vertical coordinates of both points); `ms` sets the marker sizes.

```
ax.set_xlabel("$\\alpha$ (up orbital)")
ax.set_ylabel("$\\beta$ (down orbital)")
ax.set_title("Hartree-Fock energy landscape at $U = 4t$")
ax.legend(loc="upper right", fontsize=8)
save_figure(fig, "hf_landscape",
```

Axis labels, title, the legend in the upper right corner, and `save_figure` for Figure 13c.6. Then

```
check(abs(E_map.min() + 0.5) < 1e-5 and abs(hf_energy(np.pi / 4, np.pi / 4, 4.0)
                                            - 0.0) < 1e-12,
      "at U = 4t: minimum -0.5 t, restricted value 0")
```

requires the smallest value on the grid to be $-2t^2/U = -0.5$ (to 10^{-5}, the accuracy of the grid of angles) and the restricted value to be $-2 + 4/2 = 0$.

What Figure 13c.6 shows. The landscape is lowest (dark) in two basins, around $(\alpha, \beta) \approx (0.26, 1.31)$ and its mirror image $(1.31, 0.26)$, where the energy is $-0.5t$; there $\beta \approx \pi/2 - \alpha$: the up electron sits mostly on one site and the down electron mostly on the other. The restricted point at $(0.785, 0.785)$ lies between the basins on a pass: moving along the line $\beta = \pi/2 - \alpha$ lowers the energy, moving along $\beta = \alpha$ raises it, so it is a saddle with the energy 0. The highest energies (yellow) are in the corners $(0, 0)$ and $(\pi/2, \pi/2)$, where both electrons sit on the same site.

In [16], the Hohenberg-Kohn map and the exact Kohn-Sham potential.

```
deltas = np.linspace(-4.0, 4.0, 81)
density_maps = {U: np.array([two_site(1.0, U, d)[2] for d in deltas])
```

```
                for U in (0.0, 2.0, 4.0)}
for U, n_left in density_maps.items():
    check(np.all(np.diff(n_left) > 0),
          f"U = {U:.0f}: n_L increases strictly with Delta (one-to-one map)")
```

81 site-energy differences Δ from -4 to 4 in steps of 0.1. The **dictionary comprehension** `{U: ... for U in ...}` stores, for $U = 0, 2, 4$, the exact density n_L of every Δ (the third number returned by `two_site`). The three checks require each map to rise strictly: different Δ give different densities (Section 13.8).

```
def kohn_sham_delta(n_left, t=1.0):
    """The site-energy difference of non-interacting electrons with density n_L."""
    excess = n_left - 1.0
    return 2.0 * t * excess / np.sqrt(1.0 - excess ** 2)

def free_density(delta_s, t=1.0):
    """n_L of two non-interacting electrons with the site energies -+delta_s/2."""
    values, vectors = np.linalg.eigh(np.array([[-delta_s / 2, -t],
                                               [-t, delta_s / 2]]))
    return 2.0 * vectors[0, 0] ** 2
```

`kohn_sham_delta` is the inversion formula $\Delta_s = 2t\,x/\sqrt{1-x^2}$, $x = n_L - 1$, of Section 13.10. `free_density` solves the non-interacting problem directly: the lowest eigenvector of the 2×2 matrix, whose L component squared, times two electrons, is n_L.

```
delta_s = {U: kohn_sham_delta(n) for U, n in density_maps.items()}
rebuilt = max(abs(free_density(ds) - n) for U in density_maps
              for ds, n in zip(delta_s[U], density_maps[U]))
check(rebuilt < 1e-12, "the Kohn-Sham site energies reproduce the exact densities")
check(np.max(np.abs(delta_s[0.0] - deltas)) < 1e-12,
      "without interaction the Kohn-Sham potential is the true one")
```

For every U and every exact density the cell computes Δ_s, puts it back into the non-interacting problem and checks that the exact density comes out (to 10^{-12}); for $U = 0$ the Kohn-Sham potential must be the true one, $\Delta_s = \Delta$.

In [17], the density map.

```
fig, ax = plt.subplots()
for U, style in ((0.0, ":"), (2.0, "--"), (4.0, "-")):
    ax.plot(deltas, density_maps[U], style, label=f"$U = {U:.0f}t$")
ax.axhline(1.0, color="gray", lw=0.8)
ax.set_xlabel("site-energy difference $\\Delta$ ($t$)")
ax.set_ylabel("exact density on the left site $n_L$")
ax.set_title("Hohenberg-Kohn on two sites: the potential determines the density")
ax.legend()
save_figure(fig, "density_map",
```

The loop draws $n_L(\Delta)$ for $U = 0$ (dotted, `":"`), $2t$ (dashed) and $4t$ (solid); the label writes U without decimals (`:.0f`). `axhline(1.0, ...)` draws a thin grey horizontal line at $n_L = 1$, the density of the symmetric sites. Then the axis labels with the unit t of Δ, the title, the legend, and `save_figure` for Figure 13c.7.

What Figure 13c.7 shows. All three curves pass through $n_L = 1$ at $\Delta = 0$ and rise strictly from left to right, so no horizontal line meets a curve twice: each density belongs to exactly one Δ, which is the Hohenberg-Kohn statement on two sites. Without repulsion the curve is steep, from about 0.11 to 1.89 over $-4 \le \Delta \le 4$ (it is $1 + \Delta/\sqrt{\Delta^2 + 4}$); with $U = 4t$ it only reaches about 0.55 and 1.45, because the repulsion opposes putting both electrons on the lower site.

In [18], the mean field and the parts of the exact Kohn-Sham potential.

```
def mean_field_excess(delta, U, t=1.0):
    """The self-consistent x = n_L - 1 of restricted Hartree + exchange."""
    low, high = -1.0, 1.0
    for _ in range(80):  # bisection on x - G(x), which increases with x
        middle = 0.5 * (low + high)
        shifted = delta - U * middle
        if middle - shifted / np.sqrt(shifted ** 2 + 4 * t * t) > 0:
            high = middle
        else:
            low = middle
    return 0.5 * (low + high)
```

In the restricted mean field each electron feels U times the density of the other label on each site, which shifts the site-energy difference to $\Delta - U(n_L - 1)$; the self-consistent excess $x = n_L - 1$ solves $x = G(x) = (\Delta - Ux)/\sqrt{(\Delta - Ux)^2 + 4t^2}$ (derived in Section 13.21). The function finds the root by **bisection**: it starts with the interval $[-1, 1]$, which contains the root, and 80 times halves it, keeping the half in which $x - G(x)$ changes sign (this difference increases with x, because G decreases, so there is exactly one root). `for _ in range(80)` repeats 80 times; the name `_` says that the counter is not used.

```
mf_delta_s = np.array([d - 4.0 * mean_field_excess(d, 4.0) for d in deltas])
nonzero = np.abs(deltas) > 1e-9  # every Delta except 0
hx_part = {U: -U * (density_maps[U] - 1.0) for U in (2.0, 4.0)}  # at the exact n_L
c_part = {U: delta_s[U] - deltas - hx_part[U] for U in (2.0, 4.0)}  # the rest
report("U = 4t, Delta = 2t: Hartree-exchange part", f"{hx_part[4.0][60]:.6f}")
report("U = 4t, Delta = 2t: correlation part", f"{c_part[4.0][60]:.6f}")
```

`mf_delta_s` is the site-energy difference of the self-consistent mean field at $U = 4t$. `nonzero` is a list of true and false values that is false only at $\Delta = 0$. For $U = 2t$ and $4t$, the Hartree-exchange part of the screening, evaluated at the EXACT density, is $\Delta_{Hx} = -U(n_L - 1)$, and the correlation part is the rest, $\Delta_c = \Delta_s - \Delta - \Delta_{Hx}$. At $U = 4t$, $\Delta = 2t$ (entry 60) they are -0.588239 and -1.114408: correlation does more than half of the screening there.

```
for U in (2.0, 4.0):
    check(np.all(c_part[U][nonzero] * deltas[nonzero] < 0.0),
          f"U = {U:.0f}t: the correlation part has the sign opposite to Delta")
check(np.all(np.abs(mf_delta_s[nonzero]) > np.abs(delta_s[4.0][nonzero])),
      "U = 4t: the mean field screens less than the exact Kohn-Sham potential")
```

`c_part[U][nonzero]` keeps the entries with $\Delta \neq 0$. The checks require the correlation part to have the sign opposite to Δ (it screens further, like the Hartree-exchange part) and the mean-field potential to be larger in size than the exact Kohn-Sham one (it screens less).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.4))
left.plot(deltas, deltas, ":", color="gray", label="$\\Delta_s = \\Delta$ ($U = 0$)")
left.plot(deltas, delta_s[2.0], "--", label="exact Kohn-Sham, $U = 2t$")
left.plot(deltas, delta_s[4.0], color="black", lw=2.0,
          label="exact Kohn-Sham, $U = 4t$")
left.plot(deltas, mf_delta_s, "-.", label="mean field, $U = 4t$")
left.set_xlabel("true site-energy difference $\\Delta$ ($t$)")
left.set_ylabel("Kohn-Sham site-energy difference $\\Delta_s$ ($t$)")
left.set_title("The exact Kohn-Sham potential")
left.legend(fontsize=8)
```

The left panel draws, against the true Δ: the grey dotted line $\Delta_s = \Delta$ (the answer without interaction), the exact Kohn-Sham Δ_s for $U = 2t$ (dashed) and $U = 4t$ (thick black), and the self-consistent mean field for $U = 4t$ (dash-dotted), with axis labels, title and legend.

```
right.plot(deltas, delta_s[4.0] - deltas, color="black", lw=2.0,
           label="total screening $\\Delta_s - \\Delta$")
right.plot(deltas, hx_part[4.0], "--", label="Hartree-exchange $\\Delta_{Hx}$")
right.plot(deltas, c_part[4.0], color="tab:red", label="correlation $\\Delta_c$")
right.axhline(0.0, color="gray", lw=0.8)
right.set_xlabel("true site-energy difference $\\Delta$ ($t$)")
right.set_ylabel("parts of $\\Delta_s - \\Delta$ ($t$)")
right.set_title("Its parts at the exact density, $U = 4t$")
right.legend(fontsize=8)
save_figure(fig, "ks_inversion",
```

The right panel draws, for $U = 4t$, the total screening $\Delta_s - \Delta$ (thick black), the Hartree-exchange part (dashed) and the correlation part (red; `"tab:red"` is the red of matplotlib's standard colours), with a grey zero line, axis labels, title and legend. `save_figure` saves Figure 13c.8, and the last check of the cell

```
check(np.all(np.abs(delta_s[4.0][nonzero]) < np.abs(deltas[nonzero])),
      "the repulsion screens the potential: |Delta_s| < |Delta|")
```

requires $|\Delta_s| < |\Delta|$ for every $\Delta \neq 0$ at $U = 4t$: the repulsion screens the potential.

What Figure 13c.8 shows. On the left, every interacting curve is flatter than the dotted line $\Delta_s = \Delta$: the non-interacting electrons need a smaller site-energy difference than the true one to reproduce the exact density, because the repulsion, which the Kohn-Sham electrons do not have, already pushes against piling up on the lower site. At $\Delta = 4t$ the exact Δ_s is about $2.3t$ for $U = 2t$ and about $1.0t$ for $U = 4t$; the mean field for $U = 4t$ gives about $1.55t$, between the two: it screens less than the exact potential. On the right, at $U = 4t$, both parts of the screening have the sign opposite to Δ; the correlation part is the larger one for $|\Delta|$ up to about $3.4t$ (at $\Delta = 2t$: -1.114 against -0.588, the numbers printed by the cell), and the Hartree-exchange part beyond.

In [19], the last check.

```
figure_names = ["slater_determinants", "operator_matrices", "density_matrices",
                "two_site_energies", "double_occupancy", "hf_landscape",
                "density_map", "ks_inversion"]
missing = [name for k, name in enumerate(figure_names, 1)
           if not output_file(f"{FIGURE_FOLDER}/13c_{k}_{name}.png").is_file()]
check(missing == [], "all eight figure files exist")
check(output_file(f"{FIGURE_FOLDER}/13c_8_ks_inversion.png").is_file(),
      "the figure file 13c_8_ks_inversion.png exists")
all_checks_passed()
```

`enumerate(figure_names, 1)` pairs each name with its number $k = 1, 2, \ldots$; the list comprehension collects the names whose file `13c_k_name.png` does not exist, and the first check requires that list to be empty. The second check names the last figure file, and `all_checks_passed()` prints ALL 33 CHECKS PASSED (notebook 13c): three checks in In [2], one in In [3], two in In [4], three in In [6], one in In [7], two in In [8], one each in In [9] and In [10], two in In [11], three in In [12], two in In [14], one in In [15], five in In [16], four in In [18] and two in In [19].

13.15 The uniform gas, the local density approximation and exact local exchange

To use the Kohn-Sham equations we need an approximation for $E_{xc}[n]$. The oldest one borrows it from the only many-body system whose properties are known accurately: the **uniform gas**, infinitely many particles spread with the same density everywhere. This section computes, in three dimensions, its density matrix, its kinetic energy and its exchange energy, and shows why the exchange of a contact interaction is special.

Spherical coordinates. The integrals below are done in spherical coordinates: a point $\mathbf{r} = (x, y, z)$ is given by its distance r from the origin, the angle θ from the z axis and the angle ϕ around it, $x = r\sin\theta\cos\phi$, $y = r\sin\theta\sin\phi$, $z = r\cos\theta$. A small box with the edges dr, $r\,d\theta$ and $r\sin\theta\,d\phi$ has the volume $d^3r = r^2\sin\theta\,dr\,d\theta\,d\phi$. With $u = \cos\theta$ (so $du = -\sin\theta\,d\theta$, and θ from 0 to π is u from 1 to -1),

$$\int f\,d^3r = \int_0^\infty r^2\,dr \int_{-1}^{1} du \int_0^{2\pi} d\phi\; f,$$

and for a function of r alone this is $4\pi\int_0^\infty r^2 f\,dr$. The same holds for integrals over a wave vector $\mathbf{k}$, with $k = |\mathbf{k}|$ in place of r, and the axis may point in any direction.

Plane waves in a box. Put the gas in a cube of side ℓ and volume $V = \ell^3$ whose opposite faces are glued together (a **periodic box**). The orbitals of a free particle are the **plane waves** $e^{i\mathbf{k}\cdot\mathbf{r}}/\sqrt{V}$ with the kinetic energy $\frac{1}{2}k^2$, and periodicity allows only $\mathbf{k} = (2\pi/\ell)\,\mathbf{m}$ with three integers $\mathbf{m} = (m_x, m_y, m_z)$. Each allowed $\mathbf{k}$ occupies a little cube of volume $(2\pi/\ell)^3 = (2\pi)^3/V$, so for a large box a sum over the allowed vectors becomes an integral, $\sum_{\mathbf{k}} \to V\int d^3k/(2\pi)^3$.

The Fermi sphere. The non-interacting ground state fills all $\mathbf{k}$ with $|\mathbf{k}| < k_F$ (the **Fermi wave number**), once for each of the g labels. Counting, line by line:

$$N_\sigma = V\,\frac{\frac{4}{3}\pi k_F^3}{(2\pi)^3}, \qquad n_\sigma = \frac{N_\sigma}{V} = \frac{k_F^3}{6\pi^2}, \qquad n = g\,n_\sigma = \frac{g\,k_F^3}{6\pi^2}.$$

The first is the number of occupied plane waves of one label (the volume of the sphere divided by the volume per $\mathbf{k}$); the second divides by V and simplifies $\frac{4}{3}\pi/(8\pi^3) = 1/(6\pi^2)$; the third adds the g labels. The kinetic energy per volume is $g\int_{k<k_F} \frac{d^3k}{(2\pi)^3}\frac{k^2}{2} = \frac{g}{2\pi^2}\cdot\frac{k_F^5}{10}$ (spherical coordinates: $4\pi\int_0^{k_F} k^2\cdot\frac{k^2}{2}\,dk/(8\pi^3)$). For $g=2$, eliminating $k_F = (3\pi^2 n)^{1/3}$,

$$e_{kin}(n) = C_F\, n^{5/3}, \qquad C_F = \tfrac{3}{10}\,(3\pi^2)^{2/3} = 2.871234 \quad \text{(Notebook 13b, In [15])}.$$

The **Thomas-Fermi** model (1927) took the kinetic energy of every system to be $\int e_{kin}(n(\mathbf{r}))\,d^3r$, as if each small piece of it were a piece of uniform gas. It is too crude; the Kohn-Sham scheme keeps the kinetic energy exact through T_s and approximates only E_{xc}. Notebook 13a (Section 13.32) compares a Thomas-Fermi density with a Kohn-Sham density.

The density matrix of one label, line by line. For one label the density matrix of the filled sphere is $\rho_\sigma(\mathbf{r},\mathbf{r}') = \sum_{|\mathbf{k}|<k_F} \frac{e^{i\mathbf{k}\cdot\mathbf{r}}}{\sqrt{V}}\frac{e^{-i\mathbf{k}\cdot\mathbf{r}'}}{\sqrt{V}}$, a function of the separation $\mathbf{R} = \mathbf{r}-\mathbf{r}'$ only. For a large box, with $R = |\mathbf{R}|$ and spherical coordinates around $\mathbf{R}$ (so $\mathbf{k}\cdot\mathbf{R} = kRu$):

$$\begin{aligned}
\rho_\sigma(R) &= \int_{k<k_F} \frac{d^3k}{(2\pi)^3}\, e^{i\mathbf{k}\cdot\mathbf{R}} = \frac{1}{(2\pi)^3}\int_0^{k_F} k^2\,dk\int_{-1}^{1} du\int_0^{2\pi} d\phi\; e^{ikRu} \\
&= \frac{2\pi}{(2\pi)^3}\int_0^{k_F} k^2\,\frac{e^{ikR}-e^{-ikR}}{ikR}\,dk = \frac{1}{2\pi^2 R}\int_0^{k_F} k\,\sin(kR)\,dk \\
&= \frac{1}{2\pi^2 R}\Big[\frac{\sin(kR)}{R^2} - \frac{k\cos(kR)}{R}\Big]_0^{k_F} = \frac{\sin(k_FR) - k_FR\cos(k_FR)}{2\pi^2R^3}.
\end{aligned}$$

The first step replaces the sum by the integral; the second writes it in spherical coordinates; the third does the ϕ integral (2π) and the u integral (the antiderivative of e^{ikRu} in u is $e^{ikRu}/(ikR)$); the fourth uses $e^{i\alpha}-e^{-i\alpha} = 2i\sin\alpha$ and simplifies; the fifth integrates by parts ($\int k\sin(kR)\,dk = -k\cos(kR)/R + \int\cos(kR)/R\,dk$); the sixth inserts the limits and collects. Dividing by $n_\sigma = k_F^3/(6\pi^2)$ and writing $s = k_FR$:

$$\frac{\rho_\sigma(R)}{n_\sigma} = F(k_FR), \qquad F(s) = \frac{3\,(\sin s - s\cos s)}{s^3}.$$

Near $s=0$ the Taylor series $\sin s = s - s^3/6 + s^5/120 - s^7/5040$ and $s\cos s = s - s^3/2 + s^5/24 - s^7/720$ give $\sin s - s\cos s = s^3/3 - s^5/30 + s^7/840$, so $F(s) = 1 - s^2/10 + s^4/280 + \ldots$, and $F(0) = 1$: at zero separation the density matrix is the density. Notebook 13b (In [3], Figure 13b.1) compares F with the sums over the plane waves of finite boxes: along the x axis only m_x matters, the sine parts of m_x and $-m_x$ cancel, and $\rho_\sigma(R)/n_\sigma = \frac{1}{N_\sigma}\sum_{m_x} c(m_x)\cos(2\pi m_xR/\ell)$, where $c(m_x)$ counts the occupied lattice points with this m_x; the difference from F shrinks from 0.037 to 0.0008 as the box grows from 251 to 137059 plane waves.

The exchange hole. By Wick's theorem (Section 13.4) the probability density of finding one fermion at $\mathbf{r}$ and another at $\mathbf{r}'$ is $n(\mathbf{r})n(\mathbf{r}') - \sum_\sigma |\rho_\sigma(\mathbf{r},\mathbf{r}')|^2$ (the second term is the exchange term of the four-operator formula; only equal labels contribute). With g equally occupied labels, $n_\sigma = n/g$, and divided by n^2:

$$g_{pair}(R) = 1 - \frac{g\,n_\sigma^2 F(k_FR)^2}{n^2} = 1 - \frac{1}{g}\,F(k_FR)^2.$$

At $R = 0$ it is $1 - 1/g$: a second fermion with the same label is never found at the same point, one with another label as often as without the Pauli principle. This dip is the **exchange hole** (Figure 13b.2); its size is about $1/k_F$.

Contact interaction in the uniform gas. With $w = g_c\,\delta(\mathbf{r} - \mathbf{r}')$, Section 13.5 gives per volume $e_H = \frac{g_c}{2} n^2$ and $e_x = -\frac{g_c}{2}\sum_\sigma n_\sigma^2 = -\frac{g_c}{2g} n^2$, so

$$e_H + e_x = \frac{g_c}{2}\, n^2 \Big(1 - \frac{1}{g}\Big) = \frac{g_c}{2}\, n^2\, g_{pair}(0)\,:$$

the interaction counts only the pairs that can meet, those of different labels (Figure 13b.3).

A finite range shrinking to a contact, line by line. Replace the contact by a Gaussian of range a with the same total strength, $w_a(R) = g_c\,(2\pi a^2)^{-3/2} e^{-R^2/(2a^2)}$, whose integral over all space is g_c. Its Hartree energy is still $\frac{g_c}{2} n^2$ (for a uniform density only the integral of w enters), but its exchange energy per volume is $e_x(a) = -\frac{1}{2}\sum_\sigma n_\sigma^2 \int w_a(R)\, F(k_F R)^2\, d^3R$ (Section 13.5 with $\rho_\sigma = n_\sigma F$). Hence

$$\frac{e_x(a)}{e_x(0)} = \frac{1}{g_c}\int w_a(R)\, F(k_F R)^2\, d^3R = \frac{1}{g_c}\int_0^\infty 4\pi R^2\, w_a(R)\, F(k_F R)^2\, dR.$$

For a small range only small R matter, where $F(s)^2 = (1 - s^2/10 + \dots)^2 = 1 - s^2/5 + \dots$:

$$\frac{e_x(a)}{e_x(0)} \approx \frac{1}{g_c}\int w_a \Big(1 - \frac{k_F^2 R^2}{5}\Big) d^3R = 1 - \frac{k_F^2}{5 g_c}\int w_a\, R^2\, d^3R = 1 - \frac{k_F^2}{5}\cdot 3a^2 = 1 - \frac{3}{5}\,(k_F a)^2.$$

The first step inserts the expansion; the second uses $\int w_a\, d^3R = g_c$; the third uses $\int w_a R^2\, d^3R = 3a^2 g_c$ (the Gaussian has the variance a^2 along each of the three axes, and $R^2 = x^2 + y^2 + z^2$). So the exchange energy of a finite-range interaction approaches the contact value when the range is much smaller than the size $1/k_F$ of the exchange hole (Notebook 13b, In [8], Figure 13b.4).

For comparison: the Coulomb interaction. For electrons ($g = 2$, $w = 1/R$ in atomic units) the same formula gives

$$e_x = -\tfrac{1}{2}\cdot 2\, n_\sigma^2 \int_0^\infty 4\pi R^2\, \frac{F(k_F R)^2}{R}\, dR = -\frac{4\pi n_\sigma^2}{k_F^2}\int_0^\infty s\, F(s)^2\, ds,$$

by substituting $s = k_F R$. The integral is 9/4: COMPUTED by Notebook 13b (In [10]) to 10^{-7} with Simpson's rule up to $s = 4000$ plus the tail beyond (for large s, $F \approx -3\cos s/s^2$, so the integrand is about $9\cos^2 s/s^3$, whose average $\cos^2 = \frac{1}{2}$ gives the tail $9/(4\cdot 4000^2)$); it can also be evaluated exactly by Fourier transforms, which this book does not need. With $n_\sigma = n/2$ and $k_F = (3\pi^2 n)^{1/3}$ this is **Dirac's exchange energy** (1930),

$$e_x(n) = -\frac{3}{4}\Big(\frac{3}{\pi}\Big)^{1/3} n^{4/3} = -0.738559\, n^{4/3} \quad \text{(Notebook 13b, In [10])}.$$

It is a function of the local density because the gas is uniform; the contact exchange $-\frac{g_c}{4} n^2$ ($g = 2$) is a function of the local density because the interaction has no range (Figure 13b.5 compares the two per particle: slopes 1 and 1/3 on logarithmic axes).

Simpson's rule. Several notebooks of this chapter integrate with **Simpson's rule**. On three equally spaced points $-h, 0, h$ it integrates the parabola $a+bx+cx^2$ through the three values exactly: $\int_{-h}^{h}(a+bx+cx^2)\,dx = 2ah + \frac{2}{3}ch^3$; the values give $f(0) = a$ and $f(h) + f(-h) = 2a + 2ch^2$, so $ch^2 = \frac{1}{2}(f(h)+f(-h))-a$, and inserting, $\int = 2ah+\frac{h}{3}(f(h)+f(-h))-\frac{2}{3}ah = \frac{h}{3}[f(-h)+4f(0)+f(h)]$. Adding such panels over an even number of intervals gives $\frac{h}{3}[f_0+4f_1+2f_2+4f_3+\cdots+4f_{K-1}+f_K]$: the end values once, the odd ones four times, the inner even ones twice. (It is even exact for cubic polynomials, because the term x^3 integrates to zero on a symmetric panel.)

The local density approximation. A real density varies in space. The **local density approximation** (LDA) treats each small volume as a piece of uniform gas with the local density:

$$E_{xc}^{LDA}[n] = \int e_{xc}(n(\mathbf{r}))\,d^3r, \qquad v_{xc}^{LDA}(\mathbf{r}) = \left.\frac{de_{xc}}{dn}\right|_{n(\mathbf{r})}$$

(example (ii) of Section 13.9). For electrons its exchange part is Dirac's formula, $v_x = -(3/\pi)^{1/3}n^{1/3}$; its correlation part is taken from numerical simulations of the uniform gas, which we quote as a fact of the literature and do not use in this book. The LDA is exact for a uniform density and an approximation for every other one.

For a contact interaction exchange needs no approximation. Put $w = g_c\,\delta(\mathbf{r}-\mathbf{r}')$ (independent of the labels) into the exchange integral of Section 13.5 for ANY determinant or non-interacting ensemble:

$$E_x = -\frac{g_c}{2}\int \sum_{\sigma,\sigma'} \left|\rho(\mathbf{r}\sigma,\mathbf{r}\sigma')\right|^2 d^3r.$$

This is exactly local: it needs only the $g \times g$ matrix $\rho(\mathbf{r}\sigma,\mathbf{r}\sigma')$ at each point. For orbitals of definite label the off-diagonal entries vanish and $E_x = -\frac{g_c}{2}\int\sum_\sigma n_\sigma^2\,d^3r$; evaluated with all the label densities it is exact, evaluated with the total density alone as $-\frac{g_c}{2g}\int n^2$ it is exact only when all labels are equally occupied. Notebook 13b checks this for a non-uniform determinant in a box (In [12]: the two-point Fock form and the local form both give -19.0000000000) and for orbitals that mix the labels (In [13]: the local form needs the whole 2×2 matrix; its diagonal alone misses 1.24 of the 8.74). An "exchange-only" local functional of this kind is the Hartree-Fock energy written as a density functional; what it leaves out is correlation.

Exchange favours unequal labels, line by line. In this exchange-only picture a gas with two labels can lower its interaction energy by occupying the labels unequally, at the price of kinetic energy. With the **polarisation** $\zeta = (n_\uparrow - n_\downarrow)/n$, so $n_\uparrow = \frac{n}{2}(1+\zeta)$ and $n_\downarrow = \frac{n}{2}(1-\zeta)$: one label alone ($g=1$) has the kinetic energy $\frac{3}{10}(6\pi^2)^{2/3}n_\sigma^{5/3}$ per volume (the formula above with $g=1$), and the contact interaction gives $g_c\,n_\uparrow n_\downarrow$ (Section 13.5). Adding,

$$e(\zeta) = C_F\,n^{5/3}\,\frac{(1+\zeta)^{5/3}+(1-\zeta)^{5/3}}{2} + \frac{g_c}{4}\,n^2\,(1-\zeta^2),$$

where the kinetic part was rewritten with $\frac{3}{10}(6\pi^2)^{2/3}(\frac{n}{2})^{5/3} = \frac{1}{2}C_F n^{5/3}$ (because $6^{2/3}\,2^{-5/3} = 3^{2/3}\,2^{2/3}\,2^{-5/3} = 3^{2/3}/2$) and $n_\uparrow n_\downarrow = \frac{n^2}{4}(1-\zeta^2)$. Differentiating twice at $\zeta = 0$: $\frac{d^2}{d\zeta^2}(1\pm\zeta)^{5/3} = \frac{5}{3}\cdot\frac{2}{3}(1\pm\zeta)^{-1/3} = \frac{10}{9}$ at $\zeta = 0$, so

$$e''(0) = \frac{10}{9}\,C_F\,n^{5/3} - \frac{g_c}{2}\,n^2,$$

which is negative (the unpolarised gas is unstable) exactly when $g_c\,n^{1/3} > \gamma_c = \frac{20}{9}C_F = \frac{2}{3}(3\pi^2)^{2/3} = 6.380520$. This is a property of the exchange-only functional; correlation, left out here, weakens it (Notebook 13b, In [15], Figure 13b.7).

13.16 The exchange of the 16-component field dirac16complex

This section carries Section 13.15 over to the field of this book. In this section and in Section 13.37, Ψ is the dirac16complex field and $x_0, \ldots, x_7$ are the author's coordinates: x_1, x_2, x_3 ordinary space, x_4 the time, x_5, x_6, x_7 the three extra times, which deflate exponentially, and x_0 the hidden direction.

The matrices. The author's gamma matrices $\gamma^{(x0)}, \ldots, \gamma^{(x7)}$ are eight REAL 16×16 matrices (entries 0 and ± 1) with $\gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 2\eta^{ab}\,1$, $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in the order $x_0, \ldots, x_7$ (Chapter 4 builds them; `Revision/algebra/reports/wolfram-algebra.json`, checks reality and Clifford_relation, both PASS, as Notebook 13b checks in In [21]). So each space-like gamma squares to $+1$, $\gamma^{(x4)}$ squares to -1, and two different gammas anticommute. From them,

$$C = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}, \qquad B = -i\,C\,\gamma^{(x4)}.$$

C is real and symmetric (check C_real_symmetric of the same report, PASS); B is the indefinite (Krein) form of Chapter 10, with the number density $n = \langle \Psi^\dagger B \Psi \rangle$. Four facts, line by line. (a) $C^2 = 1$: in $C^2 = \gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}\gamma^{(x0)}\gamma^{(x1)}\gamma^{(x2)}\gamma^{(x3)}$ move the second $\gamma^{(x0)}$ to the left past three gammas (sign $(-1)^3$) and use $(\gamma^{(x0)})^2 = 1$; then move the second $\gamma^{(x1)}$ past two (sign $+1$), then the second $\gamma^{(x2)}$ past one (sign -1); the signs multiply to $(-1)(+1)(-1) = +1$ and every square is $+1$. (b) $\gamma^{(x4)}$ commutes with C: moving it through the four factors of C costs four sign changes, $(-1)^4 = 1$. (c) $B^2 = 1$: $B^2 = (-i)^2\,C\gamma^{(x4)}C\gamma^{(x4)} = -\,C\,C\,\gamma^{(x4)}\gamma^{(x4)} = -(+1)(-1) = 1$, by (b), (a) and $(\gamma^{(x4)})^2 = -1$. (d) $CBC = -i\,C\,C\,\gamma^{(x4)}C = -i\,\gamma^{(x4)}C = -i\,C\gamma^{(x4)} = B$ by (a) and (b); and $\mathrm{Tr}(BC) = -i\,\mathrm{Tr}(C\gamma^{(x4)}C) = -i\,\mathrm{Tr}(\gamma^{(x4)}C^2) = -i\,\mathrm{Tr}\,\gamma^{(x4)} = 0$, using that a trace does not change when the first factor is moved to the end, and that the trace of a single gamma vanishes ($\mathrm{Tr}\,\gamma^{(x4)} = \mathrm{Tr}(\gamma^{(x4)}\gamma^{(x1)}\gamma^{(x1)}) = -\mathrm{Tr}(\gamma^{(x1)}\gamma^{(x4)}\gamma^{(x1)}) = -\mathrm{Tr}(\gamma^{(x4)}\gamma^{(x1)}\gamma^{(x1)}) = -\mathrm{Tr}\,\gamma^{(x4)}$). Finally $\mathrm{Tr}\,1 = 16$.

The interaction and Wick's theorem. The Kohn-Sham model of Chapter 14 has the contact interaction $U(S) = \frac{\lambda}{2}S^2$ with the scalar density $S = \bar\Psi\Psi = \Psi^\dagger C\,\Psi$ (normal ordered, $\lambda > 0$ repulsive). Its expectation values follow the rule $\langle \Psi^\dagger M \Psi \rangle = \mathrm{Tr}(M\rho)$ with a local 16×16 one-body matrix ρ (Chapter 10), and the identity of Section 13.4 with the vertex $V = C$ gives, per unit volume,

$$e_H = \frac{\lambda}{2}\,(\mathrm{Tr}\,C\rho)^2, \qquad e_x = -\frac{\lambda}{2}\,\mathrm{Tr}(C\rho\,C\rho).$$

(For g ordinary labels the vertex is the unit matrix and $\rho = (n/g)\,1$, which gives back $e_x = -\frac{g_c}{2}\,g\,(n/g)^2 = -\frac{g_c}{2g}n^2$.)

The uniform good-sector gas, line by line. For the uniform gas of the good sector (no extra-time momentum, Chapter 14), with any occupation that is symmetric under $\mathbf{p} \to -\mathbf{p}$ and at any temperature, the Revision record finds $\rho = (nB + SC)/16$ (`Revision/kohn_sham/ks-theory.json`, exchange.uniformGas; Chapter 14 derives it). First the densities come back:

$$\mathrm{Tr}(B\rho) = \frac{n\,\mathrm{Tr}\,B^2 + S\,\mathrm{Tr}\,BC}{16} = \frac{16n + 0}{16} = n, \qquad \mathrm{Tr}(C\rho) = \frac{n\,\mathrm{Tr}\,CB + S\,\mathrm{Tr}\,C^2}{16} = S,$$

by linearity of the trace, $B^2 = C^2 = 1$ and $\mathrm{Tr}(BC) = \mathrm{Tr}(CB) = 0$. Then the exchange trace:

$$\begin{aligned}
\mathrm{Tr}(C\rho\,C\rho) &= \frac{1}{256}\,\mathrm{Tr}\big[C(nB + SC)\,C(nB + SC)\big] \\
&= \frac{1}{256}\big[n^2\,\mathrm{Tr}(CBCB) + nS\,\mathrm{Tr}(CBCC) + Sn\,\mathrm{Tr}(CCCB) + S^2\,\mathrm{Tr}(CCCC)\big] \\
&= \frac{1}{256}\big[n^2\,\mathrm{Tr}(B^2) + nS\,\mathrm{Tr}(CB) + Sn\,\mathrm{Tr}(CB) + S^2\,\mathrm{Tr}\,1\big] \\
&= \frac{16\,n^2 + 16\,S^2}{256} = \frac{n^2 + S^2}{16}.
\end{aligned}$$

The first line inserts ρ; the second multiplies out (four terms); the third uses $CBC = B$ in the first term and $C^2 = 1$ in the others; the fourth uses $\mathrm{Tr}\,B^2 = \mathrm{Tr}\,1 = 16$ and $\mathrm{Tr}(CB) = 0$. Hence

$$e_H = \frac{\lambda}{2}\,S^2, \qquad e_x = -\frac{\lambda}{32}\,(n^2 + S^2).$$

The Kohn-Sham potentials. The interaction energy per volume is $e_{int} = e_H + e_x = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2$. As in example (ii) of Section 13.9, the functional derivatives of $\int e_{int}$ are ordinary derivatives of e_{int}: with respect to S it shifts the mass, with respect to n it is a potential,

$$M_{eff} = m + \frac{\partial e_{int}}{\partial S} = m + \frac{15}{16}\,\lambda S, \qquad v_v = \frac{\partial e_{int}}{\partial n} = -\frac{1}{16}\,\lambda n.$$

For one filled 8-fold level at rest, $n = S$, the ratio is $e_x/e_H = -\frac{\lambda}{32}\cdot 2S^2/\frac{\lambda}{2}S^2 = -\frac{1}{8}$: the rule $E_x = -E_H/g$ of Section 13.5 with $g = 8$, the number of good-sector states per momentum.

Status. PROVED in the Revision record by two independent programs, and used unchanged by the Revision Kohn-Sham solver:

record file	checks or entries	result
`Revision/kohn_sham/reports/ks-theory-python.json`	exchange_uniform_gas, ks_potentials, filled_shell_ratio	PASS
`Revision/kohn_sham/reports/ks-theory-wolfram.json`	exchange_uniform_gas, ks_potentials	PASS
`Revision/kohn_sham/results/parameters.json`	theoryInputs: the coefficients $-1/32$, $15/16$, $-1/16$	used by the solver

Notebook 13b reproduces all of them exactly from the gamma matrices. **What is approximate.** The record's functional is Hartree plus this uniform-gas exchange, with no correlation term. For the Kohn-Sham determinants of Chapter 14, which are not uniform, the exact Fock exchange of a closed shell is still local but differs from the uniform-gas form by $+\frac{\lambda}{32}Q^2$ per volume, where Q is a further density (exactFockSlab in `Revision/kohn_sham/ks-theory.json`, labelled DIAGNOSTIC there; check exchange_slab_exact_fock of `Revision/kohn_sham/reports/ks-theory-python.json`, PASS; the solver reports this difference in the column deltaE_x_exact_fock_diag of `Revision/kohn_sham/results/exx/exact-fock-variant.csv`). Using the uniform-gas exchange and leaving out correlation is therefore the approximation of the dirac16complex Kohn-Sham model, as the omission of correlation is the approximation of the toy models of this chapter. Notebook 13b reads every record entry quoted in this section and checks it (In [17] and In [18] for the formulas and the three sympy checks; In [21] for the algebra checks, the Wolfram checks, exchange_slab_exact_fock in both reports, the DIAGNOSTIC entry with its $+\frac{\lambda}{32}Q^2$, the missing correlation term and the column of the table), so that a change of the record would stop the notebook.

13.17 Example: exchange of a contact interaction

Notebook 13b computes everything of Sections 13.15 and 13.16: the density matrix of one label of the uniform gas from its closed form and from box sums, the exchange hole for 1, 2 and 8 labels, the contact energies and the rule $E_x = -E_H/g$, the approach of a Gaussian interaction to the contact limit, Dirac's Coulomb exchange for comparison, the exactness of the local formula for any determinant (also with label-mixing orbitals), the polarisation instability, and, exactly with fractions, the exchange of the 16-component field from the Revision gamma matrices, reproducing three checks of the Revision record; finally it reads and checks the further record entries that Sections 13.16, 13.37 and 13.38 quote (the independent Wolfram verification, the exact-exchange diagnostic, the temperatures, the filling convention, the prescribed background and theorem T3). It ends with ALL 44 CHECKS PASSED (notebook 13b) and draws nine figures.

13.18 How to run Notebook 13b

Step 1. What this notebook does and what it needs.

Notebook 13b (Exchange of a contact interaction in a uniform gas) is the file `Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb` of the repository Dirac_claude. It computes the one-label density matrix of the uniform Fermi gas (closed form and box sums), its exchange hole, the Hartree and exchange energies of a contact interaction with g labels (the rule E_x = -E_H/g), the approach of a finite-range interaction to the contact limit, Dirac's exchange energy of the Coulomb interaction for comparison, the exactness of the local exchange formula for any Slater determinant, and the spin polarization that exchange favours; finally it reproduces, from the Revision gamma matrices, the exchange energy of the uniform 8-fold gas of dirac16complex recorded in the Revision Kohn-Sham theory (coefficients -1/32, potentials 15/16 and -1/16, filled-shell ratio -1/8), checks the entries of the Revision record that state the status of the dirac16complex Kohn-Sham model (the independent Wolfram verification, the exact-exchange diagnostic, the temperatures, the filling convention, the prescribed background and theorem T3), and draws nine teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these

packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13b_contact_exchange_gas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13b_contact_exchange_gas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 13b_contact_exchange_gas.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/13b.captions.json`
- `Revision/textbook/figures/13b_1_density_matrix.png`
- `Revision/textbook/figures/13b_2_exchange_hole.png`
- `Revision/textbook/figures/13b_3_contact_energies.png`
- `Revision/textbook/figures/13b_4_finite_range.png`
- `Revision/textbook/figures/13b_5_contact_vs_coulomb.png`
- `Revision/textbook/figures/13b_6_local_exchange.png`
- `Revision/textbook/figures/13b_7_polarization.png`
- `Revision/textbook/figures/13b_8_dirac_matrices.png`
- `Revision/textbook/figures/13b_9_dirac_exchange.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13b_9_dirac_exchange.png exists
ALL 44 CHECKS PASSED (notebook 13b)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 13b_contact_exchange_gas.ipynb
python -m nbconvert --execute --inplace 13b_contact_exchange_gas.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `gammas.json` or `ks-theory.json`: the notebook reads Revision records of the repository; it must be opened inside the folder `Revision/textbook/notebooks` of a complete clone of the repository, not as a single downloaded file.

13.19 Notebook 13b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The exchange energy is the part of the energy of fermions that comes from the Pauli
principle alone. In general it is an integral over TWO points, but for a contact
interaction (particles feel each other only when they are at the same point) it
becomes an integral over ONE point: it is exactly local. This notebook shows this
step by step for the uniform gas, the system from which the local density
approximation is built. It

- computes the density matrix of one label of the uniform gas in three dimensions
  from its closed form and from sums over the plane waves of a periodic box;
- draws the "exchange hole": the reduced chance of finding a second fermion close
  to a first one, for $g = 1$, $2$ and $8$ labels;
- computes the Hartree and exchange energies of a contact interaction and checks
  the rule $E_x = -E_H/g$ for equally occupied labels;
- lets a Gaussian interaction of range $a$ shrink to a contact and watches the
  exchange energy approach the contact value;
- computes Dirac's exchange energy of the Coulomb interaction for comparison;
- checks that the local exchange formula is exact for ANY Slater determinant, not
  only for the uniform gas;
- shows that exchange favours a gas in which the labels are unequally occupied
  (polarization) when the contact repulsion is strong;
- reproduces, from the Revision gamma matrices, the exchange energy of the uniform
  gas of the 16-component field dirac16complex that the Revision Kohn-Sham solver
  uses;
- reads and checks the entries of the Revision record that say on what these
  formulas rest and how the Kohn-Sham model of dirac16complex must be read;
- draws nine teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 13b (Exchange of a contact interaction in a uniform gas) is the file
`Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb` of the repository
Dirac_claude. It computes the one-label density matrix of the uniform Fermi gas (closed
form and box sums), its exchange hole, the Hartree and exchange energies of a contact
interaction with g labels (the rule E_x = -E_H/g), the approach of a finite-range
interaction to the contact limit, Dirac's exchange energy of the Coulomb interaction for
comparison, the exactness of the local exchange formula for any Slater determinant, and
the spin polarization that exchange favours; finally it reproduces, from the Revision
gamma matrices, the exchange energy of the uniform 8-fold gas of dirac16complex recorded
in the Revision Kohn-Sham theory (coefficients -1/32, potentials 15/16 and -1/16,
filled-shell ratio -1/8), checks the entries of the Revision record that state the status
of the dirac16complex Kohn-Sham model (the independent Wolfram verification, the
exact-exchange diagnostic, the temperatures, the filling convention, the prescribed
background and theorem T3), and draws nine teaching plots. It needs a computer with
Windows 11, macOS or Linux, an internet connection for the installation, the program Git,
and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
```

nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already

active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13b_contact_exchange_gas.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13b_contact_exchange_gas.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 13b_contact_exchange_gas.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/13b.captions.json‘
- ‘Revision/textbook/figures/13b_1_density_matrix.png‘
- ‘Revision/textbook/figures/13b_2_exchange_hole.png‘
- ‘Revision/textbook/figures/13b_3_contact_energies.png‘
- ‘Revision/textbook/figures/13b_4_finite_range.png‘
- ‘Revision/textbook/figures/13b_5_contact_vs_coulomb.png‘
- ‘Revision/textbook/figures/13b_6_local_exchange.png‘
- ‘Revision/textbook/figures/13b_7_polarization.png‘
- ‘Revision/textbook/figures/13b_8_dirac_matrices.png‘
- ‘Revision/textbook/figures/13b_9_dirac_exchange.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13b_9_dirac_exchange.png exists
ALL 44 CHECKS PASSED (notebook 13b)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs

  jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
  programs (‘python -m jupyter‘ does not help then: it has to find the same programs).
  Start them through Python itself, in the folder of the notebook: the first command
  below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 13b_contact_exchange_gas.ipynb
      python -m nbconvert --execute --inplace 13b_contact_exchange_gas.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
  loop" and zmq: this is a message of the package pyzmq, not an error; the run continues
  normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the
  first run after the installation: this is a message, not an error; the run continues
  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘gammas.json‘ or ‘ks-theory.json‘: the notebook reads Revision
  records of the repository; it must be opened inside the folder
  ‘Revision/textbook/notebooks‘ of a complete clone of the repository, not as a single
  downloaded file.

The first code cell below (the set-up cell) repeats these instructions as comments; then
it imports the packages, finds the repository folder and defines the helpers
‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a
check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a
RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 13b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 13b (Exchange of a contact interaction in a uniform gas) is the file
# Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb of the repository
# Dirac_claude. It computes the one-label density matrix of the uniform Fermi gas (closed
# form and box sums), its exchange hole, the Hartree and exchange energies of a contact
# interaction with g labels (the rule E_x = -E_H/g), the approach of a finite-range
# interaction to the contact limit, Dirac's exchange energy of the Coulomb interaction
# for comparison, the exactness of the local exchange formula for any Slater determinant,
# and the spin polarization that exchange favours; finally it reproduces, from the
# Revision gamma matrices, the exchange energy of the uniform 8-fold gas of
# dirac16complex recorded in the Revision Kohn-Sham theory (coefficients -1/32,
# potentials 15/16 and -1/16, filled-shell ratio -1/8), checks the entries of the
# Revision record that state the status of the dirac16complex Kohn-Sham model (the
# independent Wolfram verification, the exact-exchange diagnostic, the temperatures, the
# filling convention, the prescribed background and theorem T3), and draws nine teaching
# plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for
# the installation, the program Git, and Python 3.12 or newer (the notebooks were built
# with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
```

```
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
```

```
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git

#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
```

```
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 13b_contact_exchange_gas.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 13b_contact_exchange_gas.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 13b_contact_exchange_gas.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/13b.captions.json
# - Revision/textbook/figures/13b_1_density_matrix.png
# - Revision/textbook/figures/13b_2_exchange_hole.png
# - Revision/textbook/figures/13b_3_contact_energies.png
# - Revision/textbook/figures/13b_4_finite_range.png
# - Revision/textbook/figures/13b_5_contact_vs_coulomb.png
# - Revision/textbook/figures/13b_6_local_exchange.png
# - Revision/textbook/figures/13b_7_polarization.png
# - Revision/textbook/figures/13b_8_dirac_matrices.png
# - Revision/textbook/figures/13b_9_dirac_exchange.png
#
```

```
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 13b_9_dirac_exchange.png exists
#     ALL 44 CHECKS PASSED (notebook 13b)
#
# and the notebook must show 9 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/13b_contact_exchange_gas.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 13b_contact_exchange_gas.ipynb
#     python -m nbconvert --execute --inplace 13b_contact_exchange_gas.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
```

```
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for gammas.json or ks-theory.json: the notebook reads Revision
#   records of the repository; it must be opened inside the folder
#   Revision/textbook/notebooks of a complete clone of the repository, not as a single
#   downloaded file.
#

## 3. The words used in this notebook

- **Uniform gas**: infinitely many fermions spread with the same density everywhere;
  it is studied in a large periodic box (a box whose opposite faces are glued
  together), whose volume is then made infinite.
- **Plane wave**: the orbital $e^{i\mathbf k\cdot\mathbf r}/\sqrt V$ of a free
  particle in the box of volume $V$, with wave vector $\mathbf k$; its kinetic energy
  is $k^2/2$ (units $\hbar = m = 1$).
- **Fermi sphere, Fermi wave number** $k_F$: the ground state of the free gas fills
  every plane wave with $|\mathbf k| < k_F$, once per label.
- **Label**: an internal property with $g$ values (for electrons the spin, $g = 2$;
  for the dirac16complex gas of the Revision record, 8 states per momentum).
- **Density matrix** $\rho(x, x')$: $\sum_a \phi_a(x)\,\phi_a^*(x')$ over the occupied
  orbitals; its diagonal $\rho(x, x)$ is the density.
- **Exchange energy** $E_x = -\tfrac12\iint |\rho(x, x')|^2\,w(x, x')\,dx\,dx'$ of a
  Slater determinant with the pair interaction $w$; **Hartree energy**
  $E_H = \tfrac12\iint n(x)\,w(x, x')\,n(x')\,dx\,dx'$.
- **Contact interaction**: $w(\mathbf r, \mathbf r') = g_c\,\delta(\mathbf r -
  \mathbf r')$; it acts only when two particles are at the same point.
- **Exchange hole**: the dip in the probability of finding a second fermion near a
  first one, caused by the Pauli principle.
- **Coulomb interaction**: $w = 1/|\mathbf r - \mathbf r'|$, the repulsion of two
  electrons (atomic units).
- **Polarization** $\zeta = (n_{up} - n_{down})/n$: how unequally two labels are
  occupied.
- **Vertex**: the matrix that sits between the field components in an interaction;
```

```
  for dirac16complex the contact interaction is $(\lambda/2)\,S^2$ with
  $S = \bar\Psi\Psi = \Psi^\dagger C\,\Psi$, so the vertex is the $16 \times 16$
  matrix $C$.
- **sympy, Rational**: sympy computes with exact fractions such as $-1/32$, so its
  checks are exact, not rounded.
```

Text cell:

```
## 4. The physical and mathematical situation

**The exchange energy of a determinant.** For a Slater determinant with the density
matrix $\rho(x, x') = \sum_{a\,occupied}\phi_a(x)\phi_a^*(x')$, where $x$ stands for
the position $\mathbf r$ and the label $\sigma$ together (this $x$, and the $x$ of
the line in section 10, is not one of the author's spacetime coordinates
$x_0, \dots, x_7$; those appear only in section 12, as the labels of the gamma
matrices $\gamma^{(x0)}, \dots, \gamma^{(x7)}$), the interaction energy is
$E_H + E_x$ with

$$E_H = \tfrac12\iint n(x)\,w(x,x')\,n(x')\,dx\,dx', \qquad
E_x = -\tfrac12\iint |\rho(x,x')|^2\,w(x,x')\,dx\,dx' .$$

**Contact interaction.** With $w = g_c\,\delta(\mathbf r - \mathbf r')$ (the same for
all labels) the delta function sets $\mathbf r' = \mathbf r$ and only one integral
over space remains:

$$E_x = -\frac{g_c}{2}\int \sum_{\sigma,\sigma'}|\rho(\mathbf r\sigma,
\mathbf r\sigma')|^2\,d^3r .$$

If every orbital has a definite label, $\rho(\mathbf r\sigma, \mathbf r\sigma') = 0$
for $\sigma \ne \sigma'$ and $\rho(\mathbf r\sigma,\mathbf r\sigma) = n_\sigma(\mathbf
r)$, so $E_x = -\frac{g_c}{2}\int\sum_\sigma n_\sigma^2\,d^3r$: exactly local. With all
$g$ labels equally occupied, $n_\sigma = n/g$ and $E_x = -E_H/g$.

**The uniform gas.** In a box of volume $V$ the allowed wave vectors form a cubic
lattice of spacing $2\pi/\ell$ ($V = \ell^3$); filling $|\mathbf k| < k_F$ once per
label gives $n_\sigma = k_F^3/(6\pi^2)$. The density matrix of one label depends
only on the separation $R = |\mathbf r - \mathbf r'|$; in spherical coordinates
around $\mathbf R$,

$$\rho_\sigma(R) = \int_{k<k_F}\frac{d^3k}{(2\pi)^3}e^{i\mathbf k\cdot\mathbf R}
= \frac{1}{2\pi^2 R^3}\,[\sin(k_F R) - k_F R\cos(k_F R)] = n_\sigma\,F(k_F R),$$

$$F(s) = \frac{3\,(\sin s - s\cos s)}{s^3}, \qquad F(0) = 1 .$$

**Status.** The formulas above are exact mathematics of the free Fermi gas (PROVED:
they follow from the definitions). Sections 5 to 11 check them with numbers. Where
a closed form is compared with another exact form (sections 6, 7 and 10, the
slopes of section 9 and the curvature of section 11) the agreement is to rounding.
Where a sum or an integral is evaluated numerically, the result is COMPUTED with a
measured accuracy: the box sums of section 5 approach the closed form as the box
grows (the differences are printed), the finite-range ratio of section 8 follows
the small-range formula to $10^{-5}$ at $k_F a = 0.05$, and Simpson's rule gives
Dirac's integral $9/4$ of section 9 to $10^{-7}$. Section 11 describes the
```

```
exchange-only (Hartree-Fock) energy, not the exact one. Section 12 recomputes
exactly, with fractions, formulas that the Revision record PROVES with exact sympy
checks (exchange_uniform_gas, ks_potentials and filled_shell_ratio of its report
ks-theory-python.json) and independently with Wolfram; section 13 reads further
entries of the record and checks them.
```

Text cell:

```
## 5. The density matrix of one label of the uniform gas

The next cell defines the function $F(s)$. For small $s$ the formula
$3(\sin s - s\cos s)/s^3$ divides two tiny numbers and loses digits, so for
$s < 10^{-3}$ the function uses the first terms of its Taylor series,
$F(s) = 1 - s^2/10 + s^4/280$ (expand $\sin$ and $\cos$ and collect the powers).
The check compares the two forms at $s = 10^{-3}$.
```

In [2]:

```
import numpy as np  # arrays, matrices and linear algebra

def F(s):
    """F(s) = 3 (sin s - s cos s) / s^3, the density matrix of one label over n."""
    s = np.asarray(s, dtype=float)
    result = 1.0 - s ** 2 / 10.0 + s ** 4 / 280.0  # the Taylor series near 0
    big = s >= 1e-3  # where the closed form is accurate
    sb = s[big]
    result[big] = 3.0 * (np.sin(sb) - sb * np.cos(sb)) / sb ** 3
    return result

s_test = 1e-3
closed = 3.0 * (np.sin(s_test) - s_test * np.cos(s_test)) / s_test ** 3
series = 1.0 - s_test ** 2 / 10.0 + s_test ** 4 / 280.0
say(f"at s = 0.001: closed form {closed:.12f}, series {series:.12f}")
check(abs(closed - series) < 1e-8,
      "the closed form and the series agree at s = 0.001 (to about 9 digits)")
```

Out [2]:

```
at s = 0.001: closed form 0.999999899944, series 0.999999900000
PASS the closed form and the series agree at s = 0.001 (to about 9 digits)
```

Text cell:

```
The closed form came from an integral over the continuum of wave vectors. In a real
(finite) box the wave vectors are the lattice points $\mathbf k = (2\pi/\ell)\,
\mathbf m$ with integer $\mathbf m = (m_x, m_y, m_z)$, and the density matrix is the
SUM $\rho_\sigma(\mathbf R) = \frac1V\sum_{|\mathbf m| < m_F} e^{i\mathbf k\cdot
```

```
\mathbf R}$. Along the $x$ axis ($\mathbf R = (R, 0, 0)$) only $m_x$ matters, and the
sine parts cancel between $m_x$ and $-m_x$, so

$$\frac{\rho_\sigma(R)}{n_\sigma} = \frac{1}{N_\sigma}\sum_{m_x} c(m_x)\,
\cos\!\Big(\frac{2\pi m_x R}{\ell}\Big),$$

where $c(m_x)$ counts the lattice points with this $m_x$ inside the sphere and
$N_\sigma = \sum c(m_x)$ is the number of occupied plane waves. The next cell
computes this for spheres of radius $m_F = 4, 8, 16, 32$ lattice steps and compares
it with $F(k_F R)$, where $k_F$ is defined by the count,
$N_\sigma = \frac43\pi\,(k_F \ell/2\pi)^3$. The difference must shrink as the box
holds more particles.
```

In [3]:

```

## 6. The exchange hole

For a determinant, the probability density of finding one fermion at $\mathbf r$ and
another at $\mathbf r'$ is $n(\mathbf r)n(\mathbf r') - \sum_\sigma|\rho_\sigma(
\mathbf r,\mathbf r')|^2$ (Wick's theorem). Divided by $n^2$ it is the **pair
distribution** $g_{pair}(R) = 1 - \frac{1}{g}F(k_F R)^2$ for $g$ equally occupied
labels. At $R = 0$ it is $1 - 1/g$: a second fermion with the SAME label is never
found at the same point, one with another label is found as often as without the
Pauli principle. The next cell computes and draws it for $g = 1, 2, 8$.
```

In [5]:

```
s_fine = np.linspace(0.0, 10.0, 501)

## 7. Hartree and exchange energy of a contact interaction

For the contact interaction the energies per unit volume of the uniform gas are
$e_H = \frac{g_c}{2}n^2$ and $e_x = -\frac{g_c}{2}\sum_\sigma n_\sigma^2 =
-\frac{g_c}{2g}n^2$, so $e_H + e_x = \frac{g_c}{2}n^2\,(1 - 1/g) =
\frac{g_c}{2}n^2\,g_{pair}(0)$: the interaction energy counts only the pairs that can
meet, those with different labels. The next cell computes them for $g = 2$ and
$g = 8$ ($g_c = 1$) and checks the rule $e_x = -e_H/g$; for $g = 1$ the two cancel
exactly: a single label does not feel a contact interaction at all.
```

In [6]:

## 8. A finite-range interaction shrinking to a contact
```

```
Replace the contact by a Gaussian of range $a$ and the same total strength,
$w_a(R) = g_c\,(2\pi a^2)^{-3/2}e^{-R^2/(2a^2)}$, whose integral over all space is
$g_c$. Its Hartree energy is still $\frac{g_c}{2}n^2$ (only the integral of $w$
enters for a uniform density), but its exchange energy becomes
$e_x(a) = -\frac12\sum_\sigma n_\sigma^2\int w_a(R)\,F(k_F R)^2\,d^3R$. So
$e_x(a)/e_x(0) = \int_0^\infty 4\pi R^2\,w_a(R)\,F(k_F R)^2\,dR\,/\,g_c$. For small
$a$, $F^2 \approx 1 - s^2/5$ and $\int w_a R^2\,d^3R = 3a^2 g_c$, so
$e_x(a)/e_x(0) \approx 1 - \frac35 (k_F a)^2$. The next cell computes the ratio with
Simpson's rule on a fine grid (in the variable $s = k_F R$, with $a$ measured in
units of $1/k_F$) and checks the small-$a$ formula.
```

## 9. For comparison: Dirac's exchange energy of the Coulomb interaction

For $w = 1/R$ and $g = 2$ the same formula gives $e_x = -\frac12 \cdot 2\,
n_\sigma^2\int_0^\infty 4\pi R^2\,\frac{F(k_F R)^2}{R}\,dR = -\frac{4\pi
n_\sigma^2}{k_F^2}\int_0^\infty s\,F(s)^2\,ds$, and the integral is $9/4$, which
gives Dirac's result $e_x = -\frac34(3/\pi)^{1/3}n^{4/3}$ (with $n = 2n_\sigma =
k_F^3/(3\pi^2)$). The integrand falls only like $1/s^3$; the next cell integrates
up to $s = 4000$ and adds the tail beyond, $\int_{4000}^\infty 9\cos^2 s/s^3\,ds
\approx 9/(4\cdot 4000^2)$ (the average of $\cos^2$ is $1/2$).
```

## 11. Exchange favours polarization

Exchange lowers the energy of equal-label pairs only. A gas with two labels can
therefore lower its interaction energy by occupying the labels unequally, at the
price of more kinetic energy (the more occupied label needs a bigger Fermi sphere).
With the polarization $\zeta$, $n_{up} = n(1+\zeta)/2$, $n_{down} = n(1-\zeta)/2$,
the energy per volume in this exchange-only (Hartree-Fock) picture is

$$e(\zeta) = C_F n^{5/3}\,\frac{(1+\zeta)^{5/3} + (1-\zeta)^{5/3}}{2}
+ \frac{g_c}{4}n^2(1 - \zeta^2), \qquad C_F = \tfrac{3}{10}(3\pi^2)^{2/3}.$$

The second derivative at $\zeta = 0$ is $\frac{10}{9}C_F n^{5/3} - \frac{g_c}{2}n^2$,
which turns negative (the unpolarized gas becomes unstable) when
$g_c n^{1/3} > \gamma_c = \frac{20}{9}C_F = \frac23(3\pi^2)^{2/3}$. The next cell
checks this threshold with a difference quotient and draws $e(\zeta) - e(0)$ for
```

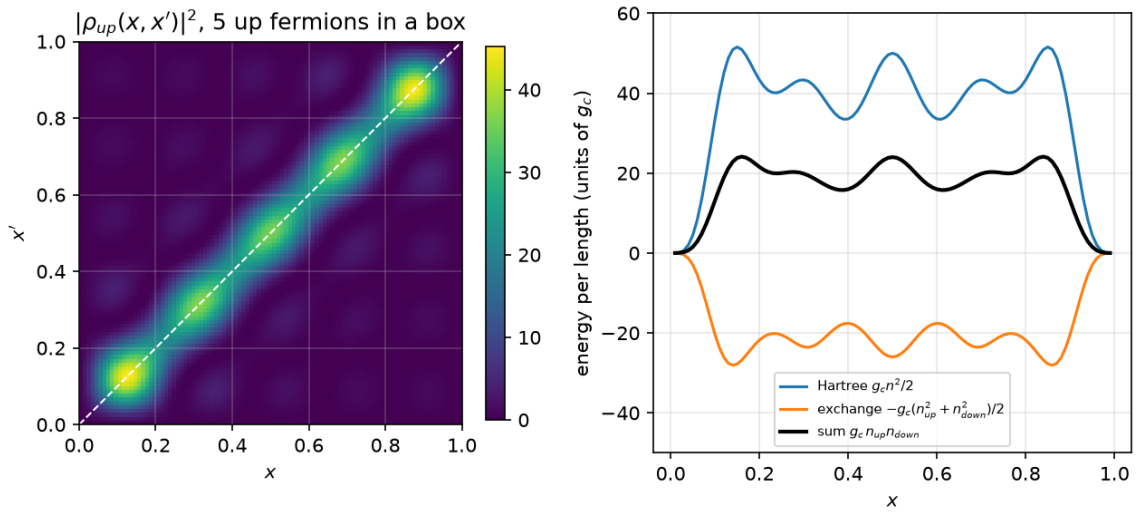

Figure 357: Left: the two-point function $|\rho_{up}(x,x')|^2$ of five fermions with label up in the box $0<x<1$ as a heat map (both axes the position; bright means large); a contact interaction uses only its diagonal $x=x'$ (dashed). Right: the local Hartree energy density, the local exchange energy density and their sum $g_c\, n_{up} n_{down}$ along the box (5 up and 3 down fermions, $g_c=1$): exchange removes the same-label part of the Hartree energy point by point. ## 12. The same exchange for the 16-component field dirac16complex

The Kohn-Sham model of the dirac16complex field in the Revision record has the
contact interaction $U = (\lambda/2)\,S^2$ with the scalar density
$S = \bar\Psi\Psi = \Psi^\dagger C\,\Psi$. Its expectation values follow the rule
$\langle\Psi^\dagger M\Psi\rangle = \mathrm{Tr}(M\rho)$ with a local
$16 \times 16$ one-body matrix $\rho$, and Wick's theorem gives, exactly as for the
labels above,

$$e_H = \frac{\lambda}{2}\,(\mathrm{Tr}\,C\rho)^2, \qquad
e_x = -\frac{\lambda}{2}\,\mathrm{Tr}(C\rho\,C\rho).$$

(For $g$ ordinary labels the vertex is the unit matrix and $\rho = (n/g)\,1$, which
gives back $e_x = -\frac{g_c}{2}\,n^2/g$.) For the uniform good-sector gas the
Revision record finds $\rho = (n B + S C)/16$, with the number density
$n = \mathrm{Tr}(B\rho)$ and $B = -i\,C\gamma^{(x4)}$. The next cell reads the
author's gamma matrices EXACTLY (as fractions) from the Revision record, builds $C$
and $B$, and checks them against the matrices stored in the same record.
```

In [16]:

```
import sympy as sp  # exact algebra with fractions and symbols

## 13. What the Revision record says about the dirac16complex model

Section 12 recomputed the exchange formulas of the Revision record from the gamma
matrices. The record also states on what these formulas rest, how good they are,
and how the Kohn-Sham model of dirac16complex that uses them must be read. The
next two cells read these entries and check each of them, so that a change of the
```

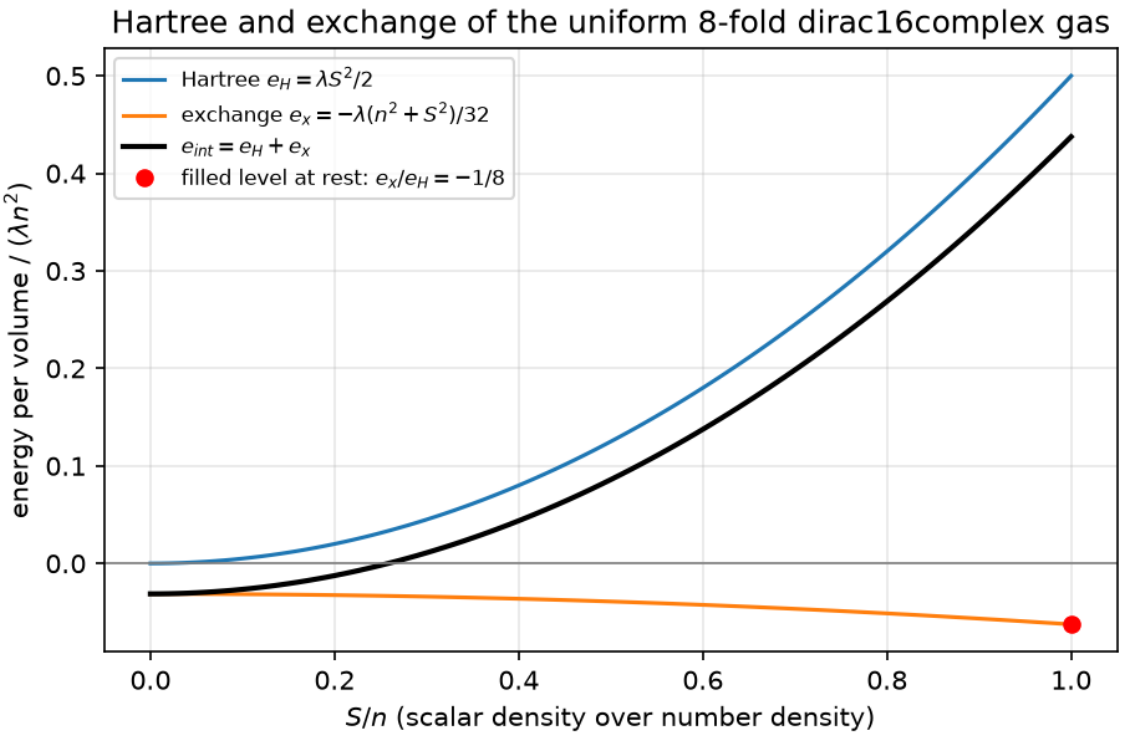

Figure 360: The Hartree energy $e_H = \lambda S^2/2$, the exchange energy $e_x = -\lambda(n^2 + S^2)/32$ and their sum per unit volume of the uniform good-sector gas of dirac16complex, in units of λn^2, against S/n (pure number), as recorded in the Revision Kohn-Sham theory and reproduced here from the gamma matrices. The red point is one filled level at rest ($S = n$), where $e_x = -e_H/8$, the rule $-1/g$ with $g = 8$. (Notebook 13b, figure 9.)

```
record stops this notebook with a failed check. A **report** of the record is a
file that lists checks, each with a name and a verdict (PASS or FAIL). The first
cell checks:

- the algebra report of the Wolfram verification: the checks reality (the gamma
  matrices are real), Clifford_relation
  ($\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}$) and C_real_symmetric are PASS;
- the Wolfram verification of the Kohn-Sham theory, a second program independent
  of the sympy one: the checks exchange_uniform_gas and ks_potentials (the formulas
  of section 12) and exchange_slab_exact_fock are PASS;
- the sympy verification: the checks exchange_slab_exact_fock and
  hf_wick_contraction (the rule of Wick's theorem that section 12 used) are PASS;
- what is approximate: for the non-uniform Kohn-Sham states the exact (Fock)
  exchange is still local but differs from the uniform-gas formula by
  $+\frac{\lambda}{32}Q^2$ per volume, where $Q$ is a further density; the theory
  file labels this entry DIAGNOSTIC, the solver's parameter file states the same
  difference, and the solver reports it in the column deltaE_x_exact_fock_diag of
  its table exact-fock-variant.csv; and the functional has no correlation term.
```

Text cell:

```
The second cell checks how the Kohn-Sham model of dirac16complex must be read:

- the solver's parameter file: the temperatures $T = 0.01$, $0.02$ and $0.05$ (in
  units of the mass $m$), and the first excited state by an ensemble Delta-SCF
  (one particle moved from the highest occupied group of equal levels to the
  lowest empty group, spread evenly over each group);
- which levels the particles fill is a CONVENTION of the theory file whose
  justification is OPEN, and the history $a_4 = AHx_4$ along which the states are
  computed is a PRESCRIBED BACKGROUND (the parameter file says so);
- the report on the source conditions of the $a_4$ field equations: the checks
  ks_history_is_a_prescribed_background, ks_profiles_violate_algebraic_condition
  (the Kohn-Sham states violate the condition $p_3 + p_t = 2p_0$ that the $a_4$
  equations put on their source) and ks_profiles_depend_on_x0 (their profiles
  depend on the hidden coordinate $x_0$) are PASS;
- the pairing theorem T3 (the Kohn-Sham universes of mass $+M$ and $-M$ have equal
  energies and energy-momentum tensors) is checked by two independent programs, a
  Python one and a Wolfram one; ten checks of the theorem that are present in
  both reports (the maps of the block Hamiltonian, of its equation, of the tip condition
  and of the brane parities, the orbital densities, the mean field, the equality
  of the energies and energy-momentum profiles, the exact spectra at zero
  momentum, the matrix $\Gamma$ as the block map, and the mirror copy) are PASS in
  both. T3 is an exact map between two sets of solutions; it does not show that
  any universe is created.

## 15. What this notebook showed

- The density matrix of one label of the uniform gas is $n_\sigma F(k_F R)$ with
  $F(s) = 3(\sin s - s\cos s)/s^3$; finite boxes approach it as they grow.
- The Pauli principle digs an exchange hole of depth $1/g$ at contact; a contact
  interaction therefore feels only pairs of different labels:
  $E_H + E_x = \frac{g_c}{2}\int n^2(1 - 1/g)$, i.e. $E_x = -E_H/g$, and for a single
  label the interaction cancels completely.
- The exchange energy of a contact interaction is EXACTLY local, for the uniform gas
  and for every Slater determinant (with label-mixing orbitals it is local in the
  local $2\times 2$ density matrix); a finite range spoils this when the range
  becomes comparable with the size $1/k_F$ of the exchange hole. The Coulomb
  interaction gives Dirac's $-\frac34(3/\pi)^{1/3}n^{4/3}$ instead.
- In the exchange-only picture a strong contact repulsion makes the unpolarized gas
  unstable at $g_c n^{1/3} = \frac23(3\pi^2)^{2/3}$.
- For the 16-component field the vertex is the matrix $C$, and the same Wick rule
  gives $e_x = -\frac{\lambda}{32}(n^2 + S^2)$, $M_{eff} = m + \frac{15}{16}\lambda S$,
  $v_v = -\frac{1}{16}\lambda n$ and the filled-shell ratio $-1/8$: exactly the
  numbers of the Revision Kohn-Sham theory and of its solver (REPRODUCED here from
  the gamma matrices).
- The Revision record verifies these formulas with two independent programs and
  states their limits: the exact Fock exchange of the non-uniform Kohn-Sham states
  differs by $+\frac{\lambda}{32}Q^2$ (a DIAGNOSTIC of the record), there is no
  correlation term, the filling of the levels is a CONVENTION, and the history
  $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND; ten checks of theorem T3 are PASS
  in both of its reports (CHECKED here by reading the record).
```

13.20 Line-by-line walk-through of Notebook 13b

The notebook has 21 code cells. **In [1]** is the set-up cell, identical to In [1] of Notebook 13c (explained line by line in Section 13.14) except that its name is `"13b"` and its comment lines hold the instructions of Section 13.18.

In [2], the function F.

```
import numpy as np  # arrays, matrices and linear algebra
```

The cell loads numpy under the short name `np`, as in Notebook 13c.

```
def F(s):
    """F(s) = 3 (sin s - s cos s) / s^3, the density matrix of one label over n."""
    s = np.asarray(s, dtype=float)
    result = 1.0 - s ** 2 / 10.0 + s ** 4 / 280.0  # the Taylor series near 0
    big = s >= 1e-3  # where the closed form is accurate
    sb = s[big]
    result[big] = 3.0 * (np.sin(sb) - sb * np.cos(sb)) / sb ** 3
    return result
```

`np.asarray(s, dtype=float)` turns the argument, a number or an array, into an array of floating-point numbers. For small s the closed form divides two tiny numbers and loses digits, so the function first fills `result` with the Taylor series of Section 13.15 everywhere, then marks the places where $s \geq 10^{-3}$ (`big` is an array of true and false values), takes those values (`s[big]`) and overwrites the result there with the closed form.

```
s_test = 1e-3
closed = 3.0 * (np.sin(s_test) - s_test * np.cos(s_test)) / s_test ** 3
series = 1.0 - s_test ** 2 / 10.0 + s_test ** 4 / 280.0
say(f"at s = 0.001: closed form {closed:.12f}, series {series:.12f}")
check(abs(closed - series) < 1e-8,
      "the closed form and the series agree at s = 0.001 (to about 9 digits)")
```

At the switching point both forms are computed and printed with 12 decimals: 0.999999899944 and 0.999999900000. They differ by $6 \cdot 10^{-11}$: the closed form has already lost several digits to rounding (the exact value is $1 - 10^{-7} + 3.6 \cdot 10^{-15}$), which is why the series is used below this point.

In [3], box sums.

```
s_grid = np.linspace(0.0, 12.0, 121)  # s = k_F R from 0 to 12
box_results = {}
for m_F in (4, 8, 16, 32):
    m = np.arange(-m_F, m_F + 1)  # the possible integers m_x, m_y, m_z
    my, mz = np.meshgrid(m, m, indexing="ij")  # all pairs (m_y, m_z)
    q = my ** 2 + mz ** 2
    counts = np.array([np.count_nonzero(q < m_F ** 2 - mx ** 2) for mx in m])
    N_label = int(counts.sum())  # occupied plane waves of one label
```

For spheres of radius $m_F = 4, 8, 16, 32$ lattice steps: `np.arange(-m_F, m_F + 1)` is the list of integers from $-m_F$ to m_F; `np.meshgrid` makes all pairs (m_y, m_z), and `q` their $m_y^2 + m_z^2$. For each m_x, `np.count_nonzero(q < m_F ** 2 - mx ** 2)` counts the pairs with $m_x^2 + m_y^2 + m_z^2 < m_F^2$: the number $c(m_x)$ of occupied plane waves with this m_x. Their sum is N_σ.

```
    kF_ell = 2.0 * np.pi * (3.0 * N_label / (4.0 * np.pi)) ** (1.0 / 3.0)
    R_over_ell = s_grid / kF_ell  # the separations R / ell for these s
    ratio = np.array([np.sum(counts * np.cos(2.0 * np.pi * m * r))
                      for r in R_over_ell]) / N_label
    box_results[m_F] = (N_label, ratio)
```

```
    deviation = np.max(np.abs(ratio - F(s_grid)))
    say(f"m_F = {m_F:2d}: {N_label:6d} plane waves; largest difference from "
        f"F = {deviation:.5f}")
```

The Fermi wave number is defined by the count, $N_\sigma = \frac{4}{3}\pi(k_F\ell/2\pi)^3$, solved for $k_F\ell$. For each s the separation is $R/\ell = s/(k_F\ell)$, and `ratio` is the box sum $\frac{1}{N_\sigma}\sum_{m_x} c(m_x)\cos(2\pi m_x R/\ell)$ of Section 13.15. The cell stores the result and prints the largest difference from F on the grid of s.

```
deviations = [np.max(np.abs(box_results[m_F][1] - F(s_grid)))
              for m_F in (4, 8, 16, 32)]
shrinking = all(a > b for a, b in zip(deviations, deviations[1:]))
check(shrinking and deviations[-1] < 2e-3,
      "the box sums approach the closed form F as the box holds more particles")
```

`zip(deviations, deviations[1:])` pairs each difference with the next one; `all(a > b ...)` is true when every difference is larger than the next. The check also requires the largest box to be within $2 \cdot 10^{-3}$ of F. The printed differences are 0.03729, 0.01218, 0.00184 and 0.00083 for 251, 2103, 17071 and 137059 plane waves.

In [4], the density matrix as a picture.

```
fig, ax = plt.subplots()
ax.plot(s_grid, F(s_grid), color="black", lw=2.0,
        label="continuum $F(k_F R) = 3(\\sin s - s\\cos s)/s^3$")
```

One panel; the closed form F on the 121 values of s as a thick black line. In the label, `\\sin` reaches matplotlib as `\sin`, which it draws as the function name sin.

```
for m_F, marker in ((4, "o"), (32, "x")):
    N_label, ratio = box_results[m_F]
    ax.plot(s_grid[::3], ratio[::3], marker, ms=4,
            label=f"box sum, {N_label} plane waves")
ax.axhline(0.0, color="gray", lw=0.8)
```

For the smallest box ($m_F = 4$, circles, style `"o"`) and the largest ($m_F = 32$, crosses, `"x"`) the loop takes the stored count and box sum and draws every third value (`[::3]` takes the entries 0, 3, 6, ...), as markers without a connecting line, so that the black curve stays visible; the label gives the number of plane waves. `axhline(0.0, ...)` draws the zero line.

```
ax.set_xlabel("$s = k_F R$ (separation times Fermi wave number)")
ax.set_ylabel("$\\rho_\\sigma(R) / n_\\sigma$")
ax.set_title("Density matrix of one label of the uniform gas")
ax.legend(fontsize=8)
save_figure(fig, "density_matrix",
```

Axis labels (both quantities are pure numbers), title, legend and `save_figure` for Figure 13b.1; one line of its caption is an f-string that writes the two plane-wave counts, 251 and 137059, into the caption.

What Figure 13b.1 shows. The density matrix of one label starts at 1 for $R = 0$ (there it is the density itself), falls to zero near $k_F R = 4.5$ (the first zero of $\sin s - s\cos s$, where $\tan s = s$), swings to a small negative minimum of about -0.086 near $k_F R = 5.76$, and oscillates with a shrinking amplitude. A fermion "remembers" another one of its label only within a distance of a few $1/k_F$. The crosses of the large box lie on the curve; the circles of the small box (251 plane waves) deviate visibly beyond $k_F R \approx 4$, by at most 0.037.

In [5], the exchange hole.

```
s_fine = np.linspace(0.0, 10.0, 501)
fig, ax = plt.subplots()
for g in (1, 2, 8):
    pair = 1.0 - F(s_fine) ** 2 / g  # the pair distribution
    ax.plot(s_fine, pair, label=f"$g = {g}$ labels: $g_{{pair}}(0) = {1 - 1 / g:.3f}$")
    check(abs(pair[0] - (1.0 - 1.0 / g)) < 1e-15,
          f"the pair distribution at contact is 1 - 1/g for g = {g}")
```

For $g = 1, 2, 8$ the cell computes $g_{pair} = 1 - F^2/g$ of Section 13.15 on 501 values of s from 0 to 10, draws it (in an f-string a doubled brace prints one brace, so the label shows g_{pair}, followed by the value $1 - 1/g$ with three decimals), and checks its value at $s = 0$, the first entry `pair[0]`.

```
ax.axhline(1.0, color="gray", ls="--", lw=0.8)
ax.set_xlabel("$k_F R$")
ax.set_ylabel("pair distribution $g_{pair}(R)$")
ax.set_title("The exchange hole of the uniform gas")
ax.legend(fontsize=8)
save_figure(fig, "exchange_hole",
```

A grey dashed horizontal line at 1 (the keyword `ls`, short for line style, set to two hyphens, makes it dashed), the value without the Pauli principle; axis labels, title, legend, and `save_figure` for Figure 13b.2.

What Figure 13b.2 shows. Far from a fermion (beyond about $k_F R = 4$) all three curves are at 1: there the Pauli principle has no effect. Near it they dip to $1 - 1/g$ at contact: to 0 for one label (no second fermion can come close), to $\frac{1}{2}$ for two labels (only the half with the other label can), and to 0.875 for eight labels. The more labels, the shallower the hole, because a smaller fraction $1/g$ of the other fermions shares the first one's label.

In [6], contact energies.

```
G_C = 1.0  # the strength of the contact interaction
densities = np.linspace(0.0, 2.0, 41)  # n from 0 to 2 (particles per volume)

def contact_energies(n, g):
    """(e_H, e_x) per volume for g equally occupied labels: n_sigma = n / g."""
    e_hartree = 0.5 * G_C * n ** 2
    e_exchange = -0.5 * G_C * g * (n / g) ** 2  # -(g_c/2) sum over g labels
    return e_hartree, e_exchange
```

The function returns $e_H = \frac{g_c}{2} n^2$ and $e_x = -\frac{g_c}{2} \sum_\sigma n_\sigma^2$ with the g equal label densities n/g, for 41 densities from 0 to 2.

```
for g in (1, 2, 8):
    e_hartree, e_exchange = contact_energies(densities, g)
    ratio = e_exchange[1:] / e_hartree[1:]  # skip n = 0 (0/0)
    check(np.allclose(ratio, -1.0 / g, rtol=0, atol=1e-15),
          f"e_x = -e_H/g for g = {g}")
e_hartree, e_exchange = contact_energies(densities, 1)
check(np.max(np.abs(e_hartree + e_exchange)) == 0.0,
      "for a single label the contact interaction cancels exactly")
```

`[1:]` leaves out the first entry, $n = 0$, where the ratio would be $0/0$. Three checks of $e_x/e_H = -1/g$, and one that for $g = 1$ the sum is exactly zero.

In [7], the energies as pictures.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.0), sharey=True)
for ax, g in zip(axes, (2, 8)):
    e_hartree, e_exchange = contact_energies(densities, g)
    ax.plot(densities, e_hartree, label="Hartree $e_H = g_c n^2/2$")
    ax.plot(densities, e_exchange, label=f"exchange $e_x = -e_H/{g}$")
    ax.plot(densities, e_hartree + e_exchange, color="black", lw=2.0,
            label="sum $e_H + e_x$")
```

Two panels with a common vertical axis (`sharey=True`: both use the same scale, so the curves can be compared by eye). For $g = 2$ (left panel) and $g = 8$ (right panel) the loop computes the two energy densities on the 41 densities and draws e_H, e_x and, as a thick black line, their sum.

```
    ax.axhline(0.0, color="gray", lw=0.8)
    ax.set_xlabel("density $n$")
    ax.set_title(f"$g = {g}$ labels")
    ax.legend(fontsize=8)
axes[0].set_ylabel("energy per volume (units of $g_c$)")
save_figure(fig, "contact_energies",
```

Still inside the loop: the zero line, the horizontal label, a title that names g, and a legend for each panel. After the loop, only the left panel (`axes[0]`) gets the vertical label, which the right panel shares; `save_figure` saves Figure 13b.3.

What Figure 13b.3 shows. The Hartree energy $n^2/2$ is the same parabola in both panels (it reaches 2 at $n = 2$). The exchange energy mirrors a part of it below zero: half of it for two labels (-1 at $n = 2$), one eighth for eight labels (-0.25). The sum is therefore half of the Hartree energy for $g = 2$ and seven eighths of it for $g = 8$: the more labels, the larger the fraction of pairs that can meet, and the less exchange removes.

In [8], a finite range.

```
def simpson(values, step):
    """Simpson's rule for equally spaced values (an odd number of them)."""
    return step / 3.0 * (values[0] + values[-1] + 4.0 * values[1:-1:2].sum()
                         + 2.0 * values[2:-1:2].sum())
```

Simpson's rule of Section 13.15: `values[1:-1:2]` are the entries 1, 3, 5, ... (every second one, starting at 1, without the last), weighted 4; `values[2:-1:2]` are the inner even entries 2, 4, ..., weighted 2; the two ends are weighted 1.

```
s_int = np.linspace(0.0, 80.0, 400001)  # s = k_F R; the Gaussian is tiny beyond
ds = s_int[1] - s_int[0]
F2 = F(s_int) ** 2

def exchange_ratio(kF_a):
    """e_x(a) / e_x(0) for the Gaussian of range a (k_F a given)."""
    norm = (2.0 * np.pi * kF_a ** 2) ** -1.5  # makes the integral of w_a equal g_c
    gauss = norm * np.exp(-s_int ** 2 / (2.0 * kF_a ** 2))
    return simpson(4.0 * np.pi * s_int ** 2 * gauss * F2, ds)
```

The integral of Section 13.15 is written in the variable $s = k_F R$, so lengths are measured in units of $1/k_F$ and the range enters only as $k_F a$: the ratio is $\int_0^\infty 4\pi s^2 \, (2\pi (k_F a)^2)^{-3/2} e^{-s^2/(2(k_F a)^2)} F(s)^2 \, ds$, integrated by Simpson's rule on 400001 points from 0 to 80 (spacing 0.0002; beyond 80 the Gaussian is negligible for the ranges used).

```
ranges = np.logspace(-2, 1, 31)  # k_F a from 0.01 to 10
ratios = np.array([exchange_ratio(r) for r in ranges])
for r in (0.01, 0.1, 1.0):
    say(f"k_F a = {r:5.2f}: e_x(a)/e_x(0) = {exchange_ratio(r):.6f}, "
        f"small-a formula {1.0 - 0.6 * r ** 2:.6f}")
check(abs(exchange_ratio(0.05) - (1.0 - 0.6 * 0.05 ** 2)) < 1e-5,
      "for small range the ratio is 1 - (3/5)(k_F a)^2")
check(np.all(np.diff(ratios) < 0.0) and ratios[0] > 0.9999,
      "the exchange energy grows towards the contact value as the range shrinks")
```

`np.logspace(-2, 1, 31)` gives 31 numbers from 10^{-2} to 10^{1}, equally spaced on a logarithmic scale. The printed lines compare the ratio with $1 - \frac{3}{5}(k_F a)^2$: they agree at $k_F a = 0.01$ (0.999940) and nearly at 0.1, and differ at 1 (0.588864 against 0.4), where the expansion no longer holds. The checks: the small-range formula at $k_F a = 0.05$, and the ratio falls with every increase of the range and is above 0.9999 at the smallest one.

In [9], the ratio as a picture.

```
fig, ax = plt.subplots()
ax.semilogx(ranges, ratios, "o-", ms=3, color="black",
            label="$e_x(a)/e_x(0)$, Gaussian of range $a$")
small = ranges[ranges < 0.6]
ax.semilogx(small, 1.0 - 0.6 * small ** 2, "--",
            label="small-range formula $1 - (3/5)(k_F a)^2$")
```

`ax.semilogx` draws like `plot`, but with a logarithmic horizontal axis, on which the 31 ranges from 10^{-2} to 10 are equally spaced. The black dots joined by a line are the computed ratios. `ranges[ranges < 0.6]` keeps only the ranges below 0.6 (an array indexed by an array of true and false values keeps the entries where the value is true), and for them the dashed curve is the small-range formula $1 - \frac{3}{5}(k_F a)^2$; for larger ranges the formula is meaningless (it becomes negative beyond $k_F a = 1.29$).

```
ax.set_ylim(0.0, 1.05)
ax.set_xlabel("range times Fermi wave number, $k_F a$")
ax.set_ylabel("exchange energy relative to contact")
ax.set_title("A finite-range interaction shrinking to a contact")
ax.legend(fontsize=8)
save_figure(fig, "finite_range",
```

`set_ylim(0.0, 1.05)` fixes the vertical range from 0 to 1.05; then the labels, the title, the legend and `save_figure` for Figure 13b.4.

What Figure 13b.4 shows. For ranges up to about $k_F a = 0.1$ the ratio is indistinguishable from 1: the interaction acts as a contact, and its exchange energy is the local contact value. Between 0.1 and 1 the ratio falls, first along the dashed parabola $1 - \frac{3}{5}(k_F a)^2$, then faster (0.589 at $k_F a = 1$), and for $k_F a = 10$ it is nearly 0: when the interaction reaches much farther than the exchange hole (size $1/k_F$), only a small part of it acts inside the hole, and the exchange energy almost disappears relative to the contact value.

In [10], Dirac's exchange.

```
S_MAX = 4000.0
s_long = np.linspace(0.0, S_MAX, 4000001)
integral_9_4 = simpson(s_long * F(s_long) ** 2, s_long[1] - s_long[0])
integral_9_4 += 9.0 / (4.0 * S_MAX ** 2)  # the tail beyond S_MAX
report("integral of s F(s)^2 from 0 to infinity", f"{integral_9_4:.8f}")
check(abs(integral_9_4 - 2.25) < 1e-7, "the Coulomb exchange integral is 9/4")
```

$\int_0^{4000} sF(s)^2\,ds$ by Simpson's rule on 4000001 points (spacing 0.001), plus the tail $9/(4 \cdot 4000^2)$ of Section 13.15 (`+=` adds to the variable). The result prints as 2.25000000 and the check requires it to be within 10^{-7} of 9/4.

```
dirac = 0.75 * (3.0 / np.pi) ** (1.0 / 3.0)  # e_x = -dirac n^(4/3)
n_test = 0.3
kF_test = (3.0 * np.pi ** 2 * n_test) ** (1.0 / 3.0)  # g = 2
e_x_coulomb = -4.0 * np.pi * (n_test / 2) ** 2 / kF_test ** 2 * integral_9_4
report("Dirac's constant (3/4)(3/pi)^(1/3)", f"{dirac:.6f}")
check(abs(e_x_coulomb + dirac * n_test ** (4.0 / 3.0)) < 1e-8,
      "the Coulomb exchange of the electron gas is -(3/4)(3/pi)^(1/3) n^(4/3)")
```

Dirac's constant is 0.738559. At the density $n = 0.3$ the cell evaluates $e_x = -4\pi n_\sigma^2\, I/k_F^2$ with $n_\sigma = n/2$ and the computed integral I, and checks that it equals $-0.738559\, n^{4/3}$.

In [11], exchange per particle.

```
n_values = np.logspace(-3, 1, 41)
contact_per_particle = 0.25 * G_C * n_values  # |e_x / n| for the contact, g = 2
coulomb_per_particle = dirac * n_values ** (1.0 / 3.0)  # |e_x / n|, Coulomb
slope_contact = np.polyfit(np.log(n_values), np.log(contact_per_particle), 1)[0]
slope_coulomb = np.polyfit(np.log(n_values), np.log(coulomb_per_particle), 1)[0]
```

For 41 densities from 10^{-3} to 10, the sizes of the exchange energy per particle: $g_c n/4$ for the contact with two labels ($e_x/n = -\frac{g_c}{2 \cdot 2} n$) and $0.738559\, n^{1/3}$ for the Coulomb gas. `np.polyfit(X, Y, 1)` fits

the straight line $Y = pX + c$ through the points, and `[0]` takes its slope p; with $X = \ln n$ and Y the logarithm of a power n^p, the slope is the power.

```
say(f"slopes: contact {slope_contact:.6f}, Coulomb {slope_coulomb:.6f}")
check(abs(slope_contact - 1.0) < 1e-12 and abs(slope_coulomb - 1.0 / 3.0) < 1e-12,
      "exchange per particle grows like n (contact) and n^(1/3) (Coulomb)")
```

The cell prints the slopes 1.000000 and 0.333333 and checks them to 10^{-12} (the points lie exactly on straight lines, so the fit is exact up to rounding).

```
fig, ax = plt.subplots()
ax.loglog(n_values, contact_per_particle, label="contact, $g_c = 1$: $n/4$")
ax.loglog(n_values, coulomb_per_particle, "--",
          label="Coulomb (Dirac): $0.7386\\,n^{1/3}$")
ax.set_xlabel("density $n$")
ax.set_ylabel("$|e_x|/n$, exchange energy per particle")
ax.set_title("Exchange per particle: contact versus Coulomb ($g = 2$)")
ax.legend()
save_figure(fig, "contact_vs_coulomb",
```

`ax.loglog` draws with both axes logarithmic: the contact curve solid, the Coulomb curve dashed (in the label, `\\,` is a small space in the formula). Labels, title, legend and `save_figure` for Figure 13b.5.

What Figure 13b.5 shows. On logarithmic axes both curves are straight lines: the contact exchange per particle rises with slope 1 (ten times the density gives ten times the exchange per particle), the Coulomb exchange with slope 1/3. The lines cross where $n/4 = 0.7386\, n^{1/3}$, at $n = (2.954)^{3/2} \approx 5.1$: below that density the Coulomb exchange per particle is the larger one, above it the contact exchange.

In [12], exact locality for a non-uniform determinant.

```
P = 99  # interior grid points of the box 0 < x < 1
h = 1.0 / (P + 1)
x = h * np.arange(1, P + 1)
W = G_C * np.eye(P) / h  # the contact interaction on the grid

def box_orbitals(count):
    """The lowest box orbitals sqrt(2) sin(m pi x), m = 1..count, as columns."""
    return np.array([np.sqrt(2.0) * np.sin(m * np.pi * x)
                     for m in range(1, count + 1)]).T
```

A line $0 < x < 1$ with 99 grid points, spacing $h = 1/100$. On the grid the delta function is the unit matrix divided by h (a sum over the grid times h then gives back g_c). `box_orbitals(count)` returns the lowest orbitals of a particle in the box as the columns of a matrix (`.T` transposes the list of rows).

```
phi_up, phi_down = box_orbitals(5), box_orbitals(3)
rho_up = phi_up @ phi_up.T  # rho_up(x, x') = sum_a phi_a(x) phi_a(x')
```

```
rho_down = phi_down @ phi_down.T
n_up, n_down = np.diag(rho_up), np.diag(rho_down)  # the label densities
fock = -0.5 * h * h * (np.sum(rho_up ** 2 * W) + np.sum(rho_down ** 2 * W))
local = -0.5 * G_C * h * np.sum(n_up ** 2 + n_down ** 2)
```

Five fermions with label up and three with label down. The matrix product of the orbital columns with their transpose is the density matrix of each label, $\rho(x,x') = \sum_a \phi_a(x)\phi_a(x')$, and its diagonal the label density. `fock` is the two-point exchange $-\frac{1}{2}\sum_{x,x'} h^2 |\rho_\sigma(x,x')|^2 W(x,x')$ summed over the labels (`rho_up ** 2 * W` multiplies entry by entry); `local` is $-\frac{g_c}{2}\sum_x h\,(n_\uparrow^2 + n_\downarrow^2)$.

```
report("exchange energy, two-point (Fock) form", f"{fock:.10f}")
report("exchange energy, local form", f"{local:.10f}")
check(abs(h * n_up.sum() - 5.0) < 1e-12 and abs(h * n_down.sum() - 3.0) < 1e-12,
      "the box determinant holds 5 up and 3 down fermions")
check(abs(fock - local) < 1e-12,
      "the contact exchange of a non-uniform determinant is exactly local")
```

Both forms print as -19.0000000000 (Exercise 10 derives this number by hand). The checks require the particle numbers $h\sum n_\uparrow = 5$ and $h\sum n_\downarrow = 3$ and the agreement of the two forms to 10^{-12}. (On the grid the two forms are equal term by term, because W is zero off the diagonal; the check confirms that the code implements both formulas correctly.)

In [13], label-mixing orbitals.

```
rng = np.random.default_rng(12345)  # a fixed seed: the same numbers every run
raw = rng.normal(size=(2 * P, 5)) + 1j * rng.normal(size=(2 * P, 5))
q_matrix = np.linalg.qr(raw)[0]  # five orthonormal columns of length 2P
spinor = (q_matrix / np.sqrt(h)).reshape(P, 2, 5)  # [point, label, orbital]
```

Five random orthonormal complex columns of length 2×99 (the QR factorisation of a random matrix with a fixed seed), divided by $\sqrt{h}$ so that $\sum |\phi|^2 h = 1$. `.reshape(P, 2, 5)` reads each column as 99 pairs of numbers: `spinor[x, s, a]` is the value of orbital a at the point x with the label s. Each orbital now has an up part and a down part.

```
# pair[x, a, b] = sum over the label of phi_a*(x, label) phi_b(x, label)
pair = np.einsum("xsa,xsb->xab", spinor.conj(), spinor)
exact = -0.5 * G_C * h * np.sum(np.abs(pair) ** 2)
# rho[x, s, t] = sum_a phi_a(x, s) phi_a*(x, t): the local 2 x 2 density matrix
rho_local = np.einsum("xsa,xta->xst", spinor, spinor.conj())
local_all = -0.5 * G_C * h * np.sum(np.abs(rho_local) ** 2)
diagonal = np.einsum("xss->xs", rho_local).real  # n_up(x), n_down(x)
local_diagonal = -0.5 * G_C * h * np.sum(diagonal ** 2)
```

The two comment lines (they start with `#` and are not executed) state in formulas what the line below each of them computes. `pair[x, a, b]` is $\sum_s \phi_a^*(xs)\,\phi_b(xs)$, and `exact` is the exact exchange $-\frac{1}{2}\sum_{a,b} w_{abba}$ with $w_{abba} = g_c \sum_x h\,|\sum_s \phi_a^*\phi_b|^2$, which is the integral of Section 13.4 for a label-independent contact (put $w = g_c\,\delta$ into w_{abba} and do the delta integral). `rho_local[x, s, t]` is the local 2×2 density matrix $\sum_a \phi_a(xs)\phi_a^*(xt)$, and `local_all` the local formula of Section 13.15 with all label pairs. `np.einsum("xss->xs", ...)` takes the diagonal of each 2×2 matrix (the label densities), and `local_diagonal` the local formula with the diagonal only.

```
say(f"exact {exact:.10f}; local, all label pairs {local_all:.10f}; "
    f"local, label diagonal only {local_diagonal:.10f}")
check(abs(exact - local_all) < 1e-10,
      "with label-mixing orbitals the exchange is local in the 2 x 2 matrix rho")
check(abs(exact - local_diagonal) > 0.1,
      "the label diagonal alone misses the label-mixing exchange")
```

The cell prints -8.7398756465, -8.7398756465 and -7.5021209026 and checks that the first two agree to 10^{-10} and that the third differs from them by more than 0.1 (it misses 1.2377547439, the part of the exchange carried by the off-diagonal entries of the local 2×2 matrix).

In [14], the two-point function and the local energies.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2))
image = left.imshow(rho_up ** 2, origin="lower", extent=(0, 1, 0, 1),
                    cmap="viridis")
left.plot([0, 1], [0, 1], "w--", lw=1.0)  # the diagonal x = x'
left.set_xlabel("$x$")
left.set_ylabel("$x'$")
left.set_title("$|\\rho_{up}(x, x')|^2$, 5 up fermions in a box")
fig.colorbar(image, ax=left, shrink=0.85)
```

On the left, `rho_up ** 2` (the square of every entry; the entries are real) is $|\rho_\uparrow(x, x')|^2$ of the box determinant, drawn as a heat map over the square $0 < x, x' < 1$; the style string (the letter w, for white, and two hyphens) draws the diagonal $x = x'$ as a white dashed line; axis labels, title and colour scale follow.

```
right.plot(x, 0.5 * G_C * (n_up + n_down) ** 2, label="Hartree $g_c n^2/2$")
right.plot(x, -0.5 * G_C * (n_up ** 2 + n_down ** 2),
           label="exchange $-g_c(n_{up}^2 + n_{down}^2)/2$")
right.plot(x, G_C * n_up * n_down, color="black", lw=2.0,
           label="sum $g_c\\,n_{up} n_{down}$")
```

On the right, along the box: the local Hartree energy density $\frac{g_c}{2}(n_\uparrow + n_\downarrow)^2$, the local exchange energy density $-\frac{g_c}{2}(n_\uparrow^2 + n_\downarrow^2)$, and (thick black) the product $g_c\, n_\uparrow n_\downarrow$, which Section 13.5 showed to be their sum.

```
right.set_ylim(-50.0, 60.0)  # room below the curves for the legend
right.set_xlabel("$x$")
right.set_ylabel("energy per length (units of $g_c$)")
right.legend(fontsize=7, loc="lower center")
save_figure(fig, "local_exchange",
```

`set_ylim(-50.0, 60.0)` fixes the vertical range so that the legend, placed at the bottom centre (`loc="lower center"`), does not cover the curves; labels and `save_figure` for Figure 13b.6. Then

```
check(np.allclose(0.5 * (n_up + n_down) ** 2 - 0.5 * (n_up ** 2 + n_down ** 2),
                  n_up * n_down, atol=1e-12),
      "Hartree plus exchange of a contact is g_c n_up n_down at every point")
```

confirms point by point that the Hartree plus the exchange energy density equals $g_c\, n_\uparrow n_\downarrow$ (here $g_c = 1$).

What Figure 13b.6 shows. On the left, $|\rho_\uparrow(x, x')|^2$ is large only near the diagonal, with five bright spots along it (the density of five fermions has five bumps) and faint ripples away from it: the density matrix of a determinant falls off with the distance $|x - x'|$, just as $F(k_F R)$ does in the uniform gas. A contact interaction samples only the diagonal. On the right, the Hartree energy density (up to about 52) and the exchange energy density (down to about -28) both follow the bumps of the densities, and their sum, $n_\uparrow n_\downarrow$, is everywhere smaller than the Hartree part: exchange removes, point by point, the energy of the same-label pairs.

In [15], polarisation.

```
C_F = 0.3 * (3.0 * np.pi ** 2) ** (2.0 / 3.0)
gamma_c = (2.0 / 3.0) * (3.0 * np.pi ** 2) ** (2.0 / 3.0)

def energy_polarized(zeta, coupling):
    """e(zeta) at n = 1 for g_c = coupling (exchange-only picture)."""
    kinetic_part = C_F * ((1 + zeta) ** (5 / 3) + (1 - zeta) ** (5 / 3)) / 2
    return kinetic_part + 0.25 * coupling * (1 - zeta ** 2)
```

The constants $C_F = \frac{3}{10}(3\pi^2)^{2/3}$ and $\gamma_c = \frac{2}{3}(3\pi^2)^{2/3}$, and the energy $e(\zeta)$ of Section 13.15 at $n = 1$ (so $g_c n^{1/3} = g_c$, the argument `coupling`). The exponent `5 / 3` is written with whole numbers; in Python the division `/` always gives a floating-point number, $1.6666\ldots$.

```
report("C_F", f"{C_F:.6f}")
report("threshold gamma_c = g_c n^(1/3)", f"{gamma_c:.6f}")
```

They print as $C_F = 2.871234$ and $\gamma_c = 6.380520$.

```
d = 1e-3
curvature = [(energy_polarized(d, c) - 2 * energy_polarized(0.0, c)
              + energy_polarized(-d, c)) / d ** 2
             for c in (0.99 * gamma_c, 1.01 * gamma_c)]
check(curvature[0] > 0 > curvature[1],
      "the unpolarized gas becomes unstable at g_c n^(1/3) = (2/3)(3 pi^2)^(2/3)")
```

The second difference $(e(d) - 2e(0) + e(-d))/d^2$ approximates $e''(0)$ (Section 13.2). Just below the threshold ($0.99\gamma_c$) it must be positive, just above ($1.01\gamma_c$) negative; `curvature[0] > 0 > curvature[1]` tests both at once.

```
zetas = np.linspace(-1.0, 1.0, 401)
fig, ax = plt.subplots()
for gamma in (0.5, 1.0, 1.1, 1.5):
    curve = energy_polarized(zetas, gamma * gamma_c) - energy_polarized(0.0,
                                                                        gamma * gamma_c)
    ax.plot(zetas, curve / C_F, label=f"$\\gamma = {gamma}$")
```

401 polarisations from -1 (all fermions down) to 1 (all up). For the couplings $\gamma = 0.5, 1, 1.1, 1.5$ in units of the threshold ($g_c = \gamma\,\gamma_c$), `curve` is $e(\zeta) - e(0)$ (the statement continues on the next line inside the open parenthesis), and the loop draws it divided by C_F, that is in units of $C_F n^{5/3}$ at $n = 1$.

```
ax.axhline(0.0, color="gray", lw=0.8)
ax.set_xlabel("polarization $\\zeta = (n_{up} - n_{down})/n$")
ax.set_ylabel("$(e(\\zeta) - e(0)) / (C_F n^{5/3})$")
ax.set_title("Exchange favours unequal labels at strong contact repulsion")
ax.legend()
save_figure(fig, "polarization",
```

The zero line, axis labels, title, legend and `save_figure` for Figure 13b.7.

What Figure 13b.7 shows. For $\gamma = 0.5$ the curve is a bowl with its lowest point at $\zeta = 0$: equal labels are stable. For $\gamma = 1$ it is extremely flat near $\zeta = 0$ (the second derivative vanishes there) and still rises towards $\zeta = \pm 1$. For $\gamma = 1.1$ the curve bends down at $\zeta = 0$, has shallow minima near $\zeta = \pm 0.9$ and comes back up slightly at $\zeta = \pm 1$. For $\gamma = 1.5$ it falls all the way to $\zeta = \pm 1$: in this exchange-only picture the gas would rather put every fermion into one label.

In [16], the gamma matrices, exactly.

```
import sympy as sp  # exact algebra with fractions and symbols

gamma_record = json.loads(repository_file("Revision/algebra/gammas.json")
                          .read_text(encoding="utf-8"))

def exact_matrix(rows):
    """A sympy matrix of exact fractions from the record's rows of numbers."""
    return sp.Matrix([[sp.Rational(str(entry)) for entry in row] for row in rows])
```

`sympy` computes with exact fractions and symbols. The Revision record `Revision/algebra/gammas.json` is read as text (`read_text`) and turned into Python lists and dictionaries by `json.loads`. `exact_matrix` turns a list of rows of numbers into a sympy matrix of exact fractions: `str(entry)` writes each number as text and `sp.Rational` reads that text as a fraction, so no rounding can occur.

```
gamma = [exact_matrix(rows) for rows in gamma_record["gamma"]]  # x0 .. x7
C = gamma[0] * gamma[1] * gamma[2] * gamma[3]  # C = g(x0) g(x1) g(x2) g(x3)
B = -sp.I * C * gamma[4]  # B = -i C g(x4)
B_record = (exact_matrix(gamma_record["B"]["re"])
            + sp.I * exact_matrix(gamma_record["B"]["im"]))
check(C == exact_matrix(gamma_record["C"]) and B == B_record,
      "C and B built from the gammas equal the matrices of the record")
check(C * C == sp.eye(16) and B * B == sp.eye(16) and C == C.T,
      "C is symmetric with C^2 = 1, and B^2 = 1")
```

The record lists the eight gammas in the order $x_0, \ldots, x_7$, so `gamma[k]` is $\gamma^{(xk)}$: `gamma[0]` is $\gamma^{(x0)}$ and `gamma[4]` is $\gamma^{(x4)}$; for sympy matrices `*` is the matrix product and `sp.I` is i. The first check

compares C and B with the matrices stored in the same record (B is stored as its real and imaginary parts); the second checks exactly the facts $C^2 = 1$, $B^2 = 1$ and C symmetric (`C.T` is the transpose) of Section 13.16.

In [17], the exchange of the uniform gas, exactly.

```
n_sym, S_sym, lam = sp.symbols("n S lambda", real=True)
rho = (n_sym * B + S_sym * C) / 16
check(sp.simplify((B * rho).trace() - n_sym) == 0
      and sp.simplify((C * rho).trace() - S_sym) == 0,
      "Tr(B rho) = n and Tr(C rho) = S")
e_H = sp.expand(lam / 2 * (C * rho).trace() ** 2)
e_x = sp.expand(-lam / 2 * (C * rho * C * rho).trace())
say(f"e_H = {e_H}")
say(f"e_x = {e_x}")
```

Three real symbols n, S, λ; the matrix $\rho = (nB + SC)/16$; the check that the densities come back ($\mathrm{Tr}\, B\rho = n$, $\mathrm{Tr}\, C\rho = S$; `.trace()` is the trace and `sp.simplify` brings the difference to its simplest form, which must be 0). `e_H` and `e_x` are the Hartree and exchange formulas of Section 13.16, multiplied out by `sp.expand`; they print as `S**2*lambda/2` and `-S**2*lambda/32 - lambda *n**2/32`.

```
theory = json.loads(repository_file("Revision/kohn_sham/ks-theory.json")
                    .read_text(encoding="utf-8"))
gas = theory["exchange"]["uniformGas"]
coefficient_n2 = sp.Rational(gas["coefficient_n2"])  # "-1/32" in the record
coefficient_S2 = sp.Rational(gas["coefficient_S2"])
check(e_H == lam * S_sym ** 2 / 2, "the Hartree energy is (lambda/2) S^2")
recorded = lam * (coefficient_n2 * n_sym ** 2 + coefficient_S2 * S_sym ** 2)
check(sp.expand(e_x - recorded) == 0
      and coefficient_n2 == coefficient_S2 == sp.Rational(-1, 32),
      "e_x = -(lambda/32)(n^2 + S^2)",
      record="Revision/kohn_sham/reports/ks-theory-python.json, check "
             "exchange_uniform_gas")
```

The cell reads the Revision Kohn-Sham theory record and its two exchange coefficients, stored as the texts "-1/32", which `sp.Rational` reads as exact fractions. The checks: the Hartree energy is $\frac{\lambda}{2}S^2$, and the exchange energy computed here equals the recorded one, with both coefficients $-1/32$; the PASS line names the Revision check exchange_uniform_gas that it reproduces.

In [18], the potentials and the solver's numbers.

```
e_int = e_H + e_x
mass_coefficient = sp.simplify(sp.diff(e_int, S_sym) / (lam * S_sym))  # 15/16
vector_coefficient = sp.simplify(sp.diff(e_int, n_sym) / (lam * n_sym))  # -1/16
filled_ratio = sp.simplify((e_x / e_H).subs(n_sym, S_sym))  # n = S
```

`sp.diff(e_int, S_sym)` is $\partial e_{int}/\partial S$; divided by λS it is the coefficient $15/16$ of $M_{eff} - m$; in the same way $\partial e_{int}/\partial n$ divided by λn gives $-1/16$. `.subs(n_sym, S_sym)` replaces n by S in e_x/e_H: the ratio of one filled level at rest, $-1/8$.

```
say(f"M_eff = m + ({mass_coefficient}) lambda S;  v_v = ({vector_coefficient}) "
    f"lambda n;  E_x/E_H at n = S: {filled_ratio}")
```

The printed line shows all three exact fractions: M_eff = m + (15/16) lambda S; v_v = (-1/16) lambda n; E_x/E_H at n = S: -1/8.

```
potentials = theory["exchange"]["kohnShamPotentials"]
check(mass_coefficient == sp.Rational(potentials["Meff_coefficient_of_lambda_S"])
      == sp.Rational(15, 16)
      and vector_coefficient == sp.Rational(potentials["vv_coefficient_of_lambda_n"])
      == sp.Rational(-1, 16),
      "M_eff = m + (15/16) lambda S and v_v = -(1/16) lambda n",
      record="Revision/kohn_sham/reports/ks-theory-python.json, check ks_potentials")
check(filled_ratio == sp.Rational(-1, 8),
      "one filled 8-fold level at rest: E_x/E_H = -1/8",
      record="Revision/kohn_sham/reports/ks-theory-python.json, check "
             "filled_shell_ratio")
```

The coefficients are compared with the record's texts "15/16" and "-1/16" (a chain `a == b == c` means `a == b and b == c`), and the ratio with $-1/8$; the PASS lines name the Revision checks ks_potentials and filled_shell_ratio.

```
solver = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                    .read_text(encoding="utf-8"))["theoryInputs"]
check(solver["exchangeCoefficientN2"] == solver["exchangeCoefficientS2"] == -1 / 32
      and solver["MeffCoefficientOfLambdaS"] == 15 / 16
      and solver["vvCoefficientOfLambdaN"] == -1 / 16,
      "the Revision solver uses exactly these coefficients (parameters.json)")
```

The Revision solver's parameter file stores the coefficients it uses as floating-point numbers. The fractions $-1/32$, $15/16$ and $-1/16$ have denominators that are powers of 2, so they are stored exactly in binary, and the comparison with `==` is exact.

```
report_checks = {c["name"]: c["verdict"] for c in json.loads(repository_file(
    "Revision/kohn_sham/reports/ks-theory-python.json").read_text(
    encoding="utf-8"))["checks"]}
check(all(report_checks[name] == "PASS" for name in
          ("exchange_uniform_gas", "ks_potentials", "filled_shell_ratio")),
      "the three Revision checks are recorded as PASS")
```

The last check reads the Revision report itself, makes a dictionary from check name to verdict, and requires the three checks reproduced above to be recorded as PASS.

In [19], the matrices as pictures.

```
C_numbers = np.array(C.tolist(), dtype=float)
B_imaginary = np.array([[float(sp.im(entry)) for entry in row] for row in B.tolist()])
check(all(sp.re(entry) == 0 for entry in B), "B is purely imaginary")
check(all(np.count_nonzero(row) == 1 for row in np.vstack([C_numbers, B_imaginary])),
      "every row of C and of B has exactly one nonzero entry")
```

`C.tolist()` gives the rows of the sympy matrix, which numpy turns into floating-point numbers; `sp.im` takes the imaginary part of each entry of B. The checks: every real part of B is 0, and every row of C and of B (stacked into one table by `np.vstack`) has exactly one nonzero entry.

```
fig, axes = plt.subplots(1, 2, figsize=(9.0, 4.2))
for ax, matrix, title in ((axes[0], C_numbers, "$C$ (real)"),
                          (axes[1], B_imaginary, "imaginary part of $B$")):
    image = ax.imshow(matrix, cmap="coolwarm", vmin=-1, vmax=1)
    ax.set_title(title)
    ax.set_xlabel("column")
    ax.set_ylabel("row")
fig.colorbar(image, ax=axes, shrink=0.8)
save_figure(fig, "dirac_matrices",
```

The loop goes through two triples (panel, matrix, title): C in the left panel and the imaginary part of B in the right one, each drawn as a heat map on the fixed scale from -1 (blue) to $+1$ (red), with row 0 at the top; one colour scale for both, and `save_figure` for Figure 13b.8.

What Figure 13b.8 shows. Each matrix has exactly one coloured square in every row and every column: C and B only exchange and re-sign the 16 components. C pairs the components 0 to 3 with 4 to 7 (entries -1) and 8 to 11 with 12 to 15 (entries $+1$); it is symmetric, as its picture is unchanged by a reflection in the main diagonal. The imaginary part of B pairs the first eight components with the last eight, with signs ± 1; together with the factor i this makes B Hermitian.

In [20], the exchange of the 8-fold gas as a picture.

```
ratio_values = np.linspace(0.0, 1.0, 101)  # S / n
e_H_curve = 0.5 * ratio_values ** 2  # e_H / (lambda n^2)
e_x_curve = -(1.0 + ratio_values ** 2) / 32.0  # e_x / (lambda n^2)
```

Dividing e_H and e_x by λn^2 leaves functions of S/n alone: $\frac{1}{2}(S/n)^2$ and $-(1+(S/n)^2)/32$, on 101 values of S/n from 0 to 1.

```
fig, ax = plt.subplots()
ax.plot(ratio_values, e_H_curve, label="Hartree $e_H = \\lambda S^2/2$")
ax.plot(ratio_values, e_x_curve, label="exchange $e_x = -\\lambda(n^2+S^2)/32$")
ax.plot(ratio_values, e_H_curve + e_x_curve, color="black", lw=2.0,
        label="$e_{int} = e_H + e_x$")
ax.plot([1.0], [-1.0 / 16.0], "o", color="red",
        label="filled level at rest: $e_x/e_H = -1/8$")
```

The two curves and their sum (thick black), and one red dot at $S/n = 1$, $e_x/(\lambda n^2) = -2/32 = -1/16$: the filled level at rest.

```
ax.axhline(0.0, color="gray", lw=0.8)
ax.set_xlabel("$S/n$ (scalar density over number density)")
ax.set_ylabel("energy per volume / $(\\lambda n^2)$")
ax.set_title("Hartree and exchange of the uniform 8-fold dirac16complex gas")
ax.legend(fontsize=8)
save_figure(fig, "dirac_exchange",
```

The zero line, labels, title, legend and `save_figure` for Figure 13b.9 (the lines after it are the caption). Then

```
check(abs(e_x_curve[-1] / e_H_curve[-1] + 1.0 / 8.0) < 1e-15,
      "the plotted curves give e_x/e_H = -1/8 at S = n")
```

checks that the plotted curves give $e_x/e_H = -1/8$ at $S = n$ (the last entries, `[-1]`).

What Figure 13b.9 shows. The Hartree energy grows from 0 at $S = 0$ to $\frac{1}{2}$ at $S = n$. The exchange energy is never zero: it is $-1/32$ even at $S = 0$, because its n^2 term does not depend on S, and $-1/16$ at $S = n$ (the red dot). Their sum is slightly negative for small S/n (below $S/n = \sqrt{1/15} \approx 0.26$, where $\frac{15}{32}S^2 = \frac{1}{32}n^2$) and reaches $7/16$ at $S = n$ (Exercise 9).

In [21], what the record says about the exchange formulas.

```
def verdicts(path):
    """The verdict of every check of a Revision report, by the name of the check."""
    checks = json.loads(repository_file(path).read_text(encoding="utf-8"))["checks"]
    return {entry["name"]: entry["verdict"] for entry in checks}
```

A **report** of the Revision record is a JSON file with a list `"checks"`; each entry has a `"name"` and a `"verdict"` (PASS or FAIL). The function `verdicts(path)` reads the report at the repository path `path` (with `repository_file` and `json.loads`, as in In [16]) and returns a dictionary from each check name to its verdict, built by a dictionary comprehension `{key: value for entry in checks}`.

```
ALGEBRA = "Revision/algebra/reports/wolfram-algebra.json"
KS_WOLFRAM = "Revision/kohn_sham/reports/ks-theory-wolfram.json"
KS_PYTHON = "Revision/kohn_sham/reports/ks-theory-python.json"
algebra = verdicts(ALGEBRA)
check(all(algebra[name] == "PASS"
          for name in ("reality", "Clifford_relation", "C_real_symmetric")),
      f"{ALGEBRA}: reality, Clifford_relation and C_real_symmetric are PASS")
```

The three names in capitals are the paths of three reports: the Wolfram verification of the algebra of the gamma matrices, and the Wolfram and the sympy verifications of the Kohn-Sham theory. The first check requires the algebra checks reality (the gammas are real), Clifford_relation ($\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}$) and C_real_symmetric to be PASS: the facts on which Section 13.16 builds. `all(...)` is true when the condition holds for every name in the tuple; the `f"..."` string puts the path into the name of the check, so the PASS line names the record file.

```
ks_wolfram, ks_python = verdicts(KS_WOLFRAM), verdicts(KS_PYTHON)
check(all(ks_wolfram[name] == "PASS" for name in
          ("exchange_uniform_gas", "ks_potentials", "exchange_slab_exact_fock")),
      f"{KS_WOLFRAM}: exchange_uniform_gas, ks_potentials and "
      "exchange_slab_exact_fock are PASS")
check(ks_python["exchange_slab_exact_fock"] == "PASS"
      and ks_python["hf_wick_contraction"] == "PASS",
      f"{KS_PYTHON}: exchange_slab_exact_fock and hf_wick_contraction are PASS")
```

The first line reads both Kohn-Sham reports (a comma on each side assigns two values at once). The Wolfram program, independent of the sympy one, must have the checks exchange_uniform_gas and ks_potentials (the formulas that In [17] and In [18] recomputed) and exchange_slab_exact_fock (the exact exchange of the non-uniform states, below) as PASS; the sympy program must have exchange_slab_exact_fock and hf_wick_contraction (the rule $\langle{:}S^2{:}\rangle = (\mathrm{Tr}\, V\rho)^2 - \mathrm{Tr}(V\rho V\rho)$ of Section 13.4) as PASS.

```
slab = theory["exchange"]["exactFockSlab"]  # the exact exchange of the KS states
correlation = theory["exchange"]["kohnShamPotentials"]["correlation"]
solver_file = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                         .read_text(encoding="utf-8"))
conventions = solver_file["conventions"]  # the conventions of the Revision solver
status_word = slab["status"].split(":")[0]  # the word before the first colon
say(f"exactFockSlab status: {status_word}; correlation: {correlation}")
```

`theory` is the theory file `Revision/kohn_sham/ks-theory.json`, read in In [17]. `slab` is its entry exactFockSlab, the exact Fock exchange of the Kohn-Sham states, and `correlation` the text of its entry correlation. `solver_file` is the whole parameter file of the Revision solver (In [18] kept only its part theoryInputs), and `conventions` its part conventions. `.split(":")[0]` cuts the status text at its colons and keeps the first piece. The cell prints exactFockSlab status: DIAGNOSTIC; correlation: none (Hartree plus exchange only).

```
check(slab["status"].startswith("DIAGNOSTIC")
      and "Delta E_x = +(lambda/32) int sqrt|g| Q^2" in slab["status"]
      and "+lambda Q^2/32" in conventions["exactExchange"]
      and correlation == "none (Hartree plus exchange only)",
      "ks-theory.json: the exact Fock exchange differs by +(lambda/32) Q^2 "
      "(DIAGNOSTIC; also in parameters.json); no correlation term")
```

`text.startswith(word)` is true when the text begins with the word, and `piece in text` when the piece occurs in it. The check requires four statements of the record that Section 13.16 quotes: the status of the exact exchange is DIAGNOSTIC; the theory file states that the uniform-gas exchange omits $+\frac{\lambda}{32}\int \sqrt{|g|}\, Q^2$; the solver's convention exactExchange states the same difference $+\lambda Q^2/32$; and the functional has no correlation term.

```
table = repository_file("Revision/kohn_sham/results/exx/exact-fock-variant.csv")
columns = table.read_text(encoding="utf-8").splitlines()[0].split(",")
check("deltaE_x_exact_fock_diag" in columns,
      "exact-fock-variant.csv has the column deltaE_x_exact_fock_diag")
```

The solver's table of the exact-exchange variant is a CSV file (comma-separated values: one line per row, the entries separated by commas). `.splitlines()[0]` is its first line, the header, and `.split(",")` cuts it into the column names; the check requires the column deltaE_x_exact_fock_diag, in which the solver reports the difference.

In [22], how the dirac16complex model must be read.

```
temperatures = solver_file["physics"]["temperatures"]
say(f"temperatures of the Revision solver: {temperatures}")
```

```
check(temperatures == [0.01, 0.02, 0.05]
      and "ensemble Delta-SCF" in conventions["deltaScf"],
      "parameters.json: T = 0.01, 0.02, 0.05 and the ensemble Delta-SCF (deltaScf)")
```

The solver's temperatures (in units of the mass m) are printed, temperatures of the Revision solver: [0.01, 0.02, 0.05], and compared with the list that Section 13.37 quotes (two lists are equal, `==`, when they have the same entries in the same order); the convention deltaScf must describe the ensemble Delta-SCF of Section 13.27.

```
filling = theory["thermodynamics"]["fillingConvention"]
check(filling.startswith("CONVENTION") and "its justification is OPEN" in filling
      and conventions["history"].startswith("PRESCRIBED BACKGROUND"),
      "the filling is a CONVENTION whose justification is OPEN (ks-theory.json); "
      "the history is a PRESCRIBED BACKGROUND (parameters.json)")
```

The theory file's fillingConvention must call the filling of the levels a CONVENTION whose justification is OPEN, and the solver's convention history must begin with PRESCRIBED BACKGROUND: the two status words of Section 13.37.

```
SOURCE = "Revision/field_equations_a4/reports/ks-source-conditions.json"
source = verdicts(SOURCE)
check(all(source[name] == "PASS" for name in
          ("ks_history_is_a_prescribed_background",
           "ks_profiles_violate_algebraic_condition", "ks_profiles_depend_on_x0")),
      f"{SOURCE}: ks_history_is_a_prescribed_background, "
      "ks_profiles_violate_algebraic_condition and ks_profiles_depend_on_x0 are PASS")
```

The report on the source conditions of the a_4 field equations must have the three checks named in Section 13.38 as PASS: the history is a prescribed background, the Kohn-Sham profiles violate the algebraic condition $p_3 + p_t = 2p_0$, and they depend on the hidden coordinate x_0.

```
T3_CHECKS = ("block_hamiltonian_map", "ode_map", "tip_condition_map",
             "brane_parities_exchanged", "orbital_densities", "mean_field_map",
             "energies_and_emt_profiles_equal", "exact_k0_spectra",
             "Gamma_is_the_block_map", "z2_mirror_copy_carries_minus_m_plus_lambda")
t3_python = verdicts("Revision/pairing/kohn_sham/reports/python-t3.json")
t3_wolfram = verdicts("Revision/pairing/kohn_sham/reports/wolfram-t3.json")
check(all(t3_python["T3." + name] == "PASS" for name in T3_CHECKS),
      "theorem T3: ten checks of python-t3.json (T3.<name>) are PASS")
check(all(t3_wolfram["T3_" + name] == "PASS" for name in T3_CHECKS),
      "theorem T3: the same ten checks of wolfram-t3.json (T3_<name>) are PASS")
```

`T3_CHECKS` lists ten checks of theorem T3 that are present in both of its reports: the maps of the block Hamiltonian, of its equation (ode_map), of the tip condition and of the brane parities, the orbital densities, the mean field, the equality of the energies and energy-momentum profiles, the exact spectra at zero momentum, the matrix Γ as the block map, and the mirror copy. The Python report names them with the prefix `T3.` and the Wolfram report with `T3_`; `+` joins two strings. Both checks require all ten to be PASS. The cell names these ten checks instead of requiring every check

of the two reports, because further checks may be added to the reports of T3; a renamed or failed check of the theorem itself stops the notebook.

In [23], the last check.

```
figure_names = ["density_matrix", "exchange_hole", "contact_energies",
                "finite_range", "contact_vs_coulomb", "local_exchange",
                "polarization", "dirac_matrices", "dirac_exchange"]
missing = [name for k, name in enumerate(figure_names, 1)
           if not output_file(f"{FIGURE_FOLDER}/13b_{k}_{name}.png").is_file()]
check(missing == [], "all nine figure files exist")
check(output_file(f"{FIGURE_FOLDER}/13b_9_dirac_exchange.png").is_file(),
      "the figure file 13b_9_dirac_exchange.png exists")
all_checks_passed()
```

The same lines as In [19] of Notebook 13c (Section 13.14), with the nine figure names of this notebook. The last line prints ALL 44 CHECKS PASSED (notebook 13b): one check in In [2] and In [3] each, three in In [5], four in In [6], two in In [8], In [10], In [12] and In [13] each, one in In [11], In [14] and In [15] each, two in In [16], three in In [17], four in In [18], two in In [19], one in In [20], five in In [21], five in In [22] and two in In [23].

13.21 Solving the Kohn-Sham equations: iteration and mixing

The loop of Section 13.10 is a map from an input density (or potential) to an output density, $n_{out} = G[n_{in}]$, and the self-consistent solution is a **fixed point** of this map, $G[n] = n$. The simplest loop, "the output becomes the next input" (**plain iteration**), often fails. This section shows why with a model small enough to follow by hand, and how the remedies work.

The model. Two sites L and R with the site energies $-\Delta/2$ and $+\Delta/2$, the hopping t and the on-site repulsion U, and two electrons with opposite labels in the lowest orbital. In the mean field each electron feels U times the density of the OTHER label on its site (the contact rule of Section 13.5: exchange removes the same-label half); with two electrons in the same orbital each label has the density $n_L/2$ on L and $n_R/2$ on R. So the one-electron Hamiltonian and the output density are

$$h[n_L] = \begin{pmatrix} -\frac{\Delta}{2} + \frac{U}{2} n_L & -t \\ -t & \frac{\Delta}{2} + \frac{U}{2} n_R \end{pmatrix}, \qquad n_R = 2 - n_L, \qquad n_L^{out} = 2\,|c_L|^2,$$

where (c_L, c_R) is the normalised lowest eigenvector of $h[n_L]$.

The lowest eigenvector of a real symmetric 2×2 matrix, in four steps. Take $\begin{pmatrix} a & -t \\ -t & b \end{pmatrix}$ with $t > 0$, and write $\delta = b - a$ and $D = \sqrt{\delta^2 + 4t^2}$. (1) The eigenvalues solve $(a-\epsilon)(b-\epsilon) - t^2 = \epsilon^2 - (a+b)\epsilon + ab - t^2 = 0$, so $\epsilon = \frac{1}{2}(a+b) \pm \frac{1}{2}\sqrt{(a+b)^2 - 4ab + 4t^2} = \frac{1}{2}(a+b) \pm \frac{1}{2}D$, because $(a+b)^2 - 4ab = (b-a)^2$; the lowest is $\epsilon = \frac{1}{2}(a+b) - \frac{1}{2}D$. (2) The first row of $(h-\epsilon)c = 0$ reads $(a-\epsilon)c_L - t\,c_R = 0$; since $a - \epsilon = \frac{1}{2}(a-b) + \frac{1}{2}D = \frac{1}{2}(D-\delta)$, the ratio of the components is $r = c_R/c_L = (D-\delta)/(2t)$. (3) From $D^2 - \delta^2 = 4t^2$, that is $4t^2 = (D-\delta)(D+\delta)$, we get $r^2 = (D-\delta)^2/((D-\delta)(D+\delta)) = (D-\delta)/(D+\delta)$. (4) The normalisation $|c_L|^2(1+r^2) = 1$ gives

$$|c_L|^2 = \frac{1}{1+r^2} = \frac{D+\delta}{2D} = \frac{1}{2}\Big(1 + \frac{b-a}{\sqrt{(b-a)^2+4t^2}}\Big).$$

The reduced map. Here, line by line,

$$b - a = \Big(\tfrac{\Delta}{2} + \tfrac{U}{2}(2-n_L)\Big) - \Big(-\tfrac{\Delta}{2} + \tfrac{U}{2}n_L\Big) = \Delta + U(1-n_L),$$
$$n_L^{out} - 1 = 2|c_L|^2 - 1 = \frac{b-a}{\sqrt{(b-a)^2+4t^2}}.$$

The first line subtracts the two diagonal entries and collects; the second inserts the result of step (4). With $x = n_L - 1$ (the excess of charge on L) we have $b - a = \Delta - Ux$, and the whole loop becomes one function of one number:

$$x_{out} = G(x) = \frac{\Delta - Ux}{\sqrt{(\Delta - Ux)^2 + 4t^2}}.$$

Numbers. Take $\Delta = 2$, $t = 1$, $U = 4$ (energies in units of t) and the start $n_L = 2$ (both electrons on the low site). Plain iteration gives (Notebook 13d, In [5])

step	**0**	**1**	**2**	**3**	**4**	**5**
n_L in	2.000000	0.292893	1.923880	0.353344	1.916644	0.359836
n_L out	0.292893	1.923880	0.353344	1.916644	0.359836	1.915809

and continues to jump between about 0.3607 and 1.9157 forever: when the electrons sit on L, the repulsion pushes them to R, and when they sit on R, it pushes them back. This is called **charge sloshing**. **Linear mixing** feeds back only a fraction β of the change, $n_L \leftarrow (1-\beta)\, n_L + \beta\, n_L^{out}$ (so $\beta = 1$ is plain iteration). With $\beta = \frac{1}{2}$ (Notebook 13d, In [6]):

step	**0**	**1**	**2**	**3**	**4**	**5**
n_L in	2.000000	1.146447	1.361898	1.314066	1.331307	1.325494
n_L out	0.292893	1.577350	1.266234	1.348548	1.319682	1.329519

The iteration converges to the self-consistent value $n_L^* = 1.326993$; input and output agree to 10^{-6} from step 13 on.

Why, line by line. Near the fixed point x^* write $x = x^* + e$ with a small error e. To first order (the tangent line), $G(x^* + e) = x^* + G'(x^*)\, e$. One step of linear mixing then gives

$$x^* + e_{new} = (1-\beta)(x^* + e) + \beta\,(x^* + G'(x^*)\, e) \quad \Longrightarrow \quad e_{new} = \big[1 - \beta\,(1 - G'(x^*))\big]\, e,$$

where the left equation is the mixing rule with the tangent line inserted, and the right one subtracts $x^* = (1-\beta)x^* + \beta x^*$ from both sides and collects the terms with e. So every step multiplies the error by the **convergence factor** $1 - \beta(1 - G')$, and the loop converges (for small errors) exactly when this number lies between -1 and 1. The slope follows from the chain rule: with $u = \Delta - Ux$,

$G = u\,(u^2+4t^2)^{-1/2}$ has $dG/du = (u^2+4t^2)^{-1/2} - u^2(u^2+4t^2)^{-3/2} = 4t^2(u^2+4t^2)^{-3/2}$, and $du/dx = -U$, so

$$G'(x) = -\frac{4Ut^2}{\left((\Delta - Ux)^2 + 4t^2\right)^{3/2}}.$$

Since $G' < 0$, the number $1 - G'$ is larger than 1, and the condition $-1 < 1 - \beta(1-G') < 1$ reads $0 < \beta(1-G') < 2$, that is

$$0 < \beta < \beta_{max} = \frac{2}{1 - G'(x^*)}.$$

With the numbers above, $x^* = 0.326993$ and $G'(x^*) = -1.687961$ (found by bisection in Notebook 13d, In [3]), so $\beta_{max} = 0.744058$. Plain iteration ($\beta = 1$) multiplies the error by $1 - 2.687961 = -1.688$: the error grows and changes its sign at every step, which is the sloshing, until the curvature of G (left out by the tangent line) stops the growth on a cycle of period 2. With $\beta = \frac{1}{2}$ the factor is -0.344, and the error shrinks by about a factor 3 per step, as the table shows. The choice $\beta = 1/(1-G') = 0.372029$ makes the factor zero. The stronger the repulsion, the steeper G and the smaller the step the loop may take: for $U = 2$, $G' = -0.688942$ and $\beta_{max} = 1.184174$, so even plain iteration converges, and plain iteration stops converging at the repulsion where $G'(x^*) = -1$, which Notebook 13d (In [12]) finds to be $U = 2.647393$ for $\Delta = 2$, $t = 1$. All these numbers are COMPUTED by Notebook 13d; the linear analysis that explains them is PROVED above for small errors.

Anderson mixing. For densities with many components the best β differs from direction to direction, and it is not known in advance. **Anderson mixing** remembers the last few inputs $w^{(i)}$ and their residuals $R^{(i)} = G[w^{(i)}] - w^{(i)}$, finds numbers c_i with $\sum_i c_i = 1$ that make the combined residual $\sum_i c_i R^{(i)}$ as small as possible, and takes as the next input $\sum_i c_i\,(w^{(i)} + \beta R^{(i)})$. The condition $\sum_i c_i = 1$ is built in by writing $c_i = \theta_i$ for the older passes and $c_{last} = 1 - \sum_i \theta_i$; then

$$\sum_i c_i R^{(i)} = R^{(last)} + \sum_i \theta_i\,(R^{(i)} - R^{(last)}),$$

which is smallest (in the sense of the sum of the squares of its entries) for the **least-squares** solution θ of $\sum_i \theta_i (R^{(i)} - R^{(last)}) \approx -R^{(last)}$, a standard problem of linear algebra that numpy's `lstsq` solves. For one variable and two remembered passes the combined residual can be made exactly zero, and the next input is the point where the straight line through the two last (input, residual) pairs crosses zero: the **secant method**, which estimates the slope of G from the history. Anderson mixing is therefore a cheap substitute for Newton's method, and it needs no tuning of β.

The Revision solver. The Revision Kohn-Sham solver of the dirac16complex field (Chapter 15) uses Anderson mixing with these settings, recorded in `Revision/kohn_sham/results/parameters.json` (numerics): it remembers 6 passes (andersonDepth), uses $\beta = 0.4$ (andersonBeta), and stops when the largest difference between the potentials that come out and those that went in is at most 10^{-11} (scfTolerance), with at most 400 passes. What it mixes is the list of its potentials at every grid point of the hidden direction (the mass shift $M_{eff} - m$, the potential v_v, and a third potential used only by one variant). It solves the same least-squares problem in an equivalent form (with a Lagrange multiplier for $\sum_i c_i = 1$) and adds two safeguards: a tiny number (10^{-12} times the

largest diagonal entry) on the diagonal of its equations, which keeps them solvable, and a restart of the remembered passes whenever the residual grows to more than ten times the best one so far (`Revision/kohn_sham/solver/src/scf.rs`). Notebooks 13d and 13a read these settings from the parameter file and use them in their own small loops.

Level crossings and smearing. With whole-number occupations (aufbau), the output density jumps whenever two levels near the highest occupied one exchange their order during the iteration; if they cross back and forth, the loop never settles, whatever β is. The remedy replaces the whole-number occupations by smooth Fermi-Dirac occupations (Section 13.26); the converged object is then an ensemble with fractional occupations near the highest level, not a single determinant.

13.22 Example: charge sloshing

Notebook 13d computes everything of Section 13.21 for the two-site model: it checks the reduced map against a direct diagonalisation, reproduces the two tables, finds the fixed point, the slope and the largest mixing parameter, compares the error histories of plain iteration, linear mixing and Anderson mixing with the Revision solver's settings (read from the parameter file), maps the long-run behaviour against β and the threshold against U. Its numbers are COMPUTED and exact up to rounding; the model shows the mechanism and is not a physical system of the book. It ends with ALL 17 CHECKS PASSED (notebook 13d) and draws six figures.

13.23 How to run Notebook 13d

Step 1. What this notebook does and what it needs.

Notebook 13d (Charge sloshing and mixing in the two-site model) is the file `Revision/textbook/notebooks/13d_charge_sloshing.ipynb` of the repository Dirac_claude. It runs the self-consistency loop of a two-site mean-field model with two electrons (site energies -1 and +1, hopping 1, repulsion 4) by diagonalising its 2 x 2 Hamiltonian, checks the reduced map x_out = G(x), reproduces the tables of plain iteration (charge sloshing between the sites) and of linear mixing, finds the fixed point and the convergence condition of linear mixing 0 < beta < 2/(1 - G'), compares plain iteration, linear mixing and Anderson mixing (with the settings of the Revision Kohn-Sham solver, read from its parameter file), maps the long-run behaviour against beta and the threshold against the repulsion, and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its

first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook,

skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13d_charge_sloshing.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13d_charge_sloshing.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 13d_charge_sloshing.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/13d.captions.json`
- `Revision/textbook/figures/13d_1_reduced_map.png`
- `Revision/textbook/figures/13d_2_cobwebs.png`
- `Revision/textbook/figures/13d_3_error_histories.png`

- `Revision/textbook/figures/13d_4_convergence_factor.png`
- `Revision/textbook/figures/13d_5_long_run_diagram.png`
- `Revision/textbook/figures/13d_6_threshold_versus_u.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13d_6_threshold_versus_u.png exists
ALL 17 CHECKS PASSED (notebook 13d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/13d_charge_sloshing.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 13d_charge_sloshing.ipynb
python -m nbconvert --execute --inplace 13d_charge_sloshing.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `parameters.json`: the notebook reads the file `Revision/kohn_sham/results/parameters.json` of the repository; it must be opened inside the folder `Revision/textbook/notebooks` of a complete clone of the repository, not as a single downloaded file.

13.24 Notebook 13d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/13d_charge_sloshing.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The self-consistency loop of density functional theory is a map from an input
density to an output density, and a solution is a fixed point of this map. The
simple loop "output becomes the next input" often fails. This notebook shows why,
with a model small enough to understand completely: two electrons on two sites. It

- runs the loop by diagonalising the $2 \times 2$ mean-field Hamiltonian and checks
  that it equals the reduced map $x_{out} = G(x)$ of one number;
- reproduces the tables of plain iteration (the density jumps between the two sites
  forever: charge sloshing) and of linear mixing with $\beta = 1/2$ (it converges);
- finds the fixed point by bisection, the slope $G'$ there, and the condition
  $0 < \beta < 2/(1 - G')$ under which linear mixing converges;
```

```
- compares the error histories of plain iteration, several linear mixings and
  Anderson mixing;
- maps the long-run behaviour of the loop against $\beta$ and the threshold against
  the repulsion $U$;
- draws six teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 13d (Charge sloshing and mixing in the two-site model) is the file
‘Revision/textbook/notebooks/13d_charge_sloshing.ipynb‘ of the repository Dirac_claude.
It runs the self-consistency loop of a two-site mean-field model with two electrons (site
energies -1 and +1, hopping 1, repulsion 4) by diagonalising its 2 x 2 Hamiltonian,
checks the reduced map x_out = G(x), reproduces the tables of plain iteration (charge
sloshing between the sites) and of linear mixing, finds the fixed point and the
convergence condition of linear mixing 0 < beta < 2/(1 - G’), compares plain iteration,
linear mixing and Anderson mixing (with the settings of the Revision Kohn-Sham solver,
read from its parameter file), maps the long-run behaviour against beta and the threshold
against the repulsion, and draws six teaching plots. It needs a computer with Windows 11,
macOS or Linux, an internet connection for the installation, the program Git, and Python
3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter,
the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):
```

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13d_charge_sloshing.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its

left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13d_charge_sloshing.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 13d_charge_sloshing.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/13d.captions.json‘
- ‘Revision/textbook/figures/13d_1_reduced_map.png‘
- ‘Revision/textbook/figures/13d_2_cobwebs.png‘
- ‘Revision/textbook/figures/13d_3_error_histories.png‘
- ‘Revision/textbook/figures/13d_4_convergence_factor.png‘
- ‘Revision/textbook/figures/13d_5_long_run_diagram.png‘
- ‘Revision/textbook/figures/13d_6_threshold_versus_u.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13d_6_threshold_versus_u.png exists
ALL 17 CHECKS PASSED (notebook 13d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/13d_charge_sloshing.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 13d_charge_sloshing.ipynb
      python -m nbconvert --execute --inplace 13d_charge_sloshing.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘parameters.json‘: the notebook reads the file ‘Revision/kohn_sham/results/parameters.json‘ of the repository; it must be opened inside the folder ‘Revision/textbook/notebooks‘ of a complete clone of the repository, not as a single downloaded file.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 13d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 13d (Charge sloshing and mixing in the two-site model) is the file
# Revision/textbook/notebooks/13d_charge_sloshing.ipynb of the repository Dirac_claude.
# It runs the self-consistency loop of a two-site mean-field model with two electrons
# (site energies -1 and +1, hopping 1, repulsion 4) by diagonalising its 2 x 2
# Hamiltonian, checks the reduced map x_out = G(x), reproduces the tables of plain
# iteration (charge sloshing between the sites) and of linear mixing, finds the fixed
# point and the convergence condition of linear mixing 0 < beta < 2/(1 - G'), compares
# plain iteration, linear mixing and Anderson mixing (with the settings of the Revision
# Kohn-Sham solver, read from its parameter file), maps the long-run behaviour against
# beta and the threshold against the repulsion, and draws six teaching plots. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
```

```
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
```

```
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 13d_charge_sloshing.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 13d_charge_sloshing.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
```

```
# 13d_charge_sloshing.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/13d.captions.json
# - Revision/textbook/figures/13d_1_reduced_map.png
# - Revision/textbook/figures/13d_2_cobwebs.png
# - Revision/textbook/figures/13d_3_error_histories.png
# - Revision/textbook/figures/13d_4_convergence_factor.png
# - Revision/textbook/figures/13d_5_long_run_diagram.png
# - Revision/textbook/figures/13d_6_threshold_versus_u.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 13d_6_threshold_versus_u.png exists
#     ALL 17 CHECKS PASSED (notebook 13d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/13d_charge_sloshing.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
```

```
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 13d_charge_sloshing.ipynb
#     python -m nbconvert --execute --inplace 13d_charge_sloshing.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for parameters.json: the notebook reads the file
#   Revision/kohn_sham/results/parameters.json of the repository; it must be opened
#   inside the folder Revision/textbook/notebooks of a complete clone of the repository,
#   not as a single downloaded file.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Two-site model**: two places L and R with one orbital each; an electron can hop
  between them (hopping $t$); the site energies are $-\Delta/2$ (L) and $+\Delta/2$
  (R).
- **Mean field**: each electron feels the other one only through its average
  density; here an electron on a site feels $U$ times the density of the other label
  on that site, i.e. $U n_L/2$ on L and $U n_R/2$ on R.
- **Density** $n_L$, $n_R = 2 - n_L$: the expected number of electrons on each site.
- **Fixed point** of a map $G$: a number $x^*$ with $G(x^*) = x^*$.
- **Plain iteration**: $x \leftarrow G(x)$; **linear mixing**:
  $x \leftarrow (1 - \beta)\,x + \beta\,G(x)$ with the mixing parameter $\beta$.
```

```
- **Charge sloshing**: the loop moves the charge back and forth between regions
  instead of settling.
- **Error**: the distance $x - x^*$ from the fixed point; **convergence factor**: the
  number by which one step multiplies the error near the fixed point.
- **Cobweb diagram**: a picture of an iteration: go vertically to the curve $G$,
  horizontally to the diagonal, vertically again, and so on.
- **Anderson mixing**: a mixing that uses several earlier steps to estimate the
  slope of $G$ (for one variable it is close to the secant method).
- **Bisection**: finding a root by halving an interval that contains it.
```

Text cell:

```
## 4. The physical and mathematical situation

Two electrons with opposite labels occupy the lowest orbital of the mean-field
Hamiltonian

$$h[n_L] = \begin{pmatrix} -\Delta/2 + U n_L/2 & -t \\ -t & \Delta/2 + U n_R/2
\end{pmatrix}, \qquad n_R = 2 - n_L,$$

so the output density is $n_L^{out} = 2|c_L|^2$, where $(c_L, c_R)$ is the
normalised lowest eigenvector. For a real symmetric matrix
$\begin{pmatrix} a & -t\\ -t & b\end{pmatrix}$ the lowest eigenvector has
$|c_L|^2 = \tfrac12\big(1 + (b - a)/\sqrt{(b - a)^2 + 4t^2}\big)$, and here
$b - a = \Delta + U(1 - n_L)$. With $x = n_L - 1$ (the excess on L) the whole loop is
one function of one number:

$$x_{out} = G(x) = \frac{\Delta - U x}{\sqrt{(\Delta - Ux)^2 + 4t^2}} .$$

Near the fixed point $x^*$, $G(x^* + e) \approx x^* + G'(x^*)\,e$, so linear mixing
multiplies the error by $1 - \beta(1 - G'(x^*))$ at every step, and it converges
exactly when this number lies between $-1$ and $1$, i.e. for
$0 < \beta < 2/(1 - G'(x^*))$. The slope is
$G'(x) = -4Ut^2/((\Delta - Ux)^2 + 4t^2)^{3/2}$.

**Numbers.** $\Delta = 2$, $t = 1$, $U = 4$ (energies in units of $t$), start
$n_L = 2$ (both electrons on the low site). **Status:** exact mathematics of a model
loop (COMPUTED here); the model shows the mechanism, not a physical system of the
book. Its only link to the Revision record is the Anderson-mixing settings, which
section 8 reads from the parameter file of the Revision Kohn-Sham solver.
```

Text cell:

```
## 5. The loop and the reduced map

The next cell defines one pass of the loop by diagonalising $h[n_L]$ with numpy, and
the closed-form map $G$, and checks that they agree for 41 inputs between 0 and 2.
```

In [2]:

```
import numpy as np  # arrays, matrices and linear algebra
```

```
DELTA, T_HOP, U = 2.0, 1.0, 4.0  # site-energy difference, hopping, repulsion

def loop_pass(n_left, delta=DELTA, t=T_HOP, u=U):
    """One pass: the output density n_L of the lowest orbital of h[n_L]."""
    n_right = 2.0 - n_left
    h = np.array([[-delta / 2 + u * n_left / 2, -t],
                  [-t, delta / 2 + u * n_right / 2]])
    values, vectors = np.linalg.eigh(h)  # levels in increasing order
    return 2.0 * vectors[0, 0] ** 2  # two electrons, |c_L|^2 each

def G(x, delta=DELTA, t=T_HOP, u=U):
    """The reduced map x_out = G(x), x = n_L - 1."""
    shift = delta - u * x
    return shift / np.sqrt(shift ** 2 + 4.0 * t * t)

inputs = np.linspace(0.0, 2.0, 41)
worst = max(abs(loop_pass(n) - 1.0 - G(n - 1.0)) for n in inputs)
check(worst < 1e-12, "the 2 x 2 diagonalisation and the reduced map G agree")
```

Out [2]:

```
PASS the 2 x 2 diagonalisation and the reduced map G agree
```

Text cell:

```
The next cell finds the fixed point $x^*$ by bisection on $x - G(x)$, which increases
with $x$ (because $G$ decreases), computes the slope $G'(x^*)$ from the formula and
from a difference quotient, and the largest and the best mixing parameters,
$\beta_{max} = 2/(1 - G')$ and $\beta_{best} = 1/(1 - G')$ (which makes the factor
zero).
```

In [3]:

## 8. Error histories and the convergence factor

The next cell runs the loop for $\beta = 1, 0.8, 0.5, 0.2$ and for the best value
$\beta_{best} = 0.372$, and also with Anderson mixing with the settings of the
Revision Kohn-Sham solver of the dirac16complex field, which it reads from the
solver's parameter file (how many earlier passes are remembered, and $\beta$; for
one variable Anderson mixing estimates the slope of $G$ from the last passes, like
the secant method). It records the error $|n_L - n_L^*|$ of every input and checks
the measured ratio of successive errors for $\beta = 1/2$ against the predicted
factor $1 - \beta(1 - G') = -0.344$.
```

## 12. What this notebook showed

- The whole self-consistency loop of the two-site mean-field model is one function
  $G(x) = (\Delta - Ux)/\sqrt{(\Delta - Ux)^2 + 4t^2}$ of one number, and its fixed
  point is the self-consistent density $n_L^* = 1.326993$.
- Plain iteration fails: the charge jumps between the sites forever (a cycle of
  period 2 near 0.3607 and 1.9157), because the slope $G'(x^*) = -1.688$ is steeper
  than $-1$.
- Linear mixing converges exactly for $0 < \beta < 2/(1 - G') = 0.744058$; each pass
  multiplies the error by $1 - \beta(1 - G')$ ($-0.344$ for $\beta = 1/2$), and
  $\beta = 1/(1 - G') = 0.372$ is the fastest.
- Anderson mixing, which estimates the slope from earlier passes, converges in a
  few passes without tuning; the Revision Kohn-Sham solver of the dirac16complex
  field uses it with depth 6 and $\beta = 0.4$ (read here from its parameter file).
- The stronger the repulsion, the smaller the step the loop may take; for
  $\Delta = 2$, $t = 1$ plain iteration converges only for $U$ below the printed
  threshold (for example $U = 2$: $\beta_{max} = 1.184$).
```

13.25 Line-by-line walk-through of Notebook 13d

The notebook has fourteen code cells. **In [1]** is the set-up cell, identical to In [1] of Notebook 13c (Section 13.14) except for the name `"13d"` and its comment lines, which hold the instructions of Section 13.23.

In [2], the loop and the reduced map.

```
import numpy as np  # arrays, matrices and linear algebra

DELTA, T_HOP, U = 2.0, 1.0, 4.0  # site-energy difference, hopping, repulsion

def loop_pass(n_left, delta=DELTA, t=T_HOP, u=U):
    """One pass: the output density n_L of the lowest orbital of h[n_L]."""
    n_right = 2.0 - n_left
    h = np.array([[-delta / 2 + u * n_left / 2, -t],
                  [-t, delta / 2 + u * n_right / 2]])
```

```
    values, vectors = np.linalg.eigh(h)  # levels in increasing order
    return 2.0 * vectors[0, 0] ** 2  # two electrons, |c_L|^2 each
```

The cell loads numpy as `np`. The model's numbers $\Delta = 2$, $t = 1$, $U = 4$ are written in one line: Python assigns the three values to the three names in order. `loop_pass` is one pass of the loop: it builds the matrix $h[n_L]$ of Section 13.21, diagonalises it with `eigh` (levels in increasing order, eigenvectors as columns), and returns $2|c_L|^2$, where `vectors[0, 0]` is the L component (row 0) of the lowest eigenvector (column 0). The arguments `delta=DELTA` and so on are **default values**: they are used when the call does not give them, so later cells can call `loop_pass(n, u=2.0)` with another repulsion.

```
def G(x, delta=DELTA, t=T_HOP, u=U):
    """The reduced map x_out = G(x), x = n_L - 1."""
    shift = delta - u * x
    return shift / np.sqrt(shift ** 2 + 4.0 * t * t)

inputs = np.linspace(0.0, 2.0, 41)
worst = max(abs(loop_pass(n) - 1.0 - G(n - 1.0)) for n in inputs)
check(worst < 1e-12, "the 2 x 2 diagonalisation and the reduced map G agree")
```

`G` is the closed form of Section 13.21. For 41 inputs from 0 to 2 the cell compares $n_L^{out} - 1$ from the diagonalisation with $G(n_L - 1)$ and checks that the largest difference is below 10^{-12}: the four-step derivation is confirmed.

In [3], the fixed point and the slope.

```
def fixed_point(delta=DELTA, t=T_HOP, u=U):
    """x* with G(x*) = x*, by bisection on [-1, 1] (x - G(x) increases)."""
    low, high = -1.0, 1.0
    for _ in range(80):
        middle = 0.5 * (low + high)
        if middle - G(middle, delta, t, u) > 0.0:
            high = middle
        else:
            low = middle
    return 0.5 * (low + high)

def slope(x, delta=DELTA, t=T_HOP, u=U):
    """G'(x) = -4 U t^2 / ((Delta - U x)^2 + 4 t^2)^(3/2)."""
    return -4.0 * u * t * t / ((delta - u * x) ** 2 + 4.0 * t * t) ** 1.5
```

`fixed_point` finds x^* by bisection: $x - G(x)$ increases with x (because G decreases), is negative at $x = -1$ and positive at $x = 1$; at each of 80 steps the cell evaluates it at the middle of the interval and keeps the half in which the sign changes. After 80 halvings the interval is far below the rounding of the computer. `slope` is the formula for G' of Section 13.21.

```
x_star = fixed_point()
g_prime = slope(x_star)
```

```
quotient = (G(x_star + 1e-6) - G(x_star - 1e-6)) / 2e-6
beta_max, beta_best = 2.0 / (1.0 - g_prime), 1.0 / (1.0 - g_prime)
```

The fixed point, the slope there, a central difference quotient $(G(x^*+10^{-6})-G(x^*-10^{-6}))/(2\cdot 10^{-6})$ as an independent estimate of the slope, and the largest and the best mixing parameters (two names assigned in one line).

```
report("fixed point n_L* = 1 + x*", f"{1.0 + x_star:.6f}")
report("slope G'(x*)", f"{g_prime:.6f}")
report("largest mixing parameter 2/(1 - G')", f"{beta_max:.6f}")
report("best mixing parameter 1/(1 - G')", f"{beta_best:.6f}")
check(abs(x_star - 0.326993) < 1e-6 and abs(g_prime + 1.687961) < 1e-6
      and abs(beta_max - 0.744058) < 1e-6,
      "x* = 0.326993, G'(x*) = -1.687961, beta_max = 0.744058")
check(abs(quotient - g_prime) < 1e-6, "the slope formula equals a difference quotient")
```

The four `report` lines print $n_L^* = 1.326993$, $G' = -1.687961$, $\beta_{max} = 0.744058$ and $\beta_{best} = 0.372029$; the two checks compare the first three with these values (to 10^{-6}) and the slope formula with the difference quotient (to 10^{-6}; the central quotient has an error of order $(10^{-6})^2$ times the third derivative, plus rounding).

In [4], the map as a picture.

```
n_in = np.linspace(0.0, 2.0, 401)
fig, ax = plt.subplots(figsize=(6.0, 5.0))
ax.plot(n_in, 1.0 + G(n_in - 1.0), color="black", lw=2.0,
        label="$n_L^{out} = 1 + G(n_L - 1)$")
ax.plot(n_in, n_in, "--", color="gray", label="diagonal $n_L^{out} = n_L$")
ax.plot([1.0 + x_star], [1.0 + x_star], "ro",
        label=f"fixed point $n_L^* = {1.0 + x_star:.6f}$")
```

`n_in` holds 401 input densities from 0 to 2. The cell draws the output $1 + G(n_L - 1)$ against the input as a thick black line, the diagonal $n_L^{out} = n_L$ grey and dashed, and the fixed point as a red dot (`"ro"`: r red, o a round marker) at (n_L^*, n_L^*), whose value the legend shows with six decimals.

```
ax.set_xlabel("input density on the left site $n_L$")
ax.set_ylabel("output density $n_L^{out}$")
ax.set_title("The self-consistency map of the two-site model")
ax.legend(fontsize=8)
save_figure(fig, "reduced_map",
```

Labels, title, legend and `save_figure` for Figure 13d.1.

What Figure 13d.1 shows. The map falls from the output 1.95 at the input $n_L = 0$ to the output 0.29 at the input $n_L = 2$: the more charge the input puts on the left site, the more the repulsion pushes the output to the right. Where the curve crosses the diagonal, input and output agree: the self-consistent density 1.326993. The crossing is steep (slope -1.69), which is the cause of all the trouble of Section 13.21.

In [5], plain iteration.

```
def iterate(beta, start=2.0, passes=6):
    """Inputs and outputs of the loop with linear mixing (beta = 1: plain)."""
    n, history = start, []
    for _ in range(passes):
        out = loop_pass(n)
        history.append((n, out))
        n = (1.0 - beta) * n + beta * out
    return history, n
```

`iterate` runs the loop with linear mixing: at each pass it computes the output, stores the pair (input, output) in the list `history` (a pair in parentheses is a **tuple**), and forms the next input $(1-\beta)n + \beta\, n^{out}$. It returns the history and the next input.

```
plain, _ = iterate(1.0)
say("step   n_L in     n_L out")
for step, (n, out) in enumerate(plain):
    say(f"{step:4d}   {n:.6f}   {out:.6f}")
expected_in = [2.000000, 0.292893, 1.923880, 0.353344, 1.916644, 0.359836]
check(all(abs(n - e) < 1e-6 for (n, _), e in zip(plain, expected_in)),
      "plain iteration reproduces the table 2.000000, 0.292893, 1.923880, ...")
```

Six passes of plain iteration ($\beta = 1$); the name `_` receives the second returned value, which is not needed. The loop prints the table of Section 13.21 (`{step:4d}` writes the step number in four places, `{n:.6f}` the density with six decimals), and the check compares the inputs with the six values of that table.

```
_, late = iterate(1.0, passes=2000)
cycle = sorted([late, loop_pass(late)])
say(f"after 2000 passes the input alternates between {cycle[0]:.4f} and "
    f"{cycle[1]:.4f}")
check(abs(loop_pass(loop_pass(late)) - late) < 1e-10 and cycle[1] - cycle[0] > 1.5,
      "plain iteration ends in a cycle of period 2 (about 0.3607 and 1.9157)")
```

After 2000 passes, `late` is the next input; with its output it forms the two values of the cycle, sorted. The check requires that two passes return to the same value (a cycle of period 2, to 10^{-10}) and that the two values are more than 1.5 apart: the charge keeps jumping between the sites.

In [6], linear mixing with $\beta = 1/2$.

```
mixed, _ = iterate(0.5)
say("step   n_L in     n_L out")
for step, (n, out) in enumerate(mixed):
    say(f"{step:4d}   {n:.6f}   {out:.6f}")
expected_in = [2.000000, 1.146447, 1.361898, 1.314066, 1.331307, 1.325494]
check(all(abs(n - e) < 1e-6 for (n, _), e in zip(mixed, expected_in)),
      "linear mixing with beta = 1/2 reproduces the table 2.000000, 1.146447, ...")
long_history, _ = iterate(0.5, passes=40)
agree = next(step for step, (n, out) in enumerate(long_history)
             if abs(n - out) < 1e-6)
report("passes until input and output agree to 1e-6 (beta = 1/2)", agree)
check(agree == 13 and abs(long_history[-1][0] - 1.326993) < 1e-6,
      "beta = 1/2 converges to 1.326993; input and output agree after 13 passes")
```

The same for $\beta = \frac{1}{2}$: the second table of Section 13.21 and its check. Then 40 passes; `next(...)` returns the first step number whose input and output agree to 10^{-6}, which is 13; the last check also requires the last input (`long_history[-1][0]`, the first element of the last pair) to be 1.326993.

In [7], cobweb diagrams.

```
def cobweb(ax, beta, passes):
    """Draw the cobweb of the loop with mixing beta on the axes ax."""
    ax.plot(n_in, 1.0 + G(n_in - 1.0), color="black", lw=1.5)
    ax.plot(n_in, n_in, "--", color="gray", lw=0.8)
    history, _ = iterate(beta, passes=passes)
    for n, out in history:
        n_next = (1.0 - beta) * n + beta * out
        ax.plot([n, n], [n, out], color="tab:red", lw=0.8)  # up to the curve
        ax.plot([n, n_next], [out, n_next], color="tab:blue", lw=0.8)  # across
    ax.plot([1.0 + x_star], [1.0 + x_star], "ko")
    ax.set_xlabel("input $n_L$")
    ax.set_ylabel("output $n_L^{out}$ and next input")
```

A **cobweb diagram** draws an iteration: from the point (input, input) on the diagonal a red segment goes vertically to the curve (the output), and a blue segment goes from there to the point (next input, next input) on the diagonal. The function draws the map and the diagonal, runs the loop, and draws the two segments of every pass (`[n, n]` and `[n, out]` are the horizontal and the vertical coordinates of the two ends of the red segment), the fixed point as a black dot (`"ko"`), and labels the axes.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.5))
cobweb(left, 1.0, 12)
left.set_title("plain iteration ($\\beta = 1$): sloshing")
cobweb(right, 0.5, 12)
right.set_title("linear mixing ($\\beta = 1/2$): converges")
save_figure(fig, "cobwebs",
```

The cell calls `cobweb` for plain iteration in the left panel and for $\beta = \frac{1}{2}$ in the right panel, 12 passes each, gives each panel its title, and saves Figure 13d.2.

What Figure 13d.2 shows. On the left the path starts at $n_L = 2$, goes down to the output 0.29, across to the input 0.29, up to the output 1.92, and so on: after a few passes it runs around the same rectangle with the corners near 0.36 and 1.92, far from the fixed point in the middle; the thick lines are the many passes drawn on top of each other. On the right each blue segment ends on the diagonal at the point halfway between the input and the output, and the path closes in on the fixed point within a few passes, in a spiral, because the error changes its sign at every pass (the factor -0.344).

In [8], error histories and Anderson mixing.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
DEPTH = int(parameters["numerics"]["andersonDepth"])  # passes remembered
BETA_ANDERSON = float(parameters["numerics"]["andersonBeta"])  # mixing parameter
```

```
check(DEPTH == 6 and BETA_ANDERSON == 0.4,
      "the Revision solver mixes with depth 6 and beta 0.4 "
      "(Revision/kohn_sham/results/parameters.json, numerics)")
```

The cell reads the parameter file of the Revision solver and takes from its part "numerics" the number of remembered passes and β; `int` and `float` make a whole number and a floating-point number of them. The check confirms the values 6 and 0.4.

```
def errors_linear(beta, passes=60):
    """|n_L - n_L*| of the inputs of linear mixing."""
    history, _ = iterate(beta, passes=passes)
    return np.array([abs(n - 1.0 - x_star) for n, _ in history])
```

The distance of every input of 60 passes of linear mixing from the fixed point $n_L^* = 1 + x^*$.

```
def errors_anderson(beta=BETA_ANDERSON, depth=DEPTH, passes=60, tolerance=1e-14):
    """|n_L - n_L*| of the inputs of Anderson mixing (one variable)."""
    n, inputs, residuals, errors = 2.0, [], [], []
    for _ in range(passes):
        errors.append(abs(n - 1.0 - x_star))
        residual = loop_pass(n) - n
        if abs(residual) < tolerance:
            break
        inputs, residuals = (inputs + [n])[-depth:], (residuals + [residual])[-depth:]
        if len(inputs) == 1:
            n = n + beta * residual
            continue
        last = residuals[-1]
        differences = np.array([[r - last for r in residuals[:-1]]])  # 1 row
        theta = np.linalg.lstsq(differences, -np.array([last]), rcond=None)[0]
        c = np.append(theta, 1.0 - theta.sum())
        n = float(sum(ci * (ni + beta * ri)
                      for ci, ni, ri in zip(c, inputs, residuals)))
    return np.array(errors)
```

Anderson mixing of Section 13.21 for one variable. Each pass records the error, computes the residual $R = n^{out} - n$ and stops (`break` leaves the loop) when it is below 10^{-14}. `(inputs + [n])[-depth:]` appends the new input and keeps the last `depth` entries (a negative index counts from the end). In the first pass there is no history, so the step is linear mixing; `continue` goes on to the next pass. Otherwise `differences` is the table with one row of the differences $R^{(i)} - R^{(last)}$, `np.linalg.lstsq` solves the least-squares problem for θ (with one equation and several unknowns it returns the solution with the smallest $\sum \theta_i^2$), `np.append` adds $c_{last} = 1 - \sum \theta_i$, and the next input is $\sum_i c_i (n^{(i)} + \beta R^{(i)})$.

```
histories = {beta: errors_linear(beta) for beta in (1.0, 0.8, 0.5, 0.2)}
histories["best"] = errors_linear(beta_best)
anderson_errors = errors_anderson()
ratio = histories[0.5][11] / histories[0.5][10]  # the ratio of two error sizes
predicted = 1.0 - 0.5 * (1.0 - g_prime)
```

The error histories for $\beta = 1, 0.8, 0.5, 0.2$ and for β_{best}, and that of Anderson mixing. `ratio` divides the error after pass 11 by the error after pass 10 for $\beta = \frac{1}{2}$, and `predicted` is the factor $1 - \beta(1 - G')$ of Section 13.21.

```
report("measured |error ratio| for beta = 1/2", f"{ratio:.6f}")
report("predicted factor 1 - beta (1 - G')", f"{predicted:.6f}")
```

They print as 0.343986 and −0.343980: the size agrees (the sign of the measured ratio is lost because errors are taken as absolute values, and the small difference is the curvature of G).

```
check(abs(ratio - abs(predicted)) < 1e-4,
      "the error shrinks by the predicted factor |1 - beta(1 - G')| = 0.344")
check(histories[1.0][-1] > 0.5 and histories[0.8][-1] > 0.1,
      "beta = 1 and beta = 0.8 (above 0.744) do not converge")
check(len(anderson_errors) < 15 and anderson_errors[-1] < 1e-12,
      "Anderson mixing converges to 1e-12 in fewer than 15 passes")
```

Three checks: the predicted factor; the failure of $\beta = 1$ and $\beta = 0.8$, both above β_{max} (their last errors are still large); and the convergence of Anderson mixing to 10^{-12} in fewer than 15 passes.

In [9], the error histories as a picture.

```
fig, ax = plt.subplots()
for key, style in ((1.0, "o-"), (0.8, "s-"), (0.5, "^-"), (0.2, "v-")):
    label = "plain iteration" if key == 1.0 else f"linear, $\\beta = {key}$"
    ax.semilogy(histories[key][:40], style, ms=3, label=label)
```

`ax.semilogy` draws with a logarithmic vertical axis; given only one list, it uses the pass numbers $0, 1, 2, \ldots$ as horizontal coordinates. For the four linear runs the loop draws the first 40 errors with its own marker (circles, squares, and triangles pointing up and down, each joined by a line); the label is "plain iteration" for $\beta = 1$ and otherwise names β (`a if condition else b` chooses).

```
best = np.maximum(histories["best"][:12], 1e-16)  # rounding may give exactly 0
ax.semilogy(best, "D-", ms=3, label=f"linear, best $\\beta = {beta_best:.3f}$")
ax.semilogy(anderson_errors, "k*-", ms=6,
            label=f"Anderson, depth {DEPTH}, $\\beta = {BETA_ANDERSON}$")
```

The first 12 errors of the best linear mixing, with diamonds (`"D-"`); `np.maximum(..., 1e-16)` replaces an error of exactly 0, which a logarithmic axis cannot show, by 10^{-16}. Then all errors of Anderson mixing as black stars joined by a line (`"k*-"`); the label shows the depth and β read from the Revision parameter file.

```
ax.set_ylim(1e-15, 10.0)
ax.set_xlabel("pass number")
ax.set_ylabel("error $|n_L - n_L^*|$")
ax.set_title("Error histories of the two-site loop")
ax.legend(fontsize=7, loc="upper right", bbox_to_anchor=(1.0, 0.86))
save_figure(fig, "error_histories",
```

`set_ylim(1e-15, 10.0)` fixes the vertical range from 10^{-15} to 10; labels and title; the legend is anchored with its upper right corner at 86 per cent of the height of the panel (`bbox_to_anchor=( 1.0, 0.86)`), a little below the top, so that it does not cover the two upper curves. `save_figure` saves Figure 13d.3.

What Figure 13d.3 shows. Plain iteration and $\beta = 0.8$ stay between about 0.2 and 1 for all 40 passes, zig-zagging: they never converge. The runs with $\beta = 0.5$ and 0.2 are straight falling lines on the logarithmic axis, which means that the error is multiplied by the same factor at every pass (0.344 and about 0.46); the first reaches 10^{-15} after about 31 passes, the second is near 10^{-13} after 40. The best $\beta = 0.372$ (factor zero for small errors) and Anderson mixing fall much faster, reaching rounding level within about 5 and 9 passes; Anderson mixing achieves this without knowing the slope G' in advance.

In [10], the convergence factor.

```
betas = np.linspace(0.0, 1.0, 501)
factor = np.abs(1.0 - betas * (1.0 - g_prime))
```

The size of the factor $|1 - \beta(1 - G')|$ for 501 values of β from 0 to 1.

```
fig, ax = plt.subplots()
ax.plot(betas, factor, color="black", lw=2.0, label="$|1 - \\beta(1 - G')|$")
ax.axhline(1.0, color="gray", ls="--")
ax.axvspan(0.0, beta_max, alpha=0.15, color="green", label="converges")
ax.axvline(beta_best, color="tab:blue", ls=":",
           label=f"best $\\beta = {beta_best:.3f}$")
```

The factor as a thick black line; the grey dashed line at 1; `axvspan(0.0, beta_max, ...)` colours the vertical band $0 < \beta < \beta_{max}$, where the loop converges, in a pale green (`alpha=0.15` makes it 85 per cent transparent); `axvline` draws a dotted vertical line at β_{best}.

```
ax.set_xlabel("mixing parameter $\\beta$")
ax.set_ylabel("error factor per pass")
ax.set_title(f"Linear mixing converges for $\\beta < {beta_max:.4f}$")
ax.legend()
save_figure(fig, "convergence_factor",
```

Labels; the title shows β_{max} with four decimals (0.7441); legend; `save_figure` for Figure 13d.4.

What Figure 13d.4 shows. A V-shaped curve: the factor falls from 1 at $\beta = 0$ (no change at all, so no progress) to 0 at $\beta_{best} = 0.372$, rises again, crosses 1 at $\beta_{max} = 0.744$ (the right edge of the green band) and reaches 1.688 at $\beta = 1$. Every β inside the band converges; the closer to β_{best}, the faster.

In [11], the long run against β.

```
beta_scan = np.linspace(0.02, 1.0, 99)
tails = []
for beta in beta_scan:
```

```
    history, _ = iterate(beta, passes=600)
    tails.append([n for n, _ in history[-30:]])
tails = np.array(tails)
spread = tails.max(axis=1) - tails.min(axis=1)
check(np.all(spread[beta_scan < 0.72] < 1e-8) and np.all(spread[beta_scan > 0.77]
                                                         > 0.05),
      "the loop converges below beta = 0.744 and oscillates above it")
```

For 99 values of β from 0.02 to 1 the cell runs 600 passes and keeps the last 30 inputs (`history[ -30:]`); `tails` becomes a table with one row per β. The spread of each row (largest minus smallest) is tiny where the loop converged and large where it ends in a cycle. The check requires a spread below 10^{-8} for every $\beta < 0.72$ and above 0.05 for every $\beta > 0.77$ (close to β_{max} the convergence or divergence is too slow to decide in 600 passes, so a small gap is left).

```
fig, ax = plt.subplots()
for beta, tail in zip(beta_scan, tails):
    ax.plot(np.full(len(tail), beta), tail, "k.", ms=2)
ax.axvline(beta_max, color="tab:red", ls="--", label=f"$\\beta_{{max}} = "
           f"{beta_max:.4f}$")
```

For every β the loop draws its 30 kept inputs as small black dots (`"k."`) above it: `np.full( len(tail), beta)` is a list of 30 copies of β, the horizontal coordinates. A red dashed vertical line marks β_{max}; its label is made of two f-strings written next to each other (the doubled braces print one brace each, so the label shows $\beta_{max} = 0.7441$).

```
ax.set_xlabel("mixing parameter $\\beta$")
ax.set_ylabel("last 30 inputs $n_L$")
ax.set_title("Where the loop ends, against $\\beta$")
ax.legend()
save_figure(fig, "long_run_diagram",
```

Labels, title, legend and `save_figure` for Figure 13d.5.

What Figure 13d.5 shows. Left of the red line all 30 dots of each β lie on one point at 1.327: the loop has converged. Right of it the dots split into two branches, the two values of the cycle of period 2; just beyond β_{max} they are close to 1.327, and they move apart as β grows, to about 0.36 and 1.92 at $\beta = 1$ (plain iteration). This splitting of one fixed point into a cycle of period 2 is called a **period-doubling bifurcation**.

In [12], a weaker repulsion and the threshold.

```
x2 = fixed_point(u=2.0)
g2 = slope(x2, u=2.0)
```

The fixed point and the slope for $U = 2$ (the keyword `u=2.0` replaces the default repulsion).

```
report("U = 2: n_L*", f"{1.0 + x2:.6f}")
report("U = 2: G'(x*)", f"{g2:.6f}")
```

```
report("U = 2: beta_max", f"{2.0 / (1.0 - g2):.6f}")
check(abs(x2 - 0.468990) < 1e-6 and abs(g2 + 0.688942) < 1e-6
      and abs(2.0 / (1.0 - g2) - 1.184174) < 1e-6,
      "U = 2: x* = 0.468990, G' = -0.688942, beta_max = 1.184174")
```

The three `report` lines print $n_L^* = 1.468990$, $G' = -0.688942$ and $\beta_{max} = 1.184174$, and the check compares them with these values (to 10^{-6}). Then

```
n = 2.0
for _ in range(200):  # plain iteration with U = 2
    n = loop_pass(n, u=2.0)
check(abs(n - 1.0 - x2) < 1e-10, "U = 2: plain iteration converges")
```

runs 200 passes of plain iteration at $U = 2$ and checks that they reach the fixed point to 10^{-10}.

```
U_scan = np.linspace(0.5, 8.0, 76)
beta_limits = np.array([2.0 / (1.0 - slope(fixed_point(u=u), u=u)) for u in U_scan])
low, high = 2.0, 4.0  # beta_max(2) > 1 > beta_max(4)
for _ in range(60):
    middle = 0.5 * (low + high)
    if 2.0 / (1.0 - slope(fixed_point(u=middle), u=middle)) > 1.0:
        low = middle
    else:
        high = middle
U_critical = 0.5 * (low + high)
```

β_{max} for 76 repulsions from 0.5 to 8 (for each one the fixed point is found again). Then a bisection in U between 2 (where $\beta_{max} > 1$) and 4 (where it is below 1) finds the repulsion at which $\beta_{max} = 1$, that is $G'(x^*) = -1$ (if β_{max} at the middle is still above 1, the threshold lies above the middle, so `low` moves up).

```
report("repulsion where plain iteration stops converging", f"{U_critical:.6f}")
check(abs(slope(fixed_point(u=U_critical), u=U_critical) + 1.0) < 1e-9,
      "at this repulsion the slope at the fixed point is exactly -1")
```

The `report` line prints $U = 2.647393$, and the check confirms that the slope at the fixed point is -1 there, to 10^{-9}.

In [13], the threshold as a picture.

```
fig, ax = plt.subplots()
ax.plot(U_scan, beta_limits, color="black", lw=2.0, label="$\\beta_{max}(U)$")
ax.axhline(1.0, color="gray", ls="--", label="plain iteration, $\\beta = 1$")
ax.axvline(U_critical, color="tab:red", ls=":",
           label=f"$U = {U_critical:.3f}$: plain iteration fails beyond")
ax.set_xlabel("repulsion $U$ (units of $t$)")
ax.set_ylabel("largest convergent mixing parameter")
ax.set_title("Stronger repulsion needs gentler mixing")
ax.legend(fontsize=8)
save_figure(fig, "threshold_versus_u",
```

The curve $\beta_{max}(U)$ as a thick black line, the grey dashed line $\beta = 1$ (plain iteration), a red dotted vertical line at the critical repulsion (its label shows $U = 2.647$), labels, title, legend and `save_figure` for Figure 13d.6.

What Figure 13d.6 shows. β_{max} falls steadily from about 1.8 at $U = 0.5$ to about 0.42 at $U = 8$. It crosses the line $\beta = 1$ at $U = 2.647$: for weaker repulsion plain iteration converges (the curve lies above the dashed line), for stronger repulsion it fails, and the mixing step must be smaller the stronger the repulsion.

In [14], the last check.

```
figure_names = ["reduced_map", "cobwebs", "error_histories", "convergence_factor",
                "long_run_diagram", "threshold_versus_u"]
missing = [name for k, name in enumerate(figure_names, 1)
           if not output_file(f"{FIGURE_FOLDER}/13d_{k}_{name}.png").is_file()]
check(missing == [], "all six figure files exist")
check(output_file(f"{FIGURE_FOLDER}/13d_6_threshold_versus_u.png").is_file(),
      "the figure file 13d_6_threshold_versus_u.png exists")
all_checks_passed()
```

The same lines as In [19] of Notebook 13c (Section 13.14), with the six figure names of this notebook. The last line prints ALL 17 CHECKS PASSED (notebook 13d): one check in In [2], two each in In [3], In [5] and In [6], four in In [8], one in In [11], three in In [12] and two in In [14].

13.26 Finite temperature: Mermin's theorem

So far the system was in its ground state. At a temperature $T > 0$ it is in a statistical mixture of states. (Boltzmann's constant is 1, so a temperature is an energy.)

Density operators. A mixture in which the state Ψ_k occurs with the probability $w_k \geq 0$ ($\sum_k w_k = 1$) is described by the **density operator** $\hat{\rho} = \sum_k w_k \, |\Psi_k\rangle\langle\Psi_k|$, where $|\Psi\rangle\langle\Psi|$ is the operator that maps a state χ to $\Psi \, \langle\Psi|\chi\rangle$ (on a grid: the column Ψ times the conjugated row $\Psi^\dagger$). It is Hermitian, $\langle\chi|\hat{\rho}\chi\rangle = \sum_k w_k |\langle\Psi_k|\chi\rangle|^2 \geq 0$ for every state, and $\mathrm{Tr}\,\hat{\rho} = \sum_k w_k = 1$ for normalised Ψ_k; so its eigenvalues p_i lie between 0 and 1 and add up to 1. The expectation value of an observable is $\mathrm{Tr}(\hat{\rho}A)$. A **function of a Hermitian matrix** $A = \sum_i a_i \, u_i u_i^\dagger$ (eigenvalues a_i, orthonormal eigenvectors u_i) is defined through its eigenvalues, $f(A) = \sum_i f(a_i) \, u_i u_i^\dagger$; for $f = \exp$ this agrees with the power series, because $A^m = \sum_i a_i^m u_i u_i^\dagger$. The **entropy** is

$$S = -\mathrm{Tr}(\hat{\rho} \ln \hat{\rho}) = -\sum_i p_i \ln p_i \;\geq 0,$$

with the rule $0 \ln 0 = 0$ (the limit of $p \ln p$ as $p \to 0$); every term is ≥ 0 because $\ln p_i \leq 0$. When the particle number is fixed only on average by a **chemical potential** μ, the equilibrium state at the temperature T minimises the **grand potential**

$$\Omega[\hat{\rho}] = \mathrm{Tr}\big[\hat{\rho}\,(\hat{H} - \mu\hat{N})\big] - T\,S[\hat{\rho}].$$

Theorem (Gibbs principle). In a finite-dimensional state space Ω has exactly one minimiser, the **Gibbs state** $\hat{\rho}_0 = e^{-(\hat{H}-\mu\hat{N})/T}/Z$ with $Z = \mathrm{Tr}\, e^{-(\hat{H}-\mu\hat{N})/T}$, and $\Omega[\hat{\rho}_0] = -T \ln Z$.

Proof, line by line. Taking the logarithm of $\hat\rho_0$ (a function of the Hermitian matrix $\hat H-\mu\hat N$),

$$\ln\hat\rho_0=-\frac{\hat H-\mu\hat N}{T}-\ln Z\quad\Longrightarrow\quad \hat H-\mu\hat N=-T\ln\hat\rho_0-T\ln Z.$$

Inserting this into Ω and using $\operatorname{Tr}\hat\rho=1$:

$$\Omega[\hat\rho]=-T\operatorname{Tr}(\hat\rho\ln\hat\rho_0)-T\ln Z+T\operatorname{Tr}(\hat\rho\ln\hat\rho)=-T\ln Z+T\,D,\qquad D=\operatorname{Tr}\big[\hat\rho\,(\ln\hat\rho-\ln\hat\rho_0)\big].$$

For $\hat\rho=\hat\rho_0$ the number D is 0, so $\Omega[\hat\rho_0]=-T\ln Z$. It remains to show **Klein's inequality** $D\ge 0$ for two density operators, with $D=0$ only when they are equal. Write $\hat\rho=\sum_i p_i|i\rangle\langle i|$ and $\hat\rho_0=\sum_j q_j|j\rangle\langle j|$ with orthonormal eigenvectors (all $q_j>0$). Then

$$\begin{aligned}D&=\sum_i p_i\ln p_i-\sum_{i,j}p_i\,|\langle i|j\rangle|^2\ln q_j=\sum_{i,j}|\langle i|j\rangle|^2\,p_i\,(\ln p_i-\ln q_j)\\&\ge\sum_{i,j}|\langle i|j\rangle|^2\,(p_i-q_j)=\sum_i p_i-\sum_j q_j=1-1=0.\end{aligned}$$

The first step evaluates the two traces in the eigenvectors of $\hat\rho$ (and expands $|i\rangle$ in the eigenvectors of $\hat\rho_0$ for the second); the second inserts $\sum_j|\langle i|j\rangle|^2=1$ (completeness) in the first sum; the inequality uses $a\ln a-a\ln b\ge a-b$ for $a\ge0$, $b>0$, which is $\ln y\le y-1$ with $y=b/a$, multiplied by $-a$ (for $a=0$ it reads $0\ge -b$); the last steps use completeness once more and the traces 1. The inequality $\ln y\le y-1$ holds because $y-1-\ln y$ has the derivative $1-1/y$, negative for $y<1$ and positive for $y>1$, so its smallest value is 0 at $y=1$, and only there. Hence $D=0$ forces $p_i=q_j$ whenever $\langle i|j\rangle\neq0$, which makes $\hat\rho$ and $\hat\rho_0$ act in the same way on every $|j\rangle$: $\hat\rho=\hat\rho_0$. □

Notebook 13e (In [3] and In [4]) builds the Gibbs state of the two-site model, checks $\Omega[\hat\rho_0]=-T\ln Z$, and finds for 2000 random density operators that Ω is always larger, with $\Omega-\Omega[\hat\rho_0]=T\,D$ to 10^{-10} (Figure 13e.1).

Mermin's theorem (1965), line by line. Fix the temperature $T>0$, the chemical potential μ and the interaction $\hat W$, and work, as in the Gibbs principle, in a finite-dimensional state space that holds every particle number (for example fermions on the points of a grid, with $0,1,2,\dots$ particles). For an external potential v write $\hat H_v=\hat T+\hat W+\hat V$, its grand potential $\Omega_v[\hat\rho]=\operatorname{Tr}[\hat\rho\,(\hat H_v-\mu\hat N)]-T\,S[\hat\rho]$, its Gibbs state $\hat\rho_v$, and n_v for the density of $\hat\rho_v$, the **equilibrium density**. The density of a mixture $\hat\rho=\sum_k w_k|\Psi_k\rangle\langle\Psi_k|$ is $n_{\hat\rho}=\sum_k w_k\,n_k$, where n_k is the density of Ψ_k, and

$$\operatorname{Tr}(\hat\rho\,\hat V)=\sum_k w_k\,\langle\Psi_k|\hat V\Psi_k\rangle=\sum_k w_k\int v\,n_k\,dx=\int v\,n_{\hat\rho}\,dx.$$

The first step uses that the trace of $|\Psi\rangle\langle\Psi|\hat V$ (on a grid: the column Ψ times the row $\Psi^\dagger\hat V$) is the number $\langle\Psi|\hat V\Psi\rangle$; the second is the rule of Section 13.3 that an external energy needs only the density, applied to each Ψ_k; the third exchanges the sum and the integral. With $v=1$ the operator $\hat V$ is $\hat N$, so also $\operatorname{Tr}(\hat\rho\,\hat N)=\int n_{\hat\rho}\,dx$.

Theorem (Mermin). If v and v' differ at some point, then $n_v\neq n_{v'}$: at a fixed T and μ the equilibrium density determines the external potential.

Proof. *Step 1: the two Gibbs states differ.* Suppose $\hat\rho_v = \hat\rho_{v'}$. Then their logarithms are equal, and by the first line of the proof of the Gibbs principle, $-(\hat H_v - \mu\hat N)/T - \ln Z = -(\hat H_{v'} - \mu\hat N)/T - \ln Z'$; multiplying by $-T$ and cancelling $\hat T + \hat W - \mu\hat N$ on both sides, $\hat V - \hat V' = T\,(\ln Z' - \ln Z)\cdot 1 = c\cdot 1$, a number c times the unit operator. Applied to the state with no particle, $\hat V - \hat V'$ gives 0 (with no particle there is no potential energy), so $c = 0$. Applied to the state with one particle at the grid point x_k, it gives $v(x_k) - v'(x_k)$ times that state, so $v(x_k) = v'(x_k)$ at every point, against the assumption. Hence $\hat\rho_v \neq \hat\rho_{v'}$. *Step 2: two strict inequalities.* Since $\hat H_v - \mu\hat N = (\hat H_{v'} - \mu\hat N) + (\hat V - \hat V')$ and the entropy does not depend on the potential, the rule above gives, for every density operator, $\Omega_v[\hat\rho] = \Omega_{v'}[\hat\rho] + \int (v - v')\, n_{\hat\rho}\, dx$. Therefore

$$\Omega_v[\hat\rho_v] < \Omega_v[\hat\rho_{v'}] = \Omega_{v'}[\hat\rho_{v'}] + \int (v - v')\, n_{v'}\, dx.$$

The first step is the Gibbs principle: $\hat\rho_v$ is the only minimiser of Ω_v, and $\hat\rho_{v'}$ is a different density operator (step 1), so its grand potential is strictly larger; the second step is the identity just stated, with $\hat\rho = \hat\rho_{v'}$. Exchanging the roles of v and v' gives in the same way

$$\Omega_{v'}[\hat\rho_{v'}] < \Omega_{v'}[\hat\rho_v] = \Omega_v[\hat\rho_v] + \int (v' - v)\, n_v\, dx.$$

Step 3: the contradiction. Suppose $n_v = n_{v'}$. Adding the two inequalities, the two integrals cancel, and $\Omega_v[\hat\rho_v] + \Omega_{v'}[\hat\rho_{v'}] < \Omega_v[\hat\rho_v] + \Omega_{v'}[\hat\rho_{v'}]$, which is false. Hence $n_v \neq n_{v'}$. □

Two differences from the Hohenberg-Kohn theorem: no non-degeneracy and no non-vanishing wave function is needed, because the Gibbs state is always the only minimiser and step 1 uses only the states with zero and one particle; and the potential is determined completely, not only up to a constant, because at a fixed μ a constant added to v changes the equilibrium state (it acts like a change of μ).

The universal functional at a temperature. For every density n of some density operator define, as in the constrained search of Section 13.8,

$$F_T[n] = \min_{\hat\rho\to n} \Big(\mathrm{Tr}[\hat\rho\,(\hat T + \hat W)] - T\,S[\hat\rho]\Big),$$

the smallest value among all density operators with the density n (we ASSUME, as there, that the minimum is attained). It depends on T but not on v or μ. Then

$$\Omega_v[\hat\rho_v] = \min_n \Big(F_T[n] + \int (v - \mu)\, n\, dx\Big).$$

Proof: by the Gibbs principle the left side is the minimum of Ω_v over all density operators. Organise the minimisation in two steps, first over the $\hat\rho$ with a given density n, then over n. For all these $\hat\rho$ the part $\mathrm{Tr}[\hat\rho\,(\hat V - \mu\hat N)] = \int (v - \mu)\, n\, dx$ is the same (the rule above, and its case $v = 1$), so the inner minimum is $F_T[n] + \int (v - \mu)\, n\, dx$; the outer minimum over n is then the minimum over all $\hat\rho$. □ This is the foundation of DFT at a temperature.

Non-interacting fermions: independent orbitals, line by line. For non-interacting fermions with orbital energies ϵ_a, $\hat H - \mu\hat N = \sum_a (\epsilon_a - \mu)\,\hat n_a$, and every occupation-number state $|n_0 n_1 \cdots\rangle$ is an eigenstate with the eigenvalue $\sum_a (\epsilon_a - \mu) n_a$. Its Gibbs weight is

$$\frac{e^{-\sum_a(\epsilon_a-\mu)n_a/T}}{Z} = \prod_a \frac{e^{-(\epsilon_a-\mu)n_a/T}}{1+e^{-(\epsilon_a-\mu)/T}}, \qquad Z = \prod_a \left(1+e^{-(\epsilon_a-\mu)/T}\right),$$

because the exponential of a sum is the product of the exponentials, and the sum over all choices $n_a \in \{0,1\}$ of a product of factors, one per orbital, is the product of the sums of each factor over $n_a = 0, 1$. So the configuration $\{n_a\}$ has the probability $\prod_a p_a(n_a)$ with

$$p_a(1) = \frac{e^{-(\epsilon_a-\mu)/T}}{1+e^{-(\epsilon_a-\mu)/T}} = \frac{1}{e^{(\epsilon_a-\mu)/T}+1} = f_a, \qquad p_a(0) = 1-f_a :$$

each orbital is an independent two-state system, occupied with the **Fermi-Dirac** probability f_a (the second step multiplies numerator and denominator by $e^{(\epsilon_a-\mu)/T}$). Because the logarithm of a product is a sum, the entropy of independent orbitals is the sum of their entropies,

$$S_s = -\sum_a \left[f_a \ln f_a + (1-f_a)\ln(1-f_a)\right].$$

Notebook 13e (In [6]) checks the product form on three orbitals: the eight Gibbs weights equal the eight products to 10^{-15}.

The Mermin-Kohn-Sham functional. The non-interacting reference system at $T > 0$ is an ensemble of orbitals ϕ_a with occupations $f_a \in [0,1]$, density $n = \sum_a f_a|\phi_a|^2$ and entropy S_s. Mermin's Kohn-Sham functional is the free energy

$$F = \sum_a f_a \Big\langle \phi_a \Big| -\frac{1}{2}\frac{d^2}{dx^2}\Big|\phi_a\Big\rangle - T\,S_s + \int v\,n\,dx + E_H[n] + F_{xc}[n],$$

with a temperature-dependent exchange-correlation part F_{xc}. Making F stationary with respect to the orbitals gives the Kohn-Sham equations of Section 13.10 unchanged. Making it stationary with respect to the occupations under the condition $\sum_a f_a = N$ (multiplier μ), line by line:

$$\frac{\partial}{\partial f_a}\Big[F - \mu\Big(\sum_b f_b - N\Big)\Big] = \epsilon_a + T\ln\frac{f_a}{1-f_a} - \mu = 0,$$
$$\ln\frac{f_a}{1-f_a} = -\frac{\epsilon_a-\mu}{T} \quad\Longrightarrow\quad f_a = \frac{1}{e^{(\epsilon_a-\mu)/T}+1}.$$

The first line uses that the energy terms change with f_a by $\langle\phi_a|-\frac{1}{2}d^2/dx^2|\phi_a\rangle + \int(v+v_H+v_{xc})|\phi_a|^2 = \epsilon_a$ (the chain rule through n), and that $\frac{d}{df}[f\ln f + (1-f)\ln(1-f)] = \ln f + 1 - \ln(1-f) - 1 = \ln\frac{f}{1-f}$; the second solves for f_a (take the exponential of both sides and solve $f/(1-f) = e^{-(\epsilon-\mu)/T}$). So the occupations are the Fermi-Dirac numbers. As $T \to 0$, $f_a \to 1$ below μ and $f_a \to 0$ above it: the aufbau rule (Figure 13e.2).

Finding μ. The particle number $\sum_a g_a f_a$ (g_a: the number of states of level a) increases strictly with μ, because each f_a does; so exactly one μ gives $\sum_a g_a f_a = N$, and **bisection** finds it: start with an interval that surely contains μ, look at its middle, keep the half in which the particle number crosses N, and repeat; every step halves the interval (Figure 13e.3). The Revision

Kohn-Sham solver fixes μ by the same condition, written in a form that loses no digits when N is large: it splits the levels at a dividing point and balances the thermally excited particles above it against the holes below it, counting a hole with $f(-x) = 1 - f(x)$ computed without a subtraction, and finds the root of this balance in a logarithmic form (named LogBalance) by Newton steps safeguarded by bisection (`Revision/kohn_sham/results/parameters.json`, conventions merminRoot and numerics merminRoot).

A form of the entropy without $\ln 0$, line by line. With $x = (\epsilon - \mu)/T$, $f = 1/(e^x + 1)$ and $1 - f = e^x/(e^x + 1)$:

$$-\ln f = \ln(1 + e^x), \qquad -\ln(1 - f) = \ln(1 + e^x) - x = \ln(1 + e^{-x}),$$
$$s(x) = -f \ln f - (1 - f)\ln(1 - f) = f \ln(1 + e^x) + (1 - f)\ln(1 + e^{-x}).$$

For $x \geq 0$ write $\ln(1+e^x) = x + \ln(1+e^{-x})$; then $s = f\,x + f\ln(1+e^{-x}) + (1-f)\ln(1+e^{-x}) = \ln(1+e^{-x}) + x\,f(x)$. Since $s(-x) = s(x)$ (exchanging f and $1-f$), for every x: $s = \ln(1+e^{-|x|}) + |x|\,f(|x|)$, a form in which no logarithm of 0 and no overflow can occur. Notebook 13e uses it.

Thermodynamics, line by line. At fixed N the energy is $E = \sum_a g_a f_a \epsilon_a$ and the free energy $F = E - TS_s$, both functions of T through the occupations and μ. (i) $dF/dT = -S_s$ (the **envelope theorem**). F depends on T explicitly (the factor T in $-TS_s$) and through the occupations:

$$\frac{dF}{dT} = \frac{\partial F}{\partial T}\Big|_f + \sum_a \frac{\partial F}{\partial f_a}\,\frac{df_a}{dT} = -S_s + \mu \sum_a g_a \frac{df_a}{dT} = -S_s + \mu\,\frac{dN}{dT} = -S_s.$$

The first step is the chain rule; the second uses the stationarity condition $\partial F/\partial f_a = g_a\mu$ found above (for a level with g_a states); the third recognises the derivative of $N = \sum_a g_a f_a$; the fourth uses that N is fixed. (ii) $C_V = T\,dS_s/dT$: the **heat capacity** $C_V = dE/dT = d(F + TS_s)/dT = -S_s + S_s + T\,dS_s/dT$. (iii) **The variance formula.** With $f = 1/(e^x + 1)$, $df/dx = -f(1-f)$, and $x = (\epsilon - \mu)/T$ changes with T by $dx/dT = -(\epsilon - \mu)/T^2 - \mu'/T$ ($\mu' = d\mu/dT$). So, with $w_a = g_a f_a (1 - f_a)$,

$$g_a \frac{df_a}{dT} = w_a\Big[\frac{\epsilon_a - \mu}{T^2} + \frac{\mu'}{T}\Big], \qquad 0 = \frac{dN}{dT} = \sum_a w_a\Big[\frac{\epsilon_a - \mu}{T^2} + \frac{\mu'}{T}\Big] \;\Rightarrow\; \frac{\mu'}{T} = -\frac{\sum_a w_a(\epsilon_a - \mu)}{T^2 \sum_a w_a},$$
$$C_V = \sum_a \epsilon_a\, g_a \frac{df_a}{dT} = \sum_a (\epsilon_a - \mu)\, g_a \frac{df_a}{dT} = \frac{1}{T^2}\Big[\sum_a w_a(\epsilon_a - \mu)^2 - \frac{\big(\sum_a w_a(\epsilon_a - \mu)\big)^2}{\sum_a w_a}\Big].$$

The first line is the chain rule and the condition of fixed N, solved for μ'; in the second line the second step subtracts $\mu \sum_a g_a\, df_a/dT = \mu\, dN/dT = 0$, and the third inserts the first line and μ'. The bracket is $\sum_a w_a$ times the **weighted variance** of the numbers $\epsilon_a - \mu$ with the weights w_a, which is never negative (it equals $\sum_a w_a(\epsilon_a - \bar\epsilon)^2$ with the weighted mean $\bar\epsilon$, a sum of non-negative terms). Hence $C_V \geq 0$.

Worked example: two levels, one particle. Levels $\epsilon_0 = 0$ and $\epsilon_1 = 1$ (one state each), one particle, $T = \frac{1}{2}$, no interaction. By symmetry $\mu = \frac{1}{2}$: then $f_0 + f_1 = \frac{1}{e^{-1}+1} + \frac{1}{e^{1}+1} = 1$ (the two fractions add to 1, as one sees by multiplying the first by e/e). So $f_0 = 1/(e^{-1} + 1) = 0.731059$, $f_1 = 0.268941$, $E = f_1\epsilon_1 = 0.268941$, $S_s = 1.164406$ (each level contributes 0.582203), and

$F = E - TS_s = 0.268941 - 0.582203 = -0.313262$. Since $\mu = \frac{1}{2}$ at every temperature, $E(T) = 1/(e^{1/(2T)}+1)$ and $C_V = dE/dT = \frac{e^{1/(2T)}}{(e^{1/(2T)}+1)^2}\cdot\frac{1}{2T^2}$, which at $T = \frac{1}{2}$ is $2e/(e+1)^2 = 0.393224$. Notebook 13e (In [8] and In [10]) computes all these numbers and checks $dF/dT = -S_s$ by a difference quotient.

13.27 Excited states: the Kohn-Sham gap, Janak's theorem and Delta-SCF

The ground-state theory says nothing directly about excited states. This section introduces the particle-hole energies, the Kohn-Sham gap, Janak's theorem and the Delta-SCF method. The Revision Kohn-Sham solver reports three of these quantities for dirac16complex, the particle-hole energies, the Kohn-Sham gap and the Delta-SCF excitation energy (the folder `Revision/kohn_sham/results/excited`); Janak's theorem is the exact statement that connects the last two.

Particle-hole excitations and the Kohn-Sham gap. In a non-interacting system, moving one particle from an occupied orbital i (it leaves a **hole**) to an empty orbital a (a **particle**) costs exactly $\epsilon_a - \epsilon_i$, because the levels do not depend on the occupations. The smallest such cost is the **Kohn-Sham gap**

$$\Delta_{KS} = \epsilon_{LUMO} - \epsilon_{HOMO},$$

where HOMO is the highest occupied orbital and LUMO the lowest unoccupied orbital (names taken over from chemistry). In the interacting system the Kohn-Sham levels move when the occupations change, so Δ_{KS} is only a first estimate of the lowest excitation energy.

Janak's theorem. Let the energy $E(\{f\})$ be evaluated with orbitals that are self-consistent for the given occupations. Then

$$\frac{\partial E}{\partial f_a} = \epsilon_a.$$

Proof. $E = \sum_b f_b\langle\phi_b| -\tfrac{1}{2}d^2/dx^2|\phi_b\rangle + E_{pot}[n]$, where E_{pot} collects $\int v\,n$, E_H and E_{xc}, and $n = \sum_b f_b|\phi_b|^2$. E depends on f_a explicitly and through the orbitals. The explicit derivative is $\langle\phi_a| -\tfrac{1}{2}d^2/dx^2|\phi_a\rangle + \int(\delta E_{pot}/\delta n)|\phi_a|^2 = \langle\phi_a|h_s\phi_a\rangle = \epsilon_a$, with the Kohn-Sham Hamiltonian h_s. The change through the orbitals is $\sum_b f_b\big(\langle d\phi_b|h_s\phi_b\rangle + \langle h_s\phi_b|d\phi_b\rangle\big) = \sum_b f_b\,\epsilon_b\,d\langle\phi_b|\phi_b\rangle = 0$, because the Kohn-Sham equations $h_s\phi_b = \epsilon_b\phi_b$ hold and the orbitals stay normalised ($\langle\phi_b|\phi_b\rangle = 1$ does not change). $\square$

Delta-SCF. The **Delta-SCF** method computes an excited state as a second self-consistent solution in which the occupations are fixed by hand: one particle is taken out of the HOMO and put into the LUMO, and the Kohn-Sham loop is run again with these occupations. The excitation energy is the difference of the two energies, $\Delta_{SCF} = E_1 - E_0$. Janak's theorem connects it with the gap: move the particle gradually, $f_{HOMO} = 1-\tau$ and $f_{LUMO} = \tau$; then by the chain rule $dE/d\tau = \partial E/\partial f_{LUMO} - \partial E/\partial f_{HOMO} = \epsilon_{LUMO}(\tau) - \epsilon_{HOMO}(\tau)$, and integrating from $\tau = 0$ to 1,

$$\Delta_{SCF} = \int_0^1 \left[\epsilon_{LUMO}(\tau) - \epsilon_{HOMO}(\tau)\right] d\tau.$$

At $\tau = 0$ the integrand is Δ_{KS}; the difference $\Delta_{SCF} - \Delta_{KS}$ measures how much the levels move when the particle is transferred (the **orbital relaxation**). The midpoint value $\epsilon_{LUMO}(\frac{1}{2}) - \epsilon_{HOMO}(\frac{1}{2})$ (Slater's **transition state**) is a good estimate of the integral when the integrand is nearly a straight line in τ. Janak's theorem and the integral formula are PROVED; that the Delta-SCF state approximates a true excited state of the interacting system is an ASSUMPTION of the method. The Revision solver uses an **ensemble** form: one particle is moved from the highest occupied group of equal levels to the lowest empty group, spread evenly over each group, which keeps the symmetries of its reduction (`Revision/kohn_sham/results/parameters.json`, conventions deltaScf).

Toy example. Take the model energy $E(f_H, f_L) = \epsilon_H^0 f_H + \epsilon_L^0 f_L + \frac{U}{2}(f_H^2 + f_L^2)$ with $\epsilon_H^0 = 0$, $\epsilon_L^0 = 1$, $U = 0.2$ (the last term plays the role of a self-interaction of each orbital). Janak's theorem gives the levels $\epsilon_H = \partial E/\partial f_H = U f_H$ and $\epsilon_L = 1 + U f_L$. In the ground state $(f_H, f_L) = (1, 0)$: $E_0 = 0.1$, $\epsilon_H = 0.2$, $\epsilon_L = 1$, so $\Delta_{KS} = 0.8$. In the Delta-SCF state $(0, 1)$: $E_1 = 1 + 0.1 = 1.1$, so $\Delta_{SCF} = 1.0$. The integral formula reproduces it: $\int_0^1 [1 + U\tau - U(1-\tau)]\, d\tau = \int_0^1 (0.8 + 0.4\tau)\, d\tau = 0.8 + 0.2 = 1$. Here the relaxation raises the excitation energy by $U = 0.2$ above the gap, and the transition state is exact because the integrand is a straight line. (In the trap of Notebook 13a, Section 13.32, the relaxation lowers it instead: its sign depends on the system.)

13.28 Example: Mermin thermodynamics and Delta-SCF

Notebook 13e checks every exact statement of Sections 13.26 and 13.27 with numbers: the Gibbs principle and Klein's inequality on the 16 states of the two-site model with 2000 random density operators, the independence of the orbitals of non-interacting fermions, the Fermi-Dirac function, the bisection for μ (and the rule by which the Revision solver fixes μ, read from its parameter file), the thermodynamics of two levels (the worked numbers 0.731059, 1.164406, −0.313262, 0.393224) and of a ladder of levels, and Janak's theorem with the Delta-SCF integral on the toy model energy. Its statements are PROVED above; its numbers are toy numbers (no Revision number is reproduced). It ends with ALL 24 CHECKS PASSED (notebook 13e) and draws seven figures.

13.29 How to run Notebook 13e

Step 1. What this notebook does and what it needs.

Notebook 13e (Finite temperature (Mermin) and excited states (Delta-SCF)) is the file `Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb` of the repository Dirac_claude. It checks the Gibbs principle and Klein's inequality on the 16 states of the two-site model with 2000 random density operators, shows that the Gibbs state of non-interacting fermions factorises into independent orbitals with Fermi-Dirac occupations, finds the chemical potential by bisection (and reads the rule by which the Revision Kohn-Sham solver fixes it), computes the free energy, energy, entropy and heat capacity of a two-level system (the worked numbers 0.731059, 1.164406, -0.313262, 0.393224) and of a ladder of levels with checks of dF/dT = -S and of the variance formula for the heat capacity, and checks Janak's theorem and the Delta-SCF integral formula on a model energy, with seven teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the

program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13e_mermin_delta_scf.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13e_mermin_delta_scf.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 13e_mermin_delta_scf.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/13e.captions.json`
- `Revision/textbook/figures/13e_1_gibbs_principle.png`
- `Revision/textbook/figures/13e_2_fermi_dirac.png`
- `Revision/textbook/figures/13e_3_bisection.png`
- `Revision/textbook/figures/13e_4_two_level_thermo.png`
- `Revision/textbook/figures/13e_5_ladder_occupations.png`
- `Revision/textbook/figures/13e_6_ladder_thermo.png`
- `Revision/textbook/figures/13e_7_janak_delta_scf.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13e_7_janak_delta_scf.png exists
ALL 24 CHECKS PASSED (notebook 13e)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 13e_mermin_delta_scf.ipynb
python -m nbconvert --execute --inplace 13e_mermin_delta_scf.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `parameters.json`: the notebook reads the file `Revision/kohn_sham/results/parameters.json` of the repository; it must be opened inside the folder `Revision/textbook/notebooks` of a complete clone of the repository, not as a single downloaded file.

13.30 Notebook 13e: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Density functional theory at a temperature $T > 0$ (Mermin's theorem) and for
excited states (Delta-SCF) rests on a few exact statements. This notebook checks
each of them with numbers. It

- checks the Gibbs principle: among all density operators of the two-site model,
  the Gibbs state $e^{-(\hat H - \mu\hat N)/T}/Z$ has the lowest grand potential
  $\Omega$, and $\Omega - \Omega_{Gibbs} = T\,D$ with Klein's $D \ge 0$ (2000 random
  density operators);
- checks that the Gibbs state of non-interacting fermions is a product of
  independent orbitals, each occupied with the Fermi-Dirac probability;
- draws the Fermi-Dirac function and finds the chemical potential by bisection;
- computes the thermodynamics of a two-level system (the worked example of the
  chapter) and of a ladder of levels: free energy, energy, entropy, heat capacity,
  with the checks $dF/dT = -S$ and $C_V = T\,dS/dT = dE/dT \ge 0$;
- checks Janak's theorem $\partial E/\partial f_a = \epsilon_a$ and the Delta-SCF
  formula $\Delta_{SCF} = \int_0^1 [\epsilon_L(\tau) - \epsilon_H(\tau)]\,d\tau$ on a
  model energy;
- draws seven teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 13e (Finite temperature (Mermin) and excited states (Delta-SCF)) is the file
`Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb` of the repository Dirac_claude.
It checks the Gibbs principle and Klein's inequality on the 16 states of the two-site
model with 2000 random density operators, shows that the Gibbs state of non-interacting
fermions factorises into independent orbitals with Fermi-Dirac occupations, finds the
chemical potential by bisection (and reads the rule by which the Revision Kohn-Sham
solver fixes it), computes the free energy, energy, entropy and heat capacity of a
two-level system (the worked numbers 0.731059, 1.164406, -0.313262, 0.393224) and of a
ladder of levels with checks of dF/dT = -S and of the variance formula for the heat
capacity, and checks Janak's theorem and the Delta-SCF integral formula on a model
energy, with seven teaching plots. It needs a computer with Windows 11, macOS or Linux,
an internet connection for the installation, the program Git, and Python 3.12 or newer
(the notebooks were built with Python 3.14.5) with these packages at exactly these
versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10,
nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook
itself imports numpy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
```

default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
```

```
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 13e_mermin_delta_scf.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 13e_mermin_delta_scf.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 13e_mermin_delta_scf.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/13e.captions.json‘
- ‘Revision/textbook/figures/13e_1_gibbs_principle.png‘
- ‘Revision/textbook/figures/13e_2_fermi_dirac.png‘
- ‘Revision/textbook/figures/13e_3_bisection.png‘
- ‘Revision/textbook/figures/13e_4_two_level_thermo.png‘
- ‘Revision/textbook/figures/13e_5_ladder_occupations.png‘
- ‘Revision/textbook/figures/13e_6_ladder_thermo.png‘
- ‘Revision/textbook/figures/13e_7_janak_delta_scf.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it

runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13e_7_janak_delta_scf.png exists
ALL 24 CHECKS PASSED (notebook 13e)
```

and the notebook must show 7 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 13e_mermin_delta_scf.ipynb
  python -m nbconvert --execute --inplace 13e_mermin_delta_scf.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues

  and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
  and Run All Cells; if it fails again, install the packages again with the pip commands
  of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for ‘parameters.json‘: the notebook reads the file
  ‘Revision/kohn_sham/results/parameters.json‘ of the repository; it must be opened
  inside the folder ‘Revision/textbook/notebooks‘ of a complete clone of the repository,
  not as a single downloaded file.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 13e (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 13e (Finite temperature (Mermin) and excited states (Delta-SCF)) is the file
# Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb of the repository Dirac_claude.
# It checks the Gibbs principle and Klein's inequality on the 16 states of the two-site
# model with 2000 random density operators, shows that the Gibbs state of non-interacting
# fermions factorises into independent orbitals with Fermi-Dirac occupations, finds the
# chemical potential by bisection (and reads the rule by which the Revision Kohn-Sham
# solver fixes it), computes the free energy, energy, entropy and heat capacity of a
# two-level system (the worked numbers 0.731059, 1.164406, -0.313262, 0.393224) and of a
# ladder of levels with checks of dF/dT = -S and of the variance formula for the heat
# capacity, and checks Janak's theorem and the Delta-SCF integral formula on a model
# energy, with seven teaching plots. It needs a computer with Windows 11, macOS or Linux,
# an internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the

#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 13e_mermin_delta_scf.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
```

```
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 13e_mermin_delta_scf.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 13e_mermin_delta_scf.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/13e.captions.json
# - Revision/textbook/figures/13e_1_gibbs_principle.png
# - Revision/textbook/figures/13e_2_fermi_dirac.png
# - Revision/textbook/figures/13e_3_bisection.png
# - Revision/textbook/figures/13e_4_two_level_thermo.png
# - Revision/textbook/figures/13e_5_ladder_occupations.png
# - Revision/textbook/figures/13e_6_ladder_thermo.png
# - Revision/textbook/figures/13e_7_janak_delta_scf.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 13e_7_janak_delta_scf.png exists
#     ALL 24 CHECKS PASSED (notebook 13e)
#
# and the notebook must show 7 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
```

```
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/13e_mermin_delta_scf.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 13e_mermin_delta_scf.ipynb
#     python -m nbconvert --execute --inplace 13e_mermin_delta_scf.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for parameters.json: the notebook reads the file
#   Revision/kohn_sham/results/parameters.json of the repository; it must be opened
#   inside the folder Revision/textbook/notebooks of a complete clone of the repository,
#   not as a single downloaded file.
#

## 3. The words used in this notebook

- **Temperature** $T$: measured as an energy (Boltzmann's constant is set to 1).
- **Density operator** $\hat\rho$: a Hermitian matrix with eigenvalues between 0 and
  1 that add up to 1; it describes a mixture of states with these probabilities.
- **Entropy** $S = -\mathrm{Tr}(\hat\rho\ln\hat\rho) = -\sum_i p_i\ln p_i$, where the
  $p_i$ are the eigenvalues of $\hat\rho$ (with $0\ln 0 = 0$).
- **Chemical potential** $\mu$: the energy that fixes the average particle number.
- **Grand potential** $\Omega[\hat\rho] = \mathrm{Tr}[\hat\rho(\hat H - \mu\hat N)]
  - T S$; **Gibbs state** $\hat\rho_0 = e^{-(\hat H - \mu\hat N)/T}/Z$ with
  $Z = \mathrm{Tr}\,e^{-(\hat H - \mu\hat N)/T}$; $\Omega[\hat\rho_0] = -T\ln Z$.
- **Klein's inequality**: $D = \mathrm{Tr}[\hat\rho(\ln\hat\rho -
  \ln\hat\sigma)] \ge 0$ for two density operators, with equality only when they are
  equal.
- **Fermi-Dirac occupation** $f(\epsilon) = 1/(e^{(\epsilon - \mu)/T} + 1)$: the
  probability that an orbital of energy $\epsilon$ is occupied.
- **Free energy** $F = E - TS$; **heat capacity** $C_V = dE/dT$ at a fixed particle
  number.
- **Bisection**: halving an interval that contains the root until it is small.
- **Janak's theorem**: the derivative of the self-consistent energy with respect to
  the occupation $f_a$ of an orbital is its level $\epsilon_a$.
- **Delta-SCF**: the excitation energy as the difference of two self-consistent
  energies, with one particle moved from the highest occupied orbital (H) to the
  lowest empty one (L).
```

Text cell:

```
## 4. The physical and mathematical situation

**Gibbs principle.** For every density operator $\hat\rho$ and the Gibbs state
$\hat\rho_0$: since $\hat H - \mu\hat N = -T\ln\hat\rho_0 - T\ln Z$,

$$\Omega[\hat\rho] = -T\ln Z + T\,\mathrm{Tr}[\hat\rho(\ln\hat\rho -
\ln\hat\rho_0)] = \Omega[\hat\rho_0] + T\,D \ge \Omega[\hat\rho_0] .$$

**Non-interacting fermions.** If $\hat H - \mu\hat N = \sum_a (\epsilon_a - \mu)\hat
n_a$, the weight of the configuration $(n_0, n_1, \dots)$ in the Gibbs state is the
product $\prod_a p_a(n_a)$ with $p_a(1) = f_a$, $p_a(0) = 1 - f_a$: the orbitals are
independent. The entropy is then $S = -\sum_a [f_a\ln f_a + (1 - f_a)\ln(1 - f_a)]$.

**Fixed particle number.** $\sum_a g_a f_a = N$ ($g_a$: the number of states of
level $a$) increases strictly with $\mu$, so exactly one $\mu$ solves it; bisection
finds it. Then $E = \sum g_a f_a\epsilon_a$, $F = E - TS$, and because $F$ is
stationary in the occupations (envelope theorem), $dF/dT = -S$ and
$C_V = dE/dT = T\,dS/dT$. With $w_a = g_a f_a(1 - f_a)$ one finds
```

```
$C_V = \frac{1}{T^2}\big[\sum_a w_a(\epsilon_a - \mu)^2 - (\sum_a w_a(\epsilon_a -
\mu))^2/\sum_a w_a\big] \ge 0$ (a weighted variance).

**Janak and Delta-SCF.** For the model energy
$E(f_H, f_L) = \epsilon_H^0 f_H + \epsilon_L^0 f_L + \tfrac{U}{2}(f_H^2 + f_L^2)$
the levels are $\epsilon_a = \partial E/\partial f_a = \epsilon_a^0 + U f_a$. Moving
a fraction $\tau$ from H to L ($f_H = 1 - \tau$, $f_L = \tau$) gives
$dE/d\tau = \epsilon_L(\tau) - \epsilon_H(\tau)$, so
$\Delta_{SCF} = E(0, 1) - E(1, 0) = \int_0^1[\epsilon_L(\tau) - \epsilon_H(\tau)]
\,d\tau$.

**Status.** Exact finite-dimensional statements (PROVED: they follow from the
definitions; this notebook checks each one to rounding); toy numbers, no Revision
number is reproduced. The Revision Kohn-Sham solver uses the same Mermin
occupations with $\mu$ fixed by $\sum g f = N$; section 8 reads this rule from the
solver's parameter file. That a Delta-SCF state approximates a true excited state
is an ASSUMPTION of the method; Janak's theorem itself is exact.
```

## 7. The Fermi-Dirac function

The next cell defines $f$ in a form that a computer can evaluate for every
argument: $e^{x}$ overflows (exceeds the largest number the computer can store,
about $10^{308}$) for $x > 709$, so the cell uses $f = e^{-\ln(1 + e^{x})}$ with
numpy's `logaddexp(0, x)` $= \ln(e^0 + e^x)$, which never overflows. It draws
$f(\epsilon)$ for four temperatures around $\mu = 0$ and checks $f(\mu) = 1/2$ and
the symmetry $f(\mu + \delta) = 1 - f(\mu - \delta)$ (a hole below $\mu$ is as
likely as a particle above it).
```

In [7]:

```
def fermi(energy, mu, temperature):

## 8. Two levels, one particle: the chemical potential by bisection

Two levels $\epsilon_0 = 0$, $\epsilon_1 = 1$ (one state each), one particle,
$T = 1/2$. The next cell finds $\mu$ by bisection on $f_0 + f_1 - 1$, recording the
width of the interval at every step, and computes the worked numbers of the
chapter. The bisection starts from an interval that surely contains $\mu$: from the
lowest level minus $50T + 5$ to the highest level plus 5, here $[-30, 6]$. At its
lower end every occupation is below $e^{-50}$, so the levels hold fewer than $N$
particles; at its upper end they hold almost all their states (here nearly 2),
more than $N = 1$. The entropy of one state of energy
$\epsilon$ is $-f\ln f - (1 - f)\ln(1 - f)$; with $x = (\epsilon - \mu)/T$ it equals
$\ln(1 + e^{-|x|}) + |x|\,f(|x|)$ (insert $f = 1/(e^x + 1)$ and simplify), a form
without $\ln 0$ that the cell uses.
```

In [8]:

The Revision Kohn-Sham solver of the dirac16complex field fixes its chemical
potential by the same condition $\sum g f = N$. The next cell reads how from the
solver's parameter file. With many particles the direct difference
$\sum g f - N$ loses digits (two large, nearly equal numbers are subtracted), so the
solver splits the levels at a dividing point and balances the thermally excited
particles above it against the holes below it; a hole is counted with $f(-x)$,
which equals $1 - f(x)$ (section 7) but is computed without a subtraction. It
finds the root of this balance, written with logarithms (the form it calls
LogBalance), by Newton steps safeguarded by bisection.

Out [17]:

```
PASS all seven figure files exist
PASS the figure file 13e_7_janak_delta_scf.png exists
ALL 24 CHECKS PASSED (notebook 13e)
```

Text cell:

```
## 13. What this notebook showed

- The Gibbs state has the lowest grand potential of all density operators; the
  excess of any other state is $T$ times Klein's $D \ge 0$ (2000 random states).
  This is the variational principle behind Mermin's finite-temperature DFT.
- For non-interacting fermions the Gibbs state is a product of independent orbitals
```

```
  with the Fermi-Dirac occupations; the entropy is the sum of the orbital entropies.
- The chemical potential is found by bisection from $\sum g f = N$; every step halves
  the interval.
- Two levels at $T = 1/2$: $f_0 = 0.731059$, $E = 0.268941$, $S = 1.164406$,
  $F = -0.313262$, $dF/dT = -S$, $C_V = 0.393224$; the heat capacity has one peak.
- For a ladder of levels the heat capacity from $dE/dT$ equals the weighted-variance
  formula, so it is never negative.
- Janak's theorem holds, and the Delta-SCF excitation energy is the integral of the
  level difference over the transferred fraction; in the model it exceeds the
  Kohn-Sham gap by $U$.
```

13.31 Line-by-line walk-through of Notebook 13e

The notebook has seventeen code cells. **In [1]** is the set-up cell, identical to In [1] of Notebook 13c (Section 13.14) except for the name `"13e"` and its comment lines, which hold the instructions of Section 13.29.

In [2], the two-site model in Fock space.

```
import itertools  # loops over combinations

import numpy as np  # arrays, matrices and linear algebra

M, DIM = 4, 16  # four orbitals, sixteen occupation-number states
a = []  # annihilation operators
for p in range(M):
    matrix = np.zeros((DIM, DIM))
    for state in range(DIM):
        if (state >> p) & 1:  # orbital p is occupied in this state
            nu = sum((state >> q) & 1 for q in range(p))  # occupied before p
            matrix[state ^ (1 << p), state] = (-1) ** nu
    a.append(matrix)
a_dag = [matrix.T for matrix in a]
n_op = [a_dag[p] @ a[p] for p in range(M)]
N_op = sum(n_op)  # the particle-number operator
```

The same construction of the 16×16 operator matrices as in In [4] of Notebook 13c (Section 13.14 explains every line), with the bit test written directly instead of through a function `bit`. `n_op` are the occupation operators and `N_op` the number operator $\hat{N}$.

```
H = -(a_dag[0] @ a[1] + a_dag[1] @ a[0] + a_dag[2] @ a[3] + a_dag[3] @ a[2]) \
    + 2.0 * (n_op[0] @ n_op[2] + n_op[1] @ n_op[3])  # t = 1, U = 2
check(np.allclose(H, H.T) and np.allclose(H @ N_op, N_op @ H),
      "H is symmetric and conserves the particle number")
```

The two-site Hamiltonian with $t = 1$, $U = 2$ on all 16 states (all particle numbers from 0 to 4). The check: H is symmetric (real Hermitian) and commutes with $\hat{N}$ ($H\hat{N} = \hat{N}H$), so it never changes the particle number.

In [3], the Gibbs state.

```
MU, TEMPERATURE = 1.0, 0.5
K = H - MU * N_op  # H - mu N

def entropy(rho):
    """S = -sum p ln p over the eigenvalues p of rho (0 ln 0 = 0)."""
    p = np.clip(np.linalg.eigvalsh(rho), 0.0, None)
    p = p[p > 1e-300]
    return float(-np.sum(p * np.log(p)))

def grand_potential(rho):
    """Omega = Tr[rho (H - mu N)] - T S."""
    return float(np.trace(rho @ K).real) - TEMPERATURE * entropy(rho)
```

$\mu = 1$, $T = 0.5$ and $K = \hat{H} - \mu\hat{N}$. `entropy` computes $-\sum_i p_i \ln p_i$ from the eigenvalues of a density operator: `np.clip(..., 0.0, None)` replaces tiny negative rounding errors by 0, and `p[p > 1e-300]` drops the zeros (the rule $0 \ln 0 = 0$). `grand_potential` is $\Omega = \mathrm{Tr}(\hat{\rho}K) - TS$.

```
k_values, k_vectors = np.linalg.eigh(K)
boltzmann = np.exp(-(k_values - k_values.min()) / TEMPERATURE)  # shifted weights
Z_shifted = boltzmann.sum()
rho_gibbs = (k_vectors * (boltzmann / Z_shifted)) @ k_vectors.T
ln_Z = np.log(Z_shifted) - k_values.min() / TEMPERATURE  # undo the shift
omega_gibbs = grand_potential(rho_gibbs)
```

The Gibbs state as a function of K: eigenvalues and eigenvectors of K, the weights $e^{-k_i/T}$ shifted by the smallest eigenvalue to avoid overflow (Section 13.14 explains the shift), and $\hat{\rho}_0 = \sum_i (w_i / \sum w)\, u_i u_i^T$. The true $\ln Z$ undoes the shift: $Z = Z_{shifted}\, e^{-k_{min}/T}$, so $\ln Z = \ln Z_{shifted} - k_{min}/T$. `omega_gibbs` is $\Omega[\hat{\rho}_0]$, computed with the function above.

```
report("Omega of the Gibbs state", f"{omega_gibbs:.10f}")
report("-T ln Z", f"{-TEMPERATURE * ln_Z:.10f}")
check(abs(omega_gibbs + TEMPERATURE * ln_Z) < 1e-12, "Omega[Gibbs] = -T ln Z")
```

The two `report` lines print $\Omega[\hat{\rho}_0]$ and $-T \ln Z$, both -3.4716265446, and the check requires them to agree to 10^{-12}.

In [4], 2000 random density operators.

```
ln_rho_gibbs = (k_vectors * (-k_values / TEMPERATURE - ln_Z)) @ k_vectors.T

def matrix_log(rho):
    """ln rho through the eigenvalues (all positive here)."""
    values, vectors = np.linalg.eigh(rho)
    return (vectors * np.log(values)) @ vectors.conj().T
```

$\ln \hat{\rho}_0 = -K/T - \ln Z$, built from the eigenvectors of K; `matrix_log` is the logarithm of a Hermitian matrix with positive eigenvalues, through its eigenvalues (Section 13.26).

```
rng = np.random.default_rng(12345)  # fixed seed: the same numbers every run
gaps, kleins = [], []
for _ in range(2000):
    A = rng.normal(size=(DIM, DIM)) + 1j * rng.normal(size=(DIM, DIM))
    random_rho = A @ A.conj().T
    random_rho /= np.trace(random_rho).real
    s = rng.uniform(0.0, 1.0)  # how far from the Gibbs state
    rho = (1.0 - s) * rho_gibbs + s * random_rho
    gaps.append(grand_potential(rho) - omega_gibbs)
    kleins.append(np.trace(rho @ (matrix_log(rho) - ln_rho_gibbs)).real)
gaps, kleins = np.array(gaps), np.array(kleins)
```

For a random complex matrix A, the matrix $AA^\dagger$ is Hermitian with non-negative eigenvalues ($\langle\chi|AA^\dagger\chi\rangle = |A^\dagger\chi|^2 \geq 0$); divided by its trace (`/=` divides the variable in place) it is a density operator. Mixed with the Gibbs state with a random weight s between 0 and 1 (`rng.uniform`), it gives states near and far from the minimum. For each, `gaps` stores $\Omega - \Omega_0$ and `kleins` Klein's D.

```
say(f"smallest Omega - Omega_0 among 2000 states: {gaps.min():.3e}")
check(np.all(gaps > 0.0), "every random density operator has Omega > Omega[Gibbs]")
check(np.max(np.abs(gaps - TEMPERATURE * kleins)) < 1e-10,
      "Omega - Omega[Gibbs] = T D with Klein's D (identity)")
```

The smallest excess is $3.878 \cdot 10^{-6}$ (`:.3e` writes a number with three decimals and a power of ten), still positive. The checks: all 2000 excesses are positive, and each equals $T\,D$ to 10^{-10}, the identity of the proof in Section 13.26.

In [5], the histogram.

```
fig, ax = plt.subplots()
bins = np.logspace(np.floor(np.log10(gaps.min())), np.ceil(np.log10(gaps.max())), 40)
ax.hist(gaps, bins=bins, color="tab:blue", edgecolor="black", lw=0.5)
ax.set_xscale("log")
```

`np.log10` is the logarithm to the base 10; `np.floor` and `np.ceil` round down and up to whole numbers, so the two arguments are the exponents of the powers of ten just below the smallest excess and just above the largest (-6 and 1 here). `np.logspace(a, b, 40)` makes 40 numbers from 10^a to 10^b, equally spaced on a logarithmic scale: the edges of the bins (the intervals in which the excesses are counted). `ax.hist` counts the excesses in each bin and draws the counts as blue bars with thin black edges, and `ax.set_xscale("log")` makes the horizontal axis logarithmic.

```
ax.set_xlabel("$\\Omega[\\hat\\rho] - \\Omega[\\hat\\rho_0]$ (units of $t$)")
ax.set_ylabel("number of random states")
ax.set_title("The Gibbs state has the lowest grand potential")
save_figure(fig, "gibbs_principle",
```

Labels (the grand potential is an energy, in units of the hopping t), title, and `save_figure` for Figure 13e.1.

What Figure 13e.1 shows. Every bar lies to the right of zero (on a logarithmic axis zero itself cannot appear, and no excess is negative): all 2000 random states have a larger grand potential

than the Gibbs state. Most excesses are between $0.1t$ and $2t$, from states mixed strongly away from the Gibbs state; a thin tail reaches down to about $4 \cdot 10^{-6}t$, from states with a mixing weight s close to 0. The closer a state is to the Gibbs state, the smaller its excess, but it never becomes negative.

In [6], independent orbitals.

```
levels3 = np.array([-0.5, 0.2, 1.0])
mu3, T3 = 0.1, 0.4
configurations = list(itertools.product((0, 1), repeat=3))
weights = np.array([np.exp(-np.dot(levels3 - mu3, c) / T3) for c in configurations])
weights /= weights.sum()  # divide by Z
f3 = 1.0 / (np.exp((levels3 - mu3) / T3) + 1.0)
products = np.array([np.prod([f3[k] if c[k] else 1.0 - f3[k] for k in range(3)])
                     for c in configurations])
```

Three orbitals with the energies -0.5, 0.2, 1.0 at $\mu = 0.1$, $T = 0.4$. The 8 configurations are all triples of zeros and ones (`itertools.product((0, 1), repeat=3)`). For each, `np.dot(levels3 - mu3, c)` is $\sum_a (\epsilon_a - \mu) n_a$, and its exponential, divided by the sum of all eight (Z), is the Gibbs weight. `products` multiplies, for each configuration, f_a for the occupied and $1 - f_a$ for the empty orbitals (`x if condition else y` chooses; `np.prod` multiplies the three factors).

```
for c, wgt, prod in zip(configurations, weights, products):
    say(f"occupations {c}: Gibbs weight {wgt:.6f}, product {prod:.6f}")
check(np.max(np.abs(weights - products)) < 1e-15,
      "the Gibbs weights are products of independent Fermi-Dirac probabilities")
```

The loop prints the eight pairs (for example 0.415797 and 0.415797 for the configuration (1, 0, 0), the most likely one: the lowest orbital, 0.6 below μ, filled, the others empty), and the check requires every weight to equal its product to 10^{-15}.

In [7], the Fermi-Dirac function.

```
def fermi(energy, mu, temperature):
    """The Fermi-Dirac occupation 1 / (exp(x) + 1), x = (energy - mu)/T, written
    as exp(-ln(1 + e^x)) so that no overflow can occur."""
    x = (np.asarray(energy, dtype=float) - mu) / temperature
    return np.exp(-np.logaddexp(0.0, x))
```

e^x exceeds the largest number the computer can store (about 10^{308}) for $x > 709$. Since $1/(e^x + 1) = e^{-\ln(1+e^x)}$, the function uses numpy's `logaddexp(0, x)` $= \ln(e^0 + e^x)$, which is computed without overflow for every x.

```
eps = np.linspace(-2.0, 2.0, 801)
check(abs(fermi(0.0, 0.0, 0.3) - 0.5) < 1e-15
      and np.allclose(fermi(eps, 0.0, 0.3), 1.0 - fermi(-eps, 0.0, 0.3), atol=1e-15),
      "f(mu) = 1/2 and f(mu + d) = 1 - f(mu - d)")
```

The check: $f(\mu) = \frac{1}{2}$, and $f(\mu + d) = 1 - f(\mu - d)$ for 801 values of d (a hole below μ is as likely as a particle above it; algebraically, $1 - \frac{1}{e^{-x}+1} = \frac{e^{-x}}{e^{-x}+1} = \frac{1}{1+e^x}$).

```
fig, ax = plt.subplots()
for temperature in (0.02, 0.1, 0.3, 1.0):
    ax.plot(eps, fermi(eps, 0.0, temperature), label=f"$T = {temperature}$")
ax.axvline(0.0, color="gray", ls="--", lw=0.8)
ax.set_xlabel("orbital energy $\\epsilon - \\mu$")
ax.set_ylabel("occupation $f$")
ax.set_title("The Fermi-Dirac occupation")
ax.legend()
save_figure(fig, "fermi_dirac",
```

The loop draws f against $\epsilon - \mu$ (with $\mu = 0$) for $T = 0.02$, 0.1, 0.3 and 1; a grey dashed vertical line marks $\epsilon = \mu$; labels, title, legend and `save_figure` for Figure 13e.2.

What Figure 13e.2 shows. At $T = 0.02$ the curve is practically a step: every orbital below μ is occupied and every orbital above it empty, the aufbau rule. As T grows, the step is smeared over a width of a few T: at $T = 1$ an orbital 2 below μ is occupied only with the probability 0.88. All four curves pass through $\frac{1}{2}$ at $\epsilon = \mu$, and each is point-symmetric about that point (the hole-particle symmetry just checked).

In [8], the chemical potential and the two-level system.

```
def chemical_potential(levels, degeneracies, N, temperature, history=None):
    """mu with sum g f = N, by bisection (the sum increases with mu)."""
    low, high = levels.min() - 50.0 * temperature - 5.0, levels.max() + 5.0
    for _ in range(100):
        middle = 0.5 * (low + high)
        if np.sum(degeneracies * fermi(levels, middle, temperature)) < N:
            low = middle  # too few particles: mu must rise
        else:
            high = middle
        if history is not None:
            history.append(high - low)
    return 0.5 * (low + high)
```

Bisection for μ (Section 13.26). The starting interval surely contains μ: at its lower end every occupation is below e^{-50}, so the levels hold fewer than N particles; at its upper end, 5 above the highest level, they hold almost all their states, more than N when N is less than the number of states. 100 halvings follow; if a list `history` is given, the width of the interval after each step is appended to it.

```
def thermodynamics(levels, degeneracies, N, temperature):
    """mu, occupations, E, S, F of non-interacting levels at fixed N."""
    mu = chemical_potential(levels, degeneracies, N, temperature)
    f = fermi(levels, mu, temperature)
    x = np.abs(levels - mu) / temperature
    s_level = np.logaddexp(0.0, -x) + x * fermi(x, 0.0, 1.0)  # entropy of a state
    S = np.sum(degeneracies * s_level)
    E = np.sum(degeneracies * f * levels)
    return mu, f, E, S, E - temperature * S
```

For given levels, degeneracies g_a, particle number and temperature: μ, the occupations, the entropy

of one state in the form $\ln(1+e^{-|x|})+|x|f(|x|)$ of Section 13.26 (`fermi(x, 0.0, 1.0)` is $1/(e^x+1)$), $S=\sum_a g_a s_a$, $E=\sum_a g_a f_a \epsilon_a$ and $F=E-TS$.

```
two_levels, ones = np.array([0.0, 1.0]), np.array([1.0, 1.0])
widths = []
chemical_potential(two_levels, ones, 1.0, 0.5, widths)
mu2, f2, E2, S2, F2 = thermodynamics(two_levels, ones, 1.0, 0.5)
```

The worked example of Section 13.26: levels 0 and 1, one state each, one particle, $T=\frac{1}{2}$. The first call records the widths of the bisection for the figure of In [10] (its result is not stored); the second computes the thermodynamics, and the five returned values are assigned to five names at once.

```
report("mu", f"{mu2:.6f}")
report("f_0, f_1", f"{f2[0]:.6f}, {f2[1]:.6f}")
report("E, S, F", f"{E2:.6f}, {S2:.6f}, {F2:.6f}")
check(abs(mu2 - 0.5) < 1e-12 and abs(f2[0] - 0.731059) < 1e-6
      and abs(f2[1] - 0.268941) < 1e-6,
      "mu = 1/2, f_0 = 0.731059, f_1 = 0.268941")
check(abs(E2 - 0.268941) < 1e-6 and abs(S2 - 1.164406) < 1e-6
      and abs(F2 + 0.313262) < 1e-6, "E = 0.268941, S = 1.164406, F = -0.313262")
```

The `report` lines print $\mu = 0.500000$, the occupations $f_0 = 0.731059$ and $f_1 = 0.268941$, and $E = 0.268941$, $S = 1.164406$ and $F = -0.313262$, and the two checks compare them with the values worked out by hand in Section 13.26 (μ to 10^{-12}, the others to 10^{-6}, the rounding of the six printed decimals).

In [9], the Revision solver's rule for μ.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
root_rule = parameters["conventions"]["merminRoot"]  # a sentence of the record
root_form = parameters["numerics"]["merminRoot"]  # the name of the canonical form
say(f"Revision solver: canonical root form {root_form}")
check(root_rule.startswith("mu from sum g f = N")
      and "holes below a split of the levels" in root_rule
      and root_form == "LogBalance",
      "the Revision solver fixes mu by sum g f = N, balancing particles and holes "
      "(Revision/kohn_sham/results/parameters.json, conventions merminRoot)")
```

The cell reads two entries of the solver's parameter file: the sentence that describes the rule (`conventions`) and the name of the form it uses (`numerics`). The check requires the sentence to start with "mu from sum g f = N" and to contain the words about particles and holes, and the form to be LogBalance (Section 13.26).

In [10], derivatives with respect to T, and the bisection history.

```
def at(temperature, levels=two_levels, degeneracies=ones, N=1.0):
    return thermodynamics(levels, degeneracies, N, temperature)
```

```
d = 1e-4
dF_dT = (at(0.5 + d)[4] - at(0.5 - d)[4]) / (2 * d)
dE_dT = (at(0.5 + d)[2] - at(0.5 - d)[2]) / (2 * d)
T_dS_dT = 0.5 * (at(0.5 + d)[3] - at(0.5 - d)[3]) / (2 * d)
```

`at(T)` is the two-level thermodynamics at the temperature T; its result is the tuple (μ, f, E, S, F), so `[2]`, `[3]`, `[4]` are E, S, F. Central difference quotients with the step 10^{-4} (with μ solved again at each temperature) give dF/dT, dE/dT and $T\,dS/dT$ at $T = \frac{1}{2}$ (the factor `0.5` in the third line is T).

```
report("dF/dT", f"{dF_dT:.6f}")
report("C_V = dE/dT", f"{dE_dT:.6f}")
check(abs(dF_dT + S2) < 1e-7, "dF/dT = -S (envelope theorem)")
check(abs(dE_dT - 0.393224) < 1e-6 and abs(T_dS_dT - dE_dT) < 1e-7,
      "C_V = dE/dT = T dS/dT = 0.393224")
```

The cell prints $dF/dT = -1.164406$ and $C_V = 0.393224$ and checks $dF/dT = -S$ (to 10^{-7}), $C_V = 0.393224$ (the value $2e/(e+1)^2$ of Section 13.26) and $dE/dT = T\,dS/dT$ (to 10^{-7}).

```
fig, ax = plt.subplots()
ax.semilogy(range(1, 51), widths[:50], "o-", ms=3)
ax.set_xlabel("bisection step")
ax.set_ylabel("width of the interval that contains $\\mu$")
ax.set_title("Bisection halves the interval at every step")
save_figure(fig, "bisection",
```

The first 50 recorded widths against the step numbers 1 to 50 (`range(1, 51)`), on a logarithmic vertical axis; labels, title and `save_figure` for Figure 13e.3. The last check

```
check(all(abs(b / a_ - 0.5) < 1e-12 for a_, b in zip(widths[:40], widths[1:41])),
      "every bisection step halves the interval")
```

requires every width to be half of the previous one (for the first 40 steps; the name `a_` avoids the name `a` of the operator list).

What Figure 13e.3 shows. The starting interval is $[-30, 6]$, 36 wide, so after the first step the width is 18. On the logarithmic axis the points then fall on a straight line, by $\log_{10} 2 = 0.30$ per step, to about $3 \cdot 10^{-14}$ after 50 steps: bisection gains one binary digit of μ at every step, whatever the function, as long as the root is inside the interval.

In [11], two levels at all temperatures.

```
temperatures = np.linspace(0.02, 3.0, 150)
table = np.array([at(T)[2:] for T in temperatures])  # columns E, S, F
C_V = np.array([T * (at(T + d)[3] - at(T - d)[3]) / (2 * d) for T in temperatures])
hot = at(1000.0)
check(table[0, 1] < 1e-8 and abs(hot[3] - np.log(4.0)) < 1e-5
      and abs(hot[2] - 0.5) < 1e-3, "S -> 0 for T -> 0; S -> ln 4, E -> 1/2 for T "
      "-> infinity")
check(np.all(C_V >= 0.0), "the heat capacity is never negative")
```

For 150 temperatures from 0.02 to 3: the table of E, S, F (`[2:]` keeps the last three entries of the tuple) and $C_V = T\,dS/dT$. The limits: at the lowest temperature $S < 10^{-8}$ (the particle sits in level 0); at $T = 1000$, practically infinite, both occupations are $\frac{1}{2}$, so $S = 2\ln 2 = \ln 4$ and $E = \frac{1}{2}$. The second check: $C_V \geq 0$ everywhere.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(temperatures, table[:, 0], label="energy $E$")
left.plot(temperatures, temperatures * table[:, 1], label="$T S$")
left.plot(temperatures, table[:, 2], color="black", label="free energy $F = E - TS$")
left.set_xlabel("temperature $T$")
left.set_ylabel("energy (level-spacing units)")
left.legend(fontsize=8)
```

`table[:, 0]` is the first column of the table (all rows), the energy; `temperatures * table[:, 1]` multiplies each entropy by its temperature; `table[:, 2]` is the free energy, drawn in black. Labels and legend of the left panel.

```
right.plot(temperatures, C_V, color="tab:red")
right.plot([0.5], [0.393224], "ko", label="$T = 1/2$: $C_V = 0.393224$")
right.set_xlabel("temperature $T$")
right.set_ylabel("heat capacity $C_V = dE/dT$")
right.legend(fontsize=8)
fig.suptitle("Two levels (0 and 1), one particle")
save_figure(fig, "two_level_thermo",
```

The right panel draws C_V in red and the worked value at $T = \frac{1}{2}$ as a black dot; then labels, legend, a title above both panels, and `save_figure` for Figure 13e.4.

What Figure 13e.4 shows. On the left, at low temperature E, TS and F are all near 0 (the particle sits in the lower level). As T grows, E rises towards $\frac{1}{2}$ (both levels equally occupied), TS grows almost linearly (towards $T\ln 4$: the entropy S_s approaches $2\ln 2 = \ln 4$, the value for two independent orbitals that are each occupied with the probability $\frac{1}{2}$, Exercise 7), and $F = E - TS$ falls ever more steeply, with the slope $-S$. On the right, the heat capacity is practically 0 below $T = 0.05$, rises to a single peak of about 0.88 near $T = 0.21$, passes through the black dot at $T = \frac{1}{2}$, and decreases slowly towards 0: energy can be absorbed only while the upper level is filling up.

In [12], a ladder of levels.

```
ladder = np.arange(60) + 0.5
twos = 2.0 * np.ones(60)
N_LADDER = 8.0

def ladder_at(T):
    return thermodynamics(ladder, twos, N_LADDER, T)

def variance_heat_capacity(T):
    """C_V = [sum w x^2 - (sum w x)^2 / sum w] / T^2, x = eps - mu, w = g f (1 - f)."""
    mu, f = ladder_at(T)[:2]
```

```
    w = twos * f * (1.0 - f)
    x = ladder - mu
    return (np.sum(w * x * x) - np.sum(w * x) ** 2 / np.sum(w)) / T ** 2
```

The levels $n + \frac{1}{2}$, $n = 0, \ldots, 59$, two states each, eight particles: the trap of Notebook 13a without interaction. `variance_heat_capacity` is the variance formula of Section 13.26.

```
T_ladder = np.linspace(0.05, 3.0, 120)
mus = np.array([ladder_at(T)[0] for T in T_ladder])
C_numeric = np.array([(ladder_at(T + d)[2] - ladder_at(T - d)[2]) / (2 * d)
                      for T in T_ladder])
C_variance = np.array([variance_heat_capacity(T) for T in T_ladder])
```

For 120 temperatures from 0.05 to 3: μ, the heat capacity as a difference quotient of E (the step `d` $= 10^{-4}$ of In [10]), and the variance formula.

```
report("mu at T = 0.05", f"{mus[0]:.6f}")
check(abs(mus[0] - 4.0) < 1e-6, "at low T, mu lies halfway between 3.5 and 4.5")
check(np.max(np.abs(C_numeric - C_variance)) < 1e-5 * max(1.0, C_variance.max()),
      "the heat capacity equals the weighted-variance formula")
check(np.all(C_variance >= 0.0), "the variance formula is never negative")
```

The cell prints $\mu = 4.000000$ at $T = 0.05$ and checks it (at low temperature the four lowest levels are full, and by the symmetry of f about μ the chemical potential lies halfway between the last full level 3.5 and the first empty one 4.5), then that the two heat capacities agree to 10^{-5} times the larger of 1 and the largest value (`max` of two numbers is the larger), and that the variance formula is never negative.

In [13], the occupations of the ladder.

```
fig, ax = plt.subplots()
for T, marker in ((0.05, "o"), (0.5, "s"), (1.0, "^"), (2.0, "v")):
    mu, f = ladder_at(T)[:2]
    ax.plot(ladder[:12], f[:12], marker + "-", ms=4,
            label=f"$T = {T}$, $\\mu = {mu:.3f}$")
ax.set_xlabel("level $\\epsilon_n = n + 1/2$")
ax.set_ylabel("occupation $f_n$ of each of the two states")
ax.set_title("Eight particles in a ladder of levels")
ax.legend(fontsize=8)
save_figure(fig, "ladder_occupations",
```

For $T = 0.05, 0.5, 1, 2$ the loop computes μ and the occupations (`[:2]` keeps the first two returned values) and draws the occupations of the twelve lowest levels against their energies; `marker + "-"` joins a marker letter and a line style into one style string, and the label shows T and μ with three decimals. Labels, title, legend and `save_figure` for Figure 13e.5.

What Figure 13e.5 shows. At $T = 0.05$ the occupation is 1 for the levels 0.5 to 3.5 and 0 above: a perfect step between 3.5 and 4.5. At $T = 0.5$ the levels 3.5 and 4.5 are partly occupied (0.73 and 0.27). At $T = 1$ and 2 the step is smeared over several levels, and particles reach the levels 8.5

and beyond. The chemical potential stays at 4.000 up to $T = 0.5$ and falls to 3.982 at $T = 1$ and 3.712 at $T = 2$: the ladder continues upwards but not downwards (no level below 0.5), so at high temperature the particles spread more to higher levels, and μ must fall to keep the number at 8.

In [14], the chemical potential and the heat capacity of the ladder.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(T_ladder, mus, color="black")
left.set_xlabel("temperature $T$")
left.set_ylabel("chemical potential $\\mu$")
right.plot(T_ladder, C_numeric, color="tab:red", label="$dE/dT$ (differences)")
right.plot(T_ladder[::6], C_variance[::6], "ko", ms=3, label="variance formula")
right.set_xlabel("temperature $T$")
right.set_ylabel("heat capacity $C_V$")
right.legend(fontsize=8)
fig.suptitle("Ladder of levels, eight particles")
save_figure(fig, "ladder_thermo",
```

Left: μ against T. Right: the heat capacity from the difference quotient as a red line and from the variance formula at every sixth temperature (`[::6]`) as black dots, so that both can be seen; labels, legend, a common title and `save_figure` for Figure 13e.6.

What Figure 13e.6 shows. On the left, μ stays at 4 up to about $T = 0.5$ and then falls, to about 3.1 at $T = 3$. On the right, the black dots lie on the red line at every temperature: the difference quotient and the weighted-variance formula agree, and both are positive. The heat capacity is nearly 0 at $T = 0.05$ (a gap of one level spacing separates the full from the empty levels), rises steeply, and approaches 8, one unit per particle, at high temperature, where each particle behaves like a classical oscillator.

In [15], Janak's theorem and Delta-SCF.

```
EPS_H0, EPS_L0, U_MODEL = 0.0, 1.0, 0.2

def model_energy(f_H, f_L):
    return EPS_H0 * f_H + EPS_L0 * f_L + 0.5 * U_MODEL * (f_H ** 2 + f_L ** 2)

def model_levels(f_H, f_L):
    """Janak: eps_a = dE/df_a = eps_a^0 + U f_a."""
    return EPS_H0 + U_MODEL * f_H, EPS_L0 + U_MODEL * f_L
```

The model energy of Section 13.27 and its levels.

```
h_step = 1e-6
for f_H, f_L in ((1.0, 0.0), (0.5, 0.5), (0.3, 0.9)):
    dE_dfH = (model_energy(f_H + h_step, f_L) - model_energy(f_H - h_step, f_L)) \
        / (2 * h_step)
    dE_dfL = (model_energy(f_H, f_L + h_step) - model_energy(f_H, f_L - h_step)) \
        / (2 * h_step)
    check(np.allclose((dE_dfH, dE_dfL), model_levels(f_H, f_L), atol=1e-9),
          f"Janak: dE/df_a = eps_a at (f_H, f_L) = ({f_H}, {f_L})")
```

At three pairs of occupations the derivatives of the energy are computed as central difference quotients and compared with the levels (three checks).

```
taus = np.linspace(0.0, 1.0, 101)
integrand = np.array([model_levels(1 - t, t)[1] - model_levels(1 - t, t)[0]
                      for t in taus])
gap_KS = integrand[0]
delta_SCF = model_energy(0.0, 1.0) - model_energy(1.0, 0.0)
step = taus[1] - taus[0]
janak_integral = step / 3 * (integrand[0] + integrand[-1]
                             + 4 * integrand[1:-1:2].sum() + 2 * integrand[2:-1:2].sum())
```

101 values of the transferred fraction τ; the level difference $\epsilon_L(\tau) - \epsilon_H(\tau)$ at $(f_H, f_L) = (1-\tau, \tau)$ (the function `model_levels` returns the pair (ϵ_H, ϵ_L), so `[1]` is ϵ_L and `[0]` is ϵ_H); the gap (its value at $\tau = 0$); the Delta-SCF energy $E(0,1) - E(1,0)$; and the integral of the level difference by Simpson's rule (Section 13.15) on the 101 values.

```
report("Kohn-Sham gap", f"{gap_KS:.6f}")
report("Delta-SCF", f"{delta_SCF:.6f}")
report("integral of eps_L - eps_H over tau", f"{janak_integral:.6f}")
report("transition state (tau = 1/2)", f"{integrand[50]:.6f}")
check(abs(gap_KS - 0.8) < 1e-12 and abs(delta_SCF - 1.0) < 1e-12
      and abs(janak_integral - delta_SCF) < 1e-12 and abs(integrand[50] - 1.0) < 1e-12,
      "gap 0.8, Delta-SCF 1.0 = the Janak integral = the transition state")
check(abs(delta_SCF - gap_KS - U_MODEL) < 1e-12, "Delta-SCF - gap = U (relaxation)")
```

The `report` lines print 0.800000, 1.000000, 1.000000 and the transition-state value 1.000000 (entry 50 is $\tau = \frac{1}{2}$). The last two checks require these four values (Simpson's rule is exact here, because the integrand is a straight line) and $\Delta_{SCF} - \Delta_{KS} = U$.

In [16], the transfer as a picture.

```
energies_tau = np.array([model_energy(1 - t, t) for t in taus])
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(taus, energies_tau - energies_tau[0], color="black")
left.set_xlabel("transferred fraction $\\tau$")
left.set_ylabel("$E(\\tau) - E(0)$")
left.set_title("energy along the transfer")
```

`energies_tau` is the model energy $E(1-\tau, \tau)$ at every τ; the left panel draws its rise $E(\tau) - E(0)$ in black, with labels and a title.

```
right.fill_between(taus, 0.0, integrand, alpha=0.25, label="area = Delta-SCF = 1")
right.plot(taus, integrand, color="black", label="$\\epsilon_L - \\epsilon_H$")
right.plot([0.0], [gap_KS], "s", ms=8, label="Kohn-Sham gap 0.8")
right.plot([0.5], [integrand[50]], "^", ms=8, label="transition state 1.0")
right.set_ylim(0.0, 1.3)
right.set_xlabel("transferred fraction $\\tau$")
right.set_ylabel("level difference")
right.legend(fontsize=8, loc="lower right")
```

`right.fill_between(taus, 0.0, integrand, ...)` shades the area between the zero line and the level difference (`alpha=0.25`: light), which by Janak's theorem is the Delta-SCF energy; the level difference itself as a black line; the gap as a large square at $\tau = 0$ and the transition state as a large triangle at $\tau = \frac{1}{2}$; the vertical range from 0 to 1.3; labels and a legend in the lower right corner.

```
fig.suptitle("Janak's theorem and Delta-SCF ($\\epsilon_H^0 = 0$, "
             "$\\epsilon_L^0 = 1$, $U = 0.2$)")
save_figure(fig, "janak_delta_scf",
```

A title above both panels (two strings joined into one) with the parameters of the model, and `save_figure` for Figure 13e.7.

What Figure 13e.7 shows. On the left the energy rises from 0 to 1.0 as one whole particle is moved from H to L, slightly curved upwards, because its slope, the level difference, grows with τ. On the right that slope is the straight line $0.8 + 0.4\tau$ from the gap 0.8 (square) to 1.2; the shaded area under it is 1.0, the Delta-SCF energy, and the value at the midpoint (triangle) is also exactly 1.0, because the line is straight. The gap underestimates the excitation energy by $U = 0.2$, the orbital relaxation of this model.

In [17], the last check.

```
figure_names = ["gibbs_principle", "fermi_dirac", "bisection", "two_level_thermo",
                "ladder_occupations", "ladder_thermo", "janak_delta_scf"]
missing = [name for k, name in enumerate(figure_names, 1)
           if not output_file(f"{FIGURE_FOLDER}/13e_{k}_{name}.png").is_file()]
check(missing == [], "all seven figure files exist")
check(output_file(f"{FIGURE_FOLDER}/13e_7_janak_delta_scf.png").is_file(),
      "the figure file 13e_7_janak_delta_scf.png exists")
all_checks_passed()
```

The same lines as In [19] of Notebook 13c (Section 13.14), with the seven figure names of this notebook. The last line prints ALL 24 CHECKS PASSED (notebook 13e): one check each in In [2], In [3], In [6], In [7] and In [9], two each in In [4], In [8] and In [11], three each in In [10] and In [12], five in In [15] and two in In [17].

13.32 A complete Kohn-Sham calculation: eight fermions in a trap

This section puts every piece of the chapter together in one small but complete Kohn-Sham calculation, the example of Notebook 13a. It is a teaching model: its numbers are COMPUTED by the notebook and belong to no physical system of the book. (Its letter x is the position on a line, not a spacetime coordinate.)

The model. $N = 8$ identical fermions on a line, four with the label up and four with the label down, in the **harmonic trap** $v(x) = x^2/2$, with the contact repulsion $w(x, x') = g_c\,\delta(x - x')$ of strength $g_c = 2$. Units: $\hbar = m = \omega = 1$, where ω is the angular frequency of the trap; energies are in units of $\hbar\omega$ and lengths in units of $\sqrt{\hbar/(m\omega)}$. Without interaction a particle in the trap has the levels $\frac{1}{2}, \frac{3}{2}, \frac{5}{2}, \ldots$, and the ground state of the eight fermions fills the four lowest levels with two fermions each: $E = 2(\frac{1}{2} + \frac{3}{2} + \frac{5}{2} + \frac{7}{2}) = 16$.

The energy functional. With the four lowest orbitals $\phi_0, \dots, \phi_3$ each occupied by one up and one down fermion, the density is $n = 2\sum_{a=0}^{3} \phi_a^2$ with $n_\uparrow = n_\downarrow = n/2$, and the energy of the determinant is (Section 13.5)

$$E = T_s + \int v\, n\, dx + E_H + E_x, \qquad E_H = \frac{g_c}{2}\int n^2\, dx, \qquad E_x = -\frac{g_c}{2}\int (n_\uparrow^2 + n_\downarrow^2) dx = -\frac{g_c}{4}\int n^2\, dx,$$

with $T_s = 2\sum_{a=0}^{3} \int \phi_a \left(-\frac{1}{2}\phi_a''\right) dx$. For a contact interaction the exchange of a determinant is exactly this local formula (Section 13.5); the correlation energy is left out. So this is an **exchange-only** Kohn-Sham scheme, which for a contact interaction is the same as the Hartree-Fock approximation: an approximation to the true ground state, whose error is the correlation energy (Section 13.7 showed how large it can be on two sites).

The Kohn-Sham potential, line by line. The functional derivatives are

$$\frac{\delta E_H}{\delta n} = g_c\, n, \qquad \frac{\delta E_x}{\delta n_\uparrow} = -g_c\, n_\uparrow = -\frac{g_c}{2}\, n,$$

by example (i) of Section 13.9 (for E_x applied to the up density, with the down density held fixed). A fermion with label up therefore feels

$$v_s = v + g_c\, n - \frac{g_c}{2}\, n = v + w, \qquad w = \frac{g_c}{2}\, n,$$

the Hartree push of everybody minus the exchange with its own label, and the same holds for label down. w is the **mean-field potential**. A solution of the Kohn-Sham equations is a w for which the orbitals of $v + w$ give back $w_{out} = g_c n/2 = w$; the **residual** of one pass is $r = \max_x |w_{out}(x) - w(x)|$, and the loop stops when $r \le 10^{-11}$, the stopping rule of the Revision solver (Section 13.21).

The energy, two ways, line by line. Multiply the Kohn-Sham equation of orbital a by ϕ_a, integrate and sum with the occupation 2:

$$2\sum_{a=0}^{3} \epsilon_a = T_s + \int v_s\, n\, dx = T_s + \int v\, n\, dx + \frac{g_c}{2}\int n^2\, dx,$$

$$E = T_s + \int v\, n\, dx + \frac{g_c}{4}\int n^2\, dx = 2\sum_{a=0}^{3} \epsilon_a - \frac{g_c}{4}\int n^2\, dx = 2\sum_{a=0}^{3} \epsilon_a - (E_H + E_x).$$

The first line is the computation of Section 13.10 with $v_s = v + g_c n/2$; the second writes $E_H + E_x = \frac{g_c}{4}\int n^2$ and subtracts the first line. This **double-counting formula** gives the same energy as the direct sum of the four parts, which the notebook checks.

Stability of the equal-label solution. So far the up and down densities were forced to be equal. Would the fermions lower their energy by separating the labels, as on two sites at strong repulsion (Section 13.7)? Let each label have its own potential: a fermion with label up feels $v + g_c n - g_c n_\uparrow = v + g_c n_\downarrow$, and one with label down $v + g_c n_\uparrow$, and the energy is $E = T_s + \int v\, n + g_c \int n_\uparrow n_\downarrow$ (Section 13.5). Started from a strongly separated guess, the loop for the two potentials together may return to equal densities; but that alone does not show stability, because the loop can also converge

to a **saddle**: a self-consistent solution from which some change of the densities LOWERS the energy. Only the energy decides: the equal-label solution is a minimum when every small label-separating change raises the energy. Notebook 13a shows both cases: on two sites with $U = 4t$ the loop started from a small separation converges to the equal labels although separating them lowers the energy (a saddle), and in the trap every label-separating trial family raises the energy, quadratically for small separations (a minimum along these families).

The variational principle at work. The Kohn-Sham equations make the energy stationary in the orbitals, and for the ground state the stationary point is a minimum. A one-parameter test: for each number c, take the four lowest orbitals of the trial potential $v + c\,n_{scf}$ (n_{scf} the self-consistent density) and evaluate the same energy formula with them. At $c = g_c/2 = 1$ these are the self-consistent orbitals; the energy must be smallest there, and near the minimum the curve is flat (a small error in the orbitals makes only a second-order error in the energy).

Three simpler pictures. (a) **No interaction**: $w = 0$. (b) **Hartree only**: drop the exchange, $v_s = v + g_c n$; every fermion is then also repelled by its own density (the self-interaction of Section 13.5). (c) **Thomas-Fermi**: the kinetic energy of each small piece of the line is that of a uniform gas with the local density. For a uniform gas on a line with two labels, the plane waves with $|k| < k_F$ are filled, two per wave number, and in a box of length ℓ the wave numbers are spaced by $2\pi/\ell$; line by line:

$$N = 2 \cdot \frac{2k_F}{2\pi/\ell} = \frac{2k_F\,\ell}{\pi} \quad\Longrightarrow\quad n = \frac{2k_F}{\pi},$$
$$\frac{E_{kin}}{\ell} = 2\int_{-k_F}^{k_F} \frac{dk}{2\pi}\,\frac{k^2}{2} = \frac{1}{2\pi}\cdot\frac{2k_F^3}{3} = \frac{k_F^3}{3\pi} = \frac{\pi^2\,n^3}{24}.$$

The first line counts the occupied wave numbers (the interval of length $2k_F$ divided by the spacing, times two labels) and divides by ℓ; the second sums $k^2/2$ over them per unit length (a sum over wave numbers becomes $\ell\int dk/(2\pi)$), integrates ($\int_{-k_F}^{k_F} k^2\,dk = 2k_F^3/3$), and inserts $k_F = \pi n/2$. Minimising $\int[\pi^2 n^3/24 + v\,n + \frac{g_c}{4}n^2]\,dx$ at fixed $\int n\,dx = N$ with the multiplier μ (Section 13.9) gives, where $n > 0$,

$$\frac{\pi^2}{8}\,n^2 + \frac{g_c}{2}\,n = \mu - v(x) \quad\Longrightarrow\quad n = \frac{-b + \sqrt{b^2 + 4a\,(\mu - v)}}{2a}, \qquad a = \frac{\pi^2}{8},\ b = \frac{g_c}{2},$$

the positive root of a quadratic equation at each point, and $n = 0$ where $v > \mu$; μ is found by bisection so that the density holds 8 particles. Thomas-Fermi uses no orbitals, so it cannot show the four bumps of the Kohn-Sham density (its **shell structure**).

The Hellmann-Feynman theorem. How does the energy change with the strength g_c? The Kohn-Sham energy is $E(g_c) = \mathcal{E}[\phi^*(g_c); g_c]$, the functional evaluated at its stationary orbitals ϕ^*. By the chain rule, $dE/dg_c = \partial\mathcal{E}/\partial g_c + \sum(\text{derivative with respect to the orbitals}) \cdot d\phi^*/dg_c$, and the second part vanishes because $\mathcal{E}$ is stationary in the orbitals (with their normalisation kept), exactly as in the envelope theorem of Section 13.26. Only the explicit dependence remains, $E_H + E_x = \frac{g_c}{4}\int n^2$:

$$\frac{dE}{dg_c} = \frac{1}{4}\int n^2\,dx.$$

The virial theorem at $g_c = 0$. For a particle in the harmonic trap the kinetic and the trap energy

of every level are equal. Line by line, for a normalised stationary state ϕ: the stretched states $\phi_\lambda(x) = \sqrt{\lambda}\,\phi(\lambda x)$ are normalised, their kinetic energy is $\lambda^2 T$ and their trap energy V/λ^2 (substitute $y = \lambda x$ in the integrals), so $E(\lambda) = \lambda^2 T + V/\lambda^2$. A stationary state makes the energy stationary under every change of the state, in particular under stretching, so $dE/d\lambda = 2\lambda T - 2V/\lambda^3 = 0$ at $\lambda = 1$, that is $T = V$. At $g_c = 0$ the kinetic and the trap energy of the eight fermions are therefore equal, 8 each.

The first excited state. The Kohn-Sham gap is $\epsilon_4 - \epsilon_3$ of the ground state. The Delta-SCF energy moves one up fermion from orbital 3 (HOMO) to orbital 4 (LUMO) and solves the loop again (Section 13.27). By Janak's theorem it equals the integral of $\epsilon_4(\tau) - \epsilon_3(\tau)$ over the moved fraction τ from 0 to 1, which the notebook computes with Simpson's rule on nine values of τ.

What the notebook finds (COMPUTED, Notebook 13a). The grid (200 points in $-6 < x < 6$) reproduces the levels $n + \frac{1}{2}$ of the trap to 0.013 (In [3]; an error of order h^2, Section 13.2); all numbers below are those of this grid model, exact for it up to the stopping rule of the loop, and they differ from the continuum model by an error of the same size, about 10^{-2} (at $g_c = 0$ the grid energy is 15.990192 instead of 16, In [23]). Plain iteration needs 40 passes, linear mixing with $\beta = 0.7$ needs 23 and with $\beta = 0.3$ needs 73 (In [6]), Anderson mixing with the Revision settings 19 (In [8]); all reach the same potential to 10^{-9} (Figure 13a.2), and plain iteration overshoots: the first density is too narrow, the second too wide (In [10], Figure 13a.3). The Kohn-Sham levels are 2.119598, 3.006214, 3.877952, 4.723945 (occupied) and 5.496606 (LUMO) (In [11]). The energy is $E = 21.851498$ by both formulas, made of $T_s = 6.726297$, $\int v\,n = 9.521279$, $E_H = 11.207843$ and $E_x = -5.603922 = -E_H/2$ (In [14]). From a strongly separated start the two-label loop returns to equal labels (In [16]); the energy test shows that along three label-separating families the equal-label solution is a minimum, while on two sites with $U = 4t$ the loop converges to a saddle (In [17], In [18], Figure 13a.6). In the trial family the lowest energy is at $c = 1.00$ (In [19], Figure 13a.7). The root-mean-square widths of the cloud are 1.413346 (no interaction), 1.542829 (Kohn-Sham) and 1.659857 (Hartree only): the repulsion spreads the cloud, and the self-interaction of Hartree spreads it too much (In [21], Figure 13a.8). $dE/dg_c = 2.801961$ both as a difference quotient and as $\frac{1}{4}\int n^2$ (In [23]). The Kohn-Sham gap is 0.772662, the Delta-SCF energy 0.714594 (equal to the Janak integral), and the transition-state estimate 0.712784 (In [25]): here the orbital relaxation lowers the excitation energy.

13.33 Example: the one-dimensional Kohn-Sham toy

Notebook 13a carries out the calculation of Section 13.32 from the first line to the last: the grid and its check against the exact levels of the trap; the Kohn-Sham map; plain iteration, linear mixing and Anderson mixing with exactly the settings of the Revision Kohn-Sham solver, read from its parameter file (its only link to the Revision record); the converged state with its potentials and density; the energy two ways and the functional-derivative test; the stability of the equal-label solution; the variational principle; the Hartree and Thomas-Fermi comparisons; the switching-on of the interaction with the Hellmann-Feynman theorem; and the first excited state by Delta-SCF with Janak's theorem. It ends with ALL 36 CHECKS PASSED (notebook 13a) and draws ten figures.

13.34 How to run Notebook 13a

Step 1. What this notebook does and what it needs.

Notebook 13a (A one-dimensional Kohn-Sham toy with self-consistency) is the file `Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb` of the repository Dirac_claude. It solves the Kohn-Sham equations of eight fermions with two labels in a one-dimensional harmonic trap with a contact repulsion (Hartree plus the exact local exchange of this interaction, no correlation) on a grid, by plain iteration, by linear mixing and by Anderson mixing with the settings of the Revision Kohn-Sham solver; it checks the particle number, the two energy formulas, that the mean-field potential is the functional derivative of the interaction energy, the variational principle, the stability of the equal-label solution and the Hellmann-Feynman theorem, compares the result with the Hartree and the Thomas-Fermi approximations, computes the first excited state by Delta-SCF and checks Janak's theorem, and draws ten teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 13a_kohn_sham_1d_toy.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 13a_kohn_sham_1d_toy.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 13a_kohn_sham_1d_toy.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/13a.captions.json`
- `Revision/textbook/figures/13a_1_trap_orbitals.png`
- `Revision/textbook/figures/13a_2_scf_convergence.png`
- `Revision/textbook/figures/13a_3_first_iterations.png`
- `Revision/textbook/figures/13a_4_ks_potentials.png`
- `Revision/textbook/figures/13a_5_density_orbitals.png`
- `Revision/textbook/figures/13a_6_label_separation.png`
- `Revision/textbook/figures/13a_7_variational_scan.png`
- `Revision/textbook/figures/13a_8_approximations.png`
- `Revision/textbook/figures/13a_9_coupling_scan.png`
- `Revision/textbook/figures/13a_10_delta_scf.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13a_10_delta_scf.png exists
ALL 36 CHECKS PASSED (notebook 13a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 13a_kohn_sham_1d_toy.ipynb
python -m nbconvert --execute --inplace 13a_kohn_sham_1d_toy.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `parameters.json`: the notebook reads the file `Revision/kohn_sham/results/parameters.json` of the repository; it must be opened inside the folder `Revision/textbook/notebooks` of a complete clone of the repository, not as a single downloaded file.

13.35 Notebook 13a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook solves a small but complete Kohn-Sham problem from the first line to the
last, so that every step of density functional theory can be seen at work. Eight
identical fermions, four with the label "up" and four with the label "down", move on a
line in a harmonic trap and repel each other when they meet at the same point. The
notebook

- builds the one-particle Hamiltonian on a grid of 200 points and checks it against
  the exactly known levels of the harmonic trap;
- writes the Kohn-Sham potential of this model (external potential plus Hartree
  potential plus exchange potential) and solves the Kohn-Sham equations
  self-consistently in three ways: plain iteration, linear mixing, and Anderson
  mixing with exactly the settings that the Revision Kohn-Sham solver of the
  dirac16complex field uses (read from its parameter file);
- checks the particle number, computes the total energy in two different ways and
  checks that they agree, and tests with the energy whether the solution with equal
  up and down densities is stable (a converged loop alone cannot tell a minimum from
  a saddle, as two sites show);
- shows the variational principle at work: every other set of orbitals of a family
  gives a higher energy;
- compares the Kohn-Sham density with three simpler pictures: no interaction, the
  Hartree approximation (no exchange) and the Thomas-Fermi approximation (the local
  density approximation for the kinetic energy);
- switches the interaction on step by step and checks the Hellmann-Feynman theorem;
- computes the first excited state by the Delta-SCF method and checks Janak's
  theorem;
- draws ten teaching plots.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 13a (A one-dimensional Kohn-Sham toy with self-consistency) is the file
‘Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb‘ of the repository Dirac_claude.
It solves the Kohn-Sham equations of eight fermions with two labels in a one-dimensional
harmonic trap with a contact repulsion (Hartree plus the exact local exchange of this
interaction, no correlation) on a grid, by plain iteration, by linear mixing and by
Anderson mixing with the settings of the Revision Kohn-Sham solver; it checks the
```

particle number, the two energy formulas, that the mean-field potential is the functional derivative of the interaction energy, the variational principle, the stability of the equal-label solution and the Hellmann-Feynman theorem, compares the result with the Hartree and the Thomas-Fermi approximations, computes the first excited state by Delta-SCF and checks Janak's theorem, and draws ten teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 13a_kohn_sham_1d_toy.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 20 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 13a_kohn_sham_1d_toy.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the

name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 13a_kohn_sham_1d_toy.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/13a.captions.json‘
- ‘Revision/textbook/figures/13a_1_trap_orbitals.png‘
- ‘Revision/textbook/figures/13a_2_scf_convergence.png‘
- ‘Revision/textbook/figures/13a_3_first_iterations.png‘
- ‘Revision/textbook/figures/13a_4_ks_potentials.png‘
- ‘Revision/textbook/figures/13a_5_density_orbitals.png‘
- ‘Revision/textbook/figures/13a_6_label_separation.png‘
- ‘Revision/textbook/figures/13a_7_variational_scan.png‘
- ‘Revision/textbook/figures/13a_8_approximations.png‘
- ‘Revision/textbook/figures/13a_9_coupling_scan.png‘
- ‘Revision/textbook/figures/13a_10_delta_scf.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 13a_10_delta_scf.png exists
ALL 36 CHECKS PASSED (notebook 13a)
```

and the notebook must show 10 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb‘ inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

    ```
    python -m jupyterlab 13a_kohn_sham_1d_toy.ipynb
    python -m nbconvert --execute --inplace 13a_kohn_sham_1d_toy.ipynb
    ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for `parameters.json`: the notebook reads the file `Revision/kohn_sham/results/parameters.json` of the repository; it must be opened inside the folder `Revision/textbook/notebooks` of a complete clone of the repository, not as a single downloaded file.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers `save_figure` (saves a figure and shows it), `check` (stops with an AssertionError when a check fails, prints a PASS line when it passes), `report` (prints a key number as a RESULT line) and `all_checks_passed` (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 13a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 13a (A one-dimensional Kohn-Sham toy with self-consistency) is the file
# Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb of the repository Dirac_claude.
# It solves the Kohn-Sham equations of eight fermions with two labels in a
# one-dimensional harmonic trap with a contact repulsion (Hartree plus the exact local
# exchange of this interaction, no correlation) on a grid, by plain iteration, by linear
# mixing and by Anderson mixing with the settings of the Revision Kohn-Sham solver; it
# checks the particle number, the two energy formulas, that the mean-field potential is
# the functional derivative of the interaction energy, the variational principle, the
# stability of the equal-label solution and the Hellmann-Feynman theorem, compares the
```

```
# result with the Hartree and the Thomas-Fermi approximations, computes the first excited
# state by Delta-SCF and checks Janak's theorem, and draws ten teaching plots. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
```

```
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
```

```
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 13a_kohn_sham_1d_toy.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 20
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 13a_kohn_sham_1d_toy.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 13a_kohn_sham_1d_toy.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/13a.captions.json
# - Revision/textbook/figures/13a_1_trap_orbitals.png
# - Revision/textbook/figures/13a_2_scf_convergence.png
# - Revision/textbook/figures/13a_3_first_iterations.png
# - Revision/textbook/figures/13a_4_ks_potentials.png
```

```
# - Revision/textbook/figures/13a_5_density_orbitals.png
# - Revision/textbook/figures/13a_6_label_separation.png
# - Revision/textbook/figures/13a_7_variational_scan.png
# - Revision/textbook/figures/13a_8_approximations.png
# - Revision/textbook/figures/13a_9_coupling_scan.png
# - Revision/textbook/figures/13a_10_delta_scf.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 13a_10_delta_scf.png exists
#     ALL 36 CHECKS PASSED (notebook 13a)
#
# and the notebook must show 10 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/13a_kohn_sham_1d_toy.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 13a_kohn_sham_1d_toy.ipynb
#     python -m nbconvert --execute --inplace 13a_kohn_sham_1d_toy.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
```

```
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for parameters.json: the notebook reads the file
#   Revision/kohn_sham/results/parameters.json of the repository; it must be opened
#   inside the folder Revision/textbook/notebooks of a complete clone of the repository,
#   not as a single downloaded file.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Fermion**: a particle of a kind that obeys the Pauli principle: two identical
  fermions with the same label never occupy the same one-particle state.
- **Label**: an internal property of a particle that takes a few values; here two,
  "up" and "down" (like the spin of an electron). Particles with different labels
  can be told apart; particles with the same label cannot.
- **Orbital**: a one-particle wave function $\phi_a(x)$; its square $\phi_a(x)^2$ is
  the probability per unit length of finding the particle at $x$.
- **Density** $n(x)$: the expected number of particles per unit length at the point
  $x$. Its integral over the line is the particle number $N$.
- **Harmonic trap**: the external potential $v(x) = x^2/2$, a parabola; a particle in
  it has the levels $1/2, 3/2, 5/2, \dots$ (in the units below).
- **Contact interaction**: two particles feel a repulsion of strength $g_c$ only when
  they are at the same point.
- **Kohn-Sham equations**: one-particle Schroedinger equations in an effective
  potential $v_s(x)$ chosen so that their orbitals give the density of the
  interacting system.
- **Hartree potential**: the potential that one particle feels from the average
```

```
  density of all particles; **exchange potential**: the correction that comes from
  the Pauli principle (equal-label particles avoid each other).
- **Mean-field potential** $w(x)$: here the Hartree plus exchange potential, so that
  $v_s = v + w$.
- **Self-consistency**: the potential makes the orbitals, the orbitals make the
  density, the density makes the potential; a solution is self-consistent when the
  potential that comes out equals the potential that went in.
- **Iteration, residual**: one pass around the loop is an iteration; the residual is
  the largest difference between the potential that comes out and the one that went
  in.
- **Mixing**: feeding only part of the change back (linear mixing) or a combination
  of several earlier passes (Anderson mixing) to make the loop converge.
- **Grid, finite differences**: the line is replaced by equally spaced points; the
  second derivative is replaced by the difference formula
  $(f_{k+1} - 2 f_k + f_{k-1})/h^2$.
- **Eigenvalue, eigenvector**: for a matrix $A$, a number $\epsilon$ and a column
  $u$ with $A u = \epsilon u$; numpy's `eigh` finds all of them for a symmetric
  matrix.
- **Thomas-Fermi approximation**: the kinetic energy of each small piece of the
  line is taken from a uniform gas of the same density.
- **HOMO, LUMO**: the highest occupied and the lowest unoccupied orbital.
- **Delta-SCF**: an excited state computed as a second self-consistent solution in
  which one particle is moved by hand from the HOMO to the LUMO.
- **Units**: $\hbar = m = \omega = 1$, where $\omega$ is the angular frequency of the
  trap: energies are measured in units of $\hbar\omega$, lengths in units of
  $\sqrt{\hbar/(m\omega)}$, and $g_c$ in units of $\hbar\omega$ times that length.
```

```
## 4. The physical and mathematical situation

**The model.** $N = 8$ fermions on a line, four with label up and four with label
down, in the trap $v(x) = x^2/2$, with the contact repulsion
$w(x, x') = g_c\,\delta(x - x')$ of strength $g_c = 2$. The exact ground state would
be a wave function of eight variables; Kohn-Sham theory replaces it by orbitals of
one variable. (In this notebook the letter $x$ is the position on the line of the
toy model; it is not one of the author's spacetime coordinates $x_0, \dots, x_7$.)

**The Kohn-Sham equations of this model.** The orbitals obey

$$-\frac{1}{2}\,\frac{d^2\phi_a}{dx^2} + v_s(x)\,\phi_a(x) = \epsilon_a\,\phi_a(x),$$

and the four lowest orbitals are each occupied by one up and one down fermion, so

$$n(x) = 2 \sum_{a=0}^{3} \phi_a(x)^2, \qquad n_{up} = n_{down} = n/2 .$$

The energy is $E = T_s + \int v\,n\,dx + E_H + E_x$ with the kinetic energy of the
orbitals $T_s = 2\sum_{a=0}^{3} \int \phi_a\,(-\tfrac12\,d^2\phi_a/dx^2)\,dx$, the
Hartree energy $E_H = \tfrac{g_c}{2}\int n^2\,dx$ and the exchange energy
$E_x = -\tfrac{g_c}{2}\int (n_{up}^2 + n_{down}^2)\,dx = -\tfrac{g_c}{4}\int n^2\,dx$.
For a contact interaction the exchange energy of a Slater determinant is EXACTLY this
local formula (Notebook 13b checks it); the correlation energy is left out. So this
is an "exchange-only" Kohn-Sham scheme, which for a contact interaction is the same
```

```
as the Hartree-Fock approximation: an approximation to the true ground state.

**The Kohn-Sham potential.** The potential is the derivative of the energy with
respect to the density (the functional derivative): $\delta E_H/\delta n = g_c n$ and
$\delta E_x/\delta n_{up} = -g_c n_{up} = -g_c n/2$, so

$$v_s(x) = v(x) + g_c\,n(x) - \tfrac{g_c}{2}\,n(x) = v(x) + w(x),
\qquad w(x) = \tfrac{g_c}{2}\,n(x).$$

**Self-consistency.** Given a mean-field potential $w$, solve for the orbitals, form
$n$, and compute $w_{out} = g_c n/2$. A solution is a $w$ with $w_{out} = w$. The
residual of one pass is $r = \max_x |w_{out}(x) - w(x)|$; the loop stops when
$r \le 10^{-11}$, the stopping rule of the Revision Kohn-Sham solver.

**The energy, two ways.** Multiply the Kohn-Sham equation by $\phi_a$, integrate
and sum with the occupations 2: $2\sum_a \epsilon_a = T_s + \int v_s\,n\,dx
= T_s + \int v\,n\,dx + \tfrac{g_c}{2}\int n^2\,dx$. Since
$E_H + E_x = \tfrac{g_c}{4}\int n^2\,dx$, this gives the double-counting formula
$E = 2\sum_{a=0}^{3}\epsilon_a - (E_H + E_x)$, which the notebook compares with the
direct sum of the four energies.

**Status.** The model and its numbers are a teaching example (COMPUTED here). Its
only link to the Revision record is the method: the same Anderson mixing and the same
stopping rule as the Revision solver for the dirac16complex field.
```

Text cell:

```
## 5. The grid and the one-particle Hamiltonian

The line is cut to the interval $-6 < x < 6$ (the orbitals of the lowest levels are
negligibly small at its ends) and replaced by $M = 200$ interior points
$x_k = -6 + k h$, $k = 1, \dots, 200$, with spacing $h = 12/201$. An orbital is the
column of its values at these points, and the orbitals vanish at the two end points
$x = \pm 6$ (hard walls). The second derivative becomes the difference formula, so
the kinetic energy $-\tfrac12\,d^2/dx^2$ becomes the matrix `T` with $1/h^2$ on the
diagonal and $-1/(2h^2)$ just above and just below it.
```

```
The next cell defines the function ‘orbitals(w)‘: it diagonalises the matrix
$T + \mathrm{diag}(v + w)$ (the Kohn-Sham Hamiltonian on the grid) and returns the
levels in increasing order and the orbitals as the columns of a matrix. numpy returns
eigenvectors of length 1 in the sense $\sum_k u_k^2 = 1$; dividing by $\sqrt h$ makes
$\sum_k \phi_k^2\,h = 1$, the grid form of $\int \phi^2\,dx = 1$. An eigenvector is
fixed only up to its sign; the function makes the first clearly nonzero value of each
orbital (counted from the left) positive, so that every run draws the same pictures.
With $w = 0$ the levels must be close to the exact levels $n + 1/2$ of the trap; the
difference formula makes errors of order $h^2$, so the check allows $0.02$.
```

## 7. Plain iteration and linear mixing

**Linear mixing** with the mixing parameter $\beta$ replaces $w$ by
$w + \beta\,(w_{out} - w)$; $\beta = 1$ is **plain iteration**
($w \leftarrow w_{out}$). The function `linear_mixing(beta)` starts from $w = 0$,
records the residual of every pass and stops at a residual of at most $10^{-11}$, or
after 150 passes. It returns the last $w$, the list of residuals, and the densities
of the first passes (for a plot below).
```

In [6]:

```
def linear_mixing(beta, tolerance=1e-11, max_passes=150):

PASS plain iteration and linear mixing with beta = 0.7 and 0.3 all converge
```

Text cell:

```
## 8. Anderson mixing with the settings of the Revision solver

**Anderson mixing** remembers the last few inputs $w^{(i)}$ and their residual
vectors $R^{(i)} = w_{out}^{(i)} - w^{(i)}$, finds numbers $c_i$ with
$\sum_i c_i = 1$ that make the combined residual $\sum_i c_i R^{(i)}$ as small as
possible (a least-squares problem), and takes as the next input
$\sum_i c_i\,(w^{(i)} + \beta R^{(i)})$. The Revision Kohn-Sham solver of the
dirac16complex field uses this method; the next cell reads its settings (how many
earlier passes it remembers, its $\beta$ and its tolerance) from the Revision
parameter file and checks them.

What the Revision solver mixes is the list of its potentials at every grid point of
the hidden direction (the mass shift $M_{eff} - m$, the potential $v_v$, and a third
potential used only by one variant), and its residual is, as here, the largest
difference between the potentials that come out and those that went in. It solves
the same least-squares problem in an equivalent form (with a Lagrange multiplier
for the condition that the $c_i$ add up to 1) and adds two safeguards that this
small toy does not need: a tiny number ($10^{-12}$ times the largest diagonal
entry) on the diagonal of its equations, which keeps them solvable, and a restart
of the remembered passes whenever the residual grows to more than ten times the
best one so far.
```

In [7]:

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
numerics = parameters["numerics"]  # the numerical settings of the Revision solver
DEPTH = int(numerics["andersonDepth"])  # how many earlier passes are remembered
```

```

PASS the Revision solver mixes with depth 6, beta 0.4 and stops at 1e-11
    (Revision/kohn_sham/results/parameters.json, numerics)
```

Text cell:

```
The next cell defines the function ‘anderson(step, w0)‘. It works for any map
‘step‘ (here ‘ks_map‘; below also maps of two potentials at once). With one
remembered pass it is linear mixing; with more, it solves the least-squares problem
with numpy’s ‘lstsq‘: writing $c_i = \theta_i$ for the older passes and
$c_{last} = 1 - \sum_i \theta_i$, the combined residual is
$R^{(last)} + \sum_i \theta_i (R^{(i)} - R^{(last)})$, which is smallest for the
least-squares solution $\theta$ of $\sum_i \theta_i (R^{(i)} - R^{(last)}) \approx
-R^{(last)}$.
```

Section 4 obtained the mean-field potential $w = g_c n/2$ as the **functional
derivative** of the interaction energy $E_H + E_x = \tfrac{g_c}{4}\int n^2\,dx$
with respect to the density. On the grid this has a concrete meaning that the next
cell tests: change the density by a small amount $\epsilon\,\eta(x)$, where $\eta$
is any fixed function (here the off-centre bump $\eta(x) = e^{-(x - 1)^2}$); then
the interaction energy changes, to first order in $\epsilon$, by
$\epsilon\int w\,\eta\,dx$. The cell compares the difference quotient
$(E_{Hx}[n + \epsilon\eta] - E_{Hx}[n - \epsilon\eta])/(2\epsilon)$ with
```

```
$\epsilon = 10^{-4}$ and the integral $\int w\,\eta\,dx$. (Because $E_H + E_x$ is
a square of $n$, the difference quotient is exact here up to rounding.)

Text cell:

```
So far the up and down densities were forced to be equal. Is that solution stable,
or would the fermions lower their energy by separating the labels? The next cell
lets the two labels have their own potentials: a fermion with label up feels the
Hartree potential of everybody minus the exchange with its own label,
$v_{up} = v + g_c n - g_c n_{up} = v + g_c n_{down}$, and the same with up and down
exchanged. It starts from a strongly separated guess (up pushed to the left, down to
the right) and runs Anderson mixing on both potentials together. At $g_c = 2$ the
loop returns to equal densities and to the same energy. This return does NOT yet
show that the equal-label solution is stable: the two cells after it show why, and
make the test that does.

```

Text cell:

```
Why the return of the loop proves nothing about stability: the loop stops wherever
the potentials that come out equal those that went in, that is at EVERY
self-consistent solution. A self-consistent solution makes the energy stationary
(no change to first order); a minimum is stationary, but so is a saddle, where
some changes raise the energy and others lower it. Anderson mixing only looks for
a point where the residual vanishes, and it can land on a saddle. The next cell
shows this on the smallest example: two sites L and R joined by the hopping
$t = 1$, one fermion with label up and one with label down, and the repulsion
$U = 4$ when both sit on the same site. Each label has its own potential
$(w_L, w_R)$ on the two sites; its orbital $(c_L, c_R)$ is the eigenvector of the
lower level of the $2 \times 2$ matrix with $w_L, w_R$ on the diagonal and $-t$
beside it; the energy of the determinant is the hopping energy $-2t\,c_L c_R$ of
each orbital plus $U(n_{L,up}\,n_{L,down} + n_{R,up}\,n_{R,down})$; and one pass of
the loop gives label up the potential $U n_{down}$ and label down $U n_{up}$,
exactly as in the trap. Equal labels, $n = (1/2, 1/2)$ for each label, are
self-consistent, with the energy $-2t + U/2 = 0$; but for $U > 2t$ the lowest
determinant puts the two labels on different sites, with the energy
```

```
$-2t^2/U = -0.5$. The cell runs the SAME function ‘anderson‘ from a slightly
separated start (push 0.5) and from a more strongly separated one (push 1), and
computes the energy along the family of separated potentials
$U/2 \pm \epsilon\,(-1, 1)$.
```

    there is a saddle
```

Text cell:

```
So a converged loop can sit on a saddle, and only the ENERGY tells a minimum from
a saddle: at a minimum every small change raises it, at a saddle some change
lowers it. The next cell makes this energy test in the trap. It builds
label-separating trial potentials $w_{up} = w_{scf} + \epsilon\,s(x)$ and
$w_{down} = w_{scf} - \epsilon\,s(x)$ for three shapes $s$: $\tanh x$ (up to the
left, down to the right), $x\,e^{-x^2/4}$ (the same, but only near the centre) and
$e^{-x^2/2}$ (up pushed outwards, down inwards), and the five sizes
$\epsilon = 0.01, 0.05, 0.2, 0.5, 1$. For each it takes the four lowest orbitals of
each label in its trial potential and evaluates the energy of this determinant with
‘labels_energy‘, which needs no self-consistency (for a contact interaction this
formula is the exact energy of the determinant). Every value must lie above the
Kohn-Sham energy; and for small $\epsilon$ the rise must be of second order, so
that five times the size gives about 25 times the rise. The cell then draws the
energies of the trap and of the two sites against $\epsilon$.

```
## 11. The variational principle at work
```

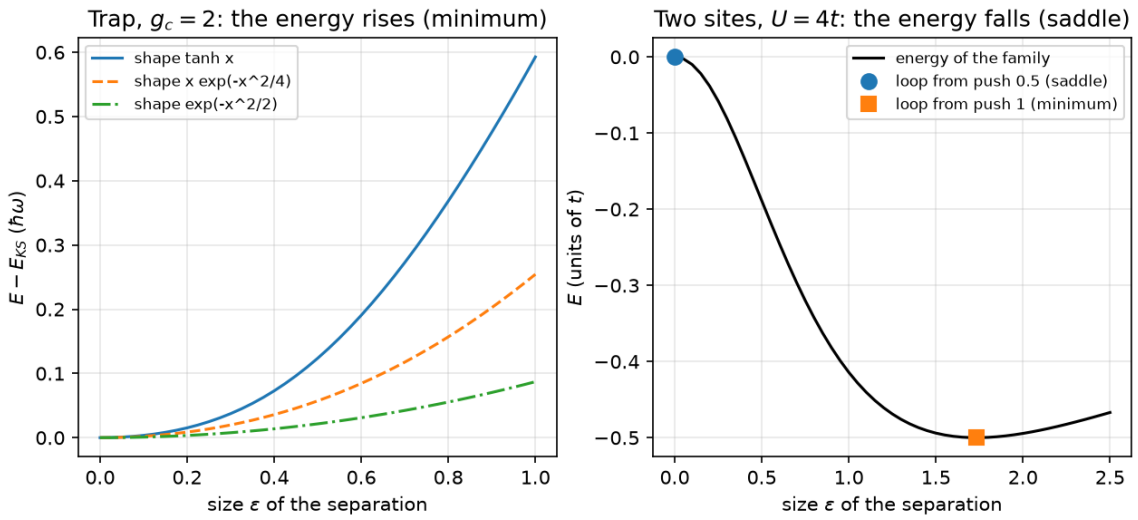

Figure 379: The energy test of stability. Left: the trap with eight fermions; the energy of the determinant made from the label-separating trial potentials $w_{scf} \pm \epsilon\, s(x)$, minus the Kohn-Sham energy, for three shapes s, against the size ϵ (pure number); vertical axis in units of $\hbar\omega$. Every curve starts flat at 0 and rises: along these families the equal-label solution is a minimum. Right: two sites with $U = 4t$; the energy of the determinant made from the potentials $U/2 \pm \epsilon\,(-1, 1)$, in units of t, against ϵ. It falls from the equal-label solution (circle, energy 0, where the loop from push 0.5 converged: a saddle) to the separated minimum $-2t^2/U = -0.5t$ (square, where the loop from push 1 converged). The converged loop could not tell the two cases apart; the energy does. (Notebook 13a, figure 6.)

```
The Kohn-Sham equations were derived by asking that the energy $E$ be stationary
when the orbitals change (with their normalisation kept): a small change of the
self-consistent orbitals changes $E$ only to second order, and for the ground state
the stationary point is a minimum. The next cell tests this on a one-parameter
family of determinants: for each number $c$ it takes the four lowest orbitals of the
potential $v + c\,n_{scf}$, puts two fermions into each, and evaluates the SAME
energy formula $E = T_s + \int v n\,dx + \tfrac{g_c}{4}\int n^2\,dx$ for them. At
$c = g_c/2 = 1$ the orbitals are exactly the self-consistent ones. The energy must be
smallest there, and larger for every other $c$.
```

In [19]:

## 12. Three simpler pictures compared

The next cell computes two other densities for comparison. **Hartree only** drops
```

```
the exchange term, so the potential is $v + g_c n$: every fermion is also repelled
by its own density (self-interaction). The **Thomas-Fermi** density uses the
uniform-gas kinetic energy at the local density instead of the orbitals. For a
uniform gas on a line with two labels, the states with wave numbers
$|k| < k_F$ are filled, two per state, so $n = 2k_F/\pi$, and the kinetic energy
per unit length is $2\int_{-k_F}^{k_F} \frac{dk}{2\pi}\frac{k^2}{2} =
k_F^3/(3\pi) = \pi^2 n^3/24$. Minimising
$\int [\pi^2 n^3/24 + v n + \tfrac{g_c}{4} n^2]\,dx$ at fixed $N$ (Lagrange
multiplier $\mu$) gives $\pi^2 n^2/8 + v + g_c n/2 = \mu$ where $n > 0$, a
quadratic equation for $n$ at each point; $\mu$ is found by bisection so that the
density holds 8 particles.
```

## 13. Switching the interaction on

The next cell solves the model for nine strengths $g_c = 0, 0.25, \dots, 2$, each
time starting from the solution of the previous strength, and records the energies.
It also checks the **Hellmann-Feynman theorem**: because the energy is stationary in
the orbitals, its derivative with respect to $g_c$ is only the explicit one,
$dE/dg_c = \tfrac14\int n^2\,dx$; the check compares this with the difference
quotient $(E(g_c + \delta) - E(g_c - \delta))/(2\delta)$ at $g_c = 2$,
$\delta = 10^{-3}$.
```

## 14. The first excited state: Kohn-Sham gap and Delta-SCF

The **Kohn-Sham gap** is the difference of the LUMO and HOMO levels of the ground
state. The **Delta-SCF** excitation energy moves one up fermion from orbital 3 (HOMO)
to orbital 4 (LUMO) and solves the loop again with these occupations; it is the
difference of the two total energies. **Janak's theorem** says that the derivative
of the self-consistent energy with respect to an occupation is the level of that
orbital. Moving a fraction $\tau$ of the fermion (occupations $1 - \tau$ in orbital
3 and $\tau$ in orbital 4 of label up) therefore gives
$dE/d\tau = \epsilon_4(\tau) - \epsilon_3(\tau)$, and

$$\Delta_{SCF} = E(1) - E(0) = \int_0^1 [\epsilon_4(\tau) - \epsilon_3(\tau)]\,d\tau .$$

The next cell solves the two-label loop for nine values $\tau = 0, 1/8, \dots, 1$
and integrates the level difference with Simpson's rule (exact for cubic
polynomials, very accurate for smooth curves).
```

## 16. What this notebook showed

- The Kohn-Sham equations of eight fermions with a contact repulsion reduce to
  one-particle equations in the potential $v_s = v + g_c n/2$: the Hartree push
  $g_c n$ minus the exchange $g_c n/2$, which removes the repulsion between fermions
  with the same label.
- The self-consistency loop converges by plain iteration, by linear mixing and by
  Anderson mixing to the same solution; the speed depends on the mixing parameter,
  and plain iteration overshoots (the density swings in and out). Anderson mixing
  with the settings of the Revision solver (depth 6, $\beta = 0.4$, tolerance
  $10^{-11}$) is the fastest without any tuning.
- The direct energy and the double-counting formula agree; $E_x = -E_H/2$ for two
  equally occupied labels; the mean-field potential $g_c n/2$ is the functional
  derivative of $E_H + E_x$. A converged two-label loop cannot tell a minimum
  from a saddle (on two sites with $U = 4t$ it converges to a saddle); the energy
  test shows that at $g_c = 2$ the equal-label solution in the trap is a minimum
  along three families of label-separating changes.
- Among a family of trial determinants the self-consistent one has the lowest
  energy, and the energy is flat there (variational principle); the derivative of
  the energy with respect to $g_c$ is $\tfrac14\int n^2\,dx$ (Hellmann-Feynman).
- Hartree alone overestimates the spreading (self-interaction); Thomas-Fermi gets
  the average shape but not the shell bumps, because it does not use orbitals.
- The Delta-SCF excitation energy is below the Kohn-Sham gap here, and it equals the
  integral of the level difference over the moved fraction (Janak's theorem).
- What was left out: the correlation energy. All numbers are those of the
  exchange-only (Hartree-Fock) approximation of this teaching model.
```

13.36 Line-by-line walk-through of Notebook 13a

The notebook has 25 code cells. **In [1]** is the set-up cell, identical to In [1] of Notebook 13c (Section 13.14) except for the name `"13a"` and its comment lines, which hold the instructions of Section 13.34.

In [2], the grid and the kinetic-energy matrix.

```
import numpy as np  # arrays of numbers, matrices and linear algebra

L_HALF = 6.0  # the grid covers -6 < x < 6
M = 200  # the number of interior grid points
h = 2.0 * L_HALF / (M + 1)  # the grid spacing 12/201
x = -L_HALF + h * np.arange(1, M + 1)  # the grid points x_k, k = 1, ..., 200
v = 0.5 * x ** 2  # the harmonic trap v(x) = x^2/2 at every point
```

The interval from -6 to 6 is cut into 201 equal steps of length $h = 12/201 = 0.059701$; the 200 inner points are the grid (`np.arange(1, M + 1)` is $1, \ldots, 200$), and the orbitals vanish at the two ends $x = \pm 6$ (hard walls; the occupied orbitals are negligibly small there anyway). `v` is the trap at every grid point.

```
# The kinetic-energy matrix: 1/h^2 on the diagonal, -1/(2 h^2) beside it.
T = (np.diag(np.full(M, 1.0 / h ** 2))
```

```
     + np.diag(np.full(M - 1, -0.5 / h ** 2), 1)
     + np.diag(np.full(M - 1, -0.5 / h ** 2), -1))
say(f"grid: {M} points, spacing h = {h:.6f}")
check(np.allclose(T, T.T), "the kinetic-energy matrix is symmetric")
```

The first line is a comment (it starts with `#` and is not executed) that names the matrix built below. `np.full(M, value)` is a list of M equal values and `np.diag(list, k)` the matrix with this list on the diagonal shifted by k places ($k = 1$ above, $k = -1$ below the main diagonal). So `T` is the matrix of $-\frac{1}{2}\,d^2/dx^2$ of Section 13.2: $1/h^2$ on the diagonal and $-1/(2h^2)$ beside it. The check confirms that it is symmetric, hence Hermitian.

In [3], the levels and orbitals of one particle.

```
def orbitals(w):
    """Levels (increasing) and orbitals (columns, int phi^2 dx = 1) of T + v + w."""
    levels, vectors = np.linalg.eigh(T + np.diag(v + w))
    phi = vectors / np.sqrt(h)  # normalise to sum phi^2 h = 1
    for a in range(M):  # fix the sign of every orbital
        first = np.argmax(np.abs(phi[:, a]) > 1e-3 * np.abs(phi[:, a]).max())
        phi[:, a] *= np.sign(phi[first, a])
    return levels, phi
```

`orbitals(w)` diagonalises the Kohn-Sham Hamiltonian on the grid, the matrix $T + \mathrm{diag}(v + w)$ for a mean-field potential w, and returns its 200 levels in increasing order and the orbitals as the columns of a matrix. numpy returns eigenvectors with $\sum_k u_k^2 = 1$; dividing by $\sqrt{h}$ makes $\sum_k \phi_k^2\, h = 1$, the grid form of $\int \phi^2\, dx = 1$. An eigenvector is fixed only up to its sign, so the loop makes the first clearly nonzero value of each orbital (counted from the left) positive: the comparison gives a list of true and false values, `np.argmax` returns the place of its first true value, and multiplying the column by the sign of the value there (`*=`, `np.sign`) makes that value positive. So every run draws the same pictures.

```
free_levels, free_phi = orbitals(np.zeros(M))  # no interaction: w = 0
exact_levels = np.arange(8) + 0.5  # 1/2, 3/2, ..., 15/2
for a in range(8):
    say(f"level {a}: grid {free_levels[a]:.6f}   exact {exact_levels[a]:.1f}")
check(np.max(np.abs(free_levels[:8] - exact_levels)) < 0.02,
      "the grid reproduces the levels n + 1/2 of the trap within 0.02")
overlaps = free_phi[:, :8].T @ free_phi[:, :8] * h  # sum_k phi_a phi_b h
check(np.allclose(overlaps, np.eye(8), atol=1e-12),
      "the orbitals are orthonormal on the grid")
```

Without interaction the eight lowest grid levels are printed beside the exact levels $n + \frac{1}{2}$: 0.499889 against 0.5, ..., 7.487394 against 7.5. The first check allows 0.02 (the difference formula makes errors of order h^2, growing with the level). `free_phi[:, :8]` keeps the first eight columns; the matrix of their sums $\sum_k \phi_a(x_k)\phi_b(x_k)\, h$ must be the unit matrix: the orbitals are orthonormal on the grid (second check).

In [4], the trap and its orbitals as a picture.

```
fig, ax = plt.subplots(figsize=(7.0, 4.6))
ax.plot(x, v, color="black", label="trap $v(x) = x^2/2$")
for a in range(6):
    style = "-" if a < 4 else ":"  # occupied: solid; empty: dotted
    ax.axhline(free_levels[a], color="gray", lw=0.6, ls="--")
    ax.plot(x, free_levels[a] + 0.6 * free_phi[:, a], style,
            label=f"orbital {a}" + (" (occupied)" if a < 4 else " (empty)"))
```

`plt.subplots(figsize=(7.0, 4.6))` makes a figure slightly taller than the standard one. The trap is drawn in black. For each of the six lowest levels the loop chooses a solid line for the four occupied levels and a dotted line for the two empty ones (`style = "-" if a < 4 else ":"`), draws a thin dashed grey horizontal line at the level, and draws the orbital around it: `free_levels[a] + 0.6 * free_phi[:, a]` is 0.6 times the orbital, shifted up by its level, so that each orbital sits on its own energy. The label joins two strings with `+`: the orbital number and either " (occupied)" or " (empty)".

```
ax.set_xlim(-5.0, 5.0)
ax.set_ylim(0.0, 8.4)  # room above the orbitals for the legend
ax.set_xlabel("position $x$")
ax.set_ylabel("energy (units of $\\hbar\\omega$)")
ax.set_title("Levels and orbitals of one particle in the trap (no interaction)")
ax.legend(fontsize=7, loc="upper center", ncol=3)
save_figure(fig, "trap_orbitals",
```

`set_xlim` and `set_ylim` fix the ranges of the axes: positions from -5 to 5 and energies from 0 to 8.4, which leaves room at the top for the legend, written in three columns (`ncol=3`) at the upper centre. Labels, title, and `save_figure` for Figure 13a.1.

What Figure 13a.1 shows. The parabola $x^2/2$ and the six levels $0.5, 1.5, \ldots, 5.5$, equally spaced by 1. Orbital 0 is a single bump, orbital 1 changes sign once, and in general orbital a has a zeros; each orbital is large where the level lies above the parabola (the region a classical particle of that energy could reach) and dies away quickly outside it. The eight fermions fill the four lowest levels (solid), two per level.

In [5], the Kohn-Sham map.

```
G_C = 2.0  # the strength g_c of the contact repulsion
N_PER_LABEL = 4  # four fermions with label up and four with label down
N_TOTAL = 2 * N_PER_LABEL

def integral(f):
    """The integral of f over the line, as the sum of f_k h."""
    return float(np.sum(f) * h)

def density(phi):
    """n(x) = 2 (phi_0^2 + phi_1^2 + phi_2^2 + phi_3^2): two fermions per orbital."""
    return 2.0 * np.sum(phi[:, :N_PER_LABEL] ** 2, axis=1)
```

```
def ks_map(w):
    """One pass of the loop: the mean-field potential g_c n / 2 made from w."""
    levels, phi = orbitals(w)
    return 0.5 * G_C * density(phi)
```

The model's numbers; `integral(f)` approximates $\int f\,dx$ by $\sum_k f_k h$ (accurate here because the functions vanish at the walls); `density(phi)` adds the squares of the four lowest orbitals along each row (`axis=1`) and doubles them; `ks_map(w)` is one pass of the loop of Section 13.32, $w \to$ orbitals $\to n \to w_{out} = g_c n/2$.

```
w_first = ks_map(np.zeros(M))  # one pass, starting from no interaction
report("largest value of the first mean-field potential", f"{w_first.max():.6f}")
check(abs(integral(2.0 * w_first / G_C) - N_TOTAL) < 1e-10,
      "the density of one pass holds exactly 8 particles")
```

One pass from $w = 0$ gives a mean-field potential with the largest value 1.887848; its density $n = 2w/g_c$ must hold 8 particles.

In [6], plain iteration and linear mixing.

```
def linear_mixing(beta, tolerance=1e-11, max_passes=150):
    """Linear mixing w <- w + beta (w_out - w), starting from w = 0."""
    w = np.zeros(M)
    residuals, first_densities = [], []
    for _ in range(max_passes):
        w_out = ks_map(w)
        residuals.append(np.max(np.abs(w_out - w)))  # the residual r
        if len(first_densities) < 5:
            first_densities.append(2.0 * w_out / G_C)  # n = 2 w_out / g_c
        if residuals[-1] <= tolerance:
            break
        w = w + beta * (w_out - w)
    return w, residuals, first_densities
```

Linear mixing of Section 13.21 for the potential: start at $w = 0$; in each pass compute w_{out}, record the residual $\max_x |w_{out} - w|$, keep the densities of the first five passes for the figure of In [10], stop when the residual is at most 10^{-11}, otherwise mix. The function returns the last w, the residuals and the first densities.

```
runs = {}
for beta in (1.0, 0.7, 0.3):
    runs[beta] = linear_mixing(beta)
    say(f"beta = {beta}: {len(runs[beta][1])} passes, last residual "
        f"{runs[beta][1][-1]:.1e}")
check(all(run[1][-1] <= 1e-11 for run in runs.values()),
      "plain iteration and linear mixing with beta = 0.7 and 0.3 all converge")
```

Three runs, stored in the dictionary `runs` under their β: 40 passes for plain iteration, 23 for $\beta = 0.7$, 73 for $\beta = 0.3$. The check requires every last residual to be at most 10^{-11}. (Unlike the two-site model of Section 13.21, plain iteration converges here, slowly.)

In [7], the settings of the Revision solver.

```
parameters = json.loads(repository_file(
    "Revision/kohn_sham/results/parameters.json").read_text(encoding="utf-8"))
numerics = parameters["numerics"]  # the numerical settings of the Revision solver
DEPTH = int(numerics["andersonDepth"])  # how many earlier passes are remembered
BETA_ANDERSON = float(numerics["andersonBeta"])  # the mixing parameter
TOLERANCE = float(numerics["scfTolerance"])  # the stopping rule
```

The cell reads the parameter file of the Revision Kohn-Sham solver and from its part "numerics" the number of remembered passes, β and the stopping rule.

```
say(f"Revision solver settings: depth {DEPTH}, beta {BETA_ANDERSON}, "
    f"tolerance {TOLERANCE:.0e}")
check(DEPTH == 6 and BETA_ANDERSON == 0.4 and abs(TOLERANCE - 1e-11) < 1e-24,
      "the Revision solver mixes with depth 6, beta 0.4 and stops at 1e-11 "
      "(Revision/kohn_sham/results/parameters.json, numerics)")
```

The printed line (`:.0e` writes a number as a power of ten without decimals) and the check confirm 6, 0.4 and 10^{-11} (the file stores the tolerance as the floating-point number nearest to 10^{-11}, so the check allows a difference below 10^{-24}).

In [8], Anderson mixing.

```
def anderson(step, w0, beta=BETA_ANDERSON, depth=DEPTH, tolerance=TOLERANCE,
             max_passes=400):
    """Anderson mixing for the fixed point step(w) = w, starting from w0."""
    w = np.array(w0, dtype=float)
    inputs, residual_vectors, residuals = [], [], []
    for _ in range(max_passes):
        residual = step(w) - w  # R = w_out - w
        residuals.append(np.max(np.abs(residual)))
        if residuals[-1] <= tolerance:
            return w, residuals
        inputs = (inputs + [w.copy()])[-depth:]  # keep the last `depth` passes
        residual_vectors = (residual_vectors + [residual])[-depth:]
        if len(inputs) == 1:
            w = w + beta * residual  # the first pass: linear mixing
            continue
        last_r = residual_vectors[-1]
        differences = np.array([r - last_r for r in residual_vectors[:-1]]).T
        theta = np.linalg.lstsq(differences, -last_r, rcond=None)[0]
        c = np.append(theta, 1.0 - theta.sum())  # the c_i; they add up to 1
        w = sum(ci * (wi + beta * ri)
                for ci, wi, ri in zip(c, inputs, residual_vectors))
    raise RuntimeError("Anderson mixing did not converge")
```

Anderson mixing of Section 13.21 for any map `step` (here `ks_map`; below also maps of two potentials at once and maps with another strength). Each pass computes the residual vector $R = w_{out} - w$ and its largest entry, and returns when that is at most the tolerance. The last `depth` inputs and

residual vectors are kept (`w.copy()` stores a copy, so later changes of `w` do not change the stored input). The first pass is linear mixing. Afterwards `differences` is the matrix whose columns are $R^{(i)} - R^{(last)}$ (200 rows, one per grid point), `np.linalg.lstsq` gives the least-squares θ of $\sum_i \theta_i (R^{(i)} - R^{(last)}) \approx -R^{(last)}$, `c` appends $1 - \sum_i \theta_i$, and the next input is $\sum_i c_i (w^{(i)} + \beta R^{(i)})$. If 400 passes are not enough, the function stops the notebook with an error.

```
w_scf, anderson_residuals = anderson(ks_map, np.zeros(M))
say(f"Anderson mixing: {len(anderson_residuals)} passes, last residual "
    f"{anderson_residuals[-1]:.1e}")
differences = [np.max(np.abs(runs[beta][0] - w_scf)) for beta in runs]
check(max(differences) < 1e-9,
      "all four routes reach the same self-consistent potential (within 1e-9)")
check(len(anderson_residuals) < len(runs[1.0][1]),
      "Anderson mixing needs fewer passes than plain iteration")
```

Anderson mixing from $w = 0$ needs 19 passes (last residual $1.8 \cdot 10^{-12}$). The checks: the three linear-mixing results agree with the Anderson result to 10^{-9} (`for beta in runs` goes through the keys of the dictionary), and Anderson needed fewer passes than plain iteration.

In [9], the residuals as a picture.

```
fig, ax = plt.subplots()
for beta, style in ((1.0, "o-"), (0.7, "s-"), (0.3, "^-")):
    name = "plain iteration" if beta == 1.0 else f"linear mixing, beta = {beta}"
    ax.semilogy(range(1, len(runs[beta][1]) + 1), runs[beta][1], style, ms=3,
                label=f"{name} ({len(runs[beta][1])} passes)")
```

For the three linear runs the loop draws the residual of every pass (`runs[beta][1]`, the list of residuals) against the pass numbers $1, 2, \ldots$ (`range(1, len(...) + 1)`), on a logarithmic vertical axis, with circles, squares and triangles; the label gives the name of the run and its number of passes.

```
ax.semilogy(range(1, len(anderson_residuals) + 1), anderson_residuals, "D-",
            ms=3, color="black",
            label=f"Anderson, depth 6, beta 0.4 ({len(anderson_residuals)} passes)")
ax.axhline(TOLERANCE, color="gray", ls="--", lw=0.8)
ax.set_xlabel("pass number")
ax.set_ylabel("residual $\\max_x |w_{out} - w|$")
ax.set_title("Self-consistency: residual versus pass ($g_c = 2$)")
ax.legend(fontsize=8)
save_figure(fig, "scf_convergence",
```

The residuals of Anderson mixing as black diamonds; a grey dashed horizontal line at the stopping rule 10^{-11}; labels, title, legend, and `save_figure` for Figure 13a.2.

What Figure 13a.2 shows. All four runs start with the residual 1.89 (the first pass from $w = 0$) and end just below the dashed line. The three linear runs are nearly straight lines on the logarithmic axis: each pass multiplies the residual by about the same factor, smallest for $\beta = 0.7$ (23 passes), larger for plain iteration (40) and largest for $\beta = 0.3$ (73). Anderson mixing falls fastest and reaches the line after 19 passes; its line is not straight, because it changes its estimate of the slope as it learns from the remembered passes.

In [10], why plain iteration is slow.

```
n_scf = 2.0 * w_scf / G_C  # the self-consistent density n = 2 w / g_c
fig, ax = plt.subplots()
for number, n_pass in enumerate(runs[1.0][2][:4], 1):
    ax.plot(x, n_pass, lw=1.0, label=f"density made by pass {number}")
ax.plot(x, n_scf, color="black", lw=2.0, label="self-consistent density")
```

The self-consistent density, and the densities made by the first four passes of plain iteration (`runs[1.0][2]` is the list of first densities of the run with $\beta = 1$, and `[:4]` keeps four of them), drawn as thin lines numbered from 1 by `enumerate(..., 1)`, and the self-consistent density as a thick black line.

```
ax.set_xlim(-5.0, 5.0)
ax.set_xlabel("position $x$")
ax.set_ylabel("density $n(x)$ (particles per unit length)")
ax.set_title("Plain iteration overshoots: the first passes")
ax.legend(fontsize=8)
save_figure(fig, "first_iterations",
```

The range of positions, labels, title, legend and `save_figure` for Figure 13a.3. Then the check

```
check(runs[1.0][2][0].max() > n_scf.max() > runs[1.0][2][1].max(),
      "the first pass is too narrow and the second too wide (overshooting)")
```

compares the largest values of the densities: the first density, made without repulsion, is higher (narrower) than the solution, and the second is lower (wider): the density swings around the solution.

What Figure 13a.3 shows. The density of pass 1 (no repulsion yet) is the highest in the middle, up to about 1.89, and the narrowest. Pass 2, made in the strong repulsion of that narrow density, is the lowest in the middle (about 1.64) and spreads furthest out. Passes 3 and 4 lie in between, closer and closer to the thick black solution, from alternating sides. All curves cross near $x = \pm 2$: the charge sloshes between the centre and the flanks, the same mechanism as in the two-site model of Section 13.21, but here the swings shrink, because the slope of the map is below 1 in size.

In [11], the converged state.

```
ks_levels, ks_phi = orbitals(w_scf)
n_ks = density(ks_phi)
for a in range(6):
    status = "occupied by 2" if a < N_PER_LABEL else "empty"
    say(f"Kohn-Sham level {a}: {ks_levels[a]:.6f} ({status})")
report("Kohn-Sham HOMO level", f"{ks_levels[3]:.6f}")
report("Kohn-Sham LUMO level", f"{ks_levels[4]:.6f}")
check(abs(integral(n_ks) - N_TOTAL) < 1e-10, "the density integrates to N = 8")
check(np.max(np.abs(n_ks - n_scf)) < 1e-10,
      "the density of the final orbitals reproduces the input density")
```

The orbitals of the self-consistent potential, their density, the six lowest levels with their occupation, and the HOMO and LUMO levels (4.723945 and 5.496606). The checks: the density holds 8 particles,

and the orbitals of $v + w_{scf}$ give back the density $2w_{scf}/g_c$ that made w_{scf}: self-consistency, to 10^{-10}.

In [12], the potentials.

```
v_hartree = G_C * n_ks  # v_H = g_c n
v_exchange = -0.5 * G_C * n_ks  # v_x = -g_c n_up = -g_c n / 2
```

The Hartree potential $g_c n$ and the exchange potential $-g_c n/2$ of Section 13.32, at the self-consistent density.

```
fig, ax = plt.subplots()
ax.plot(x, v, color="black", label="trap $v$")
ax.plot(x, v_hartree, label="Hartree $v_H = g_c n$")
ax.plot(x, v_exchange, label="exchange $v_x = -g_c n/2$")
ax.plot(x, v + v_hartree + v_exchange, lw=2.0, label="Kohn-Sham $v_s$")
for a in range(N_PER_LABEL):
    ax.axhline(ks_levels[a], color="gray", ls="--", lw=0.6)
```

The trap (black), the two potentials, and their sum $v_s = v + v_H + v_x$ as a thick line; the loop draws the four occupied Kohn-Sham levels as thin dashed grey lines.

```
ax.set_xlim(-5.0, 5.0)
ax.set_ylim(-3.0, 9.0)
ax.set_xlabel("position $x$")
ax.set_ylabel("potential (units of $\\hbar\\omega$)")
ax.set_title("The potentials of the self-consistent state ($g_c = 2$)")
ax.legend(fontsize=8)
save_figure(fig, "ks_potentials",
```

The ranges, labels, title, legend and `save_figure` for Figure 13a.4. After the caption,

```
check(np.allclose(v + v_hartree + v_exchange, v + w_scf, atol=1e-10),
      "v + v_H + v_x equals the self-consistent v + w")
```

checks that $v + v_H + v_x$ equals $v + w_{scf}$ at every point to 10^{-10}.

What Figure 13a.4 shows. The Hartree potential is a broad plateau of about 3 with small bumps (it is twice the density), the exchange potential is the same shape upside down at half the size, and the Kohn-Sham potential v_s (green, thick) is the trap lifted in the middle: its bottom is no longer at 0 but at about 1.6, and it is flattened over $-2 < x < 2$. The four occupied levels (2.12, 3.01, 3.88, 4.72) are pushed up and squeezed together compared with $0.5, 1.5, 2.5, 3.5$ without interaction.

In [13], the density as a stack of orbitals.

```
fig, ax = plt.subplots()
layers = [2.0 * ks_phi[:, a] ** 2 for a in range(N_PER_LABEL)]
ax.stackplot(x, layers, labels=[f"$2\\phi_{a}^2$" for a in range(N_PER_LABEL)],
             alpha=0.7)
```

The four contributions $2\phi_a^2$ of the occupied orbitals; `ax.stackplot` draws them on top of each other as coloured layers (orbital 0 at the bottom; `alpha=0.7` makes them 70 per cent opaque), so that the top edge is the density. The labels are made by a list comprehension, one per orbital. (In a Python string a backslash is written twice, so the label text reaches matplotlib with one backslash, which draws ϕ.)

```
ax.plot(x, n_ks, color="black", lw=1.5, label="total density $n$")
ax.set_xlim(-5.0, 5.0)
ax.set_xlabel("position $x$")
ax.set_ylabel("density (particles per unit length)")
ax.set_title("The density as the sum of the occupied orbitals")
ax.legend(fontsize=8)
save_figure(fig, "density_orbitals",
```

The total density as a black line on top of the layers; range, labels, title, legend and `save_figure` for Figure 13a.5.

What Figure 13a.5 shows. Orbital 0 contributes one central bump (blue), orbital 1 two bumps beside the centre (orange), orbital 2 three and orbital 3 four (each orbital a has a zeros, so ϕ_a^2 has $a+1$ bumps). Stacked, they give the density: about 1.6 at the centre, two peaks of about 1.71 near $x = \pm 0.57$, two shoulders of about 1.43 near $x = \pm 1.7$, and a steep fall to nearly zero by $|x| = 3.8$. These ripples on top of a smooth profile are the shell structure. Each layer holds two fermions and the whole stack eight.

In [14], the energy two ways.

```
def kinetic(phi, occupations):
    """T_s = sum_a f_a int phi_a (-1/2 phi_a'') dx with the occupations f_a."""
    return sum(f * float(phi[:, a] @ (T @ phi[:, a])) * h
               for a, f in enumerate(occupations))
```

The kinetic energy $T_s = \sum_a f_a \int \phi_a(-\frac{1}{2}\phi_a'')\,dx$, on the grid $\sum_a f_a\,(\phi_a \cdot T\phi_a)\,h$, for any list of occupations.

```
T_s = kinetic(ks_phi, [2.0] * N_PER_LABEL)
E_ext = integral(v * n_ks)
E_H = 0.5 * G_C * integral(n_ks ** 2)
E_x = -0.25 * G_C * integral(n_ks ** 2)
E_total = T_s + E_ext + E_H + E_x
E_double = 2.0 * ks_levels[:N_PER_LABEL].sum() - (E_H + E_x)
```

`[2.0] * N_PER_LABEL` is the list $[2, 2, 2, 2]$. The four parts of the energy of Section 13.32, their sum, and the double-counting formula (`ks_levels[:N_PER_LABEL].sum()` adds the four occupied levels).

```
for label, value in (("kinetic T_s", T_s), ("external int v n dx", E_ext),
                     ("Hartree E_H", E_H), ("exchange E_x", E_x)):
    say(f"{label:22} = {value:.6f}")
report("total energy E (direct sum)", f"{E_total:.6f}")
```

```
report("total energy E (double counting)", f"{E_double:.6f}")
check(abs(E_total - E_double) < 1e-9, "the two energy formulas agree")
check(abs(E_x + 0.5 * E_H) < 1e-12, "E_x = -E_H/2 for two equally occupied labels")
```

The loop goes through four pairs (name, value) and prints the parts, 6.726297, 9.521279, 11.207843 and -5.603922 (`{label:22}` pads the name with blanks to 22 characters, so that the equals signs line up); the `report` lines print both totals, 21.851498, and the checks require them to agree to 10^{-9} and $E_x = -E_H/2$ to 10^{-12} (the rule $-1/g$ with $g = 2$).

In [15], the functional derivative on the grid.

```
def interaction_energy(n):
    """E_H + E_x = (g_c/4) int n^2 dx for two equally occupied labels."""
    return 0.25 * G_C * integral(n ** 2)

eta = np.exp(-(x - 1.0) ** 2)  # a fixed change of shape, off the centre of the trap
epsilon = 1e-4  # the size of the change
quotient = (interaction_energy(n_ks + epsilon * eta)
            - interaction_energy(n_ks - epsilon * eta)) / (2.0 * epsilon)
w_ks = 0.5 * G_C * n_ks  # the mean-field potential w = g_c n / 2
```

The definition of Section 13.9 tested directly: change the density by $\pm\epsilon\eta$ with the bump $\eta = e^{-(x-1)^2}$ and $\epsilon = 10^{-4}$, and form the central difference quotient of $E_H + E_x$. By the definition it must equal $\int w\,\eta\,dx$ with $w = \delta(E_H + E_x)/\delta n = g_c n/2$, which is `w_ks`.

```
report("difference quotient of E_H + E_x along eta", f"{quotient:.10f}")
report("integral of w eta dx", f"{integral(w_ks * eta):.10f}")
check(abs(quotient - integral(w_ks * eta)) < 1e-9,
      "w = g_c n/2 is the functional derivative of E_H + E_x")
```

Both print as 2.6845567944, and the check requires agreement to 10^{-9} (because $E_H + E_x$ is a square of n, the central quotient is exact up to rounding: the terms of order ϵ^2 cancel between $+\epsilon$ and $-\epsilon$, and there are no higher terms).

In [16], the stability of equal labels.

```
def label_densities(w_pair, up_occupations, down_occupations):
    """The densities n_up, n_down and the levels for the pair of potentials."""
    up_levels, up_phi = orbitals(w_pair[:M])  # w_up: the first M numbers
    down_levels, down_phi = orbitals(w_pair[M:])  # w_down: the last M numbers
    n_up = (up_phi[:, :len(up_occupations)] ** 2) @ np.array(up_occupations)
    n_down = (down_phi[:, :len(down_occupations)] ** 2) @ np.array(down_occupations)
    return n_up, n_down, up_levels, up_phi, down_levels, down_phi
```

The two potentials are stored in one list of $2M = 400$ numbers: the first 200 for label up, the last 200 for label down (`w_pair[:M]`, `w_pair[M:]`). For each label the function solves the orbitals and forms the density with any occupations: the matrix of squared orbitals times the list of occupations is $\sum_a f_a \phi_a^2$ at every point.

```
def labels_map(w_pair, up_occupations, down_occupations):
    """One pass for two labels: w_up = g_c n_down and w_down = g_c n_up."""
    n_up, n_down = label_densities(w_pair, up_occupations, down_occupations)[:2]
    return np.concatenate([G_C * n_down, G_C * n_up])

def labels_energy(w_pair, up_occupations, down_occupations):
    """E = T_s + int v n + g_c int n_up n_down (E_H + E_x for two labels)."""
    n_up, n_down, _, up_phi, _, down_phi = label_densities(
        w_pair, up_occupations, down_occupations)
    return (kinetic(up_phi, up_occupations) + kinetic(down_phi, down_occupations)
            + integral(v * (n_up + n_down)) + G_C * integral(n_up * n_down))
```

One pass of the two-label loop: the potential of label up is $g_c n_\downarrow$ and that of label down $g_c n_\uparrow$ (Section 13.32), joined into one list by `np.concatenate`. `labels_energy` is $E = T_s + \int v\, n + g_c \int n_\uparrow n_\downarrow$.

```
FILLED = [1.0] * N_PER_LABEL  # the four lowest orbitals of each label occupied
push = 1.0 * np.tanh(x)  # pushes up-fermions to the left, down-fermions to the right
start = np.concatenate([w_scf + push, w_scf - push])
w_pair, pair_residuals = anderson(lambda q: labels_map(q, FILLED, FILLED), start)
n_up, n_down = label_densities(w_pair, FILLED, FILLED)[:2]
```

Each label has its four lowest orbitals occupied once. The start is strongly separated: $\tanh x$ rises from -1 to 1 across the trap, so adding it to the up potential pushes the up fermions to the left, and subtracting it pushes the down fermions to the right. Anderson mixing then runs on both potentials together (the `lambda` fixes the occupations), and the label densities of the result are formed.

```
say(f"two-label run: {len(pair_residuals)} passes; largest |n_up - n_down| = "
    f"{np.max(np.abs(n_up - n_down)):.1e}")
check(np.max(np.abs(n_up - n_down)) < 1e-8,
      "from a separated start the two-label loop returns to equal densities")
check(abs(labels_energy(w_pair, FILLED, FILLED) - E_total) < 1e-9,
      "the two-label run has the same energy as the equal-label solution")
```

The run needs 36 passes, and the largest difference between the label densities is $4.9 \cdot 10^{-12}$; the checks require it to be below 10^{-8} and the energy to equal the equal-label energy 21.851498 to 10^{-9}: from a strongly separated start the loop returns to equal labels. This does NOT yet show that the equal-label solution is stable: a converged loop can sit on a saddle. The next two cells show such a case and then make the test that decides, the energy test.

In [17], a loop that converges to a saddle: two sites.

```
T_HOP, U_SITE = 1.0, 4.0  # the hopping t and the on-site repulsion U of two sites
left_right = np.array([-1.0, 1.0])  # lowers the potential on L and raises it on R
```

The two-site model of Section 13.7 with the hopping $t = 1$ and the repulsion $U = 4$ (so $U = 4t$, stronger than $2t$). `left_right` is the pattern $(-1, +1)$: added to a pair of site potentials (w_L, w_R) it lowers w_L and raises w_R.

```
def site_orbital(w2):
    """(c_L, c_R): the orbital of the lower level of [[w_L, -t], [-t, w_R]]."""
    return np.linalg.eigh(np.array([[w2[0], -T_HOP], [-T_HOP, w2[1]]]))[1][:, 0]
```

For one label with the site potentials `w2` $= (w_L, w_R)$, the one-particle matrix is $\begin{pmatrix} w_L & -t \\ -t & w_R \end{pmatrix}$. `np.linalg.eigh` returns its eigenvalues in increasing order and the eigenvectors as columns; `[1][:, 0]` takes the eigenvector of the LOWER level, the occupied orbital (c_L, c_R) with $c_L^2 + c_R^2 = 1$.

```
def sites_map(q):
    """One pass on two sites, q = (w_up on L, R, w_down on L, R)."""
    n_up, n_down = site_orbital(q[:2]) ** 2, site_orbital(q[2:]) ** 2
    return np.concatenate([U_SITE * n_down, U_SITE * n_up])
```

One pass of the two-label loop on two sites, exactly as in the trap: the four numbers `q` are the potentials of label up on L and R and of label down on L and R; the occupations of the sites are the squares of the orbital components, and the new potential of label up is $Un_\downarrow$ (it feels only the other label), that of label down $Un_\uparrow$.

```
def sites_energy(q):
    """-2t (c_L c_R of up + c_L c_R of down) + U sum_sites n_up n_down."""
    c_up, c_down = site_orbital(q[:2]), site_orbital(q[2:])
    return (-2.0 * T_HOP * (c_up[0] * c_up[1] + c_down[0] * c_down[1])
            + U_SITE * np.sum(c_up ** 2 * c_down ** 2))
```

The energy of the determinant built from the two orbitals: each orbital contributes the hopping energy $-2t\, c_L c_R$, and the repulsion is U times the product of the up and down occupations on each site, summed over the two sites.

```
def sites_start(size):
    """The potentials U/2 + size (-1, 1) for label up and U/2 - size (-1, 1)."""
    return np.concatenate([0.5 * U_SITE + size * left_right,
                           0.5 * U_SITE - size * left_right])
```

A family of label-separating potentials: at `size` $= 0$ both labels have $U/2$ on both sites (the equal-label solution); a positive `size` makes site L cheaper for label up and site R cheaper for label down.

```
site_ends = {}
for site_push in (0.5, 1.0):
    q_end, site_residuals = anderson(sites_map, sites_start(site_push))
    site_ends[site_push] = q_end
    n_up_sites = site_orbital(q_end[:2]) ** 2
    energy = np.round(sites_energy(q_end), 9) + 0.0  # + 0.0 turns -0.0 into 0.0
    say(f"two sites, push {site_push}: {len(site_residuals)} passes, n_up = "
        f"({n_up_sites[0]:.6f}, {n_up_sites[1]:.6f}), energy {energy:.6f}")
```

The SAME Anderson loop as in the trap (`anderson`, In [8]) runs twice, from a small separation (push 0.5) and from a larger one (push 1). For each end it stores the potentials, prints the number of passes, the occupations of label up on L and R and the energy; `np.round(..., 9)` removes rounding noise and `+ 0.0` turns a printed -0.000000 into 0.000000. The output: from push 0.5 the loop needs 16 passes and ends at $n_\uparrow = (0.5, 0.5)$ with the energy 0, the equal-label solution; from push 1 it needs 18 passes and ends at $n_\uparrow = (0.933013, 0.066987)$ with the energy -0.5, the separated solution.

```
site_sizes = np.linspace(0.0, 2.5, 51)  # epsilon = 0, 0.05, ..., 2.5
site_family = np.array([sites_energy(sites_start(size)) for size in site_sizes])
saddle_up = site_orbital(site_ends[0.5][:2]) ** 2
```

The energy along the whole family $\epsilon = 0, 0.05, \ldots, 2.5$ (for the figure and the last check), and the occupations of label up at the end of the push-0.5 run.

```
check(np.max(np.abs(saddle_up - 0.5)) < 1e-9
      and abs(sites_energy(site_ends[0.5]) - (-2.0 * T_HOP + 0.5 * U_SITE)) < 1e-9,
      "two sites, U = 4t, push 0.5: the loop converges to equal labels, E = -2t + U/2")
check(abs(sites_energy(site_ends[1.0]) + 2.0 * T_HOP ** 2 / U_SITE) < 1e-9,
      "two sites, push 1: the loop converges to separated labels, E = -2t^2/U")
check(site_family[1] < site_family[0] - 1e-3,
      "two sites: separating the labels lowers the energy, so the equal-label "
      "solution there is a saddle")
```

Three checks. The first: from push 0.5 the loop converges to equal occupations 1/2 with the equal-label energy $-2t + U/2 = 0$. The second: from push 1 it converges to the separated energy $-2t^2/U = -0.5$ (Section 13.7). The third: already the first step of the family, $\epsilon = 0.05$, has a lower energy than $\epsilon = 0$; so the equal-label solution, although self-consistent and reached by the loop, is a saddle. A converged loop alone cannot tell a minimum from a saddle.

In [18], the energy test in the trap, and Figure 13a.6.

```
shapes = {"tanh x": np.tanh(x), "x exp(-x^2/4)": x * np.exp(-x ** 2 / 4.0),
          "exp(-x^2/2)": np.exp(-x ** 2 / 2.0)}
```

Three shapes $s(x)$ of a label-separating change: $\tanh x$ pushes label up to the left and label down to the right across the whole trap; $x\,e^{-x^2/4}$ does the same but only near the centre; $e^{-x^2/2}$ pushes label up outwards and label down inwards.

```
def separation_rise(shape, size):
    """E of the determinant made from w_scf +- size * shape, minus E_KS."""
    trial = np.concatenate([w_scf + size * shape, w_scf - size * shape])
    return labels_energy(trial, FILLED, FILLED) - E_total
```

The trial potentials are $w_\uparrow = w_{scf} + \epsilon\, s(x)$ and $w_\downarrow = w_{scf} - \epsilon\, s(x)$. `labels_energy` (In [16]) takes the four lowest orbitals of each label in its trial potential and evaluates the energy $E = T_s + \int v\, n + g_c \int n_\uparrow n_\downarrow$ of that determinant; for the contact interaction this formula is the exact energy of the determinant, so no self-consistency is needed. The function returns the energy above the Kohn-Sham energy `E_total`.

```
sizes = [0.01, 0.05, 0.2, 0.5, 1.0]
rises = {name: [separation_rise(shape, size) for size in sizes]
         for name, shape in shapes.items()}
for name, values in rises.items():
    say(f"{name:14} E - E_KS: " + " ".join(f"{value:.2e}" for value in values))
```

The rise for the five sizes $\epsilon = 0.01, 0.05, 0.2, 0.5, 1$ and each shape, printed in powers of ten (`.2e`). The output: for $\tanh x$ the rises are $3.50 \cdot 10^{-5}$, $8.81 \cdot 10^{-4}$, $1.53 \cdot 10^{-2}$, 0.124 and 0.593; for $x\, e^{-x^2/4}$ they are $2.14 \cdot 10^{-5}$ to 0.254; for $e^{-x^2/2}$, $8.58 \cdot 10^{-6}$ to $8.71 \cdot 10^{-2}$. All are positive.

```
check(all(value > 0.0 for values in rises.values() for value in values),
      "every label-separating trial determinant in the trap has a higher energy "
      "than the Kohn-Sham state")
check(all(24.0 < values[1] / values[0] < 26.0 for values in rises.values()),
      "for small separations the energy rises as epsilon^2: in the trap the "
      "equal-label solution is a minimum along these families, not a saddle")
```

Two checks. The first: every one of the fifteen trial determinants lies above the Kohn-Sham energy. The second: going from $\epsilon = 0.01$ to 0.05 (five times larger) multiplies the rise by between 24 and 26, close to $5^2 = 25$; for $\tanh x$, $8.81 \cdot 10^{-4} / 3.50 \cdot 10^{-5} \approx 25.2$. So for small separations the rise is of second order, $E - E_{KS} \approx a\,\epsilon^2$ with $a > 0$: the energy is flat (stationary) at the Kohn-Sham solution and curves upwards. Along these three families the equal-label solution is a minimum, not a saddle. (Three families are a test, not a proof for every possible change; this is a COMPUTED result for this trap at $g_c = 2$.)

```
fine_sizes = np.linspace(0.0, 1.0, 41)  # epsilon = 0, 0.025, ..., 1
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
for (name, shape), style in zip(shapes.items(), ("-", "--", "-.")):
    left.plot(fine_sizes, [separation_rise(shape, size) for size in fine_sizes],
              style, label=f"shape {name}")
```

Figure 13a.6 has two panels side by side (`plt.subplots(1, 2, ...)`). On the left, the rise for each shape on a finer grid of 41 sizes, each shape with its own line style (solid, dashed, dash-dotted).

```
left.set_xlabel("size $\\epsilon$ of the separation")
left.set_ylabel("$E - E_{KS}$ ($\\hbar\\omega$)")
left.set_title("Trap, $g_c = 2$: the energy rises (minimum)")
left.legend(fontsize=8)
```

Axis labels (the size is a pure number; the energy is in units of $\hbar\omega$), the title and the legend of the left panel.

```
right.plot(site_sizes, site_family, color="black", label="energy of the family")
right.plot([0.0], [site_family[0]], "o", ms=8,
           label="loop from push 0.5 (saddle)")
size_end = 0.5 * (site_ends[1.0][1] - site_ends[1.0][0])  # (w_R - w_L)/2 of up
right.plot([size_end], [sites_energy(site_ends[1.0])], "s", ms=8,
           label="loop from push 1 (minimum)")
```

On the right, the two-site family of In [17] as a black line, a circle at $\epsilon = 0$ where the push-0.5 loop ended, and a square where the push-1 loop ended. The square's horizontal position is $(w_R - w_L)/2$ of label up at the end, the size of the separation that the loop found.

```
right.set_xlabel("size $\\epsilon$ of the separation")
right.set_ylabel("$E$ (units of $t$)")
right.set_title("Two sites, $U = 4t$: the energy falls (saddle)")
right.legend(fontsize=8)
save_figure(fig, "label_separation",
            "The energy test of stability. Left: the trap with eight fermions; "
            "the energy of the determinant made from the label-separating trial "
            "potentials $w_{scf} \\pm \\epsilon\\,s(x)$, minus the Kohn-Sham "
            "energy, for three shapes $s$, against the size $\\epsilon$ (pure "
            "number); vertical axis in units of $\\hbar\\omega$. Every curve starts "
            "flat at 0 and rises: along these families the equal-label solution "
            "is a minimum. Right: two sites with $U = 4t$; the energy of the "
            "determinant made from the potentials $U/2 \\pm \\epsilon\\,(-1, 1)$, "
            "in units of $t$, against $\\epsilon$. It falls from the equal-label "
            "solution (circle, energy 0, where the loop from push 0.5 converged: "
            "a saddle) to the separated minimum $-2t^2/U = -0.5t$ (square, where "
            "the loop from push 1 converged). The converged loop could not tell "
            "the two cases apart; the energy does.")
```

Labels, title and legend of the right panel, and `save_figure`, which writes `13a_6_label_separation.png` with this caption, which the book prints below the figure.

What Figure 13a.6 shows. On the left, all three curves start flat at 0 and rise: for $\tanh x$ to about 0.59 at $\epsilon = 1$, for the other two shapes less, because they move fewer fermions. A flat start means that the Kohn-Sham solution is stationary; the upward curve means a minimum along these families. On the right, the two-site energy starts at 0 (the circle, where the loop from push 0.5 converged) and FALLS to the separated minimum $-0.5t$ (the square, where the loop from push 1 converged): the circle is a saddle. Both loops converged; only the energy shows which end is stable.

In [19], the variational principle.

```
def energy_of_orbitals(phi):
    """E = T_s + int v n dx + (g_c/4) int n^2 dx for 2 fermions in orbitals 0..3."""
    n = density(phi)
    return (kinetic(phi, [2.0] * N_PER_LABEL) + integral(v * n)
            + 0.25 * G_C * integral(n ** 2))

c_values = np.linspace(0.0, 2.0, 41)  # c = 0, 0.05, ..., 2
family_energies = np.array([energy_of_orbitals(orbitals(c * n_scf)[1])
                            for c in c_values])
c_best = c_values[np.argmin(family_energies)]
```

The energy formula of Section 13.32 for any set of orbitals; for 41 values of c from 0 to 2 the orbitals of the trial potential $v + c\,n_{scf}$ (`orbitals(c * n_scf)[1]`) and their energy; `c_best` the value with the lowest energy.

```
report("c of the lowest energy in the family", f"{c_best:.2f}")
check(abs(c_best - 0.5 * G_C) < 1e-9,
      "the lowest energy of the family is at c = g_c/2 (the self-consistent one)")
check(np.all(family_energies >= E_total - 1e-10),
      "no member of the family has a lower energy than the Kohn-Sham state")
```

`c_best` prints as 1.00, and the checks require it to equal $g_c/2$ (to 10^{-9}; the grid of c contains the value 1 exactly) and every member of the family to have an energy at least E_{KS} (to 10^{-10}).

In [20], the family as a picture.

```
fig, ax = plt.subplots()
ax.plot(c_values, family_energies - E_total, "o-", ms=3,
        label="$E(c) - E_{KS}$")
ax.axvline(0.5 * G_C, color="gray", ls="--", label="$c = g_c/2$ (self-consistent)")
ax.set_xlabel("$c$ in the trial potential $v + c\\,n_{scf}$")
ax.set_ylabel("energy above the Kohn-Sham energy ($\\hbar\\omega$)")
ax.set_title("Variational principle: a family of trial determinants")
ax.legend()
save_figure(fig, "variational_scan",
```

The energy above the Kohn-Sham energy against c, as dots joined by a line; a grey dashed vertical line at $c = g_c/2$; labels, title, legend and `save_figure` for Figure 13a.7.

What Figure 13a.7 shows. A curve shaped like a parabola that touches zero at $c = 1$ and is flat there: moving c by 0.05 away from 1 raises the energy by only about 0.001, while the ends lie much higher, 0.29 at $c = 0$ (the orbitals of the bare trap) and 0.72 at $c = 2$ (the orbitals of the Hartree-like potential $v + g_c n$). A first-order error in the orbitals gives only a second-order error in the energy.

In [21], Hartree only and Thomas-Fermi.

```
def hartree_map(w):
    """One pass of the Hartree approximation: w_out = g_c n (no exchange)."""
    return G_C * density(orbitals(w)[1])

w_hartree, hartree_residuals = anderson(hartree_map, np.zeros(M))
n_hartree = density(orbitals(w_hartree)[1])
n_free = density(free_phi)  # no interaction at all
```

The Hartree approximation has the mean-field potential $g_c n$ instead of $g_c n/2$; Anderson mixing solves it, and `n_hartree` is its density. `n_free` is the density without interaction.

```
def thomas_fermi(mu):
    """The Thomas-Fermi density: the positive root of a n^2 + b n = mu - v."""
    a, b = np.pi ** 2 / 8.0, 0.5 * G_C
    room = np.maximum(mu - v, 0.0)  # zero where the trap is higher than mu
    return (-b + np.sqrt(b * b + 4.0 * a * room)) / (2.0 * a)
```

The Thomas-Fermi density of Section 13.32: `np.maximum(mu - v, 0.0)` replaces $\mu - v$ by 0 where the trap is higher than μ, which makes the root 0 there.

```
low, high = 0.0, 50.0  # mu lies between these two numbers
for _ in range(60):  # bisection: halve the interval 60 times
    middle = 0.5 * (low + high)
    if integral(thomas_fermi(middle)) < N_TOTAL:
        low = middle  # too few particles: mu must be larger
    else:
        high = middle
mu_tf = 0.5 * (low + high)
n_tf = thomas_fermi(mu_tf)
```

Bisection for μ: the number of particles grows with μ; with $\mu = 0$ there are none and with $\mu = 50$ far more than 8. 60 halvings of the interval of width 50 leave a width of $50/2^{60} \approx 4 \cdot 10^{-17}$, below the rounding of the computer.

```
report("Thomas-Fermi chemical potential mu", f"{mu_tf:.6f}")
check(abs(integral(n_tf) - N_TOTAL) < 1e-9, "the Thomas-Fermi density holds 8")
check(abs(integral(n_hartree) - N_TOTAL) < 1e-10, "the Hartree density holds 8")
```

The cell prints $\mu = 5.110729$ and checks that the Thomas-Fermi and the Hartree densities hold 8 particles.

```
widths = [np.sqrt(integral(x ** 2 * n) / N_TOTAL)
          for n in (n_free, n_ks, n_hartree)]
say("root-mean-square widths: free {:.6f}, Kohn-Sham {:.6f}, Hartree {:.6f}"
    .format(*widths))
check(widths[0] < widths[1] < widths[2],
      "repulsion widens the cloud, and self-interaction (Hartree) widens it more")
```

The **root-mean-square width** $\sqrt{\int x^2 n\, dx / N}$ measures how far the cloud spreads; `.format(*widths)` puts the three numbers into the three braces of the string. The widths 1.413346, 1.542829, 1.659857 must increase in this order (last check).

In [22], four pictures of the same fermions.

```
fig, ax = plt.subplots()
ax.plot(x, n_free, ":", label="no interaction")
ax.plot(x, n_hartree, "--", label="Hartree only (self-interaction)")
ax.plot(x, n_ks, lw=2.0, color="black", label="Kohn-Sham (Hartree + exchange)")
ax.plot(x, n_tf, "-.", label="Thomas-Fermi (local kinetic energy)")
ax.set_xlim(-5.0, 5.0)
ax.set_xlabel("position $x$")
ax.set_ylabel("density (particles per unit length)")
ax.set_title("Four pictures of the same eight fermions ($g_c = 2$)")
ax.legend(fontsize=8)
save_figure(fig, "approximations",
```

The four densities, without interaction (dotted), Hartree only (dashed), Kohn-Sham (thick black) and Thomas-Fermi (dash-dotted); range, labels, title, legend and `save_figure` for Figure 13a.8.

What Figure 13a.8 shows. Without interaction the cloud is the narrowest and the highest (peaks of about 1.89); Kohn-Sham is lower and wider; Hartree only is lower and wider still, because each fermion also pushes against its own density. All three have the bumps of the four occupied orbitals. The Thomas-Fermi density is a smooth dome without bumps, close to the Kohn-Sham density on average, and it ends abruptly at $|x| = \sqrt{2\mu} = 3.20$, where the trap reaches μ (the orbital densities instead die away gradually beyond that point).

In [23], switching the interaction on.

```
def solve_at(strength, start):
    """The self-consistent w and the three energies (T_s, int v n dx, E_H + E_x)
    at the coupling strength, starting the loop from the potential start."""

    def strength_map(w):  # the Kohn-Sham map with this strength instead of G_C
        return 0.5 * strength * density(orbitals(w)[1])

    w, _ = anderson(strength_map, start)
    phi = orbitals(w)[1]
    n = density(phi)
    parts = (kinetic(phi, [2.0] * N_PER_LABEL), integral(v * n),
             0.25 * strength * integral(n ** 2))
    return w, parts
```

`solve_at` solves the model for any strength: the inner function `strength_map` is the Kohn-Sham map with that strength, Anderson mixing solves it from the given start, and the function returns the potential and the three parts T_s, $\int v\,n$ and $E_H + E_x$.

```
strengths = np.linspace(0.0, 2.0, 9)  # g_c = 0, 0.25, ..., 2
scan, w_start = [], np.zeros(M)
for strength in strengths:
    w_start, parts = solve_at(strength, w_start)  # start from the last solution
    scan.append(parts)
scan = np.array(scan)  # one row per strength; columns: T_s, int v n, E_H + E_x
say(f"E at g_c = 0: {scan[0].sum():.6f}; at g_c = 2: {scan[-1].sum():.6f}")
check(abs(scan[-1].sum() - E_total) < 1e-9, "the scan ends at the same E as above")
```

Nine strengths from 0 to 2, each solved starting from the solution of the previous strength (a good start saves passes). The energy is 15.990192 at $g_c = 0$ (the grid's version of 16) and 21.851498 at $g_c = 2$, the same as before (check).

```
delta = 1e-3
E_plus = sum(solve_at(2.0 + delta, w_scf)[1])  # E at g_c = 2.001
E_minus = sum(solve_at(2.0 - delta, w_scf)[1])  # E at g_c = 1.999
slope = (E_plus - E_minus) / (2.0 * delta)
```

The Hellmann-Feynman test: the energies at $g_c = 2.001$ and 1.999 (each solved by Anderson mixing from the solution at $g_c = 2$; `sum(...)` adds the three parts) and their central difference quotient.

```
report("dE/dg_c at g_c = 2 (difference quotient)", f"{slope:.6f}")
report("(1/4) int n^2 dx at g_c = 2 (Hellmann-Feynman)",
```

```
       f"{0.25 * integral(n_ks ** 2):.6f}")
check(abs(slope - 0.25 * integral(n_ks ** 2)) < 1e-6,
      "Hellmann-Feynman: dE/dg_c = (1/4) int n^2 dx")
```

Both the quotient and $\frac{1}{4}\int n^2\,dx$ print as 2.801961, and the check requires agreement to 10^{-6} (the quotient has an error of order $\delta^2 = 10^{-6}$ times the third derivative, plus the effect of the loop's tolerance).

In [24], the energies of the scan.

```
fig, ax = plt.subplots()
ax.plot(strengths, scan[:, 0], "o-", ms=4, label="kinetic $T_s$")
ax.plot(strengths, scan[:, 1], "s-", ms=4, label="trap $\\int v\\,n\\,dx$")
ax.plot(strengths, scan[:, 2], "^-", ms=4, label="interaction $E_H + E_x$")
ax.plot(strengths, scan.sum(axis=1), "D-", ms=4, color="black",
        label="total $E$")
ax.set_xlabel("strength $g_c$ of the contact repulsion")
ax.set_ylabel("energy (units of $\\hbar\\omega$)")
ax.set_title("Switching the repulsion on")
ax.legend(fontsize=8)
save_figure(fig, "coupling_scan",
```

The three columns of the table `scan` against the nine strengths, with different markers, and their sum along each row (`scan.sum(axis=1)`) as the black total; labels, title, legend and `save_figure` for Figure 13a.9. After the caption, the check

```
check(abs(scan[0].sum() - 16.0) < 0.05 and abs(scan[0, 0] - scan[0, 1]) < 0.05,
      "at g_c = 0: E = 16 and T_s equals the trap energy (virial theorem)")
```

requires, at $g_c = 0$ (row 0 of the scan), the total 16 and equal kinetic and trap energies (the virial theorem of Section 13.32), both to 0.05, the accuracy of the grid.

What Figure 13a.9 shows. At $g_c = 0$ the kinetic and the trap energy are both 8 and the total is 16 (the grid gives 15.99). As the repulsion is switched on, the interaction energy grows almost linearly to 5.60; the cloud spreads, so the trap energy rises (to 9.52) and the kinetic energy falls (to 6.73): wider orbitals curve less. The total rises to 21.85 along a curve that bends slightly downwards: by the Hellmann-Feynman theorem its slope is $\frac{1}{4}\int n^2\,dx$, which is 3.07 at $g_c = 0$ (with the density without interaction) and 2.80 at $g_c = 2$, because the spreading cloud has a smaller $\int n^2\,dx$.

In [25], the first excited state.

```
taus = np.linspace(0.0, 1.0, 9)
gaps, energies, w_pair = [], [], np.concatenate([w_scf, w_scf])
for tau in taus:
    up = [1.0, 1.0, 1.0, 1.0 - tau, tau]  # orbitals 0..4 of label up
    w_pair, _ = anderson(lambda q: labels_map(q, up, FILLED), w_pair)
    up_levels = label_densities(w_pair, up, FILLED)[2]
    gaps.append(up_levels[4] - up_levels[3])  # eps_4(tau) - eps_3(tau)
    energies.append(labels_energy(w_pair, up, FILLED))
gaps, energies = np.array(gaps), np.array(energies)
n_excited = sum(label_densities(w_pair, up, FILLED)[:2])  # tau = 1: n_up + n_down
```

Nine values of the moved fraction $\tau = 0, \frac{1}{8}, \ldots, 1$. For each, label up has the occupations $1, 1, 1, 1-\tau, \tau$ in its orbitals 0 to 4 and label down its four lowest orbitals full; the two-label loop is solved by Anderson mixing, starting from the previous solution, and the level difference $\epsilon_4 - \epsilon_3$ of label up and the energy are stored. After the loop `n_excited` is the total density at $\tau = 1$, the Delta-SCF excited state.

```
step = taus[1] - taus[0]
simpson = step / 3.0 * (gaps[0] + gaps[-1] + 4.0 * gaps[1:-1:2].sum()
                        + 2.0 * gaps[2:-1:2].sum())
delta_scf = energies[-1] - energies[0]
```

Simpson's rule (Section 13.15) on the nine level differences (the name `simpson` is here a number, not a function), and the Delta-SCF energy $E(1) - E(0)$.

```
report("Kohn-Sham gap (LUMO - HOMO)", f"{gaps[0]:.6f}")
report("Delta-SCF excitation energy E(1) - E(0)", f"{delta_scf:.6f}")
report("Janak integral of eps_4 - eps_3 (Simpson)", f"{simpson:.6f}")
report("transition state eps_4 - eps_3 at tau = 1/2", f"{gaps[4]:.6f}")
check(abs(energies[0] - E_total) < 1e-9, "tau = 0 is the ground state")
check(abs(gaps[0] - (ks_levels[4] - ks_levels[3])) < 1e-9,
      "at tau = 0 the level difference is the Kohn-Sham gap")
check(abs(simpson - delta_scf) < 1e-6,
      "Janak's theorem: the integral of eps_4 - eps_3 equals Delta-SCF")
check(delta_scf < gaps[0], "orbital relaxation lowers the excitation energy here")
```

The `report` lines print the gap 0.772662, the Delta-SCF energy 0.714594, the Janak integral 0.714594 and the transition state 0.712784 (entry 4 is $\tau = \frac{1}{2}$). The four checks: $\tau = 0$ is the ground state; the level difference at $\tau = 0$ is the Kohn-Sham gap of In [11] ($5.496606 - 4.723945$); the Janak integral equals the Delta-SCF energy to 10^{-6}; and the Delta-SCF energy is below the gap here.

In [26], the excited state as a picture.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.fill_between(taus, 0.0, gaps, alpha=0.25, label="area = Delta-SCF")
left.plot(taus, gaps, "o-", color="black", label="$\\epsilon_4 - \\epsilon_3$")
left.plot([0.0], [gaps[0]], "s", ms=8, label=f"Kohn-Sham gap {gaps[0]:.4f}")
left.plot([0.5], [gaps[4]], "^", ms=8, label=f"transition state {gaps[4]:.4f}")
left.axhline(delta_scf, color="gray", ls="--", label=f"Delta-SCF {delta_scf:.4f}")
```

On the left, `left.fill_between(taus, 0.0, gaps, alpha=0.25, ...)` shades the area between zero and the level difference, which is the Delta-SCF energy by Janak's theorem; the level difference itself as black dots joined by a line; the gap as a large square at $\tau = 0$, the transition state as a large triangle at $\tau = \frac{1}{2}$, and the Delta-SCF energy as a grey dashed horizontal line, each with its value in the legend (four decimals).

```
left.set_ylim(0.0, 1.0)
left.set_xlabel("fraction $\\tau$ of the moved fermion")
left.set_ylabel("level difference ($\\hbar\\omega$)")
left.legend(fontsize=7, loc="lower left")
```

The vertical range from 0 to 1, labels, and the legend in the lower left corner, inside the shaded area.

```
right.plot(x, n_ks, color="black", label="ground state")
right.plot(x, n_excited, "--", label="excited (Delta-SCF)")
right.set_xlim(-5.0, 5.0)
right.set_xlabel("position $x$")
right.set_ylabel("density (particles per unit length)")
right.legend(fontsize=8)
fig.suptitle("The first excited state by Delta-SCF ($g_c = 2$)")
save_figure(fig, "delta_scf",
```

On the right the ground-state density (black) and the density of the Delta-SCF excited state (dashed); range, labels, legend, a common title, and `save_figure` for Figure 13a.10.

What Figure 13a.10 shows. On the left the level difference falls almost linearly from the gap 0.7727 at $\tau = 0$ to about 0.66 at $\tau = 1$: as the up fermion moves into orbital 4, the levels rearrange so that the two orbitals come closer. The shaded area, 0.7146, is the Delta-SCF energy (dashed line); it is smaller than the gap, and the midpoint value 0.7128 (triangle) is close to it, because the curve is nearly straight. On the right the excited density differs from the ground-state density mainly in the middle: the ground state has two peaks beside a dip at $x = 0$, the excited state a peak at $x = 0$ and shoulders beside it (orbital 4 has its largest value at the centre, orbital 3 a zero there), and slightly more density in the outer flanks.

In [27], the last check.

```
figure_names = ["trap_orbitals", "scf_convergence", "first_iterations",
                "ks_potentials", "density_orbitals", "label_separation",
                "variational_scan", "approximations", "coupling_scan",
                "delta_scf"]
missing = [name for k, name in enumerate(figure_names, 1)
           if not output_file(f"{FIGURE_FOLDER}/13a_{k}_{name}.png").is_file()]
check(missing == [], "all ten figure files exist")
check(output_file(f"{FIGURE_FOLDER}/13a_10_delta_scf.png").is_file(),
      "the figure file 13a_10_delta_scf.png exists")
all_checks_passed()
```

The same lines as In [19] of Notebook 13c (Section 13.14), with the ten figure names of this notebook. The last line prints ALL 36 CHECKS PASSED (notebook 13a): one check each in In [2], In [5], In [6], In [7], In [10], In [12], In [15] and In [24], two each in In [3], In [8], In [11], In [14], In [16], In [18], In [19], In [23] and In [27], three each in In [17] and In [21], and four in In [25].

13.37 From the toy models to dirac16complex

This section says which ideas of the chapter the Kohn-Sham model of dirac16complex (Chapters 14 to 16) uses, and what is different there. As in Section 13.16, x_1, x_2, x_3 are the directions of ordinary space, x_4 the time, x_5, x_6, x_7 the three extra times, which deflate exponentially (scale factor $e^{-a_4}\sin^{1/6} z$ while ordinary space inflates with $e^{a_4}\sin^{1/6} z$), and x_0 the hidden direction, $z = 6Hx_0$, with the author's constant $H > 0$.

What carries over.

- **The Kohn-Sham scheme and self-consistency.** The model is a Kohn-Sham fermion gas of dirac16complex quanta in the good sector (no momentum along the extra times), in which the 16-component equation reduces to 2×2 blocks in the hidden coordinate (Chapter 14). Its levels and orbitals are found self-consistently, with Anderson mixing of the potentials at every grid point of the hidden direction (depth 6, $\beta = 0.4$, stopping rule 10^{-11} on the largest residual; Section 13.21 and `Revision/kohn_sham/results/parameters.json`, numerics).

- **The interaction and its exchange.** The contact interaction $\frac{\lambda}{2}S^2$ with the vertex C, treated as Hartree plus the exact local exchange of the uniform 8-fold gas: $e_x = -\frac{\lambda}{32}(n^2 + S^2)$, $M_{eff} = m + \frac{15}{16}\lambda S$, $v_v = -\frac{1}{16}\lambda n$ (Section 13.16; PROVED in `Revision/kohn_sham/reports/ks-theory-python.json`, checks exchange_uniform_gas, ks_potentials, filled_shell_ratio).

- **Mermin's occupations.** At the temperatures $T = 0.01$, 0.02 and 0.05 (in units of the mass m; parameters.json, physics temperatures, checked by Notebook 13b, In [22]) the occupations are Fermi-Dirac numbers with μ fixed by $\sum gf = N$, solved in the LogBalance form (Section 13.26; parameters.json, conventions merminRoot).

- **Excited states.** The Kohn-Sham gap and the particle-hole excitations of Section 13.27, and Delta-SCF in its ensemble form over groups of equal levels (parameters.json, conventions deltaScf; Notebook 13b, In [22]).

- **Densities through the Krein form.** The number density is $n = \mathrm{Tr}(B\rho)$ with the indefinite form $B = -iC\gamma^{(x4)}$ of Chapter 10, and the scalar density is $S = \mathrm{Tr}(C\rho)$.

What is different, and its status.

- **No correlation.** The dirac16complex functional has no correlation term ("correlation: none (Hartree plus exchange only)" in `Revision/kohn_sham/ks-theory.json`), and for the non-uniform Kohn-Sham determinants its uniform-gas exchange differs from the exact local Fock exchange by $+\frac{\lambda}{32}Q^2$ (Section 13.16). These are the approximations of the model.

- **No density-functional theorem is claimed for the field.** The Hohenberg-Kohn and Mermin theorems of Sections 13.8 and 13.26 were proved for particles with a positive inner product and a Hamiltonian bounded from below. For the quantised dirac16complex field with its indefinite Krein form (Chapter 10) the book does not prove such a theorem; the model of Chapter 14 is used as a self-consistent mean-field (exchange-only) model, and whether an exact density functional exists for this field is OPEN.

- **Which levels are filled.** Particles occupy the positive branch of the levels and the brane zero modes; this filling is a CONVENTION of the record, and its justification is OPEN (`Revision/kohn_sham/ks-theory.json`, thermodynamics, fillingConvention; Notebook 13b, In [22]).

- **The background.** The history $a_4 = AHx_4$ along which the instantaneous (adiabatic) Kohn-Sham states are computed is a PRESCRIBED BACKGROUND: the Kohn-Sham states violate the conditions that the a_4 field equations put on their source (`Revision/field_equations_a4/reports/ks-source-conditions.json`; the checks are named in Section 13.38 and checked by Notebook 13b, In [22]). The time-dependent (non-adiabatic) problem is OPEN, and the mirror at the end of the hidden direction (the Z2 brane) is ASSUMED.

The pairs. Chapter 19 uses these Kohn-Sham states for theorem T3: the Kohn-Sham universes of mass $+M$ and $-M$, with the transformed boundary conditions, have equal energies and energy-momentum tensors (PROVED: `Revision/pairing/kohn_sham/reports/python-t3.json` and, independently, `wolfram-t3.json` in the same folder; ten checks of the theorem that are present in both reports, among them the equality of the energies and of the energy-momentum profiles, are PASS in both, as Notebook 13b checks in In [22]). T3 is an exact map between two sets of solutions. It does not prove that any universe is created, in pairs or otherwise: no creation process, rate or amplitude follows from these equations, and nothing in this chapter changes that.

13.38 What we proved, what we computed, what we assumed

PROVED (exact derivations in this chapter, each checked numerically by a notebook; the Revision checks are named where the record holds the statement):

- One particle: the eigenvalues of a Hermitian operator are real and its eigenvectors for different eigenvalues orthogonal; the variational principle (Section 13.2).
- Many fermions: the Pauli principle; Slater determinants of N particles are antisymmetric, normalised, vanish for equal orbitals, and have the density $\sum_a |\phi_a|^2$ (Section 13.3, from the Leibniz formula; Notebook 13c, In [2], for $N = 2$).
- Second quantisation: the anticommutation relations; Wick's theorem for a determinant and a thermal ensemble of non-interacting fermions, in every basis; $\langle :S^2: \rangle = (\mathrm{Tr}\, V\rho)^2 - \mathrm{Tr}(V\rho V\rho)$ (Section 13.4; Revision check hf_wick_contraction of `Revision/kohn_sham/reports/ks-theory-python.json`, its verdict checked by Notebook 13b, In [21]; Notebook 13c, In [4] to In [8]).
- The energy of a determinant, direct minus exchange; the cancellation of the self-interaction; the exact locality of contact exchange and $E_x = -E_H/g$ for equally occupied labels (Sections 13.5 and 13.15; Notebook 13c, In [10]; Notebook 13b, In [6], In [12], In [13]).
- The Lagrange-multiplier rule and the meaning of the multiplier; the Hartree-Fock equations (the variation written out term by term, with the Hermitian multiplier matrix), the double-counting formula and Koopmans' theorem (Section 13.6).
- The two-site model: $E_0 = \frac{1}{2}(U - \sqrt{U^2 + 16t^2})$ and the best determinant ($-2t + U/2$ for $U \le 2t$, $-2t^2/U$ beyond) (Section 13.7; Notebook 13c, In [11], In [12]).
- The Hohenberg-Kohn theorem and the constrained-search variational principle; functional derivatives; the Kohn-Sham equations and their total energy; the exact Kohn-Sham potential of two sites (Sections 13.8 to 13.10; Notebook 13c, In [16]).
- The uniform gas: $n = gk_F^3/(6\pi^2)$, C_F, the density matrix $F(k_F R)$, the exchange hole $1 - F^2/g$, the small-range law $1 - \frac{3}{5}(k_F a)^2$, Dirac's formula given the integral $9/4$, and the polarisation threshold $\frac{2}{3}(3\pi^2)^{2/3}$ (Section 13.15; Notebook 13b).
- The exchange of the 16-component field: $e_x = -\frac{\lambda}{32}(n^2 + S^2)$, $M_{eff} = m + \frac{15}{16}\lambda S$, $v_v = -\frac{1}{16}\lambda n$, the ratio $-1/8$ (Section 13.16; `Revision/kohn_sham/reports/ks-theory-python.json`, checks exchange_uniform_gas, ks_potentials and filled_shell_ratio; independently `ks-theor`

`y-wolfram.json` in the same folder, checks exchange_uniform_gas and ks_potentials; reproduced exactly by Notebook 13b, In [17], In [18], which with In [21] also checks the verdicts of both programs).

- Mixing: the reduced map of the two-site loop, the convergence factor $1-\beta(1-G')$ and the condition $0<\beta<2/(1-G')$ for small errors, the least-squares form of Anderson mixing (Section 13.21).

- Temperature: the Gibbs principle with Klein's inequality; Mermin's theorem and the universal functional at a temperature (both written out in Section 13.26); the independence of the orbitals of non-interacting fermions; the Fermi-Dirac occupations; $dF/dT=-S$, $C_V=T\,dS/dT$, the variance formula and $C_V\geq 0$ (Section 13.26; Notebook 13e).

- Excited states: Janak's theorem and the Delta-SCF integral formula (Section 13.27; Notebooks 13e and 13a).

- The trap model: its Kohn-Sham potential $v+g_c n/2$, the double-counting formula, the one-dimensional Thomas-Fermi equation, the Hellmann-Feynman theorem and the virial theorem (Section 13.32).

COMPUTED (numbers printed by the five executed notebooks of the chapter, which are stored in the folder `Revision/textbook/notebooks`). Each number is given with its uncertainty, which is of one of two kinds. The finite models of Notebooks 13b to 13e are solved exactly up to rounding; for them the brackets give the tolerance to which a check confirms the printed digits, or say how the number was located. The trap of Notebook 13a is solved on a grid of 200 points: its numbers are exact for this grid model up to the stopping rule 10^{-11} of the loop (the brackets give the checks), but they differ from the numbers of the continuum model of Section 13.32 by the error of the grid, about 10^{-2}, which the notebook measures twice: the grid levels of the trap miss the exact levels $n+\frac{1}{2}$ by up to 0.013 (In [3]), and the energy at $g_c=0$ is 15.990192 instead of the exact 16, a difference of 0.0098 (In [23]). As numbers of the continuum model, the six-decimal values of Notebook 13a are therefore good to about two decimals.

- Notebook 13c: the two-site numbers $E_0=-1.236068\,t$ and correlation energy $-0.236068\,t$ at $U=2t$ (the eigenvalue agrees with the closed form to 10^{-12}; In [11], In [12]) and the double occupancy 0.276393 (to 10^{-6}; In [14]); the place of the largest correlation energy, $U=3.335\,t$ (the closed form evaluated on a grid of step 10^{-4} in U and printed to three decimals, so uncertain by $5\cdot 10^{-4}$; no check; In [12]); and the split of the exact Kohn-Sham screening at $U=4t$, $\Delta=2t$ into -0.588239 (Hartree-exchange) and -1.114408 (correlation) (the inverted site energies reproduce the exact densities to 10^{-12}, In [16]; printed to six decimals, In [18]).

- Notebook 13b: box sums within 0.00083 of F for 137059 plane waves (a measured difference; In [3]); $\int_0^\infty sF^2\,ds=9/4$ to 10^{-7} (In [10]); the box exchange -19.0000000000 in two forms (they agree to 10^{-12}, and equal the exact -19 of Exercise 10; In [12]); the label-mixing exchange -8.7398756465 (two forms agree to 10^{-10}; In [13]).

- Notebook 13d: $n_L^*=1.326993$, $G'=-1.687961$, $\beta_{max}=0.744058$ (to 10^{-6}; In [3]), the cycle 0.3607/1.9157 (two passes return to the same value to 10^{-10}; printed to four decimals; In [5]), convergence in 13 passes at $\beta=\frac{1}{2}$ (a count; In [6]), and the threshold $U=2.647393$ (found by 60 halvings of an interval; there the slope is -1 to 10^{-9}; In [12]).

- Notebook 13e: no state among 2000 has a lower grand potential than the Gibbs state (the smallest excess, $3.9 \cdot 10^{-6}$, is a measured value for these random states; In [4]); the two-level numbers 0.731059, 1.164406, -0.313262, 0.393224 (to 10^{-6}; In [8], In [10]); the ladder's $\mu = 4$ at $T = 0.05$ (to 10^{-6}; In [12]).
- Notebook 13a (numbers of the grid model; its distance from the continuum model is about 10^{-2}, as said above): $E = 21.851498$ at $g_c = 2$ (the two formulas agree to 10^{-9}; In [14]), the Kohn-Sham gap 0.772662 (the level difference at $\tau = 0$ agrees with it to 10^{-9}; In [25]), the Delta-SCF energy 0.714594 (the Janak integral agrees to 10^{-6}; In [25]), the widths 1.413346, 1.542829 and 1.659857 (printed to six decimals; only their order is checked; In [21]) and the Hellmann-Feynman slope 2.801961 (the two ways agree to 10^{-6}; In [23]); and the Revision solver's mixing settings, read and checked exactly from `Revision/kohn_sham/results/parameters.json` (In [7]).

ASSUMED:

- that the particles are fermions (for dirac16complex: the choice of Grassmann components, Chapter 7);
- for the Hohenberg-Kohn theorem: a non-degenerate ground state, a wave function that does not vanish on a whole region, and that the constrained minima exist; for the Kohn-Sham scheme: non-interacting v-representability;
- for the Lagrange rule: the implicit function theorem (used without proof); for the Gibbs principle: a finite number of states;
- that a Delta-SCF state approximates a true excited state;
- the approximations: no correlation in the toy models (they are Hartree-Fock models); in the dirac16complex functional, the uniform-gas exchange and no correlation (Sections 13.16 and 13.37);
- for the dirac16complex model (Section 13.37): the Z2 mirror, and the history of a_4 as a prescribed background.

HYPOTHESIS: none is used in this chapter. **OPEN:** an exact density functional for the quantised dirac16complex field, the justification of its filling convention, and its time-dependent (non-adiabatic) problem (Section 13.37).

Where the background status is recorded. That the history $a_4 = AHx_4$ is a prescribed background, not a solution of the a_4 field equations with the Kohn-Sham source, is recorded in the Revision report `Revision/field_equations_a4/reports/ks-source-conditions.json` by its checks ks_history_is_a_prescribed_background, ks_profiles_violate_algebraic_condition and ks_profiles_depend_on_x0, each with the verdict PASS (Notebook 13b, In [22], reads the report and checks the three verdicts).

13.39 Exercises

Exercise 1. In the three-point example of Section 13.3, compute $\Phi(2,1)$, $\Phi(1,0)$ and $\Phi(1,1)$, and show from the definition that the two-particle determinant vanishes when $\phi_a = \phi_b$.

Answer. With $\phi_0 = (1,0,0)$ and $\phi_1 = (0,1,1)/\sqrt{2}$: $\Phi(2,1) = [\phi_0(2)\phi_1(1) - \phi_1(2)\phi_0(1)]/\sqrt{2} = [0 \cdot \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}} \cdot 0]/\sqrt{2} = 0$. $\Phi(1,0) = [\phi_0(1)\phi_1(0) - \phi_1(1)\phi_0(0)]/\sqrt{2} = [0 \cdot 0 - \frac{1}{\sqrt{2}} \cdot 1]/\sqrt{2} = -\frac{1}{2}$, as the table of Notebook 13c (In [2]) shows. $\Phi(1,1) = [\phi_0(1)\phi_1(1) - \phi_1(1)\phi_0(1)]/\sqrt{2} = 0$, because the two products are equal. If $\phi_a = \phi_b = \phi$, then $\Phi(r_1, r_2) = [\phi(r_1)\phi(r_2) - \phi(r_1)\phi(r_2)]/\sqrt{2} = 0$ for all arguments.

Exercise 2. Using only the anticommutation relations of Section 13.4, show that $\hat{n}_p^2 = \hat{n}_p$, and conclude that $\hat{n}_p$ has only the eigenvalues 0 and 1.

Answer. $\hat{n}_p^2 = a_p^\dagger a_p a_p^\dagger a_p$. The relation $\{a_p, a_p^\dagger\} = 1$ gives $a_p a_p^\dagger = 1 - a_p^\dagger a_p$, so $\hat{n}_p^2 = a_p^\dagger(1 - a_p^\dagger a_p)a_p = a_p^\dagger a_p - a_p^\dagger a_p^\dagger a_p a_p$. The relation $\{a_p^\dagger, a_p^\dagger\} = 0$ says $2a_p^\dagger a_p^\dagger = 0$, so the last term vanishes and $\hat{n}_p^2 = \hat{n}_p$. If $\hat{n}_p u = \nu u$ with $u \neq 0$, then $\nu^2 u = \hat{n}_p^2 u = \hat{n}_p u = \nu u$, so $\nu^2 = \nu$, that is $\nu = 0$ or $\nu = 1$.

Exercise 3. For the three-point example, write the density matrix $\rho = \phi_0\phi_0^T + \phi_1\phi_1^T$ as a 3×3 matrix and check $\rho^2 = \rho$ and $\operatorname{Tr}\rho = 2$.

Answer. $\phi_0\phi_0^T$ has a single 1 in the top left corner; $\phi_1\phi_1^T$ has the entries $\frac{1}{2}$ in the lower right 2×2 block. So $\rho = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix}$. Squaring, the corner gives $1 \cdot 1 = 1$, and the block $\begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}^2$ has every entry $\frac{1}{4} + \frac{1}{4} = \frac{1}{2}$, so $\rho^2 = \rho$. The trace is $1 + \frac{1}{2} + \frac{1}{2} = 2$, the number of particles, and the diagonal $(1, \frac{1}{2}, \frac{1}{2})$ is the density of Section 13.3.

Exercise 4. Solve the two-site model of Section 13.7 for $t = 1$, $U = 4$: the exact energy, the Hartree-Fock energy, the correlation energy, and the exact double occupancy.

Answer. $E_0 = \frac{1}{2}(4 - \sqrt{16 + 16}) = 2 - 2\sqrt{2} = -0.828427$. Since $U > 2t$, the best determinant is unrestricted, $E_{HF} = -2t^2/U = -0.5$. The correlation energy is $E_0 - E_{HF} = -0.328427$. The ground state lies in the 2×2 problem $\begin{pmatrix} U & -2t \\ -2t & 0 \end{pmatrix}$ on (D, S); its first row gives $(U - E_0)\, d - 2t\, s = 0$, so $s = (U - E_0)\, d/(2t) = (4 + 0.828427)\, d/2 = 2.414214\, d$. The normalisation $d^2(1 + 2.414214^2) = 1$ gives $d^2 = 1/6.828427 = 0.146447$. The double occupancy is the weight of the states LL and RR, which here is $d^2 = 0.146447$, the value of Notebook 13c (In [11]); the restricted determinant would give $\frac{1}{2}$.

Exercise 5. Fermions with two labels and a contact interaction of strength $g_c = 1$ have the label densities $n_\uparrow = 0.3$ and $n_\downarrow = 0.1$ at a point. Compute the Hartree and the exchange energy densities and check that their sum is $g_c\, n_\uparrow n_\downarrow$.

Answer. $n = 0.4$, so $e_H = \frac{g_c}{2} n^2 = 0.5 \cdot 0.16 = 0.08$ and $e_x = -\frac{g_c}{2}(n_\uparrow^2 + n_\downarrow^2) = -0.5 \cdot (0.09 + 0.01) = -0.05$. The sum is $0.03 = 0.3 \cdot 0.1 = n_\uparrow n_\downarrow$. With unequal labels the exchange is not $-e_H/2 = -0.04$: the rule $-1/g$ needs equally occupied labels.

Exercise 6. Repeat the mixing analysis of Section 13.21 for $\Delta = 2$, $t = 1$, $U = 2$: check that $x^* = 0.468990$ is the fixed point, compute $G'(x^*)$ and β_{max}, and decide whether plain iteration converges.

Answer. $\Delta - Ux^* = 2 - 0.937980 = 1.062020$, and $\sqrt{1.062020^2 + 4} = \sqrt{5.127886} = 2.264484$, so $G(x^*) = 1.062020/2.264484 = 0.468990 = x^*$. Then $G'(x^*) = -4 \cdot 2 \cdot 1/5.127886^{3/2} = -8/(5.127886 \cdot 2.264484) = -8/11.612 = -0.688942$, and $\beta_{max} = 2/(1 + 0.688942) = 1.184174$. Since $1 < \beta_{max}$, plain iteration converges: its factor $1 - (1 + 0.688942) = -0.688942$ has a size below 1, so the error

shrinks by about 0.69 per pass while changing its sign (the density still swings, but the swings die out). These are the numbers of Notebook 13d (In [12]).

Exercise 7. For the two-level example of Section 13.26 (levels 0 and 1, one particle), find the limits of f_0, E and S_s as $T \to 0$ and as $T \to \infty$.

Answer. By symmetry $\mu = \frac{1}{2}$ at every T, so $f_0 = 1/(e^{-1/(2T)} + 1)$ and $f_1 = 1 - f_0$. As $T \to 0$, $e^{-1/(2T)} \to 0$: $f_0 \to 1$, $f_1 \to 0$, $E = f_1 \to 0$, and $S_s \to 0$, because $f \ln f$ and $(1-f)\ln(1-f)$ tend to 0 when f tends to 0 or 1. As $T \to \infty$, $e^{-1/(2T)} \to 1$: $f_0, f_1 \to \frac{1}{2}$, $E \to \frac{1}{2}$, and each level contributes $-2 \cdot \frac{1}{2} \ln \frac{1}{2} = \ln 2$, so $S_s \to 2 \ln 2 = \ln 4$. Notebook 13e (In [11]) checks both limits.

Exercise 8. For the model energy $E = \epsilon_H^0 f_H + \epsilon_L^0 f_L + \frac{U}{2}(f_H^2 + f_L^2)$ with any $\epsilon_H^0 < \epsilon_L^0$ and $U < \epsilon_L^0 - \epsilon_H^0$, show that $\Delta_{SCF} - \Delta_{KS} = U$.

Answer. By Janak's theorem the levels are $\epsilon_H = \epsilon_H^0 + U f_H$ and $\epsilon_L = \epsilon_L^0 + U f_L$. In the ground state $(1,0)$ (the lower orbital filled; the condition on U keeps $\epsilon_H < \epsilon_L$ there), $\Delta_{KS} = \epsilon_L^0 - (\epsilon_H^0 + U)$. The energies are $E(1,0) = \epsilon_H^0 + \frac{U}{2}$ and $E(0,1) = \epsilon_L^0 + \frac{U}{2}$, so $\Delta_{SCF} = \epsilon_L^0 - \epsilon_H^0$, and $\Delta_{SCF} - \Delta_{KS} = U$.

Exercise 9. For the uniform 8-fold gas of dirac16complex (Section 13.16), compute e_x/e_H when $S = n/2$, and the interaction energy e_{int} when $S = n$.

Answer. With $S = n/2$: $e_x = -\frac{\lambda}{32}(n^2 + \frac{n^2}{4}) = -\frac{5}{128}\lambda n^2$ and $e_H = \frac{\lambda}{2} \cdot \frac{n^2}{4} = \frac{1}{8}\lambda n^2$, so $e_x/e_H = -\frac{5}{128} \cdot 8 = -\frac{5}{16}$: exchange removes a larger fraction of the Hartree energy than for a filled level at rest ($-\frac{1}{8}$). With $S = n$: $e_{int} = \frac{15}{32}\lambda n^2 - \frac{1}{32}\lambda n^2 = \frac{7}{16}\lambda n^2$, which is $e_H + e_x = \frac{1}{2}\lambda n^2 - \frac{1}{16}\lambda n^2$: in Figure 13b.9 the black curve ends at $7/16 = 0.4375$ at $S/n = 1$.

Exercise 10. Notebook 13b (In [12]) finds the exchange energy -19 for five up and three down fermions in the box $0 < x < 1$ with $g_c = 1$. Derive this number: show that the density $n_N = \sum_{m=1}^{N} 2\sin^2(m\pi x)$ of N fermions with one label has $\int_0^1 n_N^2\,dx = N^2 + N/2$.

Answer. $\int_0^1 n_N^2\,dx = 4\sum_{m,m'} \int_0^1 \sin^2(m\pi x)\sin^2(m'\pi x)\,dx$. With $\sin^2 A = \frac{1}{2}(1 - \cos 2A)$, the product is $\frac{1}{4}[1 - \cos 2A - \cos 2B + \cos 2A \cos 2B]$. Over $0 < x < 1$, $\int \cos(2m\pi x)\,dx = 0$ for $m \geq 1$, and $\int \cos(2m\pi x)\cos(2m'\pi x)\,dx = \frac{1}{2}$ if $m = m'$ and 0 otherwise. So each integral is $\frac{1}{4} + \frac{1}{8}[m = m']$, and $\int n_N^2 = 4[N^2 \cdot \frac{1}{4} + N \cdot \frac{1}{8}] = N^2 + \frac{N}{2}$. Then $E_x = -\frac{g_c}{2}(\int n_\uparrow^2 + \int n_\downarrow^2) = -\frac{1}{2}[(25 + 2.5) + (9 + 1.5)] = -\frac{1}{2} \cdot 38 = -19$.

14 The Kohn-Sham model of dirac16complex in the deflating primordial field

Chapter 13 taught density functional theory from zero: how the hopeless problem of many interacting quanta is replaced by a problem of independent quanta that move in a common, self-made potential, the Kohn-Sham problem. This chapter builds that problem for the quanta of the field dirac16complex in the author's primordial universe, whose three extra times deflate exponentially while ordinary space inflates. Everything is done exactly where it can be done: the change to the hidden coordinate y, the removal of the spin connection, the splitting of the 16 spinor components into eight independent pairs, the boundary conditions, the exact rescaling between the instants of the deflating history, the exact free spectra, and the exact exchange energy of the contact interaction. Four complete notebooks, 14a to 14d, repeat every step with the computer and reproduce the numbers of the Revision record.

14.1 What this chapter does

Why a Kohn-Sham model. The field dirac16complex has 16 complex anticommuting components at every point of the eight-dimensional universe of the author, and its quanta interact through the contact term $U(S) = \frac{\lambda}{2}S^2$ of the Lagrangian (Chapter 7). A state of many such quanta cannot be computed exactly. The Kohn-Sham method of Chapter 13 replaces it by a state of independent quanta, each described by its own wave function, called an **orbital**, which obeys a one-quantum equation with an effective mass M_{eff} and a potential v_v made by all the other quanta. Solving that equation self-consistently is the work of Chapter 15. This chapter prepares it: it turns the one-quantum equation into a form a computer can solve, finds its exact solutions where they exist, and derives the effective mass and potential.

What is derived, in order.

- The hidden coordinate y and the warped form of the author's metric (Section 14.2).
- The Kohn-Sham equation of dirac16complex, the good sector and the stationary-slice ansatz (Section 14.3).
- The spin-connection term $3H\gamma^{(x_0)}$, why the time derivative of a_4 drops out of it, and the factor W^{-3} that removes it (Section 14.4).
- The splitting of the 16 components into eight independent 2×2 blocks of two types (Section 14.5), and the chirality matrix Γ and the rotations of 3-space on these blocks (Section 14.6).
- The exact rescaling identity between the instants of the deflating history (Section 14.7).
- The block equation in real form and its boundary conditions at the brane and at the tip (Section 14.12), the exact free levels at zero 3-momentum (Section 14.13) and the shooting method that finds every level by an integer label (Section 14.14).
- The brane band that grows out of the zero modes when the 3-momentum is switched on, its exact slope, its redshift along the history, its insensitivity to the tip angle at the cutoff $L = 3$ and the slice 0, what the Revision record measured about the position L of the cutoff itself, and the closed shells of the free filling (Sections 14.19 to 14.21).
- The exact local exchange energy of the contact interaction, the Kohn-Sham potentials, the exact Fock exchange of the model's states and the state of the eight zero modes (Sections 14.26 and 14.27).

The four notebooks.

notebook	what it computes	PASS lines	figures
14a	the block reduction and the rescaling identity, with exact algebra	28	5

notebook	what it computes	PASS lines	figures
14b	the free spectra at zero 3-momentum, exact against numerical	20	6
14c	the brane band, its slope, redshift, symmetries and closed shells	15	6
14d	the exact local exchange, the potentials and the zero-mode state	16	4

None of them needs Rust: Notebooks 14b and 14c write the shooting function of the Revision Rust solver (the same RK4 integration and Pruefer angle) in a few lines of numpy, find its roots by plain bisection where the Rust solver uses a safeguarded Newton-bisection, and reproduce the solver's recorded numbers; Chapter 15 runs the Rust solver itself.

The status of every statement. As everywhere in this book, every statement carries one of the five labels of Chapter 0: PROVED, COMPUTED, ASSUMED, HYPOTHESIS, OPEN. In this chapter they are used as follows.

- PROVED: every identity of Sections 14.2 to 14.7, the boundary-condition facts of Section 14.12, the exact spectra of Section 14.13, the counting property of the shooting angle in Section 14.14, the slope formula of Section 14.19 and the exchange formulas of Sections 14.26 and 14.27. The counting property is proved in the text of Section 14.14 and checked numerically by Notebook 14b; each of the others is verified in the Revision record by sympy in `Revision/kohn_sham/reports/ks-theory-python.json` (in its present state 58 of 58 checks passed), most of them also by WolframScript in `Revision/kohn_sham/reports/ks-theory-wolfram.json` (46 of 46 checks passed), and again by the notebooks of this chapter; the check names are given with each statement.
- COMPUTED: the numerical levels, slopes, shifts and closed shells; each comes with its measured error and the record file it reproduces (the Rust solver's report `Revision/kohn_sham/reports/ks-rust-solver.json`, in its present state 42 of 42 checks passed, and its result files).
- ASSUMED: the good sector (no dependence on the extra times); the Z2 mirror brane at $y = 0$; the regular tip condition at the cutoff $y = -L$, $L = 3$ (a choice of the numerical model; Section 14.20 shows that at this cutoff and at the slice $a_{4,0} = 0$, where it was measured, the brane band at nonzero 3-momentum does not feel the tip angle θ, while at the later slices this is not established, and reports what the Revision record measured about the cutoff L itself: the free results with $k \neq 0$ converge as L grows, but the recorded $L = 3$ values are low by up to 1.4% in the Kohn-Sham energy, the nonzero (bulk) $k = 0$ levels approach $\pm m$ only algebraically, and the interaction energy of the brane zero modes depends strongly on L); the deflating history $a_4 = AHx_4$ along which the Kohn-Sham states are computed, which is a **prescribed background**, given and not solved for (Section 14.3); the convention that counts the zero modes at zero 3-momentum as particle levels (Section 14.21).

- OPEN: the justification of that convention (Section 14.21), the effect of the tip angle at the later slices (Section 14.20), and the behaviour of the gas when the history is not slow (the time-dependent problem, Chapter 15 and Chapter 22).
- HYPOTHESIS: none in this chapter.

Notation and units. The author's coordinates are $x_0, \dots, x_7$: x_1, x_2, x_3 are ordinary 3-space, which inflates; x_4 is the time; x_5, x_6, x_7 are the three extra times, which deflate exponentially; x_0 is the hidden space direction. The flat frame metric is $\eta = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1)$ in this order. The gamma matrix of the direction x_4 is written $\gamma^{(x_4)}$, and so on; these are the author's eight real 16×16 matrices of Chapters 4 and 5, read from the record `Revision/algebra/gammas.json`, with the Clifford relation $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}$. The matrices $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, $B = -iC\gamma^{(x_4)}$ and the chirality $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)} = \mathrm{diag}(-1_8, 1_8)$ are those of Chapter 5. The three **Pauli matrices**, written row by row, are

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \qquad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Each squares to the 2×2 unit matrix, two different ones anticommute, and their products are $\sigma_1\sigma_2 = i\sigma_3$, $\sigma_2\sigma_3 = i\sigma_1$, $\sigma_3\sigma_1 = i\sigma_2$ (and with the order reversed the sign changes). In the numbers of this chapter the author's constant H is 1 and the mass m of dirac16complex is 1, as in the Revision runs; energies, momenta and temperatures are then in units of m (which equals H), lengths in units of $1/H$.

14.2 The author's field and the hidden coordinate y

The metric. The author's primordial field is the diagonal metric whose entries, in the order $x_0, \dots, x_7$, are

$$\begin{aligned} g = \mathrm{diag}(&e^{2a_4}\sin^{1/3} z,\ e^{2a_4}\sin^{1/3} z,\ e^{2a_4}\sin^{1/3} z,\ -1, \\ &-e^{-2a_4}\sin^{1/3} z,\ -e^{-2a_4}\sin^{1/3} z,\ -e^{-2a_4}\sin^{1/3} z,\ \cot^2 z), \end{aligned}$$

with $z = 6Hx_0$ between 0 and $\pi/2$, the author's constant $H > 0$, and a function $a_4(x_4)$ of the time. A **scale factor** is the number by which a coordinate step must be multiplied to give a length: along x_1 a step dx_1 has the length $e^{a_4}\sin^{1/6} z\, dx_1$ (the square root of the entry). When a_4 grows with the time, the 3-space factor e^{a_4} grows (3-space **inflates**) and the extra-time factor e^{-a_4} shrinks exponentially (the extra times **deflate**). The history used in this book is $a_4 = AHx_4$ with $A = 1$ (Section 14.3).

The hidden coordinate. The entry $g_{00} = \cot^2 z$ makes the hidden direction awkward. We replace x_0 by

$$y = \frac{\ln(\sin z)}{6H}, \qquad z = 6Hx_0.$$

Line by line:

$$\frac{dy}{dx_0} = \frac{1}{6H} \cdot \frac{\cos z}{\sin z} \cdot 6H = \cot z.$$

Rule: the chain rule; the derivative of $\ln u$ is $1/u$ times the derivative of u, the derivative of $\sin z$ is $\cos z$, and $dz/dx_0 = 6H$.

$$dy^2 = \cot^2 z \, dx_0^2 = g_{00} \, dx_0^2.$$

Rule: square the previous line. So y measures length along the hidden direction, and in the coordinate y the metric entry is simply 1.

$$e^{6Hy} = \sin z, \qquad \sin^{1/3} z = e^{2Hy}.$$

Rule: multiply the definition of y by $6H$ and take the exponential of both sides; then take the power $1/3$.

When z runs from 0 to $\pi/2$, $\sin z$ runs from 0 to 1 and y from $-\infty$ to 0. The end $y \to -\infty$ ($z \to 0$) is called the **tip**; the end $y = 0$ ($z = \pi/2$), where the author's coordinate patch ends, is called the **brane**. The **warp factor** is $W = e^{Hy}$; by the last line, $\sin^{1/3} z = W^2$, and the metric takes the **warped form**

$$ds^2 = e^{2Hy} \left[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 + dx_6^2 + dx_7^2) \right] - dx_4^2 + dy^2.$$

Its scale factors (the entries of the diagonal **vielbein**, the square roots of the absolute values of the metric entries) are

$$h = (e^{a_4}W,\ e^{a_4}W,\ e^{a_4}W,\ 1,\ e^{-a_4}W,\ e^{-a_4}W,\ e^{-a_4}W,\ 1).$$

The volume. The square root of the absolute value of the determinant of a diagonal metric is the product of its scale factors:

$$\sqrt{|g|} = (e^{a_4}W)^3 \cdot 1 \cdot (e^{-a_4}W)^3 \cdot 1 = e^{3a_4} e^{-3a_4} W^6 = W^6 = e^{6Hy}.$$

Rule: multiply the eight entries of h; the powers e^{3a_4} and e^{-3a_4} cancel. In the author's x_0 chart the same product is $\sin z \cdot \cot z = \cos z$; the two differ by the factor $dy/dx_0 = \cot z$, as they must. Neither contains a_4: while 3-space inflates and the extra times deflate, the volume of the seven directions other than the time stays the same. Toward the tip the factor W^6 goes to zero: at $y = -3$ it is e^{-18}. Status: PROVED; checks geometry_hidden_coordinate, geometry_sqrt_det and geometry_warped_form of `Revision/kohn_sham/reports/ks-theory-python.json` (the first two also in the Wolfram report `Revision/kohn_sham/reports/ks-theory-wolfram.json`).

The momentum weight. A plane wave $e^{ik_1 x_1}$ along 3-space has the coordinate momentum k_1; the length of a coordinate step is $e^{a_4}W \, dx_1$, so the momentum per unit length, the one a quantum feels, is $k_1/(e^{a_4}W)$. We write

$$\kappa(y, x_4) = \frac{1}{e^{a_4} W} = e^{-Hy - a_4(x_4)}$$

for this **momentum weight**. It grows toward the tip (a given coordinate momentum costs more energy far from the brane) and, at a fixed y, it decreases as a_4 grows (3-momenta are **redshifted** while 3-space inflates).

14.3 The Kohn-Sham equation, the good sector and the stationary-slice ansatz

The Kohn-Sham equation. The field equation of dirac16complex is $\gamma^\mu D_\mu \Psi = (m + U'(S))\Psi$ (Chapter 7), where $\gamma^\mu = \gamma^{(\mu)}/h_\mu$ are the curved gammas and $D_\mu = \partial_\mu + \Omega_\mu$ is the covariant derivative with the spin connection Ω_μ (Chapter 6). In the Kohn-Sham model every orbital obeys the one-quantum equation

$$\gamma^\mu D_\mu \Psi = \big(M_{\text{eff}}(y) - i\, v_v(y)\, \gamma^{(x_4)}\big)\Psi,$$

where the **effective mass** $M_{\text{eff}} = m + \frac{15}{16}\lambda S$ and the **vector potential** $v_v = -\frac{1}{16}\lambda n$ are made by all the quanta through their scalar density S and number density n. Sections 14.26 and 14.27 derive these two formulas exactly; until then M_{eff} and v_v are any two real functions of y, written M and v for short.

The good sector (ASSUMED). We look only for orbitals that do not depend on the extra times x_5, x_6, x_7. Chapters 8 and 10 explain why: modes with enough momentum along the extra times grow without bound (the problem is ill-posed in the sense of Hadamard), and a quantum space of states with a positive norm has been built only for single good-sector momenta with frozen coefficients (Chapter 10); a positive-norm space of states for the whole field is OPEN. This restriction is an assumption of the Revision theory, not a result.

The box. The three directions of 3-space are taken as a **torus** of coordinate size ℓ: a quantum leaving the box on one side comes back on the other, so the allowed coordinate momenta are $\mathbf{k} = \Delta k\,(n_1, n_2, n_3)$ with whole numbers n_1, n_2, n_3 and $\Delta k = 2\pi/\ell$. The Revision runs use $\Delta k = 0.25$, so $\ell = 8\pi \approx 25.13$. The extra times have the coordinate volume v_t ($v_t = 1$ in the runs).

The ansatz. An **ansatz** is a guessed form of the solution with unknown parts to be determined. We try

$$\Psi = e^{i\mathbf{k}\cdot\mathbf{x}}\, W(y)^{-3}\, \chi(y, x_4),$$

a plane wave along 3-space, the factor $W^{-3} = e^{-3Hy}$, and a column χ of 16 unknown functions of y and of the time. Section 14.4 shows that χ obeys exactly, for every history $a_4(x_4)$, an equation of the form

$$i\,\partial_{x_4}\chi = h(x_4)\,\chi,$$

with a Hermitian matrix operator h that depends on the time only through $a_4(x_4)$. This is the exact evolution of one orbital in the mean field.

The stationary-slice (adiabatic) ansatz. A **slice** is one instant x_4 of the history; $a_{4,0} = a_4(x_4)$ is the value of a_4 there. At a slice we freeze h at its value $h(a_{4,0})$ and look for the stationary orbitals

$$h(a_{4,0})\,\chi = \varepsilon\,\chi, \qquad \Psi = e^{-i\varepsilon x_4}\,e^{i\mathbf{k}\cdot\mathbf{x}}\,W^{-3}\,\chi(y)\,/\sqrt{\ell^3 v_t}, \qquad \int_{-L}^{0}\chi^\dagger\chi\,dy = 1.$$

The number ε is the **level** (the energy of the orbital), and the hidden direction is cut at $y = -L$ ($L = 3$ in the runs). The Kohn-Sham state of the slice fills the lowest particle levels. This is the **adiabatic** picture: if h changes slowly enough along the history, a quantum stays in the level it occupies. The exact evolution conserves the 3-momentum, the block and the brane parity of every orbital (all defined below), so a quantum can only make transitions between levels of the same kind; Chapter 15 measures how slowly h changes. The record states this in `Revision/kohn_sham/ks-theory.json`, section adiabaticity.

The history is a PRESCRIBED BACKGROUND. The Kohn-Sham record works on the backgrounds $b_4 = 1$ of the author's metric (the second function $b_4(x_4)$ of the metric of 2026-10-14 is put equal to 1; Chapter 3). The slices are taken along the history $a_4 = AHx_4$ with $A = 1$, so $a_{4,0} = 0, 0.5, 1, 1.5, 2$ are five instants. This history is prescribed, not solved for: the field equations of a_4 (Chapter 12) allow the linear member $a_4 = AHx_4$ only with a source whose three pressures are equal and whose energy density is constant, and the Kohn-Sham states violate these conditions (their sources depend on x_0, and $p_3 \neq p_t$). The record `Revision/field_equations_a4/reports/ks-source-conditions.json` proves this with its checks ks_profiles_depend_on_x0, ks_profiles_violate_algebraic_condition and ks_history_is_a_prescribed_background (Chapter 17 explains it in full). So the Kohn-Sham gas is a **test field** on a given background: it feels the deflating field but does not act back on it.

14.4 The spin connection, the term 3H γ(x0) and the factor W^(-3)

What we need. The operator $\gamma^\mu D_\mu = \sum_\mu \gamma^\mu\partial_\mu + \sum_\mu \gamma^\mu\Omega_\mu$ contains the spin connection only through the matrix $\sum_\mu \gamma^\mu\Omega_\mu$. Chapter 6 derived the canonical spin connection in general; here we compute this one matrix for the diagonal vielbein h of Section 14.2, with a_4 an arbitrary function of x_4, so that the result holds along every history.

Step 1: the Christoffel symbols of a diagonal metric. For a metric $g = \mathrm{diag}(g_{11}, \ldots, g_{00})$ the Christoffel symbols $\Gamma^n{}_{mk} = \frac{1}{2}g^{nl}(\partial_m g_{lk} + \partial_k g_{lm} - \partial_l g_{mk})$ (sum over l) reduce to

$$\Gamma^n{}_{mk} = \frac{\delta_{mn}\,\partial_k g_{nn} + \delta_{kn}\,\partial_m g_{nn} - \delta_{mk}\,\partial_n g_{mm}}{2g_{nn}} \qquad \text{(no sum)}.$$

Rule: g^{nl} is zero unless $l = n$, where it is $1/g_{nn}$, and g_{lk} is zero unless $l = k$; the symbol δ_{mn} is 1 when $m = n$ and 0 otherwise. So a symbol is nonzero only when two of its three indices are equal.

Step 2: the connection coefficients. The vielbein postulate (Chapter 6) gives, for the diagonal vielbein with entries h_A,

$$\omega_\mu{}^A{}_B = h_A\,\partial_\mu(1/h_B)\,\delta_{AB} + h_A\,\Gamma^A{}_{\mu B}/h_B \qquad \text{(no sum)}.$$

Only $A \neq B$ will matter below, because the generators $S^{AB} = \frac{1}{4}(\gamma^{(A)}\gamma^{(B)} - \gamma^{(B)}\gamma^{(A)})$ vanish for

$A = B$. Take a direction l whose scale factor h_l depends on the coordinates, and $A \neq B$. From Step 1, with $g_{ll} = \eta_{ll} h_l^2$:

$$\Gamma^l{}_{lB} = \frac{\partial_B g_{ll}}{2 g_{ll}} = \frac{\partial_B h_l}{h_l}, \qquad \Gamma^A{}_{ll} = -\frac{\partial_A g_{ll}}{2 g_{AA}} = -\eta_{ll}\eta_{AA}\frac{h_l\,\partial_A h_l}{h_A^2},$$

and every other $\Gamma^A{}_{lB}$ with $A \neq B$ is zero. Rule: Step 1 with two equal indices; $\partial(h^2) = 2h\,\partial h$; and $1/\eta_{AA} = \eta_{AA}$ because $\eta_{AA} = \pm 1$. Inserting into the formula for ω:

$$\omega_l{}^l{}_B = \frac{\partial_B h_l}{h_B}, \qquad \omega_l{}^A{}_l = -\eta_{ll}\eta_{AA}\frac{\partial_A h_l}{h_A}.$$

Step 3: the matrix Ω_l. With $\Omega_\mu = \frac{1}{2}\sum_{A,B}\eta_{AA}\,\omega_\mu{}^A{}_B\,S^{AB}$ (Chapter 6):

$$\Omega_l = \tfrac{1}{2}\sum_{B\neq l}\eta_{ll}\frac{\partial_B h_l}{h_B}S^{lB} + \tfrac{1}{2}\sum_{A\neq l}\eta_{AA}\Big(-\eta_{ll}\eta_{AA}\frac{\partial_A h_l}{h_A}\Big)S^{Al} = \eta_{ll}\sum_{B\neq l}\frac{\partial_B h_l}{h_B}\,S^{lB}.$$

Rule: insert Step 2; in the second sum $\eta_{AA}\eta_{AA} = 1$, rename A as B and use $S^{Bl} = -S^{lB}$, so that the two sums are equal and add up. Since $\gamma^{(l)}\gamma^{(B)} = -\gamma^{(B)}\gamma^{(l)}$ for $B \neq l$, $S^{lB} = \frac{1}{2}\gamma^{(l)}\gamma^{(B)}$.

Step 4: one direction's contribution. Multiply by the curved gamma $\gamma^l = \gamma^{(l)}/h_l$:

$$\frac{\gamma^{(l)}}{h_l}\,\Omega_l = \frac{\eta_{ll}}{2h_l}\sum_{B\neq l}\frac{\partial_B h_l}{h_B}\,\gamma^{(l)}\gamma^{(l)}\gamma^{(B)} = \frac{1}{2}\sum_{B\neq l}\frac{\partial_B \ln h_l}{h_B}\,\gamma^{(B)}.$$

Rule: $\gamma^{(l)}\gamma^{(l)} = \eta_{ll}$ (the Clifford relation), $\eta_{ll}\eta_{ll} = 1$, and $\partial_B h_l/h_l = \partial_B \ln h_l$.

Step 5: the author's field. Here the scale factors depend only on x_4 (through a_4) and on y, and $h_{x_4} = h_y = 1$. For a 3-space direction, $\ln h_l = a_4 + Hy$, so $\partial_{x_4}\ln h_l = a_4'$ (the derivative da_4/dx_4) and $\partial_y \ln h_l = H$; Step 4 gives $\frac{1}{2}a_4'\gamma^{(x_4)} + \frac{1}{2}H\gamma^{(x_0)}$. For an extra time, $\ln h_l = -a_4 + Hy$, which gives $-\frac{1}{2}a_4'\gamma^{(x_4)} + \frac{1}{2}H\gamma^{(x_0)}$. For x_4 and y themselves the scale factor is the constant 1, so $\Omega_{x_4} = \Omega_y = 0$. (In the vielbein language the frame direction of y is that of x_0, so the gamma that goes with y is $\gamma^{(x_0)}$.) Adding the eight contributions:

$$\sum_\mu \gamma^\mu\Omega_\mu = 3\cdot\tfrac{1}{2}a_4'\gamma^{(x_4)} - 3\cdot\tfrac{1}{2}a_4'\gamma^{(x_4)} + 6\cdot\tfrac{1}{2}H\gamma^{(x_0)} = 3H\gamma^{(x_0)}.$$

Rule: three inflating directions, three deflating directions, six warped directions. **The time-direction pieces of the three inflating directions, $+\frac{3}{2}a_4'\gamma^{(x_4)}$, and of the three deflating extra times, $-\frac{3}{2}a_4'\gamma^{(x_4)}$, cancel exactly**, for every history; what survives comes from the warp. Status: PROVED; checks `spin_connection_compatibility` (the curved gammas are covariantly constant, the proof that this is the right connection), `spin_connection_slash_3H`, `spin_connection_time_terms_cancel` and `spin_connection_time_term_value` of `Revision/kohn_sham/reports/ks-theory-python.json` (the first three also in the Wolfram report). Notebook 14a recomputes all of it with sympy and draws the eight contributions (its figure 3). That the surviving term $3H\gamma^{(x_0)}$ belongs to the diagonal vielbein, and can be removed by a change of frame or of the field, is the scope correction of Chapter 8.

Step 6: the factor W^{-3} removes it. Insert the ansatz $\Psi = e^{i\mathbf{k}\cdot\mathbf{x}}W^{-3}\chi(y,x_4)$ into $\gamma^\mu D_\mu\Psi = \sum_\mu \gamma^\mu\partial_\mu\Psi + 3H\gamma^{(x_0)}\Psi$, term by term.

$$\gamma^{(x_0)}\partial_y(e^{-3Hy}\chi) = e^{-3Hy}(\gamma^{(x_0)}\partial_y\chi - 3H\gamma^{(x_0)}\chi).$$

Rule: the product rule and $\partial_y e^{-3Hy} = -3He^{-3Hy}$. The term $-3H\gamma^{(x_0)}\chi$ cancels the $+3H\gamma^{(x_0)}\chi$ of the spin connection.

$$\frac{\gamma^{(x_j)}}{e^{a_4}W}\,\partial_j e^{i\mathbf{k}\cdot\mathbf{x}} = i\kappa k_j\gamma^{(x_j)}\,e^{i\mathbf{k}\cdot\mathbf{x}}, \qquad j=1,2,3.$$

Rule: $\partial_j e^{i\mathbf{k}\cdot\mathbf{x}} = ik_j e^{i\mathbf{k}\cdot\mathbf{x}}$, and $1/(e^{a_4}W) = \kappa$ (Section 14.2). The time term is $\gamma^{(x_4)}\partial_{x_4}\chi$ (the scale factor of x_4 is 1), and the extra times give nothing (good sector). Dividing by the common factor $e^{i\mathbf{k}\cdot\mathbf{x}}e^{-3Hy}$, the Kohn-Sham equation becomes

$$\gamma^{(x_0)}\partial_y\chi + \gamma^{(x_4)}\partial_{x_4}\chi + i\kappa k_j\gamma^{(x_j)}\chi = (M - iv\gamma^{(x_4)})\chi \qquad \text{(sum over } j=1,2,3).$$

The spin connection has disappeared, exactly and for every history. Without the factor W^{-3} the term $3H\gamma^{(x_0)}\chi$ would survive. Status: PROVED; checks ansatz_removes_spin_connection and ansatz_without_W3_term_survives.

Step 7: the Hamiltonian form. Solve the last equation for the time derivative, line by line.

$$\gamma^{(x_4)}\partial_{x_4}\chi = M\chi - iv\gamma^{(x_4)}\chi - \gamma^{(x_0)}\partial_y\chi - i\kappa k_j\gamma^{(x_j)}\chi.$$

Rule: move every term except the time term to the right side.

$$\partial_{x_4}\chi = -M\gamma^{(x_4)}\chi - iv\chi + \gamma^{(x_4)}\gamma^{(x_0)}\partial_y\chi + i\kappa k_j\gamma^{(x_4)}\gamma^{(x_j)}\chi.$$

Rule: multiply from the left by $-\gamma^{(x_4)}$; on the left $-\gamma^{(x_4)}\gamma^{(x_4)} = -\eta_{44} = 1$; on the right $-\gamma^{(x_4)}(-iv\gamma^{(x_4)}) = iv\gamma^{(x_4)}\gamma^{(x_4)} = -iv$.

$$i\partial_{x_4}\chi = h\chi, \qquad h = i\gamma^{(x_4)}\gamma^{(x_0)}\partial_y - \kappa k_j\gamma^{(x_4)}\gamma^{(x_j)} + M(-i\gamma^{(x_4)}) + v.$$

Rule: multiply by i and use $i\cdot i = -1$.

Why h is Hermitian. A matrix X is **Hermitian** when it equals its conjugate transpose, $X^\dagger = X$; an operator is Hermitian (self-adjoint) when $\int \varphi^\dagger(h\chi)\,dy = \int (h\varphi)^\dagger\chi\,dy$ for all allowed columns φ, χ; then its levels are real and orbitals of different levels are orthogonal. Each piece of h qualifies. (i) $\gamma^{(x_4)}\gamma^{(x_0)}$ is real and symmetric: $(\gamma^{(x_4)}\gamma^{(x_0)})^T = (\gamma^{(x_0)})^T(\gamma^{(x_4)})^T = \gamma^{(x_0)}(-\gamma^{(x_4)}) = \gamma^{(x_4)}\gamma^{(x_0)}$, by the symmetry pattern $(\gamma^a)^T = \eta_{aa}\gamma^a$ of Chapter 5 and the anticommutation of two different gammas; so $i\gamma^{(x_4)}\gamma^{(x_0)}$ is anti-Hermitian, ∂_y is anti-Hermitian too (integration by parts, when the boundary terms vanish, Section 14.12), and the product of the two, which commute, is Hermitian. (ii) $\gamma^{(x_4)}\gamma^{(x_j)}$ for a 3-space direction is real and symmetric by the same rule, hence Hermitian. (iii) $(-i\gamma^{(x_4)})^\dagger = i(\gamma^{(x_4)})^T = -i\gamma^{(x_4)}$, and $(-i\gamma^{(x_4)})^2 = -\eta_{44} = 1$. (iv) v is a real number times the unit matrix. Status: PROVED; check hamiltonian_16_hermitian.

The flat measure. The Hilbert norm of the problem is $\int \chi^\dagger \chi \, dy$: since $\sqrt{|g|}\,\Psi^\dagger\Psi = e^{6Hy}e^{-6Hy}\chi^\dagger\chi$, it is the integral of $\sqrt{|g|}\,\Psi^\dagger\Psi$ over the hidden direction, with the plain measure dy. It does not contain a_4.

14.5 Eight blocks of two components

Only $|\mathbf{k}|$ matters. Section 14.6 shows that a rotation of 3-space does not change the levels. So we may turn $\mathbf{k}$ into the direction x_1, $\mathbf{k} = (k, 0, 0)$. Then h contains only the three gammas $\gamma^{(x_0)}$, $\gamma^{(x_1)}$, $\gamma^{(x_4)}$, and it is convenient to name three products:

$$A_0 = \gamma^{(x_0)}, \qquad A_1 = \gamma^{(x_0)}\gamma^{(x_1)}, \qquad A_4 = \gamma^{(x_0)}\gamma^{(x_4)}.$$

Two rules from Chapter 5. Let P be a product of p different gammas. (Rule 1) Moving a gamma γ^c from the left of P to its right gives the sign $(-1)^{p-1}$ if γ^c is one of the factors and $(-1)^p$ if it is not, because passing each different factor costs a sign. (Rule 2) $PP = (-1)^{p(p-1)/2}$ times the product of the η of its factors.

Three labels. Define

$$J = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_4)}, \qquad K_1 = \gamma^{(x_2)}\gamma^{(x_3)}, \qquad K_2 = \gamma^{(x_5)}\gamma^{(x_6)}.$$

By Rule 1, J ($p = 3$) commutes with its own three factors and anticommutes with the five other gammas; K_1 ($p = 2$) anticommutes with $\gamma^{(x_2)}$, $\gamma^{(x_3)}$ and commutes with the six others; K_2 anticommutes with $\gamma^{(x_5)}$, $\gamma^{(x_6)}$ and commutes with the others. A product of gammas commutes with J when it contains an even number of factors that anticommute with J. Therefore all three commute with A_0, A_1, A_4 (built from $\gamma^{(x_0)}, \gamma^{(x_1)}, \gamma^{(x_4)}$), with C (for J the two anticommuting factors $\gamma^{(x_2)}, \gamma^{(x_3)}$ give two signs, which cancel), with $B = -iC\gamma^{(x_4)}$, and with each other. By Rule 2:

$$J^2 = (-1)^3\,\eta_{00}\eta_{11}\eta_{44} = (-1)(1)(1)(-1) = +1,$$

$$K_1^2 = (-1)^1\eta_{22}\eta_{33} = -1, \qquad K_2^2 = (-1)^1\eta_{55}\eta_{66} = -1.$$

So J has the eigenvalues $j = \pm 1$, and K_1, K_2 have the eigenvalues is_2, is_3 with $s_2, s_3 = \pm 1$ (if $Xu = cu$ for a column $u \neq 0$ and $X^2 = 1$, then $u = X^2u = c^2u$, so $c^2 = 1$; with $X^2 = -1$ the same step gives $c^2 = -1$). Status: PROVED; check blocks_commuting_set.

The projectors. A **projector** is a matrix with $P^2 = P$; its eigenvalues are 0 or 1 (from $\lambda^2 = \lambda$), so its trace equals the number of eigenvalues 1, its **rank** (the dimension of the space it projects onto). For each of the eight label triples put

$$P(j, s_2, s_3) = \frac{1 + jJ}{2} \cdot \frac{1 - is_2K_1}{2} \cdot \frac{1 - is_3K_2}{2}.$$

Each factor is $\frac{1}{2}(1 + X)$ with $X^2 = 1$ ($(jJ)^2 = 1$, $(-is_2K_1)^2 = -K_1^2 = 1$), hence a projector; the three factors commute, so their product is a projector; it keeps exactly the columns with $J = j$,

$K_1 = is_2$, $K_2 = is_3$. Multiplied out, P is $\frac{1}{8}$ times the unit matrix plus seven products of different gammas (J, K_1, K_2, JK_1, JK_2, K_1K_2, JK_1K_2, each with a number in front), and every product of one or more different gammas has trace 0 (Rule 5 of Chapter 5). So

$$\operatorname{tr} P(j, s_2, s_3) = \tfrac{1}{8} \operatorname{tr} 1 = \tfrac{16}{8} = 2.$$

The eight projectors have rank 2 and add up to the unit matrix: **the 16 components split into eight blocks of two**. Status: PROVED; check blocks_projectors.

A basis in each block. Inside a block, $A_0 = \gamma^{(x_0)}$ squares to 1 and A_1 anticommutes with it ($A_1 = \gamma^{(x_0)}\gamma^{(x_1)}$ contains $\gamma^{(x_0)}$ once and $p = 2$, so by Rule 1 the sign is -1), so A_0 has the eigenvalue $+1$ once and -1 once in the block. The record chooses

$$v_+ = 8\, P(j, s_2, s_3)\, \tfrac{1}{2}(1 + \gamma^{(x_0)})\, e_c, \qquad v_- = A_1 v_+,$$

where e_c is the first unit column (counting c from 0) that gives a nonzero v_+. Then $A_0 v_+ = v_+$ and $A_0 v_- = A_0 A_1 v_+ = -A_1 A_0 v_+ = -v_-$. The 16 columns v_+, v_- of the eight blocks, in the order $(j, s_2, s_3) = (1,1,1), (1,1,-1), (1,-1,1), (1,-1,-1), (-1,1,1), (-1,1,-1), (-1,-1,1), (-1,-1,-1)$, form the matrix U; every entry of U is 0, ± 1 or $\pm i$, every column has length $\sqrt{8} = 2\sqrt{2}$, and $V = U/(2\sqrt{2})$ is **unitary** ($V^\dagger V = 1$: a change of basis that keeps lengths). The seed columns are $c = 4, 0, 0, 4, 0, 4, 4, 0$. The record stores U entry by entry in `Revision/kohn_sham/ks-theory.jso n` (blockBasis), and the Rust solver uses it. Status: PROVED; check blocks_basis_unitary.

The block forms. In the basis (v_+, v_-) of one block every matrix that commutes with J, K_1, K_2 becomes a 2×2 matrix. Column k of the 2×2 matrix is the image of the k-th basis vector. Line by line:

$$A_0 \to \sigma_3.$$

Rule: $A_0 v_+ = v_+$ and $A_0 v_- = -v_-$.

$$A_1 \to \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = -i\sigma_2.$$

Rule: $A_1 v_+ = v_-$ (first column $(0,1)$), and $A_1 v_- = A_1 A_1 v_+ = -v_+$ (second column $(-1,0)$), because $A_1^2 = -1$ by Rule 2.

$$A_4 \to j\sigma_1.$$

Rule: A_4 anticommutes with A_0 (Rule 1), so it has no diagonal entries; and $A_0 A_1 A_4 = \gamma^{(x_0)}\gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_0)}\gamma^{(x_4)} = \gamma^{(x_1)}\gamma^{(x_0)}\gamma^{(x_4)} = -J$, which is the number $-j$ in the block; with $\sigma_3(-i\sigma_2) = -i\sigma_3\sigma_2 = -\sigma_1$ the condition $-\sigma_1 A_4 = -j$ gives $A_4 = j\sigma_1$.

$$C = A_1 K_1 \to (-i\sigma_2)(is_2) = s_2\sigma_2, \qquad B = -iJK_1 \to -i\, j\, (is_2) = j s_2.$$

Rule: $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)} = A_1K_1$; and $JK_1 = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_4)}\gamma^{(x_2)}\gamma^{(x_3)} = C\gamma^{(x_4)}$ after moving $\gamma^{(x_4)}$ past two gammas (two signs), so $B = -iC\gamma^{(x_4)} = -iJK_1$. So B is a number in every block, $+1$ or -1: the **Krein sign** js_2 of the block.

$$\gamma^{(x_4)} = A_0A_4 \to ij\sigma_2, \qquad \gamma^{(x_1)} = A_0A_1 \to -\sigma_1, \qquad \gamma^{(x_4)}\gamma^{(x_1)} \to (ij\sigma_2)(-\sigma_1) = -j\sigma_3.$$

Rule: $A_0A_0 = 1$; the Pauli products $\sigma_3\sigma_1 = i\sigma_2$, $\sigma_3\sigma_2 = -i\sigma_1$, $\sigma_2\sigma_1 = -i\sigma_3$.

The record lists eleven such forms (for $\gamma^{(x_0)}$, A_1, A_4, B, C, $BC = -i\gamma^{(x_4)} \to j\sigma_2$, $\gamma^{(x_4)}\gamma^{(x_1)}$, $B\gamma^{(x_0)} \to js_2\sigma_3$, J, K_1, K_2); Notebook 14a checks all of them. Not every matrix is block diagonal: $\gamma^{(x_2)}$, $\gamma^{(x_5)}$ and $\gamma^{(x_0)}\gamma^{(x_2)}$ anticommute with J and connect different blocks, which is why $\mathbf{k}$ was turned along x_1. Status: PROVED; checks blocks_forms and blocks_not_everything_block_diagonal.

The block Hamiltonian. Put the forms into h of Section 14.4 with $\mathbf{k} = (k, 0, 0)$: $i\gamma^{(x_4)}\gamma^{(x_0)} = -iA_4 \to -ij\sigma_1$; $-\kappa k\gamma^{(x_4)}\gamma^{(x_1)} \to j\kappa k\sigma_3$; $M(-i\gamma^{(x_4)}) \to jM\sigma_2$. So in every block of type j

$$h_j = j\left[-i\sigma_1\frac{d}{dy} + M\sigma_2 + \kappa k\,\sigma_3\right] + v.$$

It depends on j but not on s_2, s_3: there are only **two types of block**, four blocks of each type. Status: PROVED; check block_hamiltonian.

The first-order form. The eigenvalue equation $h_j\chi = \varepsilon\chi$ is a pair of first-order differential equations. Line by line:

$$-ij\sigma_1\chi' = (\varepsilon - v)\chi - j(M\sigma_2 + \kappa k\sigma_3)\chi.$$

Rule: move the terms without derivative to the right; χ' is $d\chi/dy$.

$$\chi' = ij(\varepsilon - v)\sigma_1\chi - i\,(M\sigma_1\sigma_2 + \kappa k\,\sigma_1\sigma_3)\chi.$$

Rule: multiply from the left by $ij\sigma_1$; $(ij\sigma_1)(-ij\sigma_1) = j^2\sigma_1^2 = 1$ and $j \cdot j = 1$.

$$\chi' = N\chi, \qquad N = M\sigma_3 - \kappa k\,\sigma_2 + ij(\varepsilon - v)\,\sigma_1.$$

Rule: $\sigma_1\sigma_2 = i\sigma_3$, $\sigma_1\sigma_3 = -i\sigma_2$, so $-i(iM\sigma_3 - i\kappa k\sigma_2) = M\sigma_3 - \kappa k\sigma_2$. Status: PROVED; check block_ode_equivalent.

The two types mirror each other. Write $h_j - v = jD(M,k)$ with $D(M,k) = -i\sigma_1\,d/dy + M\sigma_2 + \kappa k\sigma_3$. Then:

- $h_{-1} - v = -(h_{+1} - v)$. For $v = 0$ the levels of the blocks $j = -1$ are the negatives of those of $j = +1$.
- $\sigma_3 D(M,k)\sigma_3 = i\sigma_1\,d/dy - M\sigma_2 + \kappa k\sigma_3 = -D(M,-k)$, because $\sigma_3\sigma_1\sigma_3 = -\sigma_1$ and $\sigma_3\sigma_2\sigma_3 = -\sigma_2$. Hence $\sigma_3 h_j(k)\sigma_3 = h_{-j}(-k)$: the orbital $\sigma_3\chi$ of $(-j,-k)$ has the same level as the orbital χ of (j,k).

Status: PROVED; check block_type_relation.

14.6 The chirality matrix Γ on the blocks, and the rotations of 3-space

Γ pairs the two types. The chirality Γ is a product of all eight gammas, so it anticommutes with every gamma (Rule 1 with $p = 8$: a factor passes seven others), with every product of an odd number of gammas such as J, and commutes with every even product such as K_1, K_2. If $Jv = jv$, then $J\Gamma v = -\Gamma Jv = -j\,\Gamma v$, while $K_1\Gamma v = \Gamma K_1 v$: so Γ maps the block (j, s_2, s_3) onto the block $(-j, s_2, s_3)$. In the block basis its 2×2 entry between the paired blocks is $s_2\sigma_2$ (computed in Notebook 14a, In [16]; its figure 4 shows where these entries sit). Status: PROVED; check blocks_relation_to_Gamma.

Γ reverses the mass. Line by line:

$$\sigma_2 D(M,k)\sigma_2 = i\sigma_1\frac{d}{dy} + M\sigma_2 - \kappa k\sigma_3 = -D(-M,k).$$

Rule: $\sigma_2\sigma_1\sigma_2 = -\sigma_1$, $\sigma_2\sigma_2\sigma_2 = \sigma_2$, $\sigma_2\sigma_3\sigma_2 = -\sigma_3$.

$$\sigma_2 h_j(M,k)\sigma_2 = j\big(-D(-M,k)\big) + v = h_{-j}(-M,k).$$

Rule: $h_j = jD + v$ and $\sigma_2\sigma_2 = 1$. So if χ solves the block equation of type j with the mass M, then $\sigma_2\chi$ solves the block equation of type $-j$ with the mass $-M$, at the same k, the same potential v and the same level ε. Because $\sigma_2(\chi_1, \chi_2) = (-i\chi_2, i\chi_1)$, the map also exchanges the two brane conditions $\chi_2(0) = 0$ and $\chi_1(0) = 0$ of Section 14.12. Status: PROVED; check block_Gamma_map.

The same fact is visible in 16 components without blocks. Γ anticommutes with every γ^μ and commutes with every Ω_μ (a sum of products of two gammas), so $\gamma^\mu D_\mu(\Gamma\Psi) = -\Gamma\gamma^\mu D_\mu\Psi$. If $\gamma^\mu D_\mu\Psi = (M - iv\gamma^{(x_4)})\Psi$, then

$$\gamma^\mu D_\mu(\Gamma\Psi) = -\Gamma\big(M - iv\gamma^{(x_4)}\big)\Psi = \big(-M - iv\gamma^{(x_4)}\big)\Gamma\Psi,$$

where the last step uses $\Gamma\gamma^{(x_4)} = -\gamma^{(x_4)}\Gamma$. Here M and v are regarded as given functions of y. In the full theory they are made by the quanta themselves, and how the parameters m, λ and the boundary conditions transform is the content of the pairing theorems: T1 for the field equations, which Chapter 18 proves (the chirality MATRIX Γ carries the solutions of the Lagrangian with (m, λ) to those with $(-m, -\lambda)$), and T3 for the Kohn-Sham states, which Chapter 19 proves. On the blocks, σ_2 also exchanges the tip condition $b(-L) = 0$ with $a(-L) = 0$ (Section 14.12). The maps of this theory are matrices. The author's gammas are real, so for a real field plain complex conjugation changes nothing and is not a charge conjugation; the charge-conjugation matrices of the theory are $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$ (Chapter 5). The map used here is the chirality matrix Γ itself, the real matrix map of the theorem T1, which reverses the mass; on the blocks it acts as $s_2\sigma_2$ from the block (j, s_2, s_3) to the block $(-j, s_2, s_3)$.

What this does and does not say (honesty). The map Γ is an exact map between two sets of solutions: every solution with the mass M has a partner with the mass $-M$. It says nothing about whether a partner is ever realised, and nothing about a process that would create universes, in pairs or otherwise. Chapters 18 to 20 give the complete statements of the pairing theorems T1, T2, Q and T3 and the precise list of what they do not establish.

Rotations of 3-space. A rotation by the angle θ in the (x_1, x_2) plane acts on spinors with the matrix $R = \cos\frac{\theta}{2} + \sin\frac{\theta}{2}\, G$, $G = \gamma^{(x_1)}\gamma^{(x_2)}$. Line by line, with $c = \cos\frac{\theta}{2}$, $s = \sin\frac{\theta}{2}$:

$$G^2 = -1, \qquad (c + sG)(c - sG) = c^2 - s^2 G^2 = c^2 + s^2 = 1.$$

Rule: Rule 2 with $p = 2$ and $\eta_{11}\eta_{22} = 1$; so $R^{-1} = c - sG$.

$$\gamma^{(x_1)} G = \gamma^{(x_2)}, \qquad G\gamma^{(x_1)} = -\gamma^{(x_2)}, \qquad R\gamma^{(x_1)} = \gamma^{(x_1)} R^{-1}.$$

Rule: $\gamma^{(x_1)}\gamma^{(x_1)} = 1$ and $\gamma^{(x_2)}\gamma^{(x_1)} = -\gamma^{(x_1)}\gamma^{(x_2)}$; so G anticommutes with $\gamma^{(x_1)}$, which turns $c + sG$ into $c - sG$ when $\gamma^{(x_1)}$ passes it.

$$R\gamma^{(x_1)} R^{-1} = \gamma^{(x_1)}(c - sG)^2 = \gamma^{(x_1)}\big(\cos\theta - \sin\theta\, G\big) = \cos\theta\, \gamma^{(x_1)} - \sin\theta\, \gamma^{(x_2)}.$$

Rule: $(c - sG)^2 = c^2 - s^2 - 2csG$ (with $G^2 = -1$), the double-angle formulas $c^2 - s^2 = \cos\theta$, $2cs = \sin\theta$, and $\gamma^{(x_1)}G = \gamma^{(x_2)}$. So R turns the momentum term $k\gamma^{(x_1)}$ into the same momentum in a rotated direction. And R commutes with $\gamma^{(x_0)}$, $\gamma^{(x_4)}$, B and C (each contains $\gamma^{(x_1)}$ and $\gamma^{(x_2)}$ both or neither, so the signs cancel), so it changes nothing else in h. Hence the levels of the whole 16-component problem depend on $|\mathbf{k}|$ only, and $\mathbf{k} = (k, 0, 0)$ is no loss of generality. Status: PROVED; check rotation_invariance. (The labels j themselves refer to the direction of $\mathbf{k}$: a rotation by π, $R = G$, anticommutes with J and turns the blocks (j, k) into $(-j, -k)$, in agreement with the σ_3 relation of Section 14.5.)

14.7 The exact rescaling identity between the slices

Where the slice enters. Look at the block Hamiltonian h_j of Section 14.5. The slice $a_{4,0}$ appears only in the momentum term, through

$$\kappa k = e^{-Hy - a_{4,0}}\, k = e^{-Hy}\, \big(k\, e^{-a_{4,0}}\big).$$

Rule: $e^{u+w} = e^u e^w$. Line by line, what follows:

- At the slice $a_{4,0}$ the allowed momenta are $\Delta k\, \mathbf{n}$ (Section 14.3). By the line above they act exactly like the momenta $\Delta k\, e^{-a_{4,0}}\, \mathbf{n}$ at the slice 0. So every level and every orbital of the slice $a_{4,0}$ equals a level and orbital of the slice 0 with the lattice spacing $\Delta k\, e^{-a_{4,0}}$.
- The lattice spacing $\Delta k\, e^{-a_{4,0}}$ belongs to the box size $\ell e^{a_{4,0}}$ (because $\Delta k = 2\pi/\ell$).
- Densities carry the factor $P = e^{-6Hy}/(\ell^3 v_t)$ (the orbital is spread over the coordinate volume $\ell^3 v_t$ of 3-space and the extra times, and $e^{-6Hy} = 1/\sqrt{|g|}$ turns a density per unit y into a density per unit proper volume). If the partner problem at the slice 0 has the box $\ell e^{a_{4,0}}$ and the extra-time volume $v_t e^{-3a_{4,0}}$, its factor is $e^{-6Hy}/(\ell^3 e^{3a_{4,0}} v_t e^{-3a_{4,0}}) = P$: the same proper densities.
- The interaction enters only through the proper densities (Section 14.26), so self-consistency, the energy and every profile agree as well.

Hence, exactly (for the free gas, with the interaction, at every temperature):

$$\mathrm{KS}(a_{4,0};\ \Delta k,\ v_t,\ \lambda) = \mathrm{KS}(0;\ \Delta k\, e^{-a_{4,0}},\ v_t\, e^{-3a_{4,0}},\ \lambda).$$

In words: a later slice of the deflating history is the slice 0 with all 3-momenta redshifted by $e^{-a_{4,0}}$ and the same proper box. The proper size of 3-space has grown by $e^{a_{4,0}}$, the proper volume of the extra times has shrunk by $e^{-3a_{4,0}}$, and the proper 7-volume has not changed. Equivalently, keeping the extra-time volume v_t, the partner has the coupling $\lambda e^{3a_{4,0}}$ and every proper density multiplied by $e^{-3a_{4,0}}$ (the coupling enters only as λ times a density). Status: PROVED; check rescaling_identity. The Rust solver solved each partner problem independently and found the same levels to 1.5×10^{-13} and the same energies and profiles to 3.3×10^{-13} (checks rescaling_identity_between_slices and rescaling_identity_energy_profiles of `Revision/kohn_sham/reports/ks-rust-solver.json`; the partner numbers are in `Revision/kohn_sham/results/rescaling/rescaling.csv`). For the slice $a_{4,0} = 0.5$ the partner has $\Delta k\, e^{-0.5} = 0.151632664928$ and $v_t\, e^{-1.5} = 0.223130160148$ (Notebook 14a, Out [18]).

14.8 Example: Notebook 14a, the block reduction and the rescaling identity

Notebook 14a repeats Sections 14.2 to 14.7 with exact computer algebra. It reads the author's gammas from the Revision record, checks the Clifford relation and the matrices C, B, Γ, verifies the hidden coordinate and the determinant, computes the canonical spin connection of the warped metric with a_4 an arbitrary function of the time and shows that $\sum_\mu \gamma^\mu \Omega_\mu = 3H\gamma^{(x_0)}$ with the time-direction pieces cancelling, verifies that W^{-3} removes it, builds the Hamiltonian, the labels J, K_1, K_2, the projectors, the block basis (compared entry by entry with the record) and the block forms, checks the two block types, the matrix Γ on the blocks, the rotations and the rescaling identity, and compares the partner spacings and volumes with all 60 rows of the Rust record. It draws five figures. It runs in about 30 seconds (two cells do exact algebra with 16×16 matrices of symbols and take about 10 seconds each), and its last line is ALL 28 CHECKS PASSED (notebook 14a).

14.9 How to run Notebook 14a

Step 1. What this notebook does and what it needs.

Notebook 14a (The reduction of the Kohn-Sham equation to eight 2x2 blocks and the rescaling identity) is the file `Revision/textbook/notebooks/14a_block_reduction.ipynb` of the repository Dirac_claude. It rebuilds from the author's real 16 x 16 gamma matrices every exact step that turns the 16-component Kohn-Sham equation of dirac16complex in the deflating primordial field into eight independent 2 x 2 equations in the hidden coordinate y: the warped form of the metric, the spin-connection term 3H gamma^(x0) (the time-direction pieces of the three inflating and the three deflating directions cancel), the factor W^(-3) that removes it, the three commuting labels J, K1, K2 and the block basis V, the block forms of every matrix of the equation, the chirality matrix Gamma that pairs the blocks of opposite type and reverses the mass, and the exact rescaling identity between the slices of the deflating history; it checks every step against the Revision records and draws five teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were

built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 14a_block_reduction.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 14a_block_reduction.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error,

every check passed; open the notebook with `jupyter lab 14a_block_reduction.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/14a.captions.json`
- `Revision/textbook/figures/14a_1_hidden_coordinate.png`
- `Revision/textbook/figures/14a_2_inflation_deflation.png`
- `Revision/textbook/figures/14a_3_spin_connection_terms.png`
- `Revision/textbook/figures/14a_4_block_structure.png`
- `Revision/textbook/figures/14a_5_rescaling.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of this notebook exist
ALL 28 CHECKS PASSED (notebook 14a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/14a_block_reduction.ipynb` inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 14a_block_reduction.ipynb
python -m nbconvert --execute --inplace 14a_block_reduction.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 7 and 8 seem to hang: they do exact algebra with 16 x 16 matrices of symbols and take about 10 seconds each on a laptop; wait until the PASS lines appear.

14.10 Notebook 14a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/14a_block_reduction.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The Kohn-Sham equation of dirac16complex in the author's primordial field is an
equation for 16 complex functions of the eight coordinates $x_0, \dots, x_7$. This
```

```
notebook turns it, step by exact step, into eight independent equations for TWO
functions of ONE coordinate, the hidden coordinate $y$. Every step is computed here
with exact algebra (sympy) from the author's gamma matrices and compared with the
Revision record, which made the same computation twice (in sympy and in
WolframScript). The steps are:

- the hidden coordinate $y$ and the warped form of the author's metric
  (figures 1 and 2);
- the spin connection: the only term that survives in the Dirac operator is
  $3H\gamma^{(x_0)}$; the time-direction pieces of the three inflating and of the
  three deflating directions cancel (figure 3);
- the factor $W^{-3} = e^{-3Hy}$ in the orbital removes this term exactly;
- the equation becomes $i\,\partial_{x_4}\chi = h\,\chi$ with a Hermitian $h$;
- three matrices $J, K_1, K_2$ commute with $h$ and split the 16 components into
  eight blocks of two; the block basis $V$ is built and compared entry by entry
  with the Revision record (figure 4);
- in every block the equation is $h_j = j[-i\sigma_1\,d/dy + M\sigma_2 +
  \kappa k\sigma_3] + v$, and only two types of blocks exist ($j = \pm 1$);
- the chirality MATRIX $\Gamma$ maps a block of type $j$ with mass $M$ onto a
  block of type $-j$ with mass $-M$;
- the slice $a_{4,0}$ of the deflating history enters only through
  $k\,e^{-a_{4,0}}$: the exact rescaling identity (figure 5).

The notebook prints a line starting with PASS for every check (28 in all) and
saves five figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 14a (The reduction of the Kohn-Sham equation to eight 2x2 blocks and the
rescaling identity) is the file ‘Revision/textbook/notebooks/14a_block_reduction.ipynb‘
of the repository Dirac_claude. It rebuilds from the author's real 16 x 16 gamma matrices
every exact step that turns the 16-component Kohn-Sham equation of dirac16complex in the
deflating primordial field into eight independent 2 x 2 equations in the hidden
coordinate y: the warped form of the metric, the spin-connection term 3H gamma^(x0) (the
time-direction pieces of the three inflating and the three deflating directions cancel),
the factor W^(-3) that removes it, the three commuting labels J, K1, K2 and the block
basis V, the block forms of every matrix of the equation, the chirality matrix Gamma that
pairs the blocks of opposite type and reverses the mass, and the exact rescaling identity
between the slices of the deflating history; it checks every step against the Revision
records and draws five teaching figures. It needs a computer with Windows 11, macOS or
Linux, an internet connection for the installation, the program Git, and Python 3.12 or
newer (the notebooks were built with Python 3.14.5) with these packages at exactly these
versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10,
nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook
itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program
that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**
```

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on

the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 14a_block_reduction.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 14a_block_reduction.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 14a_block_reduction.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/14a.captions.json‘
- ‘Revision/textbook/figures/14a_1_hidden_coordinate.png‘
- ‘Revision/textbook/figures/14a_2_inflation_deflation.png‘
- ‘Revision/textbook/figures/14a_3_spin_connection_terms.png‘
- ‘Revision/textbook/figures/14a_4_block_structure.png‘

- ‘Revision/textbook/figures/14a_5_rescaling.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all five figure files of this notebook exist
ALL 28 CHECKS PASSED (notebook 14a)
```

and the notebook must show 5 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/14a_block_reduction.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 14a_block_reduction.ipynb
  python -m nbconvert --execute --inplace 14a_block_reduction.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues

normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 7 and 8 seem to hang: they do exact algebra with 16 x 16 matrices of symbols and take about 10 seconds each on a laptop; wait until the PASS lines appear.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 14a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 14a (The reduction of the Kohn-Sham equation to eight 2x2 blocks and the
# rescaling identity) is the file Revision/textbook/notebooks/14a_block_reduction.ipynb
# of the repository Dirac_claude. It rebuilds from the author's real 16 x 16 gamma
# matrices every exact step that turns the 16-component Kohn-Sham equation of
# dirac16complex in the deflating primordial field into eight independent 2 x 2 equations
# in the hidden coordinate y: the warped form of the metric, the spin-connection term 3H
# gamma^(x0) (the time-direction pieces of the three inflating and the three deflating
# directions cancel), the factor W^(-3) that removes it, the three commuting labels J,
# K1, K2 and the block basis V, the block forms of every matrix of the equation, the
# chirality matrix Gamma that pairs the blocks of opposite type and reverses the mass,
# and the exact rescaling identity between the slices of the deflating history; it checks
# every step against the Revision records and draws five teaching figures. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
```

```
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 14a_block_reduction.ipynb
#
```

```
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 14a_block_reduction.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 14a_block_reduction.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/14a.captions.json
# - Revision/textbook/figures/14a_1_hidden_coordinate.png
# - Revision/textbook/figures/14a_2_inflation_deflation.png
# - Revision/textbook/figures/14a_3_spin_connection_terms.png
# - Revision/textbook/figures/14a_4_block_structure.png
# - Revision/textbook/figures/14a_5_rescaling.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all five figure files of this notebook exist
#     ALL 28 CHECKS PASSED (notebook 14a)
#
# and the notebook must show 5 figures below the cells that draw them.
```

```
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/14a_block_reduction.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 14a_block_reduction.ipynb
#     python -m nbconvert --execute --inplace 14a_block_reduction.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - the cells of sections 7 and 8 seem to hang: they do exact algebra with 16 x 16
#   matrices of symbols and take about 10 seconds each on a laptop; wait until the PASS
#   lines appear.

```
## 3. The words used in this notebook

- **Coordinates $x_0, \dots, x_7$**: the author's names. $x_1, x_2, x_3$ are
  ordinary 3-space; $x_4$ is the time; $x_5, x_6, x_7$ are the three EXTRA TIMES;
  $x_0$ is the hidden space direction. In Python lists they have the positions
  0 to 7.
- **Metric, scale factor**: the metric says how long a small step $dx_\mu$ is.
  A scale factor multiplies a coordinate step: along $x_1$ a step $dx_1$ has the
  length $e^{a_4} \sin^{1/6} z \, dx_1$.
- **Inflating, deflating**: $a_4(x_4)$ grows with the time $x_4$. Then
  $e^{a_4}$ grows (3-space inflates) and $e^{-a_4}$ shrinks exponentially (the
  three extra times deflate).
- **Slice**: one instant $x_4$ of the history; $a_{4,0} = a_4(x_4)$ is the value
  of $a_4$ there. The history $a_4 = A H x_4$ is a PRESCRIBED BACKGROUND (it is
  given, not solved for, and the Kohn-Sham gas does not act back on it).
- **Hidden coordinate $y$**: $y = \ln(\sin z)/(6H)$ with $z = 6 H x_0$; it measures
  proper length along $x_0$.
- **Warp factor $W$**: $W = e^{Hy}$; the scale factors of the six directions
  $x_1, x_2, x_3, x_5, x_6, x_7$ contain $W$.
- **Gamma matrices $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$**: the author's real
  $16 \times 16$ matrices with $\gamma^a\gamma^b + \gamma^b\gamma^a =
  2\eta^{ab}$ (the Clifford relation); in the code `g1`, ..., `g0`.
- **Spin connection $\Omega_\mu$**: the matrices that the curvature of space adds
  to the derivative of a spinor: $D_\mu = \partial_\mu + \Omega_\mu$.
- **Hermitian matrix**: equal to its conjugate transpose, $X^\dagger = X$; its
  eigenvalues are real. **Unitary**: $V^\dagger V = 1$ (a change of basis that
  keeps lengths).
- **Commute, anticommute**: $XY = YX$, or $XY = -YX$.
- **Projector**: a matrix with $P^2 = P$; its rank is the dimension of the space
  it projects onto.
- **Block**: a $2 \times 2$ piece on the diagonal of a matrix that has no other
  nonzero entries in its rows and columns.
- **Pauli matrices** $\sigma_1 = [[0,1],[1,0]]$, $\sigma_2 = [[0,-i],[i,0]]$,
  $\sigma_3 = [[1,0],[0,-1]]$ (written row by row).
- **Chirality matrix $\Gamma$** $= \gamma^{(x_0)}\gamma^{(x_1)}\cdots
  \gamma^{(x_7)}$: a MATRIX (not a complex conjugation); here it equals
  diag$(-1, \dots, -1, 1, \dots, 1)$.
- **sympy**: computes exactly with symbols and fractions; a check made with
  sympy is an exact identity, not a numerical approximation.
- **Revision record**: the files under `Revision/` that hold the verified
  computations; a PASS line ending with "reproduces ..." names the record file
  and the check that this notebook computed again.
```

Text cell:

```
## 4. The physical and mathematical situation
```

```
The author's metric is diagonal. In the order $x_0, \dots, x_7$ its entries are
$e^{2a_4}\sin^{1/3}z$ (three times), $-1$, $-e^{-2a_4}\sin^{1/3}z$ (three times)
and $\cot^2 z$, with $z = 6Hx_0$ between $0$ and $\pi/2$ and $H > 0$. The signs
$\eta = (+,+,+,+,-,-,-,-)$ say which directions are space-like ($+$) and which
are time-like ($-$).

In the Kohn-Sham model (the mean-field description of many quanta) every quantum
obeys the equation

$$\gamma^\mu D_\mu \Psi = (M_{\rm eff} - i v_v \gamma^{(x_4)})\Psi ,$$

where $M_{\rm eff}(y)$ is the effective mass and $v_v(y)$ the vector potential
made by all the other quanta (their formulas are not needed here). We use the
GOOD SECTOR: $\Psi$ does not depend on the extra times $x_5, x_6, x_7$. This is
an ASSUMPTION of the Revision theory: only without extra-time dependence does the
quantised field have a space of states with a positive norm, and modes with
enough momentum along the extra times grow without bound. We look for orbitals of
the form

$$\Psi = e^{i \mathbf{k}\cdot\mathbf{x}}\, W(y)^{-3}\, \chi(y, x_4),$$

a plane wave with 3-momentum $\mathbf k$ along 3-space, the factor $W^{-3}$, and a
column $\chi$ of 16 functions of $y$ and the time. The notebook shows that
$\chi$ obeys $i\,\partial_{x_4}\chi = h\chi$ and that $h$ splits into eight
$2\times2$ blocks. At one instant (one slice) the stationary orbitals solve
$h\chi = \varepsilon\chi$: the stationary-slice (adiabatic) ansatz of the
Revision theory.

Status of the statements: every identity of this notebook is PROVED (exact, and
verified twice in the Revision record); the good sector is ASSUMED; the history
$a_4 = A H x_4$ is a PRESCRIBED BACKGROUND.
```

Text cell:

```
## 5. The author's gamma matrices

The Revision record `Revision/algebra/gammas.json` stores the eight matrices
$\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$ as lists of rows; `gamma[a]` is
$\gamma^{(x_a)}$. The next cell reads them, turns them into exact sympy
matrices and checks the Clifford relation $\gamma^a\gamma^b + \gamma^b\gamma^a =
2\eta^{ab}\,1$ for all 64 pairs $(a, b)$. It also defines the helper
`record_check`, which reads the verdict of a named check from a Revision report;
every check below that repeats a Revision check also requires that the record
says PASS.
```

In [2]:

```
import numpy as np  # floating-point arrays and matrices
import sympy as sp  # exact algebra with symbols

```

Text cell:

```
The next cell builds three products that the theory uses again and again:

- $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$, the product of
  the four space-like gammas; the Dirac adjoint is $\bar\Psi = \Psi^\dagger C$.
- $B = -i\,C\,\gamma^{(x_4)}$, the matrix of the positive inner product of the
  good sector ($\langle\Psi^\dagger X \Psi\rangle = u^\dagger B X u$ for one
  quantum in the mode $u$).
- $\Gamma = \gamma^{(x_0)}\gamma^{(x_1)}\cdots\gamma^{(x_7)}$, the chirality
  matrix.

It checks that $C$ is real and symmetric with $C^2 = 1$, that $B$ is Hermitian
with $B^2 = 1$, that $\Gamma$ is diagonal with eight entries $-1$ followed by
eight entries $+1$, and three product rules used later: $BC = -i\gamma^{(x_4)}$,
```

```
$C\gamma^{(x_4)} = iB$ and $CBC = B$. (‘X.H‘ is the conjugate transpose
$X^\dagger$ in sympy and ‘X.T‘ the transpose.)

```
## 6. The hidden coordinate y and the warped form of the metric

Along $x_0$ the metric has the entry $g_{00} = \cot^2 z$ with $z = 6Hx_0$. We
replace $x_0$ by

$$y = \frac{\ln(\sin z)}{6H}.$$

Line by line:

1. Differentiate with the chain rule: $dy/dx_0 = \frac{1}{6H}\cdot\frac{\cos z}
   {\sin z}\cdot 6H = \cot z$.
2. Square: $dy^2 = \cot^2 z\, dx_0^2 = g_{00}\,dx_0^2$. So $y$ measures proper
   length along the hidden direction, and in the new coordinate the entry is 1.
3. Exponentiate the definition: $e^{6Hy} = \sin z$, hence $\sin^{1/3} z =
   e^{2Hy} = W^2$ with the warp factor $W = e^{Hy}$.
4. Range: $z \to 0$ (the TIP) gives $\sin z \to 0$ and $y \to -\infty$; $z =
   \pi/2$ (the end of the author’s coordinate patch, the BRANE) gives $y = 0$.

The metric becomes the warped form

$$ds^2 = e^{2Hy}\left[e^{2a_4}(dx_1^2 + dx_2^2 + dx_3^2) - e^{-2a_4}(dx_5^2 +
dx_6^2 + dx_7^2)\right] - dx_4^2 + dy^2 .$$

Its scale factors (the vielbein entries) are $h = (e^{a_4}W, e^{a_4}W, e^{a_4}W,
1, e^{-a_4}W, e^{-a_4}W, e^{-a_4}W, 1)$. The square root of the absolute value
```

```
of the determinant is their product: $e^{3a_4}W^3\cdot e^{-3a_4}W^3 = W^6 =
e^{6Hy}$. In the author's $x_0$ chart it is $\sin z \cdot \cot z = \cos z$; the
two differ by the factor $dy/dx_0 = \cot z$ of step 1. Neither depends on $a_4$:
while 3-space inflates and the extra times deflate, the 7-volume stays the same.

The next cell verifies steps 1 to 3 and the determinant with sympy.
```

```
## 7. The spin connection and the term 3H gamma^(x0)

A spinor needs the covariant derivative $D_\mu\Psi = \partial_\mu\Psi +
\Omega_\mu\Psi$. For the diagonal vielbein $h_a$ of section 6 the canonical spin
connection (the one fixed by the vielbein postulate) is computed in three steps:

1. The Christoffel symbols $\Gamma^n_{mk} = \frac12 g^{nl}(\partial_m g_{lk} +
   \partial_k g_{lm} - \partial_l g_{mk})$. For a diagonal metric only the terms
   with two equal indices survive: $\Gamma^n_{mk} = [\delta_{mn}\partial_k g_{nn}
   + \delta_{kn}\partial_m g_{nn} - \delta_{mk}\partial_n g_{mm}]/(2g_{nn})$.
2. The connection coefficients $\omega_\mu{}^A{}_B = h_A\,\partial_\mu(1/h_B)\,
   \delta^A_B + h_A\,\Gamma^A_{\mu B}/h_B$ (no sum over $A$, $B$).
3. $\Omega_\mu = \frac12\sum_{A,B}\eta_{AA}\,\omega_\mu{}^A{}_B\,S^{AB}$ with
   $S^{AB} = \frac14(\gamma^A\gamma^B - \gamma^B\gamma^A)$.

The next cell does these three steps with $a_4$ an arbitrary function of $x_4$
(so it holds along any history), checks that the curved gammas $\gamma^\mu =
```

```
\gamma^{(\mu)}/h_\mu$ are covariantly constant ($\nabla_\mu\gamma^\nu = 0$: 64
matrix equations, the proof that the connection is the right one), and computes
the only combination that enters the Dirac operator,
$\gamma^\mu\Omega_\mu = \sum_\mu (\gamma^{(\mu)}/h_\mu)\,\Omega_\mu$. It takes
about 10 seconds.
```

Text cell:

```
Where does $3H\gamma^{(x_0)}$ come from, and where did the time derivative $a_4'$
go? The next cell splits $\gamma^\mu\Omega_\mu$ into the contributions of the
eight directions. Each contribution $(\gamma^{(\mu)}/h_\mu)\Omega_\mu$ turns out
to be a combination $c_4\gamma^{(x_4)} + c_0\gamma^{(x_0)}$. Because
$\gamma^{(x_4)}\gamma^{(x_4)} = -1$, $\gamma^{(x_0)}\gamma^{(x_0)} = +1$ and the
trace of $\gamma^{(x_4)}\gamma^{(x_0)}$ is 0, the coefficients are found with
traces: $c_4 = -\mathrm{Tr}(X\gamma^{(x_4)})/16$ and $c_0 =
\mathrm{Tr}(X\gamma^{(x_0)})/16$. The cell checks that each contribution is
exactly $c_4\gamma^{(x_4)} + c_0\gamma^{(x_0)}$, prints the coefficients, and
checks the two facts of the Revision record: the three inflating directions give
$+\frac32 a_4'\gamma^{(x_4)}$, the three deflating directions give
$-\frac32 a_4'\gamma^{(x_4)}$, so the time-direction pieces cancel; and
$\Omega_{x_4} = \Omega_y = 0$.

## 8. The factor W^(-3) removes the spin connection
```

```
Insert $\Psi = e^{i\mathbf k\cdot\mathbf x}W^{-3}\chi(y, x_4)$ into
$\gamma^\mu D_\mu\Psi = \sum_\mu\gamma^\mu\partial_\mu\Psi + 3H\gamma^{(x_0)}\Psi$
(section 7). Term by term:

1. $y$: $\partial_y(W^{-3}\chi) = W^{-3}(\partial_y\chi - 3H\chi)$ because
   $\partial_y e^{-3Hy} = -3He^{-3Hy}$. With $\gamma^y = \gamma^{(x_0)}$ the term
   $-3H\gamma^{(x_0)}\chi$ cancels the $+3H\gamma^{(x_0)}\chi$ of the spin
   connection.
2. 3-space: $\partial_j e^{i\mathbf k\cdot\mathbf x} = ik_j e^{i\mathbf k\cdot
   \mathbf x}$ and $\gamma^{x_j} = \gamma^{(x_j)}/(e^{a_4}W)$, so the term is
   $i\kappa k_j\gamma^{(x_j)}$ with the momentum weight $\kappa = e^{-Hy-a_4}$.
3. Time: $\gamma^{x_4} = \gamma^{(x_4)}$ acts on $\partial_{x_4}\chi$.
4. Extra times: nothing depends on $x_5, x_6, x_7$ (good sector).

So, dividing by the common factor $e^{i\mathbf k\cdot\mathbf x}W^{-3}$:

$$\gamma^\mu D_\mu\Psi \to \gamma^{(x_0)}\partial_y\chi + \gamma^{(x_4)}
\partial_{x_4}\chi + i\kappa\,k_j\gamma^{(x_j)}\chi .$$

The next cell verifies this with sympy for a column of 16 arbitrary functions
$\chi_A(y, x_4)$ and an arbitrary history $a_4(x_4)$, and verifies that WITHOUT
the factor $W^{-3}$ the term $3H\gamma^{(x_0)}\chi$ survives. It takes about 5
seconds.

## 9. The equation i d_x4 chi = h chi and its Hermitian pieces

With the reduced operator of section 8 the Kohn-Sham equation reads

$$\gamma^{(x_0)}\partial_y\chi + \gamma^{(x_4)}\partial_{x_4}\chi +
i\kappa k_j\gamma^{(x_j)}\chi = (M - iv\gamma^{(x_4)})\chi$$

($M$ the effective mass, $v$ the vector potential). Solve for the time
derivative, line by line:

1. Move everything except the time term to the right: $\gamma^{(x_4)}
   \partial_{x_4}\chi = (M - iv\gamma^{(x_4)})\chi - \gamma^{(x_0)}\partial_y\chi
   - i\kappa k_j\gamma^{(x_j)}\chi$.
2. Multiply from the left by $-\gamma^{(x_4)}$; since $\gamma^{(x_4)}
   \gamma^{(x_4)} = -1$, the left side becomes $\partial_{x_4}\chi$.
3. Multiply by $i$: $i\partial_{x_4}\chi = h\chi$ with
   $h = i\gamma^{(x_4)}\gamma^{(x_0)}\partial_y - \kappa k_j\gamma^{(x_4)}
   \gamma^{(x_j)} + M(-i\gamma^{(x_4)}) + v$.

$h$ is Hermitian (so the levels are real and the norm $\int\chi^\dagger\chi\,dy$
is conserved) because: $\gamma^{(x_4)}\gamma^{(x_0)}$ is real and symmetric, so
$i\gamma^{(x_4)}\gamma^{(x_0)}$ is anti-Hermitian, and $\partial_y$ is
anti-Hermitian too (integration by parts when the boundary terms vanish), so their
product is Hermitian; $\gamma^{(x_4)}\gamma^{(x_j)}$ and $-i\gamma^{(x_4)}$ are
Hermitian matrices. The next cell checks the three lines with 16-component
columns of symbols for $\partial_y\chi$ and $\chi$, and the Hermitian pieces.
```

## 10. Three matrices that commute with everything: J, K1, K2

Rotations of 3-space do not change the levels (section 14), so we may take
$\mathbf k = (k, 0, 0)$ along $x_1$. Then $h$ is built from the three gammas
$\gamma^{(x_0)}$, $\gamma^{(x_1)}$, $\gamma^{(x_4)}$ only; the first-order form
$\chi' = N_{16}\chi$ of the equation (section 12) uses the three products
$A_0 = \gamma^{(x_0)}$, $A_1 = \gamma^{(x_0)}\gamma^{(x_1)}$,
$A_4 = \gamma^{(x_0)}\gamma^{(x_4)}$, and the densities contain $B$ and $C$.

A rule for products of different gammas: moving $\gamma^c$ through a product of
$p$ different gammas gives the sign $(-1)^{p-1}$ if $\gamma^c$ is one of the
factors and $(-1)^p$ if it is not. With it one finds three matrices that commute
with $A_0, A_1, A_4, B, C$ and with each other:

$$J = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_4)},\quad K_1 = \gamma^{(x_2)}
\gamma^{(x_3)},\quad K_2 = \gamma^{(x_5)}\gamma^{(x_6)} .$$

Their squares: $J^2 = (-1)^3(\gamma^{(x_0)})^2(\gamma^{(x_1)})^2(\gamma^{(x_4)})^2
= (-1)(1)(1)(-1) = +1$ (reversing three factors needs three swaps), $K_1^2 =
-(\gamma^{(x_2)})^2(\gamma^{(x_3)})^2 = -1$, $K_2^2 = -(-1)(-1) = -1$. So $J$
has the eigenvalues $j = \pm1$ and $K_1, K_2$ the eigenvalues $is_2, is_3$ with
$s_2, s_3 = \pm1$. The joint eigenspace with the labels $(j, s_2, s_3)$ is the
range of the projector

$$P(j, s_2, s_3) = \frac{1 + jJ}{2}\cdot\frac{1 - is_2K_1}{2}\cdot
\frac{1 - is_3K_2}{2} .$$

The next cell checks the commutation relations and the squares, builds the
eight projectors and checks that each has rank 2, that $P^2 = P$, and that the
eight add up to the unit matrix: the 16 components split into 8 blocks of 2.
```

In [12]:

```
A0, A1, A4 = g0, g0 * g1, g0 * g4  # the matrices of the equation (k along x1)

## 11. The block basis V

In each eigenspace we choose two basis vectors adapted to the equation. Since
$A_0 = \gamma^{(x_0)}$ squares to 1, $\frac12(1 + \gamma^{(x_0)})$ projects on its
eigenvalue $+1$. Take the first unit column $e_c$ (counting $c$ from 0) for which
$v_+ = 8\,P(j, s_2, s_3)\,\frac12(1 + \gamma^{(x_0)})\,e_c$ is not zero; then
$\gamma^{(x_0)}v_+ = v_+$. Put $v_- = A_1v_+$. Because $A_1$ anticommutes with
$A_0$, $\gamma^{(x_0)}v_- = -v_-$. The 16 columns $v_+, v_-$ of the eight blocks,
in the label order $(1,1,1), (1,1,-1), \dots, (-1,-1,-1)$, form the matrix $U$,
and $V = U/(2\sqrt2)$.

The next cell builds $U$ and $V$, prints the seed columns $c$, checks that $V$
is unitary and that every entry of $U$ is $0$, $\pm1$ or $\pm i$, and compares $U$
entry by entry with the basis stored in the Revision record
‘Revision/kohn_sham/ks-theory.json‘ (which the Rust solver uses).
```

In [13]:

```
columns, seeds = [], []
for P in projectors:
    P_plus = P * (I16 + g0) / 2  # project on gamma^(x0) = +1 inside the block
    c = next(c for c in range(16) if not P_plus[:, c].is_zero_matrix)
    seeds.append(c)
    v_plus = 8 * P_plus[:, c]
    columns += [v_plus, A1 * v_plus]  # v+ and v- = A1 v+
U = sp.Matrix.hstack(*columns)  # 16 x 16, entries 0, +-1, +-i
V = U / (2 * sp.sqrt(2))  # the unitary block basis

## 12. Every matrix of the equation in the block basis

The next cell computes $V^\dagger XV$ for the eleven matrices $X$ that occur in
the equation and in the densities, checks that each is block diagonal (zero
outside the eight $2\times2$ diagonal blocks), and checks the form of each
block against the table of the Revision record. In the block with the labels
$(j, s_2, s_3)$ the forms are printed below. A number such as $js_2$ means that
number times the $2\times2$ unit matrix. It also checks that NOT every matrix is
block diagonal: $\gamma^{(x_2)}$, $\gamma^{(x_5)}$ and
$\gamma^{(x_0)}\gamma^{(x_2)}$ anticommute with $J$ and connect different blocks
(that is why $\mathbf k$ was put along $x_1$), while $\gamma^{(x_1)}$ is block
diagonal.
```

Text cell:

```
The next cell draws the block structure. To have one matrix of the equation
without derivatives, it uses the matrix $N_{16}$ of the first-order form
$\chi' = N_{16}\chi$ of the stationary equation at one point: from section 9 with
$\partial_{x_4}\chi = -i\varepsilon\chi$ and $\mathbf k = (k,0,0)$ one gets
$N_{16} = M\gamma^{(x_0)} + i(\varepsilon - v)\gamma^{(x_0)}\gamma^{(x_4)}
- i\kappa k\,\gamma^{(x_0)}\gamma^{(x_1)}$. The cell takes the sample values
$M = 1$, $\varepsilon = 0.5$, $v = 0$, $\kappa k = 0.7$ and shows the absolute
values of the entries of $N_{16}$ in the original basis (left), of
$V^\dagger N_{16}V$ in the block basis (middle; the thin lines mark the eight
$2\times2$ blocks), and of $V^\dagger\Gamma V$ (right): the chirality matrix is
NOT block diagonal, it connects each block to the block with the opposite $j$
(section 13).
```

## 13. The 2x2 block Hamiltonian, its two types and the matrix Gamma

With the forms of section 12 the Hamiltonian of section 9 becomes, in every
block of type $j$ ($\mathbf k = (k, 0, 0)$):

$$h_j = j\left[-i\sigma_1\frac{d}{dy} + M\sigma_2 + \kappa k\,\sigma_3\right] + v .$$

It depends on $j$ only, not on $s_2, s_3$: there are only TWO types of block,
four blocks of each. The eigenvalue equation $h_j\chi = \varepsilon\chi$ is the
same as the first-order system $\chi' = N\chi$ with
$N = M\sigma_3 - \kappa k\sigma_2 + ij(\varepsilon - v)\sigma_1$. Two exact
relations follow:

- $h_{-1} - v = -(h_{+1} - v)$: the two types have mirrored spectra (for $v = 0$
  the levels of $j = -1$ are the negatives of those of $j = +1$); and
  $\sigma_3 h_j(k)\sigma_3 = h_{-j}(-k)$: the orbital $\sigma_3\chi$ of
  $(-j, -k)$ has the same level as the orbital $\chi$ of $(j, k)$.
- $\sigma_2 h_j(M, k)\sigma_2 = h_{-j}(-M, k)$. This is the block form of the
  chirality MATRIX $\Gamma$: $\Gamma$ maps the block $(j, s_2, s_3)$ onto
  $(-j, s_2, s_3)$ with the $2\times2$ entry $s_2\sigma_2$, so it maps a solution
  with mass $M$ in a block of type $j$ onto a solution with mass $-M$ in a block
  of type $-j$, at the same $k$ and the same level. It also exchanges the two
  brane conditions $\chi_2(0) = 0$ and $\chi_1(0) = 0$. This is the mass-reversing
  matrix map of the pairing theorem T1. (The gammas are real; for a real field
  plain complex conjugation does nothing and is not a charge conjugation. The
  maps of the theory are MATRICES such as $\Gamma$.)

The next cell checks the block Hamiltonian in all eight blocks, the equivalence
with $\chi' = N\chi$, the two type relations and the block form of $\Gamma$.

## 14. Rotations of 3-space: only |k| matters

A rotation by the angle $\theta$ in the $(x_1, x_2)$ plane acts on spinors with
the matrix $R = \cos(\theta/2) + \sin(\theta/2)\gamma^{(x_1)}\gamma^{(x_2)}$. Its
inverse is $\cos(\theta/2) - \sin(\theta/2)\gamma^{(x_1)}\gamma^{(x_2)}$: with
$G = \gamma^{(x_1)}\gamma^{(x_2)}$, $c = \cos(\theta/2)$, $s = \sin(\theta/2)$
and $G^2 = -1$ one gets $(c + sG)(c - sG) = c^2 - s^2G^2 = c^2 + s^2 = 1$.
The next cell checks this, and that $R$ commutes with $\gamma^{(x_0)}$,
$\gamma^{(x_4)}$, $B$ and $C$ (so it does not change the rest of $h$) and that it
turns $k\gamma^{(x_1)}$ into
$k(\cos\theta\,\gamma^{(x_1)} - \sin\theta\,\gamma^{(x_2)})$, the same momentum
in a rotated direction. So the levels depend on $|\mathbf k|$ only, and
$\mathbf k = (k, 0, 0)$ is no loss of generality.
```

In [17]:

```
theta = sp.symbols("theta", real=True)

## 15. The exact rescaling identity between slices

Look at where the slice $a_{4,0}$ enters the block Hamiltonian: only through
$\kappa k = e^{-Hy}\,(k\,e^{-a_{4,0}})$. Line by line:

1. The 3-space directions form a coordinate torus of size $\ell$; the allowed
   momenta are $\mathbf k = \Delta k\,(n_1, n_2, n_3)$ with integers $n_i$ and
   $\Delta k = 2\pi/\ell$ (the Revision solver uses $\Delta k = 0.25$).
2. At the slice $a_{4,0}$ the lattice $\Delta k\,\mathbf n$ therefore acts exactly
   like the lattice $\Delta k\,e^{-a_{4,0}}\,\mathbf n$ at the slice 0: every
   level and every orbital is the same.
3. Densities carry the factor $P = e^{-6Hy}/(\ell^3 v_t)$ ($v_t$ the coordinate
   volume of the extra times). The slice-0 problem with the spacing
   $\Delta k\,e^{-a}$ has the box size $\ell e^{a}$; choosing its extra-time
   volume $v_t e^{-3a}$ gives $(\ell e^a)^3 v_t e^{-3a} = \ell^3 v_t$: the SAME
   factor $P$, so the same proper densities.

Hence, exactly (for the free gas, with the interaction, at every temperature):
$\mathrm{KS}(a_{4,0}; \Delta k, v_t, \lambda) = \mathrm{KS}(0; \Delta k\,
e^{-a_{4,0}}, v_t e^{-3a_{4,0}}, \lambda)$. Equivalently, with the same box
$v_t$ and the coupling $\lambda e^{3a_{4,0}}$, with every proper density
multiplied by $e^{-3a_{4,0}}$ (the coupling enters only as $\lambda$ times a
density). The next cell verifies the three statements with sympy and then
computes the partner spacings and extra-time volumes of the four later slices,
which the Rust solver used to solve every partner problem independently; they
must equal the columns `partner_dk` and `partner_v_t` of the Revision record
`rescaling.csv`.
```

ALL 28 CHECKS PASSED (notebook 14a)
```

Text cell:

```
## 17. What this notebook showed

- The hidden coordinate $y = \ln(\sin z)/(6H)$ turns the author's metric into the
  warped form with $W = e^{Hy}$; the 7-volume factor $W^6$ does not contain
  $a_4$ (PROVED; reproduces the Revision checks).
- In the Dirac operator the spin connection contributes only $3H\gamma^{(x_0)}$,
  for every history $a_4(x_4)$: the time-direction pieces $+\frac32 a_4'$ of the
  three inflating directions and $-\frac32 a_4'$ of the three deflating extra
  times cancel exactly (PROVED).
```

```
- The factor $W^{-3}$ removes this term; the equation becomes
  $i\partial_{x_4}\chi = h\chi$ with a Hermitian $h$ (PROVED).
- $J, K_1, K_2$ split the 16 components into eight blocks of two; the block
  basis equals the one in ‘Revision/kohn_sham/ks-theory.json‘ entry by entry; in
  each block $h_j = j[-i\sigma_1 d/dy + M\sigma_2 + \kappa k\sigma_3] + v$ with
  only two types $j = \pm1$ (PROVED).
- The chirality matrix $\Gamma$ pairs the block types and maps mass $M$ to $-M$:
  a matrix map, the one of the pairing theorem T1 (PROVED here at the level of the
  block equation).
- The slice of the prescribed deflating history enters only as
  $k\,e^{-a_{4,0}}$: a later slice is the slice 0 with redshifted lattice
  momenta and the same proper 7-volume (the exact rescaling identity, PROVED; the
  partner numbers equal those of the Rust solver’s record).
- ASSUMED: the good sector (no dependence on the extra times). PRESCRIBED
  BACKGROUND: the history $a_4 = AHx_4$.
```

14.11 Line-by-line walk-through of Notebook 14a

The notebook has 20 code cells, In [1] to In [20]. This section explains every line of every one of them, in order: a line or a small group of lines is quoted, then explained. Docstrings (the texts in triple quotes under a `def` line, which say what a function does) and some comment lines are left out of the quotations; the complete cells are printed in Section 14.10.

In [1], the set-up cell. Every line that starts with `#` is a **comment**, which Python skips. The first part of the cell, down to the lines of `-` and `=` signs, is the complete run instructions of Section 14.9 again, as comments, so that the notebook file carries its own instructions. The code starts after the heading THE SET-UP; it computes no physics and is the same in every notebook of the book, except for the line that names the notebook. The notebooks 14b, 14c and 14d have exactly this cell with their own name, and their walk-throughs refer back to this paragraph.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of a package) so that the code can use it. `json`, `os`, `textwrap` and `pathlib` come with Python. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or a folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python code), which show a picture file below a cell.

```
NOTEBOOK_ID = "14a"  # this notebook: chapter 14, example a
```

A **variable** is a name for a value; this line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"14a"`. The figure files are named after it.

```
def find_repository_root():
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. `Path.cwd()` is the folder in which Jupyter runs the notebook (the folder that holds it), and `.resolve()` writes it as a complete address. `here.parents` lists the folders above it; `[here, *here.parents]` is the list that starts with `here` and continues with them (the star unpacks one list into another). The `for` loop visits these folders one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains the file `Revision /textbook/requirements.txt` (the list of the book's packages) is the repository, and `return` hands it back. If no folder qualifies, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The comment lines say in short what this paragraph explains. The first statement calls the function and names its result `REPO`. It is never printed, because it differs from computer to computer, while the printed output of a notebook must not. The second line chooses where files are written. `os.environ` holds the **environment variables** of the program (named texts that it receives from the computer); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and the default `str(REPO)` (the repository folder as a string) otherwise. When you run the notebook the variable is not set, so the files go into the repository; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    return REPO / relative

def output_file(relative):
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small functions. `repository_file("Revision/...")` gives the full path of a repository file, for reading a Revision record. `output_file("Revision/...")` gives the full path at which to write

a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder that will hold it, together with any missing folder above it, and does nothing if the folder exists.

```
def say(text):
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, the width of a page of the book; `textwrap.fill` breaks the text at blanks and starts every line after the first with four blanks. This is why some printed lines below continue on an indented second line.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

matplotlib reads personal settings from a file on your computer if you have one; `matplotlib.rcdefaults()` returns to the built-in settings, so that the figures are the same on every computer. `plt.rcParams.update({...})` then sets four settings for every figure: the size (7.0 by 4.2 inches), the size of the letters (10 points) and a faint grid of lines behind the curves (`grid.alpha` 0.3 means 30 per cent opaque). The braces make a **dictionary**: pairs of a key and a value, written `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: a name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/14a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes an empty JSON dictionary `{}` and a line end into the captions file; `encoding="utf-8"` fixes how letters are stored as bytes, and `newline="\n"` stores the same line end on Windows, macOS and Linux.

```
def save_figure(fig, name, caption):
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
```

```
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

`setdefault(name, value)` returns the number already stored for this figure name, or stores and returns one more than the number of figures so far: the figures are numbered 1, 2, 3, and a cell that is run twice keeps its number. The file name joins the notebook id, the number and the name, for example `14a_1_hidden_coordinate.png`. `fig.savefig` writes a PNG picture with 150 dots per inch, cuts away the empty margin (`bbox_inches="tight"`) and stores no program name (`metadata`), so that two runs write the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time at the end of the cell. The caption is stored, the whole dictionary is written to the captions file (`json.dumps` turns it into JSON text with sorted keys, one item per line), `display(Image(...))` shows the saved picture below the cell, and the last line prints where it was saved. The caption given to `save_figure` is the caption that the book prints under the figure.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection, written with square brackets). `check` is the function behind every PASS line: if the condition is false, `raise AssertionError(...)` stops the notebook with a message that names the check; otherwise the name is appended to the list and the line PASS and the name is printed. When the check repeats a number or a verdict of the Revision record, the argument `record` names the record file and its check, and a second line starting with `reproduces` is printed. (An `if` statement is used instead of Python's `assert`, because `python -O` would skip an `assert`.)

```
def report(label, value, unit=""):
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT (the provenance file of the notebook lists these lines). `x if c else y` is the value `x` when `c` is true and `y` otherwise, so the unit is added

only when one is given. `all_checks_passed` prints the last line of the notebook with the number of checks that passed; `len` is the length of a list. The last statement prints the only output of the cell, Out [1].

In [2], the gammas and the Clifford relation.

```
import numpy as np  # floating-point arrays and matrices
import sympy as sp  # exact algebra with symbols
```

numpy computes with **floating-point numbers** (numbers with about 16 significant digits, which the computer rounds after every operation); sympy computes **exactly** with whole numbers, fractions and symbols such as H. Every identity of this notebook is checked with sympy, so a PASS means an exact identity, not an approximation; numpy is used only for the figures.

```
PY_REPORT = "Revision/kohn_sham/reports/ks-theory-python.json"
WL_REPORT = "Revision/kohn_sham/reports/ks-theory-wolfram.json"
```

The two reports of the Revision record of the Kohn-Sham theory: the sympy checker and the WolframScript verifier.

```
def record_check(name):
    verdicts = {}
    for report in (PY_REPORT, WL_REPORT):
        data = json.loads(repository_file(report).read_text(encoding="utf-8"))
        found = [c["verdict"] for c in data["checks"] if c["name"] == name]
        verdicts[report] = found[0] if found else "absent"
    return (verdicts[PY_REPORT] == "PASS"
            and verdicts[WL_REPORT] in ("PASS", "absent"))
```

`record_check(name)` reads both reports (`read_text` reads the file, `json.loads` turns the JSON text into Python lists and dictionaries) and looks for the check called `name` in the list `data["checks"]`. The bracketed expression is a **list comprehension**: it collects `c["verdict"]` for every check `c` whose name matches. If the check is found, its verdict (PASS or FAIL) is kept; otherwise the word absent. The function returns true when the sympy report says PASS and the Wolfram report says PASS or has no check of that name. Every check below that repeats a Revision check uses it, so the notebook passes only if the record itself passed.

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
g = [sp.Matrix(m) for m in fixture["gamma"]]  # g[0] = gamma^(x0) ... g[7] = gamma^(x7)
eta = [int(v) for v in fixture["eta"]]  # +1 space-like, -1 time-like
g0, g1, g2, g3, g4, g5, g6, g7 = g  # gN is gamma^(xN)
I16, Z16 = sp.eye(16), sp.zeros(16)  # the 16 x 16 unit and zero matrices
```

The record `Revision/algebra/gammas.json` stores the eight matrices as lists of rows of whole numbers, in the order $x_0, \ldots, x_7$. `sp.Matrix(m)` turns each into an exact sympy matrix; `g[0]` is $\gamma^{(x_0)}$ and `g[7]` is $\gamma^{(x_7)}$ (Python counts from 0, like the author's coordinates). `eta` is the list of the eight signs. The third line gives the eight matrices the names `g0` to `g7` (unpacking a list into names), so `gN` is $\gamma^{(x_N)}$. `sp.eye(16)` is the unit matrix and `sp.zeros(16)` the zero matrix.

```
say(f"eta in the order x0 ... x7: {eta}")
entries = sorted({int(e) for m in g for e in m})  # the different entries
say(f"the entries of the eight gamma matrices are the integers {entries}")
```

The first line prints the signs. The second collects every entry of every matrix into a **set** (braces without colons: a collection in which each value occurs once) and sorts it; the printout shows that the only entries are -1, 0 and 1: the gammas are real.

```
clifford = all(g[a] * g[b] + g[b] * g[a] == (2 * eta[a] if a == b else 0) * I16
               for a in range(8) for b in range(8))
check(clifford and eta == [1, 1, 1, 1, -1, -1, -1, -1]
      and record_check("clifford_relation"),
      "the Clifford relation gamma^a gamma^b + gamma^b gamma^a = 2 eta^ab",
      record=f"{PY_REPORT}, check clifford_relation")
```

`range(8)` runs through 0 to 7, so the two `for` clauses visit all 64 pairs (a, b); `all(...)` is true when every comparison is true. For each pair the anticommutator $\gamma^a\gamma^b + \gamma^b\gamma^a$ (the operator `*` multiplies sympy matrices) is compared exactly with $2\eta^{aa}$ times the unit matrix when $a = b$ and with the zero matrix otherwise. The check also requires the signs $\eta = (+,+,+,+,-,-,-,-)$ and the recorded verdict; Out [2] shows its PASS line and the record it reproduces.

In [3], the matrices C, B and Γ.

```
C = g0 * g1 * g2 * g3  # the matrix of the Dirac adjoint
B = -sp.I * C * g4  # the matrix of the positive inner product
Gamma = g0 * g1 * g2 * g3 * g4 * g5 * g6 * g7  # the chirality matrix
```

The three products of Chapter 5; `sp.I` is the imaginary unit i.

```
check(C.T == C and C * C == I16 and B.H == B and B * B == I16
      and Gamma == sp.diag(*([-1] * 8 + [1] * 8)) and record_check("C_B_Gamma"),
      "C real symmetric with C^2 = 1, B Hermitian with B^2 = 1, Gamma = diag(-1, 1)",
      record=f"{PY_REPORT}, check C_B_Gamma")
```

`C.T` is the transpose and `B.H` the conjugate transpose. `[-1] * 8 + [1] * 8` is the list of eight entries -1 followed by eight entries $+1$, and `sp.diag(*...)` the diagonal matrix with these entries (the star hands the list over as separate numbers). So the check says: C is symmetric (it is real because the gammas are) with $C^2 = 1$; B is Hermitian with $B^2 = 1$; $\Gamma = \mathrm{diag}(-1_8, 1_8)$.

```
check(B * C == -sp.I * g4 and C * g4 == sp.I * B and C * B * C == B
      and record_check("BC_and_Cg4"),
      "BC = -i gamma^(x4), C gamma^(x4) = i B and C B C = B",
      record=f"{PY_REPORT}, check BC_and_Cg4")
```

Three product rules used in Section 14.5 and in Notebook 14d. They follow from the definitions: $C\gamma^{(x_4)} = iB$ is $B = -iC\gamma^{(x_4)}$ multiplied by i; $BC = -iC\gamma^{(x_4)}C = -iCC\gamma^{(x_4)} = -i\gamma^{(x_4)}$ because C commutes with $\gamma^{(x_4)}$ (a time-like gamma is not a factor of C, and C has four factors) and $C^2 = 1$; and $CBC = C(-i\gamma^{(x_4)}) = -iC\gamma^{(x_4)} = B$.

In [4], the hidden coordinate and the determinant.

```
H = sp.symbols("H", positive=True)  # the author's constant H > 0
y_neg = sp.symbols("y", negative=True)  # the hidden coordinate inside the patch
x0, z = sp.symbols("x0 z", positive=True)
```

`sp.symbols` makes symbols; the options tell sympy what it may assume: $H > 0$, $y < 0$ (inside the patch), $x_0 > 0$ and $z > 0$. With these assumptions sympy can simplify square roots and inverse sines correctly.

```
z_of_y = sp.asin(sp.exp(6 * H * y_neg))  # z(y): the solution of sin z = e^(6Hy)
dx0_dy = sp.diff(z_of_y / (6 * H), y_neg)  # x0 = z/(6H) differentiated in y
ok_line = sp.simplify(sp.cot(z_of_y) ** 2 * dx0_dy ** 2 - 1) == 0  # g00 dx0^2 = dy^2
```

The first line solves $\sin z = e^{6Hy}$ for z with the inverse sine, `sp.asin`. The second differentiates $x_0 = z/(6H)$ with respect to y (`sp.diff(expression, variable)`). The third checks step 2 of Section 14.2 in the form $\cot^2 z\,(dx_0/dy)^2 = 1$, which is $\cot^2 z\,dx_0^2 = dy^2$: `sp.simplify` brings the expression to its simplest form, and the comparison `== 0` asks whether it is exactly zero.

```
ok_warp = sp.simplify(sp.sin(z_of_y) ** sp.Rational(1, 3)
                      - sp.exp(2 * H * y_neg)) == 0  # sin^(1/3) z = e^(2Hy)
ok_dy = sp.simplify(sp.diff(sp.log(sp.sin(6 * H * x0)) / (6 * H), x0)
                    - sp.cot(6 * H * x0)) == 0  # dy/dx0 = cot z
check(ok_line and ok_warp and ok_dy and record_check("geometry_hidden_coordinate"),
      "y = ln(sin z)/(6H): dy = cot z dx0 and sin^(1/3) z = e^(2Hy)",
      record=f"{PY_REPORT}, check geometry_hidden_coordinate")
```

`sp.Rational(1, 3)` is the exact fraction 1/3 (the Python expression `1/3` would be a rounded floating-point number). The first test is step 3 of Section 14.2, $\sin^{1/3} z = e^{2Hy}$; the second is step 1, $dy/dx_0 = \cot z$, differentiating the definition $y = \ln(\sin 6Hx_0)/(6H)$ directly. The check combines the three tests.

```
a0 = sp.symbols("a0", real=True)  # the value of a4 at one slice
third = sp.Rational(1, 3)
metric_x0 = ([sp.exp(2 * a0) * sp.sin(z) ** third] * 3 + [-1]
             + [-sp.exp(-2 * a0) * sp.sin(z) ** third] * 3 + [sp.cot(z) ** 2])
det_x0 = sp.simplify(sp.Abs(sp.prod(metric_x0)))  # |det g| in the x0 chart
say(f"|det g| in the x0 chart of the author = {det_x0}")
check(sp.simplify(det_x0 - sp.cos(z) ** 2) == 0 and record_check("geometry_sqrt_det"),
      "|det g| = cos^2 z in the x0 chart; it does not contain a4",
      record=f"{PY_REPORT}, check geometry_sqrt_det")
```

`metric_x0` is the list of the eight diagonal entries of the author's metric in his x_0 chart (a list times 3 repeats it three times; `+` joins lists). The determinant of a diagonal matrix is the product of its diagonal entries (`sp.prod`), and `sp.Abs` takes its absolute value. sympy prints `cos(z)**2` (Out [4]; `**` is the power): the cubes of the 3-space and extra-time entries give $e^{6a_0}\sin z$ and $-e^{-6a_0}\sin z$, the factors e^{6a_0} and e^{-6a_0} cancel, the signs $(-1)(-1) = 1$, and $\sin z \cdot \sin z \cdot \cot^2 z = \cos^2 z$. The square root is $\cos z$, as Section 14.2 says.

In [5], figure 1.

```
z_values = np.linspace(1e-3, np.pi / 2, 600)  # z from almost 0 to pi/2
y_of_z = np.log(np.sin(z_values)) / 6.0  # y = ln(sin z)/(6H) with H = 1
y_values = np.linspace(-3.0, 0.0, 301)  # the hidden coordinate from -L to 0
```

`np.linspace(start, stop, count)` makes `count` equally spaced numbers from `start` to `stop`; `1e-3` means 10^{-3} (the value $z = 0$ itself would give $\ln 0$). numpy applies `np.log` and `np.sin` to every number of an array at once. The third line is the hidden coordinate from the cutoff $-L = -3$ of the Revision solver to the brane.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(z_values, y_of_z, color="C0")
left.set_xlabel("$z = 6 H x_0$ (radians)")
left.set_ylabel("$y = \\ln(\\sin z)/(6H)$")
left.set_title("the hidden coordinate $y$ ($H = 1$)")
left.annotate("tip: $y \\to -\\infty$", (0.03, -1.0), fontsize=9)
left.annotate("brane: $y = 0$", (1.05, -0.15), fontsize=9)
```

`plt.subplots(1, 2, ...)` makes a figure with one row of two panels (called **axes** in matplotlib), named `left` and `right`, 10 by 4 inches. `plot(x, y)` draws a curve; `"C0"` is the first colour of matplotlib's standard list. The labels are written in LaTeX between dollar signs, with a doubled backslash because a single backslash starts a special character in a Python string. `annotate(text, (x, y))` writes a text at a point of the panel.

```
right.semilogy(y_values, np.exp(y_values), label="warp $W = e^{Hy}$")
right.semilogy(y_values, np.exp(2 * y_values), "--",
               label="$\\sin^{1/3} z = W^2$")
right.semilogy(y_values, np.exp(6 * y_values), ":",
               label="volume factor $\\sqrt{|g|} = W^6$")
right.set_xlabel("$y$ (units of $1/H$)")
right.set_ylabel("factor (logarithmic scale)")
right.set_title("the factors of the warped metric")
right.legend(fontsize=8)
```

`semilogy` draws with a **logarithmic vertical axis**: equal distances mean equal factors (each tick is ten times the one below). On such an axis an exponential e^{cy} is a straight line of slope c. The three curves are W, W^2 and W^6 with $H = 1$; the third argument of `semilogy`, a short text called a **format string**, sets the line style: two hyphens draw a dashed line and a colon a dotted one (the plain `plot` lines of this book use the same format strings); `legend` shows the `label` texts in a box.

```
save_figure(fig, "hidden_coordinate",
            "Left: the hidden coordinate $y = \\ln(\\sin z)/(6H)$ against "
            ...)
```

The figure is saved as `14a_1_hidden_coordinate.png` with its caption (the long caption, printed under the figure in Section 14.10, is shortened here to `...`). **What figure 14a.1 shows.** Left: y against z; the curve drops steeply to minus infinity as $z \to 0$ (the tip; the plot stops at $z = 10^{-3}$, $y = -1.15$) and approaches 0 with zero slope at the brane $z = \pi/2$ (because $dy/dz = \cot z/(6H)$ vanishes there). Right: the three straight lines with slopes 1, 2 and 6 on the logarithmic axis; all

equal 1 at the brane, and at the cutoff $y = -3$ the volume factor is $e^{-18} \approx 1.5 \times 10^{-8}$. This small proper volume near the tip is why the proper densities of Notebook 14d become large there.

In [6], figure 2.

```
a4_values = np.linspace(0.0, 2.0, 201)  # a4 along the history (= x4 for A = H = 1)
slices = [0.0, 0.5, 1.0, 1.5, 2.0]  # the five slices of the Revision solver
```

The values of a_4 from 0 to 2 (along the history $a_4 = AHx_4$ with $A = H = 1$ these are also the times x_4), and the five slices of the Revision runs.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
left.plot(a4_values, np.exp(a4_values), label="3-space: $e^{a_4}$ (inflates)")
left.plot(a4_values, np.exp(-a4_values), "--",
          label="extra times: $e^{-a_4}$ (deflates)")
left.plot(a4_values, np.exp(3 * a4_values) * np.exp(-3 * a4_values), ":",
          color="black", label="7-volume: $e^{3a_4} e^{-3a_4} = 1$")
left.set_xlabel("$a_4 = A H x_4$ (with $A = H = 1$: the time $x_4$)")
left.set_ylabel("scale factor at the brane $y = 0$")
left.set_title("inflation and deflation along the history")
left.legend(fontsize=8)
```

The left panel draws the 3-space scale factor e^{a_4}, the extra-time scale factor e^{-a_4} and the product of their cubes, all at the brane where $W = 1$.

```
for a in slices:  # one curve per slice
    right.semilogy(y_values, np.exp(-y_values - a), label=f"$a_{{4,0}} = {a}$")
right.set_xlabel("$y$ (units of $1/H$)")
right.set_ylabel("$\\kappa = e^{-Hy - a_{4,0}}$ (logarithmic)")
right.set_title("the momentum weight at five slices")
right.legend(fontsize=8)
save_figure(fig, "inflation_deflation",
            ...)
```

The loop draws the momentum weight $\kappa = e^{-y-a}$ ($H = 1$) for each slice a; in an f-string a doubled brace `{{` prints one brace, so the label reads $a_{4,0} = 0.5$ and so on. **What figure 14a.2 shows.** Left: e^{a_4} grows to $e^2 \approx 7.4$, e^{-a_4} falls to $e^{-2} \approx 0.14$, and the dotted line stays at 1: inflation of 3-space and deflation of the extra times exactly balance in the volume. Right: five parallel straight lines falling from left to right: κ is largest at the tip ($e^3 \approx 20$ at $y = -3$ for the slice 0), and each later slice lies lower by the factor $e^{-0.5}$: the same coordinate momentum costs less energy as 3-space inflates.

In [7], the spin connection. This cell carries out Steps 1 to 3 of Section 14.4 with sympy.

```
X = (sp.Symbol("y", real=True),) + sp.symbols("x1:8", real=True)  # y, x1..x7
Y, x4 = X[0], X[4]  # the hidden coordinate and the time
a4 = sp.Function("a4", real=True)(x4)  # a4 is any function of the time x4
a4p = sp.diff(a4, x4)  # its derivative a4'
```

`sp.symbols("x1:8")` makes the seven symbols $x_1, \ldots, x_7$; a one-element **tuple** (a list in round brackets) with the symbol y put in front of them gives the eight coordinates, with y in the place of x_0 (position 0), so `X[k]` is x_k for $k \geq 1$. The frame factors `vb` are in the same order: 1 for y, $e^{a_4}W$ for x_1, x_2, x_3, 1 for x_4 and $e^{-a_4}W$ for the extra times (the metric on the background $b_4 = 1$; the author's metric of 2026-10-14 has the factor $b_4^{1/2}$ in the extra times, Chapter 3). `sp.Function("a4")(x4)` is an unknown function $a_4(x_4)$, so everything below holds along every history; `a4p` is its derivative a_4'.

```
W = sp.exp(H * Y)  # the warp factor
vb = [sp.Integer(1)] + [sp.exp(a4) * W] * 3 + [sp.Integer(1)] + [sp.exp(-a4) * W] * 3
gdiag = [eta[i] * vb[i] ** 2 for i in range(8)]  # the diagonal metric entries
```

`vb` is the list of the eight scale factors h of Section 14.2 (`sp.Integer(1)` is the exact number 1), and `gdiag` the metric entries $\eta_{ii}h_i^2$, which reproduce the warped form.

```
def christoffel(n, m, k):
    total = 0
    if m == n:
        total += sp.diff(gdiag[n], X[k])
    if k == n:
        total += sp.diff(gdiag[n], X[m])
    if m == k:
        total -= sp.diff(gdiag[m], X[n])
    return sp.simplify(total / (2 * gdiag[n]))
```

Step 1 of Section 14.4, the formula for ${\Gamma^n}_{mk}$ of a diagonal metric: each `if` adds one of the three terms when its Kronecker delta is 1 (`+=` adds to a variable, `-=` subtracts).

```
Chr = [[[christoffel(n, m, k) for k in range(8)] for m in range(8)]
       for n in range(8)]
S = [[(g[a] * g[b] - g[b] * g[a]) / 4 for b in range(8)] for a in range(8)]
```

`Chr[n][m][k]` holds all $8^3 = 512$ Christoffel symbols, and `S[a][b]` the 64 generators $S^{ab} = \frac{1}{4}(\gamma^a\gamma^b - \gamma^b\gamma^a)$.

```
Omega = []  # Omega[mu] is the 16 x 16 matrix Omega_mu
for mu in range(8):
    total = sp.zeros(16)
    for A in range(8):
        for Bi in range(8):
            w = (vb[A] * sp.diff(1 / vb[Bi], X[mu]) if A == Bi else 0) \
                + vb[A] * Chr[A][mu][Bi] / vb[Bi]  # omega_mu^A_B (step 2)
            w = sp.simplify(w)
            if w != 0:
                total += sp.Rational(1, 2) * eta[A] * w * S[A][Bi]  # step 3
    Omega.append(sp.simplify(total))
```

For each direction μ the double loop over the frame indices A and B (`Bi`, because `B` is the matrix B) computes the connection coefficient ${\omega_\mu}^A{}_B$ of Step 2 (a backslash at the end of a line continues

the statement on the next line) and adds $\frac{1}{2}\eta_{AA}\,\omega_\mu{}^A{}_B\,S^{AB}$ to the matrix Ω_μ (Step 3); terms with a zero coefficient are skipped to save time. `append` puts the finished Ω_μ at the end of the list.

```
compatible = all(
    (sp.diff(g[n] / vb[n], X[m])
     + sum((Chr[n][m][l] * g[l] / vb[l] for l in range(8)), Z16)
     + Omega[m] * g[n] / vb[n] - g[n] / vb[n] * Omega[m]).applyfunc(sp.simplify)
    .is_zero_matrix for m in range(8) for n in range(8))
check(compatible and record_check("spin_connection_compatibility"),
      "the curved gammas are covariantly constant (64 matrix equations)",
      record=f"{PY_REPORT}, check spin_connection_compatibility")
```

The proof that Ω_μ is the right connection: the **curved gammas** $\gamma^\nu = \gamma^{(\nu)}/h_\nu$ must be **covariantly constant**, $\partial_\mu\gamma^\nu + \Gamma^\nu{}_{\mu\lambda}\gamma^\lambda + [\Omega_\mu, \gamma^\nu] = 0$, for all 64 pairs (μ, ν), where $[X, Y] = XY - YX$ is the **commutator**. `sum(..., Z16)` adds sixteen-by-sixteen matrices starting from the zero matrix; `applyfunc(sp.simplify)` simplifies every entry; `.is_zero_matrix` is true when every entry is 0.

```
slash = sp.simplify(sum((g[m] / vb[m] * Omega[m] for m in range(8)), Z16))
check((slash - 3 * H * g0).is_zero_matrix and record_check("spin_connection_slash_3H"),
      "gamma^mu Omega_mu = 3H gamma^(x0) exactly, for every history a4(x4)",
      record=f"{PY_REPORT}, check spin_connection_slash_3H")
```

The sum $\sum_\mu \gamma^\mu\Omega_\mu$ (often written with a slash through Ω, hence the name), compared with $3H\gamma^{(x_0)}$. Out [7] shows the two PASS lines.

In [8], where 3Hγ(x0) comes from.

```
names = ["x0 (y)", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
PRIME = sp.Symbol("da4dx4")  # a name for the derivative da4/dx4 in the printout
c4_list, c0_list = [], []  # the coefficients of gamma^(x4) and gamma^(x0)
split_ok = True
```

Names for the printout, a symbol that stands for a_4' when it is printed, two empty lists and a flag that starts true.

```
for m in range(8):
    part = sp.simplify(g[m] / vb[m] * Omega[m])  # the contribution of direction m
    c4 = sp.simplify(-(part * g4).trace() / 16)
    c0 = sp.simplify((part * g0).trace() / 16)
    split_ok &= (part - c4 * g4 - c0 * g0).applyfunc(sp.simplify).is_zero_matrix
    c4_list.append(c4)
    c0_list.append(c0)
    shown_c4 = str(c4.subs(a4p, PRIME))  # write da4dx4 for da4/dx4
    say(f"direction {names[m]:7}: c4 = {shown_c4:12} c0 = {c0}")
check(split_ok, "every contribution is c4 gamma^(x4) + c0 gamma^(x0)")
```

For each direction the contribution $X = (\gamma^{(\mu)}/h_\mu)\Omega_\mu$ of Step 4. If $X = c_4\gamma^{(x_4)} + c_0\gamma^{(x_0)}$, then $X\gamma^{(x_4)} = -c_4 + c_0\gamma^{(x_0)}\gamma^{(x_4)}$, and since the **trace** (the sum of the diagonal entries) of the unit

matrix is 16 and that of a product of two different gammas is 0, $\mathrm{tr}(X\gamma^{(x_4)}) = -16c_4$; in the same way $\mathrm{tr}(X\gamma^{(x_0)}) = 16c_0$. These are the second and third lines. The fourth line checks that X is exactly $c_4\gamma^{(x_4)} + c_0\gamma^{(x_0)}$ (`&=` keeps the flag true only if every direction passes). `subs(a4p, PRIME)` replaces the derivative by the printable name, and the format `:7` and `:12` pads the texts to 7 and 12 characters, so that the printout forms columns. Out [8] shows $c_4 = a_4'/2$ and $c_0 = H/2$ for x_1, x_2, x_3; $c_4 = 0$, $c_0 = 0$ for x_4 and for y; $c_4 = -a_4'/2$ and $c_0 = H/2$ for x_5, x_6, x_7: exactly Step 5 of Section 14.4.

```
inflating = sp.simplify(sum(c4_list[1:4]))  # x1, x2, x3
deflating = sp.simplify(sum(c4_list[5:8]))  # x5, x6, x7
say("sum of c4 over the inflating directions x1, x2, x3: "
    f"{inflating.subs(a4p, PRIME)}")
say("sum of c4 over the deflating directions x5, x6, x7: "
    f"{deflating.subs(a4p, PRIME)}")
say(f"sum of c0 over all directions: {sp.simplify(sum(c0_list))}")
```

`c4_list[1:4]` is the part of the list from position 1 up to, but not including, position 4 (the directions x_1, x_2, x_3), and `c4_list[5:8]` the positions 5 to 7 (x_5, x_6, x_7). The printout: $3a_4'/2$, $-3a_4'/2$ and $3H$.

```
check(sp.simplify(inflating - sp.Rational(3, 2) * a4p) == 0
      and sp.simplify(deflating + sp.Rational(3, 2) * a4p) == 0
      and Omega[4].is_zero_matrix and Omega[0].is_zero_matrix
      and record_check("spin_connection_time_terms_cancel")
      and record_check("spin_connection_time_term_value"),
      "the da4/dx4 pieces +3/2 and -3/2 cancel; Omega_x4 = Omega_y = 0",
      record=f"{PY_REPORT}, checks spin_connection_time_terms_cancel and "
             "spin_connection_time_term_value")
```

The two facts of the record: the pieces $+\frac{3}{2}a_4'$ of the inflating and $-\frac{3}{2}a_4'$ of the deflating directions, and $\Omega_{x_4} = \Omega_y = 0$ (positions 3 and 7 of the list).

In [9], figure 3.

```
c4_numbers = [float(c.subs(a4p, 1).subs(H, 1)) for c in c4_list]  # da4/dx4 = H = 1
c0_numbers = [float(c.subs(a4p, 1).subs(H, 1)) for c in c0_list]
positions = np.arange(8)  # one group of two bars per direction
```

The coefficients become ordinary numbers by putting $a_4' = 1$ and $H = 1$ (`float` turns an exact number into a floating-point one); `np.arange(8)` is the array 0, 1, ..., 7, one position per direction.

```
fig, ax = plt.subplots(figsize=(8.0, 4.0))
ax.bar(positions - 0.2, c4_numbers, width=0.38,
       label="coefficient of $\\gamma^{(x_4)}$ (per unit $da_4/dx_4$)")
ax.bar(positions + 0.2, c0_numbers, width=0.38,
       label="coefficient of $\\gamma^{(x_0)}$ (per unit $H$)")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xticks(positions)
ax.set_xticklabels(["$x_0$", "$x_1$", "$x_2$", "$x_3$", "$x_4$", "$x_5$", "$x_6$",
                    "$x_7$"])
```

`bar(x, heights, width=...)` draws bars; the two sets are shifted by -0.2 and $+0.2$ so that they stand side by side. `axhline` draws the horizontal line at 0; `set_xticks` and `set_xticklabels` put the names of the directions under the groups.

```
ax.set_xlabel("direction $\\mu$ of the term $(\\gamma^{(\\mu)}/h_\\mu)\\,"
              "\\Omega_\\mu$")
ax.set_ylabel("coefficient")
ax.set_title("$\\gamma^\\mu\\Omega_\\mu = 3H\\gamma^{(x_0)}$: "
             "the $da_4/dx_4$ pieces cancel")
ax.legend(fontsize=8)
save_figure(fig, "spin_connection_terms",
            ...)
```

Labels, title, legend and saving. **What figure 14a.3 shows.** Above x_1, x_2, x_3 two bars of height $+\frac{1}{2}$; above x_5, x_6, x_7 a bar of height $-\frac{1}{2}$ (the coefficient of $\gamma^{(x_4)}$) and one of $+\frac{1}{2}$ (the coefficient of $\gamma^{(x_0)}$); nothing above x_4 and x_0. The six left bars of the $\gamma^{(x_4)}$ coefficient add to zero (inflation against deflation), the six bars of the $\gamma^{(x_0)}$ coefficient add to $3H$.

In [10], the factor W^(-3).

```
k1, k2, k3 = sp.symbols("k1 k2 k3", real=True)  # the 3-momentum
chi = sp.Matrix([sp.Function(f"chi{i}")(Y, x4) for i in range(16)])
phase = sp.exp(sp.I * (k1 * X[1] + k2 * X[2] + k3 * X[3]))  # the plane wave
kappa = sp.exp(-H * Y - a4)  # the momentum weight
```

The three components of $\mathbf{k}$; a column `chi` of 16 unknown functions $\chi_0(y, x_4), \ldots, \chi_{15}(y, x_4)$; the plane wave $e^{i\mathbf{k}\cdot\mathbf{x}}$; and the weight $\kappa = e^{-Hy - a_4(x_4)}$.

```
def dirac(Psi):
    result = sp.zeros(16, 1)
    for m in range(8):
        result += g[m] / vb[m] * (sp.diff(Psi, X[m]) + Omega[m] * Psi)
    return result
```

The Dirac operator $\gamma^\mu D_\mu \Psi = \sum_\mu (\gamma^{(\mu)}/h_\mu)(\partial_\mu \Psi + \Omega_\mu \Psi)$ with the spin connection of In [7]; `sp.zeros(16, 1)` is a zero column.

```
reduced = (g0 * sp.diff(chi, Y) + g4 * sp.diff(chi, x4)
           + sp.I * kappa * (k1 * g1 + k2 * g2 + k3 * g3) * chi)
with_W3 = sp.simplify(dirac(phase * W ** -3 * chi) / (phase * W ** -3))
without_W3 = sp.simplify(dirac(phase * chi) / phase)
```

`reduced` is the operator of Step 6 of Section 14.4 applied to χ. `with_W3` applies the full Dirac operator to $e^{i\mathbf{k}\cdot\mathbf{x}} W^{-3}\chi$ and divides by the common factor; `without_W3` does the same without W^{-3}.

```
check((with_W3 - reduced).applyfunc(sp.simplify).is_zero_matrix
      and record_check("ansatz_removes_spin_connection"),
      "with W^(-3): the reduced operator g0 d_y + g4 d_x4 + i kappa k.g, exactly",
```

```
      record=f"{PY_REPORT}, check ansatz_removes_spin_connection")
check((without_W3 - reduced - 3 * H * g0 * chi).applyfunc(sp.simplify)
      .is_zero_matrix and record_check("ansatz_without_W3_term_survives"),
      "without W^(-3) the term 3H gamma^(x0) chi survives",
      record=f"{PY_REPORT}, check ansatz_without_W3_term_survives")
```

With the factor the result equals the reduced operator exactly; without it, the difference is exactly $3H\gamma^{(x_0)}\chi$. The cell takes about 5 seconds.

In [11], the Hamiltonian and its Hermitian pieces.

```
M, v = sp.symbols("M v", real=True)  # effective mass and vector potential
chi_s = sp.Matrix(sp.symbols("c0:16"))  # chi at one point (16 symbols)
dchi_s = sp.Matrix(sp.symbols("d0:16"))  # d chi/dy at that point
kap = sp.symbols("kappa", positive=True)
kg = kap * (k1 * g1 + k2 * g2 + k3 * g3)  # kappa k.gamma
```

The derivation of Step 7 is pure algebra at one point, so χ and χ' are replaced by two columns of 16 independent symbols, and κ by a positive symbol.

```
# line 1 and 2: d chi/dx4 = -g4 [(M - i v g4) chi - g0 chi' - i kappa k.g chi]
dt_chi = -g4 * ((M * I16 - sp.I * v * g4) * chi_s - g0 * dchi_s - sp.I * kg * chi_s)
# line 3: h chi with the four pieces of h
h_chi = (sp.I * g4 * g0 * dchi_s - kap * g4 * (k1 * g1 + k2 * g2 + k3 * g3) * chi_s
         + M * (-sp.I * g4) * chi_s + v * chi_s)
check((sp.I * dt_chi - h_chi).expand().is_zero_matrix,
      "i d_x4 chi = h chi with h = i g4 g0 d_y - kappa k_j g4 g_j + M(-i g4) + v")
```

The two comment lines name the lines of Step 7 that the statement below each writes out. `dt_chi` is $\partial_{x_4}\chi$ from the first two lines of Step 7 (move the terms, multiply by $-\gamma^{(x_4)}$); `h_chi` is $h\chi$ with the four pieces of the third line. The check confirms $i\,\partial_{x_4}\chi = h\chi$ after multiplying out (`expand`).

```
hermitian = ((g4 * g0).T == g4 * g0 and all((-g4 * gj).H == -g4 * gj
                                            for gj in (g1, g2, g3))
             and (-sp.I * g4).H == -sp.I * g4 and (-sp.I * g4) ** 2 == I16)
check(hermitian and record_check("hamiltonian_16_hermitian"),
      "g4 g0 real symmetric; g4 g_j and -i g4 Hermitian; (-i g4)^2 = 1",
      record=f"{PY_REPORT}, check hamiltonian_16_hermitian")
```

The Hermitian pieces of Section 14.4: $\gamma^{(x_4)}\gamma^{(x_0)}$ symmetric, $-\gamma^{(x_4)}\gamma^{(x_j)}$ Hermitian for the three 3-space directions, $-i\gamma^{(x_4)}$ Hermitian with square 1.

In [12], the labels J, K1, K2 and the projectors.

```
A0, A1, A4 = g0, g0 * g1, g0 * g4  # the matrices of the equation (k along x1)
J, K1, K2 = g0 * g1 * g4, g2 * g3, g5 * g6
commute = all((P * Q - Q * P).is_zero_matrix for P in (J, K1, K2)
              for Q in (A0, A1, A4, B, C, J, K1, K2))
check(commute and J * J == I16 and K1 * K1 == -I16 and K2 * K2 == -I16
      and record_check("blocks_commuting_set"),
      "J, K1, K2 commute with A0, A1, A4, B, C and each other; J^2 = 1, K^2 = -1",
      record=f"{PY_REPORT}, check blocks_commuting_set")
```

The matrices of Section 14.5; `commute` tests the 24 commutators of each of J, K_1, K_2 with each of A_0, A_1, A_4, B, C, J, K_1, K_2; the check adds the three squares.

```
labels = [(j, s2, s3) for j in (1, -1) for s2 in (1, -1) for s3 in (1, -1)]
projectors = [(I16 + j * J) / 2 * (I16 - sp.I * s2 * K1) / 2
              * (I16 - sp.I * s3 * K2) / 2 for (j, s2, s3) in labels]
check(all(P.rank() == 2 and (P * P - P).is_zero_matrix for P in projectors)
      and sum(projectors, Z16) == I16 and record_check("blocks_projectors"),
      "eight projectors P(j, s2, s3) of rank 2 that add up to 1",
      record=f"{PY_REPORT}, check blocks_projectors")
```

`labels` lists the eight triples in the order of the record, $(1,1,1), (1,1,-1), \ldots, (-1,-1,-1)$. `projectors` builds $P(j, s_2, s_3)$ for each. The check: each has `rank()` 2 and $P^2 = P$, and the eight add up to the unit matrix.

In [13], the block basis.

```
columns, seeds = [], []
for P in projectors:
    P_plus = P * (I16 + g0) / 2  # project on gamma^(x0) = +1 inside the block
    c = next(c for c in range(16) if not P_plus[:, c].is_zero_matrix)
    seeds.append(c)
    v_plus = 8 * P_plus[:, c]
    columns += [v_plus, A1 * v_plus]  # v+ and v- = A1 v+
```

For each block: `P_plus` projects onto the block and onto $\gamma^{(x_0)} = +1$. Its columns are the images of the unit columns e_c (`P_plus[:, c]` is column c). `next(...)` returns the first c whose column is not zero, the **seed**. Then $v_+ = 8\,P_+ e_c$, and both v_+ and $v_- = A_1 v_+$ are added to the list (`+=` appends a list to a list).

```
U = sp.Matrix.hstack(*columns)  # 16 x 16, entries 0, +-1, +-i
V = U / (2 * sp.sqrt(2))  # the unitary block basis
say(f"seed columns c of the eight blocks: {seeds}")
```

`hstack` places the 16 columns side by side into the matrix U; $V = U/(2\sqrt{2})$. Out [13] prints the seeds 4, 0, 0, 4, 0, 4, 4, 0.

```
theory = json.loads(repository_file("Revision/kohn_sham/ks-theory.json")
                    .read_text(encoding="utf-8"))
as_number = {"0": 0, "1": 1, "-1": -1, "I": sp.I, "-I": -sp.I}
U_record = sp.Matrix([[as_number[e] for e in row] for row in
                      theory["blockBasis"]["unnormalisedColumns2Sqrt2V"]])
```

The record stores U row by row as texts such as `"I"` and `"-1"`; the dictionary `as_number` turns each text into the exact number, and `U_record` is the recorded matrix.

```
check(sp.simplify(V.H * V) == I16 and set(U) <= {0, 1, -1, sp.I, -sp.I}
      and seeds == theory["blockBasis"]["seedColumns0Based"]
```

```
      and record_check("blocks_basis_unitary"),
      "V = U/(2 sqrt 2) is unitary, U has entries 0, +-1, +-i",
      record=f"{PY_REPORT}, check blocks_basis_unitary")
check(U == U_record,
      "U equals the basis of the Revision record entry by entry",
      record="Revision/kohn_sham/ks-theory.json, blockBasis.unnormalisedColumns2Sqrt2V")
```

The first check: $V^\dagger V = 1$, the set of entries of U is contained in (`<=`) the set $\{0, \pm 1, \pm i\}$, and the seeds equal the recorded ones. The second: U equals the recorded matrix in all 256 entries. This is the basis the Rust solver uses.

In [14], the block forms.

```
s1 = sp.Matrix([[0, 1], [1, 0]])  # the Pauli matrices
s2m = sp.Matrix([[0, -sp.I], [sp.I, 0]])
s3 = sp.Matrix([[1, 0], [0, -1]])
I2 = sp.eye(2)
```

The Pauli matrices (`s2m` is σ_2; the name `s2` is used for the label s_2) and the 2×2 unit matrix.

```
def blocks_of(Xm):
    Yb = sp.simplify(V.H * Xm * V)
    diagonal = [Yb[2 * b:2 * b + 2, 2 * b:2 * b + 2] for b in range(8)]
    rebuilt = sp.zeros(16)
    for b in range(8):
        rebuilt[2 * b:2 * b + 2, 2 * b:2 * b + 2] = diagonal[b]
    return diagonal, rebuilt == Yb
```

`blocks_of(X)` changes X to the block basis, $V^\dagger X V$, cuts out the eight 2×2 blocks on the diagonal (rows and columns $2b$ and $2b+1$ of block b), rebuilds a matrix from these blocks alone, and returns the blocks and whether the rebuilt matrix equals $V^\dagger X V$, that is, whether X is block diagonal.

```
expected = [  # (name, matrix, the block form as a function of (j, s2, s3))
    ("gamma^(x0)", g0, lambda j, a, b: s3, "sigma3"),
    ("gamma^(x0) gamma^(x1)", A1, lambda j, a, b: -sp.I * s2m, "-i sigma2"),
    ("gamma^(x0) gamma^(x4)", A4, lambda j, a, b: j * s1, "j sigma1"),
    ("B", B, lambda j, a, b: j * a * I2, "j s2"),
    ("C", C, lambda j, a, b: a * s2m, "s2 sigma2"),
    ("BC = -i gamma^(x4)", B * C, lambda j, a, b: j * s2m, "j sigma2"),
    ("gamma^(x4) gamma^(x1)", g4 * g1, lambda j, a, b: -j * s3, "-j sigma3"),
    ("B gamma^(x0)", B * g0, lambda j, a, b: j * a * s3, "j s2 sigma3"),
    ("J", J, lambda j, a, b: j * I2, "j"),
    ("K1", K1, lambda j, a, b: sp.I * a * I2, "i s2"),
    ("K2", K2, lambda j, a, b: sp.I * b * I2, "i s3"),
]
```

A list of eleven entries, one per line: the name, the matrix, its expected block form and the text to print. A `lambda` is a short nameless function: `lambda j, a, b:  j * s1` returns $j\sigma_1$ for the labels $(j, s_2, s_3) = (j, a, b)$; so the name `a` stands for s_2 and `b` for s_3 inside these lines (they are not the

real-form components of Section 14.12). Line by line the expected forms are: $\gamma^{(x_0)} \to \sigma_3$; $A_1 \to -i\sigma_2$; $A_4 \to j\sigma_1$; $B \to js_2$ times the 2×2 unit matrix `I2`; $C \to s_2\sigma_2$; $BC \to j\sigma_2$; $\gamma^{(x_4)}\gamma^{(x_1)} \to -j\sigma_3$; $B\gamma^{(x_0)} \to js_2\sigma_3$; $J \to j$; $K_1 \to is_2$; $K_2 \to is_3$. These are the eleven forms of Section 14.5; the two not derived there follow from them: $BC = (js_2)(s_2\sigma_2) = j\sigma_2$ because $s_2^2 = 1$, and $B\gamma^{(x_0)} = (js_2)\sigma_3$.

```
all_forms = True
for name, Xm, form, text in expected:
    diagonal, only_diagonal = blocks_of(Xm)
    ok = only_diagonal and all(diagonal[i] == form(*labels[i]) for i in range(8))
    all_forms &= ok
    say(f"{name:24} -> {text:12} in block (j, s2, s3): {ok}")
check(all_forms and record_check("blocks_forms"),
      "all eleven matrices are block diagonal with the forms of the record",
      record=f"{PY_REPORT}, check blocks_forms")
```

For each matrix: block diagonal, and in block i equal to the expected form at the labels of that block. Out [14] prints True for all eleven.

```
not_diagonal = (not blocks_of(g2)[1] and not blocks_of(g5)[1]
                and not blocks_of(g0 * g2)[1] and blocks_of(g1)[1])
check(not_diagonal and record_check("blocks_not_everything_block_diagonal"),
      "gamma^(x2), gamma^(x5), gamma^(x0)gamma^(x2) connect blocks; gamma^(x1) not",
      record=f"{PY_REPORT}, check blocks_not_everything_block_diagonal")
```

`blocks_of(X)[1]` is the second returned value, the yes-or-no answer. $\gamma^{(x_2)}$, $\gamma^{(x_5)}$ and $\gamma^{(x_0)}\gamma^{(x_2)}$ are not block diagonal; $\gamma^{(x_1)}$ is.

In [15], figure 4.

```
N16 = (1 * g0 + sp.I * sp.Rational(1, 2) * g0 * g4
       - sp.I * sp.Rational(7, 10) * g0 * g1)  # M = 1, eps = 1/2, v = 0, kappa k = 7/10
```

The first-order matrix of the stationary equation in 16 components, $N_{16} = M\gamma^{(x_0)} + i(\varepsilon - v)\gamma^{(x_0)}\gamma^{(x_4)} - i\kappa k\,\gamma^{(x_0)}\gamma^{(x_1)}$ (from Step 7 of Section 14.4 with $\partial_{x_4}\chi = -i\varepsilon\chi$, multiplied by $\gamma^{(x_0)}$), at sample values. With the block forms it becomes $N = M\sigma_3 - \kappa k\sigma_2 + ij(\varepsilon - v)\sigma_1$ in every block.

```
pictures = [
    (np.abs(np.array(N16.evalf(), dtype=complex)), "$|N_{16}|$, original basis"),
    (np.abs(np.array(sp.simplify(V.H * N16 * V).evalf(), dtype=complex)),
     "$|V^\\dagger N_{16} V|$, block basis"),
    (np.abs(np.array(sp.simplify(V.H * Gamma * V).evalf(), dtype=complex)),
     "$|V^\\dagger \\Gamma V|$: pairs of blocks"),
]
```

Three matrices to draw, each with its title: `evalf()` turns exact entries into decimal numbers, `np.array(..., dtype=complex)` into a numpy array of complex numbers, and `np.abs` takes the absolute value of every entry.

```
fig, axes = plt.subplots(1, 3, figsize=(11.5, 3.9))
fig.subplots_adjust(wspace=0.45)  # room between the panels for the colour bars
for ax, (values, title) in zip(axes, pictures):
    image = ax.imshow(values, cmap="Blues", vmin=0.0, interpolation="nearest")
    ax.set_title(title, fontsize=9)
    ax.set_xticks([0, 5, 10, 15])
    ax.set_yticks([0, 5, 10, 15])
    ax.set_xlabel("column")
    ax.set_ylabel("row")
    ax.grid(False)  # no grid lines over the matrix
    fig.colorbar(image, ax=ax, shrink=0.75)
```

`zip` pairs each panel with its picture. `imshow` draws a matrix as a **heat map**: one small square per entry, coloured by its value (`cmap="Blues"`: white for 0, dark blue for the largest value; `interpolation="nearest"` keeps the squares sharp). `colorbar` adds the scale of colours beside the panel.

```
for ax in axes[1:]:  # mark the 2 x 2 blocks in the block basis
    for edge in np.arange(1.5, 15.0, 2.0):
        ax.axhline(edge, color="gray", linewidth=0.4)
        ax.axvline(edge, color="gray", linewidth=0.4)
save_figure(fig, "block_structure",
            ...)
```

In the second and third panels thin gray lines are drawn between rows and columns 1 and 2, 3 and 4, and so on (`np.arange(1.5, 15.0, 2.0)` is 1.5, 3.5, ..., 13.5), which frame the eight blocks. **What figure 14a.4 shows.** Left: in the original basis the entries of N_{16} are spread over the whole matrix in a diamond pattern. Middle: in the block basis only the eight 2×2 blocks on the diagonal are nonzero. In every block the diagonal entries are $\pm M$ ($|1|$) and the two off-diagonal entries have the sizes $|\kappa k + j\varepsilon| = 1.2$ and $|j\varepsilon - \kappa k| = 0.2$; in the first four blocks ($j = +1$) the large one is above the diagonal, in the last four ($j = -1$) below it: the two block types are visible. Right: $V^{\dagger}\Gamma V$ has entries of size 1 only between the block b and the block $b \pm 4$, the pairs $(j, s_2, s_3) \leftrightarrow (-j, s_2, s_3)$.

In [16], the block Hamiltonian, its two types and Γ.

```
ok_h = True
for i, (j, a, b) in enumerate(labels):  # the three pieces of h in block i
    Vb = V[:, 2 * i:2 * i + 2]
    ok_h &= sp.simplify(Vb.H * (sp.I * g4 * g0) * Vb + sp.I * j * s1).is_zero_matrix
    ok_h &= sp.simplify(Vb.H * (-g4 * g1) * Vb - j * s3).is_zero_matrix
    ok_h &= sp.simplify(Vb.H * (-sp.I * g4) * Vb - j * s2m).is_zero_matrix
check(ok_h and record_check("block_hamiltonian"),
      "h_j = j[-i sigma1 d/dy + M sigma2 + kappa k sigma3] + v in all 8 blocks",
      record=f"{PY_REPORT}, check block_hamiltonian")
```

`enumerate` gives each block its number `i` together with its labels. `Vb` holds the two basis columns of the block. The three lines check the three matrix pieces of h (with **k** along x_1): $i\gamma^{(x_4)}\gamma^{(x_0)} \to -ij\sigma_1$, $-\gamma^{(x_4)}\gamma^{(x_1)} \to j\sigma_3$, $-i\gamma^{(x_4)} \to j\sigma_2$. Together they give h_j.

```
eps = sp.symbols("epsilon", real=True)  # the level
```

```
def h_algebraic(j, M_, k_, kap_):
    return j * (M_ * s2m + kap_ * k_ * s3)

def N_matrix(j, M_, k_, eps_, v_, kap_):
    return M_ * s3 - kap_ * k_ * s2m + sp.I * j * (eps_ - v_) * s1
```

The level ε as a symbol; `h_algebraic` is the part of $h_j - v$ without the derivative, $j(M\sigma_2 + \kappa k\sigma_3)$; `N_matrix` is the matrix N of the first-order form.

```
kk = sp.symbols("k", real=True)
# h chi = eps chi  <=>  -i j sigma1 chi' = (eps - v - j(M s2 + kappa k s3)) chi
ok_ode = all(sp.simplify(-sp.I * j * s1 * N_matrix(j, M, kk, eps, v, kap)
                         - ((eps - v) * I2 - h_algebraic(j, M, kk, kap)))
             .is_zero_matrix for j in (1, -1))
check(ok_ode and record_check("block_ode_equivalent"),
      "h_j chi = eps chi is the same as d chi/dy = N chi",
      record=f"{PY_REPORT}, check block_ode_equivalent")
```

`kk` is the momentum k as a real symbol. The comment line says what the check is about: the equation $h_j\chi = \varepsilon\chi$ reads $-ij\sigma_1\chi' = (\varepsilon - v)\chi - j(M\sigma_2 + \kappa k\sigma_3)\chi$ (the first line of the first-order form in Section 14.5; `<=>` means "is the same as"). If $\chi' = N\chi$, this holds for every χ exactly when $-ij\sigma_1 N = (\varepsilon - v) - j(M\sigma_2 + \kappa k\sigma_3)$, which is checked for both types.

```
d_term = -sp.I * s1  # the matrix in front of d/dy (times j)
ok_types = ((h_algebraic(1, M, kk, kap) + h_algebraic(-1, M, kk, kap))
            .is_zero_matrix
            and (s3 * h_algebraic(1, M, kk, kap) * s3
                 - h_algebraic(-1, M, -kk, kap)).is_zero_matrix
            and (s3 * d_term * s3 + d_term).is_zero_matrix)
check(ok_types and record_check("block_type_relation"),
      "h_(-1) - v = -(h_(+1) - v) and sigma3 h_j(k) sigma3 = h_(-j)(-k)",
      record=f"{PY_REPORT}, check block_type_relation")
```

The two type relations of Section 14.5: the algebraic parts of the two types add to zero; σ_3 turns the algebraic part of $(+1, k)$ into that of $(-1, -k)$; and $\sigma_3(-i\sigma_1)\sigma_3 = i\sigma_1$, so the derivative term changes sign as j does.

```
YG = sp.simplify(V.H * Gamma * V)
pairs = [(a, b) for a in range(8) for b in range(8)
         if not YG[2 * a:2 * a + 2, 2 * b:2 * b + 2].is_zero_matrix]
say(f"Gamma connects the blocks (from, to): {pairs}")
```

Γ in the block basis, and the list of the block pairs (a, b) between which it has a nonzero 2×2 entry. Out [16] prints the eight pairs $(0,4), (1,5), \ldots, (7,3)$.

```
ok_pairs = (pairs == [(0, 4), (1, 5), (2, 6), (3, 7), (4, 0), (5, 1), (6, 2), (7, 3)]
            and all(YG[2 * a:2 * a + 2, 2 * b:2 * b + 2] == labels[a][1] * s2m
```

```
                    for (a, b) in pairs)
            and (Gamma * J + J * Gamma).is_zero_matrix
            and (Gamma * K1 - K1 * Gamma).is_zero_matrix
            and (Gamma * K2 - K2 * Gamma).is_zero_matrix)
check(ok_pairs and record_check("blocks_relation_to_Gamma"),
      "Gamma maps block (j, s2, s3) onto (-j, s2, s3) with the entry s2 sigma2",
      record=f"{PY_REPORT}, check blocks_relation_to_Gamma")
```

Block b and block $b+4$ differ only in j (the order of `labels`); each entry is $s_2\sigma_2$ (`labels[a][1]` is the s_2 of block a); Γ anticommutes with J and commutes with K_1, K_2.

```
ok_map = ((s2m * h_algebraic(1, M, kk, kap) * s2m
           - h_algebraic(-1, -M, kk, kap)).is_zero_matrix
          and (s2m * d_term * s2m + d_term).is_zero_matrix)
check(ok_map and record_check("block_Gamma_map"),
      "sigma2 h_j(M, k) sigma2 = h_(-j)(-M, k): Gamma reverses the mass",
      record=f"{PY_REPORT}, check block_Gamma_map")
```

Section 14.6 line by line: σ_2 turns the algebraic part of $(j=1, M)$ into that of $(j=-1, -M)$ at the same k, and changes the sign of the derivative term.

In [17], rotations.

```
theta = sp.symbols("theta", real=True)
R = sp.cos(theta / 2) * I16 + sp.sin(theta / 2) * g1 * g2  # the spinor rotation
R_inverse = sp.cos(theta / 2) * I16 - sp.sin(theta / 2) * g1 * g2  # its inverse
rotated = sp.simplify(R * (kk * g1) * R_inverse)
```

The spinor rotation of Section 14.6, its inverse, and the rotated momentum term $R(k\gamma^{(x_1)})R^{-1}$.

```
ok_rotation = (sp.simplify(R * R_inverse) == I16
               and sp.simplify(rotated - kk * (sp.cos(theta) * g1
                                               - sp.sin(theta) * g2)).is_zero_matrix
               and all((R * Xm - Xm * R).is_zero_matrix for Xm in (g0, g4, B, C)))
check(ok_rotation and record_check("rotation_invariance"),
      "a 3-space rotation commutes with g0, g4, B, C and rotates k: only |k| counts",
      record=f"{PY_REPORT}, check rotation_invariance")
```

Three facts: $RR^{-1}=1$; $R\,k\gamma^{(x_1)}R^{-1} = k(\cos\theta\,\gamma^{(x_1)} - \sin\theta\,\gamma^{(x_2)})$; R commutes with $\gamma^{(x_0)}$, $\gamma^{(x_4)}$, B, C.

In [18], the rescaling identity.

```
a_sym, y_sym = sp.symbols("a y", real=True)
ell, v_t, lam = sp.symbols("ell v_t lambda", positive=True)

def h_slice(j, k_, a_):
    return j * (M * s2m + sp.exp(-H * y_sym - a_) * k_ * s3)
```

```
def proper_factor(ell_, v_t_):
    return sp.exp(-6 * H * y_sym) / (ell_ ** 3 * v_t_)
```

Symbols for the slice $a_{4,0}$ (`a_sym`), the hidden coordinate, the box size ℓ, the extra-time volume v_t and the coupling λ. `h_slice` is the algebraic part of h_j at a slice, with $\kappa = e^{-Hy-a}$; `proper_factor` is the factor P of the proper densities.

```
ok_h_slice = all(sp.simplify(h_slice(j, kk, a_sym)
                             - h_slice(j, kk * sp.exp(-a_sym), 0)).is_zero_matrix
                 for j in (1, -1))
ok_box = sp.simplify(proper_factor(ell, v_t) - proper_factor(
    ell * sp.exp(a_sym), v_t * sp.exp(-3 * a_sym))) == 0
ok_lambda = sp.simplify(lam * proper_factor(ell, v_t) - lam * sp.exp(3 * a_sym)
                        * proper_factor(ell * sp.exp(a_sym), v_t)) == 0
check(ok_h_slice and ok_box and ok_lambda and record_check("rescaling_identity"),
      "KS(a4,0; dk, v_t, lambda) = KS(0; dk e^(-a4,0), v_t e^(-3 a4,0), lambda)",
      record=f"{PY_REPORT}, check rescaling_identity")
```

The three statements of Section 14.7: the block Hamiltonian at the slice a with momentum k equals the one at the slice 0 with momentum ke^{-a}; the box $(\ell e^{a}, v_t e^{-3a})$ has the same factor P; and the coupling λe^{3a} times the density factor of the box $(\ell e^{a}, v_t)$ equals λ times the original factor.

```
rows = repository_file("Revision/kohn_sham/results/rescaling/rescaling.csv") \
    .read_text(encoding="utf-8").splitlines()
header = rows[0].split(",")
table = [dict(zip(header, row.split(","))) for row in rows[1:]]
```

The Rust solver's record of the partner problems, a **CSV file** (comma-separated values: a table as text, one row per line, the cells separated by commas, the first line the column names). `splitlines` cuts the text into lines and `split(",")` a line into cells; `dict(zip(header, cells))` makes a dictionary from column name to cell for every row.

```
worst = 0.0
for a in slices[1:]:
    dk_partner = 0.25 * np.exp(-a)  # the partner lattice spacing
    vt_partner = 1.0 * np.exp(-3 * a)  # the partner extra-time volume (v_t = 1)
    say(f"slice a4,0 = {a}: partner dk = {dk_partner:.12f}, "
        f"partner v_t = {vt_partner:.12f}")
    for row in table:
        if float(row["a4"]) == a:
            worst = max(worst, abs(float(row["partner_dk"]) / dk_partner - 1),
                        abs(float(row["partner_v_t"]) / vt_partner - 1))
check(len(table) == 60 and worst < 1e-14,
      "the partner spacings and volumes equal those of all 60 rows of the record",
      record="Revision/kohn_sham/results/rescaling/rescaling.csv, columns "
             "partner_dk and partner_v_t")
```

For each later slice (`slices[1:]` leaves out the slice 0) the partner spacing $0.25\,e^{-a}$ and the partner volume e^{-3a} are computed and printed with 12 decimals (the format `:.12f`). For every row of the record at that slice the relative difference is taken, and the largest is kept in `worst`. The record has 60 rows (three particle numbers, five couplings and four later slices) and agrees to better than 10^{-14}. Out [18] shows the partner numbers, for example 0.151632664928 and 0.223130160148 for $a_{4,0} = 0.5$.

In [19], figure 5.

```
ell_value = 2 * np.pi / 0.25  # the coordinate box size of the solver (dk = 0.25)
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
for n2 in (1, 2, 3, 4, 5, 6):  # the first shells n1^2 + n2^2 + n3^2
    left.semilogy(a4_values, 0.25 * np.sqrt(n2) * np.exp(-a4_values),
                  label=f"$n^2 = {n2}$")
```

The box size $\ell = 2\pi/0.25$; the left panel draws, for the first six lattice shells ($|\mathbf{k}| = 0.25\sqrt{n^2}$), the redshifted momentum $|\mathbf{k}|e^{-a_{4,0}}$ against the slice.

```
left.set_xlabel("slice $a_{4,0}$")
left.set_ylabel("$|\\mathbf{k}|\\,e^{-a_{4,0}}$ (units of $H$, logarithmic)")
left.set_title("redshift of the lattice momenta")
left.legend(fontsize=8, ncol=2)
right.semilogy(a4_values, (ell_value * np.exp(a4_values)) ** 3,
               label="3-space box $(\\ell e^{a_{4,0}})^3$")
right.semilogy(a4_values, np.exp(-3 * a4_values), "--",
               label="extra-time box $v_t e^{-3a_{4,0}}$")
right.semilogy(a4_values, ell_value ** 3 * np.exp(3 * a4_values)
               * np.exp(-3 * a4_values), ":", color="black",
               label="7-volume $\\ell^3 v_t$ (constant)")
```

Labels (`ncol=2` puts the legend in two columns), and in the right panel the proper volumes at the brane of the 3-space box, of the extra-time box and their product.

```
right.set_xlabel("slice $a_{4,0}$")
right.set_ylabel("proper volume at $y = 0$ (logarithmic)")
right.set_title("the boxes inflate and deflate, the 7-volume stays")
right.legend(fontsize=8)
save_figure(fig, "rescaling",
            ...)
```

What figure 14a.5 shows. Left: six parallel straight lines of slope -1 on the logarithmic axis: every lattice momentum is redshifted by the same factor $e^{-a_{4,0}}$, so the ordering of the shells never changes. Right: the 3-space box grows from $(8\pi)^3 \approx 1.6 \times 10^4$ by the factor $e^6 \approx 403$, the extra-time box shrinks from 1 to $e^{-6} \approx 0.0025$, and their product, the dotted line, stays constant. This is the rescaling identity in a picture: a later slice is the slice 0 with a finer momentum lattice and the same proper box.

In [20], the last check.

```
figure_names = ["14a_1_hidden_coordinate.png", "14a_2_inflation_deflation.png",
                "14a_3_spin_connection_terms.png", "14a_4_block_structure.png",
```

```
                "14a_5_rescaling.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all five figure files of this notebook exist")
all_checks_passed()
```

The five figure files must exist where the notebook wrote them; the last line prints ALL 28 CHECKS PASSED (notebook 14a). The 28 checks are: 1 in In [2], 2 in In [3], 2 in In [4], 2 in In [7], 2 in In [8], 2 in In [10], 2 in In [11], 2 in In [12], 2 in In [13], 2 in In [14], 5 in In [16], 1 in In [17], 2 in In [18] and 1 in In [20].

14.12 The block equation in real form and the boundary conditions

The real form. In every block the stationary equation is $\chi' = N\chi$ with $N = M\sigma_3 - \kappa k\,\sigma_2 + ij(\varepsilon - v)\sigma_1$ (Section 14.5). Write the two components of χ as $\chi = (a, ib)$ with two real functions $a(y)$ and $b(y)$, and write $K = \kappa k$ and $\varepsilon' = \varepsilon - v$ for short. Line by line:

$$\sigma_3\chi = (a,\ -ib), \qquad \sigma_2\chi = (b,\ ia), \qquad \sigma_1\chi = (ib,\ a).$$

Rule: multiply each Pauli matrix of Section 14.1 with the column (a, ib); for example the first entry of $\sigma_2\chi$ is $(-i)(ib) = -i^2 b = b$.

$$N\chi = \Big(Ma - Kb - j\varepsilon' b,\ \ i\big[(j\varepsilon' - K)a - Mb\big]\Big).$$

Rule: $N\chi = M\sigma_3\chi - K\sigma_2\chi + ij\varepsilon'\sigma_1\chi$, entry by entry; in the first entry $ij\varepsilon'(ib) = i^2 j\varepsilon' b = -j\varepsilon' b$; the second entry is $-iMb - iKa + ij\varepsilon' a$, which is i times the bracket.

$$a' = Ma - (K + j\varepsilon')\,b, \qquad b' = (j\varepsilon' - K)\,a - Mb.$$

Rule: $\chi' = (a', ib')$; compare the first entries, and the second entries divided by i. Every coefficient is a real number, so a solution that starts with real values a, b stays real: the computer needs only real numbers. Status: PROVED; the record states this form as blockEquation.realForm in `Revision/kohn_sham/ks-theory.json`, and Notebook 14b checks it with sympy (In [2]).

The densities of one orbital. From the three products above and $\chi^\dagger = (a, -ib)$ (the conjugate transpose of the column, with a, b real):

$$\chi^\dagger\chi = a^2 + b^2, \qquad \chi^\dagger\sigma_2\chi = 2ab, \qquad \chi^\dagger\sigma_3\chi = a^2 - b^2, \qquad \chi^\dagger\sigma_1\chi = 0.$$

Rule: multiply the row $(a, -ib)$ with each column; for example $\chi^\dagger\sigma_2\chi = a\cdot b + (-ib)(ia) = ab + ab$, and $\chi^\dagger\sigma_1\chi = a(ib) + (-ib)a = 0$. These four numbers become the number density, the scalar density, the density Q and the current along y of the orbital (Sections 14.26 and 14.27). Status: PROVED (the multiplication above); the record states the same four formulas as blockEquation.realFormDensities in `Revision/kohn_sham/ks-theory.json`.

The current along y is the same at every point. The number $\chi^\dagger\sigma_1\chi$ is the flow along the hidden direction of the U(1) charge of the field (the **current** along y). Of this charge only the local

conservation law is proved; its total is constant only under the ASSUMED no-flux condition at the brane $z = \pi/2$ (Chapter 5, Section 5.6), and the brane parity conditions of the Kohn-Sham record assumed below ($\chi_2(0) = 0$ or $\chi_1(0) = 0$, which its Z2 mirror gives through the parity relation $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$) are such a condition: they make the current vanish at the brane. The gluing of the T2 mirror partner in Chapter 18, which imposes no parity condition (no matching of the field across the brane is derived there, Section 18.28), is not one: the exact solutions of Section 18.21 carry charge through the brane, and gluing does not stop that flow. For every solution of the block equation, complex or real:

$$\frac{d}{dy}(\chi^\dagger\sigma_1\chi) = \chi'^\dagger\sigma_1\chi + \chi^\dagger\sigma_1\chi' = \chi^\dagger(N^\dagger\sigma_1 + \sigma_1 N)\chi.$$

Rule: the product rule; then $\chi' = N\chi$ and $\chi'^\dagger = (N\chi)^\dagger = \chi^\dagger N^\dagger$.

$$N^\dagger = M\sigma_3 - K\sigma_2 - ij\varepsilon'\sigma_1.$$

Rule: the Pauli matrices are Hermitian, M, K, ε' are real, and the complex conjugate of i is $-i$.

$$N^\dagger\sigma_1 + \sigma_1 N = M(\sigma_3\sigma_1 + \sigma_1\sigma_3) - K(\sigma_2\sigma_1 + \sigma_1\sigma_2) - ij\varepsilon'\sigma_1\sigma_1 + ij\varepsilon'\sigma_1\sigma_1 = 0.$$

Rule: two different Pauli matrices anticommute, so the first two brackets are zero, and the last two terms cancel. So the current has the same value at every y. The density $\chi^\dagger\chi$ is not constant: its derivative is $\chi^\dagger(N^\dagger + N)\chi$ with $N^\dagger + N = 2M\sigma_3 - 2K\sigma_2 \neq 0$. Status: PROVED; check bc_current_conserved_along_y of `Revision/kohn_sham/reports/ks-theory-python.json` and of the Wolfram report.

Why the two ends must stop the current. Section 14.4 called h Hermitian "when the boundary terms vanish". Here is the boundary term. For two columns φ and χ of functions of y:

$$\varphi^\dagger h_j\chi - (h_j\varphi)^\dagger\chi = -ij\varphi^\dagger\sigma_1\chi' - ij\varphi'^\dagger\sigma_1\chi = \frac{d}{dy}\big[-ij\,\varphi^\dagger\sigma_1\chi\big].$$

Rule, for the first equality: the part of h_j without derivative, $j(M\sigma_2+K\sigma_3)+v$, is a Hermitian matrix, so it gives $\varphi^\dagger X\chi-(X\varphi)^\dagger\chi = \varphi^\dagger X\chi-\varphi^\dagger X^\dagger\chi = 0$; the derivative part gives $\varphi^\dagger(-ij\sigma_1\chi')-(-ij\sigma_1\varphi')^\dagger\chi$, and $(-ij\sigma_1\varphi')^\dagger = +ij\varphi'^\dagger\sigma_1$. Rule, for the second: the product rule backwards. Integrating from $-L$ to 0:

$$\int_{-L}^{0}\varphi^\dagger h_j\chi\,dy - \int_{-L}^{0}(h_j\varphi)^\dagger\chi\,dy = -ij\big[\varphi^\dagger\sigma_1\chi\big]_{y=-L}^{y=0}.$$

Rule: the integral of a derivative is the difference of its end values. So h_j is self-adjoint (the two integrals are equal, the levels are real and orbitals of different levels are orthogonal, Section 14.4) exactly when the boundary conditions make $\varphi^\dagger\sigma_1\chi$ vanish at both ends: the conditions must **kill the current**. Status: PROVED; check bc_self_adjoint_boundary_term (both reports).

The brane at $y = 0$ (ASSUMED). The author's coordinate patch ends at $y = 0$, where $z = \pi/2$. Something must be said about what lies beyond it. The Revision theory ASSUMES a **Z2 mirror**

(also called an **orbifold**): the patch $y \le 0$ is glued at $y = 0$ to a mirror copy of itself, with the warp $e^{-H|y|}$ on both sides, and a field on the doubled interval obeys $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$. At $y = 0$ this relation says $\Psi(0) = \pm\gamma^{(x_0)}\Psi(0)$, that is $(1 \mp \gamma^{(x_0)})\chi(0) = 0$. In every block $\gamma^{(x_0)}$ is σ_3 (Section 14.5), and $1 - \sigma_3 = \mathrm{diag}(0, 2)$, $1 + \sigma_3 = \mathrm{diag}(2, 0)$. Hence two kinds of orbitals, called the two **parities**:

- EVEN parity (upper sign): $\chi_2(0) = 0$; in real form $b(0) = 0$.
- ODD parity (lower sign): $\chi_1(0) = 0$; in real form $a(0) = 0$.

Both kill the current, because $\chi^\dagger\sigma_1\chi = \chi_1^*\chi_2 + \chi_2^*\chi_1$ (the star is the complex conjugate) is zero when χ_1 or χ_2 is zero. Status: the mirror is ASSUMED; the two conditions follow from it (PROVED; check bc_brane_parity_conditions, both reports).

What the mirror does to the mass. Let χ solve $\chi'(y) = N(y)\chi(y)$ and put $\tilde\chi(y) = \sigma_3\chi(-y)$. Line by line:

$$\tilde\chi'(y) = -\sigma_3\chi'(-y) = -\sigma_3 N(-y)\chi(-y) = -\sigma_3 N(-y)\sigma_3\,\tilde\chi(y).$$

Rule: the chain rule (the derivative of $\chi(-y)$ is $-\chi'(-y)$), then the equation at the point $-y$, then $\chi(-y) = \sigma_3\tilde\chi(y)$ because $\sigma_3\sigma_3 = 1$.

$$-\sigma_3 N\sigma_3 = -M\sigma_3 - K\sigma_2 + ij\varepsilon'\sigma_1.$$

Rule: $\sigma_3\sigma_3\sigma_3 = \sigma_3$, $\sigma_3\sigma_2\sigma_3 = -\sigma_2$, $\sigma_3\sigma_1\sigma_3 = -\sigma_1$. This is the matrix N with M replaced by $-M$. So $\tilde\chi$ solves the block equation with the mass $-M(-y)$, the potential $v(-y)$ and the weight $\kappa(-y)$ (the weight of the mirror copy). The doubled problem is therefore mirror-symmetric only if the mass is **odd** across the brane. The densities say the same: under the map the number density and Q (built from $\chi^\dagger\chi$ and $\chi^\dagger\sigma_3\chi$) are even, while the scalar density S (built from $\chi^\dagger\sigma_2\chi$) and the current change sign, because σ_3 commutes with 1 and σ_3 and anticommutes with σ_2 and σ_1. Since $M_{\text{eff}} = m + \frac{15}{16}\lambda S$ (Section 14.27) and S is odd, the mirror copy carries $(-m, +\lambda)$. Status: PROVED; checks bc_mirror_map_PA and bc_mirror_parities_of_densities (both reports).

What this does and does not say (honesty). The pair $(+m, -m)$ of the patch and its mirror copy is the mirror pair of the pairing theorem T3, which Chapter 19 proves. It is an exact map between solutions of the equations with an ASSUMED boundary construction. It does not say that a mirror copy, a second universe or a pair of universes is created by any process: no creation process, rate or amplitude follows from these equations (Chapters 18 to 20 give the complete statements and the list of what is not proved).

The tip (ASSUMED: a chosen cutoff condition). The hidden coordinate runs to minus infinity at the tip, which a computer cannot reach. The Revision solver stops at $y = -L$ ($L = 3$) and imposes there one member of the family

$$(1 - Q(\theta))\chi(-L) = 0, \qquad Q(\theta) = \cos\theta\,\sigma_3 + \sin\theta\,\sigma_2.$$

Line by line, why every member kills the current. First, $Q^\dagger = Q$ (rule: σ_3, σ_2 are Hermitian, $\cos\theta$ and $\sin\theta$ are real). Second, $Q^2 = \cos^2\theta + \sin^2\theta + \cos\theta\sin\theta(\sigma_3\sigma_2 + \sigma_2\sigma_3) = 1$ (rule: multiply out;

each $\sigma^2 = 1$ and the bracket is zero). Third, $Q\sigma_1 = -\sigma_1 Q$ (rule: σ_1 anticommutes with σ_3 and with σ_2). Now if $Q\chi = \chi$ at the end point, then

$$\chi^\dagger \sigma_1 \chi = \chi^\dagger \sigma_1 Q\chi = -\chi^\dagger Q\sigma_1 \chi = -(Q\chi)^\dagger \sigma_1 \chi = -\chi^\dagger \sigma_1 \chi,$$

so $\chi^\dagger \sigma_1 \chi = 0$ there. Rule: replace χ by $Q\chi$, move Q to the left with the third fact, use $Q^\dagger = Q$, then $Q\chi = \chi$ again. The canonical choice is $\theta = 0$: $(1 - \sigma_3)\chi(-L) = 0$, that is $\chi_2(-L) = 0$, $b(-L) = 0$, the **regular tip**. In real form a member θ is satisfied by the starting point $(a, b) = (\cos\frac{\theta}{2}, \sin\frac{\theta}{2})$ at $y = -L$ (Exercise 14.3), which is where the shooting of Section 14.14 starts. Status: the algebra is PROVED (check bc_tip_family, both reports); the choice of the condition is ASSUMED.

Zero current everywhere. An **orbital** is a solution that satisfies the brane condition and the tip condition. Its current is zero at the two ends and the same at every y, so it is zero everywhere. (For a real solution (a, b) it is zero anyway, by the densities above.)

Why the tip hardly matters when the 3-momentum is not zero. Toward the tip the weight $\kappa = e^{-Hy - a_{4,0}}$ grows without bound, and for large κ the matrix N is dominated by its momentum term, $N \approx -\kappa k\, \sigma_2$. Line by line:

- σ_2 has the eigenvalues $s = +1$ and $s = -1$ (it squares to 1 and its trace is 0), with eigenvectors u_+ and u_-.
- On u_s the equation $\chi' \approx -\kappa k \sigma_2 \chi$ reads $\chi' \approx -s\kappa k\, \chi$.
- Its solution is $\chi \propto \exp(sk\kappa/H)\, u_s$. Rule: the derivative of e^{-Hy} is $-He^{-Hy}$, so the derivative of κ/H is $-\kappa$, and the chain rule gives the derivative of $\exp(sk\kappa/H)$ as $(sk)(-\kappa)\exp(sk\kappa/H)$.
- For $k > 0$ the branch $s = +1$ grows enormously toward the tip and the branch $s = -1$ decays toward the tip (for $k < 0$ the two exchange their roles). The decaying branch, $\sigma_2\chi = -\chi$ for $k > 0$, is the **regular** one.
- An orbital is therefore suppressed at the cutoff, compared with its size at a point y, by about the factor $\exp(-|k|(\kappa(-L) - \kappa(y))/H)$. Rule: the ratio of $\exp(-|k|\kappa/H)$ at the two points.

Whatever condition is imposed at $y = -L$ acts on a part of the orbital that is already this small, so for $k \neq 0$ the levels should change by about this factor at most; this last step is an estimate, not a proof. At the slice $a_{4,0} = 0$, between the brane and the cutoff, $\kappa(-L) - \kappa(0) = e^{HL} - 1 = e^3 - 1 \approx 19.09$, and for the smallest lattice momentum $k = 0.25$ the factor is 8.47×10^{-3} (the column suppression_factor of `Revision/kohn_sham/results/spectrum/tip-angle.csv`). At a later slice the difference is smaller by the factor $e^{-a_{4,0}}$, $\kappa(-L) - \kappa(0) = e^{-a_{4,0}}(e^{HL} - 1)$ (rule: $\kappa = e^{-Hy - a_{4,0}}$ at the two points): along the history the redshifted orbitals reach farther toward the tip, and the position L of the cutoff begins to matter (Section 14.20). At $k = 0$ there is no suppression and the tip condition matters: there the choice $\theta = 0$ selects the brane zero mode of Section 14.13. Status: the two asymptotic branches, the regular branch and the suppression factor of the orbital are PROVED (check bc_tip_asymptotics, both reports); the bound on the change of the levels is an estimate, whose size is COMPUTED in Section 14.20 (check free_tip_angle_insensitivity of `Revision/kohn_sham/reports/ks-rust-solver.json`, record `Revision/kohn_sham/results/spectrum/tip-angle.csv`).

14.13 The exact free levels at zero 3-momentum

Take $k = 0$, $v = 0$ and a constant mass $M > 0$. The real form becomes $a' = Ma - j\varepsilon b$, $b' = j\varepsilon a - Mb$. These two equations can be solved by hand, completely. The solutions are the first test of any numerical method for the model.

Step 1: one equation of second order. Suppose $\varepsilon \neq 0$. Line by line:

$$a = \frac{b' + Mb}{j\varepsilon}.$$

Rule: solve the second equation for a (add Mb and divide by $j\varepsilon \neq 0$).

$$a' = \frac{b'' + Mb'}{j\varepsilon}.$$

Rule: differentiate; M, j, ε are constants.

$$b'' + Mb' = M(b' + Mb) - j^2\varepsilon^2 b.$$

Rule: insert the two lines into the first equation $a' = Ma - j\varepsilon b$ and multiply by $j\varepsilon$.

$$b'' = (M^2 - \varepsilon^2)\, b.$$

Rule: $j^2 = 1$, and Mb' cancels on both sides.

The general solution of this equation depends on the sign of $M^2 - \varepsilon^2$ (check each by differentiating twice): if $\varepsilon^2 > M^2$, write $M^2 - \varepsilon^2 = -p^2$ with $p > 0$, and $b = A\sin(py) + B\cos(py)$; if $\varepsilon^2 < M^2$, write $M^2 - \varepsilon^2 = q^2$ with $q > 0$, and $b = Ae^{qy} + Be^{-qy}$; if $\varepsilon^2 = M^2$, then $b = A + By$. Here A and B are constants.

Step 2: even parity, $b(0) = 0$ and $b(-L) = 0$.

- $\varepsilon^2 > M^2$: $b(0) = B = 0$, so $b = A\sin(py)$; then $b(-L) = -A\sin(pL) = 0$ with $A \neq 0$ requires $pL = n\pi$, $n = 1, 2, 3, \ldots$ Hence the levels $\varepsilon = \pm\sqrt{M^2 + (n\pi/L)^2}$.
- $\varepsilon^2 < M^2$, $\varepsilon \neq 0$: $b(0) = A + B = 0$ gives $b = A(e^{qy} - e^{-qy})$, and $b(-L) = A(e^{-qL} - e^{qL}) = 0$ forces $A = 0$ (because $e^{qL} > e^{-qL}$); then $b = 0$ and $a = (b' + Mb)/(j\varepsilon) = 0$: no orbital.
- $\varepsilon^2 = M^2$: $b(0) = A = 0$ and $b(-L) = -BL = 0$, so $b = 0$ and again no orbital.
- $\varepsilon = 0$ (Step 1 does not apply): the equations separate, $a' = Ma$ and $b' = -Mb$, so $a = Ae^{My}$, $b = Be^{-My}$. The brane condition $b(0) = B = 0$ makes $b = 0$ everywhere, which also satisfies $b(-L) = 0$. So $\chi = (Ae^{My}, 0)$ is an orbital with $\varepsilon = 0$, for every L: the **brane zero mode**, largest at the brane.

The constant of the zero mode follows from the normalisation $\int_{-L}^{0} a^2\, dy = 1$:

$$\int_{-L}^{0} A^2 e^{2My}\,dy = A^2\,\frac{1-e^{-2ML}}{2M} = 1, \qquad A = \sqrt{\frac{2M}{1-e^{-2ML}}}.$$

Rule: the integral of e^{2My} is $e^{2My}/(2M)$; evaluate at 0 and $-L$ and subtract; solve for $A > 0$.

Step 3: odd parity, $a(0) = 0$ and $b(-L) = 0$.

- $\varepsilon^2 > M^2$: the solution with $b(-L) = 0$ is $b = A\sin(p(y+L))$ (the general solution written around the point $-L$, where the cosine term must vanish). By Step 1, $a(0) = 0$ means $b'(0) + Mb(0) = 0$, that is $A[p\cos(pL) + M\sin(pL)] = 0$. So the levels are $\varepsilon = \pm\sqrt{M^2+p^2}$ where $p > 0$ solves

$$f(p) = M\sin(pL) + p\cos(pL) = 0, \qquad \text{equivalently} \qquad \tan(pL) = -\frac{p}{M}.$$

Rule: divide by $M\cos(pL)$, which is not zero (if $\cos(pL) = 0$ then $f = \pm M \neq 0$).

- $\varepsilon^2 < M^2$, $\varepsilon \neq 0$: $b = A(e^{q(y+L)} - e^{-q(y+L)})$, and $b'(0) + Mb(0) = A[q(e^{qL} + e^{-qL}) + M(e^{qL} - e^{-qL})] = 0$ forces $A = 0$ (the bracket is positive): no orbital.
- $\varepsilon^2 = M^2$: $b = B(y+L)$ and $b'(0) + Mb(0) = B(1+ML) = 0$ forces $B = 0$: no orbital.
- $\varepsilon = 0$: $a = Ae^{My}$ with $a(0) = A = 0$, and $b = Be^{-My}$ with $b(-L) = Be^{ML} = 0$, so $B = 0$: there is no zero mode of odd parity.

Step 4: the odd roots. Count the roots of $f(p) = M\sin(pL) + p\cos(pL)$ for $p > 0$. At $p = (n+\frac{1}{2})\pi/L$ the sine is $(-1)^n$ and the cosine 0, so $f = M(-1)^n$; at $p = (n+1)\pi/L$ the sine is 0 and the cosine $(-1)^{n+1}$, so $f = p(-1)^{n+1}$. The two values have opposite signs, so f has a root in between (rule: a continuous function that changes sign on an interval is zero somewhere in it). It has exactly one there: on this interval $\tan(pL)$ rises from minus infinity to 0 while $-p/M$ falls, so the two curves meet once; and on the intervals from $n\pi/L$ to $(n+\frac{1}{2})\pi/L$ there is no root, because there $\tan(pL) > 0 > -p/M$. So the roots are $p_0 < p_1 < p_2 < \dots$, one in each interval $((n+\frac{1}{2})\pi/L,\ (n+1)\pi/L)$.

Summary (PROVED). At $k = 0$, $v = 0$, constant $M > 0$ and the canonical tip:

parity	**levels**	**orbital**
even	0 (the brane zero mode)	$(\sqrt{2M/(1-e^{-2ML})}\,e^{My},\ 0)$
even	$\pm\sqrt{M^2+(n\pi/L)^2}$, $n = 1, 2, \dots$	$b = \sin(n\pi y/L)$, $a = (b' + Mb)/(j\varepsilon)$
odd	$\pm\sqrt{M^2+p_n^2}$, $\tan(p_nL) = -p_n/M$	$b = \sin(p_n(y+L))$, $a = (b' + Mb)/(j\varepsilon)$

Apart from the zero mode, every level has $|\varepsilon| > M$: the free spectrum has a gap from $-M$ to M that contains only the zero modes. Every level of one block type is held by its four blocks (s_2, s_3), so it is 4-fold per type and 8-fold in all (for $v = 0$ the levels of the type $j = -1$ are the negatives of

those of $j = +1$, Section 14.5, and the set of levels above is symmetric). Status: PROVED; check bc_exact_k0_spectra (both reports).

The numbers for $M = 1$, $L = 3$ (Notebook 14b, Out [4]): the first odd roots are $p_0 = 0.818548$, $p_1 = 1.744313$, $p_2 = 2.734844$; the lowest odd level is $\sqrt{1 + p_0^2} = 1.292292828069\,m$ and the lowest positive even level is $\sqrt{1 + (\pi/3)^2} = 1.447971930402\,m$. The Rust solver's record `Revision/kohn_sham/results/spectrum/free-k0-analytic.csv` lists 54 such exact levels (labels -3 to 5, both parities, $(m, L) = (1, 3), (1, 2), (2, 3)$) next to its numerical ones (check free_k0_analytic_spectra of `Revision/kohn_sham/reports/ks-rust-solver.json`); Notebook 14b reproduces both columns.

The labels. The Revision solver names the levels by integer **labels**: even parity, label 0 is the zero mode, label $n > 0$ the n-th positive level and $-n$ its negative; odd parity, label $l \geq 0$ is the level $+\sqrt{M^2 + p_l^2}$ and label $l \leq -1$ the level $-\sqrt{M^2 + p_{-l-1}^2}$. Section 14.14 shows that these labels are not arbitrary names: they count half-turns.

14.14 Shooting with a Pruefer angle: every level has a label

Shooting. For nonzero k, or a mass and a potential that depend on y, the block equation cannot be solved by hand, and the computer finds the levels by **shooting** (Chapter 2): start at one end with the condition there, integrate to the other end, and adjust the energy until the condition there holds too. Here the start is the tip, with $(a, b) = (\cos\frac{\theta}{2}, \sin\frac{\theta}{2})$ at $y = -L$, which is $(1, 0)$ for the canonical $\theta = 0$; the real form is integrated from $y = -L$ to $y = 0$ for a trial energy ε; and ε is a level of even parity if $b(0) = 0$, of odd parity if $a(0) = 0$.

The Pruefer angle. Write the point (a, b) of the plane in polar form, $a = r\cos\theta$, $b = r\sin\theta$, with the length $r = \sqrt{a^2 + b^2} > 0$ and the angle θ (the **Pruefer angle**, after the mathematician Pruefer). On a computer the angle of a point is the function atan2(b, a), which returns a value between $-\pi$ and π; following it **continuously** means adding or subtracting 2π whenever that value jumps, so that $\theta(y)$ has no jumps and can count whole turns. Line by line:

$$a' = r'\cos\theta - r\theta'\sin\theta, \qquad b' = r'\sin\theta + r\theta'\cos\theta.$$

Rule: the product rule and the chain rule.

$$ab' - ba' = r^2\theta'(\cos^2\theta + \sin^2\theta) = r^2\theta'.$$

Rule: multiply out; the terms with r' cancel; $\cos^2\theta + \sin^2\theta = 1$.

$$ab' - ba' = j\varepsilon'(a^2 + b^2) - K(a^2 - b^2) - 2Mab.$$

Rule: insert the real form, $a[(j\varepsilon' - K)a - Mb] - b[Ma - (K + j\varepsilon')b]$, and collect the terms.

$$\theta' = j\varepsilon' - K\cos 2\theta - M\sin 2\theta.$$

Rule: divide the last two lines by r^2, with $a^2 - b^2 = r^2(\cos^2\theta - \sin^2\theta) = r^2\cos 2\theta$ and $2ab = 2r^2\sin\theta\cos\theta = r^2\sin 2\theta$ (the double-angle formulas). The equation for θ does not contain r, so the

angle can be followed by itself. Status: PROVED; Notebook 14b checks the last line with sympy (In [6]).

The angle at the brane grows with the energy. Let $a_\varepsilon = \partial a/\partial\varepsilon$ and $b_\varepsilon = \partial b/\partial\varepsilon$ be the rates at which the solution changes when the trial energy changes (the tip values do not depend on ε), and put $w = ab_\varepsilon - ba_\varepsilon$. By the same rule as for θ', with ε in place of y, $\partial\theta/\partial\varepsilon = w/r^2$. Line by line:

$$w' = a'b_\varepsilon + ab'_\varepsilon - b'a_\varepsilon - ba'_\varepsilon.$$

Rule: the product rule.

$$a'_\varepsilon = Ma_\varepsilon - (K + j\varepsilon')b_\varepsilon - jb, \qquad b'_\varepsilon = (j\varepsilon' - K)a_\varepsilon - Mb_\varepsilon + ja.$$

Rule: differentiate the real form with respect to ε; the product rule applied to $j\varepsilon' b$ and $j\varepsilon' a$ gives the extra terms $-jb$ and $+ja$, since $\partial\varepsilon'/\partial\varepsilon = 1$.

$$w' = j(a^2 + b^2) = jr^2.$$

Rule: insert the real form and the last line into the first line; every term that contains M, K or ε' appears twice with opposite signs and cancels, and what is left is $a(ja) - b(-jb)$.

$$\frac{\partial\theta(0)}{\partial\varepsilon} = \frac{w(0)}{r(0)^2} = \frac{j}{r(0)^2}\int_{-L}^{0} r^2\,dy.$$

Rule: $w(-L) = 0$, because the starting point does not depend on ε ($a_\varepsilon = b_\varepsilon = 0$ at $y = -L$); integrate $w' = jr^2$ from $-L$ to 0. So the **shooting function** $\Phi(\varepsilon) = j\,\theta(0)$ has the derivative $\int r^2 dy/r(0)^2 > 0$: it grows strictly with the energy. Status: PROVED (this derivation); Notebook 14b confirms it numerically for $k = 0$ and $k = 0.75$ (In [7]).

Every level has an integer label. $b(0) = 0$ means that $\theta(0)$ is a whole multiple of π; $a(0) = 0$ means that $\theta(0)$ is $\pi/2$ plus a whole multiple of π. With $\Phi = j\theta(0)$:

$$\text{even level: } \Phi(\varepsilon) = l\pi, \qquad \text{odd level: } \Phi(\varepsilon) = \frac{\pi}{2} + l\pi, \qquad l = \ldots, -1, 0, 1, \ldots$$

The integer l is the **label** of the level. Because Φ grows strictly, it passes every target value at most once. It passes every target value at least once, because it runs from $-\infty$ to $+\infty$. Line by line:

$$\theta(0) - \theta(-L) = \int_{-L}^{0} \theta'\,dy = j\varepsilon L - j\int_{-L}^{0} v\,dy - \int_{-L}^{0} \big(K\cos 2\theta + M\sin 2\theta\big)\,dy.$$

Rule: integrate the equation of the Pruefer angle from $-L$ to 0, with $\varepsilon' = \varepsilon - v$ (the integral of the constant $j\varepsilon$ over an interval of length L is $j\varepsilon L$).

$$\big|\Phi(\varepsilon) - \varepsilon L\big| \le |\theta(-L)| + \int_{-L}^{0} |v|\,dy + \int_{-L}^{0} \big(|K| + |M|\big)\,dy.$$

Rule: multiply the last line by j (with $j^2 = 1$ this gives $\Phi = j\theta(0)$ on the left and εL as the first term on the right), move every other term to the right side, and use $|j| = 1$, $|\cos 2\theta| \le 1$, $|\sin 2\theta| \le 1$ and the rule that the size of an integral is at most the integral of the size. The right side does not depend on ε: the start angle $\theta(-L)$ is fixed by the tip condition, and v, K and M are given functions of y. So $\Phi(\varepsilon)$ stays within a fixed distance of the straight line εL: for very negative ε it lies below every target value, for very positive ε above it, and because it has no jumps it passes the target value in between (the intermediate value theorem, Section 2.12). Hence there is exactly one level for every label and parity, no level can be missed and none can be counted twice. Status: PROVED (this derivation; it is not a separate check of the Revision record, and Notebook 14b confirms the labels numerically). At $k = 0$ these are exactly the labels of Section 14.13 (Figure 14b.6 shows the angles).

Finding a level. The notebooks of this chapter find a level by plain **bisection** on $\Phi(\varepsilon) -$ target (Chapter 2): they keep an interval with the target between $\Phi(\text{lo})$ and $\Phi(\text{hi})$ and halve it 72 times, starting from $[-20, 20]$. After 72 halvings the interval has the length $40/2^{72} \approx 8.5 \times 10^{-21}$, far below the spacing of floating-point numbers near 1 (about 2.2×10^{-16}): the result is the level of the integrated equation to the last digit the computer can hold, and the error that remains is the error of the integration. The Revision Rust solver finds the root of the same function Φ with fewer evaluations, by the **safeguarded Newton-bisection** of Section 2.24 (the function find_level of `Revision/kohn_sham/solver/src/shoot.rs`): it widens a bracket around a first guess until $\Phi -$ target changes sign, then takes Newton steps with the derivative $d\Phi/d\varepsilon = \int r^2 dy / r(0)^2$ derived above, takes the midpoint of the bracket instead whenever a Newton step would leave the bracket or the last step has not at least halved the mismatch $|\Phi - \text{target}|$, and stops when the bracket, or its last Newton step, is shorter than the tolerance 10^{-13} (rootTolerance of `Revision/kohn_sham/results/parameters.json`). Both find the root of the same integrated Φ, so the two sets of levels agree to far below 10^{-11}; Notebook 14b measures the largest difference, 7.1×10^{-15} (In [8]).

The integration (RK4). The real form is integrated with the classical fourth-order Runge-Kutta method of Chapter 2, with G steps of size $h = L/G$ (the Revision solver uses $G = 900$ for $L = 3$, so $h = 1/300$). RK4 needs the coefficient $K = \kappa k$ at the nodes and at the midpoints of the steps, that is on a fine grid of $2G + 1$ points. Its error is proportional to h^4: halving the step divides the error of a level by $2^4 = 16$. The Revision record measured exactly this: doubling the step number ($G = 1800$ for $L = 3$, 1200 for $L = 2$) divided the errors of the 39 levels whose error is above 10^{-11} by the median factor 16.00, and the largest errors were 5.050×10^{-8} with the canonical and 3.157×10^{-9} with the refined step (check refined_free_spectra_convergence_order of `Revision/kohn_sham/reports/ks-rust-determinism.json`). Status: COMPUTED; Notebook 14b repeats the measurement (In [10]).

14.15 Example: Notebook 14b, the free spectra exact and numerical

Notebook 14b does Sections 14.12 to 14.14 with the computer. With sympy it checks the real form, the mirror map and the parities of the densities, the brane conditions, the boundary term, the tip family, the constant current, the exact solutions of Section 14.13 and the equation of the Pruefer angle, each against the verdict of the Revision record. With numpy it writes the shooting function of the Revision Rust solver in about forty lines (RK4 on the fine grid, the Pruefer angle followed step by step) with plain bisection on the labels (the Rust solver uses the safeguarded Newton-bisection of Section 14.14 instead), finds the 54 levels of the record and compares them with the exact levels and with the Rust numbers, repeats the fourth-order measurement, and compares the numerical

orbitals with the exact ones. It draws six figures. It needs no Rust. It runs in about 40 seconds (two cells integrate the equation for hundreds of energies at once, 72 times over, and take 10 to 20 seconds each), and its last line is ALL 20 CHECKS PASSED (notebook 14b).

14.16 How to run Notebook 14b

Step 1. What this notebook does and what it needs.

Notebook 14b (The free Kohn-Sham spectrum at zero 3-momentum: exact formulas against numerical shooting) is the file `Revision/textbook/notebooks/14b_free_spectra.ipynb` of the repository Dirac_claude. For the free field (no interaction, constant mass M, zero 3-momentum) it writes the 2 x 2 block equation of dirac16complex in real form, derives its boundary conditions (the ASSUMED Z2 mirror brane at y = 0 and the regular tip at y = -L) and their consequences, solves the equation exactly (the brane zero mode, the even levels plus or minus the square root of M^2 + (n pi/L)^2, the odd levels from tan(pL) = -p/M), solves it again numerically with a fourth-order Runge-Kutta shooting method whose Pruefer angle gives every level an integer label, and compares the two: it reproduces the free spectra, the zero mode and the measured fourth-order convergence of the Revision Rust solver and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 14b_free_spectra.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 40 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 14b_free_spectra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 14b_free_spectra.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/14b.captions.json`
- `Revision/textbook/figures/14b_1_odd_condition.png`
- `Revision/textbook/figures/14b_2_shooting_function.png`
- `Revision/textbook/figures/14b_3_spectrum_ladder.png`
- `Revision/textbook/figures/14b_4_rk4_convergence.png`
- `Revision/textbook/figures/14b_5_orbitals.png`
- `Revision/textbook/figures/14b_6_pruefer_angle.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files of this notebook exist
ALL 20 CHECKS PASSED (notebook 14b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/14b_free_spectra.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 14b_free_spectra.ipynb
python -m nbconvert --execute --inplace 14b_free_spectra.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.

- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 9 and 10 run for 10 to 20 seconds each: they integrate the equation for hundreds of energies at once, 72 times over; wait until the PASS lines appear.

14.17 Notebook 14b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/14b_free_spectra.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

In the Kohn-Sham model of dirac16complex in the deflating primordial field every
orbital is described by a pair of functions $\chi = (\chi_1, \chi_2)$ of the
hidden coordinate $y$ between the tip cutoff $y = -L$ and the brane $y = 0$. This
notebook studies the simplest case completely: no interaction ($v = 0$, constant
mass $M$) and zero 3-momentum ($k = 0$). It

- writes the $2\times2$ block equation in real form and checks it;
- derives and checks the boundary conditions: the Z2 mirror brane at $y = 0$
  (ASSUMED) with its two parities, the regular tip at $y = -L$ (a CHOSEN cutoff
  condition), and what they imply (no current through the ends, real levels);
- solves the equation exactly: the brane zero mode $\varepsilon = 0$, the even
  levels $\pm\sqrt{M^2 + (n\pi/L)^2}$ and the odd levels from
  $\tan(pL) = -p/M$ (figure 1);
- solves it again numerically with the shooting function of the Revision Rust
  solver: fourth-order Runge-Kutta (RK4) shooting with a Pruefer angle that
  gives every level an integer label, the levels found by bisection
  (figures 2 and 6);
- compares the two for 54 levels and reproduces the Rust solver's record to
  about $10^{-14}$ (figure 3);
- measures the fourth-order convergence of the method (figure 4) and draws the
  orbitals against the exact ones (figure 5).

It prints a PASS line for every check (20 in all) and saves six figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**
```

Notebook 14b (The free Kohn-Sham spectrum at zero 3-momentum: exact formulas against numerical shooting) is the file ‘Revision/textbook/notebooks/14b_free_spectra.ipynb‘ of the repository Dirac_claude. For the free field (no interaction, constant mass M, zero 3-momentum) it writes the 2 x 2 block equation of dirac16complex in real form, derives its boundary conditions (the ASSUMED Z2 mirror brane at y = 0 and the regular tip at y = -L) and their consequences, solves the equation exactly (the brane zero mode, the even levels plus or minus the square root of M^2 + (n pi/L)^2, the odd levels from tan(pL) = -p/M), solves it again numerically with a fourth-order Runge-Kutta shooting method whose Pruefer angle gives every level an integer label, and compares the two: it reproduces the free spectra, the zero mode and the measured fourth-order convergence of the Revision Rust solver and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 14b_free_spectra.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 40 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.

**Step 6. Or run the notebook without a browser (headless).**

In the repository folder, with the environment active, run:

Windows, macOS and Linux:
```

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 14b_free_spectra.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 14b_free_spectra.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/14b.captions.json‘
- ‘Revision/textbook/figures/14b_1_odd_condition.png‘
- ‘Revision/textbook/figures/14b_2_shooting_function.png‘
- ‘Revision/textbook/figures/14b_3_spectrum_ladder.png‘
- ‘Revision/textbook/figures/14b_4_rk4_convergence.png‘
- ‘Revision/textbook/figures/14b_5_orbitals.png‘
- ‘Revision/textbook/figures/14b_6_pruefer_angle.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS all six figure files of this notebook exist
    ALL 20 CHECKS PASSED (notebook 14b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file

  ‘Revision/textbook/notebooks/14b_free_spectra.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 14b_free_spectra.ipynb
      python -m nbconvert --execute --inplace 14b_free_spectra.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 9 and 10 run for 10 to 20 seconds each: they integrate the equation for hundreds of energies at once, 72 times over; wait until the PASS lines appear.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 14b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 14b (The free Kohn-Sham spectrum at zero 3-momentum: exact formulas against
# numerical shooting) is the file Revision/textbook/notebooks/14b_free_spectra.ipynb of
# the repository Dirac_claude. For the free field (no interaction, constant mass M, zero
# 3-momentum) it writes the 2 x 2 block equation of dirac16complex in real form, derives
# its boundary conditions (the ASSUMED Z2 mirror brane at y = 0 and the regular tip at y
# = -L) and their consequences, solves the equation exactly (the brane zero mode, the
# even levels plus or minus the square root of M^2 + (n pi/L)^2, the odd levels from
# tan(pL) = -p/M), solves it again numerically with a fourth-order Runge-Kutta shooting
# method whose Pruefer angle gives every level an integer label, and compares the two: it
```

```
# reproduces the free spectra, the zero mode and the measured fourth-order convergence of
# the Revision Rust solver and draws six teaching figures. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
```

```
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
```

```
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 14b_free_spectra.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 40
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 14b_free_spectra.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 14b_free_spectra.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/14b.captions.json
# - Revision/textbook/figures/14b_1_odd_condition.png
# - Revision/textbook/figures/14b_2_shooting_function.png
# - Revision/textbook/figures/14b_3_spectrum_ladder.png
# - Revision/textbook/figures/14b_4_rk4_convergence.png
```

```
# - Revision/textbook/figures/14b_5_orbitals.png
# - Revision/textbook/figures/14b_6_pruefer_angle.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files of this notebook exist
#     ALL 20 CHECKS PASSED (notebook 14b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/14b_free_spectra.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 14b_free_spectra.ipynb
#     python -m nbconvert --execute --inplace 14b_free_spectra.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
```

```
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - the cells of sections 9 and 10 run for 10 to 20 seconds each: they integrate the
#   equation for hundreds of energies at once, 72 times over; wait until the PASS lines
#   appear.

## 3. The words used in this notebook

- **Hidden coordinate $y$**: proper length along the hidden direction $x_0$;
  the brane is at $y = 0$, the tip cutoff at $y = -L$ (here $L = 3$, $2$).
- **Block equation**: in each of eight $2\times2$ blocks the Kohn-Sham
  equation is $h_j\chi = \varepsilon\chi$ with
  $h_j = j[-i\sigma_1\,d/dy + M\sigma_2 + \kappa k\,\sigma_3] + v$, where
  $j = \pm1$ is the block type, $M$ the (effective) mass, $\kappa k$ the
  weighted 3-momentum and $v$ the vector potential.
- **Level, orbital**: an energy $\varepsilon$ for which a solution exists that
  satisfies both boundary conditions; that solution is the orbital.
- **Real form**: writing $\chi = (a, ib)$ with real $a$, $b$ makes all
  coefficients real.
- **Boundary condition**: a condition on the solution at an end of the interval.
- **Z2 mirror brane**: the ASSUMED picture that the patch $y \le 0$ is glued at
  $y = 0$ to a mirror copy and the field obeys the parity relation
  $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$; the relation (not the gluing alone)
  gives the even parity ($b(0) = 0$) and the odd parity ($a(0) = 0$).
- **Regular tip**: the chosen condition $b(-L) = 0$ at the cutoff.
- **Current**: $\chi^\dagger\sigma_1\chi$, the flow of the U(1) charge along
  $y$; a good boundary condition makes it vanish at the ends.
- **Self-adjoint**: the Hamiltonian satisfies $\int\varphi^\dagger h\chi\,dy =
  \int(h\varphi)^\dagger\chi\,dy$; then the levels are real.
- **Shooting**: start the solution at one end with the condition there,
  integrate to the other end, and adjust $\varepsilon$ until the condition there
```

```
  holds too.
- **RK4**: the classical fourth-order Runge-Kutta method for $u' = f(y, u)$ with
  step $h$: four slopes per step, error per unit length proportional to $h^4$.
- **Pruefer angle** $\theta = \mathrm{atan2}(b, a)$: the angle of the point
  $(a, b)$ in the plane; counting its half-turns labels the levels.
- **Bisection**: halve an interval that contains a root, keep the half where the
  function changes sign, repeat.
- **Simpson's rule**: an integration rule with the weights $1, 4, 2, 4, \dots,
  4, 1$ times (step/3).
```

Text cell:

```
## 4. The physical and mathematical situation

The Revision theory (‘Revision/kohn_sham/ks-theory.json‘) reduces the Kohn-Sham
equation exactly to the block equation $h_j\chi = \varepsilon\chi$ above, with
$\kappa(y) = e^{-Hy - a_{4,0}}$ at the slice $a_{4,0}$ of the deflating history.
In this notebook $k = 0$, so $\kappa$ drops out and the slice does not matter;
$v = 0$ and $M$ is a constant. The equation is then simple enough to solve by
hand, and these exact solutions are the first test of every numerical solver of
the model: the Revision Rust solver checked itself against them (its record
‘Revision/kohn_sham/results/spectrum/free-k0-analytic.csv‘). Here we write the
same numerical method with numpy, so that every step can be read, and we check
that it gives the same numbers.

Units: $H = 1$ and energies in units of the mass $m$ (the canonical runs use
$m = 1$, $L = 3$); the cases $(m, L) = (1, 2)$ and $(2, 3)$ test other values.

Status: the exact solutions are PROVED (and verified in the Revision record);
the numerical levels are COMPUTED (error measured against the exact ones); the
brane condition is ASSUMED; the tip condition is a chosen cutoff condition.
```

Text cell:

```
## 5. The block equation in real form

The eigenvalue equation $h_j\chi = \varepsilon\chi$ is the same as the
first-order system (Revision record, ‘blockEquation.ode‘)

$$\chi' = N\chi,\qquad N = M\sigma_3 - \kappa k\,\sigma_2 + ij(\varepsilon - v)
\sigma_1 .$$

Write $\chi = (a, ib)$ with real functions $a$, $b$ and $K = \kappa k$. Then,
multiplying out the Pauli matrices:

$$a' = Ma - (K + j(\varepsilon - v))\,b,\qquad b' = (j(\varepsilon - v) - K)\,a
- Mb .$$

All coefficients are real, so a real starting point gives a real solution. The
next cell lets sympy multiply $N$ with $(a, ib)$ and checks that the result is
$(a', ib')$ with the two lines above.

## 6. The boundary conditions

**The brane (ASSUMED).** The Revision theory glues the patch $y \le 0$ at
$y = 0$ to a mirror copy (a Z2 orbifold, with the mirror warp $e^{-H|y|}$) and
asks $\Psi(-y) = \pm\gamma^{(x_0)}\Psi(y)$. At $y = 0$ this says
$(1 \mp \gamma^{(x_0)})\chi(0) = 0$; since $\gamma^{(x_0)} = \sigma_3$ in every
block: EVEN parity $\chi_2(0) = 0$, i.e. $b(0) = 0$; ODD parity $\chi_1(0) = 0$,
i.e. $a(0) = 0$. Line by line, what the mirror map does: if $\chi$ solves
$\chi'(y) = N(y)\chi(y)$, then $\tilde\chi(y) = \sigma_3\chi(-y)$ has
$\tilde\chi'(y) = -\sigma_3N(-y)\sigma_3\tilde\chi(y)$, and with
$\sigma_3\sigma_{1,2}\sigma_3 = -\sigma_{1,2}$ this is the same equation with the
mass $-M(-y)$, the potential $v(-y)$ and the weight $\kappa(-y)$. So the doubled
problem is mirror-symmetric only if the mass is ODD across the brane: the mirror
copy carries $-m$ (with the same $\lambda$), the $(+m, -m)$ mirror pair of the
pairing theorem T3. Under the map, $\chi^\dagger\chi$ and
$\chi^\dagger\sigma_3\chi$ are even, $\chi^\dagger\sigma_2\chi$ and the current
$\chi^\dagger\sigma_1\chi$ odd.

**The tip (chosen).** At the cutoff $y = -L$ the family $(1 - Q(\theta))\chi(-L)
= 0$ with $Q = \cos\theta\,\sigma_3 + \sin\theta\,\sigma_2$ is allowed;
$Q^\dagger = Q$, $Q^2 = 1$ and $Q\sigma_1 + \sigma_1Q = 0$, so every member
kills the current. The canonical choice is $\theta = 0$: $b(-L) = 0$.

**Why these conditions.** Integrating by parts, $\varphi^\dagger h_j\chi -
(h_j\varphi)^\dagger\chi = \frac{d}{dy}[-ij\,\varphi^\dagger\sigma_1\chi]$; if
both ends kill the current, the boundary terms vanish and $h_j$ is
self-adjoint: the levels are real and orbitals of different levels are
orthogonal. Moreover $\chi^\dagger\sigma_1\chi$ is constant in $y$ on every
solution ($N^\dagger\sigma_1 + \sigma_1N = 0$), while $\chi^\dagger\chi$ is not.

The next cell checks all of this with sympy, as the Revision record did.

## 7. The exact solutions at zero 3-momentum

Take $k = 0$, $v = 0$ and a constant $M > 0$. The real form becomes
$a' = Ma - j\varepsilon b$, $b' = j\varepsilon a - Mb$. Line by line:

1. If $\varepsilon \ne 0$, solve the second equation for $a$:
   $a = (b' + Mb)/(j\varepsilon)$.
2. Differentiate: $a' = (b'' + Mb')/(j\varepsilon)$.
3. Put 1 and 2 into the first equation and multiply by $j\varepsilon$ (with
   $j^2 = 1$): $b'' + Mb' = M(b' + Mb) - \varepsilon^2 b$, that is
   $b'' = (M^2 - \varepsilon^2)\,b$.
4. EVEN parity, $b(0) = 0$ and $b(-L) = 0$: a solution that vanishes at both
   ends needs $M^2 - \varepsilon^2 = -p^2 < 0$, $b = \sin(py)$, and
   $\sin(-pL) = 0$, so $p = n\pi/L$: $\varepsilon = \pm\sqrt{M^2 + (n\pi/L)^2}$,
   $n = 1, 2, \dots$
5. EVEN parity and $\varepsilon = 0$: the equations decouple, $a' = Ma$,
   $b' = -Mb$; $b = 0$ satisfies both conditions and $a = e^{My}$: the BRANE
   ZERO MODE, largest at the brane, for every $L$.
6. ODD parity, $a(0) = 0$ and $b(-L) = 0$: $b = \sin(p(y + L))$ and, by 1,
   $a(0) = 0$ means $b'(0) + Mb(0) = 0$, i.e. $p\cos(pL) + M\sin(pL) = 0$, or
   $\tan(pL) = -p/M$; then $\varepsilon = \pm\sqrt{M^2 + p^2}$. In each interval
   $(n + \frac12)\pi/L < p < (n + 1)\pi/L$ there is exactly one root $p_n$.

Every level holds 4 states per block type (the four blocks of the same $j$),
8 in all. The next cell verifies 4 to 6 with sympy and computes the exact levels
for the labels $-3, \dots, 5$ of both parities and the three cases
$(m, L) = (1, 3), (1, 2), (2, 3)$, in the label convention of the Rust solver
(even: label 0 the zero mode, label $n > 0$ the $n$-th positive level, $-n$ its
negative; odd: label $l \ge 0$ the root $p_l$ with the plus sign, label
$l \le -1$ the root $p_{-l-1}$ with the minus sign). The odd roots are found by
bisection in their intervals, as the Rust solver does. The exact levels must
equal the column ‘eps_analytic‘ of the Rust solver’s record.
```

## 8. The shooting method and the Pruefer angle

Shooting: start at the tip with the tip condition, $(a, b) = (\cos\frac\theta2,
\sin\frac\theta2)$ (for the canonical $\theta = 0$ this is $(1, 0)$, so
```

```
$b(-L) = 0$), integrate the real form from $y = -L$ to $y = 0$ for a trial
energy $\varepsilon$, and look at the end point. The level is the energy for
which the brane condition holds.

To count, use the Pruefer angle $\theta(y) = \mathrm{atan2}(b, a)$, followed
continuously. Line by line:

1. $a = r\cos\theta$, $b = r\sin\theta$, so $\theta' = (ab' - ba')/r^2$.
2. Insert the real form: $ab' - ba' = j\varepsilon'(a^2 + b^2) - K(a^2 - b^2) -
   2Mab$ with $\varepsilon' = \varepsilon - v$.
3. With $a^2 - b^2 = r^2\cos2\theta$ and $2ab = r^2\sin2\theta$:
   $\theta' = j(\varepsilon - v) - K\cos2\theta - M\sin2\theta$.
4. The derivative of the end angle with respect to the energy is
   $d\theta(0)/d\varepsilon = j\int_{-L}^0 r^2\,dy\,/\,r(0)^2$; so
   $\Phi(\varepsilon) = j\,\theta(0)$ grows strictly with $\varepsilon$.

The brane condition says: even, $b(0) = 0$, i.e. $\Phi = l\pi$; odd, $a(0) = 0$,
i.e. $\Phi = \pi/2 + l\pi$, with an integer label $l$. Because $\Phi$ only grows,
and $\Phi(\varepsilon) - \varepsilon L$ stays bounded (so $\Phi$ runs from
$-\infty$ to $+\infty$), each label has exactly one level, no level can be
missed, and bisection on $\Phi(\varepsilon) - $ target always finds it.

The next cell checks line 3 with sympy and defines the two numerical tools of
the notebook: `shoot`, written exactly as in the Rust solver (classical RK4 with
$G$ steps on $[-L, 0]$, the coefficients taken at the nodes and step midpoints
of a fine grid of $2G + 1$ points, the angle unwrapped after every step), and
`levels` (plain bisection, 72 halvings of the interval $[-20, 20]$, which reaches
the resolution of floating-point numbers; the Rust solver finds the same root
with a safeguarded Newton-bisection that stops at the tolerance $10^{-13}$).
Both work on whole arrays of energies at once (numpy), which makes them fast.
```

## 9. All 54 levels: numerical against exact

The next cell computes the 54 levels (labels $-3$ to $5$, both parities, three
cases) by shooting and bisection, with the step numbers of the Rust solver:
$G = 900$ for $L = 3$ and $G = 600$ for $L = 2$ (the same step $h = 1/300$). It
```

```
checks three things:

- the numerical levels equal the Rust solver's column `eps_numeric` to
  $10^{-11}$ (both programs integrate the same RK4 discretisation and find the
  root of the same shooting function, this notebook by plain bisection down to
  the last digit, the Rust solver by a safeguarded Newton-bisection that stops
  at its tolerance $10^{-13}$ or sooner; the printed largest difference is of
  order $10^{-14}$);
- the largest numerical errors $|\varepsilon_{\rm num} -
  \varepsilon_{\rm exact}|$, for $|\varepsilon| < 4m$ and above, equal the ones
  the Rust check `free_k0_analytic_spectra` measured (read from its record) and
  lie below its tolerances $5\times10^{-9}$ and $3\times10^{-7}$;
- the zero mode comes out as exactly 0.

It prints the levels of the case $m = 1$, $L = 3$ next to the exact ones, the
largest difference from the Rust levels and the two largest errors.
```

## 10. Fourth-order convergence

RK4 has an error proportional to $h^4$: halving the step should divide the error
of every level by $2^4 = 16$. The Rust solver's refined run (the record
`ks-rust-determinism.json`, check `refined_free_spectra_convergence_order`)
doubled the step number ($G = 1800$ for $L = 3$, $1200$ for $L = 2$) and found,
over the 39 levels whose canonical error exceeds $10^{-11}$, the median error
ratio 16.00, with the largest errors $5.050\times10^{-8}$ (canonical) and
$3.157\times10^{-9}$ (refined). The next cell repeats this measurement. It takes
about 15 seconds.
```

## 11. The orbitals

The orbital of a level is the solution $(a, b)$ itself, normalised so that
$\int_{-L}^0(a^2 + b^2)\,dy = 1$. The next cell defines ‘orbital‘, again as in
the Rust solver: it keeps $(a, b)$ at the nodes, fills the step midpoints by
cubic Hermite interpolation (from the values and the derivatives at the two
neighbouring nodes, error of order $h^4$), and normalises with Simpson’s rule on
the fine grid. It then checks the brane zero mode against the exact
$a = \sqrt{2M/(1 - e^{-2ML})}\,e^{My}$, $b = 0$ (the Rust check
‘free_zero_mode_exact‘: $\varepsilon = 0$ exactly, $b = 0$ exactly, $a$ to
$10^{-9}$), and the first even and odd orbitals against the exact ones of
section 7 (normalised the same way and with the sign that makes $a(-L) > 0$).
```

In [12]:

```
def orbital(eps, k=0.0, j=1.0, M=1.0, L=3.0, G=900, H=1.0, a4=0.0, tip=0.0):
    """The normalised orbital (y, a, b) on the fine grid of 2G + 1 points."""
```

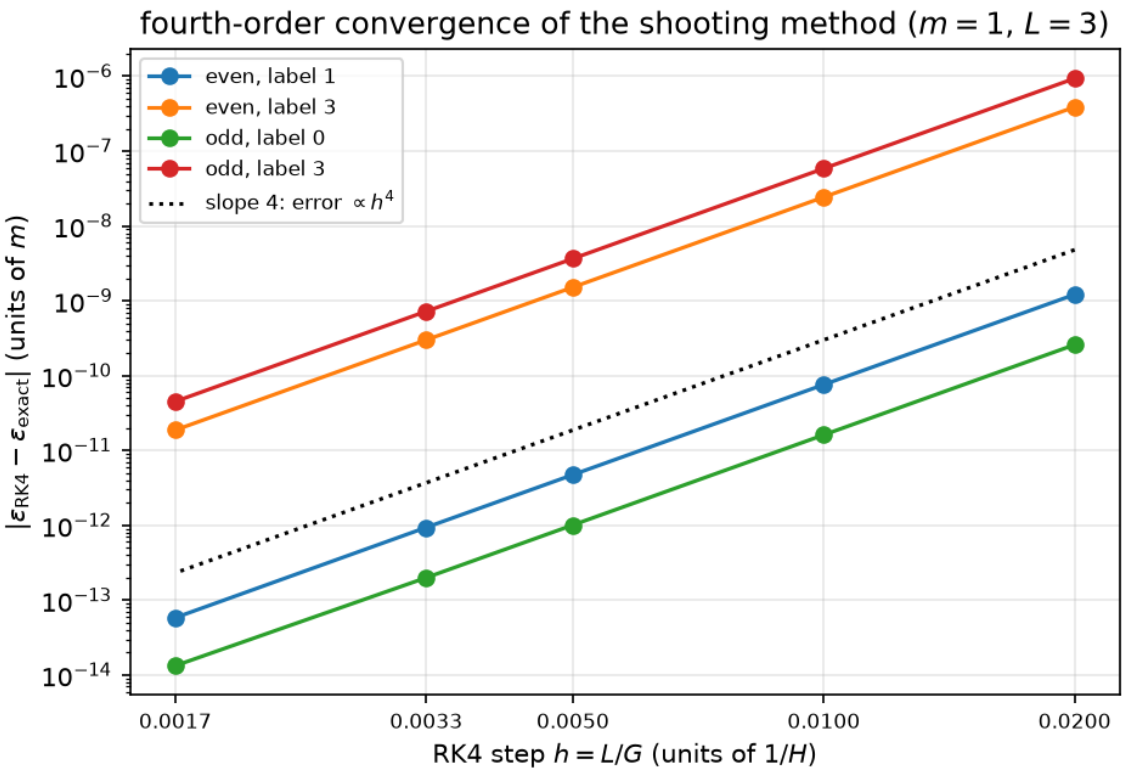

Figure 392: The error of four numerical levels ($m = 1$, $L = 3$; even labels 1 and 3, odd labels 0 and 3) against the RK4 step $h = L/G$ for $G = 150, 300, 600, 900, 1800$, on logarithmic axes (both in units of $m = H = 1$). The points fall on lines parallel to the dotted line of slope 4: halving the step divides the error by 16, the order of the classical Runge-Kutta method; higher levels have larger errors because their orbitals oscillate faster. (Notebook 14b, figure 4.)

check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all six figure files of this notebook exist")
all_checks_passed()
```

Out [15]:

```
PASS all six figure files of this notebook exist
ALL 20 CHECKS PASSED (notebook 14b)
```

Text cell:

```
## 13. What this notebook showed

- The block equation of the Kohn-Sham model is real in the variables
  $\chi = (a, ib)$ (PROVED).
- The ASSUMED Z2 mirror brane gives the two parities $b(0) = 0$ and $a(0) = 0$;
  the mirror map turns the mass $M(y)$ into $-M(-y)$, so a mirror-symmetric
  doubled problem has the mass $-m$ in the mirror copy; the chosen regular tip
  gives $b(-L) = 0$; both ends kill the current and make $h_j$ self-adjoint
  (PROVED; reproduces the Revision checks).
- At $k = 0$ without interaction the levels are exactly $0$ (the brane zero mode
  $e^{My}$), $\pm\sqrt{M^2 + (n\pi/L)^2}$ (even) and $\pm\sqrt{M^2 + p^2}$ with
  $\tan(pL) = -p/M$ (odd); for $m = 1$, $L = 3$ the lowest positive levels are
  $1.2922928281\,m$ (odd) and $1.4479719304\,m$ (even) (PROVED).
- RK4 shooting with the Pruefer angle finds every level by its label; the 54
  numerical levels equal the Rust solver's to about $10^{-14}$, their errors are
  within the Rust tolerances, and halving the step divides the error by 16.00
  (median over 39 levels): the method is of fourth order (COMPUTED, error
  measured).
- The numerical orbitals equal the exact ones; the zero mode is exactly
  $\varepsilon = 0$, $b = 0$.
```

14.18 Line-by-line walk-through of Notebook 14b

The notebook has 15 code cells, In [1] to In [15]. As in Section 14.11, a line or a small group of lines is quoted and then explained; docstrings and the long caption texts are left out of the quotations (the captions are printed under the figures in Section 14.17).

In [1], the set-up cell. Its code is, line for line, the code of In [1] of Notebook 14a, which Section 14.11 explains, with one exception: the line

```
NOTEBOOK_ID = "14b"  # this notebook: chapter 14, example b
```

gives this notebook its name, so that its figure files start with 14b and its captions go into the file `Revision/textbook/figures/14b.captions.json`. Its comment lines are the run instructions of Section 14.16. Out [1] is the line Set-up of notebook 14b complete.

In [2], the real form.

```
import math  # exp, cos, sin of single numbers

import numpy as np  # floating-point arrays
import sympy as sp  # exact algebra with symbols
```

`math` is the module of Python for single numbers (square roots, π, sine, cosine ...); numpy computes with whole arrays of floating-point numbers at once; sympy computes exactly with symbols.

```
PY_REPORT = "Revision/kohn_sham/reports/ks-theory-python.json"
WL_REPORT = "Revision/kohn_sham/reports/ks-theory-wolfram.json"
RUST_REPORT = "Revision/kohn_sham/reports/ks-rust-solver.json"
```

The names of three Revision reports: the sympy and the WolframScript checks of the theory, and the report of the Rust solver.

```
def record_check(name, reports=(PY_REPORT, WL_REPORT)):
    verdicts = []
    for report in reports:
        data = json.loads(repository_file(report).read_text(encoding="utf-8"))
        found = [c["verdict"] for c in data["checks"] if c["name"] == name]
        verdicts.append(found[0] if found else "absent")
    return verdicts[0] == "PASS" and all(v in ("PASS", "absent") for v in verdicts)
```

The same idea as `record_check` of Notebook 14a, with one improvement: the reports to read are a parameter with a **default value** (`reports=(PY_REPORT, WL_REPORT)` is used when the call gives no second argument). A call can name other reports, for example `record_check("free_zero_mode_exact", (RUST_REPORT,))`; the comma after `RUST_REPORT` makes a **tuple** with one element. The function collects the verdict of the check `name` in every report (or the word absent) and returns true when the first report says PASS and every report says PASS or absent.

```
s1 = sp.Matrix([[0, 1], [1, 0]])  # the Pauli matrices
s2 = sp.Matrix([[0, -sp.I], [sp.I, 0]])
s3 = sp.Matrix([[1, 0], [0, -1]])
I2 = sp.eye(2)
a, b, M, K, e, v = sp.symbols("a b M K epsilon v", real=True)
ok_all = True
```

The three Pauli matrices (in this notebook `s2` is σ_2), the 2×2 unit matrix, six real symbols (a, b, the mass M, $K = \kappa k$, e for ε and v) and a flag.

```
for j in (1, -1):
    N = M * s3 - K * s2 + sp.I * j * (e - v) * s1  # the matrix of chi' = N chi
    derivative = sp.expand(N * sp.Matrix([a, sp.I * b]))  # N times (a, i b)
    a_prime = M * a - (K + j * (e - v)) * b  # the real form
    b_prime = (j * (e - v) - K) * a - M * b
    ok = (sp.expand(derivative[0] - a_prime) == 0
          and sp.expand(derivative[1] - sp.I * b_prime) == 0)
    ok_all &= ok
    say(f"j = {j:+d}: d chi/dy = N chi with chi = (a, i b) gives the real form: "
        f"{ok}")
```

For both block types: the matrix N; the product $N\chi$ for $\chi = (a, ib)$, multiplied out by `sp.expand`; the right sides of the real form of Section 14.12; and the test that the first entry of $N\chi$ is a' and the second is ib'. The format `{j:+d}` prints the whole number j with its sign ($+1$ or -1); two strings written next to each other are joined into one. Out [2] shows True twice.

```
theory = json.loads(repository_file("Revision/kohn_sham/ks-theory.json")
                    .read_text(encoding="utf-8"))
say("record: " + theory["blockEquation"]["realForm"])
check(ok_all, "the real form da/dy = M a - (K + j(eps - v)) b, "
      "db/dy = (j(eps - v) - K) a - M b")
```

The Revision theory record is read and its entry blockEquation.realForm is printed, so that the reader can compare it with the derived form (Out [2], third line); then the first PASS line.

In [3], the boundary conditions.

```
y = sp.symbols("y", real=True)
H, a0, k = sp.symbols("H a0 k", real=True)
Mf = sp.Function("M", real=True)(y)  # a mass that depends on y
vf = sp.Function("v", real=True)(y)  # a potential that depends on y
kap = sp.exp(-H * y - a0)  # the momentum weight kappa(y)
```

Symbols for y, H, the slice $a_{4,0}$ (`a0`) and k, and two unknown real functions $M(y)$ and $v(y)$: everything below then holds for every mass profile and every potential, as in the self-consistent problem, not only for constants. `kap` is $\kappa(y)$.

```
def N_of(j, M_, v_, kap_):
    return M_ * s3 - kap_ * k * s2 + sp.I * j * (e - v_) * s1
```

The matrix N as a function of the block type, the mass, the potential and the weight.

```
ok_mirror = True
for j in (1, -1):  # chi~(y) = s3 chi(-y) solves chi~' = -s3 N(-y) s3 chi~
    mirrored = -s3 * N_of(j, Mf.subs(y, -y), vf.subs(y, -y), kap.subs(y, -y)) * s3
    target = N_of(j, -Mf.subs(y, -y), vf.subs(y, -y), kap.subs(y, -y))
    ok_mirror &= sp.simplify(mirrored - target).is_zero_matrix
check(ok_mirror and record_check("bc_mirror_map_PA"),
      "the mirror map chi(y) -> sigma3 chi(-y) turns M(y) into -M(-y)",
      record=f"{PY_REPORT}, check bc_mirror_map_PA")
```

`subs(y, -y)` replaces y by $-y$, so `Mf.subs(y, -y)` is $M(-y)$. `mirrored` is $-\sigma_3 N(-y)\sigma_3$, the matrix of the equation that $\tilde{\chi}(y) = \sigma_3\chi(-y)$ solves (Section 14.12), and `target` is N with the mass $-M(-y)$, the potential $v(-y)$ and the weight $\kappa(-y)$; they must be equal for both block types.

```
even = {name: (s3 * X * s3 - X).is_zero_matrix
        for name, X in {"n": I2, "S": s2, "Q": s3, "current": s1}.items()}
say(f"even under the mirror map: {even}")
check(even == {"n": True, "S": False, "Q": True, "current": False}
      and record_check("bc_mirror_parities_of_densities"),
      "n and Q are even, S and the current odd: the mirror copy carries -m",
      record=f"{PY_REPORT}, check bc_mirror_parities_of_densities")
```

A **dictionary comprehension** (braces with `key: value for ...`): for each density and its 2×2 matrix (the number density with 1, S with σ_2, Q with σ_3, the current with σ_1; `.items()` gives the

pairs of a dictionary) the value is true when $\sigma_3 X \sigma_3 = X$. That is the condition for the density to be even: the mirrored orbital has at y the density $\chi(-y)^\dagger \sigma_3 X \sigma_3 \chi(-y)$, which equals the density of the original orbital at $-y$ exactly when $\sigma_3 X \sigma_3 = X$. Out [3] prints the dictionary.

```
c1f, c2f = sp.Function("chi1")(y), sp.Function("chi2")(y)
current = sp.expand((sp.Matrix([c1f, c2f]).H * s1 * sp.Matrix([c1f, c2f]))[0])
check(current.subs(c2f, 0) == 0 and current.subs(c1f, 0) == 0
      and record_check("bc_brane_parity_conditions"),
      "both brane parities (chi2(0) = 0 or chi1(0) = 0) kill the current",
      record=f"{PY_REPORT}, check bc_brane_parity_conditions")
```

Two unknown complex functions χ_1, χ_2; the current $\chi^\dagger \sigma_1 \chi$ (a 1×1 matrix, whose single entry is `[0]`); putting $\chi_2 = 0$ (even parity) or $\chi_1 = 0$ (odd parity) makes it zero.

```
phi = sp.Matrix([sp.Function("phi1")(y), sp.Function("phi2")(y)])
chi = sp.Matrix([c1f, c2f])
ok_adjoint = True
for j in (1, -1):
    def h_on(w, j=j):  # h_j applied to the column w
        return j * (-sp.I * s1 * sp.diff(w, y) + Mf * s2 * w + kap * k * s3 * w) \
            + vf * w
    difference = (phi.H * h_on(chi))[0] - (h_on(phi).H * chi)[0]
    boundary = sp.diff(-sp.I * j * (phi.H * s1 * chi)[0], y)
    ok_adjoint &= sp.simplify(sp.expand(difference - boundary)) == 0
check(ok_adjoint and record_check("bc_self_adjoint_boundary_term"),
      "phi^dag h chi - (h phi)^dag chi = d/dy[-i j phi^dag sigma1 chi]",
      record=f"{PY_REPORT}, check bc_self_adjoint_boundary_term")
```

Two columns of unknown functions φ and χ. Inside the loop, `h_on(w)` applies $h_j = j[-i\sigma_1 \, d/dy + M\sigma_2 + \kappa k \sigma_3] + v$ to a column; the argument `j=j` stores the current value of `j` in the function (a function defined in a loop otherwise reads the loop variable only when it is called). `difference` is $\varphi^\dagger h_j \chi - (h_j \varphi)^\dagger \chi$, `boundary` is $\frac{d}{dy}[-ij\varphi^\dagger \sigma_1 \chi]$; they must be equal (Section 14.12).

```
th = sp.symbols("theta", real=True)
Q = sp.cos(th) * s3 + sp.sin(th) * s2  # the tip family
check(sp.simplify(Q * Q - I2).is_zero_matrix and Q.H == Q
      and sp.simplify(Q * s1 + s1 * Q).is_zero_matrix and record_check("bc_tip_family"),
      "the tip family Q(theta): Q^dag = Q, Q^2 = 1, Q sigma1 = -sigma1 Q",
      record=f"{PY_REPORT}, check bc_tip_family")
```

The three facts of the tip family: $Q^2 = 1$, $Q^\dagger = Q$, $Q\sigma_1 + \sigma_1 Q = 0$.

```
kp = sp.symbols("kappa", positive=True)
ok_current = True
for j in (1, -1):
    Nn = M * s3 - kp * k * s2 + sp.I * j * (e - v) * s1
    ok_current &= sp.simplify(Nn.H * s1 + s1 * Nn).is_zero_matrix
    density_changes = not sp.simplify(Nn.H + Nn).is_zero_matrix
check(ok_current and density_changes and record_check("bc_current_conserved_along_y"),
      "the current is constant along y on every solution, the density is not",
      record=f"{PY_REPORT}, check bc_current_conserved_along_y")
```

For both types: $N^\dagger\sigma_1 + \sigma_1 N = 0$ (the current is constant) and $N^\dagger + N \neq 0$ (the density is not). The variable `density_changes` is set anew in each pass; the check uses the value of the last pass, $j = -1$, which is the same as for $j = +1$. Out [3] shows six PASS lines.

In [4], the exact solutions and the record.

```
Lc = sp.symbols("L", positive=True)
n_int = sp.symbols("n", integer=True, positive=True)
ok_exact = sp.simplify(sp.diff(sp.exp(M * y), y) - M * sp.exp(M * y)) == 0  # step 5
```

The symbol L (named `Lc` because the plain name `L` is used for numbers below) and a positive whole number n. The first test is the zero mode: the derivative of e^{My} is Me^{My}, so $a = e^{My}$ solves $a' = Ma$ (step 5 of the notebook's section 7 is Step 2 of Section 14.13, case $\varepsilon = 0$).

```
for j in (1, -1):  # step 4: b = sin(n pi y/L), a = (b' + M b)/(j eps)
    p_n = n_int * sp.pi / Lc
    eps_n = sp.sqrt(M ** 2 + p_n ** 2)
    b_n = sp.sin(p_n * y)
    a_n = (sp.diff(b_n, y) + M * b_n) / (j * eps_n)
    ok_exact &= sp.simplify(sp.diff(a_n, y) - (M * a_n - j * eps_n * b_n)) == 0
    ok_exact &= b_n.subs(y, 0) == 0 and sp.simplify(b_n.subs(y, -Lc)) == 0
```

The even levels of Step 2: $b = \sin(n\pi y/L)$, $a = (b' + Mb)/(j\varepsilon_n)$. The second equation of the real form, $b' = j\varepsilon a - Mb$, holds by the construction of a; the loop checks the first one, $a' = Ma - j\varepsilon b$, and the two conditions $b(0) = 0$ and $b(-L) = \sin(-n\pi) = 0$ (sympy knows that the sine of a whole multiple of π is zero, because n was declared a whole number).

```
p = sp.symbols("p", positive=True)  # step 6 (j = +1)
b_odd = sp.sin(p * (y + Lc))
eps_odd = sp.sqrt(M ** 2 + p ** 2)
a_odd = (sp.diff(b_odd, y) + M * b_odd) / eps_odd
ok_exact &= sp.simplify(sp.diff(a_odd, y) - (M * a_odd - eps_odd * b_odd)) == 0
ok_exact &= sp.simplify(a_odd.subs(y, 0) * eps_odd
                        - (p * sp.cos(p * Lc) + M * sp.sin(p * Lc))) == 0
check(ok_exact and record_check("bc_exact_k0_spectra"),
      "the zero mode, the even levels and the odd condition tan(pL) = -p/M",
      record=f"{PY_REPORT}, check bc_exact_k0_spectra")
```

The odd levels of Step 3 for $j = +1$: $b = \sin(p(y + L))$ vanishes at $y = -L$; a is built as before; the first equation is checked; and $\varepsilon\, a(0) = p\cos(pL) + M\sin(pL)$, so $a(0) = 0$ is exactly the condition $f(p) = 0$.

```
def odd_roots(m, L, count):
    roots = []
    for n in range(count):
        lo, hi = (n + 0.5) * math.pi / L, (n + 1.0) * math.pi / L
        f = lambda q: m * math.sin(q * L) + q * math.cos(q * L)
        f_lo = f(lo)
        for _ in range(200):
```

```
            mid = 0.5 * (lo + hi)
            if mid <= lo or mid >= hi:  # the interval cannot shrink any more
                break
            if (f(mid) > 0.0) == (f_lo > 0.0):
                lo = mid
            else:
                hi = mid
        roots.append(0.5 * (lo + hi))
    return roots
```

The first `count` roots of $f(p) = m\sin(pL) + p\cos(pL)$ by **bisection**, one in each interval of Step 4. `f` is the function as a `lambda`; `f_lo` its value at the left end. The inner loop runs at most 200 times (the name `_` is used for a loop counter whose value is not needed); it stops earlier when the midpoint is no longer strictly inside the interval, which happens when the two ends are neighbouring floating-point numbers. If f has the same sign at the midpoint as at the left end, the root lies in the right half and `lo` moves to the midpoint; otherwise `hi` does. (The sign at the left end never changes, because `lo` only moves to points of the same sign.)

```
def exact_level(m, L, parity, label):
    if parity == "even":
        if label == 0:
            return 0.0
        return math.copysign(math.sqrt(m * m + (label * math.pi / L) ** 2), label)
    roots = odd_roots(m, L, 6)
    if label >= 0:
        return math.sqrt(m * m + roots[label] ** 2)
    return -math.sqrt(m * m + roots[-label - 1] ** 2)
```

The exact level of a given parity and label, in the label convention of Section 14.13. `math.copysign(x, label)` is the size of x with the sign of the label.

```
CASES = [(1.0, 3.0), (1.0, 2.0), (2.0, 3.0)]  # (m, L)
LABELS = list(range(-3, 6))  # the labels -3 ... 5
record_rows = repository_file(
    "Revision/kohn_sham/results/spectrum/free-k0-analytic.csv"
).read_text(encoding="utf-8").splitlines()
header = record_rows[0].split(",")
record = [dict(zip(header, row.split(","))) for row in record_rows[1:]]
```

The three cases (m, L) and the nine labels: with two parities, $3 \times 9 \times 2 = 54$ levels. The record of the Rust solver is a CSV file with the columns m, L, parity, label, eps_numeric, eps_analytic and difference; each row becomes a dictionary from column name to text, as in In [18] of Notebook 14a.

```
exact = {}  # (m, L, parity, label) -> exact level
for m_, L_ in CASES:
    for label in LABELS:
        for parity in ("even", "odd"):
            exact[(m_, L_, parity, label)] = exact_level(m_, L_, parity, label)
worst = max(abs(exact[(float(r["m"]), float(r["L"]), r["parity"], int(r["label"]))]
                - float(r["eps_analytic"])) for r in record)
```

A dictionary whose keys are tuples $(m, L, \text{parity}, \text{label})$ holds the 54 exact levels. `worst` is the largest difference between them and the column eps_analytic of the record (each text is turned into a number with `float` or `int`).

```
say(f"(m, L) = (1, 3): odd roots p = "
    + ", ".join(f"{q:.6f}" for q in odd_roots(1.0, 3.0, 3)) + ", ...")
lowest_odd = exact[(1.0, 3.0, "odd", 0)]  # the lowest odd level, m = 1, L = 3
lowest_even = exact[(1.0, 3.0, "even", 1)]  # the lowest positive even level
report("lowest odd level for m = 1, L = 3", f"{lowest_odd:.12f}", "m")
report("lowest positive even level for m = 1, L = 3", f"{lowest_even:.12f}", "m")
check(len(record) == 54 and worst < 1e-12,
      "the 54 exact levels equal the column eps_analytic of the record",
      record="Revision/kohn_sham/results/spectrum/free-k0-analytic.csv, eps_analytic")
```

`", ".join(...)` joins the three roots, each written with 6 decimals, into one text separated by commas. Then the two RESULT lines, $1.292292828069\,m$ and $1.447971930402\,m$, and the check that the record has 54 rows that agree with the exact levels to better than 10^{-12}. Out [4] shows two PASS lines.

In [5], figure 1.

```
p_values = np.linspace(0.0, 7.0, 1401)
f_values = 1.0 * np.sin(3.0 * p_values) + p_values * np.cos(3.0 * p_values)
roots_13 = odd_roots(1.0, 3.0, 6)
fig, ax = plt.subplots(figsize=(8.0, 4.0))
for n in range(6):  # the intervals in which the roots lie
    ax.axvspan((n + 0.5) * math.pi / 3.0, (n + 1.0) * math.pi / 3.0, color="C0",
               alpha=0.08)
```

1401 values of p from 0 to 7, the function $f(p)$ for $M = 1$, $L = 3$, and its first six roots. `axvspan(x1, x2, ...)` shades the vertical strip between x_1 and x_2; `alpha=0.08` makes it almost transparent. The six strips are the intervals $((n + \frac{1}{2})\pi/3, (n + 1)\pi/3)$.

```
ax.plot(p_values, f_values, color="C0", label="$f(p) = M\\sin(pL) + p\\cos(pL)$")
ax.plot(roots_13, [0.0] * 6, "o", color="C3", label="roots $p_0, p_1, \\dots$")
ax.axhline(0.0, color="black", linewidth=0.8)
ax.set_xlabel("$p$ (wave number along $y$, units of $H$)")
ax.set_ylabel("$f(p)$")
ax.set_title("the odd-parity condition $\\tan(pL) = -p/M$ for $M = 1$, $L = 3$")
ax.legend(fontsize=8, loc="lower left")
save_figure(fig, "odd_condition",
            "The odd-parity level condition for $M = 1$ and $L = 3$: the function "
            ...)
```

The curve, the six roots as red dots on the axis (`[0.0] * 6` is a list of six zeros; the format string `"o"` draws dots without a line), the horizontal axis line, labels, title, legend and saving. **What figure 14b.1 shows.** The function $f(p)$ oscillates with a growing amplitude (the term $p\cos(pL)$ grows with p). It starts at $f(0) = 0$, which is not a level ($p = 0$ gives $b = 0$), and crosses zero once in every shaded strip and nowhere else, at $p_0 = 0.8185$, $p_1 = 1.744$, $p_2 = 2.735$, ... as Step 4 of Section 14.13 proved; each crossing is a pair of odd levels $\pm\sqrt{1 + p_n^2}$.

In [6], the Pruefer angle and the shooting tools.

```
r_s, t_s = sp.symbols("r t", positive=True)  # polar coordinates of (a, b)
a_p = r_s * sp.cos(t_s)
b_p = r_s * sp.sin(t_s)
j_s = sp.symbols("j")
num = a_p * ((j_s * e - K) * a_p - M * b_p) - b_p * (M * a_p - (K + j_s * e) * b_p)
pruefer = j_s * e - K * sp.cos(2 * t_s) - M * sp.sin(2 * t_s)
check(sp.simplify(num / r_s ** 2 - pruefer) == 0,
      "d theta/dy = j(eps - v) - K cos 2theta - M sin 2theta")
```

The point $(a, b) = (r\cos\theta, r\sin\theta)$ with symbols r and θ (`t_s`), a symbol j, the expression $ab' - ba'$ with the real form inserted (`num`, written with $v = 0$, so that e stands for $\varepsilon - v$), and the claimed θ'. The check: $(ab' - ba')/r^2$ equals it (Section 14.14).

```
def shoot(eps, k=0.0, j=1.0, M=1.0, L=3.0, G=900, H=1.0, a4=0.0, tip=0.0,
          keep=False):
    eps, k, j = np.broadcast_arrays(np.asarray(eps, dtype=float),
                                    np.asarray(k, dtype=float),
                                    np.asarray(j, dtype=float))
```

`shoot` integrates the real form from the tip to the brane for many energies at once and returns $\Phi = j\theta(0)$. Its parameters have default values (the canonical $M = 1$, $L = 3$, $G = 900$, $H = 1$, slice 0, tip angle 0), so a call can name only what differs. `np.asarray` turns a single number or a list into a numpy array; `np.broadcast_arrays` brings the arrays to a common shape (a single number is repeated), so that `eps`, `k` and `j` may each be one number or an array of the same length.

```
    nf = 2 * G + 1  # the fine grid: nodes and step midpoints
    y_fine = -L * ((nf - 1 - np.arange(nf)) / (nf - 1))
    e_minus_Hy = np.exp(-H * y_fine)  # e^(-Hy) on the fine grid
    kk = k * np.exp(-a4)  # k e^(-a4,0): kappa k = kk e^(-Hy)
    h = L / G
```

The fine grid of $2G + 1$ points from $y = -L$ to $y = 0$ (`np.arange(nf)` is $0, 1, \ldots, 2G$, so the first point is $-L$ and the last 0); e^{-Hy} on it; the redshifted momentum $ke^{-a_{4,0}}$, so that $K = \kappa k$ is `kk` times e^{-Hy}; and the step $h = L/G$.

```
    a_ = np.full(eps.shape, math.cos(0.5 * tip))  # the tip condition
    b_ = np.full(eps.shape, math.sin(0.5 * tip))
    theta = np.full(eps.shape, 0.5 * tip)
    raw = np.arctan2(b_, a_)
    je = j * eps
    path = [(theta, a_, b_)]
```

The starting point $(a, b) = (\cos\frac{\theta}{2}, \sin\frac{\theta}{2})$ for every energy (`np.full(shape, value)` is an array filled with one value), the starting angle $\theta(-L) = \theta_{\text{tip}}/2$, `raw`, the angle as `np.arctan2` returns it (between $-\pi$ and π), the products $j\varepsilon$, and a list that will keep the path when it is asked for.

```
    for i in range(G):
        K0, K1, K2 = (kk * e_minus_Hy[2 * i], kk * e_minus_Hy[2 * i + 1],
                      kk * e_minus_Hy[2 * i + 2])  # K at y, y + h/2, y + h
        p1a, p1b = M * a_ - (K0 + je) * b_, (je - K0) * a_ - M * b_
        a2, b2 = a_ + 0.5 * h * p1a, b_ + 0.5 * h * p1b
        p2a, p2b = M * a2 - (K1 + je) * b2, (je - K1) * a2 - M * b2
        a3, b3 = a_ + 0.5 * h * p2a, b_ + 0.5 * h * p2b
        p3a, p3b = M * a3 - (K1 + je) * b3, (je - K1) * a3 - M * b3
        a4_, b4_ = a_ + h * p3a, b_ + h * p3b
        p4a, p4b = M * a4_ - (K2 + je) * b4_, (je - K2) * a4_ - M * b4_
        a_ = a_ + h / 6.0 * (p1a + 2.0 * p2a + 2.0 * p3a + p4a)
        b_ = b_ + h / 6.0 * (p1b + 2.0 * p2b + 2.0 * p3b + p4b)
```

One RK4 step per pass, for all energies at once. Step i goes from the node $2i$ of the fine grid to the node $2i + 2$; `K0`, `K1`, `K2` are K at its start, its midpoint and its end. The four slopes of RK4 (Chapter 2): `p1` at the start, `p2` at the midpoint with half a step along `p1`, `p3` at the midpoint with half a step along `p2`, `p4` at the end with a whole step along `p3`; each slope is the right side of the real form, $(Ma - (K + j\varepsilon)b,\ (j\varepsilon - K)a - Mb)$, with $v = 0$. The new point adds $h/6$ times the weighted sum with the weights $1, 2, 2, 1$. (The name `a4_` with a final underscore is the trial point of the fourth slope; `a4` without it is the slice.)

```
        new = np.arctan2(b_, a_)
        step = new - raw  # the change of the angle, brought into (-pi, pi]
        step = np.where(step > np.pi, step - 2 * np.pi,
                        np.where(step <= -np.pi, step + 2 * np.pi, step))
        theta = theta + step
        raw = new
        if keep:
            path.append((theta, a_, b_))
```

Following the angle continuously: the change of the raw angle over one step is brought into the interval from $-\pi$ to π (`np.where(condition, x, y)` takes `x` where the condition holds and `y` elsewhere; a jump of almost 2π of the raw angle is the passage through $\pm\pi$, not a real turn) and added to `theta`. The step is so small that the true change of the angle over one step is much less than π. With `keep=True` the angle and the point after every step are stored.

```
    if keep:
        return j * theta, [np.array(q) for q in zip(*path)]
    return j * theta
```

The result is $\Phi = j\theta(0)$. With `keep=True` also the paths: `zip(*path)` regroups the list of triples (θ, a, b) into three sequences, each turned into an array with one row per node ($G + 1$ rows) and one column per energy.

```
def target(parity, label):
    offset = np.where(np.asarray(parity) == "even", 0.0, 0.5 * np.pi)
    return offset + np.asarray(label, dtype=float) * np.pi
```

The value of Φ at a level: $l\pi$ for even parity and $\pi/2 + l\pi$ for odd parity, for arrays of parities and labels.

```
def levels(k, j, parity, label, iterations=72, **options):
    k, j, parity, label = np.broadcast_arrays(
        np.asarray(k, dtype=float), np.asarray(j, dtype=float),
        np.asarray(parity), np.asarray(label))
    goal = target(parity, label)
    lo, hi = np.full(k.shape, -20.0), np.full(k.shape, 20.0)
    for _ in range(iterations):
        mid = 0.5 * (lo + hi)
        g = shoot(mid, k, j, **options) - goal
        lo = np.where(g <= 0.0, mid, lo)  # g = 0: an exact level
        hi = np.where(g >= 0.0, mid, hi)
    return 0.5 * (lo + hi)
```

The levels with given momenta, block types, parities and labels, all at once, by 72 bisections of $[-20, 20]$ (Section 14.14). `**options` collects any further named arguments (for example `M=2.0` or `G=1800`) and hands them on to `shoot`. In each pass Φ is computed at the midpoints; where it is at or below the target, the level lies above the midpoint and `lo` moves there; where it is at or above, `hi` moves there. If Φ equals the target exactly, both ends move to the midpoint and the level is found exactly; this is what happens for the zero mode (In [8]).

```
say("defined: shoot(eps, k, j, M, L, G, ...) and levels(k, j, parity, label, ...)")
```

Out [6]: the PASS line of the angle equation and this line.

In [7], the shooting function and figure 2.

```
trial = np.linspace(-4.0, 4.0, 801)  # 801 trial energies
phi_curve = shoot(trial, 0.0, 1.0)  # Phi for k = 0, j = +1 (both parities)
grows = bool(np.all(np.diff(phi_curve) > 0.0))
grows_k = all(bool(np.all(np.diff(shoot(np.linspace(-4.0, 3.96, 200), 0.75, jj)) > 0))
              for jj in (1.0, -1.0))
check(grows and grows_k,
      "Phi(eps) grows strictly with eps (k = 0 and k = 0.75, both block types)")
```

$\Phi(\varepsilon)$ at 801 energies from -4 to 4 in one call. `np.diff` gives the differences of neighbouring values; `np.all(... > 0.0)` is true when every difference is positive, that is when Φ grows strictly; `bool` turns numpy's answer into a plain true or false. The same test for $k = 0.75$, 200 energies and both block types. One PASS line: the monotonicity proved in Section 14.14, seen numerically.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
ax.plot(trial, phi_curve / np.pi, color="C0", label="$\\Phi(\\varepsilon)/\\pi$")
for label in range(-3, 4):  # the targets in units of pi
    ax.axhline(label, color="C1", linewidth=0.7)
    ax.axhline(label + 0.5, color="C2", linewidth=0.7, linestyle="--")
```

The curve Φ/π and the targets: solid lines at the whole numbers (even), dashed lines at the half numbers (odd).

```
even_levels = [exact[(1.0, 3.0, "even", l)] for l in range(-2, 3)]
odd_levels = [exact[(1.0, 3.0, "odd", l)] for l in range(-2, 2)]
ax.plot(even_levels, range(-2, 3), "o", color="C1",
        label="even levels: $\\Phi = l\\pi$")
ax.plot(odd_levels, [l + 0.5 for l in range(-2, 2)], "s", color="C2",
        label="odd levels: $\\Phi = \\pi/2 + l\\pi$")
```

The exact levels of the labels -2 to 2 (even) and -2 to 1 (odd), drawn as circles and squares at the heights of their targets.

```
ax.set_xlabel("trial energy $\\varepsilon$ (units of $m$)")
ax.set_ylabel("$\\Phi(\\varepsilon) / \\pi$")
ax.set_title("the shooting function for $k = 0$, $j = +1$, $m = 1$, $L = 3$")
ax.legend(fontsize=8, loc="upper left")
save_figure(fig, "shooting_function",
            "The shooting function $\\Phi(\\varepsilon) = j\\,\\theta(0)$ (the "
            ...)
```

What figure 14b.2 shows. The curve rises from about -3.6 to $+3.6$ (in units of π) as the trial energy goes from -4 to 4, never falling. Every circle and square sits exactly on the curve where it crosses its target line: the crossings are the levels, one per label. Between -1 and 1 the curve is almost flat and crosses only the line 0, at $\varepsilon = 0$: the gap $(-M, M)$ contains only the zero mode. Where the levels are dense, the curve is steep.

In [8], all 54 levels.

```
numeric = {}  # (m, L, parity, label) -> numerical level at the canonical step
for m_, L_ in CASES:
    pars = np.array([p_ for l_ in LABELS for p_ in ("even", "odd")])
    labs = np.array([l_ for l_ in LABELS for p_ in ("even", "odd")])
    found = levels(0.0, 1.0, pars, labs, M=m_, L=L_, G=round(900 * L_ / 3))
    for p_, l_, x in zip(pars, labs, found):
        numeric[(m_, L_, str(p_), int(l_))] = float(x)
```

For each case, the 18 parities and labels as two arrays (the double list comprehension runs over the labels and, for each, over the two parities), and the 18 levels found in one call with $k = 0$, $j = +1$, the mass m, the cutoff L and $G = 900L/3$ steps (900 for $L = 3$, 600 for $L = 2$: always the step $h = 1/300$ of the Rust solver). `round` gives the nearest whole number. The levels go into the dictionary `numeric`.

```
say("m = 1, L = 3:  label  even (numerical)   even (exact)    "
    "odd (numerical)    odd (exact)")
for l_ in LABELS:
    row = [numeric[(1.0, 3.0, "even", l_)], exact[(1.0, 3.0, "even", l_)],
           numeric[(1.0, 3.0, "odd", l_)], exact[(1.0, 3.0, "odd", l_)]]
    say(f"               {l_:+d}   " + "  ".join(f"{x:15.10f}" for x in row))
```

A table of the case $m = 1$, $L = 3$: for each label the numerical and exact levels of both parities, each printed in 15 places with 10 decimals (`{x:15.10f}`).

```
rust_diff = max(abs(numeric[(float(r["m"]), float(r["L"]), r["parity"],
                             int(r["label"]))] - float(r["eps_numeric"]))
                for r in record)
report("largest difference from the Rust solver's levels", f"{rust_diff:.1e}", "m")
check(rust_diff < 1e-11,
      "the 54 numerical levels equal those of the Rust solver",
      record="Revision/kohn_sham/results/spectrum/free-k0-analytic.csv, eps_numeric")
```

The largest difference between the notebook's numerical levels and the Rust solver's (column eps_numeric), printed as a RESULT line with one decimal (`.1e`). The two programs integrate the same RK4 discretisation and look for the roots of the same shooting function Φ; they differ only in the root finder (plain bisection to the last digit here, the safeguarded Newton-bisection with the tolerance 10^{-13} in the Rust solver, Section 14.14) and in rounding. The check requires agreement to 10^{-11}; Out [8] shows the difference $7.1 \times 10^{-15}\,m$.

```
errors = {key: abs(numeric[key] - exact[key]) for key in numeric}
low = max(err for key, err in errors.items() if abs(exact[key]) < 4.0)
high = max(err for key, err in errors.items() if abs(exact[key]) >= 4.0)
report("largest error for |eps| < 4 m", f"{low:.2e}", "m")
report("largest error for |eps| >= 4 m", f"{high:.2e}", "m")
```

The errors against the exact levels, and the largest of them below and above $|\varepsilon| = 4m$, printed with two decimals (`.2e`). The Rust check free_k0_analytic_spectra measured the same two numbers; the next lines read them from its record.

```
import re  # regular expressions: patterns that find numbers in a text

def record_detail(name, report_file):
    """The detail text of the check called name in a Revision report."""
    data = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
    return [c["detail"] for c in data["checks"] if c["name"] == name][0]
```

`re` is Python's module for **regular expressions**, patterns that describe pieces of text. `record_detail` reads a report as `record_check` does (In [2]), keeps the checks with the given name and returns the detail text of the first, the sentence in which the record states its numbers. The argument is called `report_file` and not `report`, so that inside the function it does not hide the helper `report` of the set-up cell.

```
detail = record_detail("free_k0_analytic_spectra", RUST_REPORT)
rec_low, tol_low, rec_high, tol_high = re.findall(r"\d+(?:\.\d+)?e-\d+", detail)
check(f"{low:.2e}" == f"{float(rec_low):.2e}"
      and f"{high:.2e}" == f"{float(rec_high):.2e}"
      and low < float(tol_low) and high < float(tol_high)
      and record_check("free_k0_analytic_spectra", (RUST_REPORT,)),
      f"largest errors {low:.2e} for |eps| < 4 m and {high:.2e} above, as in the "
      f"record, below its tolerances {tol_low} and {tol_high}",
      record=f"{RUST_REPORT}, check free_k0_analytic_spectra")
```

The detail of the Rust check ends with the words

```
max |difference| 7.23e-10 for |eps| < 4 m (tolerance 5e-9, RK4 error ~ (h eps)^4),
5.05e-8 for 4 m <= |eps| < 7 m (tolerance 3e-7)
```

(one line in the record). The pattern `\d+(?:\.\d+)?e-\d+` describes a number with a negative power of ten: one or more digits (`\d+`), then, if present, a point and more digits (the group `(?:\.\d+)` followed by `?`, which makes it optional), then `e-` and digits; the `r` before the string keeps the backslashes as they are. `re.findall` returns every piece of the text that fits the pattern, in order: the texts `7.23e-10`, `5e-9`, `5.05e-8` and `3e-7`, which are unpacked into the four names (if the record ever stated a different number of such numbers, the unpacking would fail and the notebook would stop). The check requires: the notebook's two largest errors, written with two decimals, equal the record's, written the same way (`float` turns a text into a number, so the record's `5.05e-8` is written `5.05e-08`); both lie below the record's tolerances; and the record's verdict is PASS. Because the numbers are read from the record, the check fails if the record is ever recomputed with different results.

```
check(all(numeric[(m_, L_, "even", 0)] == 0.0 for m_, L_ in CASES),
      "the brane zero mode comes out as exactly eps = 0")
```

The last check: the zero mode is exactly 0 in all three cases. Why exactly: the first midpoint of the bisection is $\varepsilon = 0$; there, with $k = 0$ and the start $b = 0$, every RK4 slope of b is exactly zero, so b stays exactly 0, the angle stays exactly 0, $\Phi-$ target is exactly 0, and both ends of the interval jump to 0. Out [8] shows the table, three RESULT lines and three PASS lines: the largest difference from the Rust levels 7.1×10^{-15}, and the largest errors 7.23×10^{-10} below $4m$ and 5.05×10^{-8} above, the numbers of the record. In the table the numerical and exact levels agree in all 10 printed decimals for the even labels -2 to 2 and the odd labels -1 and 0; the odd labels -2, 1 and 2 differ by one unit in the 10th decimal (for example 2.0106285601 against 2.0106285600 for the odd label 1), and the higher labels differ in the 8th to 10th decimal (for example 5.3306254627 against 5.3306254587 for the even label 5): the error grows with the level, because the orbital oscillates faster.

In [9], figure 3.

```
fig, ax = plt.subplots(figsize=(8.0, 5.0))
for position, (m_, L_) in enumerate(CASES):
    x0 = 3.0 * position  # the horizontal place of this ladder
    for l_ in LABELS:
        for shift, parity, color, marker in ((0.0, "even", "C0", "o"),
                                             (1.2, "odd", "C1", "s")):
            level = exact[(m_, L_, parity, l_)]
            ax.plot([x0 + shift - 0.4, x0 + shift + 0.4], [level, level],
                    color=color, linewidth=1.5)
            ax.plot([x0 + shift], [numeric[(m_, L_, parity, l_)]], marker,
                    color=color, markersize=4)
    ax.fill_between([x0 - 0.5, x0 + 1.7], -m_, m_, color="gray", alpha=0.12)
```

For each case a **level ladder** at the horizontal place $x_0 = 0, 3, 6$: every exact level is a short horizontal line (from $x_0 + \text{shift} - 0.4$ to $x_0 + \text{shift} + 0.4$), even parity at the left and odd parity 1.2 further right, and the numerical level is a marker in its middle. `fill_between(x, y1, y2)` shades the band from $-m$ to m across the ladder.

```
ax.set_xlim(-0.6, 8.4)
ax.set_ylim(-7.0, 9.5)
ax.set_xticks([0.6, 3.6, 6.6])
ax.set_xticklabels(["$m = 1$, $L = 3$", "$m = 1$, $L = 2$", "$m = 2$, $L = 3$"])
ax.plot([], [], "o-", color="C0", label="even parity (line exact, dot numerical)")
ax.plot([], [], "s-", color="C1", label="odd parity (line exact, square numerical)")
ax.set_ylabel("level $\\varepsilon$ (units of $H = 1$)")
ax.set_title("the free $k = 0$ spectra, labels $-3$ to $5$")
ax.legend(fontsize=8, loc="lower right")
save_figure(fig, "spectrum_ladder",
            "The free $k = 0$ spectra for the three cases $(m, L) = (1, 3)$, "
            ...)
```

The ranges of the axes, the names of the three ladders under them, and two empty plots (`ax.plot( [], [], ...)` draws nothing) whose only purpose is to put the two styles into the legend. **What figure 14b.3 shows.** Three ladders. In each, the shaded band from $-m$ to m contains only the even zero mode at 0. For $m = 2$ the band is twice as wide and the lowest levels move out with it; for $L = 2$ the levels are farther apart than for $L = 3$, because the wave numbers $n\pi/L$ are larger. The even and odd levels alternate. On this scale every marker sits exactly on its line.

In [10], fourth-order convergence.

```
refined = {}
for m_, L_ in CASES:
    pars = np.array([p_ for l_ in LABELS for p_ in ("even", "odd")])
    labs = np.array([l_ for l_ in LABELS for p_ in ("even", "odd")])

    for p_, l_, x in zip(pars, labs, found):
        refined[(m_, L_, str(p_), int(l_))] = float(x)
refined_errors = {key: abs(refined[key] - exact[key]) for key in refined}
```

The same 54 levels with twice as many steps ($G = 1800$ for $L = 3$, 1200 for $L = 2$, the refined run of the Revision solver) and their errors.

```
ratios = sorted(errors[key] / refined_errors[key] for key in errors
                if errors[key] > 1e-11 and refined_errors[key] > 0.0)
median = ratios[len(ratios) // 2]
```

For every level whose canonical error is above 10^{-11} (smaller errors are dominated by rounding), the ratio of the canonical to the refined error, sorted. The **median** is the middle value of the sorted list: `len(ratios) // 2` is the position of the middle (`//` divides and drops the remainder; with 39 ratios it is the 20th value, position 19 counting from 0).

```
report("number of levels with a canonical error above 1e-11", len(ratios))
report("median error ratio canonical / refined", f"{median:.2f}")
report("largest error, canonical step", f"{max(errors.values()):.3e}", "m")
report("largest error, refined step", f"{max(refined_errors.values()):.3e}", "m")
```

Four RESULT lines: the number of ratios, the median ratio with two decimals, and the largest canonical and refined errors with three decimals and an exponent (`f"{x:.3e}"`).

```
DETERMINISM = "Revision/kohn_sham/reports/ks-rust-determinism.json"
detail = record_detail("refined_free_spectra_convergence_order", DETERMINISM)
rec_canonical, rec_refined = re.search(r"canonical (\S+), refined (\S+);",
                                       detail).groups()
rec_median, rec_count = re.search(r"ratio (\S+) over (\d+) levels",
                                  detail).groups()
```

The detail text of the record's check, read with `record_detail` of In [8], is

```
analytic k = 0 spectra: max error canonical 5.050e-08, refined 3.157e-09; median
error ratio 16.00 over 39 levels (RK4 order 4 predicts 16)
```

(one line in the record). `re.search` finds the first place where a pattern fits, and `.groups()` returns the pieces of text matched by the bracketed parts of the pattern: `\S+` is one or more characters that are not spaces, `\d+` one or more digits. So the first pattern picks out the texts `5.050e-08` and `3.157e-09` (the words "canonical" and "refined", the comma and the semicolon fix where they stand), and the second the texts `16.00` and `39`. If the record's sentence had another form, `re.searc h` would find nothing, return `None`, and `.groups()` would stop the notebook with an error.

```
check(len(ratios) == int(rec_count) and f"{median:.2f}" == rec_median
      and f"{max(errors.values()):.3e}" == rec_canonical
      and f"{max(refined_errors.values()):.3e}" == rec_refined
      and record_check("refined_free_spectra_convergence_order", (DETERMINISM,)),
      f"{len(ratios)} levels, median error ratio {median:.2f}, largest errors "
      f"{max(errors.values()):.3e} and {max(refined_errors.values()):.3e}",
      record=f"{DETERMINISM}, check refined_free_spectra_convergence_order")
```

The check that the notebook's four numbers equal the record's: 39 levels (`int` turns the text into a whole number), the median ratio 16.00 (RK4's $2^4 = 16$), and the largest errors 5.050×10^{-8} and 3.157×10^{-9}. The comparison is made on the printed texts, written in the same form as the record writes them, and the numbers come from the record itself, so a recomputed record with other numbers would make the check fail. The name of the check is built from the notebook's own numbers.

In [11], figure 4.

```
chosen = [("even", 1), ("even", 3), ("odd", 0), ("odd", 3)]
steps = [150, 300, 600, 900, 1800]
curves = {key: [] for key in chosen}
for G_ in steps:
    found = levels(0.0, 1.0, np.array([p_ for p_, l_ in chosen]),
                   np.array([l_ for p_, l_ in chosen]), M=1.0, L=3.0, G=G_)
    for key, x in zip(chosen, found):
        curves[key].append(abs(float(x) - exact[(1.0, 3.0) + key]))
```

Four levels and five step numbers; for each step number the four levels in one call, and their errors appended to four lists. `(1.0, 3.0) + key` joins two tuples into the key $(1, 3, \text{parity}, \text{label})$.

```
h_values = np.array([3.0 / G_ for G_ in steps])
fig, ax = plt.subplots(figsize=(7.0, 4.6))
for (parity, label), errs in curves.items():
    ax.loglog(h_values, errs, "o-", label=f"{parity}, label {label}")
ax.loglog(h_values, 3e-2 * h_values ** 4, ":", color="black",
          label="slope 4: error $\\propto h^4$")
```

The steps $h = 3/G$; `loglog` draws with logarithmic axes in both directions, on which a power law h^4 is a straight line of slope 4; the dotted guide line is $0.03\,h^4$.

```
ax.set_xticks(h_values)  # one tick at each step used
ax.set_xticklabels([f"{x:.4f}" for x in h_values], fontsize=8)
ax.xaxis.set_minor_locator(matplotlib.ticker.NullLocator())  # no extra ticks
ax.set_xlabel("RK4 step $h = L/G$ (units of $1/H$)")
ax.set_ylabel("$|\\varepsilon_{\\rm RK4} - \\varepsilon_{\\rm exact}|$ (units of $m$)")
ax.set_title("fourth-order convergence of the shooting method ($m = 1$, $L = 3$)")
ax.legend(fontsize=8)
```

One tick mark at each step used, labelled with 4 decimals; `NullLocator` removes the small extra ticks that a logarithmic axis draws by default.

```
fourth = all(12.0 < errs[i] / errs[i + 1] < 20.0 for errs in curves.values()
             for i in range(2))  # halving h from 0.02 to 0.005: ratios near 16
check(fourth, "halving the step divides each error by about 16 (between 12 and 20)")
save_figure(fig, "rk4_convergence",
            "The error of four numerical levels ($m = 1$, $L = 3$; even labels 1 "
            ...)
```

For the first three step numbers (150, 300, 600: $h = 0.02$, 0.01, 0.005) each halving must divide each of the four errors by a factor between 12 and 20. **What figure 14b.4 shows.** Four straight lines parallel to the dotted line of slope 4, from errors near 10^{-6} at $h = 0.02$ down to 10^{-13} or 10^{-14} at $h = 0.0017$: the method is of fourth order over the whole range. The lines of the higher levels (labels 3) lie about three powers of ten above those of the lowest levels.

In [12], the orbitals.

```
def orbital(eps, k=0.0, j=1.0, M=1.0, L=3.0, G=900, H=1.0, a4=0.0, tip=0.0):
    _, (theta_n, a_n, b_n) = shoot(eps, k, j, M=M, L=L, G=G, H=H, a4=a4, tip=tip,
                                   keep=True)
    nf, h = 2 * G + 1, L / G
    y_fine = -L * ((nf - 1 - np.arange(nf)) / (nf - 1))
    K_fine = k * np.exp(-a4) * np.exp(-H * y_fine)
```

The orbital of one level. `shoot(..., keep=True)` returns the angle and the paths; `_` receives Φ, which is not needed, and the paths are unpacked into three arrays (one value per node, since a single energy is given). Then the fine grid and $K = \kappa k$ on it.

```
    a_f, b_f = np.zeros(nf), np.zeros(nf)
    a_f[0::2], b_f[0::2] = a_n, b_n  # the node values
    da = M * a_f - (K_fine + j * eps) * b_f  # the derivatives at the nodes
    db = (j * eps - K_fine) * a_f - M * b_f
```

Two arrays for the fine grid; `a_f[0::2]` is every second entry starting at 0, the nodes, which receive the node values. `da` and `db` are the derivatives a', b' from the real form; only their values at the nodes are used below.

```
    for f in range(1, nf, 2):  # cubic Hermite value at each midpoint
        a_f[f] = 0.5 * (a_f[f - 1] + a_f[f + 1]) + h / 8.0 * (da[f - 1] - da[f + 1])
        b_f[f] = 0.5 * (b_f[f - 1] + b_f[f + 1]) + h / 8.0 * (db[f - 1] - db[f + 1])
```

The midpoints (odd positions 1, 3, 5, ...) get their values by **cubic Hermite interpolation**: the cubic polynomial that has the values f_0, f_1 and the derivatives f_0', f_1' at the two neighbouring nodes, a step h apart, has at the midpoint the value $\frac{1}{2}(f_0 + f_1) + \frac{h}{8}(f_0' - f_1')$ (Exercise 14.4). Its error is of order h^4, like that of RK4.

```
    weights = np.full(nf, 2.0)  # Simpson: 1, 4, 2, 4, ..., 4, 1 times (h/2)/3
    weights[1::2] = 4.0
    weights[0] = weights[-1] = 1.0
    weights *= 0.5 * h / 3.0
    norm = math.sqrt(float(np.sum(weights * (a_f ** 2 + b_f ** 2))))
    return y_fine, a_f / norm, b_f / norm, weights
```

Simpson's rule (Chapter 2) on the fine grid, whose spacing is $h/2$: the weights $1, 4, 2, 4, \ldots, 4, 1$ times $(h/2)/3$ (`weights[1::2]` are the odd positions, `weights[-1]` the last entry). The integral $\int (a^2 + b^2) dy$ is the weighted sum, and dividing a, b by its square root normalises the orbital. The function returns the grid, the normalised components and the weights.

```
y_f, a_zero, b_zero, simpson = orbital(numeric[(1.0, 3.0, "even", 0)])
a_exact = math.sqrt(2.0 / (1.0 - math.exp(-6.0))) * np.exp(y_f)
deviation = float(np.max(np.abs(a_zero - a_exact)))
check(numeric[(1.0, 3.0, "even", 0)] == 0.0 and np.all(b_zero == 0.0)
      and deviation < 1e-9 and record_check("free_zero_mode_exact", (RUST_REPORT,)),
      "zero mode: eps = 0 and b = 0 exactly, a = sqrt(2M/(1 - e^(-2ML))) e^(My)",
      record=f"{RUST_REPORT}, check free_zero_mode_exact")
```

The zero mode of $m = 1$, $L = 3$ against the exact $a = \sqrt{2/(1 - e^{-6})}\, e^{y}$ (Section 14.13 with $M = 1$, $L = 3$): its level is exactly 0, its b is exactly 0 at every point, and a agrees to 10^{-9}, as in the Rust check free_zero_mode_exact.

```
def exact_orbital(parity, label, m_=1.0, L_=3.0):
    level = exact[(m_, L_, parity, label)]
    p_ = math.sqrt(level ** 2 - m_ ** 2)
    if parity == "even":
        b_e = np.sin(p_ * y_f)
        a_e = (p_ * np.cos(p_ * y_f) + m_ * b_e) / level
    else:
        b_e = np.sin(p_ * (y_f + L_))
        a_e = (p_ * np.cos(p_ * (y_f + L_)) + m_ * b_e) / level
    sign = 1.0 if a_e[0] > 0 else -1.0  # the sign with a(-L) > 0
    norm = math.sqrt(float(np.sum(simpson * (a_e ** 2 + b_e ** 2))))
    return sign * a_e / norm, sign * b_e / norm
```

The exact orbitals of Section 14.13 for $j = +1$: $p = \sqrt{\varepsilon^2 - m^2}$, b the sine, $a = (b' + mb)/\varepsilon$ written out ($b' = p\cos$). An orbital is fixed only up to a constant factor; the numerical one starts with $a(-L) = 1 > 0$, so the exact one is given the sign that makes $a(-L) > 0$ (`a_e[0]` is its value at $y = -L$) and is normalised with the same Simpson weights.

```
shown = {}
worst_orbital = 0.0
for parity, label in (("even", 1), ("odd", 0)):
    _, a_num, b_num, _ = orbital(numeric[(1.0, 3.0, parity, label)])
    a_ex, b_ex = exact_orbital(parity, label)
    worst_orbital = max(worst_orbital, float(np.max(np.abs(a_num - a_ex))),
                        float(np.max(np.abs(b_num - b_ex))))
    shown[(parity, label)] = (a_num, b_num, a_ex, b_ex)
check(worst_orbital < 1e-8,
      "the even label 1 and odd label 0 orbitals equal the exact ones to 1e-8")
```

The numerical and exact orbitals of the even level 1 and the odd level 0, their largest difference over all points (below 10^{-8}), and a dictionary `shown` that keeps them for the figure. Out [12] shows two PASS lines.

In [13], figure 5.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 3.8), sharey=True)
panels = [("zero mode, $\\varepsilon = 0$", a_zero, b_zero, a_exact,
           np.zeros_like(a_exact)),
          (f"even label 1, $\\varepsilon = {lowest_even:.4f}$",) + shown[("even", 1)],
          (f"odd label 0, $\\varepsilon = {lowest_odd:.4f}$",) + shown[("odd", 0)]]
```

Three panels side by side that share the vertical axis (`sharey=True`), and for each a tuple of the title, the numerical a, b and the exact a, b; `(title,) + shown[...]` puts the title in front of the stored four arrays, and `np.zeros_like` is an array of zeros of the same shape (the exact b of the zero mode).

```
for ax, (title, a_num, b_num, a_ex, b_ex) in zip(axes, panels):
    ax.plot(y_f, a_num, color="C0", label="$a$ (numerical)")
    ax.plot(y_f, b_num, "--", color="C1", label="$b$ (numerical)")
    ax.plot(y_f[::60], a_ex[::60], ".", color="black", label="exact")
    ax.plot(y_f[::60], b_ex[::60], ".", color="black")
    ax.set_title(title, fontsize=9)
    ax.set_xlabel("$y$ (units of $1/H$)")
axes[0].set_ylabel("orbital component (normalised)")
axes[0].legend(fontsize=8, loc="upper left")
save_figure(fig, "orbitals",
            "The normalised orbitals $\\chi = (a, ib)$ of three free $k = 0$ "
            ...)
```

In each panel the numerical a (solid) and b (dashed) and every 60th point of the exact ones as black dots (`[::60]` takes every 60th entry). **What figure 14b.5 shows.** Left: the zero mode, a rising like e^y from 0.07 at the tip to 1.42 at the brane, $b = 0$: the orbital lives at the brane. Middle: the

even level 1, b a half sine wave that vanishes at both ends, a falling from $+0.42$ to -0.42. Right: the odd level 0, b vanishing at the tip, a vanishing at the brane. All black dots lie on the curves.

In [14], figure 6.

```
picks = [("even", l_) for l_ in range(4)] + [("odd", l_) for l_ in range(3)]
energies = np.array([numeric[(1.0, 3.0, p_, l_)] for p_, l_ in picks])
_, (theta_path, _, _) = shoot(energies, 0.0, 1.0, keep=True)
y_nodes = np.linspace(-3.0, 0.0, 901)
end_values = theta_path[-1] / np.pi
goals = np.array([l_ + (0.0 if p_ == "even" else 0.5) for p_, l_ in picks])
check(np.max(np.abs(end_values - goals)) < 1e-9,
      "the Pruefer angle ends on its target l pi or (l + 1/2) pi for every level")
```

Seven levels (even labels 0 to 3, odd labels 0 to 2), one call of `shoot` that keeps the angle paths (an array with 901 rows, the nodes, and seven columns), the 901 node positions, the end angles in units of π (`theta_path[-1]` is the last row) and the targets l or $l + \frac{1}{2}$. The check: every path ends on its target to 10^{-9}.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
for column, (p_, l_) in enumerate(picks):
    style = "-" if p_ == "even" else "--"
    ax.plot(y_nodes, theta_path[:, column] / np.pi, style,
            label=f"{p_}, label {l_}")
ax.set_xlabel("$y$ (units of $1/H$; tip at $-3$, brane at $0$)")
ax.set_ylabel("Pruefer angle $\\theta(y)/\\pi$")
ax.set_title("the Pruefer angle counts the half-turns ($m = 1$, $L = 3$, $k = 0$)")
ax.legend(fontsize=8, ncol=2, loc="upper left")
save_figure(fig, "pruefer_angle",
            "The Pruefer angle $\\theta(y) = \\mathrm{atan2}(b, a)$ in units of "
            ...)
```

`theta_path[:, column]` is one column, the path of one level; even levels are drawn solid, odd ones dashed. **What figure 14b.6 shows.** All curves start at 0 at the tip ($b(-3) = 0$) and climb to their targets at the brane: the even labels 0, 1, 2, 3 end at 0, 1, 2, 3 and the odd labels 0, 1, 2 at 0.5, 1.5, 2.5. The zero mode stays at 0 all the way. A higher level turns faster: the label counts the half-turns of the point (a, b) between the tip and the brane.

In [15], the last check.

```
figure_names = ["14b_1_odd_condition.png", "14b_2_shooting_function.png",
                "14b_3_spectrum_ladder.png", "14b_4_rk4_convergence.png",
                "14b_5_orbitals.png", "14b_6_pruefer_angle.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all six figure files of this notebook exist")
all_checks_passed()
```

The six figure files must exist where the notebook wrote them; the last line prints ALL 20 CHECKS PASSED (notebook 14b). The 20 checks are: 1 in In [2], 6 in In [3], 2 in In [4], 1 in In [6], 1 in In [7], 3 in In [8], 1 in In [10], 1 in In [11], 2 in In [12], 1 in In [14] and 1 in In [15].

14.19 The brane band and its exact slope

What happens when the 3-momentum is switched on. At $k = 0$ the free spectrum has eight zero modes, four in the blocks of type $j = +1$ and four in those of type $j = -1$ (Section 14.13). For $k \neq 0$ the momentum term $j\kappa k\,\sigma_3$ of h_j moves them. In the blocks $j = +1$ the even level of label 0 rises with k: this is the **brane band**, because its orbital stays at the brane. In the blocks $j = -1$ the even level of label 0 falls by exactly the same amount, because $h_{-1} = -h_{+1}$ for $v = 0$ (Section 14.5): its levels are the negatives of those of $j = +1$, with the label l of even parity going to $-l$. How fast does the band rise? Its slope at $k = 0$ can be computed exactly.

The Hellmann-Feynman rule. Let $h(k)$ be a self-adjoint operator that depends on a number k, with boundary conditions that do not depend on k, and let $h(k)\chi = \varepsilon(k)\chi$ with $\int \chi^\dagger \chi \, dy = 1$. Line by line:

$$\varepsilon = \int \chi^\dagger h \chi \, dy.$$

Rule: multiply $h\chi = \varepsilon\chi$ from the left by $\chi^\dagger$, integrate, and use the normalisation.

$$\frac{d\varepsilon}{dk} = \int \frac{\partial \chi^\dagger}{\partial k} h\chi \, dy + \int \chi^\dagger h \frac{\partial \chi}{\partial k} \, dy + \int \chi^\dagger \frac{\partial h}{\partial k} \chi \, dy.$$

Rule: the product rule for the three factors.

$$\int \frac{\partial \chi^\dagger}{\partial k} h\chi \, dy + \int \chi^\dagger h \frac{\partial \chi}{\partial k} \, dy = \varepsilon \int \Big(\frac{\partial \chi^\dagger}{\partial k} \chi + \chi^\dagger \frac{\partial \chi}{\partial k} \Big) dy = \varepsilon \frac{d}{dk} \int \chi^\dagger \chi \, dy = 0.$$

Rule: in the first integral $h\chi = \varepsilon\chi$; in the second h is self-adjoint, so $\int \chi^\dagger h\, \partial_k \chi \, dy = \int (h\chi)^\dagger \partial_k \chi \, dy = \varepsilon \int \chi^\dagger \partial_k \chi \, dy$ (the derivative $\partial_k \chi$ obeys the same boundary conditions, because they do not depend on k); then the product rule backwards, and the normalisation integral is the constant 1. Hence

$$\frac{d\varepsilon}{dk} = \int \chi^\dagger \frac{\partial h}{\partial k} \chi \, dy.$$

In words: the rate of change of a level is the expectation value of the rate of change of the operator.

The slope of the band. Line by line:

$$\frac{\partial h_j}{\partial k} = j\kappa(y)\, \sigma_3.$$

Rule: in $h_j = j[-i\sigma_1 \, d/dy + M\sigma_2 + \kappa k \sigma_3] + v$ only the last term contains k.

$$\frac{d\varepsilon}{dk}\Big|_{k=0} = j \int_{-L}^{0} \kappa(y)\, \chi^\dagger \sigma_3 \chi \, dy = j \int_{-L}^{0} e^{-Hy - a_{4,0}}\, a(y)^2 \, dy.$$

Rule: the Hellmann-Feynman rule at $k = 0$, where the orbital is the zero mode $\chi = (a, 0)$ and $\chi^\dagger \sigma_3 \chi = a^2 - b^2 = a^2$ (Section 14.12).

$$c = \frac{\int_{-L}^{0} e^{-Hy-a_{4,0}} e^{2My}\, dy}{\int_{-L}^{0} e^{2My}\, dy}.$$

Rule: $a^2 = A^2 e^{2My}$ with $A^2 = 1/\int_{-L}^{0} e^{2My} dy$ (the normalisation); we call c the slope of the band of type $j = +1$, so that $d\varepsilon/dk = jc$.

$$\int_{-L}^{0} e^{-Hy} e^{2My}\, dy = \frac{1 - e^{-(2M-H)L}}{2M - H}, \qquad \int_{-L}^{0} e^{2My}\, dy = \frac{1 - e^{-2ML}}{2M}.$$

Rule: $e^{-Hy} e^{2My} = e^{(2M-H)y}$; the integral of e^{sy} is e^{sy}/s, evaluated at 0 and $-L$ (here $2M \neq H$).

$$c = e^{-a_{4,0}}\, \frac{2M}{2M - H}\, \frac{1 - e^{-(2M-H)L}}{1 - e^{-2ML}}.$$

Rule: divide the two integrals and take the constant factor $e^{-a_{4,0}}$ out of the first. For $M = H = 1$:

$$c = e^{-a_{4,0}}\, \frac{2(1 - e^{-L})}{1 - e^{-2L}} = \frac{2e^{-a_{4,0}}}{1 + e^{-L}}.$$

Rule: $1 - e^{-2L} = (1 - e^{-L})(1 + e^{-L})$ (the difference of two squares). For $L = 3$ and $a_{4,0} = 0$: $c = 2/(1+e^{-3}) = 1.9051482536$. Status: PROVED; check brane_band_slope of `Revision/kohn_sham/reports/ks-theory-python.json` and of the Wolfram report, and the value braneBandSlope_M1_H1_L3_a0 = 1.9051482536448664 under checksNumeric in `Revision/kohn_sham/ks-theory.json`.

What the formula says. Three things. (1) The band starts linearly, $\varepsilon \approx ck$, like the energy of a massless particle, although the mass m is not zero: the mass term only keeps the orbital at the brane. The slope is the average of the momentum weight κ over the zero-mode orbital (the integral above), and it is larger than the value $e^{-a_{4,0}}$ of κ at the brane because the orbital reaches somewhat toward the tip, where κ is larger. (2) For a long hidden interval, $L \to \infty$, the slope tends to $2M/(2M - H)$, which is 2 for $M = H = 1$; for $L = 2$, 3, 4 it is 1.761594, 1.905148, 1.964028 (Notebook 14c, Out [5]). (3) Along the deflating history the slope shrinks like $e^{-a_{4,0}}$: at the five slices $a_{4,0} = 0, 0.5, 1, 1.5, 2$ the exact values are 1.905148253645, 1.155530827134, 0.700864874900, 0.425096034942, 0.257833778515 (Notebook 14c, Out [5]).

The band is an odd function of k. The relation $\sigma_3 h_j(k) \sigma_3 = h_{-j}(-k)$ of Section 14.5 says that the level of (j, k) equals the level of $(-j, -k)$ with the same label; and $h_{-1} = -h_{+1}$ says that the level of $(-1, k)$ with even label 0 is minus the level of $(+1, k)$ with even label 0. Together: $\varepsilon_{\text{band}}(-k) = \varepsilon_{-1}(k) = -\varepsilon_{\text{band}}(k)$. So $\varepsilon_{\text{band}}(k)/k = c + dk^2 + \ldots$ contains only even powers of k. The Revision solver used this to measure the slope numerically: with $R(k) = \varepsilon(k)/k$ at $k_1 = 10^{-4}$ and $k_2 = 2 \times 10^{-4}$,

$$\frac{4R(k_1) - R(k_2)}{3} = \frac{4(c + dk_1^2) - (c + 4dk_1^2)}{3} = c.$$

Rule: $k_2 = 2k_1$, so $k_2^2 = 4k_1^2$, and the terms with d cancel (**Richardson extrapolation**, Chapter 2; what remains is of order k^4). The Rust solver found the exact $c\, e^{-a_{4,0}}$ at all five slices to $1.87 \times$

10^{-12} (relative; check free_brane_band_slope of `Revision/kohn_sham/reports/ks-rust-solver.json`; the values are in `Revision/kohn_sham/results/spectrum/brane-band-slope.csv`). Status: COMPUTED; Notebook 14c reproduces the five values.

The band at larger momenta. The record `Revision/kohn_sham/results/spectrum/brane-band.csv` follows the band and three other levels from $k = 0$ to $k = 4$ at the slice 0. At the first lattice shell, $k = \Delta k = 0.25$, the band is at $0.4307336786\,m$ (Notebook 14c, Out [3]), a little below the straight line $ck = 0.476$: the band bends downward. At $k = 4$ it is at $4.992\,m$. The lowest level that is not on the brane band at $k = 0$ is the odd level of label 0 at $1.2922928281\,m$ (Section 14.13), called the **bulk edge**; all other levels start at or above it (Figure 14c.1). Status: COMPUTED.

14.20 The band along the deflating history, and the tip

The redshift. By the exact rescaling identity (Section 14.7) every level at the slice $a_{4,0}$ equals the level at the slice 0 with the redshifted momentum: $\varepsilon(k, a_{4,0}) = \varepsilon(ke^{-a_{4,0}}, 0)$. So the whole band shrinks toward zero along the history: at a later slice the same lattice momentum k sits lower on the band. The Rust solver checked the identity for the three momenta $k = 0.25, 1, 2.5$, the five slices and three sectors, and found the two sides equal to the last bit, with the difference 0 (check free_rescaling_relation_and_band_monotone of the Rust report; the same check found the band strictly increasing in k on $[0, 4]$). Status: PROVED (the identity), COMPUTED (the check).

The gap of the eight zero modes along the history. In the free state $N = 8$ the eight zero modes are filled and the lowest empty particle level is the brane band at the first lattice shell, $k = 0.25$. This level is the **gap** of the state. At the five slices it is

slice $a_{4,0}$	**0**	**0.5**	**1**	**1.5**	**2**
gap of the free $N = 8$ state (units of m)	0.4307336786	0.2726448766	0.1703492513	0.1050152416	0.0641594107

(Notebook 14c, Out [7]; the rows $N = 8$ of `Revision/kohn_sham/results/spectrum/closed-shells.csv`). The gap shrinks almost like $e^{-a_{4,0}}$ (for small momenta the band is nearly $c\,ke^{-a_{4,0}}$): as 3-space inflates, the lattice momenta are redshifted and the empty levels come down toward the filled zero modes. Status: COMPUTED. (Chapter 15 asks whether the gas can follow this change: the adiabaticity of the history.)

The tip angle does not matter for the band (at the cutoff $L = 3$ and the slice 0). Section 14.12 showed that an orbital with $k \neq 0$ is suppressed at the cutoff by about $\exp(-|k|(\kappa(-L) - \kappa(y))/H)$, so the band level should hardly change if the tip condition is changed. The Rust solver computed the band with the tip angles $\theta = 0, 0.5, 1$ (record `Revision/kohn_sham/results/spectrum/tip-angle.csv`): at $k = 0.25$ the level moves by -8.58×10^{-6} and -2.74×10^{-5}, while the suppression factor is 8.47×10^{-3}; at $k = 0.5$ by -2.49×10^{-9} and -8.58×10^{-9} against 7.17×10^{-5}; at $k = 1$ only by rounding errors (below 10^{-15}) against 5.14×10^{-9} (check free_tip_angle_insensitivity of the Rust report: every shift lies below the suppression factor). Notebook 14c computes the shifts for ten momenta from 0.1 to 1 (Out [11]): each step of 0.1 in k makes them 11 to 33 times smaller, faster than the suppression factor itself (which falls by $e^{0.1(e^3-1)} \approx 6.7$ per step), until they reach the rounding level of the computer at $k = 0.9$. Status: COMPUTED. Both the record and the notebook work at the slice $a_{4,0} = 0$. So, at the cutoff $L = 3$ and the slice $a_{4,0} = 0$, where it was

measured (record: $k = 0.25, 0.5, 1$; Notebook 14c: $k = 0.1$ to 1), the choice of the tip angle θ in the ASSUMED tip condition is harmless for the brane band at every lattice momentum $k \neq 0$ (the lattice momenta above 1 were not run, but there the suppression factor lies below 5.14×10^{-9} and the computed shifts are at the rounding level already from $k = 0.9$; the other levels with $k \neq 0$ were not computed with another tip angle, and for them only the estimate of Section 14.12 applies); at $k = 0$, where it selects the zero mode, it is a real assumption of the model.

The tip angle at the later slices (not established). By the rescaling identity above, the lattice momentum k at the slice $a_{4,0}$ acts like the momentum $ke^{-a_{4,0}}$ at the slice 0, and there the suppression factor of Section 14.12 is no longer small: for the first lattice shell, $k = 0.25$, it is $\exp(-0.25e^{-a_{4,0}}(e^3 - 1))$, which is 0.173 at the slice 1 and 0.524 at the slice 2. Rule: $0.25(e^3 - 1) = 4.771$; times $e^{-1} = 0.3679$ this is 1.755, and $e^{-1.755} = 0.173$; times $e^{-2} = 0.1353$ it is 0.646, and $e^{-0.646} = 0.524$. The notebook's own smallest momentum points the same way: by the identity, its shift 1.2×10^{-3} for $\theta = 1$ at $k = 0.1$ and the slice 0 (Out [11]) is the shift at $k = 0.25$ and the slice $\ln 2.5 = 0.92$, more than forty times the shift 2.74×10^{-5} at $k = 0.25$ and the slice 0. Neither the Revision record nor a notebook of this chapter computes the tip angle at the later slices, where the gaps of the table above at the slices 0.5 to 2 and the recorded Kohn-Sham states of those slices live; so at those slices the insensitivity to θ is not established (OPEN).

The position L of the cutoff (measured by the Revision record). The angle is one question; where the cutoff sits is another. The Revision record measures it in `Revision/kohn_sham/tip_convergence/` (its README, "Answer in brief"; the report `Revision/kohn_sham/tip_convergence/tip-convergence.json`, 7 of 7 checks PASS; `Revision/docs/KOHN_SHAM_DEFLATING_FIELD.md`, sections 5, 15.3 and 15.4): $L = 3$ to 6 in steps of 0.5, with the step $h = 1/300$ of the record and every run repeated at $h/2$; a copy of the solver that reads L from the environment reproduces the committed matrix byte for byte at $L = 3$, and the independent reference solver agrees at $L = 3$ and 4. No notebook of this chapter repeats the study; its findings, with the record's numbers:

- The free results with $k \neq 0$ converge as L grows, faster than exponentially, because of the suppression of Section 14.12 (at the cutoff it is $\exp(-|k|e^{L-a_{4,0}}/H)$). But the recorded $L = 3$ values are low by up to 1.4% in the Kohn-Sham energy E_{KS} and 12% in the y-pressure integral $2\mathrm{Vol}_7 \int e^{6Hy} p_0 \, dy$ at $a_{4,0} = 2$ ($N = 136$, $\lambda = 0$: 12.44507 against the extrapolated 12.62207, and 8.47270 against 9.63839): at the late slice the redshifted brane band reaches the tip. The gap of the free $N = 8$ state in the table above is low in the same way: 0.4307336786 against the extrapolated 0.4307456266 at the slice 0 (2.8×10^{-5} relative), but 0.06415941073 against 0.06563459278 at the slice 2 (2.2×10^{-2} relative).

- The nonzero $k = 0$ levels approach $\pm m$ only algebraically, like $(n\pi)^2/(2mL^2)$ (for large L, from the exact levels of Section 14.13, $\sqrt{m^2 + (n\pi/L)^2} - m \approx (n\pi)^2/(2mL^2)$; the record verifies all 84 $k = 0$ levels of its scan against the exact formulas to $1.42 \times 10^{-10}\, m$). The bulk edge $1.2923\, m$ that defines $N = 688$ (Section 14.21) is an $L = 3$ value: $1.0977\, m$ at $L = 6$, and m as $L \to \infty$. From $L = 3.5$ on, the $N = 688$ ground state at $a_{4,0} = 0$ occupies $k = 0$ bulk levels, its Kohn-Sham gap 0.0452 closes, and its energy does not converge up to $L = 6$.

- The interaction energy of the brane zero modes depends strongly on L. Their proper density grows toward the tip like $e^{(6H-2m)|y|}$ (Section 14.27; exact, and verified by the record), so for $N = 8$ the recorded $E_{\mathrm{KS}} = \mp 9.868 \times 10^{-4}$ at $L = 3$ ($\lambda = \pm\lambda_1$, every slice) is about one third of the large-L value $\mp 3.0046 \times 10^{-3}$ (extrapolated from $\lambda = -\lambda_1$ at $a_{4,0} = 2$, the only interacting $N = 8$ state solved up to $L = 6$). The self-consistent iteration fails at some larger

L for 13 of the 19 interacting states studied (a failure of the iteration, not a proof that no self-consistent state exists), and for 7 of them the limit of E_{KS} is not established.

Status: COMPUTED by the Revision record with its two solvers (the L-dependence of the $k = 0$ levels and of the zero-mode density is exact and verified there). So the cutoff $L = 3$ is itself a choice that shapes the recorded numbers: within the percentages above for the free results with $k \neq 0$, and decisively for the nonzero $k = 0$ levels, for $N = 688$ at $a_{4,0} = 0$ and for the interaction energy of the zero modes.

14.21 Particles, degeneracies and closed shells

Lattice shells. On the 3-torus the allowed momenta are $\mathbf{k} = \Delta k\,(n_1, n_2, n_3)$ with whole numbers n_i (Section 14.3). All vectors with the same $n^2 = n_1^2 + n_2^2 + n_3^2$ have the same length $|\mathbf{k}| = \Delta k\sqrt{n^2}$ and form a **shell**; their number is written $r_3(n^2)$. For example $r_3(0) = 1$ (only $(0,0,0)$), $r_3(1) = 6$ (the six vectors $(\pm1,0,0)$, $(0,\pm1,0)$, $(0,0,\pm1)$) and $r_3(2) = 12$ (two entries ±1 and one 0: three places for the 0 times four sign choices). The first values are $r_3 = 1, 6, 12, 8, 6, 24, 24, 12, 30$ for $n^2 = 0, 1, 2, 3, 4, 5, 6, 8, 9$; no vector has $n^2 = 7$, because the squares below 8 are 0, 1 and 4, and no three of them add up to 7.

Degeneracy. The levels depend on $|\mathbf{k}|$ only (Section 14.6), and the four blocks (s_2, s_3) of one type have the same Hamiltonian (Section 14.5). So every level of the block type j on the shell n^2 holds $4r_3(n^2)$ states: four blocks times $r_3(n^2)$ directions. Status: PROVED (the argument above; the record states it as blockEquation.degeneracy in `Revision/kohn_sham/ks-theory.json`).

Particles and the sea (ASSUMED convention; its justification is OPEN). The free spectrum has positive and negative levels. In the quantised theory (Chapter 10) the field is normal ordered: the negative levels form the filled **sea**, which is not counted, and the quanta that are counted, the **particles**, occupy the positive levels. The Revision theory adopts the following rule: in each sector (shell, block type, parity) the particle levels are those whose level in the free problem ($\lambda = 0$) is positive, together with the zero modes at $k = 0$, each followed continuously when the interaction is switched on; the sea contributes nothing to the particle number and the densities. The zero modes need a decision: at $k = 0$ and $v = 0$ the spectrum of h_{+1} is minus that of h_{-1}, so a level at exactly zero is its own mirror image and the sign does not decide whether it is a particle or a sea level. Counting it as a particle level is a stated CONVENTION of the record (ks-theory.json, thermodynamics.fillingConvention), and its justification is OPEN. (The words particle and sea are used here in this technical sense only; nothing in this chapter is a statement about matter and antimatter, which Chapter 21 treats.)

Because Φ grows with ε (Section 14.14), the particle levels of a sector are exactly the labels $l \geq l_{\min}$, where $l_{\min}$ is the first label whose target lies above $\Phi(0)$, the value of the shooting function at $\varepsilon = 0$ (and at $k = 0$, even parity, the zero mode has $\Phi(0) = 0$ exactly on the target of label 0). The Rust solver verified this for every shell $n^2 \leq 30$ and every sector, and found that the level closest to zero, apart from the zero modes, is $0.4307\,m$: the brane band at the first shell (check free_particle_branch_labels of the Rust report). Status: COMPUTED.

Closed shells. The **aufbau** (German for building up) fills the particle states from the lowest level upward. A particle number N is a **closed shell** when the filling ends exactly at the end of a group of degenerate levels (levels equal within 10^{-9}), so that the state is unique. At the slice

0 the first closed shells are built like this (record `Revision/kohn_sham/results/spectrum/closed-shells.csv`, reproduced by Notebook 14c, Out [14]):

N	**the last group filled**	**states added**	**its level (units of m)**
8	the zero modes, both block types	$4 + 4 = 8$	0
32	the brane band on the shell $n^2 = 1$	$4 \times 6 = 24$	0.4307336786
80	the brane band on the shell $n^2 = 2$	$4 \times 12 = 48$	0.5879568528
112	the brane band on the shell $n^2 = 3$	$4 \times 8 = 32$	0.7040995646
136	the brane band on the shell $n^2 = 4$	$4 \times 6 = 24$	0.7996457668
232	the brane band on the shell $n^2 = 5$	$4 \times 24 = 96$	0.8823195405

Only the brane band of the blocks $j = +1$ appears on the shells $n^2 \geq 1$ in this table: the band of the blocks $j = -1$ is negative (sea), and every other level lies higher. The list of closed shells at the slice 0 continues $328, 376, 496, 592, 688, 696, 728, \ldots$ up to the energy $1.6\,m$ (22 closed shells in all). The shell $N = 696$ is the first that fills a level off the brane band: the odd level of label 0 at $k = 0$, at the bulk edge $1.2922928281\,m$.

The particle numbers of the Revision runs. The Revision solver chose its three particle numbers by a rule fixed in advance (record `Revision/kohn_sham/results/parameters.json`, particleNumbers): $N = 8$, the zero modes; N_{large}, the largest closed shell whose last filled level lies below the bulk edge, which is 688; and N_{mid}, the closed shell nearest to $N_{\text{large}}/4 = 172$, which is 136 (the neighbours 136 and 232 are 36 and 60 away). Status: COMPUTED; Notebook 14c repeats the rule and finds 8, 136, 688. The rule is applied at the cutoff $L = 3$: the bulk edge is an $L = 3$ value ($1.0977\,m$ at $L = 6$, and m as $L \to \infty$), so $N = 688$ is itself an $L = 3$ choice (Section 14.20).

At a later slice. At the slice $a_{4,0} = 0.5$ the redshifted band holds many more states below the same energy: 55 closed shells below $1.6\,m$ instead of 22 (Notebook 14c, Out [14]; Figure 14c.6).

14.22 Example: Notebook 14c, the brane band

Notebook 14c does Sections 14.19 to 14.21 with the computer, with the shooting method of Notebook 14b (now also for nonzero 3-momenta and any slice). It computes the brane band and three other levels for k from 0 to 4 and compares 324 levels with the Rust record; it derives the slope formula with sympy, checks the integral of Section 14.19 on the numerical zero mode, measures the slope by Richardson extrapolation at the five slices and for two other cutoffs; it checks the rescaling identity for 45 levels and the gap of the state $N = 8$ at the five slices; it checks the two block-type symmetries; it measures the effect of the tip angle at the cutoff $L = 3$ and the slice 0; and it builds the lattice shells, the particle labels, the closed shells at the slices 0 and 0.5 and the particle numbers of the Revision runs, all against the Rust records. It draws six figures and needs no Rust. It runs in about 90 seconds (the cells of its sections 8 to 11 integrate the equation for hundreds of energies at once, 72 times over, and take 5 to 20 seconds each), and its last line is ALL 15 CHECKS PASSED (notebook 14c).

14.23 How to run Notebook 14c

Step 1. What this notebook does and what it needs.

Notebook 14c (The brane band: free Kohn-Sham levels at nonzero 3-momentum along the deflating history) is the file `Revision/textbook/notebooks/14c_brane_band.ipynb` of the repository Dirac_claude. With the fourth-order Runge-Kutta shooting function of the Revision Rust solver (the levels found by bisection) it computes the free Kohn-Sham levels of dirac16complex at nonzero 3-momentum k: the brane band that grows out of the zero modes, its slope c at k = 0 from the Hellmann-Feynman rule and its exact formula, the redshift of the band along the prescribed deflating history and the exact rescaling identity eps(k, a4) = eps(k e^(-a4), 0), the mirror symmetries of the two block types, the insensitivity of the band to the tip angle at the cutoff L = 3 and the slice 0, the particle branch, the lattice degeneracies 4 r3(n2) and the closed shells of the free aufbau with the particle numbers 8, 136 and 688; it reproduces the Revision Rust solver's records of all of these and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
```

```
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 14c_brane_band.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a

number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 14c_brane_band.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 14c_brane_band.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/14c.captions.json`
- `Revision/textbook/figures/14c_1_band_structure.png`
- `Revision/textbook/figures/14c_2_band_slope.png`
- `Revision/textbook/figures/14c_3_band_redshift.png`
- `Revision/textbook/figures/14c_4_block_type_mirror.png`
- `Revision/textbook/figures/14c_5_tip_insensitivity.png`
- `Revision/textbook/figures/14c_6_closed_shells.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files of this notebook exist
ALL 15 CHECKS PASSED (notebook 14c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/14c_brane_band.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 14c_brane_band.ipynb
python -m nbconvert --execute --inplace 14c_brane_band.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 8 to 11 run for 5 to 20 seconds each: they integrate the equation for hundreds of energies at once, 72 times over; wait until the PASS lines appear.

14.24 Notebook 14c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/14c_brane_band.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

At zero 3-momentum the free Kohn-Sham spectrum of dirac16complex contains eight
zero modes ($\varepsilon = 0$) sitting at the brane. This notebook follows what
happens when the 3-momentum $k$ is switched on, at the five slices
$a_{4,0} = 0, 0.5, 1, 1.5, 2$ of the PRESCRIBED deflating history. It

- computes the BRANE BAND (the level that grows out of the zero modes) and three
  other low levels for $k$ from 0 to 4 and reproduces the Rust solver's record
  (figure 1);
- derives the slope $c = d\varepsilon/dk$ at $k = 0$ with the Hellmann-Feynman
  rule, $c = e^{-a_{4,0}}\,\frac{2M}{2M - H}\,\frac{1 - e^{-(2M-H)L}}
  {1 - e^{-2ML}}$, and checks it numerically at every slice (figure 2);
- checks the exact rescaling identity $\varepsilon(k, a_{4,0}) =
  \varepsilon(k\,e^{-a_{4,0}}, 0)$: along the history the band is redshifted
  (figure 3);
- checks the mirror symmetries of the two block types $j = \pm1$ (figure 4);
- shows that, at the cutoff $L = 3$ and the slice $a_{4,0} = 0$, the band does
  not feel the tip angle $\theta$ (figure 5);
- finds the particle branch, the degeneracies $4r_3(n^2)$ of the torus lattice
  and the closed shells of the free aufbau, with the particle numbers
  $N = 8, 136, 688$ of the Revision runs (figure 6).

It prints a PASS line for every check (15 in all) and saves six figures.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 14c (The brane band: free Kohn-Sham levels at nonzero 3-momentum along the
deflating history) is the file ‘Revision/textbook/notebooks/14c_brane_band.ipynb‘ of the
repository Dirac_claude. With the fourth-order Runge-Kutta shooting function of the
Revision Rust solver (the levels found by bisection) it computes the free Kohn-Sham
levels of dirac16complex at nonzero 3-momentum k: the brane band that grows out of the
zero modes, its slope c at k = 0 from the Hellmann-Feynman rule and its exact formula,
the redshift of the band along the prescribed deflating history and the exact rescaling
identity eps(k, a4) = eps(k e^(-a4), 0), the mirror symmetries of the two block types,
the insensitivity of the band to the tip angle at the cutoff L = 3 and the slice 0, the
particle branch, the lattice degeneracies 4 r3(n2) and the closed shells of the free
```

aufbau with the particle numbers 8, 136 and 688; it reproduces the Revision Rust solver's records of all of these and draws six teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 14c_brane_band.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 2 minutes on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 14c_brane_band.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 14c_brane_band.ipynb‘ (in the same folder, without running the cells again) to read the

printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/14c.captions.json‘
- ‘Revision/textbook/figures/14c_1_band_structure.png‘
- ‘Revision/textbook/figures/14c_2_band_slope.png‘
- ‘Revision/textbook/figures/14c_3_band_redshift.png‘
- ‘Revision/textbook/figures/14c_4_block_type_mirror.png‘
- ‘Revision/textbook/figures/14c_5_tip_insensitivity.png‘
- ‘Revision/textbook/figures/14c_6_closed_shells.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all six figure files of this notebook exist
ALL 15 CHECKS PASSED (notebook 14c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/14c_brane_band.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.

- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

    python -m jupyterlab 14c_brane_band.ipynb
    python -m nbconvert --execute --inplace 14c_brane_band.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- the cells of sections 8 to 11 run for 5 to 20 seconds each: they integrate the equation for hundreds of energies at once, 72 times over; wait until the PASS lines appear.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 14c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 14c (The brane band: free Kohn-Sham levels at nonzero 3-momentum along the
# deflating history) is the file Revision/textbook/notebooks/14c_brane_band.ipynb of the
# repository Dirac_claude. With the fourth-order Runge-Kutta shooting function of the
# Revision Rust solver (the levels found by bisection) it computes the free Kohn-Sham
# levels of dirac16complex at nonzero 3-momentum k: the brane band that grows out of the
# zero modes, its slope c at k = 0 from the Hellmann-Feynman rule and its exact formula,
# the redshift of the band along the prescribed deflating history and the exact rescaling
# identity eps(k, a4) = eps(k e^(-a4), 0), the mirror symmetries of the two block types,
# the insensitivity of the band to the tip angle at the cutoff L = 3 and the slice 0, the
# particle branch, the lattice degeneracies 4 r3(n2) and the closed shells of the free
# aufbau with the particle numbers 8, 136 and 688; it reproduces the Revision Rust
# solver's records of all of these and draws six teaching figures. It needs a computer
# with Windows 11, macOS or Linux, an internet connection for the installation, the
# program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
```

```
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
```

```
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
```

```
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 14c_brane_band.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 2
# minutes on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 14c_brane_band.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 14c_brane_band.ipynb (in the same folder, without running the cells again) to read the
# printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/14c.captions.json
# - Revision/textbook/figures/14c_1_band_structure.png
# - Revision/textbook/figures/14c_2_band_slope.png
# - Revision/textbook/figures/14c_3_band_redshift.png
# - Revision/textbook/figures/14c_4_block_type_mirror.png
# - Revision/textbook/figures/14c_5_tip_insensitivity.png
# - Revision/textbook/figures/14c_6_closed_shells.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
```

```
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all six figure files of this notebook exist
#     ALL 15 CHECKS PASSED (notebook 14c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/14c_brane_band.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 14c_brane_band.ipynb
#     python -m nbconvert --execute --inplace 14c_brane_band.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - the cells of sections 8 to 11 run for 5 to 20 seconds each: they integrate the
#   equation for hundreds of energies at once, 72 times over; wait until the PASS lines
#   appear.
#
```

## 3. The words used in this notebook

- **Level, orbital, label**: an energy $\varepsilon$ of the block equation
  $h_j\chi = \varepsilon\chi$, its solution, and the integer that counts its
  Pruefer half-turns (even parity: $\Phi = l\pi$, odd: $\Phi = \pi/2 + l\pi$).
- **3-momentum $k$**: the momentum along ordinary 3-space; on the coordinate
  torus of size $\ell$ the allowed vectors are $\Delta k\,(n_1, n_2, n_3)$ with
  integers $n_i$ and $\Delta k = 2\pi/\ell = 0.25$ (in units of $H$).
- **Shell**: all lattice vectors with the same $n^2 = n_1^2 + n_2^2 + n_3^2$;
  $r_3(n^2)$ is their number (for example $r_3(1) = 6$).
- **Brane band**: the even-parity level of label 0 in the blocks $j = +1$, which
  is the zero mode at $k = 0$ and rises with $k$.
- **Slope $c$**: $d\varepsilon/dk$ of the brane band at $k = 0$.
- **Hellmann-Feynman rule**: for a normalised eigenvector, the derivative of
  the level is the expectation value of the derivative of the Hamiltonian:
  $d\varepsilon/dk = \langle\chi|\,\partial h/\partial k\,|\chi\rangle$.
- **Slice, history**: the slice $a_{4,0}$ is the value of $a_4$ at one instant;
  the history $a_4 = AHx_4$ is a PRESCRIBED BACKGROUND (given, not solved for).
- **Redshift**: a 3-momentum $k$ acts like $k\,e^{-a_{4,0}}$ at the slice
  $a_{4,0}$: momenta shrink as 3-space inflates.
- **Tip condition**: the condition $(1 - Q(\theta))\chi(-L) = 0$ at the cutoff
  $y = -L$; $\theta = 0$ ($b(-L) = 0$) is the canonical choice.
- **Particle branch, sea**: by a CONVENTION of the Revision theory, the levels
  that are positive in the free problem (and the $k = 0$ zero modes) are
  particle levels; the negative branch is the filled, normal-ordered sea.
- **Aufbau, closed shell**: fill the $N$ lowest particle states; $N$ is a closed
  shell when the filling ends exactly at the end of a degenerate group of levels.
- **Bulk edge**: the lowest level that is not on the brane band (here a $k = 0$
  level of the odd parity).
- **Richardson extrapolation**: combining two finite-difference estimates so that
  their leading errors cancel.
```

Text cell:

```
## 4. The physical and mathematical situation

In each $2\times2$ block of type $j$ the free Kohn-Sham equation is
$h_j\chi = \varepsilon\chi$ with $h_j = j[-i\sigma_1\,d/dy + M\sigma_2 +
\kappa(y)k\,\sigma_3]$, the momentum weight $\kappa(y) = e^{-Hy - a_{4,0}}$, the
ASSUMED Z2 mirror brane at $y = 0$ (even: $b(0) = 0$, odd: $a(0) = 0$) and the
regular tip $b(-L) = 0$ at the cutoff $y = -L$; in real form $\chi = (a, ib)$:
$a' = Ma - (\kappa k + j\varepsilon)b$, $b' = (j\varepsilon - \kappa k)a - Mb$.

The momentum term $\kappa k\sigma_3$ pushes the orbitals toward the brane
($\kappa$ grows toward the tip) and lifts the zero modes into a band. Every level
holds $4r_3(n^2)$ states for each block type (four blocks times the number of
lattice directions of the shell). The canonical parameters of the Revision
solver are $H = m = 1$, $L = 3$, $\Delta k = 0.25$, the slices $a_{4,0} = 0,
0.5, 1, 1.5, 2$, and RK4 with $G = 900$ steps.

Status: the slope formula and the rescaling identity are PROVED (exact); the
numerical levels are COMPUTED (they reproduce the Rust solver's records); the
brane condition is ASSUMED; the tip condition is a chosen cutoff condition; the
history is a PRESCRIBED BACKGROUND; the counting of the zero modes as particles
is a CONVENTION whose justification is OPEN.
```

Text cell:

```
## 5. The shooting tools

The next cell defines the numerical tools. ‘shoot‘ is the shooting function of
the Revision Rust solver: it integrates the real form from the tip ($(a, b) =
(\cos\frac\theta2, \sin\frac\theta2)$, canonical $\theta = 0$) to the brane with
classical RK4 ($G$ steps; the coefficients at the nodes and step midpoints of a
fine grid of $2G + 1$ points) and follows the Pruefer angle $\mathrm{atan2}(b, a)$
step by step; it returns $\Phi = j\,\theta(0)$, which grows strictly with
$\varepsilon$. ‘levels‘ finds the energy with $\Phi = $ target (even $l\pi$, odd
$\pi/2 + l\pi$) by 72 bisections of $[-20, 20]$ (the Rust solver finds the same
root with a safeguarded Newton-bisection that stops at the tolerance
$10^{-13}$). ‘orbital‘ returns a normalised orbital on the fine grid (cubic
Hermite values at the midpoints, Simpson's rule for the norm). All three accept
arrays (numpy), so that hundreds of levels are found at once. It also reads the
Rust solver's records with a small CSV reader and defines ‘record_check‘, which
reads the verdict of a named check.
```

## 6. The brane band and three other levels for k from 0 to 4
```

```
The Rust solver's record `brane-band.csv` lists, for $k = 0, 0.05, 0.10, \dots,
4$ at the slice $a_{4,0} = 0$, the brane band (block type $j = +1$, even, label
0), the next even level of $j = +1$ (label 1), the lowest odd level of $j = +1$
(label 0), and the even level of label 1 in the blocks $j = -1$. The next cell
computes these $4\times81$ levels in one call (and, for the figure, the brane
band of the blocks $j = -1$, label 0), and checks that they equal the record to
$10^{-11}$. The $k$ values are made exactly as in the Rust program, by adding
0.05 again and again (so that the last digits agree). It also checks that the
band rises strictly with $k$.
```

In [3]:

```
k_list, kk = [], 0.0
while kk <= 4.0 + 1e-12:  # 0, 0.05, 0.10, ... as the Rust program makes them

## 7. The slope of the band at k = 0: the Hellmann-Feynman rule

Line by line:

1. If $h(k)\chi = \varepsilon(k)\chi$ with $\int\chi^\dagger\chi\,dy = 1$ and
   boundary conditions that do not depend on $k$, then $\varepsilon =
   \int\chi^\dagger h\chi\,dy$, and differentiating, the terms with
   $d\chi/dk$ add up to $\varepsilon\,\frac{d}{dk}\int\chi^\dagger\chi\,dy = 0$
   ($h$ is self-adjoint): $d\varepsilon/dk = \int\chi^\dagger(\partial_k h)\chi
   \,dy$.
2. Here $\partial_k h_j = j\kappa(y)\sigma_3$ and, at $k = 0$, $\chi$ is the zero
   mode $(a, 0)$ with $a^2 \propto e^{2My}$, so $\chi^\dagger\sigma_3\chi = a^2$.
3. Hence $d\varepsilon/dk = jc$ with
   $c = \int_{-L}^0 e^{-Hy - a_{4,0}}e^{2My}\,dy\,/\int_{-L}^0 e^{2My}\,dy$.
4. Doing the two integrals: $c = e^{-a_{4,0}}\,\frac{2M}{2M - H}\,
   \frac{1 - e^{-(2M - H)L}}{1 - e^{-2ML}}$; for $M = H = 1$:
   $c = e^{-a_{4,0}}\,\frac{2(1 - e^{-L})}{1 - e^{-2L}} = \frac{2e^{-a_{4,0}}}
   {1 + e^{-L}}$, which is $1.9051482536$ for $L = 3$, $a_{4,0} = 0$.

The next cell does step 4 with sympy, compares the value with the Revision
record (‘checksNumeric.braneBandSlope_M1_H1_L3_a0‘ of ks-theory.json), computes
the integral of step 3 numerically from the zero-mode orbital (Simpson), and
measures the slope numerically at the five slices as the Rust solver did:
levels at $k = 10^{-4}$ and $2\times10^{-4}$, and the Richardson combination
$c = (4\varepsilon_1/10^{-4} - \varepsilon_2/(2\times10^{-4}))/3$, which removes
the $k^2$ error of $\varepsilon/k$. These must equal the record
‘brane-band-slope.csv‘. Finally it measures the slope for $L = 2$ and $L = 4$.

## 8. The deflating history: redshift and the exact rescaling identity

The slice enters the block equation only through $\kappa k = e^{-Hy}(k\,
e^{-a_{4,0}})$, so EXACTLY $\varepsilon(k, a_{4,0}) = \varepsilon(k\,e^{-a_{4,0}},
0)$ for every level. The next cell checks this as the Rust solver did (check
`free_rescaling_relation_and_band_monotone`): for $k = 0.25, 1, 2.5$, the five
slices and three sectors, the level at the slice and the level at slice 0 with
the rescaled momentum agree to $10^{-12}$. It then computes the brane band at
the five slices for the figure, and the gap of the free $N = 8$ state at every
slice: the eight zero modes are filled and the next level is the band at the
```

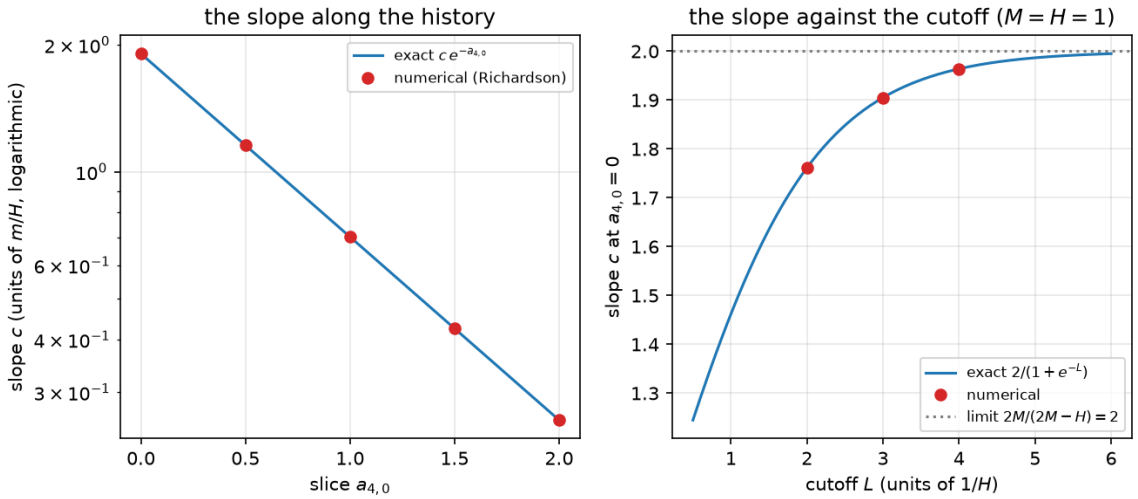

Figure 396: The slope $c = d\varepsilon/dk$ of the brane band at $k = 0$ ($M = H = 1$). Left: against the slice $a_{4,0}$ from 0 to 2, logarithmic vertical axis; the numerical Richardson values (dots) lie on the exact line $c\,e^{-a_{4,0}}$ with $c = 1.9051$ for $L = 3$: the band is redshifted along the history. Right: against the cutoff L (units of $1/H$) at $a_{4,0} = 0$; exact curve $2/(1+e^{-L})$ and numerical values for $L = 2, 3, 4$; for a long hidden interval the slope tends to $2M/(2M-H) = 2$. ## 9. The mirror symmetries of the two block types

Two exact relations of the block Hamiltonian (for $v = 0$): $h_{-1} = -h_{+1}$,
so the levels of $j = -1$ are the negatives of those of $j = +1$, with the
labels $l \to -l$ (even) and $l \to -l - 1$ (odd); and $\sigma_3h_j(k)\sigma_3 =
h_{-j}(-k)$, so the level of $(j = -1, -k)$ with label $l$ equals the level of
$(j = +1, k)$ with the same label. The next cell checks both for the shells
$n^2 = 0, 1, 2, 5, 9$ ($k = 0.25\sqrt{n^2}$) and the labels $-3$ to $3$ of both
parities (the Rust check `free_block_type_symmetries`), and computes the even
levels of both block types for $k$ from 0 to 2 for the figure.

Text cell:

```
## 10. The tip angle does not matter for the band (at the cutoff L = 3, slice 0)

For $k \ne 0$ an orbital is suppressed toward the tip like
$\exp(-k(\kappa(-L) - \kappa(y))/H)$ (the Revision record,
‘boundaryConditions.tip‘): the term $\kappa k\sigma_3$ grows toward the tip and
pushes the orbital away. So the level cannot depend much on the condition
imposed there. The next cell computes the brane band with the tip angles
$\theta = 0, 0.5, 1$ for $k = 0.25, 0.5, 1$ (the record ‘tip-angle.csv‘) and
checks that the shift from $\theta = 0$ is below the suppression factor
$\exp(-k(e^{HL} - 1)/H)$ (the Rust check ‘free_tip_angle_insensitivity‘); then
it computes the shifts for ten momenta from 0.1 to 1 for the figure.

Like the record, this section works at the slice $a_{4,0} = 0$ only (the default
‘a4=0.0‘ of ‘levels‘). At a later slice the lattice momentum $k$ acts like
$k\,e^{-a_{4,0}}$ at the slice 0 (the rescaling identity of section 8), and
there the suppression factor is no longer small: for $k = 0.25$ it is
$\exp(-0.25\,e^{-a_{4,0}}(e^{3} - 1))$, about $0.17$ at $a_{4,0} = 1$ and
$0.52$ at $a_{4,0} = 2$. Neither this notebook nor the Revision record computes
the tip angle at the later slices, so there the insensitivity is not
established.
```

```
This concerns the tip ANGLE at the fixed cutoff $L = 3$. The position $L$ of the
cutoff is a different question, which this notebook does not compute: the
Revision record measures it for $L = 3$ to $6$
(‘Revision/kohn_sham/tip_convergence/‘, report ‘tip-convergence.json‘, 7 of 7
checks PASS). The free results with $k \ne 0$ converge, but the recorded
$L = 3$ values are low by up to 1.4% in $E_{KS}$ and 12% in the $p_0$ integral at
$a_{4,0} = 2$ (the redshifted brane band reaches the tip); the nonzero (bulk)
$k = 0$ levels approach $\pm m$ only algebraically; and the interaction energy
of the brane zero modes depends strongly on $L$.
```

Text cell:

```
The next cell draws the shifts against $k$ on a logarithmic axis, together with
the suppression factor. Shifts below about $10^{-15}$ are rounding noise of the
floating-point numbers (their exact values differ from computer to computer); a
shift below $10^{-16}$ (or exactly 0) is drawn at $10^{-16}$, so that it fits on
the logarithmic axis. The printed list above shows the size of the drop: each
step of $0.1$ in $k$ makes the shift 11 to 33 times smaller (the suppression
factor itself only about $e^{0.1(e^3 - 1)} = 6.7$ times), until it reaches the
rounding level at $k = 0.9$.

## 11. Particles, degeneracies and closed shells

**Shells.** The lattice vectors $(n_1, n_2, n_3)$ with the same
$n^2 = n_1^2 + n_2^2 + n_3^2$ have the same $|k| = 0.25\sqrt{n^2}$; $r_3(n^2)$
counts them (the first values, checked against the Rust unit test, are
$r_3 = 1, 6, 12, 8, 6, 24, 24, 12, 30$ for $n^2 = 0, 1, 2, 3, 4, 5, 6, 8, 9$; no
vector has $n^2 = 7$). Each level of a block type then holds $4r_3(n^2)$ states.

**Particles (CONVENTION).** In each sector (shell, $j$, parity) the particle
levels are those with $\varepsilon > 0$ in the free problem, plus the $k = 0$
zero modes; the negative ones form the sea. Because $\Phi$ grows with
$\varepsilon$, the particle levels are exactly the labels $l \ge l_{\min}$, where
$l_{\min}$ is the first label whose target lies above $\Phi(0)$. The Rust check
‘free_particle_branch_labels‘ verified this for all shells $n^2 \le 30$ and
found the level closest to zero (away from the zero modes) at $0.4307\,m$.

**Closed shells.** Filling the particle states from the bottom (the aufbau),
$N$ is a closed shell when it ends exactly at the end of a group of degenerate
levels (equal within $10^{-9}$). The Rust solver listed them up to
$\varepsilon = 1.6\,m$ at every slice (‘closed-shells.csv‘), and chose its
particle numbers by a rule: $N = 8$ (the zero modes), $N_{\rm large}$ = the
largest closed shell below the BULK EDGE (the lowest level not on the brane
band, the smaller of the odd label 0 and the even label 1 at $k = 0$), and
$N_{\rm mid}$ = the closed shell nearest to $N_{\rm large}/4$
(‘parameters.json‘). The next cell computes all of this for the slices 0 and
0.5. It takes about 20 seconds.
```

The next cell builds the closed shells at the slices 0 and 0.5 as the Rust
solver does: for every shell (in the order of $n^2$) and sector it finds the
particle levels $l_{\min}, l_{\min} + 1, \dots$ up to $1.6\,m$; it stops at the
first shell $n^2 > 0$ that has no level below $1.6\,m$; it sorts all levels by
energy (and by name), groups levels that agree within $10^{-9}$, and adds up the
degeneracies $4r_3(n^2)$. Each level is named ‘n2:j:parity:label‘. The table
must equal the record row by row (the numbers $N$, the names of the last group,
the energies to $10^{-11}$). Then it finds the bulk edge and the particle numbers
and compares them with ‘parameters.json‘.

```
## 13. What this notebook showed

- The eight zero modes become the brane band when the 3-momentum is switched
  on; its slope at $k = 0$ is $c = e^{-a_{4,0}}\frac{2M}{2M - H}\frac{1 -
  e^{-(2M-H)L}}{1 - e^{-2ML}}$, $1.90514825360$ for $M = H = 1$, $L = 3$ (PROVED
  by the Hellmann-Feynman rule; COMPUTED numerically at all five slices; the
  values reproduce the Rust solver's records).
- Along the PRESCRIBED deflating history every level obeys the exact rescaling
  identity $\varepsilon(k, a_{4,0}) = \varepsilon(k e^{-a_{4,0}}, 0)$: the band
  is redshifted, and the gap of the free $N = 8$ state falls from $0.4307\,m$ at
  $a_{4,0} = 0$ to $0.0642\,m$ at $a_{4,0} = 2$.
- The two block types have mirrored spectra, $\mathrm{spec}\,h_{-1} =
  -\mathrm{spec}\,h_{+1}$, and $\sigma_3$ maps $(j, k)$ to $(-j, -k)$.
- At the cutoff $L = 3$ and the slice 0 the band lives at the brane: changing
  the tip angle shifts it by less than $\exp(-k(e^{HL} - 1)/H)$. At a later
  slice the factor is $\exp(-k\,e^{-a_{4,0}}(e^{HL} - 1)/H)$, which is not small
  for the lowest lattice momenta, and the tip angle is not computed there (by
  this notebook or by the record). Moving the cutoff $L$ itself
  is another matter (not computed here): the Revision record
  'Revision/kohn_sham/tip_convergence/' finds the $L = 3$ values low by up to
  1.4% in $E_{KS}$ at $a_{4,0} = 2$, where the redshifted band reaches the tip.
- With the CONVENTION that the positive free levels and the zero modes are
  particle levels (its justification is OPEN), the free aufbau has the closed
  shells $8, 32, 80, 112, 136, \dots, 688$ below the bulk edge $1.2923\,m$; the
  Revision runs use $N = 8, 136, 688$ (reproduced from the rule).
- ASSUMED: the Z2 mirror brane. CHOSEN: the regular tip at $L = 3$.
```

14.25 Line-by-line walk-through of Notebook 14c

The notebook has 16 code cells, In [1] to In [16]. Docstrings and the long caption texts are again left out of the quotations; the captions are printed under the figures in Section 14.24.

In [1], the set-up cell. The code of In [1] of Notebook 14a (Section 14.11), line for line, except

```
NOTEBOOK_ID = "14c"  # this notebook: chapter 14, example c
```

which names this notebook. Its comment lines are the run instructions of Section 14.23.

In [2], the tools.

```
import math  # exp, cos, sin of single numbers

import numpy as np  # floating-point arrays
import sympy as sp  # exact algebra with symbols

RUST_REPORT = "Revision/kohn_sham/reports/ks-rust-solver.json"
SPECTRUM = "Revision/kohn_sham/results/spectrum"  # the folder of the records
```

The three modules of In [2] of Notebook 14b, the name of the Rust solver's report, and the folder of its spectrum records.

```
def record_check(name, report=RUST_REPORT):
    data = json.loads(repository_file(report).read_text(encoding="utf-8"))
    return [c["verdict"] for c in data["checks"] if c["name"] == name] == ["PASS"]
```

A simpler `record_check`: true when the report (by default the Rust report) holds exactly one check of this name and its verdict is PASS (the list of all verdicts of that name must be the one-element list `["PASS"]`).

```
def read_csv(relative):
    lines = repository_file(relative).read_text(encoding="utf-8").splitlines()
    header = lines[0].split(",")
    return [dict(zip(header, line.split(","))) for line in lines[1:]]
```

A small CSV reader: the rows of a record as a list of dictionaries from column name to text, as in Notebooks 14a and 14b.

```
def shoot(eps, k=0.0, j=1.0, a4=0.0, M=1.0, L=3.0, G=900, H=1.0, tip=0.0,

    if keep:
        return j * theta, [np.array(q) for q in zip(*path)]
    return j * theta
```

The function `shoot` of Notebook 14b (Section 14.18 explains every line), with one change: the slice `a4` is now the fourth argument and may also be an array, so that levels at different slices are computed in one call. The first two lines therefore bring four inputs to a common shape; `*(...)` hands the four arrays made by the generator over as four separate arguments.

```
def target(parity, label):
    offset = np.where(np.asarray(parity) == "even", 0.0, 0.5 * np.pi)
    return offset + np.asarray(label, dtype=float) * np.pi

def levels(k, j, parity, label, a4=0.0, iterations=72, **options):
    k, j, parity, label, a4 = np.broadcast_arrays(
        np.asarray(k, dtype=float), np.asarray(j, dtype=float), np.asarray(parity),
        np.asarray(label), np.asarray(a4, dtype=float))
    goal = target(parity, label)
    lo, hi = np.full(k.shape, -20.0), np.full(k.shape, 20.0)
    for _ in range(iterations):
        mid = 0.5 * (lo + hi)
        g = shoot(mid, k, j, a4, **options) - goal
        lo = np.where(g <= 0.0, mid, lo)
        hi = np.where(g >= 0.0, mid, hi)
    return 0.5 * (lo + hi)
```

`target` and `levels` as in Notebook 14b, with the slice `a4` as an extra input that may differ from level to level.

```
def orbital(eps, k=0.0, j=1.0, a4=0.0, M=1.0, L=3.0, G=900, H=1.0):
    _, (_, a_n, b_n) = shoot(eps, k, j, a4, M=M, L=L, G=G, H=H, keep=True)
    nf, h = 2 * G + 1, L / G
    y_fine = -L * ((nf - 1 - np.arange(nf)) / (nf - 1))
    K_fine = k * math.exp(-a4) * np.exp(-H * y_fine)
    a_f, b_f = np.zeros(nf), np.zeros(nf)
    a_f[0::2], b_f[0::2] = a_n, b_n
    da = M * a_f - (K_fine + j * eps) * b_f
    db = (j * eps - K_fine) * a_f - M * b_f
    for f in range(1, nf, 2):  # cubic Hermite values at the midpoints
        a_f[f] = 0.5 * (a_f[f - 1] + a_f[f + 1]) + h / 8.0 * (da[f - 1] - da[f + 1])
        b_f[f] = 0.5 * (b_f[f - 1] + b_f[f + 1]) + h / 8.0 * (db[f - 1] - db[f + 1])
    weights = np.full(nf, 2.0)  # Simpson weights 1, 4, 2, ..., 4, 1 times (h/2)/3
    weights[1::2] = 4.0
    weights[0] = weights[-1] = 1.0
    weights *= 0.5 * h / 3.0
    norm = math.sqrt(float(np.sum(weights * (a_f ** 2 + b_f ** 2))))
    return y_fine, a_f / norm, b_f / norm, weights
```

The normalised orbital of one level, exactly as `orbital` of Notebook 14b (In [12] there): the node values from `shoot`, cubic Hermite values at the midpoints, Simpson's weights and the normalisation. Here the slice is a single number, so `math.exp` suffices.

```
SLICES = [0.0, 0.5, 1.0, 1.5, 2.0]  # the slices of the Revision solver
say("defined: shoot, levels, orbital, read_csv, record_check")
```

The five slices of the history and the only output of the cell.

In [3], the band and three other levels.

```
k_list, kk = [], 0.0
while kk <= 4.0 + 1e-12:  # 0, 0.05, 0.10, ... as the Rust program makes them
    k_list.append(kk)
    kk += 0.05
k_band = np.array(k_list)
```

The momenta $0, 0.05, 0.10, \ldots, 4$, made by adding 0.05 again and again, as the Rust program does. A `while` loop repeats as long as its condition holds. The decimal number 0.05 is not exactly representable in binary floating point, so the sums differ in the last digits from $0.05\,n$; making them the same way as the Rust program makes the last digits agree with the record (and the small 10^{-12} in the condition makes sure that the last value, about 4, is included).

```
sectors = [(1.0, "even", 0), (1.0, "even", 1), (1.0, "odd", 0), (-1.0, "even", 1),
           (-1.0, "even", 0)]  # (j, parity, label); the last one for the figure
K_all = np.concatenate([k_band] * len(sectors))
J_all = np.concatenate([[j_] * len(k_band) for j_, _, _ in sectors])
P_all = np.concatenate([[p_] * len(k_band) for _, p_, _ in sectors])
L_all = np.concatenate([[l_] * len(k_band) for _, _, l_ in sectors])
found = levels(K_all, J_all, P_all, L_all).reshape(len(sectors), len(k_band))
band, bulk_even, odd0, minus_even1, minus_band = found
```

Five sectors (block type, parity, label): the brane band, the even label 1 and the odd label 0 of $j = +1$, the even label 1 of $j = -1$ (the four levels of the record), and the even label 0 of $j = -1$ for the figure. `np.concatenate` joins lists end to end, so the four arrays hold all $5 \times 81 = 405$ combinations; one call of `levels` finds all of them, and `reshape` arranges the result as 5 rows of 81. The last line unpacks the five rows into five names.

```
rows = read_csv(f"{SPECTRUM}/brane-band.csv")
record = np.array([[float(r[c]) for r in rows] for c in
                   ("eps_band_a0", "eps_band_bulk_even_l1", "eps_odd_l0",
                    "eps_jm1_even_l1")])
k_record = np.array([float(r["k"]) for r in rows])
say(f"k = 0.25: brane band {band[5]:.10f}, odd level {odd0[5]:.10f} (units of m)")
```

The record's four columns as an array of 4 rows of 81 numbers, its momenta, and a printed sample: position 5 of the list is $k = 0.25$.

```
check(len(rows) == 81 and np.max(np.abs(k_record - k_band)) < 1e-15
      and np.max(np.abs(found[:4] - record)) < 1e-11,
      "the 324 levels equal the record brane-band.csv",
      record=f"{SPECTRUM}/brane-band.csv")
check(bool(np.all(np.diff(band) > 0.0)) and np.max(np.abs(minus_band + band)) < 1e-12,
      "the band rises strictly with k; the j = -1 band is its mirror image -eps")
```

The first check: 81 rows, the same momenta, and the first four rows of levels (`found[:4]`, $4 \times 81 = 324$ levels) equal to the record to 10^{-11}. The second: the band rises strictly, and the band of $j = -1$ is exactly its negative (Section 14.19). Out [3] prints the band at $k = 0.25$, 0.4307336786, and the odd level 1.9195133815, and two PASS lines.

In [4], figure 1.

```
c_theory = 2.0 / (1.0 + math.exp(-3.0))  # the slope for M = H = 1, L = 3, a4,0 = 0
fig, ax = plt.subplots(figsize=(9.5, 4.8))
ax.plot(k_band, band, color="C0", linewidth=2, label="brane band ($j = +1$, even, 0)")
ax.plot(k_band, bulk_even, color="C1", label="$j = +1$, even, label 1")
ax.plot(k_band, odd0, color="C2", label="$j = +1$, odd, label 0")
ax.plot(k_band, minus_even1, color="C4", label="$j = -1$, even, label 1")
ax.plot(k_band, minus_band, "--", color="C0",
        label="$j = -1$, even, label 0 (sea)")
```

The slope $c = 2/(1 + e^{-3})$ of Section 14.19 and the five level curves; the band is drawn thick.

```
ax.plot(k_band[:13], c_theory * k_band[:13], ":", color="black",
        label="first order: $c\\,k$, $c = 1.9051$")
ax.axhline(odd0[0], color="gray", linewidth=0.8, linestyle="-.")
ax.annotate("bulk edge 1.2923", (2.6, odd0[0] - 0.55), fontsize=8,
            color="gray")  # just below the dash-dotted line
```

The straight line ck for the first 13 momenta ($k \leq 0.6$), and a dash-dotted horizontal line at the bulk edge, the odd level at $k = 0$ (`odd0[0]`), with its name written just below it.

```
ax.set_xlabel("3-momentum $k$ (units of $H$), slice $a_{4,0} = 0$")
ax.set_ylabel("level $\\varepsilon$ (units of $m$)")
ax.set_title("the free levels at nonzero 3-momentum ($m = 1$, $L = 3$)")
ax.legend(fontsize=7, loc="center left", bbox_to_anchor=(1.01, 0.5))
save_figure(fig, "band_structure",
            "The free Kohn-Sham levels against the 3-momentum $k$ (units of "
            ...)
```

Labels, title, and a legend placed outside the panel on the right (`bbox_to_anchor=(1.01, 0.5)` anchors its left centre just beyond the right edge). **What figure 14c.1 shows.** The brane band starts at 0, follows the dotted line ck for small k, bends below it and then rises almost straight to about $5\,m$ at $k = 4$. Its mirror image, the dashed band of $j = -1$, falls to about $-5\,m$: it belongs to the sea. The three other levels start at or above the bulk edge $1.2923\,m$ (the even level 1 of $j = -1$ dips slightly below its start before rising) and rise roughly parallel to the band. Nothing else enters the region between the band and the bulk edge.

In [5], the slope.

```
Ms, Hs, Ls = sp.symbols("M H L", positive=True)
ys, a4s = sp.symbols("y a", real=True)
ratio = (sp.integrate(sp.exp(-Hs * ys - a4s) * sp.exp(2 * Ms * ys), (ys, -Ls, 0))
         / sp.integrate(sp.exp(2 * Ms * ys), (ys, -Ls, 0)))  # step 3
formula = (sp.exp(-a4s) * 2 * Ms / (2 * Ms - Hs) * (1 - sp.exp(-(2 * Ms - Hs) * Ls))
           / (1 - sp.exp(-2 * Ms * Ls)))  # step 4
```

Symbols, the ratio of the two integrals of Section 14.19 computed by `sp.integrate(expression, (variable, lower, upper))`, and the closed formula.

```
same = sp.simplify((ratio - formula).subs({Ms: 1, Hs: 1, Ls: 3})) == 0 and \
    sp.simplify((ratio - formula).subs({Ms: 2, Hs: 1, Ls: 3})) == 0
c_exact = float(formula.subs({Ms: 1, Hs: 1, Ls: 3, a4s: 0}))
```

The ratio and the formula agree exactly for $(M, H, L) = (1, 1, 3)$ and $(2, 1, 3)$, for every slice (the symbol a stays free); `subs` with a dictionary replaces several symbols at once. `c_exact` is the number c for $M = H = 1$, $L = 3$, slice 0.

```
theory = json.loads(repository_file("Revision/kohn_sham/ks-theory.json")
                    .read_text(encoding="utf-8"))
c_record = float(theory["checksNumeric"]["braneBandSlope_M1_H1_L3_a0"])
report("slope c for M = H = 1, L = 3, a4,0 = 0", f"{c_exact:.13f}", "m/H")
check(same and abs(c_exact - c_record) < 1e-15 and abs(c_exact - c_theory) < 1e-15
      and record_check("brane_band_slope",
                       "Revision/kohn_sham/reports/ks-theory-python.json"),
      "c = e^(-a4,0) (2M/(2M - H)) (1 - e^(-(2M-H)L))/(1 - e^(-2ML)) = 1.9051482536",
      record="Revision/kohn_sham/ks-theory.json, checksNumeric "
             "braneBandSlope_M1_H1_L3_a0")
```

The value of the record, the RESULT line 1.9051482536449, and the check: the formula, the record's number, the short form $2/(1 + e^{-3})$ of In [4] and the verdict of the sympy report all agree.

```
y_f, a_zero, b_zero, simpson = orbital(0.0)  # the zero mode at k = 0
c_integral = float(np.sum(simpson * np.exp(-y_f) * a_zero ** 2))  # step 3
check(abs(c_integral - c_exact) < 1e-9,
      "the integral of kappa a^2 over the numerical zero mode gives c")
```

The numerical zero mode, and the Hellmann-Feynman integral $\int \kappa\, a^2 dy$ (with $\kappa = e^{-y}$ at the slice 0) by Simpson's rule: it equals c to 10^{-9}.

```
tiny = np.array([1e-4, 2e-4] * 5)  # two small momenta at each slice
slice_of = np.repeat(SLICES, 2)
small = levels(tiny, 1.0, "even", 0, a4=slice_of).reshape(5, 2)
c_numeric = (4.0 * small[:, 0] / 1e-4 - small[:, 1] / 2e-4) / 3.0
```

The two small momenta 10^{-4} and 2×10^{-4}, five times; `np.repeat(SLICES, 2)` repeats every slice twice (0, 0, 0.5, 0.5, ...), so that each slice gets both momenta. The ten band levels in one call, arranged as 5 rows of 2, and the Richardson combination $(4R(k_1) - R(k_2))/3$ of Section 14.19 for each slice.

```
rows = read_csv(f"{SPECTRUM}/brane-band-slope.csv")
c_rows = np.array([float(r["c_numeric"]) for r in rows])
for a_, c_ in zip(SLICES, c_numeric):
    say(f"slice a4,0 = {a_}: c numerical {c_:.12f}, "
        f"c e^(-a4,0) exact {c_exact * math.exp(-a_):.12f}")
```

The Rust solver's numerical slopes, and a printed comparison of the notebook's numerical slopes with the exact $c\, e^{-a_{4,0}}$ at each slice (Out [5]).

```
check(np.max(np.abs(c_numeric / c_rows - 1.0)) < 1e-11
      and np.max(np.abs(c_numeric / (c_exact * np.exp(-np.array(SLICES))) - 1.0))
      < 1e-9 and record_check("free_brane_band_slope"),
      "the numerical slope equals c e^(-a4,0) at all five slices",
      record=f"{SPECTRUM}/brane-band-slope.csv and {RUST_REPORT}, check "
             "free_brane_band_slope")
```

The notebook's slopes equal the Rust slopes to 10^{-11} and the exact ones to 10^{-9} (relative), and the Rust check passed.

```
c_by_L = {}
for L_ in (2.0, 4.0):  # the slope for two other cutoffs
    pair = levels(np.array([1e-4, 2e-4]), 1.0, "even", 0, L=L_, G=round(300 * L_))
    c_by_L[L_] = (4.0 * pair[0] / 1e-4 - pair[1] / 2e-4) / 3.0
c_by_L[3.0] = float(c_numeric[0])
exact_by_L = {L_: 2.0 / (1.0 + math.exp(-L_)) for L_ in (2.0, 3.0, 4.0)}
```

The slope for the cutoffs $L = 2$ and $L = 4$ by the same Richardson combination (with $G = 300L$ steps, the same step $h = 1/300$), the slope for $L = 3$ from the slice 0 above, and the exact $2/(1+e^{-L})$ for the three cutoffs, as a dictionary comprehension.

```
say("c for L = 2, 3, 4: " + ", ".join(f"{c_by_L[L_]:.6f}" for L_ in (2.0, 3.0, 4.0))
    + " (exact " + ", ".join(f"{exact_by_L[L_]:.6f}" for L_ in (2.0, 3.0, 4.0)) + ")")
check(all(abs(c_by_L[L_] - exact_by_L[L_]) < 1e-9 for L_ in (2.0, 4.0)),
      "the slope formula holds for L = 2 and L = 4 too")
```

A printed line with the three numerical and the three exact slopes, 1.761594, 1.905148, 1.964028 (they agree in all six decimals), and the check for the two new cutoffs. Out [5] shows four PASS lines.

In [6], figure 2.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0))
a_grid = np.linspace(0.0, 2.0, 201)
left.semilogy(a_grid, c_exact * np.exp(-a_grid), color="C0",
              label="exact $c\\,e^{-a_{4,0}}$")
left.semilogy(SLICES, c_numeric, "o", color="C3", label="numerical (Richardson)")
left.set_xlabel("slice $a_{4,0}$")
left.set_ylabel("slope $c$ (units of $m/H$, logarithmic)")
left.set_title("the slope along the history")
left.legend(fontsize=8)
```

Left panel: the exact slope $c\,e^{-a_{4,0}}$ for 201 slices from 0 to 2 on a logarithmic axis, and the five numerical values as red dots.

```
L_grid = np.linspace(0.5, 6.0, 221)
right.plot(L_grid, 2.0 / (1.0 + np.exp(-L_grid)), color="C0",
           label="exact $2/(1 + e^{-L})$")
right.plot(list(c_by_L), list(c_by_L.values()), "o", color="C3", label="numerical")
right.axhline(2.0, color="gray", linestyle=":", label="limit $2M/(2M - H) = 2$")
right.set_xlabel("cutoff $L$ (units of $1/H$)")
right.set_ylabel("slope $c$ at $a_{4,0} = 0$")
right.set_title("the slope against the cutoff ($M = H = 1$)")
right.legend(fontsize=8)
save_figure(fig, "band_slope",
            "The slope $c = d\\varepsilon/dk$ of the brane band at $k = 0$ "
            ...)
```

Right panel: the exact slope $2/(1 + e^{-L})$ for cutoffs from 0.5 to 6, the three numerical values (`list(c_by_L)` is the list of the keys of the dictionary, the cutoffs, and `c_by_L.values()` the slopes), and the limit 2 as a dotted line. **What figure 14c.2 shows.** Left: the five dots lie on a straight line on the logarithmic axis, falling from 1.905 to 0.258: the slope decreases exactly like $e^{-a_{4,0}}$, the redshift. Right: the slope grows with the cutoff and approaches 2 from below; the three dots lie on the curve.

In [7], the rescaling identity and the gap of $N = 8$.

```
test_k = [0.25, 1.0, 2.5]
test_sectors = [(1.0, "even", 0), (1.0, "odd", 0), (-1.0, "even", 1)]
combos = [(a_, k_, s_) for a_ in SLICES for k_ in test_k for s_ in test_sectors]
```

Three momenta and three sectors (the band, the odd label 0, the even label 1 of $j = -1$), and all $5 \times 3 \times 3 = 45$ combinations with the slices.

```
at_slice = levels(np.array([k_ for a_, k_, s_ in combos]),
                  np.array([s_[0] for a_, k_, s_ in combos]),
                  np.array([s_[1] for a_, k_, s_ in combos]),
                  np.array([s_[2] for a_, k_, s_ in combos]),
                  a4=np.array([a_ for a_, k_, s_ in combos]))
at_zero = levels(np.array([k_ * math.exp(-a_) for a_, k_, s_ in combos]),
                 np.array([s_[0] for a_, k_, s_ in combos]),
                 np.array([s_[1] for a_, k_, s_ in combos]),
                 np.array([s_[2] for a_, k_, s_ in combos]))
```

The 45 levels twice: at their slices with the momentum k, and at the slice 0 with the momentum $ke^{-a_{4,0}}$ (`a4` is then the default 0).

```
check(np.max(np.abs(at_slice - at_zero)) < 1e-12
      and record_check("free_rescaling_relation_and_band_monotone"),
      "eps(k, a4,0) = eps(k e^(-a4,0), 0) for 45 levels at the five slices",
      record=f"{RUST_REPORT}, check free_rescaling_relation_and_band_monotone")
```

They agree to 10^{-12}: the rescaling identity of Section 14.7 for the levels.

```
k_fig = np.linspace(0.0, 4.0, 41)
band_slices = levels(np.tile(k_fig, 5), 1.0, "even", 0,
                     a4=np.repeat(SLICES, len(k_fig))).reshape(5, len(k_fig))
gaps = levels(np.full(5, 0.25), 1.0, "even", 0, a4=np.array(SLICES))
```

For the figure, the band at 41 momenta at each of the five slices: `np.tile(k_fig, 5)` repeats the whole list five times, `np.repeat` repeats each slice 41 times, so the pairs match. Then the gaps: the band at $k = 0.25$ at the five slices.

```
shells_record = read_csv(f"{SPECTRUM}/closed-shells.csv")
gap_record = [float(r["gap"]) for r in shells_record if r["N_closed"] == "8"]
for a_, g_ in zip(SLICES, gaps):
    say(f"slice a4,0 = {a_}: gap of the free N = 8 state {g_:.10f} m")
check(len(gap_record) == 5 and np.max(np.abs(gaps - np.array(gap_record))) < 1e-11,
      "the N = 8 gaps at the five slices equal the record",
      record=f"{SPECTRUM}/closed-shells.csv, rows N_closed = 8")
```

The column gap of the five rows with $N = 8$ of the closed-shell record, the five printed gaps (the table of Section 14.20) and the check. Out [7] shows two PASS lines.

In [8], figure 3.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.0), sharey=True)
for index, a_ in enumerate(SLICES):
    left.plot(k_fig, band_slices[index], label=f"$a_{{4,0}} = {a_}$")
```

```
    right.plot(k_fig * math.exp(-a_), band_slices[index], "o", markersize=3,
               label=f"$a_{{4,0}} = {a_}$")
right.plot(k_fig, band_slices[0], color="black", linewidth=0.8,
           label="slice 0 band")
```

Left: the band against k at each slice. Right: the same levels against the redshifted momentum $ke^{-a_{4,0}}$ as dots, and the band of the slice 0 as a thin black line.

```
left.set_xlabel("3-momentum $k$ (units of $H$)")
left.set_ylabel("brane band $\\varepsilon$ (units of $m$)")
left.set_title("the band at five slices")
left.legend(fontsize=8)
right.set_xlabel("redshifted momentum $k\\,e^{-a_{4,0}}$ (units of $H$)")
right.set_title("all slices on one curve")
right.legend(fontsize=7)
save_figure(fig, "band_redshift",
            "The brane band along the prescribed deflating history. Left: the "
            ...)
```

What figure 14c.3 shows. Left: five curves from the origin, the later slices lower: at $k = 4$ the band is near $5\,m$ at the slice 0 and below $1\,m$ at the slice 2. Right: all dots fall on the black curve; a later slice covers only a shorter piece of it (up to $4e^{-a_{4,0}}$). This is the rescaling identity: nothing but the momentum scale changes along the history.

In [9], the block-type symmetries.

```
sym_k = [0.25 * math.sqrt(n2) for n2 in (0, 1, 2, 5, 9)]
sym_l = list(range(-3, 4))
grid = [(k_, l_) for k_ in sym_k for l_ in sym_l]
K_s = np.array([k_ for k_, l_ in grid])
L_s = np.array([l_ for k_, l_ in grid])
```

The momenta of five shells ($k = 0.25\sqrt{n^2}$ for $n^2 = 0, 1, 2, 5, 9$), the labels -3 to 3, and their 35 combinations as two arrays.

```
plus_even = levels(K_s, 1.0, "even", L_s)
minus_even = levels(K_s, -1.0, "even", -L_s)
plus_odd = levels(K_s, 1.0, "odd", L_s)
minus_odd = levels(K_s, -1.0, "odd", -L_s - 1)
flipped_even = levels(-K_s, -1.0, "even", L_s)
flipped_odd = levels(-K_s, -1.0, "odd", L_s)
```

Six sets of levels: both parities of $j = +1$; those of $j = -1$ with the mirrored labels ($l \to -l$ for even parity and $l \to -l - 1$ for odd parity, the label map of Section 14.13, because the target $\pi/2 + l\pi$ goes to $-(\pi/2 + l\pi) = \pi/2 + (-l - 1)\pi$); and those of $j = -1$ at the reversed momentum $-k$ with the same labels.

```
mirror = max(np.max(np.abs(plus_even + minus_even)),
             np.max(np.abs(plus_odd + minus_odd)))
```

```
flip = max(np.max(np.abs(flipped_even - plus_even)),
           np.max(np.abs(flipped_odd - plus_odd)))
check(mirror < 1e-12 and flip < 1e-12 and record_check("free_block_type_symmetries"),
      "spec h_(-1) = -spec h_(+1) and eps_(-1)(-k) = eps_(+1)(k), label by label",
      record=f"{RUST_REPORT}, check free_block_type_symmetries")
```

The two relations of Section 14.5: the levels of $j = -1$ are minus those of $j = +1$ (`mirror`), and the level of $(-1, -k)$ equals that of $(+1, k)$ (`flip`); both to 10^{-12}, label by label.

```
k_mirror = np.linspace(0.0, 2.0, 41)
fig_labels = list(range(-2, 3))
plus_curves = levels(np.tile(k_mirror, 5), 1.0, "even",
                     np.repeat(fig_labels, len(k_mirror))).reshape(5, -1)
minus_curves = levels(np.tile(k_mirror, 5), -1.0, "even",
                      np.repeat(fig_labels, len(k_mirror))).reshape(5, -1)
say("even levels at k = 2, labels -2 ... 2:")
say("  j = +1: " + ", ".join(f"{x:.4f}" for x in plus_curves[:, -1]))
say("  j = -1: " + ", ".join(f"{x:.4f}" for x in minus_curves[:, -1]))
```

For the figure, the even levels of labels -2 to 2 for 41 momenta from 0 to 2, for both types (`reshape( 5, -1)`: five rows, the length of each row worked out by numpy). The printout of the last column, $k = 2$: for $j = +1$ the levels -6.3742, -4.4814, 2.6976, 5.4109, 7.1695 and for $j = -1$ the same numbers with the opposite signs, in the opposite order (Out [9]).

In [10], figure 4.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(10.0, 4.2), sharey=True)
for row, label in enumerate(fig_labels):
    left.plot(k_mirror, plus_curves[row], label=f"label {label}")
    right.plot(k_mirror, minus_curves[row], label=f"label {label}")
for ax, title in ((left, "block type $j = +1$"), (right, "block type $j = -1$")):
    ax.axhline(0.0, color="black", linewidth=0.6)
    ax.set_xlabel("3-momentum $k$ (units of $H$)")
    ax.set_title(title + ", even parity")
    ax.legend(fontsize=7, loc="upper left")
left.set_ylabel("level $\\varepsilon$ (units of $m$)")
save_figure(fig, "block_type_mirror",
            "The even-parity levels with labels $-2$ to $2$ against the "
            ...)
```

Five curves in each panel, the zero line, labels and titles (a loop over the two panels sets what they share). **What figure 14c.4 shows.** Left ($j = +1$): the label 0 curve starts at 0 and rises (the brane band); labels 1 and 2 start at 1.448 and 2.321 and rise; labels -1 and -2 are their mirror images below zero. Right ($j = -1$): the same picture turned upside down: the label 0 curve falls from 0 (the sea partner of the band).

In [11], the tip angle.

```
tip_rows = read_csv(f"{SPECTRUM}/tip-angle.csv")
tip_k = np.array([0.25, 0.5, 1.0])
```

```
tip_levels = {th: levels(tip_k, 1.0, "even", 0, tip=th) for th in (0.0, 0.5, 1.0)}
suppression = np.exp(-tip_k * (math.exp(3.0) - 1.0))  # H = 1, L = 3
worst_tip, below = 0.0, True
```

The record of the Rust solver (9 rows), the three momenta of the record, the band at these momenta for the three tip angles (a dictionary from the angle to an array of three levels; `tip=th` is handed on to `shoot` through `**options`), the suppression factor $\exp(-k(e^3 - 1))$ at the brane for $H = 1$, $L = 3$ and the slice 0, and two variables for the results.

```
for r in tip_rows:
    i_k = list(tip_k).index(float(r["k"]))
    mine = tip_levels[float(r["theta_tip"])][i_k]
    worst_tip = max(worst_tip, abs(mine - float(r["eps"])))
    shift = mine - tip_levels[0.0][i_k]
    below &= abs(shift) <= max(suppression[i_k], 1e-12)
check(len(tip_rows) == 9 and worst_tip < 1e-11 and below
      and record_check("free_tip_angle_insensitivity"),
      "the band levels equal tip-angle.csv; the shifts are below the suppression",
      record=f"{SPECTRUM}/tip-angle.csv and {RUST_REPORT}, check "
             "free_tip_angle_insensitivity")
```

For every row: the position of its momentum in the list (`index` finds it), the notebook's level for its angle and momentum, the largest difference from the recorded level, and the shift from the angle 0, which must not exceed the suppression factor (or 10^{-12}, the size of rounding, whichever is larger).

```
k_tip = np.linspace(0.1, 1.0, 10)
shifts = {th: np.abs(levels(k_tip, 1.0, "even", 0, tip=th)
                     - levels(k_tip, 1.0, "even", 0, tip=0.0)) for th in (0.5, 1.0)}
def shown(x):
    return f"{x:.1e}" if x >= 1e-14 else "below 1e-14 (rounding)"

for k_, s5, s10 in zip(k_tip, shifts[0.5], shifts[1.0]):
    say(f"k = {k_:.1f}: shift for theta = 0.5: {shown(s5)}, for theta = 1: "
        f"{shown(s10)}")
```

The shifts for ten momenta $0.1, 0.2, \ldots, 1$ and the angles 0.5 and 1. The small function `shown` writes a shift with one decimal and an exponent, or, below 10^{-14}, the words "below 1e-14 (rounding)": such tiny numbers are rounding errors and differ from computer to computer, and the printed output of a notebook must be the same everywhere. Out [11] prints the ten lines of Section 14.20: 4.6×10^{-4} and 1.2×10^{-3} at $k = 0.1$, down to 7.7×10^{-14} and 2.7×10^{-13} at $k = 0.8$, and rounding from $k = 0.9$ on.

In [12], figure 5.

```
fig, ax = plt.subplots(figsize=(7.5, 4.4))
k_line = np.linspace(0.1, 1.0, 91)
ax.semilogy(k_line, np.exp(-k_line * (math.exp(3.0) - 1.0)), color="black",
            label="suppression $\\exp(-k(e^{HL} - 1)/H)$")
```

```
for th, marker in ((0.5, "o"), (1.0, "s")):
    ax.semilogy(k_tip, np.maximum(shifts[th], 1e-16), marker, markersize=5,
                label=f"$|\\varepsilon(\\theta = {th}) - \\varepsilon(\\theta = 0)|$")
```

The suppression factor as a line on a logarithmic axis, and the shifts as circles and squares; `np.maximum(x, 1e-16)` replaces any shift below 10^{-16} (or exactly 0, whose logarithm does not exist) by 10^{-16}, so that it can be drawn.

```
ax.axhline(1e-15, color="gray", linestyle=":", linewidth=0.8)
ax.annotate("rounding level", (0.75, 2e-15), fontsize=8, color="gray")
ax.set_xlabel("3-momentum $k$ (units of $H$)")
ax.set_ylabel("shift of the band level (units of $m$, logarithmic)")
ax.set_title("the band does not feel the tip angle ($L = 3$, slice 0)")
ax.legend(fontsize=8)
save_figure(fig, "tip_insensitivity",
            "The change of the brane-band level when the tip condition "
            ...)
```

A dotted line at 10^{-15}, the rounding level, with its name. **What figure 14c.5 shows.** Both rows of markers fall steeply, by a factor 11 to 33 per step of 0.1, much faster than the black suppression line, and stay below it by two to six powers of ten; the squares ($\theta = 1$) lie a little above the circles ($\theta = 0.5$). At $k = 0.9$ and 1 the markers sit at the rounding level, where their exact positions are noise.

In [13], shells and particle labels.

```
def shells(n2_max):
    r = math.isqrt(n2_max) + 1
    count = [0] * (n2_max + 1)
    for x in range(-r, r + 1):
        for y_ in range(-r, r + 1):
            for z_ in range(-r, r + 1):
                s = x * x + y_ * y_ + z_ * z_
                if s <= n2_max:
                    count[s] += 1
    return [(n2, c) for n2, c in enumerate(count) if c > 0]
```

The shells up to $n^2_{\max}$ by counting: `math.isqrt` is the whole-number square root (rounded down), so every integer vector with $n^2 \le n^2_{\max}$ has entries between $-r$ and r; the three loops visit all of them and count each n^2. The result is the list of pairs $(n^2, r_3(n^2))$ with $r_3 > 0$.

```
check(shells(9) == [(0, 1), (1, 6), (2, 12), (3, 8), (4, 6), (5, 24), (6, 24),
                    (8, 12), (9, 30)],
      "r3(n2) = 1, 6, 12, 8, 6, 24, 24, 12, 30 for n2 = 0, 1, 2, 3, 4, 5, 6, 8, 9")
SECTORS = [(1, "even"), (1, "odd"), (-1, "even"), (-1, "odd")]
SIGN = {1: "+1", -1: "-1"}
```

The first values of r_3 (Section 14.21; no shell 7), the four sectors of a shell, and the texts $+1$, -1 used in the names of the levels.

```
def lowest_particle_labels(pairs, a4):
    k_ = np.array([0.25 * math.sqrt(n2) for n2, _, _, _ in pairs])
    j_ = np.array([float(j) for _, _, j, _ in pairs])
    par = np.array([p for _, _, _, p in pairs])
    phi0 = shoot(0.0, k_, j_, a4)
    offset = np.where(par == "even", 0.0, 0.5 * np.pi)
    l_min = np.floor((phi0 - offset) / np.pi).astype(int) + 1
    nearest = np.round((phi0 - offset) / np.pi).astype(int)
    zero_mode = (k_ == 0.0) & (np.abs(phi0 - offset - nearest * np.pi) < 1e-12)
    return np.where(zero_mode, nearest, l_min), phi0, offset, k_, j_, par
```

For a list of sectors ($n^2, r_3, j,$ parity): their momenta, types and parities as arrays, and $\Phi(0)$, the shooting function at $\varepsilon = 0$. Since Φ grows with ε, a label is a particle label when its target lies above $\Phi(0)$; the first such label is $\lfloor(\Phi(0) - \text{offset})/\pi\rfloor + 1$ (`np.floor` rounds down; `astype(int)` makes whole numbers). The exception is a zero mode: at $k = 0$, when $\Phi(0)$ lies exactly on a target (to 10^{-12}; `&` is "and" for arrays), that label itself is the first particle label (the convention of Section 14.21). The function returns these labels and the arrays it made.

```
pairs30 = [(n2, r3, j, p) for n2, r3 in shells(30) for j, p in SECTORS]
l_min, phi0, offset, k30, j30, p30 = lowest_particle_labels(pairs30, 0.0)
e_first = levels(k30, j30, p30, l_min)
e_below = levels(k30, j30, p30, l_min - 1)
zero_k = k30 == 0.0
```

All sectors of the shells up to $n^2 = 30$; their first particle labels at the slice 0; the levels of these labels and of the labels just below; and a marker for the sectors with $k = 0$.

```
branch_ok = (np.all(e_below < 0.0)
             and np.all(e_first[zero_k & (p30 == "even")] == 0.0)
             and np.all(e_first[~(zero_k & (p30 == "even"))] > 0.0))
closest = float(min(np.min(e_first[~(zero_k & (p30 == "even"))]),
                    np.min(-e_below)))
report("level closest to zero away from the zero modes (n2 <= 30)",
       f"{closest:.4f}", "m")
check(branch_ok and f"{closest:.4f}" == "0.4307"
      and record_check("free_particle_branch_labels"),
      "particles are the labels l >= l_min in every sector (n2 <= 30)",
      record=f"{RUST_REPORT}, check free_particle_branch_labels")
```

The particle rule holds when every level just below the first particle label is negative, the first particle level is exactly 0 in the even sectors at $k = 0$ (the zero modes) and positive in all other sectors (`~` is "not" for arrays; an array indexed by a true-false array keeps the entries marked true). `closest` is the level nearest to zero apart from the zero modes, from above or from below: $0.4307\,m$, as in the Rust check. Out [13] shows two PASS lines.

In [14], the closed shells.

```
def closed_shells(a4, n2_max, e_max=1.6):
    pairs = [(n2, r3, j, p) for n2, r3 in shells(n2_max) for j, p in SECTORS]
```

```
    l_next, _, _, k_, j_, par = lowest_particle_labels(pairs, a4)
    found_levels = []  # (energy, degeneracy, name, n2)
    active = np.arange(len(pairs))
```

The free aufbau at one slice, up to the energy $1.6\,m$. For every sector the next label to compute starts at its first particle label; `active` lists the sectors that are still open (all, at the start).

```
    while len(active) > 0:  # one more label in every sector that is still open
        e_ = levels(k_[active], j_[active], par[active], l_next[active], a4=a4)
        keep = e_ <= e_max
        for index, energy in zip(active[keep], e_[keep]):
            n2, r3, j, p = pairs[index]
            found_levels.append((float(energy), 4.0 * r3,
                                 f"{n2}:{SIGN[j]}:{p}:{l_next[index]}", n2))
        active = active[keep]
        l_next[active] += 1
```

In each pass the next level of every open sector is computed at once; the levels at or below $1.6\,m$ are stored with their degeneracy $4r_3(n^2)$ and a name such as `1:+1:even:0` (shell, block type, parity, label); a sector whose next level lies above $1.6\,m$ is closed, because its higher labels lie higher still; the open sectors move on to the next label.

```
    with_levels = {n2 for _, _, _, n2 in found_levels}
    stop = next(n2 for n2, _ in shells(n2_max) if n2 > 0 and n2 not in with_levels)
    found_levels = [lev for lev in found_levels if lev[3] < stop]
    found_levels.sort(key=lambda lev: (lev[0], lev[2]))
```

The set of shells that have a level below $1.6\,m$, the first shell $n^2 > 0$ without one (the band rises with $|\mathbf{k}|$, so no later shell can contribute; this is the rule of the Rust solver), only the levels of the shells before it, sorted by energy and, for equal energies, by name.

```
    table, total, i = [], 0.0, 0
    while i < len(found_levels):  # group the degenerate levels
        e0, group, names = found_levels[i][0], 0.0, []
        while i < len(found_levels) and found_levels[i][0] - e0 <= 1e-9:
            group += found_levels[i][1]
            names.append(found_levels[i][2])
            i += 1
        total += group
        following = found_levels[i][0] if i < len(found_levels) else float("nan")
        table.append((int(total), e0, following, ";".join(names)))
    return table, stop
```

Walking through the sorted levels, the levels within 10^{-9} of the first level of a group are collected into one degenerate group; after each group the running total N is a closed shell, stored with the energy of the group, the energy of the next level (or `nan`, "not a number", at the end) and the names of the group joined by semicolons.

```
agree = True
tables = {}
for a_, n2_max in ((0.0, 40), (0.5, 80)):
    table, stop = closed_shells(a_, n2_max)
    tables[a_] = table
    mine_rows = [r for r in shells_record if float(r["a4"]) == a_]
    same = len(table) == len(mine_rows) and all(
        int(r["N_closed"]) == t[0] and r["levels_of_the_last_group"] == t[3]
        and abs(float(r["eps_last_filled"]) - t[1]) < 1e-11
        for r, t in zip(mine_rows, table))
    agree &= same and stop < n2_max
    say(f"slice {a_}: {len(table)} closed shells up to 1.6 m, the first shell "
        f"without a level below 1.6 m is n2 = {stop}; equal to the record: {same}")
check(agree, "the closed shells of the slices 0 and 0.5 equal the record row by row",
      record=f"{SPECTRUM}/closed-shells.csv, rows a4 = 0 and 0.5")
say("slice 0: N = " + ", ".join(str(t[0]) for t in tables[0.0]))
```

The closed shells at the slices 0 (shells up to $n^2 = 40$) and 0.5 (up to 80; the redshifted band needs more shells), compared row by row with the record: the same numbers N, the same names of the last group, the same energies to 10^{-11}; and the stopping shell must lie inside the range searched. Out [14] prints 22 closed shells at the slice 0 (stopping shell $n^2 = 20$) and 55 at the slice 0.5 (stopping shell 53), and the list of N at the slice 0.

```
bulk_edge = float(min(levels(0.0, 1.0, "odd", 0), levels(0.0, 1.0, "even", 1)))
below_edge = [t for t in tables[0.0] if t[1] < bulk_edge and t[2] - t[1] > 1e-6]
N_large = below_edge[-1][0]
N_mid = min((t[0] for t in below_edge if t[0] >= 8),
            key=lambda n: abs(n - N_large / 4))
```

The bulk edge, the smaller of the odd level 0 and the even level 1 at $k = 0$; the closed shells whose last level lies below it (and are separated from the next level by more than 10^{-6}); N_{large}, the last of them; and N_{mid}, the one nearest to $N_{\mathrm{large}}/4$ (`min` with `key=` picks the element with the smallest value of the key function).

```
parameters = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                        .read_text(encoding="utf-8"))
numbers = parameters["particleNumbers"]
report("bulk edge", f"{bulk_edge:.12f}", "m")
report("particle numbers N", f"8, {N_mid}, {N_large}")
check(abs(bulk_edge - numbers["bulkEdge"]) < 1e-12 and N_large == 688
      and N_mid == 136 and numbers["values"] == [8.0, 136.0, 688.0],
      "the bulk edge 1.2922928281 and the particle numbers 8, 136, 688",
      record="Revision/kohn_sham/results/parameters.json, particleNumbers")
```

The record of the Revision runs, the two RESULT lines (the bulk edge $1.292292828069\,m$ and the numbers 8, 136, 688) and the check against the record. Out [14] shows two PASS lines.

In [15], figure 6.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
for a_, style in ((0.0, "-"), (0.5, "--")):
```

```
    energies = [t[1] for t in tables[a_]]
    counts = [t[0] for t in tables[a_]]
    ax.step(energies, counts, style, where="post",
            label=f"slice $a_{{4,0}} = {a_}$")
```

For each slice a **staircase**: `step(x, y, where="post")` draws a horizontal line from each point to the next value of x, then a vertical jump; here x is the energy of the last filled group and y the closed-shell number N.

```
ax.axvline(bulk_edge, color="gray", linestyle="-.", linewidth=0.8)
ax.annotate("bulk edge", (bulk_edge + 0.015, 15), fontsize=8, color="gray")
last_filled = {t[0]: t[1] for t in tables[0.0]}  # N -> its last filled level
for n_ in (8, N_mid, N_large):
    t_ = last_filled[n_]
    ax.plot([t_], [n_], "o", color="C3")
    ax.annotate(f"N = {n_}", (t_ + 0.02, n_ * 0.75), fontsize=8, color="C3")
```

A vertical line at the bulk edge, and the three particle numbers of the Revision runs as red dots at their last filled levels, with their names.

```
ax.set_yscale("log")
ax.set_xlabel("energy of the last filled level (units of $m$)")
ax.set_ylabel("closed-shell particle number $N$ (logarithmic)")
ax.set_title("the free aufbau: closed shells up to $1.6\\,m$")
ax.legend(fontsize=8, loc="upper left")
save_figure(fig, "closed_shells",
            "The closed shells of the free aufbau: the particle number $N$ "
            ...)
```

A logarithmic vertical axis, labels and title. **What figure 14c.6 shows.** At the slice 0 (solid) the staircase stays at $N = 8$ up to $0.43\,m$ (the gap), then climbs in steps, one per lattice shell of the band, to 688 just below the bulk edge and to 1552 at $1.584\,m$, the last group below $1.6\,m$. At the slice 0.5 (dashed) the first step comes already at $0.27\,m$ and the staircase lies far higher: the redshifted band puts many more states below the same energy.

In [16], the last check.

```
figure_names = ["14c_1_band_structure.png", "14c_2_band_slope.png",
                "14c_3_band_redshift.png", "14c_4_block_type_mirror.png",
                "14c_5_tip_insensitivity.png", "14c_6_closed_shells.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all six figure files of this notebook exist")
all_checks_passed()
```

The six figure files must exist; the last line prints ALL 15 CHECKS PASSED (notebook 14c). The 15 checks are: 2 in In [3], 4 in In [5], 2 in In [7], 1 in In [9], 1 in In [11], 2 in In [13], 2 in In [14] and 1 in In [16].

14.26 The exact local exchange of the contact interaction

What is needed. The quanta of dirac16complex interact through the contact term $U = \frac{\lambda}{2} S^2$ of the Lagrangian, with the scalar density $S = \bar{\Psi}\Psi = \Psi^\dagger C \Psi$, normal ordered in the quantised theory; $\lambda > 0$ is a repulsion, and λ has the dimension mass^{-6} because the field has the dimension 7/2 in eight dimensions (`Revision/kohn_sham/ks-theory.json`, units). The Kohn-Sham model needs the energy of this interaction in a Kohn-Sham state, a Slater determinant of orbitals or a thermal mixture of them (Chapter 13), as a function of the densities. This section derives it exactly. The result is surprising and very useful: the exchange energy, which for most interactions depends on the orbitals in a complicated way, is here an ordinary function of two densities at the same point.

The expectation-value rule (Chapter 10). For one quantum in the mode u (a column of 16 numbers), the expectation value of a density $\Psi^\dagger X \Psi$ is $u^\dagger B X u$, with the matrix B of the indefinite (Krein) inner product. For many independent quanta in the modes u with the occupations f (1 for filled, 0 for empty, or a number between at a temperature),

$$\langle \Psi^\dagger X \Psi \rangle = \mathrm{Tr}(X\rho), \qquad \rho = \sum_{\text{occupied}} f\, u u^\dagger B.$$

Rule: $\mathrm{Tr}(X u u^\dagger B) = \mathrm{Tr}(u^\dagger B X u) = u^\dagger B X u$, because a trace does not change when the first factors are moved to the end, and $u^\dagger B X u$ is a single number. The 16×16 matrix ρ is the **one-body matrix** of the state. The number density and the scalar density are

$$n = \langle \Psi^\dagger B \Psi \rangle = \mathrm{Tr}(B\rho), \qquad S = \langle \bar{\Psi}\Psi \rangle = \langle \Psi^\dagger C \Psi \rangle = \mathrm{Tr}(C\rho).$$

Status: the rule is the expectation-value rule of the canonical quantisation (Chapter 10), stated in the record as exchange.expectationRule of `Revision/kohn_sham/ks-theory.json`; the two density formulas are the check gas_densities of both theory reports.

The plane waves of the good sector. In flat space ($H = 0$, so $W = 1$ and $\kappa = 1$ at the slice 0) a plane wave $e^{-i\varepsilon x_4 + i\mathbf{p}\cdot\mathbf{x}} u$ with the momentum $\mathbf{p} = (p_1, p_2, p_3, p_0)$ along the four space-like directions x_0, x_1, x_2, x_3 (the good sector has no momentum along the extra times) solves $h_{\mathbf{p}} u = \varepsilon u$ with

$$h_{\mathbf{p}} = M(-i\gamma^{(x_4)}) - \sum_a p_a\, \gamma^{(x_4)}\gamma^{(a)} \qquad (a = x_0, x_1, x_2, x_3).$$

Rule: the Hamiltonian h of Section 14.4 with $v = 0$; its derivative term $i\gamma^{(x_4)}\gamma^{(x_0)}\partial_y$ acting on $e^{ip_0 y}$ gives $i\gamma^{(x_4)}\gamma^{(x_0)}(ip_0) = -p_0\gamma^{(x_4)}\gamma^{(x_0)}$. Its square, line by line:

$$\big(-i\gamma^{(x_4)}\big)^2 = -\big(\gamma^{(x_4)}\big)^2 = 1, \qquad \big(\gamma^{(x_4)}\gamma^{(a)}\big)^2 = -\big(\gamma^{(x_4)}\big)^2\big(\gamma^{(a)}\big)^2 = 1.$$

Rule: $(\gamma^{(x_4)})^2 = \eta_{44} = -1$ and $(\gamma^{(a)})^2 = +1$ for a space-like direction; in the second, moving the second $\gamma^{(x_4)}$ to the left past $\gamma^{(a)}$ costs one sign.

$$\big(-i\gamma^{(x_4)}\big)\big(\gamma^{(x_4)}\gamma^{(a)}\big) + \big(\gamma^{(x_4)}\gamma^{(a)}\big)\big(-i\gamma^{(x_4)}\big) = -i\big(\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(a)} - \gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(a)}\big) = 0,$$

Rule: anticommutation of different gammas ($\gamma^{(x_4)}$ is moved to the left past $\gamma^{(a)}$ in the second product, which costs one sign). For two different space-like directions $a \neq b$, line by line:

$$\big(\gamma^{(x_4)}\gamma^{(a)}\big)\big(\gamma^{(x_4)}\gamma^{(b)}\big) = -\gamma^{(x_4)}\gamma^{(x_4)}\gamma^{(a)}\gamma^{(b)} = \gamma^{(a)}\gamma^{(b)}, \qquad \big(\gamma^{(x_4)}\gamma^{(b)}\big)\big(\gamma^{(x_4)}\gamma^{(a)}\big) = \gamma^{(b)}\gamma^{(a)}.$$

Rule: move the second $\gamma^{(x_4)}$ to the left past $\gamma^{(a)}$, which costs one sign, and use $\gamma^{(x_4)}\gamma^{(x_4)} = -1$; the second product is the same with a and b exchanged.

$$\big(\gamma^{(x_4)}\gamma^{(a)}\big)\big(\gamma^{(x_4)}\gamma^{(b)}\big) + \big(\gamma^{(x_4)}\gamma^{(b)}\big)\big(\gamma^{(x_4)}\gamma^{(a)}\big) = \gamma^{(a)}\gamma^{(b)} + \gamma^{(b)}\gamma^{(a)} = 0.$$

Rule: add the two products; different gammas anticommute, $\gamma^{(a)}\gamma^{(b)} = -\gamma^{(b)}\gamma^{(a)}$. Hence

$$h_{\mathbf{p}}^2 = (M^2 + p_1^2 + p_2^2 + p_3^2 + p_0^2)\,1 = E^2\,1, \qquad E = \sqrt{M^2 + p^2}.$$

Rule: multiply out the square of the sum; the squares of the five terms give M^2 and the p_a^2, and the mixed products cancel in pairs. Since $h_{\mathbf{p}}$ is Hermitian (Section 14.4), its eigenvalues are real numbers whose squares are E^2: they are $+E$ and $-E$. Its trace is zero (it is a sum of products of one or two different gammas, Chapter 5), so the two eigenvalues occur equally often: $+E$ eight times and $-E$ eight times. Every momentum carries eight positive-energy modes. The matrix

$$G_{\mathbf{p}} = \tfrac{1}{2}\big(1 + h_{\mathbf{p}}/E\big)$$

is the **projector** on them: $G_{\mathbf{p}}^2 = \frac{1}{4}(1 + 2h_{\mathbf{p}}/E + h_{\mathbf{p}}^2/E^2) = \frac{1}{4}(2 + 2h_{\mathbf{p}}/E) = G_{\mathbf{p}}$, and $\mathrm{Tr}\, G_{\mathbf{p}} = \frac{1}{2}(16 + 0) = 8$. Status: PROVED; check gas_mode_projector (both reports).

Why every symmetric occupation has $\rho = (nB + SC)/16$. The sum of $uu^\dagger$ over the eight positive-energy modes (orthonormal, because $h_{\mathbf{p}}$ is Hermitian) is the projector $G_{\mathbf{p}}$. We assume that the eight modes of one momentum carry the same occupation f, as they do in every closed shell (all eight filled) and in every thermal state (the occupation depends only on the energy, which is the same for the eight). Then these eight modes contribute $fG_{\mathbf{p}}B$ to ρ; we write the case $f = 1$, and a common factor f changes nothing below. Line by line:

$$G_{\mathbf{p}}B = \tfrac{1}{2}B + \frac{M}{2E}\big(-i\gamma^{(x_4)}\big)B - \frac{1}{2E}\sum_a p_a\gamma^{(x_4)}\gamma^{(a)}B.$$

Rule: insert $h_{\mathbf{p}}$ into $G_{\mathbf{p}}$ and multiply by B.

$$\big(-i\gamma^{(x_4)}\big)B = \big(-i\gamma^{(x_4)}\big)\big(-iC\gamma^{(x_4)}\big) = -\gamma^{(x_4)}C\gamma^{(x_4)} = -C\gamma^{(x_4)}\gamma^{(x_4)} = C.$$

Rule: $B = -iC\gamma^{(x_4)}$; $(-i)^2 = -1$; $\gamma^{(x_4)}$ commutes with C (it passes the four factors of C, none of which is $\gamma^{(x_4)}$: four signs); $(\gamma^{(x_4)})^2 = -1$.

$$G_{\mathbf{p}}B = \tfrac{1}{2}\Big(B + \frac{M}{E}\,C\Big) - \frac{1}{2E}\sum_a p_a\gamma^{(x_4)}\gamma^{(a)}B.$$

The last term changes its sign when $\mathbf{p}$ is replaced by $-\mathbf{p}$. If the state occupies $\mathbf{p}$ and $-\mathbf{p}$ equally, which is true for every closed shell and for every thermal state, these terms cancel in pairs, and each pair leaves $B + (M/E)C$ (times the common occupation). Filled negative-energy modes give in the same way $\frac{1}{2}(1 - h_{\mathbf{p}}/E)B$, whose symmetric part is $\frac{1}{2}(B - (M/E)C)$. So the one-body matrix of any such state is a combination of B and C only, $\rho = \alpha B + \beta C$. The two numbers follow from the densities:

$$n = \operatorname{Tr}(B\rho) = \alpha \operatorname{Tr}(B^2) + \beta \operatorname{Tr}(BC) = 16\alpha, \qquad S = \operatorname{Tr}(C\rho) = \alpha \operatorname{Tr}(CB) + \beta \operatorname{Tr}(C^2) = 16\beta.$$

Rule: $B^2 = C^2 = 1$, whose trace is 16, and $\operatorname{Tr}(BC) = \operatorname{Tr}(-i\gamma^{(x_4)}) = 0$ (Chapter 5: $BC = -i\gamma^{(x_4)}$). Hence

$$\rho = \frac{nB + SC}{16},$$

for every occupation that gives the eight modes of each momentum the same occupation and is symmetric under $\mathbf{p} \to -\mathbf{p}$, at every temperature (the record: "any p -> -p symmetric occupation of the 8-fold good-sector gas", `Revision/kohn_sham/ks-theory.json`, exchange.uniformGas). If only some of the eight modes of a momentum were filled, their one-body matrix would in general not be a combination of B and C, and the formula would not apply. Status: PROVED; checks gas_angular_average (both reports), gas_negative_energy_modes (sympy report) and gas_densities (both).

Wick's rule for the contact term. Write $S = \Psi^\dagger C \Psi = \sum_{A,B} \Psi_A^\dagger C_{AB} \Psi_B$, with the components $A, B = 0, \ldots, 15$. For a quasi-free state (a determinant or a thermal state of independent quanta), Wick's theorem (Section 13.4) gives the expectation of a normal-ordered product of two creation and two annihilation operators as the sum over the ways of pairing each $\Psi^\dagger$ with a Ψ, with a minus sign for the crossed pairing because the field anticommutes. With $f_{AB} = \langle \Psi_A^\dagger \Psi_B \rangle$:

$$\langle :S^2: \rangle = \sum_{A,B,C',D} C_{AB} C_{C'D} (f_{AB} f_{C'D} - f_{AD} f_{C'B}).$$

(The index C' carries a prime so that it is not confused with the matrix C.) The first product is the **direct** (Hartree) term, the second the **exchange** (Fock) term. Now the matrix form, line by line:

$$f_{AB} = \rho_{BA}.$$

Rule: $\langle \Psi^\dagger X \Psi \rangle = \sum_{A,B} X_{AB} f_{AB}$ and $\operatorname{Tr}(X\rho) = \sum_{A,B} X_{AB} \rho_{BA}$ must agree for every matrix X.

$$\sum C_{AB} C_{C'D} f_{AB} f_{C'D} = \Big(\sum_{A,B} C_{AB} \rho_{BA} \Big) \Big(\sum_{C',D} C_{C'D} \rho_{DC'} \Big) = (\operatorname{Tr} C\rho)^2.$$

Rule: the sum of a product of two factors with separate indices is the product of the two sums.

$$\sum C_{AB} C_{C'D} f_{AD} f_{C'B} = \sum C_{AB} \rho_{BC'} C_{C'D} \rho_{DA} = \operatorname{Tr}(C\rho C\rho).$$

Rule: $f_{AD} = \rho_{DA}$ and $f_{C'B} = \rho_{BC'}$; reorder the four numbers so that neighbouring indices agree, $A \to B \to C' \to D \to A$: a chain of matrix products that closes on itself is a trace. Hence

$$\langle{:}S^2{:}\rangle = \big(\operatorname{Tr} C\rho\big)^2 - \operatorname{Tr}(C\rho C\rho).$$

Status: PROVED (Section 13.4 and the lines above); the record verified it term by term on an explicit two-mode state (check hf_wick_contraction of the sympy report), and Notebook 14d repeats that on two states (In [6]).

The exact local exchange. Insert $\rho = (nB + SC)/16$. Line by line:

$$C\rho = \frac{nCB + S\,1}{16}.$$

Rule: $C^2 = 1$.

$$C\rho C\rho = \frac{n^2\,CBCB + nS\,CB + nS\,CB + S^2\,1}{256} = \frac{n^2 + 2nS\,CB + S^2}{256}.$$

Rule: multiply out the four products; $CBCB = (CBC)B = BB = 1$ by $CBC = B$ (Chapter 5) and $B^2 = 1$.

$$\operatorname{Tr}(C\rho C\rho) = \frac{16n^2 + 0 + 16S^2}{256} = \frac{n^2 + S^2}{16}.$$

Rule: $\operatorname{Tr} 1 = 16$ and $\operatorname{Tr}(CB) = 0$. The interaction energy per unit (proper) volume, $\frac{\lambda}{2}\langle{:}S^2{:}\rangle$, is therefore $e_H + e_x$ with

$$e_H = \frac{\lambda}{2}S^2, \qquad e_x = -\frac{\lambda}{2}\operatorname{Tr}(C\rho C\rho) = -\frac{\lambda}{32}(n^2 + S^2).$$

The **Hartree** term e_H and the **exchange** term e_x are both functions of the two densities at one point: the exchange of the contact interaction is exactly **local**, at every temperature, for every symmetric occupation. For one filled 8-fold level at rest the scalar and number densities are equal, $n = S$ (Exercise 14.8), and $e_x/e_H = -\frac{1}{32}\cdot 2S^2/\frac{1}{2}S^2 = -\frac{1}{8}$: the exchange removes one eighth of the Hartree energy, the rule $E_x = -E_H/g$ of Section 13.5 with the $g = 8$ modes per momentum. Status: PROVED; checks exchange_uniform_gas (both reports) and filled_shell_ratio (sympy report); the coefficients $-1/32$, $-1/32$ are recorded under exchange.uniformGas in ks-theory.json.

14.27 The Kohn-Sham potentials, the exact Fock exchange of the model's states, and the eight zero modes

The potentials. The interaction energy density is

$$e_{\text{int}}(n, S) = e_H + e_x = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2.$$

Rule: $\frac{1}{2} - \frac{1}{32} = \frac{15}{32}$. As in Chapter 13 (Section 13.9), the Kohn-Sham potential that belongs to a density is the derivative of the interaction energy density with respect to that density (for a local energy the functional derivative is an ordinary derivative). The density S multiplies the mass term of the Lagrangian, so its potential shifts the mass; the number density gives a potential that is added to h as v_v times the unit matrix:

$$M_{\text{eff}} = m + \frac{\partial e_{\text{int}}}{\partial S} = m + \frac{15}{16}\lambda S, \qquad v_v = \frac{\partial e_{\text{int}}}{\partial n} = -\frac{1}{16}\lambda n.$$

Rule: the derivative of S^2 is $2S$, and $2 \cdot \frac{15}{32} = \frac{15}{16}$, $2 \cdot \frac{1}{32} = \frac{1}{16}$. In the covariant equation v_v appears as $-iv_v\gamma^{(x_4)}$ (Section 14.3). These are the M_{eff} and v_v that Sections 14.3 to 14.25 used as given functions. Status: PROVED; check ks_potentials (both reports); the coefficients $15/16$ and $-1/16$ are recorded in ks-theory.json (exchange.kohnShamPotentials) and are the numbers 0.9375 and -0.0625 that the Rust solver reads (`Revision/kohn_sham/results/parameters.json`, theoryInputs).

The Lagrangian on shell. e_{int} is **homogeneous of degree 2**: doubling both densities multiplies it by 4. Line by line:

$$S\frac{\partial e_{\text{int}}}{\partial S} + n\frac{\partial e_{\text{int}}}{\partial n} = \frac{15}{16}\lambda S^2 - \frac{1}{16}\lambda n^2 = 2e_{\text{int}}.$$

Rule: insert the two derivatives and compare with twice e_{int}.

$$\frac{\langle L\rangle}{\sqrt{|g|}} = M_{\text{eff}}S + v_v n - mS - e_{\text{int}} = mS + 2e_{\text{int}} - mS - e_{\text{int}} = e_{\text{int}}.$$

Rule: the Lagrangian of Chapter 7 is a kinetic part minus mS minus the interaction, whose expectation value is e_{int}. On shell (for orbitals that solve the Kohn-Sham equation $\gamma^\mu D_\mu\Psi = (M_{\text{eff}} - iv_v\gamma^{(x_4)})\Psi$) the kinetic part is $\bar\Psi\gamma^\mu D_\mu\Psi = M_{\text{eff}}\bar\Psi\Psi + v_v\Psi^\dagger(-iC\gamma^{(x_4)})\Psi = M_{\text{eff}}S + v_v n$, because $\bar\Psi = \Psi^\dagger C$ and $B = -iC\gamma^{(x_4)}$ (the symmetrised form of the kinetic term has the same value on shell); then the line above gives $M_{\text{eff}}S + v_v n = mS + 2e_{\text{int}}$. This value of the Lagrangian enters the energy-momentum tensor (Chapter 15). Status: PROVED; check ks_onshell_lagrangian (both reports).

What the functional leaves out. The Kohn-Sham functional of the Revision theory is Hartree plus this uniform-gas exchange, with no correlation energy. Its states, however, are not uniform along y. The record computes the EXACT Fock exchange of such a state (exchange.exactFockSlab in ks-theory.json): take one level, closed over a shell ($\mathbf{k}$ and $-\mathbf{k}$ equally filled), with the 2×2 block density $D = \frac{1}{2}(d_0 + d_1\sigma_1 + d_2\sigma_2 + d_3\sigma_3)$ in each of the four blocks of type $j = +1$ and $\sigma_3 D\sigma_3$ in each of the four of type -1 (their degenerate partners, Section 14.5), and average it over the directions of the shell. Two facts make this average simple. First, averaging a matrix over all the rotations of a group gives a matrix that no rotation of the group changes, that is, one that commutes with all of them; and a matrix that already commutes with them is its own average. So the average over all rotations of 3-space is the projection onto the matrices that commute with the rotations, a space of dimension 64. Second, a closed shell contains only a finite set of directions, which the 24 rotations of a cube carry into each other, not all directions. But under the rotations of 3-space the 16×16 matrices split into parts of spin 0 (unchanged by every rotation) and parts of spin 1 (turned like an arrow), and nothing else; and the average of an arrow over the 24 rotations of a cube is zero, just as

its average over all rotations. So for these matrices the average over the cube equals the average over all rotations (both theory reports state this: the 16 x 16 matrices carry only spin 0 and spin 1). The result, with $Q = \langle \Psi^\dagger B \gamma^{(x_0)} \Psi \rangle$ and the y-current Y:

$$n = 8d_0, \qquad S = 8d_2, \qquad Q = 8d_3, \qquad Y = 8d_1, \qquad e_x^{\text{exact}} = -\frac{\lambda}{32}(n^2 + S^2 - Q^2 - Y^2).$$

For orbitals $Y = 0$ (Section 14.12), so the uniform-gas exchange $-\frac{\lambda}{32}(n^2 + S^2)$ omits the term $+\frac{\lambda}{32}Q^2$. The record labels this a DIAGNOSTIC: the canonical functional stays the uniform-gas one, and the Rust solver reports the omitted part and also solves an exact-Fock variant of the model, which adds the potential $w_Q \sigma_3$ with $w_Q = +\frac{\lambda}{16}Q$ to h and $+\frac{\lambda}{32}Q^2$ to e_{int}. Status: PROVED; check exchange_slab_exact_fock (both reports, by two different methods: the sympy report projects onto the 64-dimensional space of matrices that commute with the rotations, the Wolfram report averages over the 48 spinor matrices of the 24 rotations of a cube, each rotation appearing with both signs).

The size of Q. For one orbital $\chi = (a, ib)$ the three densities are proportional to $a^2 + b^2$ (n), $2ab$ (S, up to the sign j) and $a^2 - b^2$ (Q) (Section 14.12). Line by line:

$$(2ab)^2 + (a^2 - b^2)^2 = 4a^2b^2 + a^4 - 2a^2b^2 + b^4 = (a^2 + b^2)^2.$$

Rule: the binomial formulas. So for one orbital $S^2 + Q^2 = n^2$, and for a mixture of orbitals $S^2 + Q^2 \le n^2$ (Exercise 14.9): the possible states fill the disk $(S/n)^2 + (Q/n)^2 \le 1$. The uniform-gas and the exact exchange agree on the line $Q = 0$ and differ most at the top and bottom of the disk, $S = 0$, $Q = \pm n$ (Figure 14d.3).

The state of the eight zero modes ($N = 8$). The simplest Kohn-Sham state of the model fills the eight brane zero modes at $k = 0$ (both block types, even parity). Each orbital is $\chi = (a, 0)$ with $a = \sqrt{2M/(1 - e^{-2ML})}\, e^{My}$ (Section 14.13). The densities, line by line (the record's densities section in ks-theory.json):

- One orbital: $n_o = P(a^2 + b^2) = Pa^2$, $s_o = P\, j\, 2ab = 0$, $q_o = P(a^2 - b^2) = Pa^2$, with $P = e^{-6Hy}/(\ell^3 v_t)$, the factor that makes the densities proper (Section 14.7).
- The state: $n = \sum w\, g\, f\, n_o$, with the degeneracy $g = 4$ per block type, the occupation $f = 1$, and the weight $w = \frac{1}{2}$ of the ASSUMED Z2 doubled system: the orbitals are normalised on the patch, $\int_{-L}^{0} \chi^\dagger \chi \, dy = 1$, but the system consists of the patch and its mirror copy, so the patch holds half of each orbital, and the particle number $N = \sum gf$ counts the doubled system. So $n = \frac{1}{2}(4 + 4)Pa^2 = 4Pa^2$, $S = 0$ and $Q = n$.
- The proper density $n = 4e^{-6Hy}a^2/(\ell^3 v_t) \propto e^{(2M-6H)y}$ is largest at the cutoff $y = -L$ (for $M = H = 1$: e^{-4y}), although the orbital itself sits at the brane: the proper 7-volume e^{6Hy} is tiny near the tip. With $H = m = 1$, $L = 3$, $\ell = 2\pi/0.25$ and $v_t = 1$ its largest value is $n_{\max} = 82.2208638894$ (Notebook 14d, Out [12]; the column n_max of the row N8_lam0_a00 of `Revision/kohn_sham/results/ground/summary.csv`).
- To first order in λ the potentials are $M_{\text{eff}} - m = \frac{15}{16}\lambda S = 0$ and $v_v = -\frac{\lambda}{16}n$. The Revision solver calibrates its couplings by the largest first-order potential per unit λ, $n_{\max}/16 = 5.138803993$; λ_1 and λ_2 are 0.1 and 0.3 divided by it, rounded to 4 significant digits: $\lambda_1 = 0.01946$,

$\lambda_2 = 0.05838$, so that the largest first-order potential is $0.1\,m$ and $0.3\,m$ to four significant digits (after the rounding of λ it is $0.1000011\,m$ and $0.3000034\,m$, Notebook 14d, Out [12]; `Revision/kohn_sham/results/parameters.json`, couplingCalibration; the states $N = 136$ and 688 have their own, smaller couplings, fixed the same way along the whole history). This calibration is an $L = 3$ statement: the largest proper density sits at the cutoff and grows with L like $e^{(6H-2M)L}$, so the same rule applied at a larger cutoff drives λ_1 toward zero, for $N = 8$ like e^{-4L}, from 0.01946 at $L = 3$ to 1.2×10^{-7} at $L = 6$ (`Revision/kohn_sham/tip_convergence/`; `Revision/docs/KOHN_SHAM_DEFLATING_FIELD.md`, section 5); with the couplings held fixed, the interaction energy of the zero modes depends strongly on L (Section 14.20).

- The exact Fock exchange of this state vanishes: with $S = 0$ and $Q = n$, $e_x^{\text{exact}} = -\frac{\lambda}{32}(n^2 - Q^2) = 0$. In the exact-Fock variant the potential on $(a, 0)$ is $v_v + w_Q = \frac{\lambda}{16}(Q - n) = 0$ (because σ_3 acts as $+1$ on $(a, 0)$), so the zero modes stay exact solutions with $\varepsilon = 0$ and the energy of the state is exactly zero. The record's twenty self-consistent exact-Fock states with $N = 8$ (four couplings, five slices) have energies zero to rounding, below 10^{-12} (`Revision/kohn_sham/results/exx/exact-fock-variant.csv`).

Status: the formulas PROVED; the numbers COMPUTED (they reproduce the records named); the weight $w = \frac{1}{2}$ rests on the ASSUMED Z2 mirror.

14.28 Example: Notebook 14d, the exact local exchange

Notebook 14d does Sections 14.26 and 14.27 with exact algebra on the author's gamma matrices: the plane waves of the good sector and their projector, the cancellation that makes $\rho = (nB + SC)/16$, Wick's rule term by term on two explicit states, the exact local exchange and the ratio $-1/8$, the Kohn-Sham potentials and the on-shell Lagrangian (compared with the coefficients that the Rust solver read), and the exact Fock exchange of the closed-shell states by projection onto the 64-dimensional space of matrices that commute with the rotations. With numpy it computes the densities of the eight zero modes, reproduces the largest proper density, the calibration of the couplings and the zero exact-Fock energies of the record. It draws four figures, needs no Rust, runs in about 30 seconds, and its last line is ALL 16 CHECKS PASSED (notebook 14d).

14.29 How to run Notebook 14d

Step 1. What this notebook does and what it needs.

Notebook 14d (The exact local exchange of the contact interaction and the Kohn-Sham potentials) is the file `Revision/textbook/notebooks/14d_local_exchange.ipynb` of the repository Dirac_claude. It derives with exact algebra on the author's gamma matrices the Hartree-Fock energy of the contact interaction U = (lambda/2) S^2 of dirac16complex in Kohn-Sham states: the positive-energy projector of the flat good-sector plane waves, the cancellation between the momenta p and -p that makes the one-body matrix of every symmetric occupation equal to (nB + SC)/16, the bookkeeping of Wick's rule checked term by term, the exact local exchange -(lambda/32)(n^2 + S^2), the filled-shell ratio -1/8, the Kohn-Sham potentials M_eff = m + (15/16) lambda S and v_v = -lambda n/16, and the exact Fock exchange of the closed-shell slab, which differs by +(lambda/32) Q^2; it then computes the densities of the eight brane zero modes and reproduces the Revision calibration of the coupling for N = 8 and the vanishing exact-Fock energy of that state, with four

teaching figures. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 14d_local_exchange.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 14d_local_exchange.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 14d_local_exchange.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/14d.captions.json`
- `Revision/textbook/figures/14d_1_pair_average.png`
- `Revision/textbook/figures/14d_2_energy_densities.png`
- `Revision/textbook/figures/14d_3_exact_fock_ratio.png`
- `Revision/textbook/figures/14d_4_zero_mode_state.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all four figure files of this notebook exist
ALL 16 CHECKS PASSED (notebook 14d)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/14d_local_exchange.ipynb` inside the folder Dirac_claude.

- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 14d_local_exchange.ipynb
python -m nbconvert --execute --inplace 14d_local_exchange.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

14.30 Notebook 14d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/14d_local_exchange.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The quanta of dirac16complex interact through the contact term
$U = \frac\lambda2 S^2$ of the Lagrangian, $S = \bar\Psi\Psi$. The Kohn-Sham
model needs the energy of this interaction in a Kohn-Sham state (a Slater
determinant or a thermal mixture of orbitals) as a function of the densities.
This notebook derives it exactly, with the author's gamma matrices:
```

```
- the plane waves of the good sector in flat space, their energies $\pm E$ and
  the projector on the positive ones;
- why every occupation that is symmetric under $\mathbf p \to -\mathbf p$ has
  the one-body matrix $\rho = (nB + SC)/16$ (figure 1);
- the Hartree-Fock energy: Hartree $\frac\lambda2S^2$ plus the EXACT LOCAL
  EXCHANGE $-\frac{\lambda}{32}(n^2 + S^2)$, and the ratio $-1/8$ of a filled
  level at rest (figure 2);
- the Kohn-Sham potentials $M_{\rm eff} = m + \frac{15}{16}\lambda S$ and
  $v_v = -\frac{\lambda}{16}n$;
- the exact Fock exchange of a closed-shell slab state, $-\frac{\lambda}{32}
  (n^2 + S^2 - Q^2)$, which the uniform-gas formula misses by
  $+\frac{\lambda}{32}Q^2$ (figure 3);
- the densities and potentials of the eight brane zero modes (the state
  $N = 8$), which reproduce the Revision calibration of the coupling, and why the
  exact Fock exchange of that state is exactly zero (figure 4).

It prints a PASS line for every check (16 in all) and saves four figures.
```

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 14d (The exact local exchange of the contact interaction and the Kohn-Sham
potentials) is the file ‘Revision/textbook/notebooks/14d_local_exchange.ipynb‘ of the
repository Dirac_claude. It derives with exact algebra on the author’s gamma matrices the
Hartree-Fock energy of the contact interaction U = (lambda/2) S^2 of dirac16complex in
Kohn-Sham states: the positive-energy projector of the flat good-sector plane waves, the
cancellation between the momenta p and -p that makes the one-body matrix of every
symmetric occupation equal to (nB + SC)/16, the bookkeeping of Wick’s rule checked term
by term, the exact local exchange -(lambda/32)(n^2 + S^2), the filled-shell ratio -1/8,
the Kohn-Sham potentials M_eff = m + (15/16) lambda S and v_v = -lambda n/16, and the
exact Fock exchange of the closed-shell slab, which differs by +(lambda/32) Q^2; it then
computes the densities of the eight brane zero modes and reproduces the Revision
calibration of the coupling for N = 8 and the vanishing exact-Fock energy of that state,
with four teaching figures. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
```

default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
```

```
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 14d_local_exchange.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 14d_local_exchange.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 14d_local_exchange.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/14d.captions.json‘
- ‘Revision/textbook/figures/14d_1_pair_average.png‘
- ‘Revision/textbook/figures/14d_2_energy_densities.png‘
- ‘Revision/textbook/figures/14d_3_exact_fock_ratio.png‘
- ‘Revision/textbook/figures/14d_4_zero_mode_state.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every

change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all four figure files of this notebook exist
ALL 16 CHECKS PASSED (notebook 14d)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/14d_local_exchange.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 14d_local_exchange.ipynb
  python -m nbconvert --execute --inplace 14d_local_exchange.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 14d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 14d (The exact local exchange of the contact interaction and the Kohn-Sham

# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
```

```
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 14d_local_exchange.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
```

```
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 14d_local_exchange.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 14d_local_exchange.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/14d.captions.json
# - Revision/textbook/figures/14d_1_pair_average.png
# - Revision/textbook/figures/14d_2_energy_densities.png
# - Revision/textbook/figures/14d_3_exact_fock_ratio.png
# - Revision/textbook/figures/14d_4_zero_mode_state.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all four figure files of this notebook exist
#     ALL 16 CHECKS PASSED (notebook 14d)
#
# and the notebook must show 4 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
```

```
#   Revision/textbook/notebooks/14d_local_exchange.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 14d_local_exchange.ipynb
#     python -m nbconvert --execute --inplace 14d_local_exchange.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#

## 3. The words used in this notebook

- **Contact interaction**: the term $U(S) = \frac\lambda2S^2$ of the
  Lagrangian; $\lambda > 0$ is repulsive. $\lambda$ has the dimension
  mass$^{-6}$.
```

```
- **Density**: an expectation value per unit volume. Number density
  $n = \langle\Psi^\dagger B\Psi\rangle$; scalar density
  $S = \langle\bar\Psi\Psi\rangle = \langle\Psi^\dagger C\Psi\rangle$; the
  density $Q = \langle\Psi^\dagger B\gamma^{(x_0)}\Psi\rangle$. PROPER densities
  are per proper 7-volume.
- **Expectation-value rule**: for one quantum in the mode $u$,
  $\langle\Psi^\dagger X\Psi\rangle = u^\dagger BXu$; for many,
  $\langle\Psi^\dagger X\Psi\rangle = \mathrm{Tr}(X\rho)$ with the one-body
  matrix $\rho = \sum_{\rm occupied} f\,uu^\dagger B$ ($f$ the occupation).
- **Trace** $\mathrm{Tr}\,X$: the sum of the diagonal entries; $\mathrm{Tr}(XY)
  = \mathrm{Tr}(YX)$.
- **Normal ordering** $:\;:$: the operators of the free sea are reordered so
  that the vacuum has zero energy; it removes the infinite sea contributions.
- **Quasi-free state, Wick's rule**: a Slater determinant or a thermal state of
  independent quanta; the expectation of four field operators is a sum of
  products of two-operator expectations (a "direct" and an "exchange" term).
- **Hartree term, exchange term**: the direct and the exchange part of the
  interaction energy. **Hartree-Fock**: keeping both, for a quasi-free state.
- **Kohn-Sham potential**: the derivative of the interaction energy density with
  respect to a density; it enters the one-quantum equation.
- **Uniform gas**: quanta in flat space, the same in every place.
- **Closed-shell slab**: the Kohn-Sham states of the model, uniform along 3-space
  but not along the hidden coordinate $y$, with complete lattice shells filled.
- **Commutant**: all matrices that commute with a given set of matrices.
- **Zero modes, $N = 8$**: the eight brane-bound orbitals at zero 3-momentum,
  $\chi = (a, 0)$ with $a \propto e^{My}$; filling them gives the state $N = 8$.
```

Text cell:

```
## 4. The physical and mathematical situation

The Revision theory (‘Revision/kohn_sham/ks-theory.json‘, section ‘exchange‘)
builds the Kohn-Sham functional of dirac16complex from the Hartree-Fock energy of
the uniform good-sector gas, which turns out to be LOCAL (a function of the
densities at one point) at every temperature. The steps, each exact:

1. In flat space a plane wave $e^{-i\varepsilon x_4 + i\mathbf p\cdot\mathbf x}$
   of the good sector solves $h_{\mathbf p}u = \varepsilon u$ with
   $h_{\mathbf p} = M(-i\gamma^{(x_4)}) - p_a\gamma^{(x_4)}\gamma^{(a)}$, the sum
   over the four space-like directions $x_0, x_1, x_2, x_3$.
2. $h_{\mathbf p}^2 = (M^2 + p^2)\,1$: the energies are $\pm E$,
   $E = \sqrt{M^2 + p^2}$, each 8 times.
3. The interaction energy needs $\langle{:}S^2{:}\rangle$, which Wick's rule
   turns into $(\mathrm{Tr}\,C\rho)^2 - \mathrm{Tr}(C\rho C\rho)$.
4. For symmetric occupations $\rho = (nB + SC)/16$, and the second trace is
   $(n^2 + S^2)/16$.

Status: every formula here is PROVED (exact; verified twice in the Revision
record). The use of the uniform-gas exchange for the slab states of the model is
the canonical functional of the Revision theory (an approximation: no
correlation energy); the exact Fock exchange of the slab is a DIAGNOSTIC.
```

Text cell:

```
## 5. The gamma matrices, B and C

The next cell reads the author's gamma matrices from the Revision record
`Revision/algebra/gammas.json` (`g0` is $\gamma^{(x_0)}$, ..., `g7` is
$\gamma^{(x_7)}$), builds $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}
\gamma^{(x_3)}$ and $B = -iC\gamma^{(x_4)}$, and checks the facts used below:
$B$ and $C$ square to 1, $\mathrm{Tr}\,B^2 = \mathrm{Tr}\,C^2 = 16$,
$\mathrm{Tr}\,BC = 0$, $CBC = B$, and $(-i\gamma^{(x_4)})B = C$. It also defines
`record_check`, which reads the verdict of a named check from the two Revision
theory reports.
```

In [2]:

```
import math  # exp, sqrt, log10 of single numbers

import numpy as np  # floating-point arrays
import sympy as sp  # exact algebra with symbols

PY_REPORT = "Revision/kohn_sham/reports/ks-theory-python.json"

```
PASS B^2 = C^2 = 1, Tr B^2 = Tr C^2 = 16, Tr BC = 0, CBC = B, (-i g4) B = C
```

Text cell:

```
## 6. The plane waves of the good sector and their projector

The four space-like directions are $x_0, x_1, x_2, x_3$; their gammas square to
$+1$, and $\gamma^{(x_4)}$ squares to $-1$. Line by line:

1. $h_{\mathbf p} = M(-i\gamma^{(x_4)}) - \sum_a p_a\gamma^{(x_4)}\gamma^{(a)}$.
2. Squaring: $(-i\gamma^{(x_4)})^2 = -(\gamma^{(x_4)})^2 = 1$;
   $(\gamma^{(x_4)}\gamma^{(a)})^2 = -(\gamma^{(x_4)})^2(\gamma^{(a)})^2 = 1$;
   all mixed products anticommute and cancel in pairs. So
   $h_{\mathbf p}^2 = (M^2 + p_1^2 + p_2^2 + p_3^2 + p_0^2)\,1 = E^2\,1$.
3. Hence $G_{\mathbf p} = \frac12(1 + h_{\mathbf p}/E)$ satisfies
   $G_{\mathbf p}^2 = G_{\mathbf p}$: it projects on the energy $+E$; its trace
   is 8 because $h_{\mathbf p}$ is traceless: eight positive-energy modes.

The next cell checks the three lines with sympy.
```

    gas_mode_projector
```

Text cell:

```
## 7. Why every symmetric occupation gives rho = (nB + SC)/16

The one-body matrix of the eight positive-energy modes at momentum $\mathbf p$
is $G_{\mathbf p}B$. Split it into a part that does not depend on the direction
of $\mathbf p$ and a part that is linear in $\mathbf p$:

$$G_{\mathbf p}B = \frac12\left(B + \frac ME(-i\gamma^{(x_4)})B\right) -
\frac1{2E}\sum_a p_a\gamma^{(x_4)}\gamma^{(a)}B .$$

The linear part changes sign under $\mathbf p \to -\mathbf p$. So if the
occupation is the same for $\mathbf p$ and $-\mathbf p$ (true for every closed
```

```
shell and for the thermal states), the linear parts cancel in pairs, and with
$(-i\gamma^{(x_4)})B = C$ what is left is $\frac12(B + \frac ME C)$. The same
holds for an average over all directions (the average of each component of a
direction over the sphere is 0). For the negative-energy modes,
$\frac12(1 - h_{\mathbf p}/E)B$, the result is $\frac12(B - \frac ME C)$. Adding
up any such occupation therefore gives a combination of $B$ and $C$ only,
$\rho = \alpha B + \beta C$; and since $\mathrm{Tr}(B\rho) = 16\alpha = n$ and
$\mathrm{Tr}(C\rho) = 16\beta = S$,

$$\rho = \frac{nB + SC}{16}.$$

The next cell checks the pair cancellation, the sphere averages of the three
components (exact integrals), both mode types and the trace formulas.
```

In [4]:

```
p_flip = {p1: -p1, p2: -p2, p3: -p3, p0: -p0}

## 8. Wick's rule for the contact term

For a quasi-free state with the two-operator expectations
$f_{AB} = \langle\Psi_A^\dagger\Psi_B\rangle = \rho_{BA}$ (the expectation-value
rule), Wick's rule gives for the normal-ordered square of
$S = \Psi^\dagger C\Psi = \sum_{AB}\Psi_A^\dagger C_{AB}\Psi_B$
```

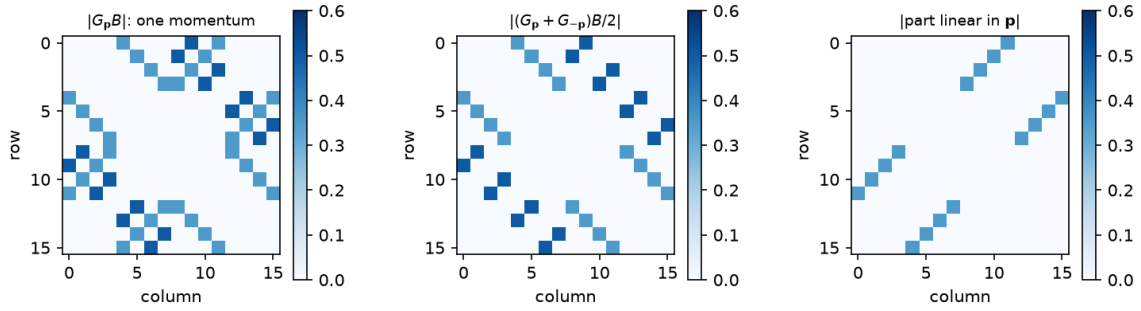

Figure 401: Absolute values of the entries (rows and columns 0 to 15, darker is larger) of the one-body matrix of the eight positive-energy plane waves for $M = 1$ and the momentum $\mathbf{p} = (1, 0, 0, 0)$, $E = \sqrt{2}$: left for one momentum, middle averaged with $-\mathbf{p}$, which leaves exactly $(B + C/\sqrt{2})/2$, a combination of B and C only; right the part linear in $\mathbf{p}$, which cancels between $\mathbf{p}$ and $-\mathbf{p}$. Every occupation that is symmetric under $\mathbf{p} \to -\mathbf{p}$ therefore has the one-body matrix $(nB + SC)/16$. (Notebook 14d, figure 1.)

```
$$\langle{:}S^2{:}\rangle = \sum_{ABCD}C_{AB}C_{CD}\,(f_{AB}f_{CD} -
f_{AD}f_{CB}) .$$

The first product is the DIRECT (Hartree) term, the second, with the minus sign
of the anticommuting fields, the EXCHANGE (Fock) term. In matrix language the
first sum is $(\mathrm{Tr}\,C\rho)^2$ and the second is $\mathrm{Tr}(C\rho C
\rho)$. The next cell checks this bookkeeping term by term, as the Revision
record did, for the explicit two-mode state with the mode vectors $u_1, u_2$ of
the record, and for a second two-mode state $v_1, v_2$ with less symmetry: it
adds up the $16^4$ terms of the sum (only those with nonzero $C$ entries are
kept, 256 of them) and compares with the two traces.
```

## 9. The exact local exchange and the filled-shell ratio

With $\rho = (nB + SC)/16$ (line by line, using $CBC = B$, $C^2 = 1$,
$\mathrm{Tr}\,B^2 = \mathrm{Tr}\,C^2 = 16$, $\mathrm{Tr}\,BC = 0$):

1. $C\rho = (nCB + S)/16$.
2. $(C\rho)^2 = (n^2CBCB + nS\,CB + nS\,CB + S^2)/256 = (n^2 + 2nS\,CB +
   S^2)/256$, because $CBCB = BB = 1$.
3. $\mathrm{Tr}(C\rho C\rho) = (16n^2 + 0 + 16S^2)/256 = (n^2 + S^2)/16$.
4. The energy density is $\frac\lambda2\langle{:}S^2{:}\rangle = e_H + e_x$ with
   the Hartree term $e_H = \frac\lambda2S^2$ and the EXCHANGE
   $e_x = -\frac\lambda2\mathrm{Tr}(C\rho C\rho) = -\frac{\lambda}{32}(n^2 + S^2)$.

This is exact, at every temperature, for every symmetric occupation: the exchange
of the contact interaction is LOCAL. For one filled 8-fold level at rest
($n = S = 8$ per unit volume): $e_x/e_H = -\frac{1}{32}\cdot128/(\frac12\cdot64)
= -\frac18$. The next cell checks 1 to 4 and the ratio.

## 10. The Kohn-Sham potentials

The interaction energy density is $e_{\rm int}(n, S) = e_H + e_x =
\frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2$. The Kohn-Sham potentials are
its derivatives: $M_{\rm eff} = m + \partial e_{\rm int}/\partial S = m +
\frac{15}{16}\lambda S$ (it shifts the mass) and $v_v = \partial e_{\rm int}/
\partial n = -\frac{1}{16}\lambda n$ (it enters $h$ as $v_v$ times the unit
matrix). Because $e_{\rm int}$ is homogeneous of degree 2,
$S\,\partial_S e + n\,\partial_n e = 2e$, so on shell
$\langle L\rangle/\sqrt{|g|} = M_{\rm eff}S + v_vn - mS - e_{\rm int} =
e_{\rm int}$. The next cell checks this and compares the coefficients with the
Revision record (ks-theory.json) and with the numbers the Rust solver read
(parameters.json: 0.9375, -0.0625, -0.03125, -0.03125).

## 11. The exact Fock exchange of the closed-shell slab

The states of the model are not uniform along $y$, and in each block the
orbital is a $2\times2$ object. The Revision record computes the EXACT Fock
exchange of such a closed-shell state: take one level with the $2\times2$ block
density $D = \frac12(d_0 + d_1\sigma_1 + d_2\sigma_2 + d_3\sigma_3)$ in each of
the four blocks of type $j = +1$ and $\sigma_3D\sigma_3$ in each of the four of
```

```
type $-1$ (the degenerate partners), and average it over a closed shell of
3-space directions; the average is the projection onto the commutant of the
3-space rotations (the 64-dimensional space of matrices that commute with
$\gamma^{(x_1)}\gamma^{(x_2)}$, $\gamma^{(x_1)}\gamma^{(x_3)}$,
$\gamma^{(x_2)}\gamma^{(x_3)}$). The result: $n = 8d_0$, $S = 8d_2$,
$Q = \langle\Psi^\dagger B\gamma^{(x_0)}\Psi\rangle = 8d_3$, the $y$-current
$Y = 8d_1$, and

$$e_x^{\rm exact} = -\frac{\lambda}{32}(n^2 + S^2 - Q^2 - Y^2).$$

For eigen-orbitals $Y = 0$; so the uniform-gas exchange omits $+\frac{\lambda}{32}
Q^2$. The canonical functional of the Revision theory is the uniform-gas one; the
exact Fock exchange is a DIAGNOSTIC that the Rust solver reports and also solves
as a variant. The next cell repeats the computation: it reads the block basis
from the Revision record (and checks that it is unitary), builds the averaged
one-body matrix with sympy's linear solver and checks the four densities and the
exchange.

## 12. The state of the eight zero modes (N = 8)
```

The simplest Kohn-Sham state of the model fills the eight brane zero modes at $k = 0$ (both block types, even parity). Each orbital is $\chi = (a, 0)$ with $a = \sqrt{2M/(1 - e^{-2ML})}\,e^{My}$ (normalised on the patch). The densities, line by line (Revision record, ‘densities‘):

1. One orbital: $n_o = P\,(a^2 + b^2) = Pa^2$, $s_o = P\,j\,2ab = 0$, $q_o = P\,(a^2 - b^2) = Pa^2$, with $P = e^{-6Hy}/(\ell^3v_t)$ (the factor that makes the densities proper).
2. The state: $n = \sum w\,g\,f\,n_o$ with the weight $w = \frac12$ of the ASSUMED Z2 doubled system, the degeneracy $g = 4$ per block type and $f = 1$: $n = \frac12(4 + 4)Pa^2 = 4Pa^2$; $S = 0$; $Q = n$.
3. The potentials to first order in λ (free orbitals): $M_{\rm eff} - m = \frac{15}{16}\lambda S = 0$, $v_v = -\frac{\lambda}{16}n$.
4. The Revision solver calibrates its couplings by the largest first-order potential per unit λ, max over y of $\max(\frac{15}{16}|S|, |n|/16)$, here $n_{\max}/16$; λ_1 and λ_2 are 0.1 and 0.3 divided by it, rounded to 4 significant digits.
5. Exact Fock exchange: with $S = 0$ and $Q = n$, $e_x^{\rm exact} = -\frac{\lambda}{32}(n^2 - Q^2) = 0$. In the exact-Fock functional the potential is $v_v + w_Q\sigma_3$ with $w_Q = \frac{\lambda}{16}Q$, which on $(a, 0)$ acts as $\frac{\lambda}{16}(Q - n) = 0$: the zero modes stay exact solutions with $\varepsilon = 0$ and the energy of the state is exactly 0.

With $H = m = 1$, $L = 3$, $\ell = 2\pi/0.25$, $v_t = 1$, the next cell computes $n(y)$ and its maximum (at the tip $y = -3$, where $e^{-6Hy}a^2 \propto e^{(2M - 6H)y}$ is largest) and compares with the records: the largest proper density of the free state $N = 8$ (‘ground/summary.csv‘, column ‘n_max‘), the strength per λ, $\lambda_{1,2}$ and the first-order potentials (‘parameters.json‘), and the self-consistent exact-Fock energies of all twenty $N = 8$ states (‘exx/exact-fock-variant.csv‘), which must be zero to rounding.

```

Text cell:

```
## 14. What this notebook showed

- The flat good-sector plane waves have the energies $\pm\sqrt{M^2 + p^2}$, each
  8 times; every occupation symmetric under $\mathbf p \to -\mathbf p$ has the
  one-body matrix $\rho = (nB + SC)/16$ (PROVED).
- Wick's rule gives $\langle{:}S^2{:}\rangle = (\mathrm{Tr}\,C\rho)^2 -
  \mathrm{Tr}(C\rho C\rho)$, and the exchange of the contact interaction is
  exactly local: $e_x = -\frac{\lambda}{32}(n^2 + S^2)$ at every temperature;
  a filled level at rest has $e_x/e_H = -1/8$ (PROVED).
- The Kohn-Sham potentials are $M_{\rm eff} = m + \frac{15}{16}\lambda S$ and
```

```
  $v_v = -\frac{\lambda}{16}n$; on shell $\langle L\rangle/\sqrt{|g|} =
  e_{\rm int}$ (PROVED; the coefficients equal those the Rust solver used).
- For the closed-shell slab states the exact Fock exchange is
  $-\frac{\lambda}{32}(n^2 + S^2 - Q^2 - Y^2)$; the canonical (uniform-gas)
  functional omits $+\frac{\lambda}{32}Q^2$ (PROVED; a DIAGNOSTIC of the
  functional; there is no correlation energy in either).
- The eight zero modes have $S = 0$ and $Q = n$; their proper density is largest
  at the tip ($n_{\max} = 82.22$); this fixes the Revision couplings
  $\lambda_1 = 0.01946$, $\lambda_2 = 0.05838$ for $N = 8$; and their exact Fock
  exchange vanishes, so their exact-Fock energy is exactly zero (the record's
  self-consistent values are zero to rounding).
- ASSUMED: the Z2 doubled system (the weight $w = \frac12$) and the good sector.
```

14.31 Line-by-line walk-through of Notebook 14d

The notebook has 14 code cells, In [1] to In [14]. Docstrings and the long caption texts are left out of the quotations; the captions are printed under the figures in Section 14.30.

In [1], the set-up cell. The code of In [1] of Notebook 14a (Section 14.11), line for line, except

```
NOTEBOOK_ID = "14d"  # this notebook: chapter 14, example d
```

which names this notebook. Its comment lines are the run instructions of Section 14.29.

In [2], the gamma matrices, B and C.

```
import math  # exp, sqrt, log10 of single numbers

import numpy as np  # floating-point arrays
import sympy as sp  # exact algebra with symbols

PY_REPORT = "Revision/kohn_sham/reports/ks-theory-python.json"
WL_REPORT = "Revision/kohn_sham/reports/ks-theory-wolfram.json"
```

The three modules and the two theory reports.

```
def record_check(name):
    verdicts = []
    for report_file in (PY_REPORT, WL_REPORT):
        data = json.loads(repository_file(report_file).read_text(encoding="utf-8"))
        found = [c["verdict"] for c in data["checks"] if c["name"] == name]
        verdicts.append(found[0] if found else "absent")
    return verdicts[0] == "PASS" and verdicts[1] in ("PASS", "absent")
```

The `record_check` of Notebook 14a: true when the sympy report says PASS and the Wolfram report says PASS or has no check of that name. (The loop variable is called `report_file`, so that it does not hide the helper `report` of the set-up cell.)

```
fixture = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
```

```
g = [sp.Matrix(m) for m in fixture["gamma"]]
g0, g1, g2, g3, g4, g5, g6, g7 = g  # gN is gamma^(xN)
I16, Z16 = sp.eye(16), sp.zeros(16)
C = g0 * g1 * g2 * g3
B = -sp.I * C * g4
```

The author's gammas from the Revision record, exactly as in In [2] and In [3] of Notebook 14a, and the matrices C and B.

```
facts_ok = (B * B == I16 and C * C == I16 and (B * B).trace() == 16
            and (C * C).trace() == 16 and (B * C).trace() == 0 and C * B * C == B
            and (-sp.I * g4) * B == C)
check(facts_ok, "B^2 = C^2 = 1, Tr B^2 = Tr C^2 = 16, Tr BC = 0, CBC = B, (-i g4) B = C")
```

Every matrix fact used in Section 14.26, checked exactly: $B^2 = C^2 = 1$, their traces 16, $\mathrm{Tr}(BC) = 0$, $CBC = B$ and $(-i\gamma^{(x_4)})B = C$. Out [2] is one PASS line.

In [3], the plane waves and their projector.

```
M = sp.symbols("M", positive=True)  # the mass
p1, p2, p3, p0 = sp.symbols("p1 p2 p3 p0", real=True)  # the momentum
E = sp.symbols("E", positive=True)  # stands for sqrt(M^2 + p^2)
h_p = M * (-sp.I * g4) - (p1 * g4 * g1 + p2 * g4 * g2 + p3 * g4 * g3 + p0 * g4 * g0)
E_squared = M ** 2 + p1 ** 2 + p2 ** 2 + p3 ** 2 + p0 ** 2
square_ok = (h_p * h_p - E_squared * I16).applyfunc(sp.expand).is_zero_matrix
```

The mass, the four momentum components, a positive symbol E, the matrix $h_{\mathbf{p}}$ of Section 14.26, and the test $h_{\mathbf{p}}^2 = (M^2 + p^2)\,1$ entry by entry (`applyfunc(sp.expand)` multiplies out every entry).

```
G_p = (I16 + h_p / E) / 2  # the projector on the positive energy
projector_ok = ((G_p * G_p - G_p).subs(E, sp.sqrt(E_squared))
                .applyfunc(sp.simplify).is_zero_matrix
                and G_p.H == G_p and sp.simplify(G_p.trace()) == 8)
check(square_ok and projector_ok and record_check("gas_mode_projector"),
      "h_p^2 = (M^2 + p^2) 1 and G_p = (1 + h_p/E)/2 is a projector of rank 8",
      record=f"{PY_REPORT}, check gas_mode_projector")
```

$G_{\mathbf{p}}$; the test $G_{\mathbf{p}}^2 = G_{\mathbf{p}}$ after replacing E by $\sqrt{M^2 + p^2}$; $G_{\mathbf{p}}$ Hermitian; its trace 8 (for a projector the trace is the rank, Section 14.5). One PASS line.

In [4], the symmetric one-body matrix.

```
p_flip = {p1: -p1, p2: -p2, p3: -p3, p0: -p0}
pair_average = ((G_p * B + (G_p * B).subs(p_flip)) / 2).applyfunc(sp.simplify)
pair_ok = (pair_average - (B + M / E * C) / 2).applyfunc(sp.simplify).is_zero_matrix
```

A dictionary that replaces $\mathbf{p}$ by $-\mathbf{p}$; the average of $G_{\mathbf{p}}B$ and $G_{-\mathbf{p}}B$; and the test that it is $\frac{1}{2}(B + (M/E)C)$ (Section 14.26).

```
th, ph = sp.symbols("vartheta varphi", real=True)  # angles on the sphere
components = [sp.sin(th) * sp.cos(ph), sp.sin(th) * sp.sin(ph), sp.cos(th)]
sphere = [sp.integrate(sp.integrate(c * sp.sin(th), (ph, 0, 2 * sp.pi)), (th, 0, sp.pi))
          / (4 * sp.pi) for c in components]  # the averages of the components
say(f"sphere averages of the three direction components: {sphere}")
check(pair_ok and sphere == [0, 0, 0] and record_check("gas_angular_average"),
      "the average over p and -p (or over all directions) is (B + (M/E) C)/2",
      record=f"{PY_REPORT}, check gas_angular_average")
```

The same for an average over all directions of $\mathbf{p}$: a direction on the sphere has the three components $\sin\vartheta\cos\varphi$, $\sin\vartheta\sin\varphi$ and $\cos\vartheta$, with the two angles ϑ and φ; the average of a function over the sphere is its integral with the area element $\sin\vartheta\, d\varphi\, d\vartheta$ divided by the area 4π. All three components average to 0 (printed in Out [4]), so the part of $G_{\mathbf{p}}B$ linear in $\mathbf{p}$ averages away too.

```
h_0 = M * (-sp.I * g4)  # the p-independent part of h_p
negative_ok = (((I16 - h_0 / E) / 2) * B - (B - M / E * C) / 2).is_zero_matrix
check(negative_ok and record_check("gas_negative_energy_modes"),
      "negative-energy modes give (B - (M/E) C)/2: only B and C ever appear",
      record=f"{PY_REPORT}, check gas_negative_energy_modes")
```

The negative-energy modes: the part of $\frac{1}{2}(1 - h_{\mathbf{p}}/E)B$ that survives the average (the part of $h_{\mathbf{p}}$ without $\mathbf{p}$, `h_0`) is $\frac{1}{2}(B - (M/E)C)$.

```
n, S, lam = sp.symbols("n S lambda", real=True)
rho = (n * B + S * C) / 16  # the one-body matrix of a symmetric occupation
check(sp.expand((B * rho).trace()) == n and sp.expand((C * rho).trace()) == S
      and record_check("gas_densities"),
      "rho = (nB + SC)/16 has Tr(B rho) = n and Tr(C rho) = S",
      record=f"{PY_REPORT}, check gas_densities")
```

Symbols for the two densities and the coupling, the matrix $\rho = (nB + SC)/16$, and the check that it gives back n and S. Out [4] shows three PASS lines.

In [5], figure 1.

```
values = {M: 1, E: sp.sqrt(2), p1: 1, p2: 0, p3: 0, p0: 0}
one_mode = np.abs(np.array((G_p * B).subs(values).evalf(), dtype=complex))
averaged = np.abs(np.array(pair_average.subs(values).evalf(), dtype=complex))
odd_part = np.abs(np.array((G_p * B - pair_average).subs(values).evalf(),
                           dtype=complex))
```

The example $M = 1$, $\mathbf{p} = (1, 0, 0, 0)$, $E = \sqrt{2}$, and the absolute values of the entries of three matrices: $G_{\mathbf{p}}B$, its average with $-\mathbf{p}$, and their difference, the part linear in $\mathbf{p}$.

```
fig, axes = plt.subplots(1, 3, figsize=(11.5, 3.9))
fig.subplots_adjust(wspace=0.45)
titles = ["$|G_{\\mathbf{p}}B|$: one momentum",
          "$|(G_{\\mathbf{p}} + G_{-\\mathbf{p}})B/2|$",
          "$|$part linear in $\\mathbf{p}|$"]
```

```
for ax, data, title in zip(axes, (one_mode, averaged, odd_part), titles):
    image = ax.imshow(data, cmap="Blues", vmin=0.0, vmax=0.6,
                      interpolation="nearest")
    ax.set_title(title, fontsize=9)
    ax.set_xticks([0, 5, 10, 15])
    ax.set_yticks([0, 5, 10, 15])
    ax.set_xlabel("column")
    ax.set_ylabel("row")
    ax.grid(False)
    fig.colorbar(image, ax=ax, shrink=0.75)
save_figure(fig, "pair_average",
            "Absolute values of the entries (rows and columns 0 to 15, darker is "
            ...)
```

Three heat maps as in In [15] of Notebook 14a, with one common colour scale from 0 to 0.6 (`vmax=0.6`), so that the three panels can be compared. **What figure 14d.1 shows.** Left: the matrix of one momentum has entries in many places. Middle: after the average with $-\mathbf{p}$ only the entries of $\frac{1}{2}B$ (size $\frac{1}{2}$, dark) and of $\frac{M}{2E}C = \frac{1}{2\sqrt{2}}C$ (size about 0.35, lighter) remain. Right: the part linear in $\mathbf{p}$, $-\frac{1}{2E}p_1\gamma^{(x_4)}\gamma^{(x_1)}B$, with entries of size $\frac{1}{2\sqrt{2}} \approx 0.35$ in other places; it is exactly what the average with $-\mathbf{p}$ removes.

In [6], Wick's rule term by term.

```
half, i_half = sp.Rational(1, 2), sp.I / 2
u1 = sp.Matrix([half, i_half, 0, 0, 0, 0, 0, 0, half, 0, 0, 0, 0, 0, -i_half, 0])
u2 = sp.Matrix([0, 0, half, 0, -half, 0, 0, 0, 0, 0, i_half, 0, 0, 0, 0, i_half])
v1 = sp.Matrix([1, 2, 0, -1, sp.I, 0, 3, 1, 0, 1, -2, sp.I, 0, 1, 1, 0]) / 4
v2 = sp.Matrix([0, 1, sp.I, 2, 1, -1, 0, 0, 1, 0, sp.I, 1, 2, 0, -1, 1]) / 4
nonzero = [(A_, B_) for A_ in range(16) for B_ in range(16) if C[A_, B_] != 0]
wick_ok = True
```

Two pairs of mode vectors: u_1, u_2, the two-mode state of the Revision check, and v_1, v_2, a second state with less symmetry. `nonzero` lists the 16 positions (A, B) where C has a nonzero entry; only these contribute to the sum.

```
for name, modes in (("u1, u2 (record)", (u1, u2)), ("v1, v2", (v1, v2))):
    rho_2 = (modes[0] * modes[0].H + modes[1] * modes[1].H) * B  # one-body matrix
    f = rho_2.T  # f_AB = rho_BA
    brute = sp.simplify(sum(
        C[A_, B_] * C[C_, D_] * (f[A_, B_] * f[C_, D_] - f[A_, D_] * f[C_, B_])
        for A_, B_ in nonzero for C_, D_ in nonzero))
    direct = sp.simplify((C * rho_2).trace() ** 2)
    exchange = sp.simplify((C * rho_2 * C * rho_2).trace())
    say(f"state {name}: (Tr C rho)^2 = {direct}, Tr(C rho C rho) = {exchange}, "
        f"term-by-term sum = {brute}")
    wick_ok &= sp.simplify(brute - (direct - exchange)) == 0
```

For each state: the one-body matrix $\rho = (u_1u_1^\dagger + u_2u_2^\dagger)B$, the expectations $f_{AB} = \rho_{BA}$ (the transpose), the sum of Wick's rule over the $16 \times 16 = 256$ pairs of nonzero entries of C (`brute`), and the two traces. Out [6] prints, for the record's state, $(\mathrm{Tr}\, C\rho)^2 = 1/4$, $\mathrm{Tr}(C\rho C\rho) = 1/4$ and the

sum 0, and for the second state 25/64, 9/32 and 7/64: in both cases the sum equals the difference of the traces ($25/64 - 18/64 = 7/64$).

```
check(len(nonzero) == 16 and wick_ok and record_check("hf_wick_contraction"),
      "<:S^2:> = (Tr C rho)^2 - Tr(C rho C rho), checked term by term",
      record=f"{PY_REPORT}, check hf_wick_contraction")
```

One PASS line.

In [7], the exchange and the ratio $-1/8$.

```
e_x = sp.factor(-lam / 2 * (C * rho * C * rho).trace())  # the exchange energy density
say(f"e_x = -(lambda/2) Tr(C rho C rho) = {e_x}")
check(sp.simplify(e_x + lam / 32 * (n ** 2 + S ** 2)) == 0
      and record_check("exchange_uniform_gas"),
      "the exact local exchange e_x = -(lambda/32)(n^2 + S^2)",
      record=f"{PY_REPORT}, check exchange_uniform_gas")
```

$e_x = -\frac{\lambda}{2}\mathrm{Tr}(C\rho C\rho)$ with $\rho = (nB + SC)/16$, written by `sp.factor` as a product (Out [7]: `-lambda*(S**2 + n**2)/32`), and the check.

```
e_H = lam / 2 * S ** 2  # the Hartree energy density
ratio = sp.simplify((e_x / e_H).subs({n: 8, S: 8}))
say(f"one filled level at rest (n = S = 8): e_x/e_H = {ratio}")
check(ratio == sp.Rational(-1, 8) and record_check("filled_shell_ratio"),
      "a filled 8-fold level at rest has e_x/e_H = -1/8",
      record=f"{PY_REPORT}, check filled_shell_ratio")
```

The Hartree term and the ratio for one filled level at rest, $n = S = 8$ (Exercise 14.8): $-1/8$. Out [7] shows two PASS lines.

In [8], the Kohn-Sham potentials.

```
m = sp.symbols("m", real=True)
e_int = sp.expand(e_H + e_x)
M_eff = m + sp.diff(e_int, S)  # the effective mass
v_v = sp.diff(e_int, n)  # the vector potential
say(f"e_int = {e_int}")
say(f"M_eff = {M_eff},  v_v = {v_v}")
```

The bare mass m, $e_{\mathrm{int}} = e_H + e_x$, and the two potentials as derivatives (Section 14.27). Out [8] prints $e_{\mathrm{int}} = \frac{15}{32}\lambda S^2 - \frac{1}{32}\lambda n^2$ and the potentials in sympy's notation.

```
check(sp.simplify(M_eff - m - sp.Rational(15, 16) * lam * S) == 0
      and sp.simplify(v_v + lam * n / 16) == 0 and record_check("ks_potentials"),
      "M_eff = m + (15/16) lambda S and v_v = -lambda n/16",
      record=f"{PY_REPORT}, check ks_potentials")
on_shell = sp.simplify(M_eff * S + v_v * n - m * S - e_int - e_int)
check(on_shell == 0 and record_check("ks_onshell_lagrangian"),
      "on shell <L>/sqrt|g| = M_eff S + v_v n - m S - e_int = e_int",
      record=f"{PY_REPORT}, check ks_onshell_lagrangian")
```

The two potentials, and the on-shell Lagrangian: $M_{\text{eff}}S + v_v n - mS - e_{\text{int}}$ minus e_{int} must be zero.

```
theory = json.loads(repository_file("Revision/kohn_sham/ks-theory.json")
                    .read_text(encoding="utf-8"))
potentials = theory["exchange"]["kohnShamPotentials"]
gas = theory["exchange"]["uniformGas"]
inputs = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                    .read_text(encoding="utf-8"))["theoryInputs"]
```

The parts of the theory record that hold the coefficients, and the coefficients that the Rust solver read (its parameters record).

```
same = (sp.Rational(potentials["Meff_coefficient_of_lambda_S"]) == sp.Rational(15, 16)
        and sp.Rational(potentials["vv_coefficient_of_lambda_n"]) == sp.Rational(-1, 16)
        and sp.Rational(gas["coefficient_n2"]) == sp.Rational(-1, 32)
        and sp.Rational(gas["coefficient_S2"]) == sp.Rational(-1, 32)
        and inputs["MeffCoefficientOfLambdaS"] == 0.9375
        and inputs["vvCoefficientOfLambdaN"] == -0.0625
        and inputs["exchangeCoefficientN2"] == -0.03125
        and inputs["exchangeCoefficientS2"] == -0.03125)
check(same and record_check("ks_theory_json_exchange"),
      "the coefficients 15/16, -1/16, -1/32, -1/32 equal the records",
      record="Revision/kohn_sham/ks-theory.json, exchange; "
             "Revision/kohn_sham/results/parameters.json, theoryInputs")
```

The theory record stores the coefficients as texts such as "15/16", which `sp.Rational` turns into exact fractions; the solver's record stores them as decimal numbers, $0.9375 = 15/16$, $-0.0625 = -1/16$ and $-0.03125 = -1/32$ (all four are exact in binary floating point). The PASS line names both records with the parts that hold the coefficients: the section exchange of the theory record and the section theoryInputs of the solver's parameters record (two strings written next to each other are joined into one). Out [8] shows three PASS lines.

In [9], figure 2.

```
s_over_n = np.linspace(-1.0, 1.0, 401)
hartree = 0.5 * s_over_n ** 2
exchange_curve = -(1.0 + s_over_n ** 2) / 32.0
fig, ax = plt.subplots(figsize=(7.5, 4.4))
ax.plot(s_over_n, hartree, label="Hartree $e_H/(\\lambda n^2) = (S/n)^2/2$")
ax.plot(s_over_n, exchange_curve, "--",
        label="exchange $e_x/(\\lambda n^2) = -(1 + (S/n)^2)/32$")
ax.plot(s_over_n, hartree + exchange_curve, ":", color="black",
        label="$e_{\\rm int} = e_H + e_x$")
```

The ratio S/n from -1 to 1 and the three energy densities divided by λn^2: Hartree $\frac{1}{2}(S/n)^2$, exchange $-\frac{1}{32}(1 + (S/n)^2)$ and their sum.

```
ax.plot([1.0], [-1.0 / 16.0], "o", color="C3")
ax.annotate("$S = n$: $e_x = -e_H/8$", xy=(1.0, -1.0 / 16.0), xytext=(-0.05, 0.3),
```

```
            fontsize=8, color="C3", arrowprops={"arrowstyle": "->", "color": "C3"})
ax.axhline(0.0, color="gray", linewidth=0.6)
ax.set_xlabel("ratio of the scalar to the number density $S/n$")
ax.set_ylabel("energy density per $\\lambda n^2$")
ax.set_title("the Hartree-Fock energy of the contact interaction")
ax.legend(fontsize=8, loc="upper center")
save_figure(fig, "energy_densities",
            "The interaction energy densities of the contact term per unit "
            ...)
```

A red dot at $S/n = 1$ on the exchange curve, $-\frac{1}{16}$, with an arrow from its label (`annotate` with `xy` the point, `xytext` the place of the text and `arrowprops` the style of the arrow), the zero line, labels and saving. **What figure 14d.2 shows.** The Hartree parabola is zero at $S = 0$ and $\frac{1}{2}$ at $S = \pm n$. The exchange curve is small and negative everywhere, between $-\frac{1}{32}$ and $-\frac{1}{16}$. Their sum is slightly negative near $S = 0$, where only the exchange is left, and positive for larger $|S|$. At $S = n$ the exchange $-\frac{1}{16}$ is one eighth of the Hartree term $\frac{1}{2}$.

In [10], the exact Fock exchange of the closed-shell states.

```
as_number = {"0": 0, "1": 1, "-1": -1, "I": sp.I, "-I": -sp.I}
U = sp.Matrix([[as_number[e] for e in row] for row in
               theory["blockBasis"]["unnormalisedColumns2Sqrt2V"]])
V = U / (2 * sp.sqrt(2))  # the block basis of the record
labels = [(j, s2, s3) for j in (1, -1) for s2 in (1, -1) for s3 in (1, -1)]
s1 = sp.Matrix([[0, 1], [1, 0]])
s2m = sp.Matrix([[0, -sp.I], [sp.I, 0]])
s3 = sp.Matrix([[1, 0], [0, -1]])
```

The block basis V of the record (as in In [13] of Notebook 14a), the eight block labels in the record's order, and the Pauli matrices (`s2m` is σ_2).

```
d0, d1, d2, d3 = sp.symbols("d0 d1 d2 d3", real=True)
D = (d0 * sp.eye(2) + d1 * s1 + d2 * s2m + d3 * s3) / 2  # the block density
G_slab = Z16
for b, (j, _, _) in enumerate(labels):
    Vb = V[:, 2 * b:2 * b + 2]
    G_slab = G_slab + Vb * (D if j == 1 else s3 * D * s3) * Vb.H
```

A general 2×2 Hermitian block density D with four real numbers $d_0, \ldots, d_3$ (every Hermitian 2×2 matrix is a combination of 1 and the three Pauli matrices), and the 16×16 matrix of one level that has D in the four blocks of type $+1$ and $\sigma_3 D \sigma_3$ in the four of type -1: each block's 2×2 matrix is carried back to 16 components with its two basis columns, $V_b D V_b^\dagger$.

```
unknowns = sp.Matrix(16, 16, sp.symbols("x0:256"))  # a general 16 x 16 matrix
equations = []
for rotation in (g1 * g2, g1 * g3, g2 * g3):  # commute with the 3-space rotations
    equations += list(rotation * unknowns - unknowns * rotation)
solution = sp.Matrix(16, 16, list(list(sp.linsolve(equations, list(unknowns)))[0]))
```

The matrices that commute with the three generators $\gamma^{(x_1)}\gamma^{(x_2)}$, $\gamma^{(x_1)}\gamma^{(x_3)}$, $\gamma^{(x_2)}\gamma^{(x_3)}$ of the rotations of 3-space: a general matrix of 256 unknowns, the 3×256 linear equations "commutator $= 0$", and their general solution by `sp.linsolve`, which returns the set of solutions; `list(...)[0]` takes its single element, a list of 256 expressions in the unknowns that remain free.

```
free = sorted(solution.free_symbols, key=lambda s_: int(str(s_)[1:]))
basis = [solution.subs({x: (1 if x == y else 0) for x in free}) for y in free]
gram = sp.Matrix(len(basis), len(basis),
                 lambda i, k: (basis[i].H * basis[k]).trace())
coefficients = gram.LUsolve(sp.Matrix([(b_.H * G_slab).trace() for b_ in basis]))
G_avg = sp.simplify(sum((c_ * b_ for c_, b_ in zip(coefficients, basis)), Z16))
```

The free unknowns, sorted by their numbers (`str(s_)[1:]` is the name without its first letter); a basis of the solution space, one matrix for each free unknown set to 1 and the others to 0 (64 of them); the **Gram matrix** of the inner products $\mathrm{Tr}(X^\dagger Y)$ of the basis matrices; and the orthogonal projection of G_{slab} onto the space, found by solving the linear equations with the Gram matrix (`LUsolve`). The projection is the average over all directions of the shell.

```
rho_slab = G_avg * B
n_s, S_s = sp.simplify((B * rho_slab).trace()), sp.simplify((C * rho_slab).trace())
Q_s = sp.simplify((B * g0 * rho_slab).trace())
e_x_slab = sp.expand(-lam / 2 * (C * rho_slab * C * rho_slab).trace())
say(f"commutant dimension {len(basis)}; n = {n_s}, S = {S_s}, Q = {Q_s}")
say(f"V unitary: {sp.simplify(V.H * V) == I16}")
```

The averaged one-body matrix, its three densities n, S and $Q = \langle \Psi^\dagger B \gamma^{(x_0)} \Psi \rangle$, and its exchange energy. Out [10] prints the dimension 64, $n = 8d_0$, $S = 8d_2$, $Q = 8d_3$, and that V is unitary.

```
check(len(basis) == 64 and n_s == 8 * d0 and S_s == 8 * d2 and Q_s == 8 * d3
      and sp.simplify(e_x_slab + lam / 32 * (n_s ** 2 + S_s ** 2 - Q_s ** 2
                                             - (8 * d1) ** 2)) == 0
      and record_check("exchange_slab_exact_fock"),
      "exact Fock exchange of the slab: -(lambda/32)(n^2 + S^2 - Q^2 - Y^2)",
      record=f"{PY_REPORT}, check exchange_slab_exact_fock")
```

The check of Section 14.27 with $Y = 8d_1$. This cell does the heaviest algebra of the notebook. One PASS line.

In [11], figure 3.

```
grid = np.linspace(-1.0, 1.0, 401)
S_grid, Q_grid = np.meshgrid(grid, grid)  # S/n horizontally, Q/n vertically
inside = S_grid ** 2 + Q_grid ** 2 <= 1.0
ratio_grid = np.where(inside, (1.0 + S_grid ** 2 - Q_grid ** 2) / (1.0 + S_grid ** 2),
                      np.nan)
```

A square grid of 401×401 points in the plane of S/n and Q/n (`np.meshgrid` makes the two coordinate arrays of the grid), the points inside the unit disk, and there the ratio of the exact to the uniform-gas exchange, $(n^2 + S^2 - Q^2)/(n^2 + S^2)$ with $Y = 0$; outside the disk the value `np.nan` ("not a number"), which is not drawn.

```
fig, ax = plt.subplots(figsize=(6.4, 5.2))
filled = ax.contourf(S_grid, Q_grid, ratio_grid, levels=np.linspace(0.0, 1.0, 11),
                     cmap="Blues")
ax.contour(S_grid, Q_grid, ratio_grid, levels=[0.5], colors="gray", linewidths=0.8)
fig.colorbar(filled, ax=ax, label="$e_x^{\\rm exact} / e_x^{\\rm gas}$")
```

`contourf` fills the regions between the levels $0, 0.1, \ldots, 1$ of the ratio with colours, `contour` draws the line where the ratio is $\frac{1}{2}$, and the colour bar explains the colours.

```
ax.plot([0.0, 0.0], [1.0, -1.0], "o", color="C3")  # S = 0, Q = +n and -n
ax.annotate("zero modes ($N = 8$): ratio 0", (0.05, 0.9), fontsize=8, color="C3")
ax.annotate("$Q = 0$: ratio 1", (-0.95, 0.04), fontsize=8,
            color="white")  # white text on the dark band
ax.set_xlabel("$S/n$")
ax.set_ylabel("$Q/n$")
ax.set_aspect("equal")
ax.grid(False)
ax.set_title("exact Fock exchange / uniform-gas exchange")
save_figure(fig, "exact_fock_ratio",
            "The ratio of the exact Fock exchange of a closed-shell slab state, "
            ...)
```

Two red dots at $S = 0$, $Q = \pm n$, two labels, equal scales on both axes (`set_aspect("equal")`, so that the disk is round), and saving. **What figure 14d.3 shows.** A dark band (ratio near 1) across the middle of the disk, around the line $Q = 0$, where the uniform-gas formula is exact; toward the top and the bottom the colour fades and the ratio falls to 0 at the two red dots; the gray line marks the ratio $\frac{1}{2}$. The state of the eight zero modes sits at the top dot: for it the uniform-gas formula gives a nonzero exchange, while the exact exchange is zero.

In [12], the state of the eight zero modes.

```
H_val, m_val, L_val = 1.0, 1.0, 3.0
ell = 2.0 * math.pi / 0.25  # the coordinate size of the 3-torus
vol7 = ell ** 3 * 1.0  # the coordinate 7-volume ell^3 v_t
y = np.linspace(-L_val, 0.0, 1801)  # the hidden coordinate
a_sq = 2.0 * m_val / (1.0 - math.exp(-2.0 * m_val * L_val)) * np.exp(2.0 * m_val * y)
P = np.exp(-6.0 * H_val * y) / vol7  # proper-density factor
n_y = 4.0 * P * a_sq  # line 2
n_max = float(np.max(n_y))
```

The canonical numbers $H = m = 1$, $L = 3$, $\ell = 2\pi/0.25$, $v_t = 1$; 1801 points of y; a^2 of the normalised zero mode; the factor P; the proper density $n = 4Pa^2$ of Section 14.27; and its largest value.

```
summary = repository_file("Revision/kohn_sham/results/ground/summary.csv") \
    .read_text(encoding="utf-8").splitlines()
header = summary[0].split(",")
free8 = dict(zip(header, [r for r in summary if r.startswith("N8_lam0_a00,")][0]
                 .split(",")))
report("largest proper density of the free N = 8 state", f"{n_max:.10f}",
```

```
       "per unit proper 7-volume")
check(abs(n_max / float(free8["n_max"]) - 1.0) < 1e-9 and float(y[np.argmax(n_y)])
      == -3.0,
      "n_max = 4 P a^2 at the tip y = -3 equals the record",
      record="Revision/kohn_sham/results/ground/summary.csv, N8_lam0_a00, n_max")
```

The summary record of the Rust ground states, its row for $N = 8$, $\lambda = 0$, slice 0 (`startswith` finds the row whose text starts with its name), the RESULT line 82.2208638894, and the check: the notebook's value equals the record's to 10^{-9} (relative), and the maximum lies at $y = -3$ (`np.argma x` gives the position of the largest entry).

```
def round_significant(x, digits):
    exponent = math.floor(math.log10(abs(x))) - (digits - 1)
    scale = 10.0 ** (-exponent)
    return math.copysign(math.floor(abs(x) * scale + 0.5), x) / scale
```

Rounding to a number of significant digits, halves away from zero: for $x = 0.019460\ldots$ and 4 digits, $\log_{10}|x| = -1.71$, rounded down to -2, so the exponent is -5; the number is multiplied by 10^5 to $1946.0\ldots$, rounded to the whole number 1946 (adding $\frac{1}{2}$ and rounding down), and divided back: 0.01946.

```
strength = n_max / 16.0  # line 4: the largest first-order potential per lambda
lambda_1 = round_significant(0.1 / strength, 4)
lambda_2 = round_significant(0.3 / strength, 4)
parameters = json.loads(repository_file("Revision/kohn_sham/results/parameters.json")
                        .read_text(encoding="utf-8"))
calibration = [c for c in parameters["couplingCalibration"]["values"]
               if c["N"] == 8.0][0]
```

The strength $n_{\max}/16$ (with $S = 0$ only the term $|n|/16$ counts), the two couplings by the record's rule, and the record's calibration entry for $N = 8$.

```
report("strength per lambda", f"{strength:.9f}")
report("lambda_1, lambda_2", f"{lambda_1}, {lambda_2}")
report("first-order potentials", f"{lambda_1 * strength:.10f}, "
       f"{lambda_2 * strength:.10f}", "m")
check(abs(strength / calibration["strengthPerLambda"] - 1.0) < 1e-9
      and lambda_1 == calibration["lambda1"] and lambda_2 == calibration["lambda2"]
      and abs(lambda_1 * strength - calibration["firstOrderPotential1"]) < 1e-9
      and len(set(calibration["strengthPerLambdaAtSlices"])) == 1,
      "strength 5.1388, lambda_1 = 0.01946, lambda_2 = 0.05838 (the same at all "
      "slices)", record="Revision/kohn_sham/results/parameters.json, "
      "couplingCalibration N = 8")
```

Three RESULT lines (5.138803993; 0.01946, 0.05838; the first-order potentials 0.1000011257 and $0.3000033771\,m$, just above 0.1 and 0.3 because of the rounding of λ) and the check against the record; the last condition says that the record found the same strength at all five slices (a set keeps each value once, so its size is 1). That is the rescaling identity again: the zero modes do not depend on the slice.

```
exx = repository_file("Revision/kohn_sham/results/exx/exact-fock-variant.csv") \
    .read_text(encoding="utf-8").splitlines()
