Universes in Pairs

A Deep-Dive Course on the dirac16complex Fields in the Author's 4+4 Primordial Universe, with a Complete Jupyter Notebook for Every Example

dirac16complex project (with Claude Opus 5.5)

October 2026

Contents

0 How to use this book; installing the software; the honesty ledger 28

0.1 What this book teaches . . . 28
0.2 The request, and what the equations prove and do not prove . . . 30
0.3 The five labels of every statement . . . 34
0.4 How to check a statement yourself . . . 35
0.5 Conventions used everywhere . . . 35
0.6 The map of the book . . . 36
0.7 Every example is a notebook . . . 37
0.8 Installing the software . . . 38
0.9 How the notebooks are built and checked . . . 40
0.10 Example: checking the installation . . . 41
0.11 How to run Notebook 00a . . . 42
0.12 Notebook 00a: complete text . . . 47
0.13 Line-by-line walk-through of Notebook 00a . . . 68
0.14 The eight directions and the author's metric . . . 77
0.15 How to run Notebook 00b . . . 82
0.16 Notebook 00b: complete text . . . 87
0.17 Line-by-line walk-through of Notebook 00b . . . 116
0.18 The honesty ledger, and how a report is tied to its files . . . 130
0.19 How to run Notebook 00c . . . 137

0.20 Notebook 00c: complete text . . . 143
0.21 Line-by-line walk-through of Notebook 00c . . . 185
0.22 Why every run gives the same bytes . . . 212
0.23 How to run Notebook 00d . . . 217
0.24 Notebook 00d: complete text . . . 223
0.25 Line-by-line walk-through of Notebook 00d . . . 260
0.26 What we proved, what we computed, what we assumed . . . 276
0.27 Exercises . . . 278

1 Mathematics from zero I: numbers, complex numbers, vectors, matrices, indices, determinants, the generalized Kronecker delta 280

1.1 What this chapter is for . . . 280
1.2 Whole numbers and fractions, exactly . . . 282
1.3 Real numbers: the square root of 2 is not a fraction . . . 284
1.4 Floating-point numbers, rounding and cancellation . . . 285
1.5 Powers, roots, the exponential function and the logarithm . . . 286
1.6 Example: numbers, rounding and the length factors of the author's metric . . . 288
1.7 How to run Notebook 01f . . . 288
1.8 Notebook 01f: complete text . . . 293
1.9 Line-by-line walk-through of Notebook 01f . . . 327
1.10 Complex numbers: the rules of arithmetic . . . 345
1.11 The exponential series and Euler's formula . . . 347
1.12 Multiplication turns the plane; the real matrix of a complex number . . . 349
1.13 Boosts, hyperbolic functions, oscillation and growth . . . 352
1.14 Example: complex numbers, rotations and boosts . . . 354
1.15 How to run Notebook 01b . . . 354
1.16 Notebook 01b: complete text . . . 359
1.17 Line-by-line walk-through of Notebook 01b . . . 391
1.18 Vectors and matrices; the matrix product . . . 403
1.19 Permutations and their signs . . . 405
1.20 Determinants: the Leibniz formula and its six rules . . . 407
1.21 What a determinant measures, what it costs, and two matrices of the course . . . 408

1.22 Example: matrices, permutations and determinants 410
1.23 How to run Notebook 01a 410
1.24 Notebook 01a: complete text 416
1.25 Line-by-line walk-through of Notebook 01a 450
1.26 Index notation and the summation convention 464
1.27 The frame metric: lowering, raising and squared lengths 465
1.28 Symmetric and antisymmetric arrays; commutators; the Clifford relation 466
1.29 The author's metric in index notation 468
1.30 Example: index notation in the author's spacetime 469
1.31 How to run Notebook 01e 470
1.32 Notebook 01e: complete text 475
1.33 Line-by-line walk-through of Notebook 01e 509
1.34 Eigenvalues and eigenvectors; the characteristic polynomial 523
1.35 The chain matrix of any size; rotations and boosts; conjugate pairs 525
1.36 Symmetric and Hermitian matrices; the signature and Sylvester's law 527
1.37 The eigenvalues of the gamma matrices and of B; power iteration 529
1.38 Example: eigenvalues, eigenvectors and the signature (4,4) 530
1.39 How to run Notebook 01g 531
1.40 Notebook 01g: complete text 536
1.41 Line-by-line walk-through of Notebook 01g 577
1.42 The generalized Kronecker delta: the author's definition and its four cases 596
1.43 Counting the values; nine indices in eight dimensions 598
1.44 Contracting one index; the Lovelock trace factors; the Levi-Civita symbol 599
1.45 Example: the generalized Kronecker delta 601
1.46 How to run Notebook 01c 601
1.47 Notebook 01c: complete text 606
1.48 Line-by-line walk-through of Notebook 01c 645
1.49 Binary numbers, bit operations and a pseudo-random generator 664
1.50 Fingerprints, the exporter's file and the birthday problem 666
1.51 Example: reproducing the record's tests of the generalized delta 667
1.52 How to run Notebook 01d 667

1.53 Notebook 01d: complete text 672
1.54 Line-by-line walk-through of Notebook 01d 706
1.55 What we proved, what we computed, what we assumed 721
1.56 Exercises 724

2 Mathematics from zero II: several variables, ODEs, Euler and RK4, convergence, the shooting method 727

2.1 What this chapter is for 727
2.2 Differential equations 728
2.3 Taylor's theorem and the exponential series 730
2.4 Three step rules: Euler, midpoint and RK4 731
2.5 The amplification factor 733
2.6 Error, order, the log-log plot, rounding and Richardson's rule 734
2.7 The oscillator and the product of the two scale factors 736
2.8 Example: Euler, midpoint and RK4 on the deflating scale factor and the oscillator 739
2.9 How to run Notebook 02a 739
2.10 Notebook 02a: complete text 744
2.11 Line-by-line walk-through of Notebook 02a 781
2.12 Boundary-value problems and the shooting method 802
2.13 The finite square well of quantum mechanics 804
2.14 Example: shooting a string and a quantum well 807
2.15 How to run Notebook 02b 807
2.16 Notebook 02b: complete text 812
2.17 Line-by-line walk-through of Notebook 02b 847
2.18 Functions of several variables and partial derivatives 863
2.19 The chain rule and the derivatives of the author's metric 866
2.20 Example: partial derivatives of a model function and of the author's metric . . . 870
2.21 How to run Notebook 02c 870
2.22 Notebook 02c: complete text 875
2.23 Line-by-line walk-through of Notebook 02c 907
2.24 Two first-order equations, the Prüfer angle and Newton's method 919
2.25 Example: the shooting method of the Revision Kohn-Sham solver, rewritten . . . 926

2.26 How to run Notebook 02d 926
2.27 Notebook 02d: complete text 931
2.28 Line-by-line walk-through of Notebook 02d 972
2.29 What we proved, what we computed, what we assumed 991
2.30 Exercises 993

3 Spacetime geometry and the author's metric; curvature 995

3.1 What this chapter is for 995
3.2 Coordinates, indices and sums 997
3.3 The metric: lengths from coordinate steps 998
3.4 Signature: space-like and time-like directions 999
3.5 The author's metric 1000
3.6 The determinant and proper volumes 1001
3.7 Scale factors, the vielbein and the rates of expansion 1003
3.8 The deflating history: a prescribed background 1004
3.9 The hidden coordinate y and the warped form of the metric 1005
3.10 Example: the author's metric, read and checked 1006
3.11 How to run Notebook 03a 1007
3.12 Notebook 03a: complete text 1012
3.13 Line-by-line walk-through of Notebook 03a 1052
3.14 Vectors, covectors and tensors 1074
3.15 The covariant derivative and the Christoffel symbols 1076
3.16 Parallel transport and geodesics 1080
3.17 Curvature: the Riemann tensor and its contractions 1083
3.18 The curvature of the plane and of the sphere, by hand; geodesic deviation 1085
3.19 Example: curvature where it can be pictured 1087
3.20 How to run Notebook 03c 1087
3.21 Notebook 03c: complete text 1092
3.22 Line-by-line walk-through of Notebook 03c 1124
3.23 The Christoffel symbols of the author's metric 1136
3.24 The curvature of the author's metric, by hand 1139

3.25 Ricci, Einstein and Kretschmann of the author's metric; the contracted Bianchi identity . . . 1143
3.26 What Einstein's equations would ask of the source . . . 1146
3.27 Example: the curvature of the author's metric . . . 1148
3.28 How to run Notebook 03b . . . 1149
3.29 Notebook 03b: complete text . . . 1154
3.30 Line-by-line walk-through of Notebook 03b . . . 1207
3.31 Free fall in the author's metric . . . 1234
3.32 Example: free fall in the author's metric . . . 1238
3.33 How to run Notebook 03d . . . 1238
3.34 Notebook 03d: complete text . . . 1243
3.35 Line-by-line walk-through of Notebook 03d . . . 1279
3.36 What we proved, what we computed, what we assumed . . . 1293
3.37 Exercises . . . 1296

4 Clifford algebra Cl(4,4) and the author's T16 1298

4.1 Why matrices, and why sixteen components . . . 1298
4.2 The matrix tools of this chapter . . . 1300
4.3 The square-root problem and the Clifford relation . . . 1303
4.4 The eight directions of the author's space-time and their signs . . . 1305
4.5 The author's construction of T16, step by step . . . 1306
4.6 How to run Notebook 04a . . . 1311
4.7 Notebook 04a: complete text . . . 1316
4.8 Line-by-line walk-through of Notebook 04a . . . 1360
4.9 Square roots in 4+4 dimensions and the plane waves of the field . . . 1382
4.10 How to run Notebook 04b . . . 1386
4.11 Notebook 04b: complete text . . . 1391
4.12 Line-by-line walk-through of Notebook 04b . . . 1427
4.13 The 256 products: Cl(4,4) is all real 16 by 16 matrices . . . 1441
4.14 How to run Notebook 04c . . . 1444
4.15 Notebook 04c: complete text . . . 1450
4.16 Line-by-line walk-through of Notebook 04c . . . 1487

4.17 A second set of gammas and the one change of basis 1502
4.18 How to run Notebook 04d 1506
4.19 Notebook 04d: complete text 1511
4.20 Line-by-line walk-through of Notebook 04d 1548
4.21 What we proved, what we computed, what we assumed 1561
4.22 Exercises 1564

5 The matrices C, Γ and B, the groups Pin(4,4) and Spin(4,4), and the charge-conjugation matrices 1565

5.1 What this chapter does 1566
5.2 The eight real gamma matrices 1567
5.3 Six rules for products of gammas 1569
5.4 The charge matrix C and the Dirac adjoint 1571
5.5 The chirality and the two halves 1573
5.6 The matrix B and the charge density 1575
5.7 Example: Notebook 05a checks C, Γ and B 1579
5.8 How to run Notebook 05a 1579
5.9 Notebook 05a: complete text 1584
5.10 Line-by-line walk-through of Notebook 05a 1620
5.11 Groups and representations from zero 1637
5.12 Pin(4,4), Spin(4,4) and the generators S^{ab} 1639
5.13 Irreducible under Pin(4,4), two inequivalent halves under Spin(4,4) 1641
5.14 Example: Notebook 05b computes the commutants 1644
5.15 How to run Notebook 05b 1644
5.16 Notebook 05b: complete text 1649
5.17 Line-by-line walk-through of Notebook 05b 1682
5.18 Spin transformations: rotations, boosts and the double cover 1694
5.19 Example: Notebook 05d computes spin transformations 1698
5.20 How to run Notebook 05d 1698
5.21 Notebook 05d: complete text 1703
5.22 Line-by-line walk-through of Notebook 05d 1738
5.23 What do the scaled commutators generate? 1750

5.24 Example: Notebook 05f computes what the scaled commutators generate 1755
5.25 How to run Notebook 05f 1755
5.26 Notebook 05f: complete text 1760
5.27 Line-by-line walk-through of Notebook 05f 1802
5.28 Charge conjugation is a matrix 1820
5.29 The bilinears, the reality conditions and real fields 1826
5.30 Example: Notebook 05c computes the charge-conjugation matrices 1829
5.31 How to run Notebook 05c 1829
5.32 Notebook 05c: complete text 1834
5.33 Line-by-line walk-through of Notebook 05c 1874
5.34 The quantised field: operators, the indefinite form and normal ordering 1892
5.35 Example: Notebook 05e computes the conjugation of the quantised field 1897
5.36 How to run Notebook 05e 1898
5.37 Notebook 05e: complete text 1903
5.38 Line-by-line walk-through of Notebook 05e 1943
5.39 What the charge-conjugation matrices say, and do not say, about matter and antimatter 1961
5.40 What we proved, what we computed, what we assumed 1963
5.41 Exercises 1965

6 Spinors in curved 4+4 space: vielbein, spin connection and $\gamma^\mu\Omega_\mu$ 1967

6.1 What this chapter does 1968
6.2 A frame at every point: the vielbein 1970
6.3 The Christoffel symbols of the author's metric 1973
6.4 The canonical spin connection: the vielbein postulate and its solution 1975
6.5 A warm-up by hand: the flat plane in polar coordinates 1977
6.6 The spin connection of the author's metric: twelve components 1979
6.7 The spinor connection and the covariant derivative of a spinor 1980
6.8 The contraction $\gamma^\mu\Omega_\mu$, direction by direction 1983
6.9 Why a_4 drops out and b_4 does not: the divergence form 1985
6.10 The Dirac operator written out, non-triviality and the negative control 1987
6.11 Example: Notebook 06a 1989

6.12 How to run Notebook 06a 1990
6.13 Notebook 06a: complete text 1995
6.14 Line-by-line walk-through of Notebook 06a 2048
6.15 Changing the frame: local spin covariance 2082
6.16 A boost in the plane of $x4$ and $x0$ 2084
6.17 What no frame can remove: the curvature 2086
6.18 Changing the field variable: the rescaling $\Psi = \sin^{-1/2}(z)\, b_4^{-3/4}\, \chi$ 2090
6.19 Example: Notebook 06b 2092
6.20 How to run Notebook 06b 2092
6.21 Notebook 06b: complete text 2097
6.22 Line-by-line walk-through of Notebook 06b 2136
6.23 Upper and lower frame indices: the mixed contraction 2154
6.24 Why only the value $3H$ is right 2157
6.25 Example: Notebook 06c 2158
6.26 How to run Notebook 06c 2158
6.27 Notebook 06c: complete text 2164
6.28 Line-by-line walk-through of Notebook 06c 2204
6.29 The exact scope of the statement that gravity enters the field equations 2223
6.30 What we proved, what we computed, what we assumed 2225
6.31 Exercises 2227

7 The two fields and their Lagrangians; Grassmann numbers; Euler-Lagrange equations 2229

7.1 What this chapter does 2229
7.2 Paths, the action and the first variation 2231
7.3 From the principle to the Euler-Lagrange equation 2233
7.4 Energy, total derivatives and first-order Lagrangians 2236
7.5 Fields: one derivative term per coordinate, and what an extra time does 2238
7.6 Example: Notebook 07d derives the Euler-Lagrange equation 2240
7.7 How to run Notebook 07d 2240
7.8 Notebook 07d: complete text 2246
7.9 Line-by-line walk-through of Notebook 07d 2286

7.10 Grassmann numbers from zero . . . 2309
7.11 Even and odd elements, conjugation and derivatives . . . 2310
7.12 Bilinear forms, real columns and the powers of S . . . 2311
7.13 Field equations with Grassmann numbers . . . 2314
7.14 Example: Notebook 07a builds a Grassmann algebra by hand . . . 2315
7.15 How to run Notebook 07a . . . 2315
7.16 Notebook 07a: complete text . . . 2320
7.17 Line-by-line walk-through of Notebook 07a . . . 2361
7.18 The geometry the fields live in . . . 2378
7.19 The two fields and their common Lagrangian . . . 2382
7.20 Reality, the total divergence, and the connection that drops out of $\mathcal{L}$ . . . 2383
7.21 The Euler-Lagrange equations of both fields . . . 2385
7.22 The equations in the author's metric: explicit, block and evolution forms . . . 2387
7.23 Non-triviality [1] and [2], their exact scope, and an exact family of solutions . . . 2389
7.24 Example: Notebook 07b derives the field equations in the author's metric . . . 2395
7.25 How to run Notebook 07b . . . 2395
7.26 Notebook 07b: complete text . . . 2400
7.27 Line-by-line walk-through of Notebook 07b . . . 2453
7.28 Real fields and the Majorana-type negative control . . . 2478
7.29 Charge conjugation is a matrix . . . 2480
7.30 Example: Notebook 07c: real fields and the charge-conjugation matrices . . . 2483
7.31 How to run Notebook 07c . . . 2483
7.32 Notebook 07c: complete text . . . 2488
7.33 Line-by-line walk-through of Notebook 07c . . . 2524
7.34 What we proved, what we computed, what we assumed . . . 2538
7.35 Exercises . . . 2542

8 Non-triviality, its exact scope, and well-posedness 2545

8.1 What this chapter does . . . 2545
8.2 The stage: coordinates, metric, frame and the field equation . . . 2548
8.3 Frames, and why a frame is not unique . . . 2550
8.4 The Christoffel symbols and the canonical spin connection of the diagonal frame 2551

8.5 What cancels and what survives: the term $\gamma^\mu \Omega_\mu = 3H\gamma^{(0)}$ 2553
8.6 Non-triviality: the connection vanishes only in flat space 2555
8.7 The deflation is invisible in the term, but not in the curvature 2556
8.8 The connection drops out of the Lagrangian but not out of the field equation . . 2556
8.9 Another frame: the boosted frame and its term 2557
8.10 What no frame removes: the curvature of the connection 2559
8.11 The connection in the energy-momentum tensor 2560
8.12 Example: the term in two frames, computed from the definitions 2561
8.13 How to run Notebook 08c 2561
8.14 Notebook 08c: complete text 2566
8.15 Line-by-line walk-through of Notebook 08c 2602
8.16 Well-posedness: what a good evolution equation must do 2625
8.17 Plane waves with frozen coefficients and the mode matrix 2627
8.18 Growth without bound: the Cauchy problem is not well posed 2628
8.19 The Krein form is conserved; the growing waves carry Krein form zero 2630
8.20 Example: growth rates and Hadamard ill-posedness 2630
8.21 How to run Notebook 08a 2631
8.22 Notebook 08a: complete text 2636
8.23 Line-by-line walk-through of Notebook 08a 2668
8.24 The deflating history pushes every extra-time wave into growth 2681
8.25 Following one wave through the onset: the local-frame model and WKB 2683
8.26 Example: the onset of growth along the deflating history 2685
8.27 How to run Notebook 08b 2686
8.28 Notebook 08b: complete text 2691
8.29 Line-by-line walk-through of Notebook 08b 2722
8.30 Changing the field variables: the rescaling $\Psi = \sin^{-1/2} z\, \chi$ 2734
8.31 The two ends of the hidden direction and an exact family of solutions 2735
8.32 The boundary term at the patch end and the growing modes of the good sector . 2737
8.33 Example: the rescaling and the modes of the hidden direction 2738
8.34 How to run Notebook 08d 2738
8.35 Notebook 08d: complete text 2743

8.36 Line-by-line walk-through of Notebook 08d 2774
8.37 The exact scope of non-triviality and of the evolution, in one table 2786
8.38 What we proved, what we computed, what we assumed 2788
8.39 Exercises 2790

9 The energy-momentum tensor, pressures, equations of state, conservation identities 2792

9.1 What this chapter does 2793
9.2 The stage: coordinates, metric and the field dirac16complex00 2794
9.3 Two exact facts about the spin connection of this metric 2796
9.4 What an energy-momentum tensor is 2798
9.5 The diagonal entries, derived from the definition 2799
9.6 The whole tensor: its formula, its reality and its symmetry 2800
9.7 Energy density, pressures, kinetic and potential parts, equations of state 2802
9.8 The trace, and what the field equation adds 2803
9.9 The covariant divergence of a diagonal tensor 2804
9.10 The x4 identity: energy exchange between 3-space and the extra times 2808
9.11 The x0 identity: the balance along the hidden direction 2809
9.12 Where the spin connection does enter the tensor 2810
9.13 The same tensor for dirac16complex 2811
9.14 Example: the tensor at one point and the two identities 2813
9.15 How to run Notebook 09a 2813
9.16 Notebook 09a: complete text 2818
9.17 Line-by-line walk-through of Notebook 09a 2857
9.18 Condensates: exact solutions that depend on the time only 2876
9.19 The energy density, pressure and equation of state of a condensate 2878
9.20 Where condensates oscillate and where they grow 2880
9.21 The energy of the commuting field has no lower bound 2880
9.22 Example: condensates 2882
9.23 How to run Notebook 09b 2882
9.24 Notebook 09b: complete text 2887
9.25 Line-by-line walk-through of Notebook 09b 2925

9.26 The full tensor of a condensate . . . 2939
9.27 Example: the full tensor of a condensate . . . 2945
9.28 How to run Notebook 09c . . . 2945
9.29 Notebook 09c: complete text . . . 2950
9.30 Line-by-line walk-through of Notebook 09c . . . 2989
9.31 What we proved, what we computed, what we assumed . . . 3006
9.32 Exercises . . . 3008

10 Canonical quantisation in 4+4: Krein space and the good sector 3009

10.1 What this chapter does . . . 3009
10.2 The matrix B and the Krein form . . . 3012
10.3 One plane wave: the mode Hamiltonian . . . 3014
10.4 The square of h, the Krein form, and three kinds of waves . . . 3016
10.5 Krein inertia of the eigenspaces . . . 3018
10.6 The universes of masses $+m$ and $-m$ have the same one-particle spectrum . . . 3020
10.7 Example: Notebook 10a computes the one-particle spectra and their Krein inertia 3021
10.8 How to run Notebook 10a . . . 3021
10.9 Notebook 10a: complete text . . . 3026
10.10 Line-by-line walk-through of Notebook 10a . . . 3064
10.11 Quantum states, operators and fermion modes from zero . . . 3084
10.12 The canonical rule from the Lagrangian . . . 3086
10.13 The canonical conjugate is not the Hilbert adjoint: the Krein space . . . 3089
10.14 Two realisations and the expectation-value rule . . . 3090
10.15 Maps that keep the canonical rule, and the conjugation of the quantised field . . 3091
10.16 Example: Notebook 10b builds the canonical rule on a Fock space . . . 3093
10.17 How to run Notebook 10b . . . 3093
10.18 Notebook 10b: complete text . . . 3098
10.19 Line-by-line walk-through of Notebook 10b . . . 3133
10.20 The good sector: a positive Fock space for one momentum . . . 3148
10.21 The expectation-value rule and the energy-momentum tensor operator . . . 3151
10.22 The commuting field dirac16complex00: an energy unbounded below . . . 3153
10.23 Example: Notebook 10c builds the positive Fock space of one momentum . . . 3154

10.24How to run Notebook 10c 3154
10.25Notebook 10c: complete text 3159
10.26Line-by-line walk-through of Notebook 10c 3191
10.27The curved good sector: symmetric only up to a boundary term 3204
10.28Waves that do not depend on x_0, and where their Krein charge goes 3206
10.29Example: Notebook 10d studies the curved good sector 3208
10.30How to run Notebook 10d 3208
10.31Notebook 10d: complete text 3213
10.32Line-by-line walk-through of Notebook 10d 3242
10.33No invariant charge density is positive 3252
10.34The symmetries that keep the canonical rule 3254
10.35Example: Notebook 10e computes the invariant forms and the generators 3256
10.36How to run Notebook 10e 3256
10.37Notebook 10e: complete text 3261
10.38Line-by-line walk-through of Notebook 10e 3288
10.39The Krein structure along the deflating history 3296
10.40Example: Notebook 10f follows the Krein structure along the deflating history . 3300
10.41How to run Notebook 10f 3300
10.42Notebook 10f: complete text 3305
10.43Line-by-line walk-through of Notebook 10f 3339
10.44The quantum reading of the pairing 3351
10.45What the quantum reading does not establish 3355
10.46Example: Notebook 10g checks the quantum reading of the pairing 3356
10.47How to run Notebook 10g 3356
10.48Notebook 10g: complete text 3361
10.49Line-by-line walk-through of Notebook 10g 3400
10.50What we proved, what we computed, what we assumed 3418
10.51Exercises 3424
10.52Answers to the exercises 3424

11 GKD and the Lovelock tensors **3426**

11.1 What this chapter does, and why 3426

11.2 The words and symbols of this chapter 3427
11.3 The author's generalized Kronecker delta and the rule GKD 3429
11.4 Counting the values; nine labels in eight dimensions; the cost of the determinant 3431
11.5 The author's second route: two Levi-Civita tensors of the curved metric 3433
11.6 Example: the generalized Kronecker delta in Python and in Rust 3434
11.7 How to run Notebook 11a 3435
11.8 Notebook 11a: complete text 3441
11.9 Line-by-line walk-through of Notebook 11a 3482
11.10The curvature that the Lovelock sums need 3504
11.11Lovelock's equation (4.38): the three Lovelock tensors 3507
11.12Organising the sum: only nonzero curvature, no repeated label 3508
11.13Laplace's rule and the expansion along the column of h 3510
11.14Order 1 is Einstein's tensor; the trace identity 3512
11.15Order 2 is the Gauss-Bonnet tensor; order 3 is the cubic Lovelock density 3513
11.16Example: the three Lovelock tensors computed twice 3515
11.17How to run Notebook 11b 3515
11.18Notebook 11b: complete text 3522
11.19Line-by-line walk-through of Notebook 11b 3572
11.20The components of the three tensors for the author's metric 3597
11.21Their structure: equal directions, constraint, evolution factor, mean, sign and weight 3599
11.22The two conservation identities 3602
11.23Along the deflating history; an illustrative test history 3603
11.24Example: the components and identities along the deflating history 3605
11.25How to run Notebook 11c 3605
11.26Notebook 11c: complete text 3610
11.27Line-by-line walk-through of Notebook 11c 3640
11.28What we proved, what we computed, what we assumed 3652
11.29Exercises 3655

12 The field equations for a4: Einstein and Einstein-Lovelock 3658

12.1 What this chapter does, and why 3658
12.2 The words and symbols of this chapter 3659

12.3 The author's metric, its determinant and the volume of seven directions 3661
12.4 The Christoffel symbols of the author's metric 3662
12.5 The curvature computed by hand 3663
12.6 The Ricci tensor, the Ricci scalar and the Einstein tensor by hand 3665
12.7 The Lovelock tensors: the Einstein tensor and its two companions 3667
12.8 The source and the independent field equations 3668
12.9 The constraint, the evolution equation and the algebraic condition 3669
12.10The Bianchi identity and the conservation law 3671
12.11Einstein gravity: no empty universe, and the null energy condition along x0 . . . 3673
12.12The linear member: the extra times deflate by a choice of sign 3674
12.13Example: the field equations derived by computer algebra 3677
12.14How to run Notebook 12a 3677
12.15Notebook 12a: complete text 3682
12.16Line-by-line walk-through of Notebook 12a 3728
12.17Example: the source that the linear member requires 3753
12.18How to run Notebook 12b 3753
12.19Notebook 12b: complete text 3758
12.20Line-by-line walk-through of Notebook 12b 3792
12.21Solving the evolution equation for a prescribed stress 3802
12.22Example: four prescribed histories integrated with RK4 3804
12.23How to run Notebook 12c 3805
12.24Notebook 12c: complete text 3810
12.25Line-by-line walk-through of Notebook 12c 3846
12.26A condensate of dirac16complex00 as an exact source 3859
12.27Example: three exact solutions of the coupled equations 3863
12.28How to run Notebook 12d 3863
12.29Notebook 12d: complete text 3868
12.30Line-by-line walk-through of Notebook 12d 3907
12.31What we proved, what we computed, what we assumed 3924
12.32Exercises 3926

13 Many-body quantum mechanics and DFT from zero **3928**

13.1 What this chapter is for . . . 3928
13.2 One quantum particle: states, operators and the variational principle . . . 3929
13.3 Many identical fermions and Slater determinants . . . 3931
13.4 Creation and annihilation operators and Wick's theorem . . . 3934
13.5 The energy of a determinant: direct and exchange terms . . . 3937
13.6 The Hartree and Hartree-Fock equations . . . 3938
13.7 Two electrons on two sites: exact and Hartree-Fock . . . 3941
13.8 The density decides everything: the Hohenberg-Kohn theorem . . . 3943
13.9 Functionals and functional derivatives . . . 3944
13.10The Kohn-Sham equations . . . 3945
13.11Example: determinants, operators and the two-site model . . . 3946
13.12How to run Notebook 13c . . . 3947
13.13Notebook 13c: complete text . . . 3952
13.14Line-by-line walk-through of Notebook 13c . . . 3986
13.15The uniform gas, the local density approximation and exact local exchange . . . 4005
13.16The exchange of the 16-component field dirac16complex . . . 4009
13.17Example: exchange of a contact interaction . . . 4011
13.18How to run Notebook 13b . . . 4011
13.19Notebook 13b: complete text . . . 4016
13.20Line-by-line walk-through of Notebook 13b . . . 4057
13.21Solving the Kohn-Sham equations: iteration and mixing . . . 4075
13.22Example: charge sloshing . . . 4078
13.23How to run Notebook 13d . . . 4078
13.24Notebook 13d: complete text . . . 4083
13.25Line-by-line walk-through of Notebook 13d . . . 4112
13.26Finite temperature: Mermin's theorem . . . 4122
13.27Excited states: the Kohn-Sham gap, Janak's theorem and Delta-SCF . . . 4127
13.28Example: Mermin thermodynamics and Delta-SCF . . . 4128
13.29How to run Notebook 13e . . . 4128
13.30Notebook 13e: complete text . . . 4133
13.31Line-by-line walk-through of Notebook 13e . . . 4165

13.32A complete Kohn-Sham calculation: eight fermions in a trap 4176
13.33Example: the one-dimensional Kohn-Sham toy 4179
13.34How to run Notebook 13a 4179
13.35Notebook 13a: complete text 4185
13.36Line-by-line walk-through of Notebook 13a 4230
13.37From the toy models to dirac16complex 4250
13.38What we proved, what we computed, what we assumed 4252
13.39Exercises 4254

14 The Kohn-Sham model of dirac16complex in the deflating primordial field 4256
14.1 What this chapter does 4257
14.2 The author's field and the hidden coordinate y 4259
14.3 The Kohn-Sham equation, the good sector and the stationary-slice ansatz 4261
14.4 The spin connection, the term 3H γ(x0) and the factor W^(-3) 4262
14.5 Eight blocks of two components 4265
14.6 The chirality matrix Γ on the blocks, and the rotations of 3-space 4268
14.7 The exact rescaling identity between the slices 4269
14.8 Example: Notebook 14a, the block reduction and the rescaling identity 4270
14.9 How to run Notebook 14a 4270
14.10Notebook 14a: complete text 4275
14.11Line-by-line walk-through of Notebook 14a 4314
14.12The block equation in real form and the boundary conditions 4336
14.13The exact free levels at zero 3-momentum 4340
14.14Shooting with a Pruefer angle: every level has a label 4342
14.15Example: Notebook 14b, the free spectra exact and numerical 4344
14.16How to run Notebook 14b 4345
14.17Notebook 14b: complete text 4350
14.18Line-by-line walk-through of Notebook 14b 4386
14.19The brane band and its exact slope 4405
14.20The band along the deflating history, and the tip 4407
14.21Particles, degeneracies and closed shells 4409
14.22Example: Notebook 14c, the brane band 4410

14.23How to run Notebook 14c 4411
14.24Notebook 14c: complete text 4416
14.25Line-by-line walk-through of Notebook 14c 4450
14.26The exact local exchange of the contact interaction 4467
14.27The Kohn-Sham potentials, the exact Fock exchange of the model's states, and the eight zero modes 4470
14.28Example: Notebook 14d, the exact local exchange 4473
14.29How to run Notebook 14d 4473
14.30Notebook 14d: complete text 4478
14.31Line-by-line walk-through of Notebook 14d 4508
14.32What we proved, what we computed, what we assumed 4519
14.33Exercises 4522

15 Solving the Kohn-Sham equations along the deflating history 4525

15.1 What this chapter does 4525
15.2 The equations the solver must solve 4528
15.3 Finding one level: shooting with the Pruefer angle 4532
15.4 From one level to the whole gas 4536
15.5 Self-consistency, the energy, and the first excited state 4538
15.6 Example: the solver's method by hand (Notebook 15e) 4540
15.7 How to run Notebook 15e 4541
15.8 Notebook 15e: complete text 4546
15.9 Line-by-line walk-through of Notebook 15e 4583
15.10The Rust solver and its canonical matrix 4605
15.11Example: running the canonical matrix (Notebook 15a) 4606
15.12How to run Notebook 15a 4607
15.13Notebook 15a: complete text 4613
15.14Line-by-line walk-through of Notebook 15a 4652
15.15What the canonical matrix shows 4667
15.16The energy-momentum tensor of the gas, and why the gas cannot drive the history 4668
15.17Example: the energy-momentum profiles (Notebook 15b) 4672
15.18How to run Notebook 15b 4672

15.19Notebook 15b: complete text 4678
15.20Line-by-line walk-through of Notebook 15b 4714
15.21Adiabaticity: does the gas follow the moving background? 4726
15.22Example: the adiabaticity measure (Notebook 15c) 4728
15.23How to run Notebook 15c 4728
15.24Notebook 15c: complete text 4733
15.25Line-by-line walk-through of Notebook 15c 4764
15.26The gas at a temperature 4777
15.27Example: thermodynamics (Notebook 15d) 4779
15.28How to run Notebook 15d 4780
15.29Notebook 15d: complete text 4786
15.30Line-by-line walk-through of Notebook 15d 4819
15.31What we proved, what we computed, what we assumed 4832
15.32Exercises 4834

16 Checking the solution independently: the reference solver and the cross-check 4836

16.1 What this chapter does 4837
16.2 Why a second program, and what agreement can show 4839
16.3 The two solvers 4840
16.4 Order of convergence: the ratio test 4841
16.5 Richardson extrapolation and the uncertainty of the reference 4842
16.6 The uncertainty of the Rust solver: canonical and refined runs 4844
16.7 The tolerance rule, fixed in advance 4845
16.8 What the full cross-check found 4847
16.9 Example: the reference solver on a subset and the cross-check (Notebook 16a) . . 4849
16.10How to run Notebook 16a 4849
16.11Notebook 16a: complete text 4856
16.12Line-by-line walk-through of Notebook 16a 4908
16.13Inside the reference solver I: the free problem and its exact levels 4940
16.14Inside the reference solver II: the staggered grid and the matrix 4942
16.15Inside the reference solver III: counting eigenvalues, the zero mode and the brane band 4945

16.16Example: the reference method by hand (Notebook 16b) 4948
16.17How to run Notebook 16b 4949
16.18Notebook 16b: complete text 4954
16.19Line-by-line walk-through of Notebook 16b 4993
16.20How the cross-check caught a rounding error: the chemical potential 5012
16.21Example: the Mermin root (Notebook 16c) 5017
16.22How to run Notebook 16c 5017
16.23Notebook 16c: complete text 5022
16.24Line-by-line walk-through of Notebook 16c 5062
16.25What the cross-check does not test 5081
16.26What we proved, what we computed, what we assumed 5082
16.27Exercises 5084

17 The a4 equations with the Kohn-Sham source: a prescribed background 5087
17.1 What this chapter does, and why 5088
17.2 The words and symbols of this chapter 5090
17.3 The field equations of a4 and their source 5092
17.4 Condition C1: a source must not depend on x0 5094
17.5 Condition C2: the algebraic condition 5095
17.6 Condition C3: what the linear member demands 5095
17.7 The recorded Kohn-Sham states as a candidate source 5097
17.8 Example: the three conditions tested on 75 recorded ground states 5098
17.9 How to run Notebook 17a 5099
17.10Notebook 17a: complete text 5104
17.11Line-by-line walk-through of Notebook 17a 5141
17.12Why the states fail: every source must be conserved 5164
17.13The conservation law in the coordinate y 5165
17.14For a conserved source, C2 says that p0 is flat 5168
17.15The integrated law and the averaged condition 5169
17.16The time direction: energy exchange and the propagation of the constraint . . . 5171
17.17The equations averaged over the hidden direction: what can and cannot be integrated 5173
17.18Example: the conservation laws, the averaged equations, and why the states fail 5177

17.19How to run Notebook 17b 5178
17.20Notebook 17b: complete text 5183
17.21Line-by-line walk-through of Notebook 17b 5230
17.22What a prescribed background is, and what remains open 5258
17.23What we proved, what we computed, what we assumed 5259
17.24Exercises 5262

18 The pairing theorems T1, T2 and Q **5265**

18.1 What this chapter does 5265
18.2 The words of this chapter 5267
18.3 The stage: the author's metric, its frame and its spin connection 5269
18.4 The Lagrangian, the field equation, the energy-momentum tensor and the current 5272
18.5 Four matrix lemmas 5273
18.6 Example: Notebook 18a checks the four lemmas 5278
18.7 How to run Notebook 18a 5278
18.8 Notebook 18a: complete text 5284
18.9 Line-by-line walk-through of Notebook 18a 5321
18.10Theorem T1: the chirality pairing 5341
18.11The proof of T1, line by line 5342
18.12T1 in the block form of the author's field 5343
18.13What T1 says, and what it does not say 5344
18.14Theorem T2: the mirror pairing 5345
18.15The proof of T2 in a general field 5346
18.16T2 in the author's field: the mirror across the brane 5349
18.17Example: Notebook 18b proves T1 and T2 in the author's metric 5350
18.18How to run Notebook 18b 5351
18.19Notebook 18b: complete text 5356
18.20Line-by-line walk-through of Notebook 18b 5398
18.21A family of exact solutions: the fields that depend only on the time 5422
18.22The quantum reading Q 5425
18.23The proofs of Q1 to Q5 5426
18.24Example: Notebook 18c sees the theorems in numbers 5429

18.25How to run Notebook 18c 5430
18.26Notebook 18c: complete text 5435
18.27Line-by-line walk-through of Notebook 18c 5475
18.28What the pairing theorems do not establish 5498
18.29What we proved, what we computed, what we assumed 5500
18.30Exercises 5504
18.31Answers to the exercises 5505

19 T3: the Kohn-Sham universes of mass $+M$ and $-M$ 5507

19.1 What this chapter does 5508
19.2 The words of this chapter 5511
19.3 The Kohn-Sham problem of one orbital 5511
19.4 The Kohn-Sham problem of the whole gas 5514
19.5 The chirality Γ on the blocks 5516
19.6 Step 1 of the proof: an orbital and its image 5518
19.7 Step 2 of the proof: the boundary conditions 5519
19.8 Step 3 of the proof: the densities and the mean field 5520
19.9 Step 4 of the proof: self-consistency, energies and energy-momentum 5522
19.10Theorem T3: the statement, its hypotheses and its records 5524
19.11Why T3 is not T1, and the mirror copy in the Z2 orbifold 5529
19.12The exact levels at zero momentum, and what goes wrong without the transformed tip 5530
19.13Example: the proof of T3 by hand (Notebook 19b) 5533
19.14How to run Notebook 19b 5533
19.15Notebook 19b: complete text 5538
19.16Line-by-line walk-through of Notebook 19b 5577
19.17Watching T3 in the Rust solver: four universes 5600
19.18Example: the universes of mass $+M$ and $-M$ in the Rust solver (Notebook 19a) 5602
19.19How to run Notebook 19a 5603
19.20Notebook 19a: complete text 5609
19.21Line-by-line walk-through of Notebook 19a 5663
19.22What T3 says about pairs of universes, and what it does not 5690

19.23What we proved, what we computed, what we assumed 5692
19.24Exercises 5693

20 Do universes come in pairs? What the equations prove and what they do not 5695

20.1 What this chapter does, and why 5696
20.2 The words of this chapter 5699
20.3 The request and the hypothesis, read word by word 5701
20.4 Three questions: is it allowed, does it happen, how often? 5703
20.5 What is proved (1): theorem T1, line by line 5703
20.6 What is proved (2): theorem T2, the quantum reading Q and theorem T3 5706
20.7 Corollary C1, line by line 5709
20.8 Example: corollary C1 made visible 5712
20.9 How to run Notebook 20a 5712
20.10Notebook 20a: complete text 5718
20.11Line-by-line walk-through of Notebook 20a 5758
20.12One universe without a partner: an exact solution and its two partners 5783
20.13Example: one universe and its two partners, computed 5788
20.14How to run Notebook 20b 5788

Abstract

This book teaches, starting from school algebra and the calculus of one variable, the complete theory of two fields in the author's primordial universe, and every computation that the Revision record of the repository has made about them. The universe has eight directions, named as the author names them: three directions of ordinary space, x_1, x_2 and x_3, which inflate; the time x_4; three extra times, x_5, x_6 and x_7, which deflate exponentially; and a hidden space direction x_0. Four of the directions are space-like and four are time-like (signature (4,4)). The fields are dirac16complex, a spinor field with sixteen complex anticommuting (Grassmann) components, and dirac16complex00, its version with sixteen commuting components.

Part I builds the mathematics and the geometry of the author's metric. Part II builds the Clifford algebra Cl(4,4), the facts about Pin(4,4) and Spin(4,4), the charge-conjugation matrices, the Lagrangians, the field equations, the energy-momentum tensors and the canonical quantisation of the two fields. Part III builds the generalized Kronecker delta, the Lovelock tensors and the field equations for the metric function a_4. Part IV introduces density functional theory from zero and solves the Kohn-Sham model of dirac16complex in the deflating field with a Rust program, checked by an independent solver; the Kohn-Sham history of a_4 is a prescribed background, not a solution of the field equations for a_4. Part V proves the pairing theorems and examines pair creation and matter and antimatter.

The book proves exact maps between the solutions of mass $+m$ and those of mass $-m$ (the pairing theorems T1, T2, Q and T3). It does not prove that the big bang creates universes, in pairs or otherwise: no creation process, rate or amplitude follows from these equations. It proves that the charge of the theory obeys an exact local conservation law (inside the patch $0 < z < \pi/2$ of the hidden direction charge can only move: no process creates or destroys it at any point there), shows that the total charge of a universe is constant only if no charge flows through the edge $z = \pi/2$ of the hidden direction (a condition that is assumed, not derived), proves that a pair of partner solutions has total charge zero, and shows that the theory as built does not explain the excess of matter over antimatter. Every statement carries one of the labels PROVED, COMPUTED, ASSUMED, HYPOTHESIS or OPEN. Every worked example is a complete Jupyter notebook, printed in full together with complete instructions for running it on Windows, macOS and Linux, its figures and a line-by-line walk-through; every number in the text is computed by a notebook or taken from a Revision record.

0 How to use this book; installing the software; the honesty ledger

This chapter is the map of the book. It says what the book teaches and, just as important, what the equations of the book prove and what they do not prove. It explains how every statement is labelled, so that you always know whether it is proved, computed, assumed, a hypothesis or an open question. It installs the software on Windows, macOS or Linux, explains how the notebooks of the book are built and checked, and ends with the honesty ledger: the table of the main statements of the book with their labels and the files that verify them. The chapter has four worked examples, each a complete notebook: Notebook 00a checks that your computer is ready; Notebook 00b takes a first look, with numbers and pictures, at the eight directions of the author's universe and at the author's metric; Notebook 00c reads the verifier reports of the Revision record and checks the honesty ledger; Notebook 00d shows why every run of a notebook gives exactly the same bytes.

0.1 What this book teaches

The book is about a model of the very early universe proposed by the author. The universe of the model has eight directions instead of the four of everyday space and time. They are named x_0 to x_7,

as the author names them. The first, x_0, is a **hidden** direction of space. Three of them, x_1, x_2 and x_3, are the directions of ordinary space. One, x_4, is the time in which everything evolves. The last three, x_5, x_6 and x_7, behave like time as well; they are called the **extra times**. The author's **metric** (the rule that gives the length of a small step in each direction; Section 0.14 introduces it from zero) makes ordinary space grow (**inflate**) and the three extra times shrink (**deflate**) exponentially as the time x_4 runs.

Two fields live in this universe. A **field** is a rule that attaches numbers to every point of space and time: the temperature in a room attaches one number to every point, the wind three. The field **dirac16complex** attaches sixteen complex numbers of a special kind (anticommuting numbers, defined in Chapter 7) to every point; the field **dirac16complex00** attaches sixteen ordinary complex numbers. The book sets up the mathematics of both fields from zero, derives their equations and the equations of the gravitational field that they produce, introduces the density-functional (DFT) approximation, and solves the equations as far as present knowledge allows. Then it asks two questions and answers them honestly: do the equations prove that the big bang creates universes in pairs, and does the theory solve the puzzle of matter and antimatter? Section 0.2 gives the short answers; Part V of the book gives the complete proofs of what is proved and a precise list of what is not.

Every formula and every number of the book comes from the **Revision record**, the computations stored in the folder `Revision` of the repository Dirac_claude, or from the book's own notebooks, which reproduce the Revision record wherever the two overlap. (A **repository** is a folder of files whose history is kept by the program Git; Section 0.8 installs it.)

The book is written for a student who knows school algebra and the calculus of one variable (derivatives and integrals of functions of one variable), and nothing else. It is written in a way that we call a **deep dive**:

- every notion is defined, in plain words, before it is used;
- every derivation is written out line by line, and each line is followed by the rule that produced it from the line before; no step is left to "it can be shown";
- every worked example is a complete Jupyter notebook, a file of text and Python code that you run on your own computer, and the book prints it in full;
- just before each notebook the book prints the complete instructions for running it, on Windows, macOS and Linux, without sending you anywhere else;
- just after each notebook the book explains every line of its code in a section "Line-by-line walk-through";
- every number in the text names the notebook cell that computes it and, where it reproduces the Revision record, the record file and the check;
- every chapter ends with the section "What we proved, what we computed, what we assumed" and with at least five exercises with complete worked answers.

Read the chapters in order. Run each notebook when you reach it: reading a computation and doing it are different things, and the notebook lets you change a number and see what happens. Do each exercise before you read its answer.

0.2 The request, and what the equations prove and do not prove

The book answers a request of the author (2026-10-02) for a teaching book that describes every step of the formalism, derives the field equations, introduces and derives approximations of the DFT type, solves the equations as far as possible, and proves "that the 'big bang' creates universes in pairs" and that "this theory solves matter anti-matter mysteries". The first four parts of the request are carried out in Parts I to IV of the book. The last two cannot be delivered as they are worded, because the equations do not prove them, and a book that wrote them as established would teach something false. The book therefore follows one rule above every other, the **honesty rule**: it teaches exactly what the Revision record proves and computes, with every assumption, and it never writes "proved" for a statement that is not proved. The author was told this on 2026-10-02. Here is what the equations give, in plain words. Many words of this section are new. Each is defined from zero in a later chapter or a later section of this chapter; the list below gives each one a one-line meaning and names that place, so that you can follow the story now.

- **gravitational field**: in this book, the author's metric of Section 0.1, the rule for the lengths of small steps; since Einstein, gravity is described by such a rule (Chapter 3);
- a_4, H **and** z: a_4 is the function of the time x_4 in the author's metric that makes ordinary space inflate and the extra times deflate; H is a positive constant of the author; $z = 6Hx_0$ measures the position along the hidden direction, and it lies between $z = 0$ and the edge $z = \pi/2$ (Section 0.14);
- **space-like** and **time-like**: a direction along which a step is measured like a distance, or like a duration; x_0, x_1, x_2 and x_3 are space-like, x_4 to x_7 time-like (Section 0.14);
- **solution**, **boundary condition**: a solution of a field's equations is a field that satisfies them at every point; a boundary condition is a further condition that a solution must satisfy at the edge of the region in which it is defined (Chapters 2 and 14);
- Ψ (the Greek capital letter psi): a field, its sixteen components written as one column of sixteen numbers (Chapter 7);
- **commuting** and **complex conjugation**: ordinary numbers are commuting, the order of a product does not matter ($ab = ba$), while the anticommuting numbers of Chapter 7 have $ab = -ba$; complex conjugation changes the sign of the imaginary part of every complex number, $a + ib \to a - ib$ (Chapter 1);
- **mass** m: a number in the equations of a field; for a field that describes particles it is their mass (Chapter 7);
- **self-coupling** λ: the strength with which a field acts on itself (Chapter 7);
- **Lagrangian**: the function from which the equations of a field follow (Chapter 7);
- **classical field**: a field whose values are numbers, as everywhere in this chapter, and not the operators of quantum theory (Chapter 7);
- **energy-momentum tensor** T: the table of the energy and the momentum that a field carries and of the pressures it exerts (Chapter 9);

- **source**: the energy-momentum tensor of the fields as it enters the equations of gravity (Chapter 12);
- **Einstein's equations**: the field equations of gravity, which say how the source shapes the metric (Chapter 12);
- **charge** Q and **charge current** J: a number carried by a field whose density obeys an exact **local conservation law**, so that the charge of a region changes only by what flows through the boundary of the region (the law is proved at every point with $0 < z < \pi/2$; at the edge $z = \pi/2$ the **no-flux condition**, that no charge flows through the edge, is ASSUMED, not derived, and only under it is the total charge of a universe constant), and the flow of this number through space (Chapters 10, 18 and 21);
- **U(1) symmetry**: the multiplication of every component of a field by one and the same complex number of absolute value 1, which changes no equation; it is the reason why the charge obeys its local conservation law: at no point with $0 < z < \pi/2$ is charge created or destroyed, it can only flow from one place to another (Chapter 21);
- **gamma matrices**: eight fixed 16×16 matrices of the author, one for each direction, from which the equations of both fields are built (Chapter 4);
- **the matrices** C, Γ **and** B: three fixed 16×16 matrices built from gamma matrices: C is the product of the four space-like ones, Γ (the **chirality**) the product of all eight, and B the product of C and the gamma matrix of the time x_4, times $-i$; B enters the quantum theory (Chapter 5);
- **group, Pin(4,4)**: a group is a collection of transformations that can be combined and undone; Pin(4,4) is the group of the transformations of the sixteen components of a field that go with the rotations and reflections of the eight directions, rotations in a wide sense that includes the mixing of space-like and time-like directions (Chapter 5);
- **Z2 mirror**: a reflection across the edge $z = \pi/2$ of the hidden direction, imposed as a boundary condition; Z2 is the group of two elements, doing nothing and reflecting (Chapter 14);
- **quantised**: turned into a quantum theory, in which the field becomes an operator, a rule that turns one state of the system into another (Chapter 10);
- **indefinite (Krein) metric**: a rule for the squared length of a quantum state that can also give negative numbers (Chapter 10);
- **probability amplitude**: the number from which quantum theory computes how likely a process is (Chapter 10);
- **Kohn-Sham universe**: a solution of the equations of the density-functional approximation, in which the field moves in a potential computed from its own density; **self-consistent** means that this potential and this density fit each other; the mass of the field in this model is written M (Chapters 13 to 15);
- **antimatter**: matter made of antiparticles; the antiparticle of a particle has the same mass and the opposite charge, as the positron has for the electron (Chapter 21);

- **the symmetries C and CP**: C exchanges every particle with its antiparticle, P reflects space as in a mirror, and CP does both (Chapter 21);
- **thermal equilibrium**: a state in which every process runs forwards as often as backwards, so that on average nothing changes (Chapter 21);
- **photon**: the particle of light (Chapter 21);
- **discrete symmetry**: a symmetry that is a single operation, such as a reflection, and not a continuous family of operations such as the multiplications of the U(1) symmetry (Chapter 21).

Pairs of universes. Each field has a **mass** m (a number that enters its equations) and a **self-coupling** λ (the strength with which the field acts on itself). The Revision record proves exact maps between the solutions of the equations with mass $+m$ and those with mass $-m$:

- **T1** (both fields, every gravitational field): a fixed 16×16 matrix Γ, the **chirality**, turns every solution with (m, λ) into a solution with $(-m, -\lambda)$; the Lagrangian (the function from which the equations follow) changes as $L_{m,\lambda}[\Gamma\Psi] = -L_{-m,-\lambda}[\Psi]$, the energy-momentum tensor T (the table of the energy and momentum that the field carries) changes into $-T$, and the charge current J into $-J$;
- **T2** (both fields): Γ combined with the reflection of one space-like direction (an element of the group Pin(4,4)) turns (m, λ) into $(-m, \lambda)$, with the same self-coupling; in the author's universe the reflection is the Z2 mirror across the edge $z = \pi/2$ of the hidden direction (a choice of boundary condition, which is ASSUMED, not derived), and the energy-momentum tensor of the image is equal to that of the original (reflected across the mirror), not opposite to it;
- **Q** (dirac16complex): the quantum reading of T1; the image field carries the indefinite (Krein) metric $-B$ and is the same quantum system written in other variables, and there is no cancellation between two universes that are quantised independently of each other;
- **T3** (dirac16complex, the Kohn-Sham level: within the Kohn-Sham approximation, which is ASSUMED (Section 0.18), with the ASSUMED Z2 mirror and the correspondingly transformed boundary conditions): every self-consistent Kohn-Sham universe with (M, λ) has a partner with $(-M, \lambda)$, and the two have equal energies and equal energy-momentum tensors;
- **C1** (a consequence of T1): a T1 pair taken as the complete classical source of the author's metric is a zero source, and Einstein's equations then have no solution for $H > 0$.

These are PROVED, each by two independent verifiers, whose reports are:

- for T1, T2 and Q: `Revision/pairing/reports/wolfram-pairing.json` and `Revision/pairing/reports/python-pairing.json`;
- for T3: `wolfram-t3.json` and `python-t3.json`, with its completion `wolfram-t3-completion.json` and `python-t3-completion.json`, all four in the folder `Revision/pairing/kohn_sham/reports` (the completion closes gaps that a review found in the first proof:

among them, its Wolfram verifier reads the numbers that define the Kohn-Sham potentials from the Kohn-Sham record instead of writing them into the program, and it shows that the rule by which the states are filled carries over to the partner);

- for C1: T1 together with the check `einstein_no_vacuum_solution` of `Revision/field_equations_a4/reports/wolfram-a4-report.json` and the check `einstein_no_vacuum` of `Revision/field_equations_a4/reports/python-a4-report.json`.

They are exact **maps between solution sets**: if a configuration of the field is a solution of the equations, its image under the map is a solution of the equations with the mapped parameters (for T1, of the equations with $(-m, -\lambda)$ in place of (m, λ)). What is NOT proved is that any universe is **created**, in pairs or otherwise: no creation process, no rate, no probability amplitude and no dynamics of a big bang follows from these equations, and a single universe of mass $+m$ is an equally valid solution without its partner. The pairing record says so itself: the report `Revision/pairing/reports/python-pairing.json` holds, under its key `not_established`, a list of twelve things that the theorems do not establish, and Notebook 00c prints all twelve. Chapters 18 to 20 give the complete proofs and the complete list. In the honesty ledger (Section 0.18) the statement "the big bang creates universes in pairs" is therefore labelled OPEN, with the note "not proved".

Matter and antimatter. The universe we observe contains matter but almost no antimatter. In 1967 Sakharov showed that an excess of matter can grow from an equal start only if three conditions hold: there are processes that change the number of baryons (the particles of ordinary matter, such as the proton); the symmetries called C and CP are violated; and the universe departs from thermal equilibrium. Chapter 21 explains all of this from zero, with the measured size of the excess (the baryon-to-photon ratio). What this theory proves is: the charge of each field obeys an exact **local** conservation law (it follows from an exact U(1) symmetry), so no process creates or destroys charge at any point inside a universe off its edge (at every point with $0 < z < \pi/2$, where the law is proved): charge can only flow from one place to another; the total charge Q of a universe is constant only if no charge flows out through the edge $z = \pi/2$ of the hidden direction, and this **no-flux condition** is ASSUMED, not derived (whether a boundary condition at the edge supplies it is OPEN; Chapters 10, 18 and 21 show exact solutions through whose edge charge does flow, so that their total charge changes); the discrete symmetries of the theory are derived exactly (Chapter 21), among them its two charge conjugations, which are matrices, $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$; and a T1 partner (mass $-m$, self-coupling $-\lambda$) carries the opposite charge, so a T1 pair $\{+m, -m\}$ has total charge zero as classical fields (for two universes that are quantised independently of each other there is no such cancellation; this is part of Q). The idea that our universe has a partner of opposite charge (an "anti-universe") belongs to a class of ideas of which one published example is Boyle, Finn and Turok, Phys. Rev. Lett. 121, 251301 (2018). The theory as built does NOT solve the matter-antimatter problem: it has no baryons, no process that changes the number of baryons, no violation of CP, and no computation of a departure from equilibrium. To solve it, the theory would need all of these, and a computation of the excess that agrees with the measured one. That our universe actually has such a partner is a HYPOTHESIS, and every scenario built on it is labelled HYPOTHESIS.

Charge conjugation is a matrix. The author's gamma matrices are real (they contain only real numbers). For a field whose components are real numbers, plain complex conjugation changes nothing at all: it is the identity map, and it cannot be what charge conjugation means here. The charge conjugations of the theory are two matrices, derived in Chapter 5 and Chapter 21: $\mathcal{C}_+ = C$, which keeps the mass, and $\mathcal{C}_- = \Gamma C$, which reverses it. For a real commuting field the charge current J is zero and $\mathcal{C}_+$ acts as the identity (a real field is its own conjugate); for real fields

the map between matter and antimatter is the real matrix Γ together with the reversal of the mass, which is T1. (PROVED: `Revision/lead_checks/reports/charge-conjugation-and-u1.json`, the checks `charge_conjugation_matrix_plus`, `charge_conjugation_matrix_minus` and `real_fields_charge_conjugation`; Notebook 00c opens this report, prints the details of these three checks and checks that they state exactly this: Section 0.21, In [3].)

A prescribed background. The Kohn-Sham chapters let a_4 grow in proportion to the time, $a_4 = AHx_4$. This history is ASSUMED, a **prescribed background**: the computed Kohn-Sham states cannot be its source in the field equations (`Revision/field_equations_a4/reports/ks-source-conditions.json`).

0.3 The five labels of every statement

Every statement of the book that matters carries one of five labels, so that you always know how much it is worth:

label	meaning
PROVED	exact; the book gives the complete proof and, where the Revision record contains an exact computer check of the statement, names it (the report file and the name of the check)
COMPUTED	a number from a numerical computation, with its measured uncertainty and the file that holds it
ASSUMED	a starting point that the book does not derive (a convention, a physical input or an approximation); everything that depends on it says so
HYPOTHESIS	an idea that is stated and examined but not established
OPEN	a question that neither the Revision record nor this book answers

A statement can be PROVED in three ways. (1) A statement about finitely many definite objects, such as "these eight matrices of whole numbers satisfy these 64 equations", is proved by an exact computation of every case. (2) A statement in which the computer keeps the unknown quantities as symbols, such as "for every function a_4 the determinant of the metric is $\cos^2 z$", is proved by an exact symbolic computation, which holds for every value of the symbols, like a derivation by hand. (3) A statement about infinitely many cases that the computer cannot hold as symbols, such as "in every gravitational field", is proved by a general derivation in the book; an exact check at a few test points then confirms the derivation (and would catch many errors), but it is not the proof.

Examples from this chapter. "The determinant of the author's metric is $\cos^2 z$" is PROVED (way 2; Section 0.14). "The ground-state energies of the canonical and the refined run of the Revision record's Kohn-Sham solver differ by at most 1.901×10^{-12} (relative)" is COMPUTED (`Revision/kohn_sham/reports/ks-rust-determinism.json`, check `refined_ground_energies`; Notebook 00d reads it, Section 0.22). "The Z2 mirror at the edge of the hidden direction" is ASSUMED. "Our universe has a partner of opposite charge" is a HYPOTHESIS. "The big bang creates universes in

pairs" was proposed by the author as a hypothesis; as a question of this book it is OPEN, and the ledger says why: it is not proved.

0.4 How to check a statement yourself

You can check a statement at three levels.

Level 1, the derivation. Follow it line by line in the book. If a line does not follow from the line before it, you have found either a gap in your understanding or an error in the book; both are worth finding.

Level 2, the report. Every exact verifier of the Revision record writes its results into a **report**, a JSON file (a plain text file of names, numbers and lists that Python reads directly). A report lists its **checks**; each check has a name, a **verdict** (PASS or FAIL) and a detail text that says exactly what was verified. You can read a report yourself. Open a terminal, activate the Python environment of the book and go into the repository folder (Section 0.11, Step 4, gives the commands), type `python` and press Enter. Python shows its prompt, three greater-than signs, at the start of each input line. Type the text after each prompt (the lines that start with three dots are the second line of the loop; press Enter once more on the empty line after them):

```
>>> import json
>>> path = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
>>> report = json.load(open(path, encoding="utf-8"))
>>> report["summary"]["passed"], report["summary"]["total"]
(12, 12)
>>> for check in report["checks"][:3]:
...     print(check["verdict"], check["name"])
...
PASS representation_real
PASS B_imaginary_hermitian
PASS intertwiners_same_mass
>>> exit()
```

The answer `(12, 12)` says that 12 of the 12 checks of this report passed; the loop prints the verdict and the name of its first three checks. Notebook 00c does exactly this, for every report of the Revision record at once.

Level 3, the computation. Run the verifier again and compare its new report with the stored one. The verifiers need Wolfram Mathematica (which the notebooks of this book never need) or Rust, and some run for hours; Chapter 23 lists every command.

0.5 Conventions used everywhere

These conventions hold on every page. They are choices, not results (ASSUMED).

- **The names of the coordinates** are the author's: $x_0, x_1, \ldots, x_7$, always in this order. In Python lists and arrays the entries are counted from 0, so the entry of x_k has the index k: x_0 has the index 0 and x_7 the index 7. The book uses no other names or order of the coordinates.

- **The roles of the coordinates.** x_0: the hidden direction of space, through the variable $z = 6Hx_0$ with $0 < z < \pi/2$, where $H > 0$ is a constant of the author; x_1, x_2, x_3: ordinary space, which inflates; x_4: the time; x_5, x_6, x_7: the three extra times, which deflate exponentially.
- **The signs of the directions** are $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$: the directions x_0, x_1, x_2, x_3 are space-like and x_4, x_5, x_6, x_7 time-like; the **signature** is (4,4). (Section 0.14 explains these words; the Revision record states the signs in the file `Revision/algebra/gammas.json`, and its Wolfram verifier checks them: `Revision/algebra/reports/wolfram-algebra.json`, check `eta_in_author_order`.)
- **Units.** The formulas of the Revision record contain no speed of light and no Planck constant: they are written in units in which both are 1, as is usual in this kind of physics. A chapter that computes numbers says in which unit it measures them (for example in units of the mass m).
- **Files** are named by their path in the repository, written with `/` and starting at the repository folder, for example `Revision/README.md`; the book prints such names in typewriter type.

0.6 The map of the book

The book has five parts and an appendix. Each chapter uses only what earlier chapters have built.

Part I, getting ready.

- Chapter 0 (this chapter): how to use the book, the software, how the notebooks are built, the honesty ledger.
- Chapter 1: mathematics from zero, part I: numbers, complex numbers, vectors, matrices, index notation, determinants, the generalized Kronecker delta.
- Chapter 2: mathematics from zero, part II: functions of several variables, partial derivatives, differential equations and how a computer solves them, the shooting method.
- Chapter 3: the geometry of space and time: the metric, the signature (4,4), the author's metric, curvature.

Part II, spinors and fields.

- Chapter 4: the Clifford algebra and the author's sixteen gamma matrices T16.
- Chapter 5: the matrices C, Γ and B, the groups Pin(4,4) and Spin(4,4), and the charge-conjugation matrices.
- Chapter 6: spinors in the curved 4+4 space: the vielbein, the spin connection, the covariant derivative.
- Chapter 7: the two fields and their Lagrangians; Grassmann numbers; the field equations.
- Chapter 8: what non-triviality means exactly, and the growth of the extra-time modes.

- Chapter 9: the energy-momentum tensor: energy density, pressures, equations of state, conservation.
- Chapter 10: canonical quantisation in 4+4 dimensions and the Krein space.

Part III, the field equations of gravity.

- Chapter 11: the generalized Kronecker delta and the Lovelock tensors.
- Chapter 12: the field equations for a_4.

Part IV, density functional theory.

- Chapter 13: many-body quantum mechanics and density functional theory from zero.
- Chapter 14: the Kohn-Sham model of dirac16complex in the deflating field.
- Chapter 15: solving the Kohn-Sham equations with the Rust solver.
- Chapter 16: checking the solution with an independent solver.
- Chapter 17: why the Kohn-Sham history of a_4 is a prescribed background.

Part V, pairs of universes, matter and antimatter.

- Chapter 18: the pairing theorems T1, T2 and Q with complete proofs.
- Chapter 19: T3, the Kohn-Sham universes of mass $+M$ and $-M$.
- Chapter 20: do universes come in pairs? What the equations prove, and what they do not.
- Chapter 21: matter and antimatter from zero, and what this theory does and does not contribute.
- Chapter 22: open problems, and how a student could attack each.

Appendix.

- Chapter 23: reproducing everything; the glossary; the index of the checks and of the notebooks.

0.7 Every example is a notebook

Every worked example of the book is a **Jupyter notebook**: a file (with the ending `.ipynb`) that holds text and Python code in **cells**, together with everything the code printed and drew when it ran. A **markdown cell** holds text; a **code cell** holds Python code. The **kernel** is the running Python program that executes the code cells one after the other. The notebooks are numbered by chapter and letter: Notebook 00a is the first notebook of Chapter 0, Notebook 00b the second, and so on. The book prints every notebook in full, in three parts:

- a section "How to run Notebook NNx" (NN is the number of the chapter and x the letter), which gives the complete instructions for running the notebook on Windows, macOS and Linux;
- a section "Notebook NNx: complete text", which prints every cell in order, with what each code cell printed and every figure it drew;
- a section "Line-by-line walk-through of Notebook NNx", which explains every line of every code cell.

Every notebook has the same numbered sections: (1) what it computes; (2) how to run it, the same complete instructions again; (3) the words it uses; (4) the physical and mathematical situation; then the computation in small steps, each code cell preceded by a text cell that says what it does; and last, what it showed. The first code cell, the **set-up cell**, repeats the instructions as comment lines and prepares the helpers that every notebook uses.

Every computation is followed by **checks**: statements that must be true. When a check is true, the notebook prints a line that starts with PASS and names the check. When a check reproduces a number or a verdict of the Revision record, a second line starting with "reproduces" names the record file and the check in it. When a check is false, the notebook stops with an error that names the check. Lines that start with RESULT print the key numbers. The last line of every notebook says how many checks passed, for example ALL 9 CHECKS PASSED (notebook 00a).

Every figure is saved as a PNG picture file in the folder `Revision/textbook/figures`, named after the notebook, its number and a short name (for example `00a_1_parabola_tangent.png`), and the book prints it with a caption that says what is plotted, what the axes and their units are, and what you should see. The book refers to it as Figure 00a.1.

Next to every notebook lies its **provenance file**, with the same name and the ending `.PROVENANCE.md` (for example `Revision/textbook/notebooks/00a_check_installation.PROVENANCE.md`). It records what the notebook computes and from which Revision records; the complete instructions for running it; the expected output (every PASS line, every RESULT line, every figure with its caption); every file it writes; its run time and peak memory; the computer and the versions of the programs with which it was run; the sha256 fingerprints of the notebook and of every file it writes (Section 0.18 explains fingerprints); and the date and result of its last check.

0.8 Installing the software

The complete installation commands are printed in the section "How to run" before every notebook, for the first time in Section 0.11; you follow them once per computer, and later notebooks need only the steps that start JupyterLab. This section explains what each piece of software is and why it is needed, and adds the installation of Rust, which only seven notebooks need.

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). A command is typed exactly as printed and sent with the Enter key. The commands are printed in framed blocks, one command per line; where they differ between the systems, the block is labelled with the system.

Git is the program that downloads the repository and keeps track of the versions of its files. On

Windows it is installed from https://git-scm.com/download/win; on macOS it comes with the developer tools (the command `xcode-select` with the option install, printed in the instructions); on Linux it is a package of the system.

Python is the programming language of the notebooks. The book needs Python 3.12 or newer; it was built with Python 3.14.5. A **version number** such as 3.14.5 names one release of a program: the first number changes rarely, the second for new features, the third for corrections.

The repository is downloaded with one command,

```
git clone https://github.com/once-ere/Dirac_claude.git
```

which creates the folder Dirac_claude (a few hundred megabytes; the folder then needs up to about 1 GB of disk space). To get a newer version later, run `git pull` inside that folder.

A private Python environment is a folder with its own copy of Python and of the packages, so that installing the packages changes nothing else on your computer. The instructions create it in the folder dirac-book-env inside your home folder and **activate** it: from then on, in this terminal, the commands `python` and `jupyter` are those of the environment, and the prompt starts with (dirac-book-env). An environment must be activated again in every new terminal. On Windows, PowerShell refuses to run the activation script until the command with `Set-ExecutionPolicy` allows it for the one window in which it is typed; it changes nothing permanently.

The nine packages are installed with Python's installer pip at fixed (**pinned**) versions, the versions with which the book was built: numpy 2.4.6 (arrays of numbers, matrices), sympy 1.14.0 (exact algebra and calculus with symbols), mpmath 1.3.0 (numbers with as many digits as we ask for), matplotlib 3.11.0 (plots), and jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6 (the programs that show, store and run notebooks). Another version of a package may print slightly different last digits or draw slightly different pictures; Notebook 00a checks that every package has its pinned version. The pins of these nine packages and of the 93 packages they need in turn are listed in the file `Revision/textbook/requirements.txt`; with the environment active, the command below, run in the repository folder, installs all of them at once at the exact versions of the book (the commands in the run instructions install the nine and let pip choose the others):

```
python -m pip install -r Revision/textbook/requirements.txt
```

JupyterLab shows a notebook in your web browser and runs it: with the environment active, in the folder `Revision/textbook/notebooks`, the command `jupyter lab` followed by the name of the notebook file opens it, and the menu Run > Run All Cells runs every cell from the top. A notebook can also be run without a browser (**headless**) with `jupyter nbconvert`; the run instructions print the exact command.

Rust is a second programming language. The longest computations of the Revision record (the generalized Kronecker delta and the Lovelock tensors, and the Kohn-Sham solver) are Rust programs, and seven notebooks run them: 11a and 11b, 15a, 15b and 15d, 16a and 19a. Their run instructions include the following installation, which you do once per computer. **cargo** is Rust's program that turns the Rust code of a program into a program that the computer can run (it **builds** it). On Windows, download `rustup-init.exe` from https://rustup.rs, run it and accept the default choices;

if it reports that the Visual Studio C++ Build Tools are missing, let it install them (or install the workload "Desktop development with C++" from https://visualstudio.microsoft.com/visual-cpp-build-tools/ and run `rustup-init.exe` again). On macOS and Linux, run the command below and accept the default choice (on Linux first run `sudo apt install build-essential`, which provides the linker that Rust needs):

```
curl --proto "=https" --tlsv1.2 -sSf https://sh.rustup.rs | sh
```

Then open a new terminal and check the version of cargo; it must print 1.91.1 or a newer version. The two Rust programs are built with these commands, in the repository folder (the same commands on all three systems):

```
cargo --version
cargo build --release --manifest-path Revision/gkd_lovelock/code/Cargo.toml
cargo build --release --manifest-path Revision/kohn_sham/solver/Cargo.toml
```

A build writes the folder `target` next to the file `Cargo.toml` of its program (git ignores it). The two programs use no package from the internet, so cargo downloads nothing. A notebook that needs a program runs the same build command itself before it uses it.

Removing everything again is simple: delete the folders dirac-book-env and Dirac_claude in your home folder; apart from the programs Git, Python and Rust that you installed, nothing else was changed. Those programs are removed like any other program of your system (a Python that you built from its source code on Debian 12, as a troubleshooting entry of Section 0.11 describes, lies in the folder `/usr/local`); Rust removes itself with the command `rustup self uninstall`.

0.9 How the notebooks are built and checked

You do not need this section to run the notebooks; it explains why you can trust that the printed notebooks are exactly what the code produces.

No notebook of the book is edited by hand. Each one is made by a **builder**, a Python file in the folder `Revision/textbook/notebooks/src` with the same name as the notebook (for example `Revision/textbook/notebooks/src/00a_check_installation.py`), which lists the notebook's cells and its facts: its title, the Revision records it reads, the packages it needs, the files it writes, its expected run time and its last printed lines. The book's tool **nbkit** (the file `Revision/textbook/tools/nbkit.py`) turns a builder into a notebook in two steps.

Build. nbkit inserts the run instructions and the set-up cell, executes the notebook with the kernel python3 in the folder `Revision/textbook/notebooks`, with the hash seed `PYTHONHASHSEED` set to 0 (Section 0.22 explains what it is), checks every output against the rules of the book, removes everything that differs from run to run without meaning anything (time stamps and timing data), and stores the executed notebook, its figures and its captions. A build ends with the check described next, and only when that check passes does it write the provenance file.

Check. nbkit executes the notebook a second time, now with the hash seed 1 and with every file written into a scratch folder instead of the repository (the environment variable `TEXTBOOK_OUTPUT_ROOT` of the set-up cell names that folder), and compares everything byte for byte: the notebook,

every file it wrote, and the provenance file regenerated from its record. Only when everything is identical does the check print PASSED; the result and its date are stored in the provenance file. The rules that a build and a check enforce include: no error and nothing printed on the error channel; every printed line at most 89 characters of plain ASCII text (the width of a page of the book); no memory address and no folder of the build computer in the output; every figure saved at 150 dots per inch, without the name of the program that made it, and at most 1.25 times as high as it is wide; and exactly the files that the builder lists are written.

From the repository folder, with the environment active, the check of one notebook is the command

```
python Revision/textbook/notebooks/src/00a_check_installation.py check
```

(near its end it prints the line `check_00a=PASSED`, and its last line is `nbkit=OK`; the scratch folder, into which the second run writes its files, is a folder in the system's temporary folder). Because the comparison is byte for byte, it is meant for the computer on which the book was built: on another computer a figure may differ in a few bytes (for example through another version of a font library), which is harmless for the student but fails a byte-for-byte comparison. Notebook 00d shows, with small experiments, what else could make two runs differ, and how the book prevents it.

0.10 Example: checking the installation

The first notebook computes no physics. It checks that Python and the packages are installed at the right versions, prints the version of cargo when Rust is installed, does one small computation with each of numpy, sympy and mpmath, and draws two teaching plots. Run it first: if it ends with the line ALL 9 CHECKS PASSED (notebook 00a), every notebook of the book that needs no Rust can run on your computer.

The two plots illustrate two facts that the book uses again and again. We derive both here, line by line.

The tangent line of a parabola. The parabola is $y = x^2$, and we want the straight line that touches it at the point $(1, 1)$. The slope of the parabola at x is the derivative

$$\frac{d}{dx} x^2 = 2x$$

(the power rule $\frac{d}{dx} x^n = n x^{n-1}$ with $n = 2$). At $x = 1$ the slope is $2 \cdot 1 = 2$ (substitution of $x = 1$). The line through the point $(1, 1)$ with slope 2 is

$$y = 1 + 2(x - 1)$$

(the point-slope form $y = y_0 + s(x - x_0)$ of a straight line with $x_0 = 1$, $y_0 = 1$, $s = 2$), that is

$$y = 2x - 1$$

(multiply out the bracket, $2(x - 1) = 2x - 2$, and add $1 - 2 = -1$). The gap between the parabola and the line is

$$x^2 - (2x - 1) = x^2 - 2x + 1$$

(remove the bracket: a minus sign in front of a bracket changes the sign of every term in it), and

$$x^2 - 2x + 1 = (x - 1)^2$$

(the binomial formula $(a - b)^2 = a^2 - 2ab + b^2$ with $a = x$, $b = 1$). A square is never negative and is zero only when the number squared is zero, so the gap is never negative and is zero only at $x = 1$: the line touches the parabola at the single point $(1, 1)$ and lies below it everywhere else. Status: PROVED (above, by school algebra); Notebook 00a confirms it at 401 points (COMPUTED, Figure 00a.1).

A growing and a shrinking exponential. For every number t,

$$e^t \, e^{-t} = e^{t+(-t)}$$

(the law of exponents $e^u e^v = e^{u+v}$), and

$$e^{t+(-t)} = e^0 = 1$$

(the exponent is $t - t = 0$, and $e^0 = 1$ because any nonzero number to the power 0 is 1). So $e^{-t} = 1/e^t$: when e^t grows, e^{-t} shrinks by exactly the same factor. The author's metric has this pattern (Section 0.14): lengths along ordinary space carry the factor e^{a_4} and lengths along the extra times the factor e^{-a_4}, so when a_4 grows, ordinary space inflates while the extra times deflate. Status: PROVED; Notebook 00a confirms it at 401 points (COMPUTED, Figure 00a.2).

0.11 How to run Notebook 00a

Step 1. What this notebook does and what it needs.

Notebook 00a (Checking the installation) is the file `Revision/textbook/notebooks/00a_check_installation.ipynb` of the repository Dirac_claude. It prints the version of Python, of every Python package of the notebooks and of cargo (when cargo is installed), checks that every package has its pinned version, does one small computation with each of numpy, sympy and mpmath, and draws two teaching plots (a parabola with its tangent line, and a growing and a shrinking exponential). It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs

the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is

changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00a_check_installation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00a_check_installation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 00a_check_installation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/00a.captions.json`

- `Revision/textbook/figures/00a_1_parabola_tangent.png`
- `Revision/textbook/figures/00a_2_growth_and_decay.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the figure file 00a_2_growth_and_decay.png exists
ALL 9 CHECKS PASSED (notebook 00a)
```

and the notebook must show 2 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/00a_check_installation.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 00a_check_installation.ipynb
python -m nbconvert --execute --inplace 00a_check_installation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "AssertionError: check failed: every package has its pinned version": the table printed just above the error names each package with the installed and the pinned version; install the pinned versions again with the pip commands of Step 3 (with the environment active) and run the notebook again.
- "AssertionError: check failed: Python is version 3.12 or newer": the environment was made with an older Python; delete the folder dirac-book-env in your home folder and repeat Step 3 with Python 3.12 or newer.
- Debian 12: the version check of Step 2 prints 3.11, and the first of the three commands of Step 2 for a too-low version fails or is not found: those three commands add the package source ppa:deadsnakes, which serves Ubuntu only (and the command add-apt-repository comes with the package software-properties-common, which small installations lack). Debian 13 and newer have Python 3.13, which is new enough: there the two commands of Step 2 suffice. On Debian 12, build Python 3.14.5 from its source code with the commands below, in your home folder (about ten minutes; they add the command `python3.14` and leave the Python of the system unchanged), then type `python3.14` instead of `python3` in the command of Step 3 that creates the environment.

```
sudo apt install build-essential pkg-config wget libssl-dev zlib1g-dev
sudo apt install libbz2-dev libreadline-dev libsqlite3-dev
sudo apt install libffi-dev liblzma-dev libncurses-dev
wget https://www.python.org/ftp/python/3.14.5/Python-3.14.5.tgz
tar -xzf Python-3.14.5.tgz
cd Python-3.14.5
./configure
make -j 4
sudo make altinstall
cd ..
python3.14 --version
```

0.12 Notebook 00a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/00a_check_installation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell.

A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This is the first notebook of the book. It computes no physics. It checks that your
computer has everything that the notebooks of the book need, and it shows how every
notebook of the book works. It

- prints the version of Python and of every Python package that the notebooks use,
  and checks that each package has exactly the version with which the book was
  built (its *pinned* version);
- prints the version of cargo, the program that builds the Rust programs of the
  repository, when cargo is installed (only a few notebooks need it);
- does one small computation with each of the packages numpy, sympy and mpmath and
  checks the results;
- draws two teaching plots and saves them as picture files;
- prints a line that starts with PASS for every check that passes, and as its last
  line the number of checks that passed.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 00a (Checking the installation) is the file
‘Revision/textbook/notebooks/00a_check_installation.ipynb‘ of the repository
Dirac_claude. It prints the version of Python, of every Python package of the notebooks
and of cargo (when cargo is installed), checks that every package has its pinned version,
does one small computation with each of numpy, sympy and mpmath, and draws two teaching
plots (a parabola with its tangent line, and a growing and a shrinking exponential). It
needs a computer with Windows 11, macOS or Linux, an internet connection for the
installation, the program Git, and Python 3.12 or newer (the notebooks were built with
Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0,
mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2,
ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
```

installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00a_check_installation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00a_check_installation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 00a_check_installation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/00a.captions.json‘
- ‘Revision/textbook/figures/00a_1_parabola_tangent.png‘
- ‘Revision/textbook/figures/00a_2_growth_and_decay.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
    git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS the figure file 00a_2_growth_and_decay.png exists
    ALL 9 CHECKS PASSED (notebook 00a)
```

and the notebook must show 2 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/00a_check_installation.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 00a_check_installation.ipynb
      python -m nbconvert --execute --inplace 00a_check_installation.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "AssertionError: check failed: every package has its pinned version": the table printed just above the error names each package with the installed and the pinned version;

install the pinned versions again with the pip commands of Step 3 (with the environment active) and run the notebook again.
- "AssertionError: check failed: Python is version 3.12 or newer": the environment was made with an older Python; delete the folder dirac-book-env in your home folder and repeat Step 3 with Python 3.12 or newer.
- Debian 12: the version check of Step 2 prints 3.11, and the first of the three commands of Step 2 for a too-low version fails or is not found: those three commands add the package source ppa:deadsnakes, which serves Ubuntu only (and the command add-apt-repository comes with the package software-properties-common, which small installations lack). Debian 13 and newer have Python 3.13, which is new enough: there the two commands of Step 2 suffice. On Debian 12, build Python 3.14.5 from its source code with the commands below, in your home folder (about ten minutes; they add the command ‘python3.14‘ and leave the Python of the system unchanged), then type ‘python3.14‘ instead of ‘python3‘ in the command of Step 3 that creates the environment.

```
sudo apt install build-essential pkg-config wget libssl-dev zlib1g-dev
sudo apt install libbz2-dev libreadline-dev libsqlite3-dev
sudo apt install libffi-dev liblzma-dev libncurses-dev
wget https://www.python.org/ftp/python/3.14.5/Python-3.14.5.tgz
tar -xzf Python-3.14.5.tgz
cd Python-3.14.5
./configure
make -j 4
sudo make altinstall
cd ..
python3.14 --version
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 00a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 00a (Checking the installation) is the file
# Revision/textbook/notebooks/00a_check_installation.ipynb of the repository
# Dirac_claude. It prints the version of Python, of every Python package of the notebooks
# and of cargo (when cargo is installed), checks that every package has its pinned
# version, does one small computation with each of numpy, sympy and mpmath, and draws two
# teaching plots (a parabola with its tangent line, and a growing and a shrinking
# exponential). It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the
# program that shows and runs notebooks. It does not need Rust.
```

```
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
```

```
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
```

```
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 00a_check_installation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 00a_check_installation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 00a_check_installation.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/00a.captions.json
# - Revision/textbook/figures/00a_1_parabola_tangent.png
# - Revision/textbook/figures/00a_2_growth_and_decay.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
```

```
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the figure file 00a_2_growth_and_decay.png exists
#     ALL 9 CHECKS PASSED (notebook 00a)
#
# and the notebook must show 2 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/00a_check_installation.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 00a_check_installation.ipynb
#     python -m nbconvert --execute --inplace 00a_check_installation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "AssertionError: check failed: every package has its pinned version": the table
#   printed just above the error names each package with the installed and the pinned
#   version; install the pinned versions again with the pip commands of Step 3 (with the
#   environment active) and run the notebook again.
# - "AssertionError: check failed: Python is version 3.12 or newer": the environment was
#   made with an older Python; delete the folder dirac-book-env in your home folder and
#   repeat Step 3 with Python 3.12 or newer.
```

```
# - Debian 12: the version check of Step 2 prints 3.11, and the first of the three
#   commands of Step 2 for a too-low version fails or is not found: those three commands
#   add the package source ppa:deadsnakes, which serves Ubuntu only (and the command
#   add-apt-repository comes with the package software-properties-common, which small
#   installations lack). Debian 13 and newer have Python 3.13, which is new enough: there
#   the two commands of Step 2 suffice. On Debian 12, build Python 3.14.5 from its source
#   code with the commands below, in your home folder (about ten minutes; they add the
#   command python3.14 and leave the Python of the system unchanged), then type
#   python3.14 instead of python3 in the command of Step 3 that creates the environment.
#     sudo apt install build-essential pkg-config wget libssl-dev zlib1g-dev
#     sudo apt install libbz2-dev libreadline-dev libsqlite3-dev
#     sudo apt install libffi-dev liblzma-dev libncurses-dev
#     wget https://www.python.org/ftp/python/3.14.5/Python-3.14.5.tgz
#     tar -xzf Python-3.14.5.tgz
#     cd Python-3.14.5
#     ./configure
#     make -j 4
#     sudo make altinstall
#     cd ..
#     python3.14 --version
#

```
## 3. The words used in this notebook

- **Python**: the programming language of the notebooks. A *version number* such as
  3.14.5 names one release of a program: the first number (3) changes rarely, the
  second (14) for new features, the third (5) for corrections.
- **Package**: a collection of Python code that someone else wrote and that we
  *import* (load) to use it: numpy (arrays of numbers and matrices), sympy (exact
  algebra and calculus with symbols), mpmath (numbers with as many digits as we
  want), matplotlib (plots).
- **Pinned version**: the exact version of a package with which the book was built.
  Another version may print slightly different numbers or pictures.
- **Private environment**: a folder with its own copy of Python and of the packages,
```

```
  so that installing them changes nothing else on the computer.
- **Notebook, cell, kernel**: a notebook is a file made of *cells*. A *markdown
  cell* (like this one) holds text; a *code cell* holds Python code. The *kernel* is
  the running Python program that executes the code cells one after the other;
  what a code cell prints appears below it.
- **Check**: a statement that must be true. The helper `check(condition, name)` of
  the set-up cell stops the notebook with an *AssertionError* when the condition is
  false, and prints `PASS name` when it is true.
- **Figure, plot, axis**: a figure is a picture; a plot draws numbers as points or
  lines; the horizontal axis and the vertical axis are the two number lines of the
  plot. **PNG** is the file format in which the figures are saved.
- **Rust, cargo**: Rust is a second programming language used for the longest
  computations of the repository; cargo is the program that turns Rust code into a
  program that the computer can run (it *builds* it).
```

Text cell:

```
## 4. The physical and mathematical situation

There is no physics in this notebook. The two plots are warm-ups for ideas that the
book uses again and again.

The first plot shows the parabola $y = x^2$ and its tangent line at the point
$(1, 1)$. The slope of the tangent line is the derivative of $x^2$ at $x = 1$,
namely $2x = 2$, so the line is $y = 1 + 2(x - 1) = 2x - 1$. The difference
$x^2 - (2x - 1) = (x - 1)^2$ is never negative and is zero only at $x = 1$: the
line touches the parabola at one point and lies below it everywhere else.

The second plot shows a growing exponential $e^{t}$ and a shrinking exponential
$e^{-t}$. Their product is $e^{t} e^{-t} = e^{t - t} = e^{0} = 1$ for every $t$. The
author's metric has this pattern: lengths along the three directions of ordinary
space carry the factor $e^{a_4}$ and lengths along the three extra times the factor
$e^{-a_4}$, so when $a_4$ grows, ordinary space inflates and the extra times
deflate.
```

Text cell:

```
## 5. Python

The next cell reads the version of Python that runs this notebook, prints it, and
checks that it is 3.12 or newer.
```

In [2]:

```
import importlib.metadata  # reads the version numbers of installed packages
import platform  # reads the version number of Python

python_version = platform.python_version()  # a text such as "3.14.5"
say(f"Python version: {python_version}")
# The first two numbers of the version, as whole numbers: "3.14.5" -> 3 and 14.
major, minor = (int(part) for part in python_version.split(".")[:2])
```

```
# Pairs of numbers are compared like words in a dictionary: first the first number,
# then, if they are equal, the second one.
check((major, minor) >= (3, 12), "Python is version 3.12 or newer")
```

Out [2]:

```
Python version: 3.14.5
PASS Python is version 3.12 or newer
```

Text cell:

```
## 6. The packages and their versions

The dictionary ‘PINNED‘ below holds, for each package, the version with which the
book was built. The loop prints the installed and the pinned version of every
package, one line each; then the check compares them.
```

In [3]:

```
PINNED = {  # package name -> the version with which the book was built
    "numpy": "2.4.6",
    "sympy": "1.14.0",
    "mpmath": "1.3.0",
    "matplotlib": "3.11.0",
    "jupyterlab": "4.4.10",
    "nbformat": "5.10.4",
    "nbclient": "0.10.2",
    "ipykernel": "7.1.0",
    "nbconvert": "7.16.6",
}
for package, pinned in PINNED.items():
    installed = importlib.metadata.version(package)  # error if not installed
    # {package:12} pads the name with blanks to 12 characters: aligned columns.
    say(f"{package:12} installed {installed:10} pinned {pinned}")
# The packages whose installed version differs from the pinned one (a list):
different = [p for p, v in PINNED.items() if importlib.metadata.version(p) != v]
check(different == [], "every package has its pinned version")
```

Out [3]:

```
numpy        installed 2.4.6      pinned 2.4.6
sympy        installed 1.14.0     pinned 1.14.0
mpmath       installed 1.3.0      pinned 1.3.0
matplotlib   installed 3.11.0     pinned 3.11.0
jupyterlab   installed 4.4.10     pinned 4.4.10
nbformat     installed 5.10.4     pinned 5.10.4
nbclient     installed 0.10.2     pinned 0.10.2
ipykernel    installed 7.1.0      pinned 7.1.0
nbconvert    installed 7.16.6     pinned 7.16.6
PASS every package has its pinned version
```

Text cell:

```
## 7. Rust (cargo)

The next cell looks for the program cargo. If it is installed, the cell prints its
version; if it is not, the cell says so. This is not a check: only the notebooks
that run the Rust programs of the repository need cargo, and they say so in their
instructions.
```

In [4]:

```
import shutil  # finds a program on the computer
import subprocess  # runs a program and reads what it prints

cargo = shutil.which("cargo")  # where cargo is, or None when it is not installed
if cargo is None:
    say("cargo is not installed; only the notebooks that run the Rust programs of "
        "the repository need it.")
else:
    completed = subprocess.run([cargo, "--version"], capture_output=True, text=True)
    say(f"cargo version: {completed.stdout.strip()}")
```

Out [4]:

```
cargo version: cargo 1.91.1 (ea2d97820 2025-10-10)
```

Text cell:

```
## 8. Three small computations

**numpy.** The determinant of the $2 \times 2$ matrix with rows $(1, 2)$ and
$(3, 4)$ is $1 \cdot 4 - 2 \cdot 3 = -2$. numpy computes it with floating-point
numbers (numbers with about 16 significant digits), so the result may differ from
$-2$ in the last digit; the check therefore allows a difference of $10^{-12}$.
```

In [5]:

```
import numpy as np  # arrays of numbers, matrices, linear algebra

matrix = np.array([[1.0, 2.0], [3.0, 4.0]])  # the rows (1, 2) and (3, 4)
determinant = np.linalg.det(matrix)  # 1*4 - 2*3 = -2, up to rounding
report("determinant of the matrix with rows (1, 2) and (3, 4)", f"{determinant:.12f}")
check(abs(determinant - (-2.0)) < 1e-12, "numpy: the determinant is -2")
```

Out [5]:

```
RESULT determinant of the matrix with rows (1, 2) and (3, 4) = -2.000000000000
PASS numpy: the determinant is -2
```

Text cell:

```
**sympy.** sympy computes exactly, with symbols. The derivative of $\sin^2 x$ is
$2 \sin x \cos x$ by the chain rule, and $2 \sin x \cos x = \sin 2x$ by the
double-angle formula. sympy prints the derivative in its own notation (‘*‘ means
times, ‘**‘ means power), and the check asks sympy to simplify the difference to
zero.
```

In [6]:

```
import sympy as sp  # exact algebra and calculus with symbols

x = sp.symbols("x")  # a symbol: a letter that stands for any number
derivative = sp.diff(sp.sin(x) ** 2, x)  # the derivative of sin(x)^2 with respect to x
say(f"d/dx sin(x)^2 = {derivative}")
check(sp.simplify(derivative - sp.sin(2 * x)) == 0,
      "sympy: the derivative of sin(x)^2 is sin(2x)")
```

Out [6]:

```
d/dx sin(x)^2 = 2*sin(x)*cos(x)
PASS sympy: the derivative of sin(x)^2 is sin(2x)
```

Text cell:

```
**mpmath.** mpmath computes with as many digits as we ask for. The number $\pi$
begins 3.14159265358979323846264338327950288 4. Its 30th significant digit is a 7
and its 31st is a 9; because 9 is 5 or more, rounding to 30 significant digits
raises the 7 to an 8: $\pi$ to 30 significant digits is
3.14159265358979323846264338328.
```

In [7]:

```
import mpmath  # numbers with as many digits as we ask for

mpmath.mp.dps = 30  # dps = decimal places: work with 30 significant digits
pi_text = mpmath.nstr(mpmath.pi, 30)  # pi written with 30 significant digits
say(f"pi to 30 significant digits: {pi_text}")
check(pi_text == "3.14159265358979323846264338328", "mpmath: pi to 30 digits")
```

Out [7]:

```
pi to 30 significant digits: 3.14159265358979323846264338328
PASS mpmath: pi to 30 digits
```

Text cell:

```
## 9. Two teaching plots

The next cell draws the parabola $y = x^2$, its tangent line $y = 2x - 1$ at the
point $(1, 1)$, and the point itself, for $x$ from $-1$ to $3$. `np.linspace(a, b,
n)` makes $n$ equally spaced numbers from $a$ to $b$; arithmetic on such an array
acts on every number of it. The check confirms that the parabola minus the line,
$(x - 1)^2$, is never negative and is zero at $x = 1$.
```

In [8]:

```
x_values = np.linspace(-1.0, 3.0, 401)  # 401 equally spaced numbers from -1 to 3
parabola = x_values ** 2  # y = x^2 at each of these numbers
tangent = 2.0 * x_values - 1.0  # the tangent line y = 1 + 2 (x - 1) = 2x - 1
gap = parabola - tangent  # (x - 1)^2 at each number

fig, ax = plt.subplots()  # a new figure with one pair of axes
ax.plot(x_values, parabola, label="parabola $y = x^2$")
ax.plot(x_values, tangent, "--", label="tangent line $y = 2x - 1$")
ax.plot([1.0], [1.0], "o", color="black", label="the point $(1, 1)$")
ax.set_xlabel("$x$")  # the label of the horizontal axis
ax.set_ylabel("$y$")  # the label of the vertical axis
ax.set_title("A parabola and its tangent line at $x = 1$ (slope 2)")
ax.legend()  # the box that names the three curves
save_figure(fig, "parabola_tangent",
            "The parabola $y = x^2$ (solid line), its tangent line $y = 2x - 1$ at "
            "the point $(1, 1)$ (dashed line) and the point itself (black dot), for "
            "$x$ from $-1$ to $3$; horizontal axis $x$, vertical axis $y$ (pure "
            "numbers, no units). The line touches the parabola only at $(1, 1)$ "
            "and lies below it everywhere else; its slope $2$ is the derivative "
            "$2x$ of $x^2$ at $x = 1$.")
check(gap.min() >= 0.0 and abs(gap[200]) < 1e-15,
      "the tangent line lies below the parabola and touches it at x = 1")
```

Out [8]:

```
Figure 00a.1 saved as Revision/textbook/figures/00a_1_parabola_tangent.png
PASS the tangent line lies below the parabola and touches it at x = 1
```

Text cell:

```
The next cell draws $e^{t}$, $e^{-t}$ and their product for $t$ from $-2$ to $2$,
and checks that the product equals 1 at all 401 points up to rounding (a
difference of at most $10^{-14}$).
```

In [9]:

```
t = np.linspace(-2.0, 2.0, 401)  # 401 equally spaced numbers from -2 to 2
growing = np.exp(t)  # e^t
shrinking = np.exp(-t)  # e^(-t)
```

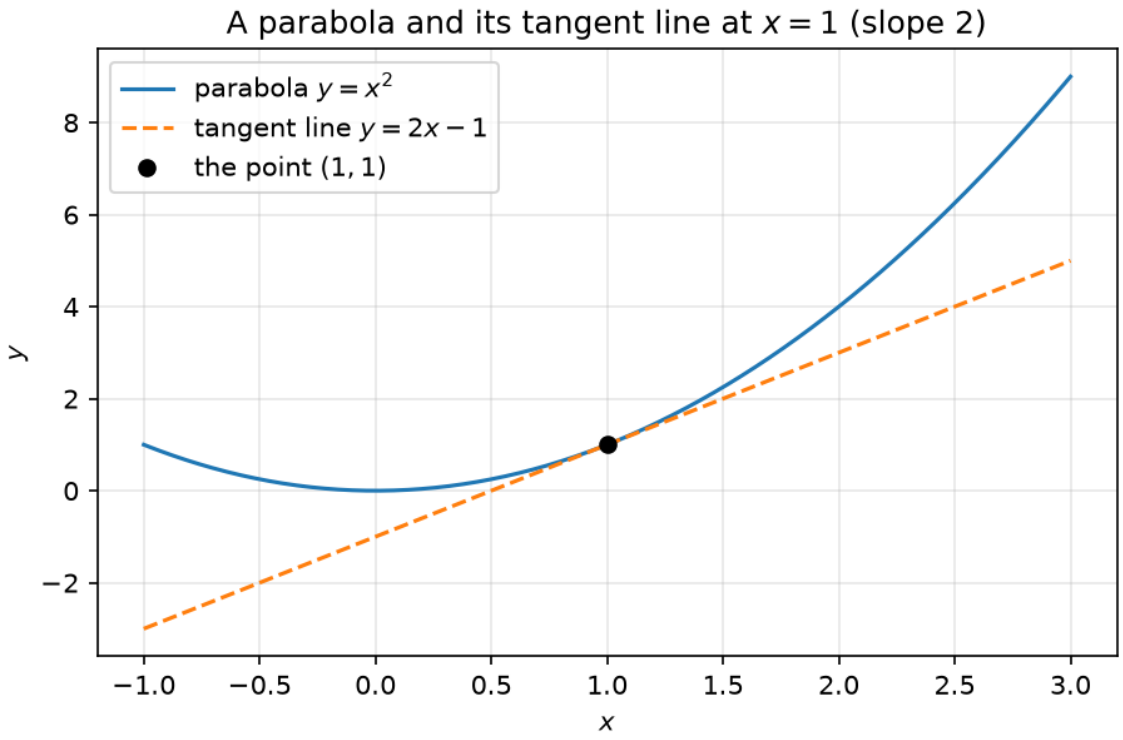

Figure 1: The parabola $y = x^2$ (solid line), its tangent line $y = 2x - 1$ at the point $(1, 1)$ (dashed line) and the point itself (black dot), for x from -1 to 3; horizontal axis x, vertical axis y (pure numbers, no units). The line touches the parabola only at $(1, 1)$ and lies below it everywhere else; its slope 2 is the derivative $2x$ of x^2 at $x = 1$. (Notebook 00a, figure 1.)

```
product = growing * shrinking  # e^t e^(-t), which is 1

fig, ax = plt.subplots()
ax.plot(t, growing, label="$e^{t}$ (grows)")
ax.plot(t, shrinking, "--", label="$e^{-t}$ (shrinks)")
ax.plot(t, product, ":", color="black", label="the product $e^{t} e^{-t} = 1$")
ax.set_xlabel("$t$")
ax.set_ylabel("value")
ax.set_title("A growing and a shrinking exponential")
ax.legend()
save_figure(fig, "growth_and_decay",
            "The growing exponential $e^{t}$ (solid line), the shrinking "
            "exponential $e^{-t}$ (dashed line) and their product (dotted line) "
            "for $t$ from $-2$ to $2$; horizontal axis $t$, vertical axis the value "
            "(pure numbers, no units). Each of the two curves is the mirror image "
            "of the other in the vertical axis $t = 0$, and their product is "
            "exactly $1$ at every $t$: what one factor gains, the other loses.")
check(np.max(np.abs(product - 1.0)) < 1e-14, "e^t times e^(-t) is 1 at every t")
```

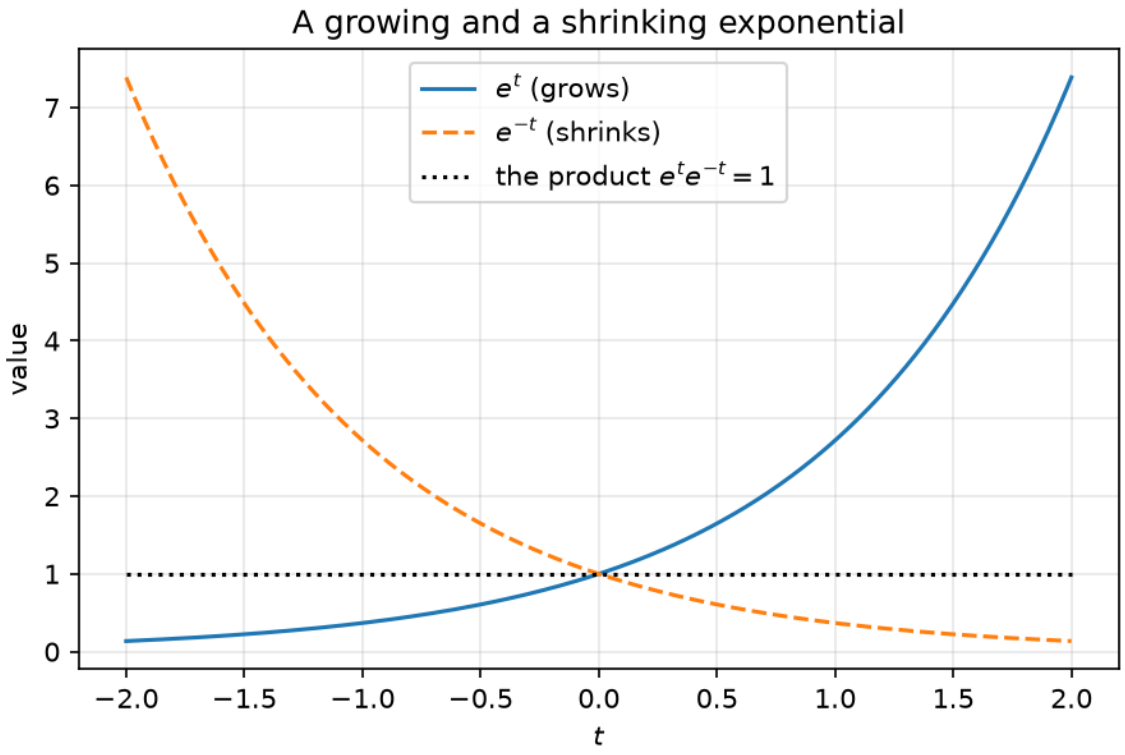

Figure 2: The growing exponential e^t (solid line), the shrinking exponential e^{-t} (dashed line) and their product (dotted line) for t from -2 to 2; horizontal axis t, vertical axis the value (pure numbers, no units). Each of the two curves is the mirror image of the other in the vertical axis $t = 0$, and their product is exactly 1 at every t: what one factor gains, the other loses. (Notebook 00a, figure 2.)

Out [9]:

```
Figure 00a.2 saved as Revision/textbook/figures/00a_2_growth_and_decay.png
PASS e^t times e^(-t) is 1 at every t
```

Text cell:

```
## 10. The last check

The last cell checks that both figure files exist in the folder
Revision/textbook/figures and prints the number of checks that passed.
```

In [10]:

```
for name in ("00a_1_parabola_tangent.png", "00a_2_growth_and_decay.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

Out [10]:

```
PASS the figure file 00a_1_parabola_tangent.png exists
PASS the figure file 00a_2_growth_and_decay.png exists
ALL 9 CHECKS PASSED (notebook 00a)
```

Text cell:

```
## 11. What this notebook showed

- Python, the pinned packages and (when it is installed) cargo work on this
  computer: every notebook of the book can run here.
- Every notebook of the book has the same form: numbered sections, a markdown cell
  before every code cell, checks that print PASS lines, figures saved with
  ‘save_figure‘, and a last line that counts the checks.
- A tangent line touches a parabola at one point and its slope is the derivative.
- A growing and a shrinking exponential with opposite exponents have the product 1:
  the pattern of the author’s metric, in which ordinary space inflates with
  $e^{a_4}$ while the three extra times deflate with $e^{-a_4}$.
```

0.13 Line-by-line walk-through of Notebook 00a

The notebook has ten code cells, In [1] to In [10]. This section explains every line of every one of them. (The label In [k] is the number that Jupyter gives a code cell when it runs it; Out [k] is what that cell printed.)

In [1], the set-up cell. Its first part repeats the complete run instructions of Section 0.11 as **comment lines**: every line that starts with `#` is a comment, which Python skips. They are there so that the notebook file carries its own instructions, even when it is copied without the book. The code starts after the line THE SET-UP between two lines of `=` signs. The set-up cell is the same in every notebook of the book, except for the one line that names the notebook.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of a package) so that the code can use it; the text after `#` on each line is a comment. `json`, `os`, `textwrap` and `pathlib` come with Python itself. `from pathlib import Path` takes the single name `Path` out of the module `pathlib`; a `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`, and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python code), which show a picture file below a cell.

```
NOTEBOOK_ID = "00a"  # this notebook: chapter 00, example a
```

A **variable** is a name for a value; this line gives the name `NOTEBOOK_ID` to the text `"00a"` (a text in quotes is called a **string**). It is the only line of the set-up code that differs from notebook to notebook; the figure files and the last printed line are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes below the `def` line is its **docstring**, a description that Python stores but does not run. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` lists the parent folder, its parent, and so on up to the top of the disk; `[here, *here.parents]` is the **list** (an ordered collection, written in square brackets) that starts with `here` and continues with all of them. The `for` loop takes the folders of this list one after the other and runs the indented lines for each. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains `Revision/textbook/requirements.txt` is the repository, and `return` hands it back and ends the function. If no folder qualifies, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do (two strings written next to each other are joined into one).

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The first code line calls the function and names its result `REPO`. As the comment says, the notebook never prints `REPO`. The last line chooses the folder below which the notebook writes its files. `os.environ` holds the **environment variables** of the running program (named texts that a program receives from the computer when it starts); `.get(name, default)` returns the value of the variable `TEXTBOOK_OUTPUT_ROOT` if it is set and the default `str(REPO)` (the repository folder as a string) otherwise, and `Path(...)` turns the string into a path. When you run the notebook the variable is not set, so the files go into the repository. The checking tool nbkit sets it to a scratch folder (Section 0.9), so that a check never changes the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

Two small functions. `repository_file("Revision/...")` gives the full path of a file of the repository, for reading. `output_file("Revision/...")` gives the full path at which to write a file; `path.parent` is the folder that will hold it, and `.mkdir(parents=True, exist_ok=True)` creates that folder together with any missing folder above it, and does nothing if it exists already.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, so that every printed line fits the width of a page of the book. `str(text)` turns any value into a string; `textwrap.fill` breaks it at blanks into lines of at most 89 characters, every line after the first starting with four blanks; `print` writes the result below the cell.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

matplotlib reads personal settings from a file on your computer if you have one. `matplotlib.rcdefaults()` returns to the built-in settings, so that the figures are the same on every computer.

`plt.rcParams.update({...})` then sets four settings for every figure of the notebook: the size of a figure (7.0 inches wide and 4.2 inches high), the size of its letters (10 points), and a faint grid of lines behind the curves (`grid.alpha` 0.3 means 30 per cent opaque). The braces `{...}` make a **dictionary**: pairs of a key and a value, written `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/00a.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes the text `{}` and a line end into the captions file: an empty dictionary of captions, which `save_figure` fills. `encoding="utf-8"` fixes how the letters are stored as bytes, and `newline="\n"` stores the same line end on every operating system (Section 0.22 explains why this matters).

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

This function saves a figure and shows it. `setdefault(name, value)` returns the number already stored for this figure name, or, for a new name, stores and returns `len(FIGURE_NUMBERS) + 1` (one more than the number of figures so far); so the figures are numbered 1, 2, 3, ... and a cell that you run twice keeps the number of its figure. The file name is made of the notebook id, the number and the name, for example `00a_1_parabola_tangent.png`. `fig.savefig` writes the picture as a PNG file with 150 dots per inch, cuts away the empty margin and, as the comments say, stores no program name in the file, so that two runs write exactly the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time at the end of the cell. The caption is stored in `CAPTIONS`, and the whole dictionary is written into the captions file: `json.dum`

`ps` turns it into JSON text with one entry per line (`indent=1`) and the keys in alphabetical order (`sort_keys=True`). `display(Image(...))` shows the saved picture below the cell; the `metadata` entry tells the book's tools which file the picture is. The last line prints where the figure was saved.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty list. `check` is the function behind every check of the book. `condition` is a statement that is either true (`True`) or false (`False`). If it is false, `raise AssertionError(...)` stops the notebook with an error that names the check. (Python also has a statement `assert` for this; the docstring says why the book does not use it: Python started with its option O, for "optimise", skips every `assert`.) If the condition is true, the name is appended to `PASSED` and a line `PASS name` is printed. `record=None` makes the third argument optional: a check that reproduces a number of the Revision record passes the record's file and check name, and `check` prints them on a second line that starts with five blanks and the word reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; `(f" {unit}" if unit else "")` adds a blank and the unit when a unit is given and nothing otherwise (an empty string counts as false). `all_checks_passed` prints the last line of every notebook; `len(PASSED)` is the number of checks that passed. The last statement prints the one line of Out [1].

In [2], Python.

```
import importlib.metadata  # reads the version numbers of installed packages
import platform  # reads the version number of Python
```

```
python_version = platform.python_version()  # a text such as "3.14.5"
say(f"Python version: {python_version}")
```

`platform.python_version()` returns the version of the running Python as a string; on the computer that built the book it is `"3.14.5"`, which the next line prints (Out [2], first line).

```
# The first two numbers of the version, as whole numbers: "3.14.5" -> 3 and 14.
major, minor = (int(part) for part in python_version.split(".")[:2])
# Pairs of numbers are compared like words in a dictionary: first the first number,
# then, if they are equal, the second one.
check((major, minor) >= (3, 12), "Python is version 3.12 or newer")
```

`python_version.split(".")` cuts the string at the dots into the list `["3", "14", "5"]`; `[:2]` keeps the first two entries; `int(part)` turns each into a whole number; and `major, minor = ...` names them 3 and 14. Python compares the pairs `(3, 14)` and `(3, 12)` as the comment says: the first numbers are equal, so the second numbers decide, and 14 is at least 12. The condition is true, and the check prints PASS Python is version 3.12 or newer.

In [3], the packages.

```
PINNED = {  # package name -> the version with which the book was built
    "numpy": "2.4.6",
    "sympy": "1.14.0",
    "mpmath": "1.3.0",
    "matplotlib": "3.11.0",
    "jupyterlab": "4.4.10",
    "nbformat": "5.10.4",
    "nbclient": "0.10.2",
    "ipykernel": "7.1.0",
    "nbconvert": "7.16.6",
}
```

The dictionary `PINNED` holds the nine packages of Section 0.8 with their pinned versions.

```
for package, pinned in PINNED.items():
    installed = importlib.metadata.version(package)  # error if not installed
    # {package:12} pads the name with blanks to 12 characters: aligned columns.
    say(f"{package:12} installed {installed:10} pinned {pinned}")
# The packages whose installed version differs from the pinned one (a list):
different = [p for p, v in PINNED.items() if importlib.metadata.version(p) != v]
check(different == [], "every package has its pinned version")
```

`PINNED.items()` gives the pairs (package, pinned version); the loop names them `package` and `pinned`. `importlib.metadata.version(package)` reads the installed version (and stops with an error if the package is not installed). In the f-string, `{package:12}` writes the name padded with blanks to 12 characters and `{installed:10}` the version padded to 10, so that the printed table of Out [3] has straight columns. The line `different = [...]` is a **list comprehension**: it collects

every package `p` whose installed version differs from its pinned version `v` (`!=` means "is not equal to"). The check requires that this list is empty, `[]`.

In [4], cargo.

```
import shutil  # finds a program on the computer
import subprocess  # runs a program and reads what it prints

cargo = shutil.which("cargo")  # where cargo is, or None when it is not installed
if cargo is None:
    say("cargo is not installed; only the notebooks that run the Rust programs of "
        "the repository need it.")
else:
    completed = subprocess.run([cargo, "--version"], capture_output=True, text=True)
    say(f"cargo version: {completed.stdout.strip()}")
```

`shutil.which("cargo")` searches the folders in which the computer looks for programs and returns the path of cargo, or the special value `None` if there is none. `if ... else` runs the first indented block when the condition is true and the second block otherwise. `subprocess.run([...])` runs cargo with the option that asks for its version (the list holds the program and the option, two hyphens followed by the word version); `capture_output=True, text=True` collects what it prints as a string in `completed.stdout`, and `.strip()` removes the line end. On the computer that built the book cargo is installed, and Out [4] shows its version, 1.91.1. This cell prints but checks nothing, because most notebooks do not need cargo.

In [5], numpy.

```
import numpy as np  # arrays of numbers, matrices, linear algebra

matrix = np.array([[1.0, 2.0], [3.0, 4.0]])  # the rows (1, 2) and (3, 4)
determinant = np.linalg.det(matrix)  # 1*4 - 2*3 = -2, up to rounding
report("determinant of the matrix with rows (1, 2) and (3, 4)", f"{determinant:.12f}")
check(abs(determinant - (-2.0)) < 1e-12, "numpy: the determinant is -2")
```

`np.array` makes a matrix from the list of its rows. `np.linalg.det` computes its determinant, $1 \cdot 4 - 2 \cdot 3 = -2$, with floating-point numbers, which keep about 16 significant digits and may be wrong in the last one (Section 0.22). `{determinant:.12f}` prints the number with 12 digits after the decimal point: Out [5] shows -2.000000000000. `abs(...)` is the absolute value, and `1e-12` means 10^{-12}: the check accepts the result when it differs from -2 by less than 10^{-12}.

In [6], sympy.

```
import sympy as sp  # exact algebra and calculus with symbols

x = sp.symbols("x")  # a symbol: a letter that stands for any number
derivative = sp.diff(sp.sin(x) ** 2, x)  # the derivative of sin(x)^2 with respect to x
say(f"d/dx sin(x)^2 = {derivative}")
check(sp.simplify(derivative - sp.sin(2 * x)) == 0,
      "sympy: the derivative of sin(x)^2 is sin(2x)")
```

`sp.symbols("x")` makes the symbol x. In Python `**` means "to the power", so `sp.sin(x) ** 2` is $\sin^2 x$, and `sp.diff(..., x)` differentiates it with respect to x; by the chain rule the result is $2\sin x\cos x$, which sympy prints as `2*sin(x)*cos(x)` (Out [6]). The check asks sympy to simplify $2\sin x\cos x - \sin 2x$; by the double-angle formula $\sin 2x = 2\sin x\cos x$ the result is exactly 0, and `== 0` tests that.

In [7], mpmath.

```
import mpmath  # numbers with as many digits as we ask for

mpmath.mp.dps = 30  # dps = decimal places: work with 30 significant digits
pi_text = mpmath.nstr(mpmath.pi, 30)  # pi written with 30 significant digits
say(f"pi to 30 significant digits: {pi_text}")
check(pi_text == "3.14159265358979323846264338328", "mpmath: pi to 30 digits")
```

`mpmath.mp.dps = 30` tells mpmath to compute with 30 significant decimal digits. `mpmath.nstr(mpmath.pi, 30)` writes π as a string with 30 significant digits, correctly rounded (the 30th digit of π is a 7 and the 31st a 9, so the 7 is rounded up to 8), and the check compares it with the known value character by character.

In [8], the parabola and its tangent line.

```
x_values = np.linspace(-1.0, 3.0, 401)  # 401 equally spaced numbers from -1 to 3
parabola = x_values ** 2  # y = x^2 at each of these numbers
tangent = 2.0 * x_values - 1.0  # the tangent line y = 1 + 2 (x - 1) = 2x - 1
gap = parabola - tangent  # (x - 1)^2 at each number
```

`np.linspace(-1.0, 3.0, 401)` makes an **array** (numpy's list of numbers) of 401 numbers from -1 to 3 with equal steps of $4/400 = 0.01$. Arithmetic on an array acts on every number in it: `x_values ** 2` is the array of the 401 squares, and `2.0 * x_values - 1.0` the array of the 401 values of the tangent line of Section 0.10. Their difference `gap` is $(x-1)^2$ at each point.

```
fig, ax = plt.subplots()  # a new figure with one pair of axes
ax.plot(x_values, parabola, label="parabola $y = x^2$")
ax.plot(x_values, tangent, "--", label="tangent line $y = 2x - 1$")
ax.plot([1.0], [1.0], "o", color="black", label="the point $(1, 1)$")
ax.set_xlabel("$x$")  # the label of the horizontal axis
ax.set_ylabel("$y$")  # the label of the vertical axis
ax.set_title("A parabola and its tangent line at $x = 1$ (slope 2)")
ax.legend()  # the box that names the three curves
```

`plt.subplots()` makes a new figure `fig` with one pair of axes `ax`. `ax.plot(xs, ys)` draws a line through the points with these coordinates; the third argument of the second `ax.plot` line, a string of two hyphens, makes that line dashed, and `"o"` in the third one draws a dot instead of a line; `label=` is the name shown in the legend, and text between dollar signs is typeset as mathematics. The remaining lines label the axes, set the title and draw the legend.

```
save_figure(fig, "parabola_tangent",
            "The parabola $y = x^2$ (solid line), its tangent line $y = 2x - 1$ at "
```

```
            "the point $(1, 1)$ (dashed line) and the point itself (black dot), for "
            "$x$ from $-1$ to $3$; horizontal axis $x$, vertical axis $y$ (pure "
            "numbers, no units). The line touches the parabola only at $(1, 1)$ "
            "and lies below it everywhere else; its slope $2$ is the derivative "
            "$2x$ of $x^2$ at $x = 1$.")
check(gap.min() >= 0.0 and abs(gap[200]) < 1e-15,
      "the tangent line lies below the parabola and touches it at x = 1")
```

`save_figure` saves the figure as `00a_1_parabola_tangent.png` with its caption (Python joins the strings written next to each other into one) and prints Figure 00a.1 saved as ... in Out [8]. The check uses `gap.min()`, the smallest of the 401 numbers of `gap`, which must not be negative, and `gap[200]`, the entry number 200 counted from 0, which belongs to $x = -1 + 200 \cdot 0.01 = 1$ and must be 0 up to 10^{-15}. What Figure 00a.1 shows: the dashed line touches the solid parabola at the black dot and stays below it on both sides, as derived in Section 0.10.

In [9], the two exponentials.

```
t = np.linspace(-2.0, 2.0, 401)  # 401 equally spaced numbers from -2 to 2
growing = np.exp(t)  # e^t
shrinking = np.exp(-t)  # e^(-t)
product = growing * shrinking  # e^t e^(-t), which is 1
```

`np.exp` is the exponential function, applied to every number of the array. The product of two arrays is taken number by number.

```
fig, ax = plt.subplots()
ax.plot(t, growing, label="$e^{t}$ (grows)")
ax.plot(t, shrinking, "--", label="$e^{-t}$ (shrinks)")
ax.plot(t, product, ":", color="black", label="the product $e^{t} e^{-t} = 1$")
ax.set_xlabel("$t$")
ax.set_ylabel("value")
ax.set_title("A growing and a shrinking exponential")
ax.legend()
```

The plotting lines work as in In [8]: a solid line for e^t, a dashed one (two hyphens) for e^{-t}, and a dotted black one (`":"`) for their product.

```
save_figure(fig, "growth_and_decay",
            "The growing exponential $e^{t}$ (solid line), the shrinking "
            "exponential $e^{-t}$ (dashed line) and their product (dotted line) "
            "for $t$ from $-2$ to $2$; horizontal axis $t$, vertical axis the value "
            "(pure numbers, no units). Each of the two curves is the mirror image "
            "of the other in the vertical axis $t = 0$, and their product is "
            "exactly $1$ at every $t$: what one factor gains, the other loses.")
check(np.max(np.abs(product - 1.0)) < 1e-14, "e^t times e^(-t) is 1 at every t")
```

`save_figure` saves the figure as `00a_2_growth_and_decay.png`. The check computes `np.abs(product - 1.0)`, the distance of each of the 401 products from 1, takes the largest with `np.max`,

and requires it to be below 10^{-14}: up to rounding, $e^t e^{-t} = 1$. What Figure 00a.2 shows: the two curves are mirror images of each other in the line $t = 0$, and the dotted product stays flat at 1.

In [10], the last check.

```
for name in ("00a_1_parabola_tangent.png", "00a_2_growth_and_decay.png"):
    check(output_file(f"{FIGURE_FOLDER}/{name}").is_file(),
          f"the figure file {name} exists")
all_checks_passed()
```

The loop runs over a **tuple** (a list in round brackets that cannot be changed) of the two figure names and checks that each file exists. `all_checks_passed()` prints the last line, ALL 9 CHECKS PASSED (notebook 00a): one check each in In [2], In [3], In [5], In [6], In [7], In [8] and In [9], and two in In [10].

0.14 The eight directions and the author's metric

Every later chapter lives in the author's universe, so we take a first look at it now, with nothing but school algebra. Chapter 3 returns to it with the full mathematics of curved space; here we need only four facts: which directions are like space and which are like time, how lengths along each direction change as the time runs, why ordinary space inflates while the extra times deflate, and why the volume does not change.

Steps and their sizes. On a flat sheet of paper with the coordinates x and y, a small step dx to the right and dy upwards has a length ds with $ds^2 = dx^2 + dy^2$: this is the theorem of Pythagoras for the right-angled triangle with the sides dx and dy. In ordinary space with the coordinates x_1, x_2, x_3 the same theorem, used twice, gives $ds^2 = dx_1^2 + dx_2^2 + dx_3^2$. A **metric** is a rule of this kind: it turns the small steps $dx_0, dx_1, \ldots, dx_7$ along the eight coordinates into one number ds^2, the squared size of the step. The rules of this book are **diagonal**: each squared step is multiplied by its own number g_{ii}, called the entry of the metric for the direction x_i, and the results are added:

$$ds^2 = g_{00}\, dx_0^2 + g_{11}\, dx_1^2 + \cdots + g_{77}\, dx_7^2.$$

The entries $g_{00}, \ldots, g_{77}$ may change from place to place and from time to time; that is what can make a space curved (Chapter 3).

Space-like and time-like. In the special relativity of Einstein (1905), in the form that Minkowski gave it in 1908, a step in space and time is measured with a minus sign in front of the time step: in units in which the speed of light is 1, the squared size of a step is $dx_1^2 + dx_2^2 + dx_3^2 - dx_4^2$ when x_4 is the time. A direction whose entry is positive is called **space-like** (a step along it is measured like a distance); a direction whose entry is negative is called **time-like** (a step along it is measured like a duration). The list of the signs of the eight directions is called η (the Greek letter eta), and the numbers of plus and minus signs form the **signature**. In the author's universe

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

in the order $x_0, \ldots, x_7$: the four directions x_0, x_1, x_2 and x_3 are space-like, the four directions x_4, x_5, x_6 and x_7 are time-like, and the signature is (4,4). Here diag(...) is the square table of numbers

(a **matrix**, Chapter 1) that has the listed numbers on its diagonal, from the top left to the bottom right, and zeros everywhere else.

The author's metric. The author gave the metric of their primordial universe as an 8×8 diagonal matrix (`Revision/SPEC.md`, section 1). Its eight entries, in the order $x_0, x_1, \ldots, x_7$, are

$$g_{00} = \cot^2 z, \qquad g_{11} = g_{22} = g_{33} = e^{2a_4} \sin^{1/3} z, \qquad g_{44} = -1,$$

$$g_{55} = g_{66} = g_{77} = -b_4 \, e^{-2a_4} \sin^{1/3} z,$$

where $z = 6Hx_0$, $H > 0$ is a constant of the author, and a_4 and b_4 are functions of the time x_4 alone, the **metric functions** (their field equations are the subject of Chapter 12); b_4 is positive. The function b_4 is the author's change of 2026-10-14: with $b_4 = 1$ the metric is the one used before that date. With the author's own weights every vacuum history has b_4 constant (`Revision/metric_b4/results/vacuum-b4.json`), and a constant b_4 is removed by rescaling x_5, x_6, x_7; the backgrounds of the later chapters therefore take $b_4 = 1$, as the Revision record does, and say so where they do (the record of the change: `Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md`). The hidden coordinate is restricted so that $0 < z < \pi/2$; this interval is called the **patch**. Here $\sin^{1/3} z$ means $(\sin z)^{1/3}$, the cube root of $\sin z$, and $\cot z = \cos z / \sin z$. Status: ASSUMED. The metric is the author's input; the book does not derive it, and Chapter 12 asks which source it would need.

We now derive the four facts. Each line of a derivation is followed, in brackets, by the rule that produced it from the line before.

Fact 1: the signs. Take any point of the patch, $0 < z < \pi/2$, any value of a_4 and any positive value of b_4.

$$\sin z > 0 \quad \text{and} \quad \cos z > 0$$

(the sine and the cosine of an angle between 0 and a right angle are positive),

$$\sin^{1/3} z > 0$$

(the cube root of a positive number is positive),

$$e^{2a_4} > 0 \quad \text{and} \quad e^{-2a_4} > 0$$

(the exponential function e^u is positive for every number u),

$$g_{11} = e^{2a_4} \sin^{1/3} z > 0 \quad \text{and} \quad g_{55} = -b_4 \, e^{-2a_4} \sin^{1/3} z < 0$$

(a product of positive numbers is positive, $b_4 > 0$, and a positive number with a minus sign in front is negative),

$$\cot z = \frac{\cos z}{\sin z} > 0, \quad \text{so} \quad g_{00} = \cot^2 z > 0$$

(a quotient of two positive numbers is positive, and the square of a nonzero number is positive). Together with $g_{44} = -1 < 0$ the signs of the eight entries are $(+,+,+,+,-,-,-,-)$, exactly the list η, at every point of the patch and for every value of a_4 and of $b_4 > 0$. Status: PROVED (by the school algebra above). The Revision record states the signs in the file `Revision/algebra/gammas.json`, and its Wolfram verifier checks them (`Revision/algebra/reports/wolfram-algebra.json`, check `eta_in_author_order`); Notebook 00b confirms the signs of the eight entries at 14457 points (COMPUTED).

Fact 2: the length factors. A step dx_1 along x_1 alone (all other steps zero) has $ds^2 = g_{11}\,dx_1^2$, so its size is $|ds| = \sqrt{|g_{11}|}\,|dx_1|$. The number $f_i = \sqrt{|g_{ii}|}$ is called the **length factor** (or scale factor) of the direction x_i: it converts a step of the coordinate into a length. For x_1:

$$f_1 = \sqrt{e^{2a_4}\sin^{1/3} z}$$

(the definition, with $|g_{11}| = g_{11}$ because $g_{11} > 0$ by Fact 1),

$$f_1 = \sqrt{e^{2a_4}}\,\sqrt{\sin^{1/3} z}$$

(the square root of a product of two nonnegative numbers is the product of their square roots),

$$f_1 = e^{a_4}\sin^{1/6} z$$

(first, $\sqrt{e^{2a_4}} = e^{a_4}$, because e^{a_4} is positive and its square is $e^{a_4}e^{a_4} = e^{2a_4}$; second, $\sqrt{u^{1/3}} = (u^{1/3})^{1/2} = u^{1/6}$ by the power rule $(u^p)^q = u^{pq}$). The same three lines give $f_2 = f_3 = e^{a_4}\sin^{1/6} z$. For the extra times, $|g_{55}| = b_4\,e^{-2a_4}\sin^{1/3} z$ (a minus sign in front of a positive number is removed by the absolute value), and the same steps, with $\sqrt{b_4}$ as one more factor, give

$$f_5 = f_6 = f_7 = b_4^{1/2}\,e^{-a_4}\sin^{1/6} z.$$

Finally $f_4 = \sqrt{|-1|} = 1$, and $f_0 = \sqrt{\cot^2 z} = |\cot z| = \cot z$ (the square root of a square is the absolute value, and $\cot z > 0$ on the patch). Status: PROVED.

Fact 3: ordinary space inflates, the extra times deflate. Fix the hidden coordinate, so that $\sin^{1/6} z$ is a fixed positive number, and let b_4 be constant. When a_4 grows, e^{a_4} grows and $e^{-a_4} = 1/e^{a_4}$ shrinks (Section 0.10): the length factors of x_1, x_2, x_3 grow (ordinary space **inflates**) and those of x_5, x_6, x_7 shrink (the extra times **deflate**). The simplest history is $a_4 = AHx_4$ with a positive constant A, and $b_4 = 1$. It is the history that the Kohn-Sham chapters use, where it is ASSUMED as a **prescribed background** (`Revision/field_equations_a4/reports/ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`), and Chapter 12 shows that the sign of A is a choice: with $-A$ in place of A the roles of growth and shrinking are exchanged. Along this history

$$f_5 = e^{-AHx_4}\sin^{1/6} z$$

(substitution of $a_4 = AHx_4$ and $b_4 = 1$ into Fact 2),

$$\frac{df_5}{dx_4} = -AH\, e^{-AHx_4} \sin^{1/6} z$$

(the chain rule: the derivative of e^u with respect to x_4 is $e^u\, du/dx_4$, here with $u = -AHx_4$ and $du/dx_4 = -AH$; the constant factor $\sin^{1/6} z$ stays in front),

$$\frac{df_5}{dx_4} = -AH\, f_5$$

(the previous line contains f_5 itself, by the first line). A quantity whose rate of change is a fixed negative multiple of itself decreases **exponentially**: in every interval of time of length $1/(AH)$ it is multiplied by the same factor $e^{-1} = 0.3679$. The same steps give $df_1/dx_4 = +AH\, f_1$: ordinary space inflates exponentially. Status: PROVED (for the ASSUMED history). In every history the product of an inflating and a deflating factor contains no a_4:

$$f_1 f_5 = b_4^{1/2}\, e^{a_4} e^{-a_4} \sin^{1/6} z\, \sin^{1/6} z = b_4^{1/2} \sin^{1/3} z$$

(the law of exponents $e^u e^v = e^{u+v}$ gives $e^{a_4 - a_4} = e^0 = 1$, and $u^{1/6} u^{1/6} = u^{1/3}$); it is constant in time whenever b_4 is.

Fact 4: the determinant and the volume factor. The **determinant** is one number computed from a square matrix (Chapter 1 defines it in general); for a diagonal matrix it is the product of the diagonal entries (a fact proved in Chapter 1 and used here). For the author's metric:

$$\det g = \cot^2 z \cdot \left(e^{2a_4} \sin^{1/3} z\right)^3 \cdot (-1) \cdot \left(-b_4\, e^{-2a_4} \sin^{1/3} z\right)^3$$

(the product of the eight entries, the three equal entries of ordinary space and the three equal entries of the extra times collected as cubes),

$$\left(e^{2a_4} \sin^{1/3} z\right)^3 = e^{6a_4} \sin z$$

(the rule $(uv)^3 = u^3 v^3$, then $(e^{2a_4})^3 = e^{6a_4}$ and $(\sin^{1/3} z)^3 = \sin z$, both by the power rule $(u^p)^q = u^{pq}$),

$$\left(-b_4\, e^{-2a_4} \sin^{1/3} z\right)^3 = (-1)^3\, b_4^3\, e^{-6a_4} \sin z = -b_4^3\, e^{-6a_4} \sin z$$

(the same rules, and $(-1)^3 = -1$),

$$\det g = \cot^2 z \cdot e^{6a_4} \sin z \cdot (-1) \cdot \left(-b_4^3\, e^{-6a_4} \sin z\right)$$

(substitution of the two cubes into the first line),

$$\det g = b_4^3 \cdot e^{6a_4} e^{-6a_4} \cdot (-1)(-1) \cdot \sin^2 z \cot^2 z$$

(the factors of a product may be taken in any order),

$$\det g = b_4^3 \sin^2 z \cot^2 z$$

($e^{6a_4} e^{-6a_4} = e^0 = 1$ by the law of exponents, and $(-1)(-1) = 1$),

$$\det g = b_4^3 \sin^2 z \cdot \frac{\cos^2 z}{\sin^2 z} = b_4^3 \cos^2 z$$

(the definition $\cot z = \cos z / \sin z$, then cancelling $\sin^2 z$, which is not zero on the patch). The determinant does not contain a_4. Its square root is

$$\sqrt{|\det g|} = \sqrt{b_4^3 \cos^2 z} = b_4^{3/2} \cos z$$

(the determinant is positive, the square root of a product of nonnegative numbers is the product of their square roots, $\sqrt{b_4^3} = b_4^{3/2}$, and the square root of a square is the absolute value, $|\cos z| = \cos z$ on the patch). This number is the **volume factor**: a small box with the coordinate sides $dx_0, \ldots, dx_7$ has the sides $f_0\,dx_0, \ldots, f_7\,dx_7$ in length, so its volume is $f_0 f_1 \cdots f_7\,dx_0 \cdots dx_7$, and the product of the length factors is $f_0 \cdots f_7 = \sqrt{|g_{00}| \cdots |g_{77}|} = \sqrt{|\det g|}$ (a product of square roots is the square root of the product). Written with the length factors of Fact 2, $f_1 f_2 f_3 f_5 f_6 f_7 = (f_1 f_5)^3 = b_4^{3/2} \sin z$ by Fact 3, and $f_0 f_4 = \cot z$, so the volume factor is $b_4^{3/2} \sin z \cot z = b_4^{3/2} \cos z$ once more. The inflation of the three directions of ordinary space and the deflation of the three extra times cancel exactly in the volume; the volume factor changes in time only through b_4, and at $b_4 = 1$ it is $\cos z$. Status: PROVED, by the derivation above and by exact symbolic computations of the Revision record that hold for every function a_4:

- the Wolfram verifier of the field theory with b_4, in its report `Revision/theory/reports/wolfram-field-theory-b4.json`, check `sqrt_det_g` ($\det g = b_4^3 \cos^2 z$);
- the Wolfram verifier of the field equations for a_4 and b_4, check `sqrt_abs_det_g_is_cos_z` ($\sqrt{|\det g|} = b_4^{3/2} \cos z$), in its report `Revision/field_equations_a4/reports/wolfram-a4-report.json`;
- at $b_4 = 1$, the Wolfram verifier of the field theory, in its report `Revision/theory/reports/wolfram-field-theory.json`, check `sqrt_det_g_is_cos_z`, and the Python verifier of the field theory, in its report `Revision/theory/reports/python-field-theory.json`, check `sqrt_det_g_equals_cos_z`.

Numbers to check by hand. Take $b_4 = 1$. At $z = \pi/4$ we have $\sin(\pi/4) = 1/\sqrt{2} = 2^{-1/2}$, so $\sin^{1/6}(\pi/4) = 2^{-1/12} = 0.9439$, and $\cot(\pi/4) = 1$, $\cos(\pi/4) = 0.7071$. With $a_4 = 0.5$ the factor of ordinary space is $e^{0.5} \cdot 0.9439 = 1.6487 \cdot 0.9439 = 1.5562$ and that of an extra time $e^{-0.5} \cdot 0.9439 = 0.6065 \cdot 0.9439 = 0.5725$; with $a_4 = 1$ they are $2.7183 \cdot 0.9439 = 2.5657$ and $0.3679 \cdot 0.9439 = 0.3472$. In every case the product of the eight factors is $\cos(\pi/4) = 0.7071$. With $b_4 = 2$ every extra-time factor is multiplied by $\sqrt{2}$ and the product by $2^{3/2} = 2.8284$. Notebook 00b prints exactly these numbers.

Example: the eight directions in numbers and pictures. Notebook 00b reads the names and the signs of the eight coordinates from the Revision record, writes the author's metric with the package sympy and compares its eight entries, one by one, with the formulas that the Revision verifiers recorded (the metric with b_4, and the metric at $b_4 = 1$), checks the signs of the entries at 14457 points, computes the determinant exactly, prints the table of the length factors above, and draws four figures: the signs as a picture, the growing and the shrinking factor, the eight length factors as bars, and the volume factor. It checks every fact of this section and ends with ALL 17 CHECKS PASSED (notebook 00b).

0.15 How to run Notebook 00b

Step 1. What this notebook does and what it needs.

Notebook 00b (The eight directions and the author's metric: a first look) is the file `Revision /textbook/notebooks/00b_eight_directions.ipynb` of the repository Dirac_claude. It reads the names and the signs of the eight coordinates x0 to x7 from the Revision record, writes the author's metric (with the functions a4 and b4) with sympy, checks that its eight entries, their signs and its determinant b4^3 cos^2 z agree with what the Revision verifiers recorded, and draws four teaching plots: the signs as a heat map, the growing and the shrinking length factors, the eight length factors as bars, and the volume factor. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00b_eight_directions.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar

of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00b_eight_directions.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 00b_eight_directions.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/00b.captions.json`
- `Revision/textbook/figures/00b_1_eta_heat_map.png`
- `Revision/textbook/figures/00b_2_scale_factors.png`
- `Revision/textbook/figures/00b_3_length_factors.png`
- `Revision/textbook/figures/00b_4_volume_factor.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the four figure files of this notebook exist
ALL 17 CHECKS PASSED (notebook 00b)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/00b_eight_directions.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 00b_eight_directions.ipynb
python -m nbconvert --execute --inplace 00b_eight_directions.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

- "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of the Revision record is missing or damaged: the repository folder is incomplete. Delete the folder Dirac_claude, download it again with the git clone command of Step 3, and open the notebook from the new folder.

0.16 Notebook 00b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/00b_eight_directions.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook is a first look at the universe of the book. It computes no new
physics; it shows, with numbers and pictures, the facts about the eight directions
and the author's metric that every later chapter uses. It

- reads the names of the eight coordinates $x_0, x_1, \dots, x_7$ and their signs from a
  file of the Revision record (the computations stored in the folder Revision of
  the repository), and prints which directions are like space and which are like
  time;
- writes the author's metric with the package sympy and checks that its eight
  entries are exactly those that the Revision verifiers recorded, that their signs
  are the recorded signs, and that its determinant is $b_4^3 \cos^2 z$;
- shows what happens when the metric function $a_4$ grows: lengths along ordinary
  space grow (inflation) and lengths along the three extra times shrink (deflation),
  while the volume factor stays the same;
- draws four teaching plots and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 00b (The eight directions and the author's metric: a first look) is the file
`Revision/textbook/notebooks/00b_eight_directions.ipynb` of the repository Dirac_claude.
It reads the names and the signs of the eight coordinates x0 to x7 from the Revision
record, writes the author's metric (with the functions a4 and b4) with sympy, checks that
its eight entries, their signs and its determinant b4^3 cos^2 z agree with what the
Revision verifiers recorded, and draws four teaching plots: the signs as a heat map, the
growing and the shrinking length factors, the eight length factors as bars, and the
volume factor. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
```

2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00b_eight_directions.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00b_eight_directions.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 00b_eight_directions.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/00b.captions.json‘
- ‘Revision/textbook/figures/00b_1_eta_heat_map.png‘
- ‘Revision/textbook/figures/00b_2_scale_factors.png‘
- ‘Revision/textbook/figures/00b_3_length_factors.png‘
- ‘Revision/textbook/figures/00b_4_volume_factor.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the four figure files of this notebook exist
ALL 17 CHECKS PASSED (notebook 00b)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/00b_eight_directions.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command

below does what ‘jupyter lab‘ does, the second what the headless command does:

```
    python -m jupyterlab 00b_eight_directions.ipynb
    python -m nbconvert --execute --inplace 00b_eight_directions.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of the Revision record is missing or damaged: the repository folder is incomplete. Delete the folder Dirac_claude, download it again with the git clone command of Step 3, and open the notebook from the new folder.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 00b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 00b (The eight directions and the author’s metric: a first look) is the file
# Revision/textbook/notebooks/00b_eight_directions.ipynb of the repository Dirac_claude.
# It reads the names and the signs of the eight coordinates x0 to x7 from the Revision
# record, writes the author’s metric (with the functions a4 and b4) with sympy, checks
# that its eight entries, their signs and its determinant b4^3 cos^2 z agree with what
# the Revision verifiers recorded, and draws four teaching plots: the signs as a heat
# map, the growing and the shrinking length factors, the eight length factors as bars,
# and the volume factor. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that
# shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
```

```
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
```

```
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
```

```
#     cd Revision/textbook/notebooks
#     jupyter lab 00b_eight_directions.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 00b_eight_directions.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 00b_eight_directions.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/00b.captions.json
# - Revision/textbook/figures/00b_1_eta_heat_map.png
# - Revision/textbook/figures/00b_2_scale_factors.png
# - Revision/textbook/figures/00b_3_length_factors.png
# - Revision/textbook/figures/00b_4_volume_factor.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the four figure files of this notebook exist
#     ALL 17 CHECKS PASSED (notebook 00b)
```

```
#
# and the notebook must show 4 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/00b_eight_directions.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 00b_eight_directions.ipynb
#     python -m nbconvert --execute --inplace 00b_eight_directions.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of
#   the Revision record is missing or damaged: the repository folder is incomplete.
#   Delete the folder Dirac_claude, download it again with the git clone command of Step
#   3, and open the notebook from the new folder.

## 3. The words used in this notebook

- **Coordinate**: a number that says where a point is along one direction. The
  author's universe has eight coordinates, named $x_0, x_1, \dots, x_7$ (the author's
  own names, in the author's order; the hidden direction $x_0$ comes first).
- **Space-like and time-like**: two kinds of direction. Along a space-like direction
  a step is measured like a distance; along a time-like direction it is measured
  like a duration. In the metric a space-like direction has a positive entry and a
  time-like direction a negative entry.
- **Metric**: the rule that turns a small step in the coordinates into its size. For
  the author's metric the rule is
  $ds^2 = g_{00} dx_0^2 + g_{11} dx_1^2 + \dots + g_{77} dx_7^2$, where $dx_i$ is the
  small step along $x_i$ and $g_{ii}$ is the $i$-th entry of the metric.
- **Diagonal matrix**: a square table of numbers that is zero everywhere except on
  the line from the top left to the bottom right (the *diagonal*). The author's
  metric is an $8 \times 8$ diagonal matrix with the entries $g_{00}, \dots, g_{77}$.
- **Determinant**: one number computed from a square matrix. For a diagonal matrix it
  is the product of the diagonal entries.
- **Signature**: the numbers of positive and of negative entries of the metric. Here
  it is (4,4): four space-like and four time-like directions.
- **Length factor**: the number $f_i = \sqrt{|g_{ii}|}$; a small step $dx_i$ along
  $x_i$ has the size $f_i \, |dx_i|$.
- **Inflate, deflate**: grow and shrink. A direction inflates when its length factor
  grows with time and deflates when it shrinks.
- **Exponential**: the function $e^{t}$; $e^{-t} = 1 / e^{t}$.
- **Logarithmic axis**: an axis on which equal steps mean equal *factors* (1, 10,
  100, ...) instead of equal differences; on it $e^{t}$ and $e^{-t}$ are straight
  lines.
- **Heat map**: a picture of a matrix in which every entry is a coloured square.
- **Symbol** (sympy): a letter that stands for any number, so that sympy can compute
  exactly with formulas instead of with decimal numbers.
- **Record, report, JSON**: the Revision folder stores its results as *JSON* files
  (plain text files of names, numbers and lists). A *report* is a JSON file in which
  a verifier program has recorded its checks, each with a name, a *verdict* (PASS or
  FAIL) and a detail text.
```

Text cell:

```
## 4. The physical and mathematical situation
```

The author's universe has eight directions. Their names and roles are:

- x_0: a hidden direction of space; space-like;
- x_1, x_2, x_3: the three directions of ordinary space; space-like; they inflate;
- x_4: the time in which everything evolves; time-like;
- x_5, x_6, x_7: the three **extra times**; time-like; they deflate exponentially.

The author's metric is diagonal, with the entries (in the order $x_0, x_1, \dots, x_7$)

$$g = \mathrm{diag}\big(\cot^2 z,\; e^{2 a_4} s,\; e^{2 a_4} s,\; e^{2 a_4} s,\; -1,\; -b_4 e^{-2 a_4} s,\; -b_4 e^{-2 a_4} s,\; -b_4 e^{-2 a_4} s\big),$$

where $s = \sin^{1/3} z$, $z = 6 H x_0$, $H > 0$ is a constant of the author, and a_4 and $b_4 > 0$ are functions of the time x_4 only. The hidden coordinate is restricted so that $0 < z < \pi/2$; there $\sin z > 0$ and $\cot z > 0$. (The function b_4 is the author's change of 2026-10-14; with $b_4 = 1$ the metric is the one used before. With the author's own weights every vacuum history has b_4 constant, and a constant b_4 is removed by rescaling x_5, x_6, x_7, so the backgrounds of the later chapters take $b_4 = 1$, as the Revision record does, and say so where they do. The record of the change is the file Revision/metric_b4/METRIC_CHANGE_PROVENANCE.md.)

Reading the metric:

1. On $0 < z < \pi/2$ every entry $e^{2 a_4} s$, $b_4 e^{-2 a_4} s$ and $\cot^2 z$ is positive. So the entries of x_0, x_1, x_2, x_3 are positive (space-like) and those of x_4, x_5, x_6, x_7 are negative (time-like): the signs are $(+, +, +, +, -, -, -, -)$, the same for every value of a_4, b_4 and z.
2. The length factor of each of x_1, x_2, x_3 is $\sqrt{e^{2 a_4} s} = e^{a_4} \sin^{1/6} z$, and that of each of x_5, x_6, x_7 is $\sqrt{b_4 e^{-2 a_4} s} = b_4^{1/2} e^{-a_4} \sin^{1/6} z$. When a_4 grows, the first grows and the second shrinks: ordinary space inflates and the extra times deflate. If a_4 grows in proportion to the time, $a_4 = A H x_4$ with a positive number A, and b_4 is constant (the simplest history; later chapters examine what source it needs, and the Kohn-Sham chapters use it as a prescribed background, an assumption), then $e^{-a_4} = e^{-A H x_4}$ shrinks exponentially in time.
3. The determinant of a diagonal matrix is the product of its diagonal entries. The three entries of ordinary space give $(e^{2 a_4} s)^3 = e^{6 a_4} s^3 = e^{6 a_4} \sin z$, because $s^3 = (\sin^{1/3} z)^3 = \sin z$. The three entries of the extra times give $(-b_4 e^{-2 a_4} s)^3 = (-1)^3 b_4^3 e^{-6 a_4} s^3 = -b_4^3 e^{-6 a_4} \sin z$. The entry of the time is -1 and that of the hidden direction is $\cot^2 z$. So $\det g = e^{6 a_4} \sin z \cdot (-b_4^3 e^{-6 a_4} \sin z) \cdot (-1) \cdot \cot^2 z = b_4^3 \sin^2 z \cot^2 z$, because $e^{6 a_4} e^{-6 a_4} = e^{0} = 1$ and $(-1)(-1) = 1$. Since $\cot z = \cos z / \sin z$, this is $b_4^3 \sin^2 z \cdot \cos^2 z / \sin^2 z = b_4^3 \cos^2 z$. It does not depend on a_4: the growth of the three space factors and the shrinking of the three extra-time factors cancel in the volume. On $0 < z < \pi/2$, $\cos z > 0$, so $\sqrt{|\det g|} = b_4^{3/2} \cos z$; it changes in time only if b_4 does, and at $b_4 = 1$ it is $\cos z$.

The notebook checks each of these statements with the computer and compares them

```
with the Revision record.
```

Text cell:

```
## 5. The eight coordinates in the Revision record

The file Revision/algebra/gammas.json of the Revision record holds the gamma
matrices of the book (they appear in later chapters) together with the names of
the coordinates and their signs. The next cell reads the file, prints a table of
the eight directions, and checks the names, the signs and the signature. It also
defines two small functions. ‘recorded_check‘ looks up one named check in a
Revision report; the cell uses it to show what the Wolfram verifier of the
Revision record recorded about the signs. ‘check_reproduces‘ is the helper ‘check‘
for a check that reproduces a Revision record: it first calls ‘sys.stdout.flush()‘,
which sends all printed text that is still waiting, and then calls ‘check‘ with
the record. (Jupyter sends printed text in pieces; flushing first keeps the PASS
line and the line ‘reproduces ...‘ below it in one piece, so that the book’s tools
read them together.)
```

In [2]:

```
import sys  # sys.stdout is the channel through which the notebook prints

```
Figure 00b.1 saved as Revision/textbook/figures/00b_1_eta_heat_map.png
```

Text cell:

```
## 6. The author's metric, written with sympy

The next cell writes the author's metric as an exact sympy matrix. `sp.symbols`
makes the symbols $x_4$, $x_0$ and $H$ (declared positive), and
`sp.Function("a4")(x4)` and `sp.Function("b4", positive=True)(x4)` make $a_4$
and $b_4$ unknown functions of the time $x_4$ ($b_4$ positive).
`sp.Rational(1, 3)` is the exact fraction $1/3$; the decimal number 0.333... would
not be exact. `sp.diag(...)` makes the diagonal matrix.

Then the cell compares the eight entries with two records:
```

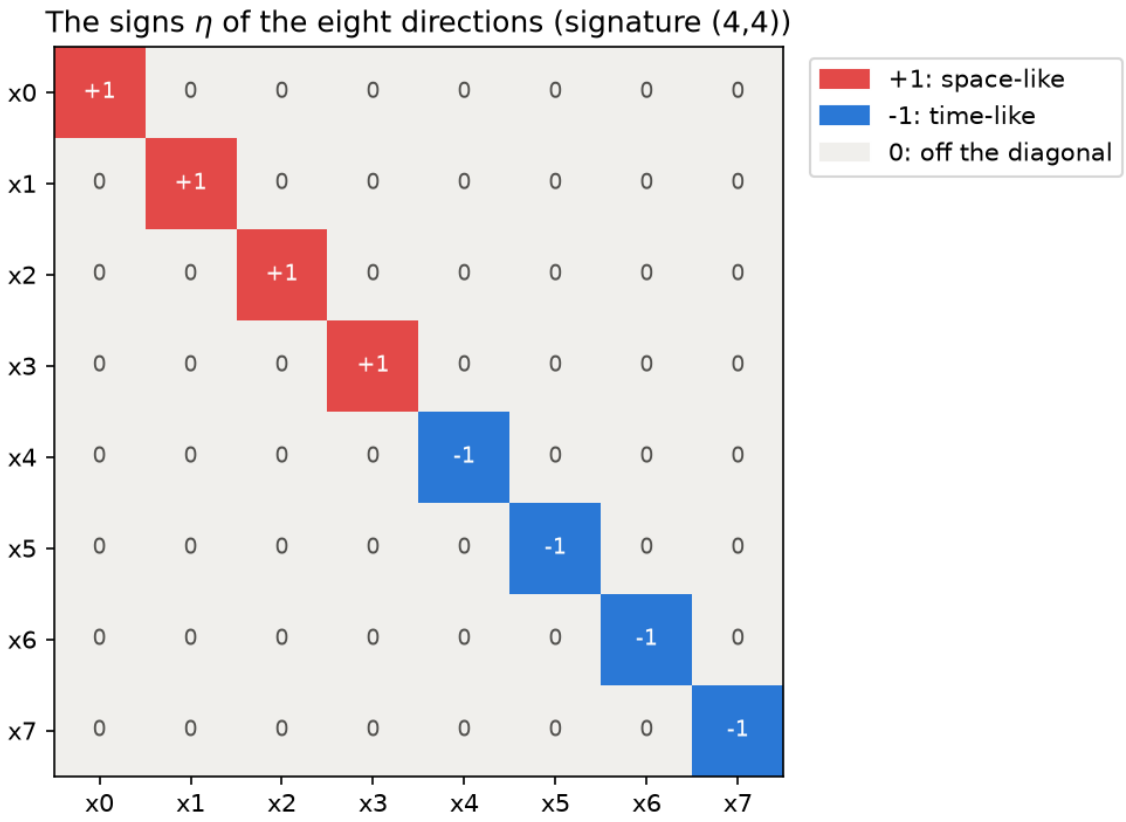

Figure 3: The signs of the author's eight directions drawn as a heat map: the 8 by 8 diagonal matrix η with the sign of each coordinate on its diagonal and 0 everywhere else; rows and columns are labelled by the coordinates x_0 to x_7, and the entries are pure numbers. Red squares are $+1$ (space-like: x_0, x_1, x_2, x_3), blue squares -1 (time-like: the time x_4 and the extra times x_5, x_6, x_7), grey squares 0. Four entries are $+1$ and four are -1: the signature is (4,4). (Notebook 00b, figure 1.)

```
- the key ‘metricDiagonal‘ of the Revision file
  Revision/metric_b4/results/metric-b4.json, the metric with $b_4$ as the
  Wolfram program of the Revision record wrote it in the notation of the program
  Mathematica, for example ‘-((b4[x4]*Sin[6*H*x0]^(1/3))/E^(2*a4[x4]))‘ for
  $-b_4 e^{-2a_4} \sin^{1/3} z$; the Wolfram verifier found it equal to the metric
  stored in the author’s notebook (its check ‘metric_equals_author_Out101‘);
- the check ‘metric_from_vielbein_equals_SPEC‘ of the Revision report
  Revision/theory/reports/python-field-theory.json, which lists the eight entries
  of the metric at $b_4 = 1$ as formulas, for example
  ‘g_x1x1 = exp(2*a4(x4))*sin(6*H*x0)**(1/3)‘.

The cell turns each formula into a sympy expression with ‘sp.sympify‘ and checks
that the eight entries come in the order $x_0, x_1, \dots, x_7$ and that the
difference of each from our entry (with $b_4 = 1$ for the second record) is
exactly zero.
```

In [4]:

```
x4, x0, H = sp.symbols("x4 x0 H", positive=True)  # time, hidden coordinate, H

```
The next cell checks the signs of the eight entries numerically. It replaces $a_4$
by a plain number $a$, $b_4$ by a plain positive number $b$ and $6 H x_0$ by a
plain number $\zeta$, turns the eight entries into numpy functions of
$(a, b, \zeta)$ with ‘sp.lambdify‘, and evaluates them on a grid of 61 values of
$a$ from $-3$ to $3$ and 79 values of $\zeta$ from 0.01 to $\pi/2 - 0.01$ (4819
points), for each of the three values $b = 0.5$, $1$ and $2$ (14457 points).
‘np.sign‘ gives $+1$ for a positive number and $-1$ for a negative one. Every entry
must have the sign that the Revision record gives for its direction, at every
point.
```

In [5]:

```
# plain numbers for a4, for b4 (positive) and for 6 H x0

Text cell:

```
The next cell computes the determinant of $g$ with sympy. ‘g.det()‘ multiplies the
eight diagonal entries; sympy cancels $e^{6 a_4} e^{-6 a_4} = 1$ by itself. To
print the result in terms of $z$, the cell replaces $6 H x_0$ by the plain number
$\zeta$ of the previous cell: sympy prints $b_4^3 \sin^2 \zeta \cot^2 \zeta$, and
‘sp.trigsimp‘ (trigonometric simplification) writes this as
$b_4^3 \cos^2 \zeta$. The first check confirms, for the determinant written with
$x_0$ and $H$, that the difference from $b_4^3 \cos^2 z$ is exactly zero, and that
the Wolfram verifier of the field theory with $b_4$ (the report
Revision/theory/reports/wolfram-field-theory-b4.json) recorded PASS for the same
statement, its check ‘sqrt_det_g‘. The second check does the same at $b_4 = 1$,
where the determinant is $\cos^2 z$, against the check ‘sqrt_det_g_is_cos_z‘ of
the earlier report Revision/theory/reports/wolfram-field-theory.json. The third
check confirms that $\det g / b_4^3$ does not change with the time $x_4$: its
derivative with respect to $x_4$ is zero, although $a_4$ depends on $x_4$; the
determinant itself changes in time only through $b_4$. The fourth check reads the
```

```
verdict that the Wolfram verifier of the field equations for $a_4$ and $b_4$ (the
report Revision/field_equations_a4/reports/wolfram-a4-report.json) recorded for its
check ‘metric_is_SPEC_section_1‘: that verifier used this same metric.

## 7. Inflation and deflation

Fix the hidden coordinate (that is, fix $z$). Then the length factor of each
direction of ordinary space is $e^{a_4}$ times the fixed number $\sin^{1/6} z$,
and that of each extra time is $b_4^{1/2} e^{-a_4}$ times the same number. This
```

```
section and the next two take $b_4 = 1$, the background of the Revision record
(a constant $b_4$ only multiplies every extra-time factor by the same number
$b_4^{1/2}$). The next cell draws $e^{a_4}$ and $e^{-a_4}$ for $a_4$ from 0 to 3,
with a logarithmic vertical axis, on which both are straight lines: the logarithm
of $e^{a_4}$ is $a_4$ and that of $e^{-a_4}$ is $-a_4$. It also draws the product
of the three factors of ordinary space and the three factors of the extra times,
$e^{3 a_4} \cdot e^{-3 a_4} = 1$ (for a general $b_4$ it is $b_4^{3/2}$), and
checks both statements.
```

## 8. The eight length factors

The next cell computes all eight length factors $f_i = \sqrt{|g_{ii}|}$ from the
sympy entries made above, at the hidden coordinate $z = \pi/4$ and $b_4 = 1$, for
three values of the metric function: $a_4 = 0$, $0.5$ and $1$. At $z = \pi/4$ we have
$\sin^{1/6}(\pi/4) = 2^{-1/12} = 0.9439$ and $\cot(\pi/4) = 1$. The cell prints
```

```
the factors as a table and draws them as bars: the bars of $x_1, x_2, x_3$ grow
with $a_4$, those of $x_5, x_6, x_7$ shrink, and those of $x_0$ and $x_4$ do not
change. The product of the eight factors is $\sqrt{|\det g|} = \cos(\pi/4) =
0.7071$ for every $a_4$. The check confirms this for the three values of $a_4$
and that the Wolfram verifier of the field equations for $a_4$ recorded PASS for
its check `sqrt_abs_det_g_is_cos_z` (the volume factor is $b_4^{3/2} \cos z$, which
is $\cos z$ at $b_4 = 1$, and does not depend on $a_4$).
```

## 9. The volume factor does not depend on $a_4$ (it is $b_4^{3/2} \cos z$)

The product of the eight length factors, $f_0 f_1 \cdots f_7 = \sqrt{|\det g|}$, is
the factor that turns a small coordinate box $dx_0 \, dx_1 \cdots dx_7$ into its
volume. The next cell computes it at $b_4 = 1$ for $a_4 = 0$, $1$ and $2$ at 200
values of $z$ between 0 and $\pi/2$, and draws it together with the curve
$\cos z$. The three sets of points lie on the same curve: the inflation of
ordinary space and the deflation of the extra times cancel in the volume. (To keep
the three sets of points visible, each is drawn only at every 12th value of $z$,
shifted by 4 values from the previous set.) It also computes the volume factor at
$a_4 = 1$, $b_4 = 2$ and draws it with the curve $2^{3/2} \cos z$: $b_4$ enters
only as the factor $b_4^{3/2}$. The first check compares the 600 values at
$b_4 = 1$ with $\cos z$ and confirms that the Python verifier of the field theory
recorded PASS for its check ‘sqrt_det_g_equals_cos_z‘; the second compares the 200
values at $b_4 = 2$ with $2^{3/2} \cos z$ and confirms that the Wolfram verifier of
the field theory with $b_4$ recorded PASS for its check ‘sqrt_det_g‘.
```

ALL 17 CHECKS PASSED (notebook 00b)
```

Text cell:

```
## 11. What this notebook showed

- The Revision record names the eight coordinates $x_0, x_1, \dots, x_7$ and gives
  their signs $(+, +, +, +, -, -, -, -)$: the hidden direction $x_0$ and ordinary
  space $x_1, x_2, x_3$ are space-like; the time $x_4$ and the extra times
  $x_5, x_6, x_7$ are time-like; the signature is (4,4).
- The author's metric with the two functions $a_4$ and $b_4$, written with sympy,
  has exactly the eight entries that the Revision verifiers recorded (with $b_4$,
  and at $b_4 = 1$), and every entry has its recorded sign at every tested point.
- When $a_4$ grows, the length factor $e^{a_4} \sin^{1/6} z$ of ordinary space
  grows (inflation) and the length factor $b_4^{1/2} e^{-a_4} \sin^{1/6} z$ of the
  extra times shrinks (deflation); if $a_4$ grows in proportion to the time and
  $b_4$ is constant, the extra times deflate exponentially.
- The determinant is $\det g = b_4^3 \cos^2 z$ exactly (PROVED by the exact
  computation), so the volume factor $\sqrt{|\det g|} = b_4^{3/2} \cos z$ does not
  depend on $a_4$: the inflation and the deflation cancel in the volume; at
  $b_4 = 1$ it is $\cos z$.
```

0.17 Line-by-line walk-through of Notebook 00b

The notebook has ten code cells, In [1] to In [10]. This section explains every line of each of them.

In [1], the set-up cell. It is the set-up cell of Notebook 00a, word for word, except for two things: its comment lines hold the run instructions of Notebook 00b (Section 0.15), and the line `NOTEBOOK_ID = "00b"` names this notebook, so that its figures are called `00b_1_eta_heat_map.png` and so on and its captions file is `Revision/textbook/figures/00b.captions.json`. Every line of its code is explained in Section 0.13. It prints one line, Set-up of notebook 00b complete: repository folder found, helpers defined.

In [2], the eight coordinates in the Revision record.

```
import sys  # sys.stdout is the channel through which the notebook prints

import numpy as np  # arrays of numbers
import sympy as sp  # exact algebra with symbols
```

The module `sys` of Python gives access to the running Python itself; the notebook needs its `sys.stdout`, the channel through which `print` writes. numpy and sympy are loaded under their usual short names `np` and `sp`, as in Notebook 00a.

```
GAMMAS_FILE = "Revision/algebra/gammas.json"  # coordinates, signs and gammas
gammas_record = json.loads(repository_file(GAMMAS_FILE).read_text(encoding="utf-8"))
coordinates = gammas_record["coordinates"]  # the names x0 ... x7, in order
eta = gammas_record["eta"]  # the sign of each direction: +1 or -1
```

The first line names the record file. In the second line, `repository_file(GAMMAS_FILE)` is its full path (Section 0.13), `.read_text(encoding="utf-8")` reads the whole file as one string, and `json.loads` turns that JSON text into Python's dictionaries and lists. The file is one big dictionary; `gammas_record["coordinates"]` takes the value stored under the key `coordinates`, the list of the eight names `["x0", ..., "x7"]`, and `gammas_record["eta"]` the list of the eight signs `[1, 1, 1, 1, -1, -1, -1, -1]`. (The same file also holds the gamma matrices of Chapter 4.)

```
ROLES = {  # the role of each coordinate in the author's universe
    "x0": "hidden direction of space",
    "x1": "ordinary space (inflates)",
    "x2": "ordinary space (inflates)",
    "x3": "ordinary space (inflates)",
    "x4": "the time",
    "x5": "extra time (deflates)",
    "x6": "extra time (deflates)",
    "x7": "extra time (deflates)",
}
```

A dictionary from each coordinate name to a short description of its role, written by the author of the notebook from Section 0.5 (the record holds the names and the signs, not the roles).

```
say("coordinate  sign  kind        role")
for name, sign in zip(coordinates, eta):
    kind = "space-like" if sign > 0 else "time-like"
    # {sign:+d} writes the sign of a whole number (+1 or -1) in front of it.
    say(f"{name:10}  {sign:+d}    {kind:10}  {ROLES[name]}")
```

The first line prints the header of a table. `zip(coordinates, eta)` pairs the two lists entry by entry: `("x0", 1)`, `("x1", 1)`, and so on; the loop names the two parts of each pair `name` and `sign`. The **conditional expression** `"space-like" if sign > 0 else "time-like"` has the first value when the condition holds and the second otherwise. In the f-string, `{name:10}` pads the name to 10 characters, `{sign:+d}` writes the whole number with its sign (`+1` or `-1`), `{kind:10}` pads the kind, and `{ROLES[name]}` looks up the role. The eight lines of the table are the first eight lines of Out [2].

```
def recorded_check(path, name):
    """The verdict (PASS or FAIL) and the detail text that the Revision report
    path recorded for its check called name."""
    data = json.loads(repository_file(path).read_text(encoding="utf-8"))
    for entry in data["checks"]:  # every check of the report, one after the other
        if entry["name"] == name:
            return entry["verdict"].upper(), entry["detail"]
    raise KeyError(f"{path} has no check {name}")
```

A function that looks up one named check in a report of the Revision record. It reads the report as in the lines above; `data["checks"]` is the list of its checks, each a dictionary with the keys `name`,

`verdict` and `detail`. The loop compares each name with the wanted one; at the first match, `return` hands back two values at once, the verdict written in capitals (`.upper()`, because some reports write `pass` in small letters) and the detail text. If no check has that name, `raise KeyError(...)` stops the notebook with a message that names the report and the check.

```
def check_reproduces(condition, name, record):
    """check(condition, name, record=record), after sending the waiting output."""
    sys.stdout.flush()  # send every printed line that is still waiting
    check(condition, name, record=record)
```

The helper for a check that reproduces a Revision record. Python collects printed text and sends it to Jupyter in pieces; `sys.stdout.flush()` sends everything that is still waiting, so that the PASS line and the line reproduces ... that `check` prints just after it arrive together, in one piece of output, and the book's tools read them as one. Then it calls the helper `check` of the set-up cell with the record.

```
ALGEBRA_REPORT = "Revision/algebra/reports/wolfram-algebra.json"
verdict, detail = recorded_check(ALGEBRA_REPORT, "eta_in_author_order")
say(f"The Wolfram verifier recorded for eta_in_author_order: {verdict}")
```

These lines read what the Wolfram verifier of the algebra recorded for its check `eta_in_author_or der` (that the signs are $(+,+,+,+,-,-,-,-)$ in the order $x_0,\ldots,x_7$). The two returned values are named `verdict` and `detail`, and the verdict is printed: PASS (Out [2], ninth line).

```
check(coordinates == ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"],
      "the record names the eight coordinates x0 to x7 in this order")
check(eta == [1, 1, 1, 1, -1, -1, -1, -1],
      "the record gives the signs (+,+,+,+,-,-,-,-) in the order x0..x7")
check(eta.count(1) == 4 and eta.count(-1) == 4,
      "four space-like and four time-like directions: the signature is (4,4)")
check(verdict == "PASS",
      "the Wolfram verifier recorded PASS for these signs (eta_in_author_order)")
```

Four checks. Two lists are equal (`==`) when they have the same entries in the same order; so the first check confirms the names and their order, the second the signs. `eta.count(1)` counts the entries equal to 1; the third check requires four of each sign, the signature (4,4). The fourth requires the recorded verdict PASS. The four PASS lines end Out [2].

In [3], the signs as a heat map.

```
from matplotlib.colors import ListedColormap  # a colour map made of a few colours
from matplotlib.patches import Patch  # a coloured square for the legend
```

Two tools of matplotlib: a **colour map** made of a short list of colours, and a coloured square for a legend.

```
eta_matrix = np.diag(eta)  # 8 x 8: the signs on the diagonal, 0 elsewhere
BLUE, GREY, RED = "#2a78d6", "#f0efec", "#e34948"
colour_map = ListedColormap([BLUE, GREY, RED])  # three colours for -1, 0, +1
```

`np.diag(eta)` makes the 8×8 matrix η of Section 0.14 from the list of its diagonal entries. The colours are written as **hexadecimal colour codes**: after `#`, three pairs of hexadecimal digits give the amounts of red, green and blue (from 00, none, to ff, 255). The colour map has three colours, in the order in which they are used for small, middle and large numbers.

```
fig, ax = plt.subplots(figsize=(6.4, 5.4))
# vmin and vmax split the numbers into three bands: -1, 0 and +1.
ax.imshow(eta_matrix, cmap=colour_map, vmin=-1.5, vmax=1.5)
```

A figure 6.4 inches wide and 5.4 inches high. `ax.imshow` draws the matrix as a grid of coloured squares, row 1 at the top. The colour map divides the interval from `vmin` $= -1.5$ to `vmax` $= 1.5$ into three equal bands, $[-1.5, -0.5]$, $[-0.5, 0.5]$ and $[0.5, 1.5]$, and gives them the three colours in order: -1 is blue, 0 grey and $+1$ red.

```
for row in range(8):
    for column in range(8):
        value = int(eta_matrix[row, column])
        text = "0" if value == 0 else f"{value:+d}"
        colour = "#52514e" if value == 0 else "white"  # readable on each colour
        ax.text(column, row, text, ha="center", va="center", color=colour,
                fontsize=9)
```

Two loops, one inside the other, visit all 64 squares; `range(8)` gives the numbers 0 to 7. `eta_matrix[row, column]` is the entry in that row and column (counted from 0), turned into a whole number with `int`. The text is `0`, or the entry with its sign. Dark grey letters are used on the light grey squares and white letters on the coloured ones. `ax.text(column, row, ...)` writes the text centred (`ha` and `va`: horizontal and vertical alignment) in the square; the horizontal position comes first, so the column comes before the row.

```
ax.set_xticks(range(8), labels=coordinates)  # label the columns x0 ... x7
ax.set_yticks(range(8), labels=coordinates)  # label the rows x0 ... x7
ax.grid(False)  # no grid lines across the squares
ax.set_title(r"The signs $\eta$ of the eight directions (signature (4,4))")
legend_squares = [Patch(color=RED, label="+1: space-like"),
                  Patch(color=BLUE, label="-1: time-like"),
                  Patch(color=GREY, label="0: off the diagonal")]
ax.legend(handles=legend_squares, loc="upper left", bbox_to_anchor=(1.02, 1.0))
```

The columns and rows are labelled with the coordinate names, the grid of the set-up cell is switched off for this picture, and the title is set. A string written with `r` in front (a **raw string**) keeps every backslash as it is, so that matplotlib receives the mathematics `$\eta$`. The legend is made of three coloured squares; `bbox_to_anchor=(1.02, 1.0)` puts its upper left corner just to the right of the picture, so that it covers no square.

```
save_figure(fig, "eta_heat_map",
            r"The signs of the author's eight directions drawn as a heat map: the "
            r"8 by 8 diagonal matrix $\eta$ with the sign of each coordinate on its "
            r"diagonal and 0 everywhere else; rows and columns are labelled by the "
```

```
        r"coordinates $x_0$ to $x_7$, and the entries are pure numbers. Red "
        r"squares are $+1$ (space-like: $x_0$, $x_1$, $x_2$, $x_3$), blue "
        r"squares $-1$ (time-like: the time $x_4$ and the extra times $x_5$, "
        r"$x_6$, $x_7$), grey squares 0. Four entries are $+1$ and four are "
        r"$-1$: the signature is (4,4).")
```

The figure is saved as `00b_1_eta_heat_map.png` with this caption (the raw strings written next to each other are joined into one) and shown; Out [3] is the figure and the line Figure 00b.1 saved as .... What Figure 00b.1 shows: the diagonal of the matrix, from the top left, has four red squares followed by four blue squares, the pattern $(+,+,+,+,-,-,-,-)$ of Fact 1 of Section 0.14.

In [4], the author's metric written with sympy.

```
x4, x0, H = sp.symbols("x4 x0 H", positive=True)  # time, hidden coordinate, H
a4 = sp.Function("a4")(x4)  # the metric function a4, an unknown function of x4
b4 = sp.Function("b4", positive=True)(x4)  # the metric function b4 > 0 of x4
z = 6 * H * x0  # the combination z = 6 H x0
third = sp.Rational(1, 3)  # the exact fraction 1/3
```

`sp.symbols` makes three symbols at once; `positive=True` tells sympy that they stand for positive numbers, which lets it simplify more. `sp.Function("a4")` makes an unknown function called `a4`, and `(x4)` makes it a function of x_4: sympy knows nothing about it except that it depends on x_4, so every result below holds for every history $a_4(x_4)$. `sp.Function("b4", positive=True)(x4)` makes the second metric function $b_4(x_4)$ in the same way, and tells sympy that its values are positive. `z` is the expression $6Hx_0$. `sp.Rational(1, 3)` is the exact fraction $1/3$; the decimal number 0.3333 would be rounded and not exact.

```
grow = sp.exp(2 * a4) * sp.sin(z) ** third  # e^(2 a4) sin^(1/3) z
shrink = b4 * sp.exp(-2 * a4) * sp.sin(z) ** third  # b4 e^(-2 a4) sin^(1/3) z
# the author's order x0, x1, ..., x7: the hidden direction x0 first
g = sp.diag(sp.cot(z) ** 2, grow, grow, grow, -1, -shrink, -shrink, -shrink)
```

The two kinds of entry of the metric, and the diagonal 8×8 matrix `g` with the eight entries of Section 0.14 in the order $x_0, \ldots, x_7$: the hidden direction first, then ordinary space, the time and the three extra times.

```
METRIC_B4_FILE = "Revision/metric_b4/results/metric-b4.json"
metric_b4 = json.loads(repository_file(METRIC_B4_FILE).read_text(encoding="utf-8"))
```

The file `Revision/metric_b4/results/metric-b4.json` is the record of the metric with b_4, written by the Wolfram program of the Revision record; its key `metricDiagonal` holds the eight diagonal entries as texts in the notation of the program Mathematica, for example `-((b4[x4]*Sin[6*H*x0]^(1/3))/E^(2*a4[x4]))` for $-b_4 e^{-2a_4} \sin^{1/3} z$, and its key `coordinates` the names of the coordinates.

```
# The Mathematica texts in Python notation: a4[x4] -> a4(x4), ^ -> **, and so on.
MATHEMATICA = [("a4[x4]", "a4(x4)"), ("b4[x4]", "b4(x4)"), ("Sin[", "sin("),
```

```
            ("Cot[", "cot("), ("]", ")"), ("^", "**")]
letters = {"a4": sp.Function("a4"), "b4": sp.Function("b4", positive=True),
           "x4": x4, "x0": x0, "H": H, "E": sp.E}
different = []  # the entries whose difference from ours is not zero
```

`MATHEMATICA` is a list of pairs (old text, new text): Mathematica writes a function value with square brackets, `a4[x4]`, and a power with `^`; Python writes `a4(x4)` and `**`. The dictionary `letters` tells sympy what each name in the translated texts means: `a4` and `b4` are the two functions, `x4`, `x0` and `H` our symbols, and `E` the number e (`sp.E`). The empty list `different` will collect the positions of entries that differ from ours.

```
for k, text in enumerate(metric_b4["metricDiagonal"]):
    for old, new in MATHEMATICA:
        text = text.replace(old, new)
    if sp.simplify(sp.sympify(text, locals=letters) - g[k, k]) != 0:
        different.append(k)
    say(f"metric-b4.json g_x{k}x{k} = {text}")
```

`enumerate(...)` gives each recorded text together with its position `k` = 0, 1, ..., 7. The inner loop makes the replacements of `MATHEMATICA` one after the other (`.replace(old, new)` replaces every occurrence of `old`). `sp.sympify` turns the translated text into a sympy expression, reading the names with the dictionary `letters`; `g[k, k]` is our diagonal entry number `k`; `sp.simplify` simplifies the difference of the two, and if it is not exactly zero, the position is noted. The loop prints each translated text: the eight lines metric-b4.json g_x0x0 = cot(6Hx0)**2 to metric-b4.json g_x7x7 = ... of Out [4]. (In the printed formulas ‘ is the power, *the product, and /E(2*a4(x4))‘ divides by e^{2a_4}, which is the same as multiplying by e^{-2a_4}.)

```
verdict, detail = recorded_check(
    "Revision/metric_b4/results/wolfram-metric-b4-report.json",
    "metric_equals_author_Out101")
check_reproduces(
    metric_b4["coordinates"] == coordinates and len(metric_b4["metricDiagonal"]) == 8
    and different == [] and verdict == "PASS",
    "our eight entries equal the metric with b4 of the Revision record, which the "
    "Wolfram verifier found equal to the metric in the author's notebook",
    "Revision/metric_b4/results/wolfram-metric-b4-report.json, check "
    "metric_equals_author_Out101")
```

The Wolfram verifier of the metric with b_4 compared this metric, component by component, with the metric stored in the author's own notebook (the output Out[101] of `Dirac_Einstein-Lovelock_4+4_Nash.nb`) and recorded the verdict of its check `metric_equals_author_Out101`. The check requires the same coordinate names in the same order as in `gammas.json`, eight entries, no difference, and the verdict PASS; Out [4] prints the PASS line and the record it reproduces.

```
THEORY_REPORT = "Revision/theory/reports/python-field-theory.json"
verdict, detail = recorded_check(THEORY_REPORT, "metric_from_vielbein_equals_SPEC")
formulas = detail.split("exactly: ", 1)[1].split("; ")  # the 8 texts "g_.. = ..."
g_at_b4_1 = g.subs(b4, 1)  # the metric at b4 = 1
```

The Python verifier of the field theory works with the metric at $b_4 = 1$, the background of the record. It recorded, in the detail of its check `metric_from_vielbein_equals_SPEC`, the eight entries that it rebuilt from its own construction (the vielbein of Chapter 6). The detail is a sentence that ends with `exactly:` followed by the eight formulas separated by a semicolon and a blank. `detail.split("exactly: ", 1)` cuts the text at the first `exactly:` into two pieces; `[1]` keeps the second piece (Python counts from 0), and `.split("; ")` cuts it into the list of the eight texts such as `g_x1x1 = exp(2*a4(x4))*sin(6*H*x0)**(1/3)`. `g.subs(b4, 1)` is our matrix with the function b_4 replaced by the number 1.

```
labels = []  # the names g_x0x0, g_x1x1, ... in the order of the record
different = []  # the entries whose difference from ours is not zero
for k, text in enumerate(formulas):
    label, formula = text.split(" = ")  # "g_x0x0" and its formula
    labels.append(label)
    recorded = sp.sympify(formula, locals=letters)  # the text as a sympy formula
    if sp.simplify(recorded - g_at_b4_1[k, k]) != 0:
        different.append(label)
```

Two empty lists, and a loop like the one above: each text is cut at `=` into the name and the formula, the name is noted in `labels`, the formula is turned into a sympy expression, and if it differs from our entry at $b_4 = 1$, the name is noted in `different`.

```
in_order = [f"g_x{k}x{k}" for k in range(8)]  # g_x0x0, ..., g_x7x7
check_reproduces(
    verdict == "PASS" and labels == in_order and different == [],
    "at b4 = 1 our eight entries equal the eight entries recorded by the Revision "
    "verifier of the field theory",
    f"{THEORY_REPORT}, check metric_from_vielbein_equals_SPEC")
```

`range(8)` gives 0 to 7, so `in_order` is the list of the names `g_x0x0` to `g_x7x7`. The check requires the recorded verdict PASS, the names in the order $x_0, \ldots, x_7$, and no difference; Out [4] ends with the PASS line and the line reproduces Revision/theory/reports/python-field-theory.json, check metric_from_vielbein_equals_SPEC.

In [5], the signs at 14457 points.

```
# plain numbers for a4, for b4 (positive) and for 6 H x0
a, zeta = sp.symbols("a zeta", real=True)
b = sp.Symbol("b", positive=True)
# x0 = zeta / (6 H) makes 6 H x0 = zeta; sympy cancels the 6 H automatically.
entries = [g[k, k].subs({a4: a, b4: b}).subs(x0, zeta / (6 * H)) for k in range(8)]
# entry_functions[k](a, b, zeta) computes the entry g_kk with numpy.
entry_functions = [sp.lambdify((a, b, zeta), entry, "numpy") for entry in entries]
```

Three new symbols, a for a value of a_4, b for a (positive) value of b_4, and ζ (zeta) for a value of z. `.subs({a4: a, b4: b})` replaces the two functions by the plain symbols, and `.subs(x0, zeta / (6 * H))` replaces x_0 by $\zeta/(6H)$, so that $z = 6Hx_0$ becomes ζ. The list `entries` holds the eight diagonal entries as formulas in a, b and ζ alone. `sp.lambdify((a, b, zeta), entry, "numpy")` turns a formula into an ordinary Python function of three numbers that computes it with numpy, fast and for whole arrays at once.

```
# Two arrays of shape 79 x 61: every combination of the 61 values of a and the 79
# values of zeta.
a_grid, zeta_grid = np.meshgrid(np.linspace(-3.0, 3.0, 61),
                                np.linspace(0.01, np.pi / 2 - 0.01, 79))
b_values = (0.5, 1.0, 2.0)  # three values of b4
wrong_signs = 0  # the number of (point, entry) pairs with a wrong sign
```

`np.linspace(-3.0, 3.0, 61)` gives 61 equally spaced values of a from -3 to 3 (steps of 0.1) and the second `np.linspace` 79 values of ζ inside the patch, from 0.01 to $\pi/2 - 0.01$. `np.meshgrid` makes two tables of 79 rows and 61 columns: in `a_grid` every row is the list of the 61 values of a, in `zeta_grid` every column is the list of the 79 values of ζ; read together, the two tables list all $61 \cdot 79 = 4819$ pairs (a, ζ). The grid is used for each of the three values $b = 0.5$, 1 and 2, so $3 \cdot 4819 = 14457$ points are tested. The counter of wrong signs starts at 0.

```
for b_value in b_values:
    for k in range(8):
        # np.full_like makes an array of the grid's shape; a constant entry such as
        # -1 is then repeated at every point.
        values = (np.full_like(a_grid, 1.0)
                  * entry_functions[k](a_grid, b_value, zeta_grid))
        wrong_signs += int(np.sum(np.sign(values) != eta[k]))
```

For each value of b and each entry k, `entry_functions[k](a_grid, b_value, zeta_grid)` computes the entry at all 4819 points of the grid at once. For the constant entry $g_{44} = -1$ the function returns the single number -1; multiplying by `np.full_like(a_grid, 1.0)`, a table of the grid's shape filled with 1.0, makes every result a table of 4819 values. `np.sign` gives $+1$ for a positive and -1 for a negative number; `!= eta[k]` compares each sign with the recorded sign of the direction, giving a table of `True` (wrong) and `False` (right); `np.sum` counts the `True` entries, and `+=` adds the count to the counter.

```
report("points of the grid", a_grid.size * len(b_values))
report("(point, entry) pairs with a sign different from eta", wrong_signs)
check_reproduces(
    wrong_signs == 0,
    "every entry has the recorded sign at all 14457 points: (+,+,+,+,-,-,-,-)",
    f"{ALGEBRA_REPORT}, check eta_in_author_order")
```

`a_grid.size` is the number of entries of the table, 4819, and `len(b_values)` is 3. Out [5] prints 14457, then 0 wrong signs, then the PASS line, which reproduces the Wolfram check `eta_in_author_order`. This is the COMPUTED confirmation of Fact 1 of Section 0.14.

In [6], the determinant.

```
determinant = g.det()  # the product of the eight diagonal entries
determinant_zeta = determinant.subs(x0, zeta / (6 * H))  # 6 H x0 replaced by zeta
say(f"det g = {determinant_zeta}")
say(f"      = {sp.trigsimp(determinant_zeta)}   (zeta stands for z = 6 H x0)")
```

`g.det()` computes the determinant of the sympy matrix exactly; sympy multiplies the eight entries and cancels $e^{6a_4}e^{-6a_4}$ by itself, as in Fact 4 of Section 0.14. For a short printout $6Hx_0$ is replaced by

ζ; sympy prints `b4(x4)**3*sin(zeta)**2*cot(zeta)**2`, and `sp.trigsimp` (simplification with the rules of trigonometry) turns it into `b4(x4)**3*cos(zeta)**2`. These are the first two lines of Out [6], the last two lines of the derivation of Fact 4.

```
WOLFRAM_THEORY_B4 = "Revision/theory/reports/wolfram-field-theory-b4.json"
verdict, detail = recorded_check(WOLFRAM_THEORY_B4, "sqrt_det_g")
say(f"The Wolfram verifier recorded for sqrt_det_g: {verdict}")
check_reproduces(
    sp.simplify(determinant - b4 ** 3 * sp.cos(z) ** 2) == 0 and verdict == "PASS",
    "det g = b4^3 cos^2 z exactly, so sqrt|det g| = b4^(3/2) cos z on 0 < z < pi/2",
    f"{WOLFRAM_THEORY_B4}, check sqrt_det_g")
```

The verdict of the Wolfram verifier of the field theory with b_4 for the same statement is read and printed (PASS). The check requires that the difference between our determinant and $b_4^3 \cos^2 z$, written with x_0 and H, simplifies to exactly 0, and that the Wolfram verifier recorded PASS.

```
WOLFRAM_THEORY = "Revision/theory/reports/wolfram-field-theory.json"
verdict, detail = recorded_check(WOLFRAM_THEORY, "sqrt_det_g_is_cos_z")
check_reproduces(
    sp.simplify(determinant.subs(b4, 1) - sp.cos(z) ** 2) == 0 and verdict == "PASS",
    "at b4 = 1: det g = cos^2 z, so sqrt|det g| = cos z",
    f"{WOLFRAM_THEORY}, check sqrt_det_g_is_cos_z")
```

The same at $b_4 = 1$: the determinant with the function b_4 replaced by 1 must be $\cos^2 z$, and the Wolfram verifier of the field theory at $b_4 = 1$ must have recorded PASS for its check `sqrt_det_g_is_cos_z`.

```
check(sp.simplify(sp.diff(determinant / b4 ** 3, x4)) == 0,
      "det g / b4^3 does not depend on the time x4: no a4 in the volume factor")
verdict, detail = recorded_check(
    "Revision/field_equations_a4/reports/wolfram-a4-report.json",
    "metric_is_SPEC_section_1")
check(verdict == "PASS",
      "the field-equation verifier recorded PASS for metric_is_SPEC_section_1")
```

`sp.diff(determinant / b4 ** 3, x4)` is the derivative of $\det g / b_4^3$ with respect to the time; after simplification it is exactly zero, although the entries contain the unknown function $a_4(x_4)$: the determinant changes in time only through b_4. The last check reads the verdict that the Wolfram verifier of the field equations for a_4 and b_4 recorded for its check that it used exactly this metric. Out [6] ends with four PASS lines.

In [7], inflation and deflation.

```
a4_values = np.linspace(0.0, 3.0, 301)  # 301 values of a4 from 0 to 3
growing = np.exp(a4_values)  # the 3-space factor e^(a4)
shrinking = np.exp(-a4_values)  # the extra-time factor e^(-a4)
six_factors = growing ** 3 * shrinking ** 3  # three of each: e^(3 a4) e^(-3 a4)
```

301 values of a_4 from 0 to 3 in steps of 0.01; at each, the factor e^{a_4} of a direction of ordinary space and the factor e^{-a_4} of an extra time at $b_4 = 1$ (both divided by the common number $\sin^{1/6} z$; a constant b_4 would only multiply the second by $b_4^{1/2}$), and the product of three of each.

```
ORANGE = "#eb6834"
fig, ax = plt.subplots()
ax.plot(a4_values, growing, color=BLUE, linewidth=2,
        label=r"$e^{a_4}$: ordinary space $x_1, x_2, x_3$ (inflates)")
ax.plot(a4_values, shrinking, color=ORANGE, linewidth=2, linestyle="--",
        label=r"$e^{-a_4}$: extra times $x_5, x_6, x_7$ (deflate)")
ax.plot(a4_values, six_factors, color="black", linewidth=1.5, linestyle=":",
        label=r"product of all six: $e^{3 a_4} e^{-3 a_4} = 1$")
```

A new colour, a new figure, and three curves: a solid blue line, a dashed orange line (the line style of two hyphens) and a dotted black line; `linewidth` is the thickness of a line in points.

```
ax.set_yscale("log")  # a logarithmic vertical axis
ax.set_xlabel(r"the metric function $a_4$ (a pure number)")
ax.set_ylabel(r"length factor divided by $\sin^{1/6} z$")
ax.set_title("As $a_4$ grows, ordinary space inflates and the extra times deflate")
```

`ax.set_yscale("log")` makes the vertical axis **logarithmic**: equal distances on it mean equal factors (0.1, 1, 10, 100). On such an axis the height of the point of e^{a_4} is proportional to $\ln e^{a_4} = a_4$, so the curve is a straight line rising with slope 1 (per factor e), and e^{-a_4} is a straight line falling with slope -1. The other lines label the axes and set the title.

```
# Direct labels at the right ends of the two lines (the numbers at a4 = 3).
ax.annotate(f"{growing[-1]:.2f}", (3.0, growing[-1]), xytext=(4, 0),
            textcoords="offset points", va="center")
ax.annotate(f"{shrinking[-1]:.4f}", (3.0, shrinking[-1]), xytext=(4, 0),
            textcoords="offset points", va="center")
ax.set_xlim(-0.1, 3.5)  # room on the right for the two numbers
ax.set_ylim(0.02, 150.0)  # room at the top for the legend
ax.legend(loc="upper left")
```

`growing[-1]` is the last entry of the array, the value at $a_4 = 3$ (a negative index counts from the end). `ax.annotate` writes the number next to the point $(3, e^3)$, shifted 4 points to the right (`xytext=(4, 0)` with `textcoords="offset points"`); likewise for e^{-3}. The limits of the axes leave room for these numbers and for the legend.

```
save_figure(fig, "scale_factors",
            r"The length factors of the author's metric at a fixed hidden "
            r"coordinate and $b_4 = 1$, divided by $\sin^{1/6} z$, against the "
            r"metric function "
            r"$a_4$ from 0 to 3 (horizontal axis, a pure number; vertical axis "
            r"logarithmic, a pure number). Solid blue: $e^{a_4}$, the factor of "
            r"each direction of ordinary space, which grows to $e^3 = 20.09$; "
            r"dashed orange: $e^{-a_4}$, the factor of each extra time, which "
```

```
            r"shrinks to $e^{-3} = 0.0498$; dotted black: the product of the three "
            r"space factors and the three extra-time factors, which stays exactly "
            r"1. On the logarithmic axis both exponentials are straight lines.")
report("e^(a4) at a4 = 3", f"{growing[-1]:.4f}")
report("e^(-a4) at a4 = 3", f"{shrinking[-1]:.6f}")
```

The figure is saved as `00b_2_scale_factors.png`, and the two values at $a_4 = 3$ are printed: $e^3 = 20.0855$ and $e^{-3} = 0.049787$ (Out [7]). What Figure 00b.2 shows: two straight lines on the logarithmic axis, one rising and one falling at the same rate, mirror images of each other in the horizontal line at 1, and the flat dotted product at 1. This is Fact 3 of Section 0.14 in a picture: whatever ordinary space gains, the extra times lose.

```
check(np.max(np.abs(six_factors - 1.0)) < 1e-12,
      "the product of the three inflating and three deflating factors is 1")
check(np.max(np.abs(np.log(growing) - a4_values)) < 1e-12
      and np.max(np.abs(np.log(shrinking) + a4_values)) < 1e-12,
      "on a logarithmic axis e^(a4) and e^(-a4) are straight lines of slope +1, -1")
```

The first check requires the product to be 1 at all 301 points up to 10^{-12} (rounding). The second uses `np.log`, the natural logarithm: $\ln e^{a_4} = a_4$ and $\ln e^{-a_4} = -a_4$ at all points, which is exactly the statement that the two curves are straight lines on the logarithmic axis.

In [8], the eight length factors.

```
AQUA = "#1baf7a"
z_fixed = np.pi / 4  # the hidden coordinate z = pi/4
a4_choices = [0.0, 0.5, 1.0]
factors = {}  # a4 -> the list of the eight length factors f0 ... f7
for a4_value in a4_choices:
    factors[a4_value] = [float(np.sqrt(abs(entry_functions[k](a4_value, 1.0,
                                                              z_fixed))))
                         for k in range(8)]  # at b4 = 1
```

A third colour, the fixed hidden coordinate $z = \pi/4$, and three values of a_4. For each value the list of the eight length factors $f_i = \sqrt{|g_{ii}|}$ of Fact 2 is computed at $b_4 = 1$ (the middle argument 1.0) with the numpy functions of In [5] (`abs` is the absolute value, `np.sqrt` the square root, `float` makes a plain Python number) and stored in the dictionary `factors` under the value of a_4.

```
say("a4    " + "  ".join(f"{name:>6}" for name in coordinates) + "  product")
for a4_value in a4_choices:
    row = "  ".join(f"{value:6.4f}" for value in factors[a4_value])
    say(f"{a4_value:<4}  {row}  {np.prod(factors[a4_value]):.4f}")
```

The table of Out [8]. `" ".join(...)` joins texts with two blanks between them; `{name:>6}` writes a name right-aligned in 6 characters, `{value:6.4f}` a number with 4 decimals in 6 characters, and `{a4_value:<4}` the value of a_4 left-aligned in 4 characters. `np.prod` multiplies all entries of a list. The printed rows are the numbers of Section 0.14: the factors of x_0 and x_4 are 1.0000; the other six are 0.9439 at $a_4 = 0$; 1.5562 and 0.5725 at $a_4 = 0.5$; 2.5657 and 0.3472 at $a_4 = 1$; and the product is 0.7071 in each row.

```
fig, ax = plt.subplots()
positions = np.arange(8)  # one group of bars per direction
width = 0.26  # the width of one bar; three bars side by side in each group
for shift, a4_value, colour in zip((-1, 0, 1), a4_choices, (BLUE, ORANGE, AQUA)):
    # edgecolor="white" with linewidth 1.5 leaves a thin gap between the bars.
    ax.bar(positions + shift * width, factors[a4_value], width, color=colour,
           edgecolor="white", linewidth=1.5, label=f"$a_4 = {a4_value:g}$")
```

A bar chart. `np.arange(8)` is the array 0, 1, ..., 7, one position per direction. For each value of a_4 the bars are shifted by -1, 0 or $+1$ bar widths, so that the three bars of a direction stand side by side. `ax.bar(positions, heights, width, ...)` draws one bar per position; `{a4_value:g}` writes the number in its shortest form (0, 0.5, 1).

```
ax.set_xticks(positions, labels=coordinates)
ax.set_xlabel("direction")
ax.set_ylabel(r"length factor $f_i = \sqrt{|g_{ii}|}$ (pure number)")
ax.set_title(r"The eight length factors at $z = \pi/4$, $b_4 = 1$, for three "
             r"values of $a_4$")
ax.legend(loc="upper center")
save_figure(fig, "length_factors",
            r"The eight length factors $f_i = \sqrt{|g_{ii}|}$ of the author's "
            r"metric at the hidden coordinate $z = \pi/4$ and $b_4 = 1$ for $a_4 = 0$ "
            r"(blue), "
            r"$a_4 = 0.5$ (orange) and $a_4 = 1$ (aqua); horizontal axis the "
            r"directions $x_0$ to $x_7$, vertical axis the factor (a pure number). "
            r"The factors of ordinary space $x_1$, $x_2$, $x_3$ grow from 0.94 to "
            r"2.57 as $a_4$ grows from 0 to 1, those of the extra times $x_5$, "
            r"$x_6$, $x_7$ shrink from 0.94 to 0.35, and those of the hidden "
            r"direction $x_0$ and of the time $x_4$ stay 1. The product of the eight "
            r"factors is $\cos(\pi/4) = 0.7071$ in all three cases.")
```

Labels, title, legend, and the figure `00b_3_length_factors.png`. What Figure 00b.3 shows: over x_0 and x_4 all three bars have the height 1; over x_1, x_2, x_3 the bars rise from blue to orange to aqua; over x_5, x_6, x_7 they fall.

```
products = [float(np.prod(factors[a4_value])) for a4_value in a4_choices]
A4_REPORT = "Revision/field_equations_a4/reports/wolfram-a4-report.json"
verdict, detail = recorded_check(A4_REPORT, "sqrt_abs_det_g_is_cos_z")
check_reproduces(
    all(abs(p - np.cos(z_fixed)) < 1e-12 for p in products) and verdict == "PASS",
    "the product of the eight factors is cos(pi/4) = 0.7071 for a4 = 0, 0.5, 1 "
    "(b4 = 1)",
    f"{A4_REPORT}, check sqrt_abs_det_g_is_cos_z")
```

The three products, and the verdict of the Wolfram check `sqrt_abs_det_g_is_cos_z` of the field equations for a_4 and b_4 (it states $\sqrt{|\det g|} = b_4^{3/2}\cos z$, which is $\cos z$ at $b_4 = 1$). `all(...)` is true when the condition holds for every product: each must equal $\cos(\pi/4)$ up to 10^{-12}. Out [8] ends with the PASS line and the record it reproduces.

In [9], the volume factor for three values of a_4 and two values of b_4.

```
z_values = np.linspace(0.005, np.pi / 2 - 0.005, 200)  # 200 values inside (0, pi/2)
```

200 values of z inside the patch.

```
def volume_factor(a4_value, b4_value):
    """The product of the eight length factors at every z of z_values."""
    product = np.ones_like(z_values)
    for k in range(8):
        values = (np.full_like(z_values, 1.0)
                  * entry_functions[k](a4_value, b4_value, z_values))
        product = product * np.sqrt(np.abs(values))
    return product
```

A function of a value of a_4 and a value of b_4. `product` starts as an array of 200 ones (`np.ones_like`) and is multiplied in turn by the eight length factors, computed at all 200 values of z at once (the 1.0-array again makes the constant entry an array). The result is the volume factor $f_0 \cdots f_7$ at every z.

```
volume = {a4_value: volume_factor(a4_value, 1.0) for a4_value in (0.0, 1.0, 2.0)}
volume_b4_2 = volume_factor(1.0, 2.0)  # a4 = 1, b4 = 2
```

A **dictionary comprehension** (a dictionary written with a `for` inside its braces) stores the volume factor at $b_4 = 1$ under each of $a_4 = 0$, 1 and 2; `volume_b4_2` is the volume factor at $a_4 = 1$, $b_4 = 2$.

```
fig, ax = plt.subplots()
ax.plot(z_values, np.cos(z_values), color="black", linewidth=1.5,
        label=r"$\cos z$")
ax.plot(z_values, 2.0 ** 1.5 * np.cos(z_values), color="black", linewidth=1.0,
        linestyle="--", label=r"$2^{3/2} \cos z$")
markers = {0.0: ("o", BLUE), 1.0: ("s", ORANGE), 2.0: ("^", AQUA)}
for start, a4_value in enumerate((0.0, 1.0, 2.0)):
    marker, colour = markers[a4_value]
    chosen = slice(4 * start, None, 12)  # every 12th point, shifted by 4
    ax.plot(z_values[chosen], volume[a4_value][chosen], marker, color=colour,
            markersize=6,
            label=rf"$f_0 \cdots f_7$ for $a_4 = {a4_value:g}$, $b_4 = 1$")
ax.plot(z_values[::12], volume_b4_2[::12], "D", color="#7a4fb0", markersize=5,
        label=r"$f_0 \cdots f_7$ for $a_4 = 1$, $b_4 = 2$")
```

The solid black curve $\cos z$ and the dashed curve $2^{3/2} \cos z$, then the computed points. The dictionary `markers` gives each value of a_4 a marker shape (`"o"` circles, `"s"` squares, `"^"` triangles) and a colour. `slice(4 * start, None, 12)` selects the entries number `4 * start`, `4 * start + 12`, `4 * star t + 24`, and so on to the end: every 12th point, starting at 0, 4 or 8, so that the three sets of markers do not hide each other. A string with both `r` and `f` in front is a raw f-string. The last `ax.plot` draws every 12th point of the volume factor at $b_4 = 2$ as purple diamonds (`"D"`; `[::12]` takes every 12th entry from the first).

```
ax.set_xlabel(r"hidden coordinate $z = 6 H x_0$ (radians)")
ax.set_ylabel(r"volume factor $\sqrt{|\det g|}$ (pure number)")
```

```
ax.set_title(r"The volume factor is $b_4^{3/2} \cos z$ for every value of $a_4$")
ax.legend(fontsize=8)
save_figure(fig, "volume_factor",
            r"The volume factor $\sqrt{|\det g|} = f_0 f_1 \cdots f_7$ of the "
            r"author's metric against the hidden coordinate $z = 6 H x_0$ from 0 to "
            r"$\pi/2$ (horizontal axis, in radians; vertical axis a pure number), "
            r"computed from the eight entries at $b_4 = 1$ for $a_4 = 0$ (blue "
            r"circles), $a_4 = 1$ (orange squares) and $a_4 = 2$ (aqua triangles), "
            r"with the curve $\cos z$ (black line), and at $a_4 = 1$, $b_4 = 2$ "
            r"(purple diamonds) with the curve $2^{3/2} \cos z$ (dashed). The three "
            r"sets at $b_4 = 1$ lie on $\cos z$: the volume factor does not depend "
            r"on $a_4$, because the inflation of ordinary space and the deflation "
            r"of the extra times cancel; it falls from 1 at $z = 0$ to 0 at "
            r"$z = \pi/2$. The set at $b_4 = 2$ lies on $2^{3/2} \cos z$: $b_4$ "
            r"enters only as the factor $b_4^{3/2}$.")
```

Labels, title, legend (in a smaller font, `fontsize=8`) and the figure `00b_4_volume_factor.png`. What Figure 00b.4 shows: circles, squares and triangles all sit on the one black curve $\cos z$, although the three values of a_4 stretch ordinary space by the factors 1, $e = 2.72$ and $e^2 = 7.39$; the diamonds sit on the dashed curve $2^{3/2} \cos z$, 2.83 times higher. This is Fact 4 of Section 0.14.

```
largest = max(float(np.max(np.abs(volume[v] - np.cos(z_values)))) for v in volume)
largest_b4_2 = float(np.max(np.abs(volume_b4_2 - 2.0 ** 1.5 * np.cos(z_values))))
report("largest difference from cos z (b4 = 1)", f"{largest:.1e}")
report("largest difference from 2^(3/2) cos z (b4 = 2)", f"{largest_b4_2:.1e}")
```

For each value of a_4 the largest distance of the 200 computed values from $\cos z$, and `max(...)` takes the largest of the three; likewise the largest distance of the values at $b_4 = 2$ from $2^{3/2} \cos z$. Out [9] prints 1.0×10^{-15} and 2.7×10^{-15}, a few times the machine epsilon of Section 0.22: only rounding.

```
verdict, detail = recorded_check(THEORY_REPORT, "sqrt_det_g_equals_cos_z")
check_reproduces(
    largest < 1e-12 and verdict == "PASS",
    "at b4 = 1 the volume factor equals cos z at 200 points for a4 = 0, 1 and 2",
    f"{THEORY_REPORT}, check sqrt_det_g_equals_cos_z")
verdict, detail = recorded_check(WOLFRAM_THEORY_B4, "sqrt_det_g")
check_reproduces(
    largest_b4_2 < 1e-12 and verdict == "PASS",
    "at a4 = 1, b4 = 2 the volume factor equals 2^(3/2) cos z at 200 points",
    f"{WOLFRAM_THEORY_B4}, check sqrt_det_g")
```

Two checks: at $b_4 = 1$ against the verdict of the Python verifier's check `sqrt_det_g_equals_cos_z`, and at $b_4 = 2$ against the verdict of the Wolfram verifier's check `sqrt_det_g` of the field theory with b_4.

In [10], the last check.

```
figure_names = ["00b_1_eta_heat_map.png", "00b_2_scale_factors.png",
                "00b_3_length_factors.png", "00b_4_volume_factor.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "the four figure files of this notebook exist")
all_checks_passed()
```

The four figure files must exist in the folder of the figures (in a check run of nbkit, in its scratch folder, which `output_file` points to). The last line prints ALL 17 CHECKS PASSED (notebook 00b): four checks in In [2], two in In [4], one in In [5], four in In [6], two in In [7], one in In [8], two in In [9] and one in In [10].

0.18 The honesty ledger, and how a report is tied to its files

The **honesty ledger** is the table of the main statements of the book, each with its label (Section 0.3), a short note where one is needed, and the reports of the Revision record that verify it. It is the book's promise in one page: whatever a later chapter says, its label is the one given here, and every reader can open the named reports and read the verdicts (Section 0.4, level 2). The ledger below has twenty rows. Every one of the 51 verifier reports of the Revision record belongs to exactly one row, and the five rows labelled HYPOTHESIS or OPEN have no report at all, because nothing in the record establishes them. Notebook 00c checks all of this and counts the checks of each row; the ledger describes the record on the date of the notebook's last verified run, which its provenance file records. (Reports in the folder `Revision/kohn_sham/reports` are written below with the short folder name `kohn_sham/reports`, and so on; every path starts in the folder `Revision`.)

statement (with its row number)	**label**	**verified in (folder Revision)**
(1) the gamma matrices, C, Γ, B; Pin(4,4) and Spin(4,4) (Chapters 4 and 5)	PROVED	`algebra/reports/wolfram-algebra.json`, `algebra/reports/python-algebra.json`
(2) the Lagrangians, field equations and energy-momentum tensor of both fields, and the canonical quantisation of dirac16complex (dirac16complex00 is a classical field and is not quantised); the geometry, the Dirac operator and the energy-momentum tensor also for a changing b_4 (Chapters 6, 7, 9 and 10)	PROVED; for a self-coupling $\lambda \neq 0$ the operator form of the energy-momentum tensor is proved only in a finite model of one set of 16 modes, and for the field on a whole slice of space it is OPEN (the field-equations record of Chapter 12 ASSUMES it)	`theory/reports/wolfram-field-theory.json`, `theory/reports/python-field-theory.json`, `theory/fock_quartic/reports/fock-quartic.json`, `theory/reports/wolfram-field-theory-b4.json`, `theory/reports/python-field-theory-b4.json`, `theory/reports/wolfram-field-theory-b4-emt-C.json`, `theory/reports/wolfram-field-theory-b4-emt-G.json`
(3) the exact scope of the non-triviality (Chapter 8)	PROVED	`theory/reports/wolfram-scope.json`, `theory/reports/python-scope.json`

statement (with its row number)	label	verified in (folder Revision)
(4) the conservation identities of the energy-momentum tensor; the spin connection (Chapters 6 and 9)	PROVED	lead_checks/reports/emt-divergence-and-spin-connection.json
(5) the field equations for a_4 and b_4; every vacuum history has b_4 constant and $a_4 = \pm H x_4$ plus a constant (Chapter 12)	PROVED	field_equations_a4/reports/wolfram-a4-report.json, field_equations_a4/reports/python-a4-report.json, field_equations_a4/reports/python-b4-block.json, metric_b4/results/vacuum-b4.json, lead_checks/reports/einstein-gauss-bonnet-a4.json
(6) the generalized Kronecker delta (GKD) and the three Lovelock tensors (Chapter 11)	PROVED	gkd_lovelock/results/lovelock-report.json, gkd_lovelock/results/gkd-selftest.json, gkd_lovelock/results/wolfram-gkd-report.json, gkd_lovelock/results/python-lovelock-report.json
(7) the curvature of the Revision record agrees with the values stored in the author's own notebooks, the earlier one ($b_4 = 1$) and the one with the metric function b_4 (Chapters 3 and 11)	PROVED; 5 of the 78 comparisons with the earlier notebook are NOT-AVAILABLE: that notebook stores no value to compare with	gkd_lovelock/comparison/author-comparison-report.json, metric_b4/results/wolfram-metric-b4-report.json, metric_b4/results/python-metric-b4-report.json
(8) the Kohn-Sham theory: the blocks, the rescaling, the exact exchange; the good-sector problem does not contain b_4 (Chapter 14)	PROVED	kohn_sham/reports/ks-theory-wolfram.json, kohn_sham/reports/ks-theory-python.json, kohn_sham/reports/ks-b4-wolfram.json

statement (with its row number)	**label**	**verified in (folder Revision)**
(9) the Kohn-Sham states along the deflating history (Chapters 15 and 16)	COMPUTED; at the chosen cutoff $L = 3$ of the hidden direction; the limit of large L is not established for every state	kohn_sham/reports/ks-rust-solver.json, kohn_sham/reports/ks-reference.json, kohn_sham/reports/ks-crosscheck.json, kohn_sham/reports/ks-rust-determinism.json, kohn_sham/reports/ks-rust-mermin-roots.json, kohn_sham/tip_convergence/tip-convergence.json
(10) the Kohn-Sham history of a_4 is a prescribed background (Chapter 17)	ASSUMED	field_equations_a4/reports/ks-source-conditions.json, field_equations_a4/ks_source/reports/ks-source-a4.json
(11) the pairing theorems T1, T2 (with the Z2 mirror ASSUMED) and Q, also with b_4 (Chapter 18)	PROVED	pairing/reports/wolfram-pairing.json, pairing/reports/python-pairing.json, metric_b4/results/consequences-b4.json
(12) T3 and its completion (with the Z2 mirror and the Kohn-Sham approximation ASSUMED): the Kohn-Sham universes of mass $+M$ and $-M$ (Chapter 19)	PROVED	pairing/kohn_sham/reports/wolfram-t3.json, pairing/kohn_sham/reports/python-t3.json, pairing/kohn_sham/reports/wolfram-t3-completion.json, pairing/kohn_sham/reports/python-t3-completion.json
(13) T3 shown on computed Kohn-Sham states of mass $+M$ and $-M$ (Chapter 19; demonstrations, not proofs)	COMPUTED	pairing/kohn_sham/reports/t3-rust-demo.json, pairing/kohn_sham/reports/t3-reference-demo.json
(14) the charge-conjugation matrices C and ΓC; the local conservation law of the U(1) charge (Chapters 5, 10 and 21)	PROVED	lead_checks/reports/charge-conjugation-and-u1.json

statement (with its row number)	label	verified in (folder Revision)
(15) the dark-sector investigation: what equations of state each field can give under stated assumptions about the observer (Chapter 22)	COMPUTED	`dark_sector/dirac16complex/reports/derivation-checks.json`, `dark_sector/dirac16complex/reports/ks-history-run.json`, `dark_sector/dirac16complex/reports/eos-checks.json`, `dark_sector/dirac16complex/reports/independent-checks.json`, `dark_sector/dirac16complex00/reports/python-derive-eos.json`, `dark_sector/dirac16complex00/reports/python-independent-numerics.json`
(16) a time-varying dark sector from the fields (Chapter 22)	HYPOTHESIS: investigated (row 15); results stated, not established	no report
(17) our universe has a partner of opposite charge (Chapters 20 and 21)	HYPOTHESIS: the T1 maps exist; that a partner exists is not shown	no report
(18) the total charge Q of one universe is constant (Chapters 18 and 21)	OPEN: holds only with no flux through the brane at $z = \pi/2$ (ASSUMED, not derived)	no report
(19) the big bang creates universes in pairs (Chapter 20)	OPEN: not proved; no creation process, rate or amplitude	no report
(20) what produces the observed excess of matter over antimatter (Chapter 21)	OPEN: the theory as built does not produce it	no report

Twelve remarks make the table exact.

- Rows 11 and 12 are PROVED theorems with an ASSUMED ingredient in their statement: T2 and T3 hold with the Z2 mirror, a choice of boundary condition at the edge of the hidden direction that the equations do not derive. A proved theorem with an assumption means: if the assumption holds, the conclusion holds.
- Rows 8, 9, 12 and 13 rest on the **Kohn-Sham approximation**, which is ASSUMED, not derived. It consists of four simplifications, each explained from zero in Chapters 13 to 15: (i) the problem is solved at one fixed instant x_4 at a time, as if the universe stood still at that instant (the stationary-slice, or adiabatic, ansatz); (ii) the action of the field on itself is replaced

by an average potential computed from the field's own density, made of the Hartree term (the interaction of the field with its own average density) and the exchange term of a uniform gas (a correction that comes from the anticommuting numbers of the field, computed exactly for a gas of the same density everywhere), while everything beyond these two terms, called correlation, is left out; (iii) only the states of such an average potential, called mean-field states, are used; (iv) the condition at the tip, the far end of the hidden direction, is chosen. The record states these hypotheses in `Revision/pairing/kohn_sham/t3-theory.json`, key `hypotheses`, and in `Revision/kohn_sham/ks-theory.json`. Rows 8 and 12 are exact statements about this approximation, and rows 9 and 13 are numbers computed in it: if the approximation is made, they hold, and a statement proved within an approximation says nothing about what lies outside it.

- Row 2 holds one report without a Wolfram counterpart, `theory/fock_quartic/reports/fock-quartic.json` (21 checks, written by one Python program with sympy and its own exact engine for the anticommutation rules of the quantum theory). It asks whether the energy-momentum tensor of dirac16complex with a self-coupling $\lambda \neq 0$ obeys, as an operator of the quantum theory, the exact relations that it obeys before quantisation (among them the relations between its energy density, its pressure and the potential of the self-coupling, Chapter 9). The answer is proved only in a finite model: one set of 16 modes (plane waves of one momentum in a flat frame, with frozen coefficients), whose quantum states number 2^{16}. There, for the solutions of the quantum field equation, the relations hold exactly, on every state, if and only if the operators are written in one particular order (the Wick, or normal, order), and they fail for every other order tested. For the field on a whole slice of space, for the dependence on the hidden direction and for the extra times nothing is proved: there the operator form is OPEN, and the field-equations record of Chapter 12 ASSUMES it; the symmetry and the conservation of this operator are not verified (Chapters 9 and 10).

- Row 9 holds, besides the two solvers and their comparisons, the report `kohn_sham/tip_convergence/tip-convergence.json` (7 checks). The Kohn-Sham states are computed with the hidden direction cut off at the tip $L = 3$, a choice (item (iv) above). This study repeats the computation for L from 3 to 6 and finds that the recorded energies of the states without self-interaction lie within 1.4% of their values at large L, except for one state, while the effects of the self-interaction depend strongly on L, and that the limit of large L is not established for every state (Chapter 14). So the numbers of row 9 are COMPUTED at $L = 3$, and the note of the row says so.

- Row 7 compares the curvature computed in the Revision record with the values that the author's own Mathematica notebooks store. Its first report compares with the earlier notebook, whose metric is the case $b_4 = 1$; 73 of its 78 checks are PASS: four checks of the inputs (one that the file holding the author's stored outputs was taken from exactly their notebook, and three of the metric, the last of which finds the author's metric equal to the Revision's in all 64 components), the Ricci scalar, all 64 components of the Einstein tensor, the first Lovelock tensor and its scalar, which all agree exactly, and two negative controls (deliberate errors that the comparison must detect, and does): $4 + 1 + 64 + 2 + 2 = 73$. For five quantities the author's notebook stores no value (for the second and third Lovelock tensors no stored output was found there, and the Christoffel symbols, the Riemann tensor and the Ricci tensor are computed there but their printing is switched off), so nothing can be compared: their verdict is NOT-AVAILABLE, which is neither PASS nor FAIL. The comparison says nothing about these five quantities; the Revision's own computation of them is checked by the reports of

row 6. Its other two reports, by the Wolfram verifier (27 checks) and the independent Python verifier (21 checks) of the metric with b_4, compare with the author's notebook `Dirac_Einstein-Lovelock_4+4_Nash.nb` of 2026-10-14: the metric, the Ricci tensor and scalar, the Einstein tensor, the three Lovelock tensors and the vacuum equations equal the outputs stored there, and at $b_4 = 1$ they equal the earlier record.

- Row 10 is labelled ASSUMED although 29 checks belong to it. Those checks show that the computed Kohn-Sham states cannot be the source of the history $a_4 = AHx_4$ in the field equations (their energy-momentum tensor depends on x_0, and it violates an algebraic condition of the field equations), and, in the second report, that no recorded Kohn-Sham state is an admissible source, so that nothing about a_4 is derived from the coupled problem. So the history cannot be derived from them and is assumed.
- Row 13 is COMPUTED, next to the PROVED row 12: its two reports solve the Kohn-Sham equations numerically for mass $+M$ and $-M$ (with the Rust solver and with the Python reference solver) and compare the two members as T3 predicts. A numerical demonstration illustrates a theorem; it does not prove it.
- Row 15 is COMPUTED. The investigation derives exact identities (with sympy), but its results, the equations of state that each field can give, are computed numbers, and they depend on an ASSUMED way in which an observer in 3-space normalises over the extra times. It states what each field can and cannot produce; it establishes neither hypothesis, which is why row 16 stays a HYPOTHESIS.
- Corollary C1 of Section 0.2 has no row of its own: it is T1 (row 11) combined with the checks `einstein_no_vacuum_solution` of `Revision/field_equations_a4/reports/wolfram-a4-report.json` and `einstein_no_vacuum` of `Revision/field_equations_a4/reports/python-a4-report.json` (row 5).
- Row 17 is a HYPOTHESIS and not a theorem, although T1 is proved. T1 says: if a universe with mass $+m$ is a solution, its image with mass $-m$ is a solution too, with the opposite charge. It does not say that the image exists alongside ours; a single universe is an equally valid solution without its partner, and for universes quantised independently of each other there is no cancellation of the charges (Q).
- Rows 14 and 18 separate what is proved about the charge from what is not. PROVED is the local law $\partial_\mu(\cos z\, J^\mu) = 0$ on every solution: no charge is made or destroyed at any point. The total charge Q of a slice of space is constant only if no charge flows through its edge, the brane at $z = \pi/2$; this no-flux condition is ASSUMED, not derived, and it fails on the exact homogeneous solutions of Chapter 18. So the constancy of the total charge is OPEN.
- Rows 19 and 20 are OPEN, not hypotheses, because the book examines them as questions and finds that the record does not answer them. Row 19: no equation of the record describes the creation of anything; the pairing record says so itself, in the list of twelve things that it does not establish (Notebook 00c prints the list). Row 20: Section 0.2 says why the theory as built does not produce the excess of matter over antimatter (it has no baryons, no process that changes their number and no violation of CP); what does produce the excess is answered neither by the Revision record nor by this book.

The ledger is the state of the record on the date of the last verified run of Notebook 00c. The Revision record may still grow (verifier reports may be added or gain checks), and the final ledger

of the book is completed when the book is assembled; Notebook 00c is the tool that keeps the table honest, because it fails when a new report appears that no row claims.

Two independent verifiers. For eleven subjects (rows 1 to 3, 5, 6, 8 and 11, the two subjects of row 12, T3 and its completion, the metric with b_4 of row 7, and the geometry and the Dirac operator with b_4 of row 2) the exact statements were checked twice: by a verifier written in the Wolfram Language and by an independent one written in Python with sympy, sharing no code. (The finite model of row 2 is the exception: one Python program checks it.) The two do not check exactly the same list of statements, but where they overlap, an error would have to be made twice, in two languages, by two separate programs, to go unnoticed. The Kohn-Sham numbers (row 9) were computed twice in the same spirit, by the Rust solver and by an independent Python reference solver, and compared with tolerances fixed in advance (Chapter 16); the study of the tip cutoff ran the reference solver for two of its states at two of its values of L, 3 and 4 (28 comparisons, check `reference_solver_at_two_L` of `kohn_sham/tip_convergence/tip-convergence.json`).

Fingerprints. A report is worth something only for the exact files it was computed from. To tie the two together, a report writes down a **fingerprint** of each file it read. The fingerprint used here is **sha256**: a fixed recipe that turns the bytes of a file, however many there are, into a number of 256 binary digits, written as 64 **hexadecimal** characters. Hexadecimal digits are the sixteen symbols 0 to 9 and a to f, standing for the numbers 0 to 15; each one carries 4 binary digits, and $64 \cdot 4 = 256$. The recipe has three properties that matter here:

- it is deterministic: the same bytes always give the same fingerprint, on every computer;
- a change of a single byte changes the fingerprint completely, not just in one place;
- nobody knows how to construct two different files with the same fingerprint, and nobody has ever found such a pair.

The first property is a fact of the recipe. The second is not proved: Notebook 00c measures it for 115 one-character changes of one sentence (COMPUTED, below), and beyond these measured cases the book relies on it, so in general it is ASSUMED. The third is believed by everyone who uses sha256 but is not proved mathematically; the book relies on it, and so it is ASSUMED.

Three words of the theory of chance. The **probability** of an event is the fraction of the equally likely cases in which it happens: a fair die shows a six in 1 of its 6 equally likely cases, so with probability 1/6. An event and its opposite (a six, and no six) have probabilities that add up to 1, because together they cover every case exactly once. Two events are **independent** when knowing whether one of them happened does not change the probability of the other; then the probability that both happen is the product of their probabilities (two dice show two sixes with probability $\frac{1}{6} \cdot \frac{1}{6} = \frac{1}{36}$, because exactly 1 of the $6 \cdot 6 = 36$ equally likely pairs is two sixes). The **expected number** of events in a list is the average number of them that happen, taken over very many repetitions; it equals the sum of the probabilities of the single events, whether or not they are independent (a rule of the theory of chance that we use without proof). For example, 12 dice show on average $12 \cdot \frac{1}{6} = 2$ sixes.

How much should a fingerprint change? Suppose the new fingerprint behaves like a string of 64 hexadecimal characters chosen at random. One character of it equals the corresponding character of the old fingerprint with probability

$$p_{\text{same}} = \frac{1}{16}$$

(the new character is one of 16 equally likely symbols, and exactly one of them is the old one), so it differs with probability

$$p_{\text{differ}} = 1 - \frac{1}{16} = \frac{15}{16}$$

(the probabilities of an event and of its opposite add up to 1). The expected number of differing characters among the 64 is

$$64 \cdot \frac{15}{16} = 4 \cdot 15 = 60$$

(the expected number of differing characters is the sum, over the 64 characters, of the probability that the character differs; and $64/16 = 4$). Notebook 00c changes each character of a sentence of 115 characters in turn and finds that between 54 and 64 characters of the fingerprint change, 60.03 on average (COMPUTED): close to what a random string gives on average.

A report of the Revision record records the fingerprints of its input files in dedicated keys (the Wolfram check of the Lovelock tensors lists 15 files in its keys `inputSha256` and `sourceSha256`, and several reports have a key `inputs`, a list of files each with its fingerprint), or inside the detail text of a check, written as (sha256 followed by the 64 characters, or only their first 16). When the fingerprint of today's file equals the recorded one, the report was computed from exactly today's file, byte for byte. Notebook 00c compares 24 of the recorded fingerprints with today's files (those of the two reports on the Lovelock tensors in Python and in the Wolfram Language, and seven in the details of five Kohn-Sham reports; it does not compare the others), and Notebook 00d compares 582 more (Section 0.22).

Example: the ledger checked by the computer. Notebook 00c does at level 2 (Section 0.4) what a careful reader would do by hand, but for every report at once. It opens the charge-conjugation report, reads its twelve checks and confirms that three of them state the charge-conjugation matrices of Section 0.2 word for word, and that a fourth proves the local conservation law of the charge and says itself that it does not establish a constant total charge; writes one function that counts the checks of a report in each of the three layouts that occur in the record; searches the folder `Revision` (without the book's own folder and the records of the workflows) for reports and finds exactly the 51 of its list; confirms that no check has the verdict FAIL (all are PASS except five comparisons with the author's own notebook that are NOT-AVAILABLE) and that the counts agree with what the reports say about themselves, with the table of `Revision/README.md`, with the Kohn-Sham cross-check and with the dark-sector summary file; builds the ledger above and checks that every report belongs to exactly one row; prints the twelve sentences of the pairing record about what it does not establish; and compares fingerprints. It draws four figures and ends with ALL 18 CHECKS PASSED (notebook 00c).

0.19 How to run Notebook 00c

Step 1. What this notebook does and what it needs.

Notebook 00c (The honesty ledger: reading and checking the Revision record) is the file `Revision/textbook/notebooks/00c_honesty_ledger.ipynb` of the repository Dirac_claude. It finds the 51 verifier reports of the Revision record, counts their checks and confirms that none has the verdict FAIL (all are PASS except five comparisons with the author's outputs that are NOT-AVAILABLE), compares the counts with the summaries of the reports and with the numbers quoted elsewhere in the record, assigns every report to its row of the honesty ledger with the labels PROVED, COMPUTED, ASSUMED, HYPOTHESIS and OPEN, prints what the pairing record itself says is not established, compares 24 recorded sha256 fingerprints with the files of today, and draws four teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00c_honesty_ledger.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00c_honesty_ledger.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 00c_honesty_ledger.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/00c.captions.json`
- `Revision/textbook/figures/00c_1_checks_by_report.png`
- `Revision/textbook/figures/00c_2_two_verifiers.png`
- `Revision/textbook/figures/00c_3_ledger.png`
- `Revision/textbook/figures/00c_4_fingerprints.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the four figure files of this notebook exist
ALL 18 CHECKS PASSED (notebook 00c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/00c_honesty_ledger.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 00c_honesty_ledger.ipynb
python -m nbconvert --execute --inplace 00c_honesty_ledger.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of the Revision record is missing or damaged: the repository folder is incomplete. Delete the folder Dirac_claude, download it again with the git clone command of Step 3, and open the notebook from the new folder.
- "AssertionError: check failed: the 24 recorded fingerprints equal the files of today": a file of the Revision record was changed after its report was written; the table printed just above the error marks it CHANGED. The command below, run in the repository folder, lists every changed file; restore a changed file with the second command (write the file name printed in the table, with the folder Revision in front, instead of FILE).

```
git status
git restore FILE
```

0.20 Notebook 00c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/00c_honesty_ledger.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook checks the honesty ledger of the book: the table that gives every
main statement of the book its label (PROVED, COMPUTED, ASSUMED, HYPOTHESIS or
OPEN) and the place where it is verified. It does what a careful reader would do
by hand, but for every report at once. It

- opens one report of the Revision record and reads its checks one by one;
- writes a function that counts the checks of a report in each of the three
  layouts that occur, searches the whole folder Revision for reports, finds 51,
  and counts the checks of all of them;
- confirms that no check has the verdict FAIL (every check is PASS except five
  comparisons with the author's own outputs that could not be made, verdict
  NOT-AVAILABLE) and that the counts agree with the summaries that the reports
  state themselves, with the table of the file Revision/README.md, with the
  counts quoted by the Kohn-Sham cross-check and with the dark-sector summary;
- assigns every report to its row of the ledger, and prints the list of what the
  pairing record itself says is NOT established;
- computes sha256 fingerprints and compares 24 of the fingerprints that the
  reports recorded for their input files with the files of today;
- draws four teaching plots and prints a PASS line for every check.

It does not run the verifier programs again (they need Wolfram Mathematica or Rust
and minutes to hours); it checks what they recorded.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 00c (The honesty ledger: reading and checking the Revision record) is the file
‘Revision/textbook/notebooks/00c_honesty_ledger.ipynb‘ of the repository Dirac_claude. It
finds the 51 verifier reports of the Revision record, counts their checks and confirms
that none has the verdict FAIL (all are PASS except five comparisons with the author's
outputs that are NOT-AVAILABLE), compares the counts with the summaries of the reports
and with the numbers quoted elsewhere in the record, assigns every report to its row of
the honesty ledger with the labels PROVED, COMPUTED, ASSUMED, HYPOTHESIS and OPEN, prints
what the pairing record itself says is not established, compares 24 recorded sha256
fingerprints with the files of today, and draws four teaching plots. It needs a computer
with Windows 11, macOS or Linux, an internet connection for the installation, the program
```

Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00c_honesty_ledger.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00c_honesty_ledger.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 00c_honesty_ledger.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/00c.captions.json‘
- ‘Revision/textbook/figures/00c_1_checks_by_report.png‘
- ‘Revision/textbook/figures/00c_2_two_verifiers.png‘
- ‘Revision/textbook/figures/00c_3_ledger.png‘
- ‘Revision/textbook/figures/00c_4_fingerprints.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the four figure files of this notebook exist
ALL 18 CHECKS PASSED (notebook 00c)
```

and the notebook must show 4 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/00c_honesty_ledger.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command

below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 00c_honesty_ledger.ipynb
python -m nbconvert --execute --inplace 00c_honesty_ledger.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of the Revision record is missing or damaged: the repository folder is incomplete. Delete the folder Dirac_claude, download it again with the git clone command of Step 3, and open the notebook from the new folder.
- "AssertionError: check failed: the 24 recorded fingerprints equal the files of today": a file of the Revision record was changed after its report was written; the table printed just above the error marks it CHANGED. The command below, run in the repository folder, lists every changed file; restore a changed file with the second command (write the file name printed in the table, with the folder Revision in front, instead of FILE).

```
git status
git restore FILE
```

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 00c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 00c (The honesty ledger: reading and checking the Revision record) is the file
# Revision/textbook/notebooks/00c_honesty_ledger.ipynb of the repository Dirac_claude. It
# finds the 51 verifier reports of the Revision record, counts their checks and confirms
# that none has the verdict FAIL (all are PASS except five comparisons with the author's
# outputs that are NOT-AVAILABLE), compares the counts with the summaries of the reports
# and with the numbers quoted elsewhere in the record, assigns every report to its row of
# the honesty ledger with the labels PROVED, COMPUTED, ASSUMED, HYPOTHESIS and OPEN,
# prints what the pairing record itself says is not established, compares 24 recorded
# sha256 fingerprints with the files of today, and draws four teaching plots. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
```

```
# and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other
# packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
```

```
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
```

```
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 00c_honesty_ledger.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 00c_honesty_ledger.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 00c_honesty_ledger.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/00c.captions.json
# - Revision/textbook/figures/00c_1_checks_by_report.png
# - Revision/textbook/figures/00c_2_two_verifiers.png
# - Revision/textbook/figures/00c_3_ledger.png
# - Revision/textbook/figures/00c_4_fingerprints.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
```

```
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the four figure files of this notebook exist
#     ALL 18 CHECKS PASSED (notebook 00c)
#
# and the notebook must show 4 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/00c_honesty_ledger.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 00c_honesty_ledger.ipynb
#     python -m nbconvert --execute --inplace 00c_honesty_ledger.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" or "KeyError" naming a file below the folder Revision: a file of
#   the Revision record is missing or damaged: the repository folder is incomplete.
#   Delete the folder Dirac_claude, download it again with the git clone command of Step
#   3, and open the notebook from the new folder.
```

```
# - "AssertionError: check failed: the 24 recorded fingerprints equal the files of
#   today": a file of the Revision record was changed after its report was written; the
#   table printed just above the error marks it CHANGED. The command below, run in the
#   repository folder, lists every changed file; restore a changed file with the second
#   command (write the file name printed in the table, with the folder Revision in front,
#   instead of FILE).
#     git status
#     git restore FILE
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Revision record**: the computations stored in the folder Revision of the
  repository, done anew for the author's metric. Every number of the book comes
  from it or from a notebook of the book.
- **Verifier, report**: a *verifier* is a program that checks statements; it writes
  its results into a *report*, a JSON file (a plain text file of names, numbers and
  lists).
- **Check, verdict**: a *check* is one statement tested by a verifier; its *verdict*
  is PASS (true) or FAIL (false). Each check also has a name and a detail text.
- **Engine**: the program that did the computation: **Wolfram Language** (the
  language of Mathematica, run with wolframscript), **Python** (with the packages
  sympy, numpy and mpmath), or **Rust** (a fast compiled language). The *lead's
  independent checks* are short Python programs that share no code with the other
  verifiers.
- **Independent**: two verifiers are independent when they share no code; when both
  agree, a programming error in one of them would have to be repeated in the other
  to go unnoticed.
- **Dictionary, list** (Python): a *list* `[a, b, c]` is an ordered collection; a
  *dictionary* `{"name": value, ...}` stores values under names (*keys*). A JSON
  file is read into dictionaries and lists.
- **The five labels**: **PROVED** (exact; the book gives the complete proof and,
  where the Revision record contains an exact computer check of the statement,
  names the report file and the check), **COMPUTED** (a number from a numerical
```

```
  computation, with its measured uncertainty and the file that holds it),
  **ASSUMED** (a starting point that the book does not derive: a convention, a
  physical input or an approximation), **HYPOTHESIS** (an idea that is stated and
  examined but not established), **OPEN** (a question that neither the Revision
  record nor the book answers).
- **Ledger**: the table of the statements, their labels and the reports that
  verify them.
- **Fingerprint (sha256)**: a number of 64 hexadecimal characters computed from the
  bytes of a file by a fixed recipe. The same file always gives the same
  fingerprint. A file that differs in a single byte has, in every case anyone has
  tried, a completely different one; this is not proved, and section 10 measures
  it for 115 changes. **Hexadecimal**: the digits 0 to 9 and the letters a to f,
  sixteen symbols in all.
```

Text cell:

```
## 4. The physical and mathematical situation

The rule above every other rule of the book is honesty: it never writes "proved"
for a statement that is not proved. To make this rule checkable, every statement
carries one of five labels and names the place where it is verified. A statement
can be checked at three levels:

1. **The derivation**: follow it line by line in the book.
2. **The report**: open the report of the verifier that checked it and read the
   verdict of the named check. This notebook works at this level.
3. **The computation**: run the verifier again and compare its new report with the
   stored one (the last chapter of the book lists every command).

Two facts make level 2 trustworthy. First, the exact statements of eleven subjects
were checked by two independent verifiers, one in Wolfram Language and one in
Python, and the Kohn-Sham numbers by two independent solvers, one in Rust and one
in Python.
Second, a report records the sha256 fingerprints of the files it read; when the
fingerprints of today's files are the same, the report belongs to exactly these
files.

A ledger row labelled OPEN or HYPOTHESIS has no report: nothing in the record
establishes it. In particular the record proves exact maps between the solutions
of mass $+m$ and those of mass $-m$ (the pairing theorems T1, T2, Q and T3), but it
does not prove that the big bang creates universes, in pairs or otherwise, and the
theory as built does not explain the excess of matter over antimatter. It proves
that no charge is made or destroyed at any point (a *local* conservation law), but
not that the total charge of a universe stays constant. The pairing record states
itself what it does not establish; the notebook prints that list.
```

Text cell:

```
## 5. One report, opened by hand

The next cell defines the function `read_report`, which reads a JSON file of the
repository into Python dictionaries and lists, and the helper `check_reproduces`.
```

‘check_reproduces‘ is the helper ‘check‘ for a check that reproduces a Revision record: it first calls ‘sys.stdout.flush()‘, which sends all printed text that is still waiting, and then calls ‘check‘ with the record. (Jupyter sends printed text in pieces; flushing first keeps the PASS line and the line ‘reproduces ...‘ below it in one piece, so that the book’s tools read them together.)

Then the cell opens the report of the lead’s independent check of the charge-conjugation matrices and of the local conservation law of the charge, Revision/lead_checks/reports/charge-conjugation-and-u1.json. It prints the program that wrote the report (its *producer*), the verdict and name of each of its 12 checks, and the summary that the report states about itself. The check confirms that our count of the verdicts PASS equals that summary.

In [2]:

```
import hashlib  # computes sha256 fingerprints
import re  # finds patterns in texts ("regular expressions")
import sys  # sys.stdout is the channel through which the notebook prints

import numpy as np  # arrays of numbers

def read_report(path):
    """The content of the JSON file path of the repository (dictionaries, lists)."""
    return json.loads(repository_file(path).read_text(encoding="utf-8"))

def check_reproduces(condition, name, record):
    """check(condition, name, record=record), after sending the waiting output."""
    sys.stdout.flush()  # send every printed line that is still waiting
    check(condition, name, record=record)

CC_REPORT = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
cc = read_report(CC_REPORT)  # a dictionary with the keys producer, summary, checks
producer = cc["producer"]
say(f"producer: {producer}")
for entry in cc["checks"]:  # each entry is a dictionary: name, verdict, detail
    verdict, name = entry["verdict"], entry["name"]
    say(f"  {verdict}  {name}")
stated = cc["summary"]  # what the report says about itself: passed and total
stated_passed, stated_total = stated["passed"], stated["total"]
say(f"the report states: {stated_passed} passed of {stated_total}")
passed = sum(1 for entry in cc["checks"] if entry["verdict"] == "PASS")
number_of_checks = len(cc["checks"])
report("checks with the verdict PASS, counted", f"{passed} of {number_of_checks}")
check_reproduces(passed == stated["passed"] == stated["total"] == 12,
                 "12 of 12 checks of the charge-conjugation report are PASS",
                 f"{CC_REPORT}, its summary")
```

Out [2]:

```

  PASS  intertwiners_reversed_mass
  PASS  charge_conjugation_matrix_plus
  PASS  charge_conjugation_matrix_minus
  PASS  majorana_conditions_consistent
  PASS  bilinears_under_charge_conjugation
  PASS  quantum_charge_conjugation_unitary_type
  PASS  real_fields_charge_conjugation
  PASS  spinor_connection_real
  PASS  u1_noether_matrix_identity
the report states: 12 passed of 12
RESULT checks with the verdict PASS, counted = 12 of 12
PASS 12 of 12 checks of the charge-conjugation report are PASS
     reproduces Revision/lead_checks/reports/charge-conjugation-and-u1.json, its summary
```

Text cell:

```
Every check also has a detail text that says exactly what was verified. The next
cell prints the details of five checks of the same report. They say, in the
report's own words, that the author's gamma matrices are real, so that plain
complex conjugation changes nothing at all in a real field (the charge conjugation
of the theory is a MATRIX, not plain complex conjugation); that the
charge-conjugation matrix which keeps the mass is $\mathcal{C}_+ = C$ and the one
which reverses the mass is $\mathcal{C}_- = \Gamma C$; that for a real commuting
field the charge current is zero and $\mathcal{C}_+$ acts as the identity, while
the real matrix $\Gamma$ with the mass reversed maps solutions to solutions; and
that the charge obeys a *local* conservation law: on every solution
$\partial_\mu(\cos z\, J^\mu) = 0$, so no charge is made or destroyed at any point.
The same detail says what this check does NOT establish: the total charge $Q$ of a
slice of space is constant only if no charge flows through its edge, the brane at
$z = \pi/2$, where the flow is not zero in general. (These statements are derived
from zero later in the book; the book labels the constancy of the total charge
OPEN.) The detail of the last check is long; the cell prints only its last two
parts, after the second-to-last semicolon, which state the result and its limit.
The details are long texts; ‘say‘ breaks each into lines of at most 89
characters. The two checks of the cell confirm that the details contain these
statements word for word.
```

In [3]:

```
details = {entry["name"]: entry["detail"] for entry in cc["checks"]}  # name -> detail
for wanted in ("representation_real", "charge_conjugation_matrix_plus",
               "charge_conjugation_matrix_minus", "real_fields_charge_conjugation",

```
## 6. Three layouts of a report, one counting function

The reports of the Revision record were written by different programs, and their
checks come in three layouts:

- **layout A**: ‘checks‘ is a list of dictionaries, each with a ‘name‘ and a
  ‘verdict‘ (written PASS or pass);
- **layout B**: ‘checks‘ is a dictionary from the name of each check to a
  dictionary with the entry ‘passed‘ (true or false);
- **layout C**: the self-test of the Rust function GKD has no ‘checks‘ but a list
  ‘results‘, one per test, each with the number of ‘mismatches‘ (wrong values).

The reports also state their own totals in different words (‘summary‘, ‘counts‘,
‘checkCount‘), and two of them as a text, such as "49/49 checks pass". The next
cell defines ‘count_checks‘, which counts the passed checks in all three layouts,
and ‘stated_summary‘, which reads the totals that a report states about itself.
It shows one report of each layout.
```

In [4]:

```
def count_checks(data):
    """(number of passed checks, number of checks), counted from the checks."""
    if isinstance(data.get("checks"), list):  # layout A
        verdicts = [entry["verdict"].upper() == "PASS" for entry in data["checks"]]
    elif isinstance(data.get("checks"), dict):  # layout B
        verdicts = [entry["passed"] is True for entry in data["checks"].values()]
    else:  # layout C: a self-test passes when it found no mismatch
        verdicts = [entry["mismatches"] == 0 for entry in data["results"]]
    # True counts as 1 and False as 0 when added.
    return sum(verdicts), len(verdicts)

## 7. All 51 reports of the Revision record

The next cell first searches the whole folder Revision for reports: JSON files
whose key ‘checks‘ holds the checks themselves (a list of checks, or a dictionary
whose every entry is a check, that is, a dictionary itself), or, like the GKD
self-test, a list ‘results‘ whose entries count ‘mismatches‘. One JSON file has a
key ‘checks‘ that holds only two numbers, the totals of another report: the
summary file Revision/dark_sector/dirac16complex/outputs/eos-summary.json. It is
not a report, and the search prints its name; the cell after the next compares its
two numbers with our count. The search skips three kinds of folders that are not
part of the record: the folder Revision/textbook of this book, the folder
Revision/workflows (the records of the programs that organised the work, rewritten
while they run; the Revision record says itself that no result depends on them),
and the build folders ‘target‘ of the Rust programs. The cell then lists the 51
verifier reports of the Revision record, grouped by folder, each with its engine
(the language of the program that wrote the report), counts the checks of each with
‘count_checks‘, and prints a table and the totals per engine.

One report has checks whose verdict is neither PASS nor FAIL: the comparison of
the Revision’s curvature with the outputs that the author stored in their own
Mathematica notebook, Revision/gkd_lovelock/comparison/author-comparison-report.json.
For five quantities the author’s notebook holds no stored value (three of them,
the Christoffel symbols, the Riemann tensor and the Ricci tensor, are computed
there with their printing switched off; for the second and third Lovelock tensors
no stored output was found there), so there is nothing to compare; their verdict
```

is NOT-AVAILABLE. Three checks follow:

1. the search finds exactly the 51 reports of the list: no report of the record is
   left out of the count (and so out of the ledger below);
2. no check of the 51 reports has the verdict FAIL: every check is PASS, except
   the five NOT-AVAILABLE comparisons of that one report;
3. for every report that states its own totals, our count equals them (the
   self-test of layout C states only its verdict, SUCCESS, which is checked
   instead).

‘folder.rglob("*.json")‘ lists every JSON file in a folder and in all its
sub-folders; ‘path.as_posix()‘ writes a path with ‘/‘; ‘path.removeprefix("Revision/")‘
removes the folder name Revision/ from the front of a path, to keep the table
narrow. Reading every JSON file of the record (a few hundred files) takes about a
second.

```

Text cell:

```
The next cell compares our counts with three other places of the record that quote
them. First, the table of the file Revision/README.md (its lines that start with
a vertical bar and a folder name) prints 49 counts as "19/19", "49/49" and so on;
the counts of the reports on the Lovelock tensors stand there twice, in the row
of their folder and in the row of the documents. The cell finds the counts in the
order in which they stand there and compares them with our counts of the reports
that the table names in that order. The function ‘re.findall‘ of the module ‘re‘
finds every piece of a text that matches a *pattern*: in the pattern
‘(\d+)/(\d+)‘, ‘\d+‘ means one or more digits, and the brackets mark the two
numbers to return. Second, the Kohn-Sham cross-check quotes, in the detail of its
check ‘inputs_all_pass‘, the counts of the three reports it read ("37/37 PASS" and
so on), found with the pattern ‘(\d+)/(\d+) PASS‘. Third, the dark-sector summary
file that the search set aside quotes, under its key ‘checks‘, the totals of the
report eos-checks.json.
```

## 8. Two independent engines

For eleven subjects the Revision record has two independent verifiers, one in
Wolfram Language and one in Python. The next cell draws, for each subject, the
number of checks of the two verifiers side by side. The two verifiers do not
check exactly the same list of statements (each also checks things the other does
not), so the numbers differ; the point is that two programs, written separately in
two different languages, both find the results of each subject correct.
```

In [8]:

```
SUBJECTS = [  # (subject, Wolfram report, Python report)

```
## 9. The honesty ledger

The next cell writes the ledger: twenty rows, each with a statement of the book,
its label, a short note where one is needed, and the reports that verify it. Every
one of the 51 reports belongs to exactly one row. The five rows labelled HYPOTHESIS
or OPEN have no report: nothing in the record establishes them, and their notes
say why. Two rows of PROVED theorems name an assumption in their statement: the
pairing theorems T2 and T3 hold with the Z2 mirror (a choice of boundary
condition) ASSUMED. Four rows (8, 9, 12 and 13) rest, in addition, on the
Kohn-Sham approximation, which is ASSUMED: a set of simplifications, stated in the
record and explained from zero later in the book. The equations are solved at one
fixed instant at a time; the action of the field on itself is replaced by an
average potential computed from the field's own density, in a stated approximate
form; and a condition at the far end of the hidden direction is chosen. Rows 8 and
12 are exact statements about this approximation, and rows 9 and 13 are numbers
computed in it. Row 2 says "dirac16complex quantised" because only that field is
quantised; the field dirac16complex00 stays a classical field. The row of the
Kohn-Sham history of $a_4$ is labelled ASSUMED
although it has 29 checks: those checks show that the computed Kohn-Sham states
cannot be the source of that history in the field equations, so the history has
to be assumed (a *prescribed background*). Three rows with reports have a note as
well. Row 2: for a self-coupling $\lambda \neq 0$ the operator form of the
energy-momentum tensor (EMT) of dirac16complex is proved only in a finite model
(one set of 16 modes, checked by one Python program, its third report); for the
field on a whole slice of space it is OPEN: nothing proves it there, and the
record of the field equations for $a_4$ assumes it. Row 7,
the comparisons of the Revision's curvature with the values that the author stored
in their own notebooks (the earlier notebook at $b_4 = 1$, and the notebook with
the metric function $b_4$ of 2026-10-14): five comparisons of the first report
could not be made (NOT-AVAILABLE).
Row 9: the Kohn-Sham states are computed with the far end of the hidden direction
cut off at $L = 3$; a study of larger $L$ (its sixth report) finds that the limit
of large $L$ is not established for every state.

Rows 13 and 15 are labelled COMPUTED as well, because they rest on numerical
computations. Row 13: the theorem T3 is proved (row 12) and, in addition,
demonstrated on computed Kohn-Sham states of mass $+M$ and $-M$; a demonstration
is not a proof.
Row 15: the author's dark-sector hypotheses were investigated; the investigation
derives exact identities, but its results, the equations of state that each field
can give, are computed numbers under stated assumptions about the observer. It
states what each field can and cannot produce; it does not establish the
hypotheses (row 16, HYPOTHESIS).

Several rows concern pairs of universes and matter and antimatter, and their words
are chosen with care. PROVED (rows 11 and 12) are exact maps between the solutions
```

of mass $+m$ and those of mass $-m$; the map T1 also reverses the charge, so a solution and its image carry opposite charges. That our universe actually has such a partner is a HYPOTHESIS (row 17: an idea of the universe and anti-universe kind, not a result). PROVED (row 14) is the local conservation law of the charge: no charge is made or destroyed at any point. That the total charge of one universe stays constant is OPEN (row 18): it holds only if no charge flows through the brane at $z = \pi/2$, a no-flux condition that is ASSUMED, not derived, and that fails on the exact homogeneous solutions found later in the book. That the big bang creates universes in pairs is not proved: no creation process, rate or amplitude follows from the equations (row 19, OPEN). The theory as built has no baryons (the particles of ordinary matter such as the proton), no process that changes their number and no violation of the CP symmetry (the exchange of particles and antiparticles combined with a mirror reflection; it must be violated for matter to win over antimatter), so it does not produce the excess of matter over antimatter that we observe. What does produce it is a question that neither the record nor the book answers (row 20, OPEN).

The cell prints the ledger and the notes, and checks that every report is used exactly once; that the HYPOTHESIS and OPEN rows have a note and no report, and every other row has reports; that only row 7 has checks that are not PASS, its five NOT-AVAILABLE comparisons; and it counts the labels.

```

Out [10]:

```
Figure 00c.3 saved as Revision/textbook/figures/00c_3_ledger.png
```

Text cell:

The pairing record states in its own words what the pairing theorems do NOT establish: the key ‘not_established‘ of the report Revision/pairing/reports/python-pairing.json is a list of twelve sentences. The next cell prints all twelve. The first says that nothing in the equations creates a universe or a pair of universes. This is why the ledger labels the statement "the big bang creates universes in pairs" OPEN.

In [11]:

```
PAIRING = "Revision/pairing/reports/python-pairing.json"
not_established = read_report(PAIRING)["not_established"]  # a list of sentences
for number, sentence in enumerate(not_established, 1):
    say(f"{number:2d}. {sentence}")
check_reproduces(len(not_established) == 12
                 and not_established[0].startswith("No creation process"),
                 "the pairing record lists 12 things it does not establish, "
                 "the first: no creation process",
                 f"{PAIRING}, key not_established")
```

Out [11]:

1. No creation process: nothing in these equations produces a universe, a pair of universes or a change of the number of universes; no transition between ’no universe’ and ’two universes’ is described.
2. No rate, probability or amplitude for creating a pair is derived; no wave function of the universe, path integral or tunnelling computation is part of these theorems.
3. No conservation law forces pairing: the theorems are symmetries (maps between solutions); a single universe with mass +m is an equally valid solution of the field

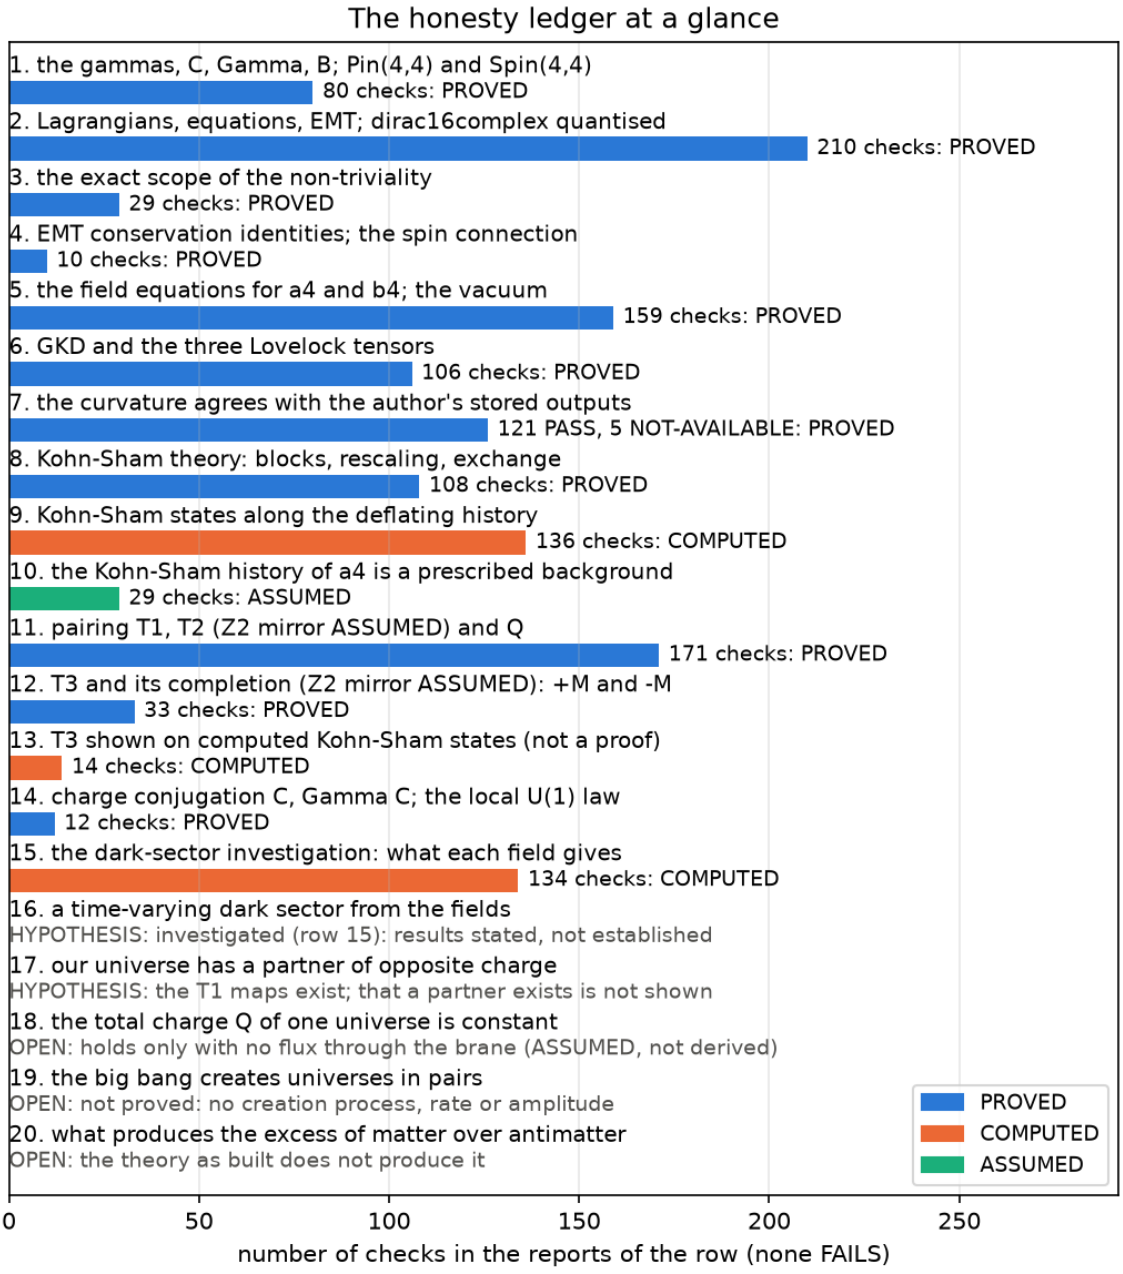

Figure 9: The honesty ledger of the book at a glance: one row per main statement (written above its bar), the length of its bar the number of checks in the reports that verify it (horizontal axis, a count), the colour its label: blue PROVED, orange COMPUTED, aqua ASSUMED. Every check is PASS except five NOT-AVAILABLE comparisons of row 7. The ASSUMED row has 29 checks, which show why the Kohn-Sham history of a_4 must be assumed. The last five rows have no bar, because no check of the record establishes them: two hypotheses (a time-varying dark sector, investigated in row 15 but not established; a partner universe of opposite charge) and three open questions (a constant total charge of one universe, which needs an assumed condition at the brane; the creation of universes in pairs, not proved; what produces the excess of matter over antimatter, which the theory as built does not produce). (Notebook 00c, figure 3.)

```
    equations without its partner.
 4. The vanishing total energy-momentum and charge of a pair (T1) is an identity for a
    field configuration and its image (classical bilinears, or one operator and its
    image); it is not a cancellation between two independently quantised universes
    (Q.no_cancellation_independent_universes).
 5. T2 does not reverse the sign of the energy-momentum tensor: the mirror universe of
    mass -m has the pulled-back T of the original, not -T.
 6. The Z2 brane at z = pi/2 and the mirror construction are ASSUMED (a boundary/orbifold
    choice), not derived from the field equations.
 7. The gravitational back-reaction (the a4 equations of SPEC section 5) is not part of
    the pairing theorems; T1 maps T -> -T, so a pair sourcing ONE common geometry would
    have zero total source, which is a statement about sources, not a derivation that
    such a geometry is created.
 8. No dynamical necessity: nothing forces the partner configuration to exist; the
    theorems are correspondences between solutions of two parameter sets, not a
    mechanism.
 9. T1 pairs (m, lambda) with (-m, -lambda): for lambda != 0 it is not a pure +m / -m
    pairing; the pure pairing (m, lambda) -> (-m, lambda) is T2, at EQUAL (not opposite)
    energy-momentum.
10. Quantum positivity: in flat 4+4 space every real-frequency energy eigenspace of the
    one-particle generator has Krein inertia (4,4) (Q.one_particle_Krein_inertia_proof)
    and every imaginary- or zero-frequency eigenspace (the growing extra-time modes) is
    Krein-neutral (Q.one_particle_complex_frequency_Krein_neutral); a positive-norm Fock
    space for either universe is not established by these theorems.
11. The brane z = pi/2 is a degenerate surface of the metric (g_00 = cot^2 z = 0, sqrt|g|
    = cos z = 0 there, geometry.brane_degenerate); no junction condition, brane tension
    or matching of the field across it is derived.
12. The Kohn-Sham level (T3) is not covered by this checker; it is proved separately in
    Revision/pairing/kohn_sham/ (check_t3.py, with its own hypotheses: ASSUMED Z2 brane,
    instantaneous mean-field Kohn-Sham states).
PASS the pairing record lists 12 things it does not establish, the first: no creation
    process
     reproduces Revision/pairing/reports/python-pairing.json, key not_established
```

Text cell:

```
## 10. Fingerprints

A sha256 fingerprint is computed from the bytes of a file (or of a text) by the
function ‘hashlib.sha256‘; ‘.hexdigest()‘ writes it as 64 hexadecimal characters.
The next cell computes the fingerprints of two texts that differ only in the case
of one letter, and shows that the two fingerprints have nothing in common.

Then it measures this for many changes: it takes one sentence of 115 characters,
changes each character in turn to the next character of the alphabet of the
computer (a to b, a blank to an exclamation mark, and so on), and counts how many
of the 64 characters of the fingerprint change. If the new fingerprint were a
random string, each of its 64 characters would equal the old one with
probability $1/16$, so on average $64 \cdot 15/16 = 60$ characters would change.
The cell draws the 115 counts as a histogram (a bar chart of how often each count
occurs).
```

RESULT characters of the sentence = 115
RESULT changed characters of the fingerprint: smallest, mean, largest = 54, 60.03, 64
```

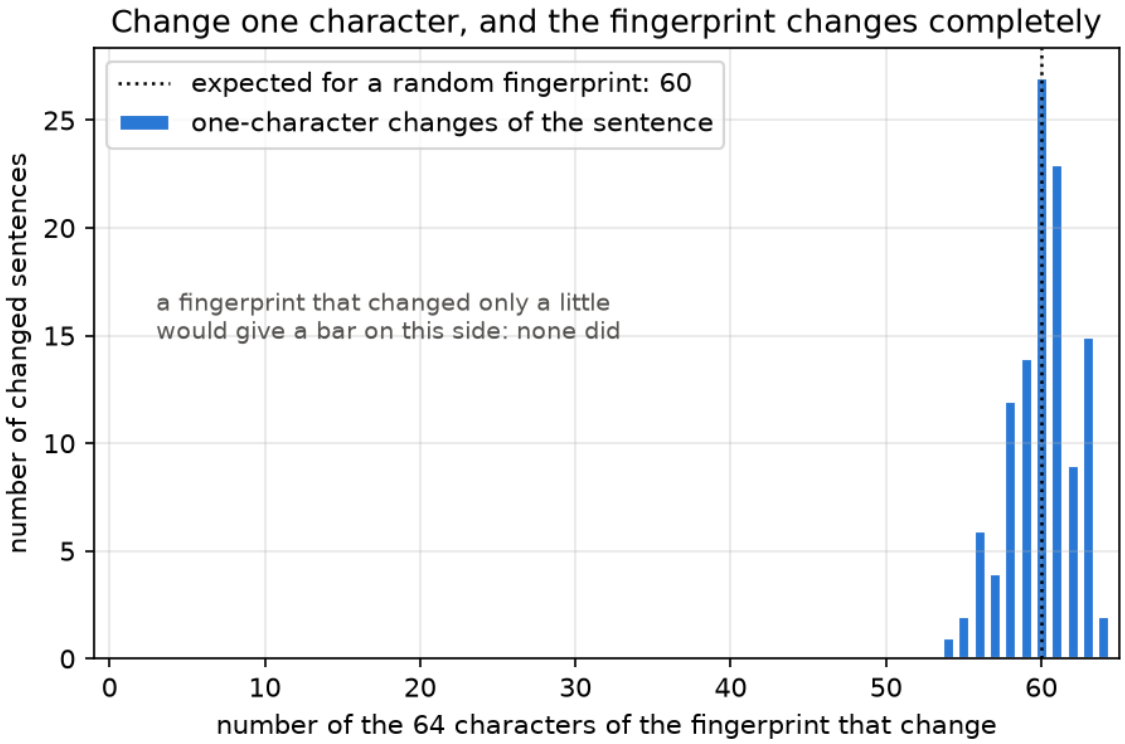

Figure 10: How much a sha256 fingerprint changes when one character of a text changes: for each of the 115 characters of one sentence, the character was replaced by the next one and the number of the 64 hexadecimal characters of the fingerprint that changed was counted; horizontal axis that number (0 to 64), vertical axis how many of the 115 altered sentences gave it. Every change altered between 54 and 64 of the 64 characters, on average 60.03, as for a random string (dotted line at 60): none of the 115 one-character changes left the fingerprint nearly the same. (Notebook 00c, figure 4.)

Out [12]:

```
Figure 00c.4 saved as Revision/textbook/figures/00c_4_fingerprints.png
PASS all 115 one-character changes alter more than half of the fingerprint
```

Text cell:

```
The reports of the Revision record write down the fingerprints of the files they
read. This notebook compares 24 of them. The report of the Wolfram check of GKD and
the Lovelock tensors records 15 (its keys ‘inputSha256‘ and ‘sourceSha256‘: the
result files, the Rust sources and its own Wolfram sources), the Python check of
```

the Lovelock tensors 2 (key ‘inputsSha256‘), and five Kohn-Sham reports write 7
more into the details of their checks, in the form ‘(sha256 95d8cbdd...)‘, either
in full (64 characters) or only the first 16 characters. Other reports record
further fingerprints (for example in a key ‘inputs‘, a list of files each with its
fingerprint); this notebook does not compare those. The next cell collects these
24, computes the fingerprints of today’s files, compares them (a shortened
fingerprint with the beginning of today’s), and prints a table. When all agree,
these reports read exactly today’s versions of these files.

## 11. The last check

The last cell checks that the four figure files of this notebook exist in the
folder Revision/textbook/figures and prints the number of checks that passed.
```

In [14]:

```
figure_names = ["00c_1_checks_by_report.png", "00c_2_two_verifiers.png",
                "00c_3_ledger.png", "00c_4_fingerprints.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "the four figure files of this notebook exist")
all_checks_passed()
```

Out [14]:

```
PASS the four figure files of this notebook exist
ALL 18 CHECKS PASSED (notebook 00c)
```

Text cell:

```
## 12. What this notebook showed

- A search of the whole folder Revision finds 51 verifier reports, the 51 of our
  list. No check has the verdict FAIL: every check is PASS except five
  comparisons with values that the author's own notebook does not store, whose
  verdict is NOT-AVAILABLE; section 7 prints how many checks there are, in all and
  per engine (Wolfram Language, Python, Rust and the lead's independent Python
  checks).
- Each report states the same totals that we counted, and the counts quoted in
  the file Revision/README.md, in the Kohn-Sham cross-check and in the
  dark-sector summary file are the same as well.
- Eleven subjects are checked by two independent verifiers, one in Wolfram Language
  and one in Python.
- Every report belongs to exactly one row of the honesty ledger. Fifteen rows have
  reports (eleven PROVED, three COMPUTED, one ASSUMED). The charge obeys a local
  conservation law (PROVED); that the total charge of one universe stays constant
  is OPEN, because it needs an assumed condition at the brane. Two rows are
  HYPOTHESIS (a time-varying dark sector, investigated but not established; a
  partner universe of opposite charge) and three are OPEN: the constancy of the
  total charge, whether the big bang creates universes in pairs (not proved), and
  what produces the excess of matter over antimatter (the theory as built does not
  produce it). The pairing record itself lists twelve things it does not
  establish, the first being any creation process.
- Each of the 115 one-character changes of a sentence changed more than half of
  the 64 characters of its sha256 fingerprint, 60.03 on average, as for a random
  string; and 24 fingerprints that the reports recorded for their input files,
  all that this notebook compares, equal those of today's files.
```

0.21 Line-by-line walk-through of Notebook 00c

The notebook has fourteen code cells, In [1] to In [14]. This section explains every line of each of them.

In [1], the set-up cell. It is the set-up cell of Notebook 00a, word for word, except that its comment lines hold the run instructions of Notebook 00c (Section 0.19) and the line `NOTEBOOK_ID = "00c"` names this notebook. Every line of its code is explained in Section 0.13. It prints Set-up of notebook 00c complete: repository folder found, helpers defined.

In [2], one report opened by hand.

```
import hashlib  # computes sha256 fingerprints
import re  # finds patterns in texts ("regular expressions")
import sys  # sys.stdout is the channel through which the notebook prints

import numpy as np  # arrays of numbers
```

Three modules of Python itself: `hashlib` computes fingerprints, `re` finds patterns in texts (In [6] explains them), `sys` gives the printing channel; and numpy.

```
def read_report(path):
    """The content of the JSON file path of the repository (dictionaries, lists)."""
    return json.loads(repository_file(path).read_text(encoding="utf-8"))

def check_reproduces(condition, name, record):
    """check(condition, name, record=record), after sending the waiting output."""
    sys.stdout.flush()  # send every printed line that is still waiting
    check(condition, name, record=record)
```

`read_report` reads a JSON file of the repository into dictionaries and lists, as explained for In [2] of Notebook 00b (Section 0.17). `check_reproduces` is the same helper as there: it sends the waiting printed text first, so that a PASS line and its line reproduces ... arrive together.

```
CC_REPORT = "Revision/lead_checks/reports/charge-conjugation-and-u1.json"
cc = read_report(CC_REPORT)  # a dictionary with the keys producer, summary, checks
producer = cc["producer"]
say(f"producer: {producer}")
```

The report of the lead's independent check of the charge-conjugation matrices and of the local conservation law of the charge (row 14 of the ledger) is read. Its key `producer` names the program that wrote it; the first two lines of Out [2] print it: `Revision/lead_checks/charge_conjugation_and_u1.py`, a short independent Python program that imports no other Revision code.

```
for entry in cc["checks"]:  # each entry is a dictionary: name, verdict, detail
    verdict, name = entry["verdict"], entry["name"]
    say(f"  {verdict}  {name}")
```

The loop prints the verdict and the name of each of its checks, the next twelve lines of Out [2]: from `representation_real` to `u1_noether_matrix_identity`, all PASS. (The line `verdict, name = a, b` gives two names at once.)

```
stated = cc["summary"]  # what the report says about itself: passed and total
stated_passed, stated_total = stated["passed"], stated["total"]
say(f"the report states: {stated_passed} passed of {stated_total}")
passed = sum(1 for entry in cc["checks"] if entry["verdict"] == "PASS")
number_of_checks = len(cc["checks"])
report("checks with the verdict PASS, counted", f"{passed} of {number_of_checks}")
check_reproduces(passed == stated["passed"] == stated["total"] == 12,
                 "12 of 12 checks of the charge-conjugation report are PASS",
                 f"{CC_REPORT}, its summary")
```

A report also states its own totals, under the key `summary`; they are printed. Then the notebook counts for itself: `sum(1 for entry in ... if ...)` adds 1 for every check whose verdict is PASS, and `len` is the number of checks. Python allows a chain of comparisons, `a == b == c == 12`, which is true only when every neighbouring pair is equal. The check requires that our count, the stated number of passed checks and the stated total are all 12. This is level 2 of Section 0.4, done by the computer.

In [3], five details of the same report.

```
details = {entry["name"]: entry["detail"] for entry in cc["checks"]}  # name -> detail
```

A **dictionary comprehension**: for every check of the report it stores the detail text under the name of the check, so that, for example, `details["representation_real"]` is the detail of the check `representation_real`.

```
for wanted in ("representation_real", "charge_conjugation_matrix_plus",
               "charge_conjugation_matrix_minus", "real_fields_charge_conjugation",
               "u1_noether_matrix_identity"):
    detail = details[wanted]
    if wanted == "u1_noether_matrix_identity":
        # This detail is long; its last two parts, after the second-to-last "; ",
        # state the result and its limit.
        detail = "; ".join(detail.split("; ")[-2:])
    say(f"{wanted}:")
    say("    " + detail)  # say breaks it into lines of at most 89 characters
```

For five check names the loop looks up the detail and prints the name and, below it and indented by four blanks, the detail; `say` (Section 0.13) breaks a long detail into lines of at most 89 characters and indents every further line by four blanks, so no line of Out [3] is wider than a page of the book. The last detail is long; `detail.split("; ")` cuts it into a list of pieces at every semicolon followed by a blank, `[-2:]` keeps the last two pieces, and `"; ".join(...)` glues them together again with the same separator: the result and its limit. Out [3] prints, in the report's own words (written with plain letters: `calC_+` is $\mathcal{C}_+$, `Psi*` is Ψ^*, `^T` marks a transposed matrix, Chapter 1, and `d_mu` is the derivative ∂_μ): that the gammas, C and S^{ab} are real, so that plain complex conjugation is the identity on a real field; that $\mathcal{C}_+ = C$ satisfies $\mathcal{C}_+^{-1}\gamma^a\mathcal{C}_+ = -(\gamma^a)^T$ for every direction a, and that its conjugate field is $\Psi^c = \Psi^*$; that $\mathcal{C}_- = \Gamma C$ satisfies $\mathcal{C}_-^{-1}\gamma^a\mathcal{C}_- = +(\gamma^a)^T$, and that its conjugate field $\Gamma\Psi^*$ solves the field equation in which the term V that holds the mass has the opposite sign (the report writes $V \to -V$); that for a real commuting field the charge current J^a is zero, $\mathcal{C}_+$ acts as the identity, and the real matrix Γ together with the reversal of the mass maps solutions to solutions (this is T1). The last detail says two things. First: "on shell the LOCAL law d_mu(cos z J^mu) = 0 holds", that is, whenever the field equations hold ("on shell"), $\partial_\mu(\cos z\, J^\mu) = 0$: charge can only flow from one place to another; no charge is made or destroyed at any point. Second, the limit: the total charge $Q = \int \cos z\, \Psi^\dagger B \Psi\, d^7x$ of a slice of space (the integral over the seven directions other than the time x_4) is constant only if no charge flows through the boundary of the slice; at the brane $z = \pi/2$, the edge of the hidden direction, the flow is not zero in general, and the report ends: "constancy of Q is NOT established by this check". The book therefore labels the local law PROVED (row 14 of the ledger) and the constancy of the total charge OPEN (row 18): it would need a no-flux condition at the brane, which is ASSUMED, not derived, and Chapter 18 shows exact solutions on which it fails.

```
R5_WORDS = [  # (check, words that its detail must contain)
    ("representation_real", "plain complex conjugation is the identity"),
    ("charge_conjugation_matrix_plus", "calC_+ = C (= sigma16)"),
    ("charge_conjugation_matrix_plus", "Psi^c = calC_+ Psibar^T = Psi*"),
    ("charge_conjugation_matrix_minus", "calC_- = Gamma C"),
    ("charge_conjugation_matrix_minus", "Psi^c = calC_- Psibar^T = Gamma Psi*"),
    ("real_fields_charge_conjugation", "J^a = -i Psi^T C gamma^a Psi = 0"),
    ("real_fields_charge_conjugation", "calC_+ acts as the identity"),
    ("real_fields_charge_conjugation", "the matrix Gamma with the mass reversed"),
]
```

The list `R5_WORDS` holds eight pairs, each a check name and a piece of text that the detail of that check must contain word for word. Together the eight pieces are the statements of Section 0.2 about charge conjugation: plain complex conjugation does nothing to a real field; the two charge-conjugation matrices are $\mathcal{C}_+ = C$ (`sigma16` is the author's name for C) and $\mathcal{C}_- = \Gamma C$, each with its conjugate field; and for a real commuting field the charge current is zero, $\mathcal{C}_+$ acts as the identity, and the map between matter and antimatter is the matrix Γ with the mass reversed.

```
check_reproduces(all(words in details[name] for name, words in R5_WORDS),
                 "the report states calC_+ = C, calC_- = Gamma C and J = 0 for a "
                 "real field",
                 f"{CC_REPORT}, checks charge_conjugation_matrix_plus, "
                 "charge_conjugation_matrix_minus and real_fields_charge_conjugation")
```

`words in text` is true when the string `words` occurs in the string `text`, and `all(...)` is true when this holds for all eight pairs. So the check confirms that the record states exactly the charge-conjugation statements of Section 0.2, and its second line names the three checks of the report in which it found them. Chapters 5 and 21 derive the statements from zero.

```
U1_WORDS = ["on shell the LOCAL law d_mu(cos z J^mu) = 0 holds",
            "is constant only if no charge flows through its boundary",
            "constancy of Q is NOT established by this check"]
check_reproduces(all(words in details["u1_noether_matrix_identity"]
                     for words in U1_WORDS),
                 "the report proves the local law and does not establish a "
                 "constant total charge",
                 f"{CC_REPORT}, check u1_noether_matrix_identity")
```

The list `U1_WORDS` holds three pieces of text that the detail of the check `u1_noether_matrix_identity` must contain word for word: the local law, the condition under which the total charge would be constant, and the report's own statement that this constancy is not established. The check confirms both halves of rows 14 and 18 of the ledger in the record's own words: what is proved, and where the proof stops. Out [3] ends with its PASS line and the line that names the check.

In [4], one counting function for three layouts.

```
def count_checks(data):
    """(number of passed checks, number of checks), counted from the checks."""
    if isinstance(data.get("checks"), list):  # layout A
```

```
        verdicts = [entry["verdict"].upper() == "PASS" for entry in data["checks"]]
    elif isinstance(data.get("checks"), dict):  # layout B
        verdicts = [entry["passed"] is True for entry in data["checks"].values()]
    else:  # layout C: a self-test passes when it found no mismatch
        verdicts = [entry["mismatches"] == 0 for entry in data["results"]]
    # True counts as 1 and False as 0 when added.
    return sum(verdicts), len(verdicts)
```

The reports were written by different programs and store their checks in three layouts. `data.get ("checks")` returns the value under the key `checks`, or `None` if there is none (where `data["ch ecks"]` would stop with an error). `isinstance(value, list)` asks whether the value is a list. In layout A the checks are a list of dictionaries with a verdict; in layout B a dictionary from each name to a dictionary with the entry `passed` (`.values()` gives the inner dictionaries, and `is True` asks for the value `True` itself); in layout C (the self-test of the Rust GKD program) a list `results` of tests, each passing when its count of `mismatches` is 0. In each case `verdicts` is a list of `True` and `False`, and the function returns the number of `True` entries and the length of the list.

```
def stated_summary(data):
    """(passed, total) as the report states them itself; None if it states none."""
    summary = data.get("summary")
    if isinstance(summary, dict):  # {"passed": n, "total": n} and similar names
        passed = summary.get("passed", summary.get("pass", summary.get("PASS")))
        return passed, summary.get("total", summary.get("checks"))
    if isinstance(summary, str):  # a text such as "49/49 checks pass"
        passed, total = re.fullmatch(r"(\d+)/(\d+) checks pass", summary).groups()
        return int(passed), int(total)
    counts = data.get("counts")
    if isinstance(counts, dict) and "pass" in counts:  # {"pass", "fail", "pending"}
        return counts["pass"], counts["pass"] + counts["fail"] + counts["pending"]
    if "checkCount" in data:  # a total and a number of failed checks
        failed = data.get("failCount", data.get("failedCount",
                                                data.get("failedCheckCount")))
        return data["checkCount"] - failed, data["checkCount"]
    return None
```

The totals that a report states about itself are written in different words: a dictionary `summary` with `passed` and `total` (or `pass` or `PASS` for the passed checks, and `checks` for the total); a text `summary` such as "49/49 checks pass" (the two reports of the field dirac16complex00 in the dark sector write it so); a dictionary `counts` with the numbers of passed, failed and pending checks; or a total `checkCount` with a number of failed checks under one of three names. `.get(key, default)` returns the default when the key is missing, so the nested `.get` calls try the names one after the other. `isinstance(summary, str)` asks whether the summary is a text (a **string**). `re.fullmatch(pat tern, text)` succeeds only when the whole text matches the pattern; in the pattern `(\d+)/(\d+) checks pass`, `\d+` stands for one or more digits and the brackets mark the two numbers (In [6] explains patterns once more); `.groups()` returns the two marked pieces as texts, and `int` turns each into a whole number. The function returns the pair (passed, total), or `None` when the report states no totals.

```
EXAMPLES = [("A", "Revision/pairing/reports/wolfram-pairing.json"),
            ("B", "Revision/gkd_lovelock/results/lovelock-report.json"),
```

```
            ("C", "Revision/gkd_lovelock/results/gkd-selftest.json")]
for layout, path in EXAMPLES:
    data = read_report(path)
    passed, total = count_checks(data)
    say(f"layout {layout}: {path}")
    say(f"    counted {passed} of {total}; stated {stated_summary(data)}")
```

One report of each layout, counted and compared with what it states: Out [4] shows the counts of the Wolfram pairing report, of the Rust Lovelock report and of the GKD self-test, which states no totals (`None`) but only its verdict.

In [5], every report of the Revision record.

```
def is_report(path):
    """True if the JSON file path (a Path) is a verifier report."""
    data = json.loads(path.read_text(encoding="utf-8"))
    if not isinstance(data, dict):
        return False
    checks = data.get("checks")
    listed = isinstance(checks, list) or (  # a list of checks, or a dictionary
        isinstance(checks, dict)  # whose every entry is a check (a dictionary)
        and all(isinstance(entry, dict) for entry in checks.values()))
    results = data.get("results")
    self_test = (isinstance(results, list) and len(results) > 0
                 and isinstance(results[0], dict) and "mismatches" in results[0])
    return listed or self_test
```

A JSON file is a verifier report when it is a dictionary whose key `checks` holds the checks themselves, or, like the GKD self-test, a non-empty list `results` whose first entry is a dictionary with the key `mismatches`. "Holds the checks themselves" means: `checks` is a list (layout A), or a dictionary each of whose entries is again a dictionary, one per check (layout B). `all(...)` is true when every entry passes the test `isinstance(entry, dict)`. The rule matters for one file of the record: the summary file of the dark sector has a key `checks` whose value is only the two numbers `{"total": 13, "pass": 13}`, the totals of another report; it is not a report, and the cell compares its two numbers in In [6] instead of counting them twice. The conditions joined by `and` are tested from the left and the testing stops at the first false one, so `results[0]` is never read from an empty or missing list; the brackets after `or (` let the condition continue on the next lines.

```
SKIPPED = ("Revision/textbook/", "Revision/workflows/")  # folders that hold no report
found_reports = []  # every report found in the folder Revision, as a relative path
not_reports = []  # JSON files with a key "checks" that holds no checks
for path in sorted(repository_file("Revision").rglob("*.json")):
    relative = path.relative_to(REPO).as_posix()  # e.g. "Revision/algebra/..."
    if relative.startswith(SKIPPED) or "/target/" in relative:
        continue  # the book, the workflow records and the Rust build folders
    if is_report(path):
        found_reports.append(relative)
    elif "checks" in read_report(relative):
        not_reports.append(relative)
report("verifier reports found in the folder Revision", len(found_reports))
say("JSON files with a key checks that holds no checks:")
```

```
for relative in not_reports:
    say("    " + relative)
```

SKIPPED is a **tuple** (a list in round brackets that cannot be changed) of two folder names. rglob("*.json") lists every file ending in .json in the folder Revision and in all its sub-folders, and sorted puts the list in a fixed order. path.relative_to(REPO) is the path from the repository folder on, and .as_posix() writes it with / on every operating system. relative.startswith(SKIPPED) is true when the path starts with either of the two names (startswith accepts a tuple and tries each of its entries). continue skips the rest of the loop for this file. Three kinds of folders are skipped, because they are not part of the record: the book's own folder Revision/textbook; the folder Revision/workflows, which holds the records of the programs that organised the work (they are rewritten while those programs run, so a half-written file could stop the notebook, and the Revision record says itself that no result depends on them); and the build folders target of the Rust programs. Every other report is collected. elif ("else if") collects, in the second list, every file that is not a report but still has a key checks, so that no such file is dropped silently. Out [5] begins with the number found, 51, and the one file of the second list, Revision/dark_sector/dirac16complex/outputs/eos-summary.json.

```
REPORTS = [  # (report, engine)
    # the gammas, C, Gamma, B, Pin(4,4) and Spin(4,4)
    ("Revision/algebra/reports/wolfram-algebra.json", "Wolfram"),
    ("Revision/algebra/reports/python-algebra.json", "Python"),
```

The list REPORTS holds the 51 reports of the record, each as a pair: the path of the report and the **engine** that did its computation, that is, the language of the program that wrote the report: "Wolfram" (the Wolfram Language), "Python", "Rust", or "lead" for the lead's short independent Python checks. A comment line before each group names its subject. The first group is the algebra of Chapters 4 and 5 (the gamma matrices, C, Γ, B and the groups), checked by a Wolfram verifier and by an independent Python verifier.

```
    # the metric with b4 (2026-10-14): curvature, the author's outputs, vacuum
    ("Revision/metric_b4/results/wolfram-metric-b4-report.json", "Wolfram"),
    ("Revision/metric_b4/results/python-metric-b4-report.json", "Python"),
    ("Revision/metric_b4/results/vacuum-b4.json", "Wolfram"),
    ("Revision/metric_b4/results/consequences-b4.json", "Wolfram"),
```

The folder Revision/metric_b4 holds the record of the author's change of 2026-10-14, the metric function b_4 (Section 0.14): a Wolfram and an independent Python verifier compute the curvature and the Lovelock tensors of the metric with b_4 and compare them with the outputs stored in the author's notebook; a Wolfram program solves the vacuum equations (every vacuum history has b_4 constant); and a Wolfram program checks the consequences of b_4 for the pairing theorems, the Kohn-Sham level and the dark sector.

```
    # the Lagrangians, field equations, EMT, quantisation; the scope; a Fock model
    ("Revision/theory/reports/wolfram-field-theory.json", "Wolfram"),
    ("Revision/theory/reports/python-field-theory.json", "Python"),
    ("Revision/theory/reports/wolfram-scope.json", "Wolfram"),
```

```
("Revision/theory/reports/python-scope.json", "Python"),
("Revision/theory/fock_quartic/reports/fock-quartic.json", "Python"),
("Revision/theory/reports/wolfram-field-theory-b4.json", "Wolfram"),
("Revision/theory/reports/python-field-theory-b4.json", "Python"),
("Revision/theory/reports/wolfram-field-theory-b4-emt-C.json", "Wolfram"),
("Revision/theory/reports/wolfram-field-theory-b4-emt-G.json", "Wolfram"),
```

The folder `Revision/theory` holds the field theory of Chapters 7, 9 and 10 (the Lagrangians, the field equations, the energy-momentum tensor, abbreviated EMT, and the quantisation of dirac16complex) and the exact scope of the non-triviality (Chapter 8), each in a Wolfram and in a Python version: four reports. A fifth report, of its sub-folder `fock_quartic`, comes from one Python program only: the energy-momentum tensor operator of dirac16complex with a self-coupling $\lambda \neq 0$ in a finite model of the quantum theory (Section 0.18, the remark on row 2). The last four reports redo the geometry, the spin connection, the Dirac operator and the energy-momentum tensor for a changing b_4: a Wolfram and a Python verifier, and two Wolfram reports on the energy-momentum tensor obtained by varying the vielbein, one for each kind of field (C for dirac16complex, G for dirac16complex00).

```
# the field equations for a4 and b4; the Kohn-Sham states as a source
("Revision/field_equations_a4/reports/wolfram-a4-report.json", "Wolfram"),
("Revision/field_equations_a4/reports/python-a4-report.json", "Python"),
("Revision/field_equations_a4/reports/python-b4-block.json", "Python"),
("Revision/field_equations_a4/reports/ks-source-conditions.json", "Python"),
("Revision/field_equations_a4/ks_source/reports/ks-source-a4.json", "Python"),
```

The field equations for a_4 and b_4 (Chapter 12), in Wolfram and in Python, and a second Python report that checks the equations of b_4 with the author's gamma matrices; the report of a Python program that tests whether the computed Kohn-Sham states can be the source of the history $a_4 = AHx_4$ (Chapter 17; its six checks show that they cannot, for every b_4); and the report of the folder `ks_source`, which writes the equations for a_4 with the Kohn-Sham states as their source (exact identities, the averages over the hidden direction, and the integration of a stated simplified system) and finds that no recorded Kohn-Sham state is an admissible source.

```
# GKD and the Lovelock tensors; the comparison with the author's outputs
("Revision/gkd_lovelock/results/lovelock-report.json", "Rust"),
("Revision/gkd_lovelock/results/gkd-selftest.json", "Rust"),
("Revision/gkd_lovelock/results/wolfram-gkd-report.json", "Wolfram"),
("Revision/gkd_lovelock/results/python-lovelock-report.json", "Python"),
("Revision/gkd_lovelock/comparison/author-comparison-report.json", "Python"),
```

The generalized Kronecker delta and the Lovelock tensors (Chapter 11): the Rust program that computes them writes a report on the tensors and a self-test of its GKD function, and a Wolfram and a Python verifier check its results independently. The fifth report compares the curvature of the Revision record with the values stored in the author's own Mathematica notebook (a Python program with sympy; row 7 of the ledger).

```
# the Kohn-Sham theory, solvers and comparisons; the tip-cutoff study
("Revision/kohn_sham/reports/ks-theory-wolfram.json", "Wolfram"),
("Revision/kohn_sham/reports/ks-theory-python.json", "Python"),
```

```
("Revision/kohn_sham/reports/ks-b4-wolfram.json", "Wolfram"),
("Revision/kohn_sham/reports/ks-rust-solver.json", "Rust"),
("Revision/kohn_sham/reports/ks-rust-determinism.json", "Python"),
("Revision/kohn_sham/reports/ks-rust-mermin-roots.json", "Python"),
("Revision/kohn_sham/reports/ks-reference.json", "Python"),
("Revision/kohn_sham/reports/ks-crosscheck.json", "Python"),
("Revision/kohn_sham/tip_convergence/tip-convergence.json", "Python"),
```

The Kohn-Sham model (Chapters 14 to 16): its theory in Wolfram and in Python; a Wolfram report showing that the Kohn-Sham problem of the good sector does not contain b_4; the Rust solver; two Python programs that examine the results of the Rust solver (the repeated and the refined run of Section 0.22, and the roots of the Mermin equation for the chemical potential, computed with 40 digits; Chapter 15); the independent Python reference solver; the cross-check that compares the two solvers (Chapter 16); and the study of the tip cutoff L of the hidden direction, a Python program that runs the Rust solver (and, for two of its states at $L = 3$ and 4, the reference solver) for L from 3 to 6 (Chapter 14; Section 0.18, the remark on row 9). The determinism report, the report on the roots and the tip-cutoff study concern the Rust solver, but their own checks are computed in Python, so their engine is Python.

```
# the dark-sector hypotheses of the two fields, investigated
("Revision/dark_sector/dirac16complex/reports/derivation-checks.json", "Python"),
("Revision/dark_sector/dirac16complex/reports/ks-history-run.json", "Python"),
("Revision/dark_sector/dirac16complex/reports/eos-checks.json", "Python"),
("Revision/dark_sector/dirac16complex/reports/independent-checks.json", "Python"),
("Revision/dark_sector/dirac16complex00/reports/python-derive-eos.json", "Python"),
("Revision/dark_sector/dirac16complex00/reports/python-independent-numerics.json",
 "Python"),
```

The investigation of the author's two dark-sector hypotheses (Chapter 22), all six reports written by Python programs. For the field dirac16complex: the exact derivation of the identities with sympy; the run of the Rust Kohn-Sham solver along the prescribed history (its checks are computed by the Python program that runs the solver, so its engine is Python); the equations of state computed from that run; and an independent implementation. For the field dirac16complex00: the derivation of its equations of state and of its models, and independent numerics. The last pair is written on two lines, the path on the first and the engine on the second, because one line would be wider than 89 characters.

```
# the pairing theorems T1, T2, Q and T3; T3 completed and demonstrated
("Revision/pairing/reports/wolfram-pairing.json", "Wolfram"),
("Revision/pairing/reports/python-pairing.json", "Python"),
("Revision/pairing/kohn_sham/reports/wolfram-t3.json", "Wolfram"),
("Revision/pairing/kohn_sham/reports/python-t3.json", "Python"),
("Revision/pairing/kohn_sham/reports/wolfram-t3-completion.json", "Wolfram"),
("Revision/pairing/kohn_sham/reports/python-t3-completion.json", "Python"),
("Revision/pairing/kohn_sham/reports/t3-rust-demo.json", "Python"),
("Revision/pairing/kohn_sham/reports/t3-reference-demo.json", "Python"),
```

The pairing theorems (Chapters 18 and 19): T1, T2 and Q in one Wolfram and one Python report; T3 in a second pair of reports; its completion (the Kohn-Sham potentials read from the Kohn-Sham

record, the filling convention carried onto the member of mass $-M$, and the statement for all 16 components) in a third pair; and two numerical demonstrations of T3, one with the Rust solver and one with the Python reference solver, both run by Python programs.

```
    # the lead's independent checks
    ("Revision/lead_checks/reports/charge-conjugation-and-u1.json", "lead"),
    ("Revision/lead_checks/reports/einstein-gauss-bonnet-a4.json", "lead"),
    ("Revision/lead_checks/reports/emt-divergence-and-spin-connection.json", "lead"),
]
```

The three short Python programs of the lead, which import no other Revision code: the charge-conjugation matrices and the local conservation law of the charge (read in In [2] and In [3]); the field equations for a_4 in Einstein's theory and with the Gauss-Bonnet term (the second Lovelock term of Chapter 11), compared with the record of Chapter 12; and the conservation identities of the energy-momentum tensor together with the spin connection (Chapters 6 and 9). The closing bracket ends the list. The table of Out [5] repeats the list with the counts.

```
check(found_reports == sorted(path for path, _ in REPORTS),
      f"the search finds exactly the {len(REPORTS)} reports of the list")
```

The search must find exactly the reports of the list: no report is missing from the list, and so from the ledger. (In `for path, _ in REPORTS` the name `_` takes the engine, which is not needed here.) When a new report is added to the record, this check fails until the new report gets its place in the list and in the ledger.

```
counted = {}  # report -> (passed, total)
header = "report (in the folder Revision)"
say(f"{header:69} engine  pass of all")
for path, engine in REPORTS:
    data = read_report(path)
    counted[path] = count_checks(data)
    passed, total = counted[path]
    short = path.removeprefix("Revision/")
    say(f"{short:69} {engine:7} {passed:4d} of {total:3d}")
```

Every report is read and counted; the pair (passed, total) is stored in the dictionary `counted` under its path. `removeprefix` removes `Revision/` from the front of the path to keep the table narrow; `{short:69}` writes the path filled with blanks to 69 characters (the longest path has 69), and `{passed:4d}` writes a whole number right-aligned in 4 characters, so that a line of the table has at most 89 characters. The 51 lines of the table in Out [5] are printed here. One line shows fewer passed checks than checks: the comparison with the author's notebook, 73 of 78.

```
all_checks = sum(total for _, total in counted.values())
all_passed = sum(passed for passed, _ in counted.values())
report("reports", len(REPORTS))
report("checks in all reports", all_checks)
report("checks with the verdict PASS", all_passed)
engine_totals = {}  # engine -> the number of its checks
```

```
for engine in ("Wolfram", "Python", "Rust", "lead"):
    engine_totals[engine] = sum(counted[path][1] for path, e in REPORTS
                                if e == engine)
    report(f"checks done with the engine {engine}", engine_totals[engine])
```

The totals over all reports, the number of passed checks, and the total per engine: for each engine the numbers of checks of its reports are added (`counted[path][1]` is the total of a report). These are the RESULT lines of Out [5]. The numbers are not written into the notebook: they are counted from the record each time, so they follow the record. In the run printed in Section 0.20 (2026-10-14, the date of the notebook's last verified run, which its provenance file records) they are 1357 checks in all, of which 1352 have the verdict PASS: 465 done with the Wolfram Language, 785 with Python, 70 with Rust and 37 by the lead's checks.

```
COMPARISON = "Revision/gkd_lovelock/comparison/author-comparison-report.json"
not_pass = [path for path, _ in REPORTS if counted[path][0] != counted[path][1]]
other_verdicts = [entry["verdict"] for entry in read_report(COMPARISON)["checks"]
                  if entry["verdict"] != "PASS"]  # the verdicts that are not PASS
not_available = other_verdicts.count("NOT-AVAILABLE")
report("checks with the verdict NOT-AVAILABLE", not_available)
```

`not_pass` lists the reports in which some check is not PASS. `other_verdicts` collects, from the comparison with the author's notebook, every verdict that is not PASS, and `.count("NOT-AVAILABLE")` counts how many of them are the word NOT-AVAILABLE: the comparisons that could not be made, because the author's notebook stores no value of the quantity (Section 0.18, row 7). Out [5] prints the number, 5.

```
check(not_pass == [COMPARISON] and len(other_verdicts) == not_available == 5
      and all_passed + not_available == all_checks
      and sum(engine_totals.values()) == all_checks,
      f"no check FAILS: {all_passed} PASS, {not_available} NOT-AVAILABLE, "
      f"{all_checks} in all")
```

The check requires four things: the only report with a check that is not PASS is the comparison; its checks that are not PASS are exactly five, and all five are NOT-AVAILABLE; the passed and the not-available checks together are all the checks, so not a single check of the 51 reports has the verdict FAIL; and the four engine totals add up to the total (each report has exactly one engine). Its PASS line prints the three numbers: 1352 PASS, 5 NOT-AVAILABLE, 1357 in all.

```
disagree = []  # reports whose own summary differs from our count
for path, _ in REPORTS:
    data = read_report(path)
    stated = stated_summary(data)
    if stated is None:  # layout C: the self-test states only its verdict
        stated = counted[path] if data["verdict"] == "SUCCESS" else None
    if stated != counted[path]:
        disagree.append(path)
check(disagree == [], "each report states the same totals that we counted")
```

For every report our count must equal what the report states about itself (for the comparison with the author's notebook: 73 PASS of 78, as its own summary says). The GKD self-test states no totals; for it the stated verdict SUCCESS is required instead. Out [5] ends with this PASS line.

In [6], three other places that quote the counts.

```
R = "Revision/"
README_ORDER = [  # the reports whose counts the README table quotes, in its order
    R + "gkd_lovelock/results/lovelock-report.json",  # row gkd_lovelock/
    R + "gkd_lovelock/results/python-lovelock-report.json",
    R + "gkd_lovelock/results/wolfram-gkd-report.json",
    R + "metric_b4/results/wolfram-metric-b4-report.json",  # row metric_b4/
    R + "metric_b4/results/python-metric-b4-report.json",
    R + "metric_b4/results/vacuum-b4.json",
    R + "metric_b4/results/consequences-b4.json",
```

`R + "..."` joins two strings. The list `README_ORDER` names, in the order in which they appear in the table of the file `Revision/README.md`, the reports of the 49 counts that table quotes: 46 different reports, three of which stand there twice, as the last lines of the list show. The first row of the table, `gkd_lovelock/`, quotes three counts: that of the Rust report on the Lovelock tensors, then those of the Python and of the Wolfram verifier. The second row, `metric_b4/`, quotes four: the Wolfram and the Python verifier of the metric with b_4, the vacuum and the consequences.

```
    R + "algebra/reports/wolfram-algebra.json",  # row algebra/
    R + "algebra/reports/python-algebra.json",
    R + "theory/reports/wolfram-field-theory.json",  # row theory/
    R + "theory/reports/python-field-theory.json",
    R + "theory/reports/wolfram-scope.json",
    R + "theory/reports/python-scope.json",
    R + "theory/fock_quartic/reports/fock-quartic.json",
    R + "theory/reports/wolfram-field-theory-b4.json",
    R + "theory/reports/python-field-theory-b4.json",
    R + "theory/reports/wolfram-field-theory-b4-emt-C.json",
    R + "theory/reports/wolfram-field-theory-b4-emt-G.json",
```

The rows `algebra/` (two counts, Wolfram then Python) and `theory/` (nine counts: the field theory, then the scope, each Wolfram then Python, the finite Fock model of the folder `theory/fock_quartic`, and the four reports with b_4).

```
    R + "field_equations_a4/reports/wolfram-a4-report.json",  # row field_equations_a4/
    R + "field_equations_a4/reports/python-a4-report.json",
    R + "field_equations_a4/reports/python-b4-block.json",
    R + "field_equations_a4/reports/ks-source-conditions.json",
    R + "field_equations_a4/ks_source/reports/ks-source-a4.json",
    R + "kohn_sham/reports/ks-theory-wolfram.json",  # row kohn_sham/
    R + "kohn_sham/reports/ks-theory-python.json",
    R + "kohn_sham/reports/ks-b4-wolfram.json",
    R + "kohn_sham/reports/ks-rust-solver.json",
    R + "kohn_sham/reports/ks-rust-determinism.json",
    R + "kohn_sham/reports/ks-rust-mermin-roots.json",
```

```
    R + "kohn_sham/reports/ks-reference.json",
    R + "kohn_sham/reports/ks-crosscheck.json",
    R + "kohn_sham/tip_convergence/tip-convergence.json",
```

The rows `field_equations_a4/` (five counts: Wolfram, Python, the block of b_4, the Kohn-Sham source conditions, and the folder `ks_source`) and `kohn_sham/` (nine counts: the theory in Wolfram and in Python, the report on b_4, the Rust solver, its determinism, the Mermin roots, the reference solver, the cross-check and the tip-cutoff study).

```
    R + "dark_sector/dirac16complex/reports/derivation-checks.json",  # dark_sector/
    R + "dark_sector/dirac16complex/reports/ks-history-run.json",
    R + "dark_sector/dirac16complex/reports/eos-checks.json",
    R + "dark_sector/dirac16complex/reports/independent-checks.json",
    R + "dark_sector/dirac16complex00/reports/python-derive-eos.json",
    R + "dark_sector/dirac16complex00/reports/python-independent-numerics.json",
```

The row `dark_sector/` (six counts: four for the field dirac16complex, two for dirac16complex00).

```
    R + "pairing/reports/wolfram-pairing.json",  # row pairing/
    R + "pairing/reports/python-pairing.json",
    R + "pairing/kohn_sham/reports/wolfram-t3.json",
    R + "pairing/kohn_sham/reports/python-t3.json",
    R + "pairing/kohn_sham/reports/wolfram-t3-completion.json",
    R + "pairing/kohn_sham/reports/python-t3-completion.json",
    R + "pairing/kohn_sham/reports/t3-rust-demo.json",
    R + "pairing/kohn_sham/reports/t3-reference-demo.json",
```

The row `pairing/` (eight counts: T1, T2 and Q in Wolfram and in Python; T3 in Wolfram and in Python; its completion in Wolfram and in Python; the two demonstrations, with the Rust solver and with the reference solver).

```
    R + "gkd_lovelock/results/lovelock-report.json",  # row docs/: LOVELOCK_GKD
    R + "gkd_lovelock/results/wolfram-gkd-report.json",
    R + "gkd_lovelock/results/python-lovelock-report.json",
]
```

The row `docs/` names the document on the Lovelock tensors together with the counts of its three reports, in the order Rust, Wolfram, Python; so these three reports stand twice in the list. The reports that the table does not quote (the GKD self-test, the comparison with the author's notebook and the lead's three checks) are not in this list.

```
readme_lines = repository_file("Revision/README.md").read_text(
    encoding="utf-8").split("\n")
table = "\n".join(line for line in readme_lines if line.startswith("| ‘"))
quoted_readme = [(int(p), int(t)) for p, t in re.findall(r"(\d+)/(\d+)", table)]
say("the README quotes: " + ", ".join(f"{p}/{t}" for p, t in quoted_readme))
report("counts quoted in the README table", len(quoted_readme))
```

The file is read and cut into lines; the lines of the table of the folders start with a vertical bar, a blank and a backtick, and they are joined again. A **regular expression** is a pattern that describes a family of texts: in `(\d+)/(\d+)`, `\d` means one digit, `+` means one or more of what stands before it, and the round brackets mark the parts to return. `re.findall` returns every match as a pair of the two marked parts, such as `("19", "19")`; `int` turns them into numbers. Out [6] prints the 49 counts found.

```
check_reproduces(quoted_readme == [counted[path] for path in README_ORDER],
                 f"the {len(README_ORDER)} counts quoted in the README equal ours",
                 "Revision/README.md, the table of the folders")
```

The 49 quoted counts must equal our counts of the 49 entries of the list, in this order.

```
CROSS = "Revision/kohn_sham/reports/ks-crosscheck.json"
detail = next(entry["detail"] for entry in read_report(CROSS)["checks"]
              if entry["name"] == "inputs_all_pass")
quoted = re.findall(r"(\d+)/(\d+) PASS", detail)  # [("37", "37"), ("42", "42"), ...]
say("the cross-check quotes: " + ", ".join(f"{p}/{t}" for p, t in quoted))
ours = [counted["Revision/kohn_sham/reports/ks-reference.json"],
        counted["Revision/kohn_sham/reports/ks-rust-solver.json"],
        counted["Revision/kohn_sham/reports/ks-rust-determinism.json"]]
numbers = ", ".join(str(total) for _, total in ours)  # e.g. "37, 42, 14"
check_reproduces([(int(p), int(t)) for p, t in quoted] == ours,
                 f"the cross-check quotes the counts {numbers} that we counted",
                 f"{CROSS}, check inputs_all_pass")
```

The Kohn-Sham cross-check read three other reports before it compared the two solvers, and quoted their counts in the detail of its check `inputs_all_pass`, in the form `37/37 PASS`. The pattern `(\d+)/(\d+) PASS` finds them; they must equal our counts of the reference report, the Rust solver report and the determinism report, in this order.

```
SUMMARY = "Revision/dark_sector/dirac16complex/outputs/eos-summary.json"
EOS = "Revision/dark_sector/dirac16complex/reports/eos-checks.json"
summary_numbers = read_report(SUMMARY)["checks"]  # a dictionary of two numbers
say(f"the dark-sector summary quotes: {summary_numbers}")
quoted_eos = (summary_numbers["pass"], summary_numbers["total"])
check_reproduces(not_reports == [SUMMARY] and quoted_eos == counted[EOS],
                 f"the dark-sector summary quotes the {counted[EOS][1]} checks of "
                 "eos-checks.json that we counted",
                 f"{SUMMARY}, key checks")
```

The summary file that the search of In [5] set aside holds, under its key `checks`, the dictionary `{'total': 13, 'pass': 13}` (Out [6] prints it as Python writes a dictionary, with single quotes). The program that writes the equations of state of the dark sector writes both this file and the report `eos-checks.json`, and the two numbers are the totals of that report. The check requires that the summary file is the only file set aside by the search and that its two numbers, in the order (passed, total), equal our count of `eos-checks.json`. Out [6] ends with this PASS line.

In [7], a bar for every report.

```
from matplotlib.patches import Patch  # a coloured square for the legend

ENGINE_COLOURS = {"Wolfram": "#2a78d6", "Python": "#eb6834", "Rust": "#1baf7a",
                  "lead": "#eda100"}
ENGINE_NAMES = {"Wolfram": "Wolfram Language", "Python": "Python",
                "Rust": "Rust", "lead": "Python, the lead's independent checks"}
```

The coloured squares of the legend (as in In [3] of Notebook 00b), a colour for each engine and its full name for the legend.

```
# The report with the most checks, and its number of checks.
largest = max((path for path, _ in REPORTS), key=lambda path: counted[path][1])
longest = counted[largest][1]
```

`max(..., key=...)` returns the path whose value under the key function is largest; `lambda p ath: counted[path][1]` is a function without a name that gives the number of checks of a report. `longest` is that largest number of checks (101, of the Wolfram pairing report, in the run printed in Section 0.20).

```
fig, ax = plt.subplots(figsize=(7.6, 11.6))
rows = np.arange(len(REPORTS))[::-1]  # the first report at the top
for row, (path, engine) in zip(rows, REPORTS):
    total = counted[path][1]
    ax.barh(row, total, height=0.72, color=ENGINE_COLOURS[engine])
    ax.text(total + 0.015 * longest, row, str(total), va="center", fontsize=9)
```

A tall figure, 7.6 by 11.6 inches, one row per report. `np.arange(51)` is 0 to 50, and `[::-1]` reverses it (a step of −1), so that the first report gets the highest row and stands at the top. `ax.barh` draws a horizontal bar of the given length in the given row, coloured by the engine; `ax.text` writes the number just after the end of the bar, at a distance of 1.5 per cent of the longest bar.

```
# The name of each report without its folder and without the ending .json:
names = [path.rsplit("/", 1)[1].removesuffix(".json") for path, _ in REPORTS]
ax.set_yticks(rows, labels=names, fontsize=8.5)
ax.set_xlim(0, 1.12 * longest)  # room for the longest bar and its number
ax.grid(False, axis="y")  # vertical grid lines only
ax.set_xlabel("number of checks in the report (none has the verdict FAIL)")
ax.set_title(f"The {len(REPORTS)} verifier reports of the Revision record: "
             f"{all_checks} checks")
ax.legend(handles=[Patch(color=ENGINE_COLOURS[e], label=ENGINE_NAMES[e])
                   for e in ENGINE_COLOURS], loc="lower right", fontsize=8)
```

`rsplit("/", 1)[1]` keeps the part after the last `/`, the file name, and `removesuffix` removes the ending. The names label the rows, in a font of 8.5 points so that 51 names fit. The horizontal axis runs from 0 to 1.12 times the longest bar, which leaves room for the longest bar and its number; because the limit is computed from the counts, the picture stays complete when a report gains checks. Only vertical grid lines are drawn; the axis label says that no check has the verdict FAIL (a bar counts all checks of its report, the five NOT-AVAILABLE ones of the comparison with the author's notebook included); the title contains the total; the legend names the four engines.

```
largest_name = largest.rsplit("/", 1)[1]  # its file name without the folders
n_wolfram, n_python, n_rust, n_lead = (engine_totals[engine] for engine in
                                       ("Wolfram", "Python", "Rust", "lead"))
totals_text = (f"{n_wolfram} Wolfram Language, {n_python} Python, {n_rust} Rust "
               f"and {n_lead} lead checks")
```

The file name of the largest report, for the caption. The four engine totals are unpacked into four names and written into a sentence for the caption, so that the caption always states the counts of the record as it is.

```
save_figure(fig, "checks_by_report",
            f"The number of checks in each of the {len(REPORTS)} verifier reports "
            r"of the Revision record (horizontal axis, a count; one bar per report, "
            r"named on the vertical axis and grouped by folder: algebra, the metric "
            r"with $b_4$, theory, field equations for $a_4$ and $b_4$, GKD and "
            r"Lovelock with the comparison with the author's outputs, Kohn-Sham, "
            r"dark sector, pairing, lead checks). "
            r"The colour gives the engine: blue Wolfram Language, orange Python, "
            r"aqua Rust, yellow the lead's independent Python checks. Of the "
            f"{all_checks} checks ({totals_text}) {all_passed} have the verdict "
            f"PASS and {not_available} the verdict NOT-AVAILABLE (comparisons with "
            r"values that the author's notebook does not store); none FAILS. The "
            f"largest report is {largest_name} with {longest} checks.")
```

The figure `00c_1_checks_by_report.png` with its caption, partly raw strings and partly f-strings (each piece of the joined caption has its own prefix). The caption takes the number of reports, the totals, the number of passed and of NOT-AVAILABLE checks and the largest report from the computation, so it always states the record as it is. What Figure 00c.1 shows: one bar per report, grouped by folder from the algebra at the top to the lead's checks at the bottom; the longest bar belongs to the report that the caption names (the Wolfram pairing report, 101 checks), and every colour occurs, so every engine contributes.

In [8], two independent engines.

```
SUBJECTS = [  # (subject, Wolfram report, Python report)
    ("the gammas, Pin(4,4), Spin(4,4)", "algebra/reports/wolfram-algebra.json",
     "algebra/reports/python-algebra.json"),
    ("the metric with b4", "metric_b4/results/wolfram-metric-b4-report.json",
     "metric_b4/results/python-metric-b4-report.json"),
    ("geometry and Dirac operator with b4",
     "theory/reports/wolfram-field-theory-b4.json",
     "theory/reports/python-field-theory-b4.json"),
    ("Lagrangians, field equations, EMT", "theory/reports/wolfram-field-theory.json",
     "theory/reports/python-field-theory.json"),
    ("scope of the non-triviality", "theory/reports/wolfram-scope.json",
     "theory/reports/python-scope.json"),
    ("field equations for a4", "field_equations_a4/reports/wolfram-a4-report.json",
     "field_equations_a4/reports/python-a4-report.json"),
```

The list `SUBJECTS` names the eleven subjects that have two independent verifiers, each as a group of three: a short name, the Wolfram report and the Python report (paths without `Revision/`). Its

first six entries are the gammas and the groups, the metric with b_4 compared with the author's notebook, the geometry and the Dirac operator with b_4, the field theory (Lagrangians, field equations, energy-momentum tensor), the scope of the non-triviality, and the field equations for a_4.

```
    ("GKD and the Lovelock tensors", "gkd_lovelock/results/wolfram-gkd-report.json",
     "gkd_lovelock/results/python-lovelock-report.json"),
    ("Kohn-Sham theory", "kohn_sham/reports/ks-theory-wolfram.json",
     "kohn_sham/reports/ks-theory-python.json"),
    ("pairing theorems T1, T2, Q", "pairing/reports/wolfram-pairing.json",
     "pairing/reports/python-pairing.json"),
    ("pairing theorem T3", "pairing/kohn_sham/reports/wolfram-t3.json",
     "pairing/kohn_sham/reports/python-t3.json"),
    ("the completion of T3", "pairing/kohn_sham/reports/wolfram-t3-completion.json",
     "pairing/kohn_sham/reports/python-t3-completion.json"),
]
```

The other five: GKD and the Lovelock tensors (the Rust results checked by Wolfram and by Python), the Kohn-Sham theory, the pairing theorems T1, T2 and Q, the theorem T3, and its completion. These are the eleven subjects of the remark "Two independent verifiers" of Section 0.18 (rows 1 to 3, 5, 6, 8 and 11 of the ledger, two subjects of row 12, one of row 7 and one more of row 2).

```
say("subject                                Wolfram  Python")
wolfram_numbers, python_numbers = [], []
for subject, wolfram, python in SUBJECTS:
    wolfram_numbers.append(counted["Revision/" + wolfram][1])
    python_numbers.append(counted["Revision/" + python][1])
    say(f"{subject:36} {wolfram_numbers[-1]:7d} {python_numbers[-1]:7d}")
```

For each subject the totals of its two reports are taken from `counted` and printed: the table of Out [8]. `[-1]` is the entry just appended.

```
widest = max(wolfram_numbers + python_numbers)  # the longest of the 22 bars
fig, ax = plt.subplots(figsize=(7.0, 6.6))
rows = np.arange(len(SUBJECTS))[::-1]
height = 0.38  # two bars in each row
ax.barh(rows + height / 2, wolfram_numbers, height, color="#2a78d6",
        edgecolor="white", linewidth=1.5, label="Wolfram Language verifier")
ax.barh(rows - height / 2, python_numbers, height, color="#eb6834",
        edgecolor="white", linewidth=1.5, label="Python verifier (sympy)")
for row, w, p in zip(rows, wolfram_numbers, python_numbers):
    ax.text(w + 0.015 * widest, row + height / 2, str(w), va="center", fontsize=8)
    ax.text(p + 0.015 * widest, row - height / 2, str(p), va="center", fontsize=8)
```

`wolfram_numbers + python_numbers` joins the two lists of eleven numbers into one list of twenty-two, and `max` finds the longest bar. The figure is 7.0 by 6.6 inches. Two bars in each row, the Wolfram bar half a bar height above the middle of the row and the Python bar half a bar height below it; the numbers are written after the ends of the bars, at a distance of 1.5 per cent of the longest bar.

```
ax.set_yticks(rows, labels=[subject for subject, _, _ in SUBJECTS])
ax.set_xlim(0, 1.12 * widest)  # room for the longest bar and its number
ax.grid(False, axis="y")
ax.set_xlabel("number of checks (every one has the verdict PASS)")
ax.set_title("Eleven subjects, each checked by two independent verifiers")
ax.legend(loc="lower right")
save_figure(fig, "two_verifiers",
            r"For each of eleven subjects of the Revision record (vertical axis), "
            r"the number of checks of its Wolfram Language verifier (blue, upper "
            r"bar) and of its independent Python verifier (orange, lower bar); "
            r"horizontal axis a count. The two verifiers share no code; each also "
            r"checks statements that the other does not, so the numbers differ. "
            f"Together they hold {sum(wolfram_numbers)} Wolfram and "
            f"{sum(python_numbers)} Python checks, all PASS.")
```

Labels, a horizontal axis from 0 to 1.12 times the longest bar (computed from the counts, as in In [7]), title, legend and the figure `00c_2_two_verifiers.png`. What Figure 00c.2 shows: every subject has two bars, so every subject was checked twice, in two languages; the bars differ in length because the two verifiers were written independently and test partly different statements.

```
report("checks of the Wolfram verifiers of the eleven subjects",
       sum(wolfram_numbers))
report("checks of the Python verifiers of the eleven subjects", sum(python_numbers))
check(all(w > 0 and p > 0 for w, p in zip(wolfram_numbers, python_numbers)),
      "each of the eleven subjects has a Wolfram and a Python verifier")
```

The two sums are printed (443 Wolfram and 404 Python checks in the run printed in Section 0.20), and the check requires a nonzero number of checks in both verifiers of every subject.

In [9], the honesty ledger.

```
R = "Revision/"
K = R + "pairing/kohn_sham/reports/"  # the folder of the T3 reports
D = R + "dark_sector/"  # the folder of the dark-sector reports
```

Three short names for the beginnings of paths, so that the lines of the ledger stay narrow: the folder `Revision/`, the folder of the reports on T3, and the folder of the dark sector.

```
LEDGER = [  # (statement, label, note, the reports that verify it)
    ("the gammas, C, Gamma, B; Pin(4,4) and Spin(4,4)", "PROVED", "",
     [R + "algebra/reports/wolfram-algebra.json",
      R + "algebra/reports/python-algebra.json"]),
    ("Lagrangians, equations, EMT; dirac16complex quantised", "PROVED",
     "the EMT operator for lambda != 0: proved only in a finite Fock model",
     [R + "theory/reports/wolfram-field-theory.json",
      R + "theory/reports/python-field-theory.json",
      R + "theory/fock_quartic/reports/fock-quartic.json",
      R + "theory/reports/wolfram-field-theory-b4.json",
      R + "theory/reports/python-field-theory-b4.json",
      R + "theory/reports/wolfram-field-theory-b4-emt-C.json",
```

```
  R + "theory/reports/wolfram-field-theory-b4-emt-G.json"]),
("the exact scope of the non-triviality", "PROVED", "",
 [R + "theory/reports/wolfram-scope.json",
  R + "theory/reports/python-scope.json"]),
```

The list `LEDGER` holds the twenty rows of the table of Section 0.18, each as a group of four: the statement, the label, the note (an empty string `""` for a row that needs none), and the list of the reports that verify the row. Rows 1 to 3 are the exact results of the algebra and of the field theory, each verified by a Wolfram and a Python report. Row 2 names the quantisation of dirac16complex only, because the field dirac16complex00 is a classical field and is not quantised. Row 2 also holds the report of the finite Fock model (`lambda != 0` is $\lambda \neq 0$ written with plain characters: `!=` means "is not equal to"), and its note says how far that report reaches: the energy-momentum tensor (EMT) operator for $\lambda \neq 0$ is proved only in that finite model (Section 0.18); its last four reports are those of the field theory with b_4.

```
("EMT conservation identities; the spin connection", "PROVED", "",
 [R + "lead_checks/reports/emt-divergence-and-spin-connection.json"]),
("the field equations for a4 and b4; the vacuum", "PROVED", "",
 [R + "field_equations_a4/reports/wolfram-a4-report.json",
  R + "field_equations_a4/reports/python-a4-report.json",
  R + "field_equations_a4/reports/python-b4-block.json",
  R + "metric_b4/results/vacuum-b4.json",
  R + "lead_checks/reports/einstein-gauss-bonnet-a4.json"]),
("GKD and the three Lovelock tensors", "PROVED", "",
 [R + "gkd_lovelock/results/lovelock-report.json",
  R + "gkd_lovelock/results/gkd-selftest.json",
  R + "gkd_lovelock/results/wolfram-gkd-report.json",
  R + "gkd_lovelock/results/python-lovelock-report.json"]),
```

Rows 4 to 6, all PROVED: the conservation identities (one report of the lead), the field equations for a_4 and b_4 with the vacuum (the Wolfram and the Python verifier, the block of b_4, the vacuum of the metric with b_4 and the lead's independent check, five reports), and GKD and the Lovelock tensors (the four reports of the folder `gkd_lovelock/results`).

```
("the curvature agrees with the author's stored outputs", "PROVED",
 "5 of 78 comparisons NOT-AVAILABLE: the author's notebook stores no value",
 [R + "gkd_lovelock/comparison/author-comparison-report.json",
  R + "metric_b4/results/wolfram-metric-b4-report.json",
  R + "metric_b4/results/python-metric-b4-report.json"]),
("Kohn-Sham theory: blocks, rescaling, exchange", "PROVED", "",
 [R + "kohn_sham/reports/ks-theory-wolfram.json",
  R + "kohn_sham/reports/ks-theory-python.json",
  R + "kohn_sham/reports/ks-b4-wolfram.json"]),
```

Row 7, PROVED, has both reports and a note, like row 2: the note says that five of the 78 comparisons with the author's earlier notebook could not be made (Section 0.18); its other two reports compare the metric with b_4 with the author's notebook of 2026-10-14. Row 8 holds the exact parts of the Kohn-Sham theory, with the report that the good-sector problem does not contain b_4.

```
("Kohn-Sham states along the deflating history", "COMPUTED",
 "at the tip cutoff L = 3; the large-L limit not established for every state",
 [R + "kohn_sham/reports/ks-rust-solver.json",
  R + "kohn_sham/reports/ks-reference.json",
  R + "kohn_sham/reports/ks-crosscheck.json",
  R + "kohn_sham/reports/ks-rust-determinism.json",
  R + "kohn_sham/reports/ks-rust-mermin-roots.json",
  R + "kohn_sham/tip_convergence/tip-convergence.json"]),
("the Kohn-Sham history of a4 is a prescribed background", "ASSUMED", "",
 [R + "field_equations_a4/reports/ks-source-conditions.json",
  R + "field_equations_a4/ks_source/reports/ks-source-a4.json"]),
```

Row 9 is COMPUTED: the numerical Kohn-Sham states, with the five reports of the two solvers and of their comparisons and, sixth, the study of the tip cutoff. Its note says that the states are computed with the cutoff $L = 3$ and that the limit of large L is not established for every state (Section 0.18). Row 10 is ASSUMED, and its two reports give the reason (Section 0.18).

```
("pairing T1, T2 (Z2 mirror ASSUMED) and Q", "PROVED", "",
 [R + "pairing/reports/wolfram-pairing.json",
  R + "pairing/reports/python-pairing.json",
  R + "metric_b4/results/consequences-b4.json"]),
("T3 and its completion (Z2 mirror ASSUMED): +M and -M", "PROVED", "",
 [K + "wolfram-t3.json", K + "python-t3.json",
  K + "wolfram-t3-completion.json", K + "python-t3-completion.json"]),
("T3 shown on computed Kohn-Sham states (not a proof)", "COMPUTED", "",
 [K + "t3-rust-demo.json", K + "t3-reference-demo.json"]),
("charge conjugation C, Gamma C; the local U(1) law", "PROVED", "",
 [R + "lead_checks/reports/charge-conjugation-and-u1.json"]),
```

Rows 11 to 14. Rows 11 and 12, PROVED: the pairing theorems, whose statements name the ASSUMED Z2 mirror where it enters (row 11 also holds the report that T1 and T2 hold unchanged with b_4); row 12 holds the four reports on T3 and on its completion. Row 13, COMPUTED: the two numerical demonstrations of T3, labelled in their statement as what they are, not a proof. Row 14, PROVED: the charge-conjugation matrices with the local conservation law of the charge; its statement says "the local U(1) law" because only the local law is proved (In [3]).

```
("the dark-sector investigation: what each field gives", "COMPUTED", "",
 [D + "dirac16complex/reports/derivation-checks.json",
  D + "dirac16complex/reports/ks-history-run.json",
  D + "dirac16complex/reports/eos-checks.json",
  D + "dirac16complex/reports/independent-checks.json",
  D + "dirac16complex00/reports/python-derive-eos.json",
  D + "dirac16complex00/reports/python-independent-numerics.json"]),
```

Row 15, COMPUTED: the six reports of the dark-sector investigation. The rows 16 to 20 have an empty list of reports and a note:

```
("a time-varying dark sector from the fields", "HYPOTHESIS",
 "investigated (row 15): results stated, not established", []),
```

```
    ("our universe has a partner of opposite charge", "HYPOTHESIS",
     "the T1 maps exist; that a partner exists is not shown", []),
    ("the total charge Q of one universe is constant", "OPEN",
     "holds only with no flux through the brane (ASSUMED, not derived)", []),
    ("the big bang creates universes in pairs", "OPEN",
     "not proved: no creation process, rate or amplitude", []),
    ("what produces the excess of matter over antimatter", "OPEN",
     "the theory as built does not produce it", []),
]
```

The five entries without reports are the honest answers of Section 0.2, written as data, so that the computer can check them. Row 16 says that the dark-sector hypothesis was investigated (row 15) and is not established. Row 18 is the limit of row 14: the total charge is constant only if no charge flows through the brane, a condition that is ASSUMED and not derived. Row 20 is written as the open question that it is, with the note that the theory as built does not produce the excess.

```
say("row label       passed of all  statement")
row_passed, row_totals = [], []
for number, (statement, label, note, paths) in enumerate(LEDGER, 1):
    passed = sum(counted[path][0] for path in paths)
    total = sum(counted[path][1] for path in paths)
    row_passed.append(passed)
    row_totals.append(total)
    say(f"{number:3d} {label:10} {passed:7d} of {total:3d}  {statement}")
```

`enumerate(LEDGER, 1)` numbers the rows from 1. For each row, the passed checks and the checks of its reports are added (a sum over an empty list is 0), kept in the lists `row_passed` and `row_totals` for the checks below and for the picture of In [10], and a line of the table of Out [9] is printed. Row 7 shows 121 of 126 (the 73 of 78 of the earlier comparison and the 48 checks of the comparison with b_4).

```
say("The notes of the rows:")
for number, (statement, label, note, paths) in enumerate(LEDGER, 1):
    if note:  # rows 2, 7 and 9, and the HYPOTHESIS and OPEN rows
        say(f"{number:3d} {label:10} {note}")
```

The notes of the eight rows that have one are printed below the table (a non-empty string counts as true in `if`): rows 2, 7 and 9 and the five rows without a report.

```
used = sorted(path for _, _, _, paths in LEDGER for path in paths)
check(used == sorted(path for path, _ in REPORTS),
      f"every one of the {len(REPORTS)} reports belongs to exactly one row")
```

`used` is the sorted list of all reports named in all rows (a comprehension with two `for` parts runs through the rows and, inside each row, through its reports). It must equal the sorted list of the 51 reports: every report appears, and none twice (a report named twice would appear twice in `used`).

```
check(all((label in ("HYPOTHESIS", "OPEN")) == (paths == [] and note != "")
          for _, label, note, paths in LEDGER)
```

```
      and all(paths != [] for _, label, _, paths in LEDGER
              if label not in ("HYPOTHESIS", "OPEN")),
      "OPEN and HYPOTHESIS rows have a note and no report; the others have reports")
```

For every row, two statements must be both true or both false: the label is HYPOTHESIS or OPEN; the row has no report and has a note. And every row with another label must have at least one report (`paths != []`; the `if` inside the brackets keeps only those rows). Together: a statement is labelled HYPOTHESIS or OPEN exactly when nothing in the record establishes it, and then the ledger says why.

```
not_all_pass = [number for number, passed, total
                in zip(range(1, len(LEDGER) + 1), row_passed, row_totals)
                if passed != total]  # the rows with a check that is not PASS
check(not_all_pass == [7] and row_totals[6] - row_passed[6] == not_available
      and "NOT-AVAILABLE" in LEDGER[6][2],
      f"only row 7 has checks that are not PASS: its {not_available} "
      "NOT-AVAILABLE comparisons")
```

`not_all_pass` lists the numbers of the rows in which the passed checks are fewer than the checks. It must be the list `[7]`, and the missing checks of row 7 must be exactly the five NOT-AVAILABLE comparisons counted in In [5]; its note (the third entry of the row, `LEDGER[6][2]`, because Python counts the rows from 0) must say so. So no row of the ledger rests on a check that failed.

```
labels = [label for _, label, _, _ in LEDGER]
check([labels.count(name) for name in
       ("PROVED", "COMPUTED", "ASSUMED", "HYPOTHESIS", "OPEN")] == [11, 3, 1, 2, 3],
      "the ledger: 11 PROVED, 3 COMPUTED, 1 ASSUMED, 2 HYPOTHESIS and 3 OPEN rows")
```

The labels are counted: eleven rows PROVED, three COMPUTED, one ASSUMED, two HYPOTHESIS and three OPEN. Out [9] ends with four PASS lines.

In [10], the ledger as a picture.

```
LABEL_COLOURS = {"PROVED": "#2a78d6", "COMPUTED": "#eb6834", "ASSUMED": "#1baf7a"}
widest = max(row_totals)  # the row with the most checks
fig, ax = plt.subplots(figsize=(8.6, 9.0))
rows = np.arange(len(LEDGER))[::-1]  # the first row of the ledger at the top
```

A colour for each label that has reports, the largest number of checks of a row (210, row 2, in the run printed in Section 0.20), a tall figure of 8.6 by 9.0 inches, and the row positions with the first row at the top.

```
for number, row, (statement, label, note, paths), passed, total in zip(
        range(1, len(LEDGER) + 1), rows, LEDGER, row_passed, row_totals):
    # The statement is written just above its bar (va="bottom": the text starts
    # at the given height and extends upwards).
    ax.text(0, row + 0.26, f"{number}. {statement}", va="bottom", fontsize=9.5)
    if total > 0:
```

```
        ax.barh(row, total, height=0.42, color=LABEL_COLOURS[label])
        if passed == total:
            after = f"{total} checks: {label}"
        else:  # row 7: say how many checks are NOT-AVAILABLE
            after = f"{passed} PASS, {total - passed} NOT-AVAILABLE: {label}"
        ax.text(total + 0.012 * widest, row, after, va="center", fontsize=9)
    else:  # no report: the label and the note, in grey
        ax.text(0, row, f"{label}: {note}", va="center", fontsize=9,
                color="#52514e")
```

`zip` runs through five lists together: the row numbers 1 to 20, the positions, the rows of the ledger, their passed checks and their totals. For each row the statement is written just above the place of its bar. A row with checks gets a bar of that length in the colour of its label, with a text after it, at a distance of 1.2 per cent of the longest bar: the number of checks and the label, or, for row 7, the numbers of PASS and of NOT-AVAILABLE checks and the label. A row without checks gets its label and its note in grey instead.

```
ax.set_yticks([])  # the statements are written above the bars instead
ax.set_xlim(0, 1.39 * widest)  # room for the longest bar and the text after it
ax.set_ylim(-0.6, len(LEDGER) - 0.1)
ax.grid(False, axis="y")
ax.set_xlabel("number of checks in the reports of the row (none FAILS)")
ax.set_title("The honesty ledger at a glance")
ax.legend(handles=[Patch(color=colour, label=label_name)
                   for label_name, colour in LABEL_COLOURS.items()],
          loc="lower right", fontsize=9)
```

No labels on the vertical axis (the statements stand above the bars). The horizontal axis runs to 1.39 times the longest bar, computed from the counts, which leaves room for the longest bar and the text after it; the vertical limits leave room for the statement of the top row; the axis label says that no check of the ledger fails; the legend names the three colours.

```
save_figure(fig, "ledger",
            r"The honesty ledger of the book at a glance: one row per main "
            r"statement (written above its bar), the length of its bar the number of "
            r"checks in the reports that verify it (horizontal axis, a count), the "
            r"colour its label: blue PROVED, orange COMPUTED, aqua ASSUMED. Every "
            r"check is PASS except five NOT-AVAILABLE comparisons of row 7. The "
            f"ASSUMED row has {row_totals[9]} checks, which show why the Kohn-Sham "
            r"history of $a_4$ must be assumed. The last five rows have no bar, "
            r"because no check of the record establishes them: two hypotheses (a "
            r"time-varying dark sector, investigated in row 15 but not established; "
            r"a partner universe of opposite charge) and three open questions (a "
            r"constant total charge of one universe, which needs an assumed "
            r"condition at the brane; the creation of universes in pairs, not "
            r"proved; what produces the excess of matter "
            r"over antimatter, which the theory as built does not produce).")
```

The figure `00c_3_ledger.png`; `row_totals[9]` is the number of checks of row 10, the ASSUMED row (28 in the run printed in Section 0.20). What Figure 00c.3 shows: fifteen bars, eleven blue,

three orange (the Kohn-Sham numbers, the demonstrations of T3 and the dark-sector investigation) and one short aqua bar (the prescribed background), and five rows without a bar at the bottom: the two hypotheses and the three open questions. The picture makes the honesty rule visible: a statement without checks is never drawn as if it had them.

In [11], what the pairing record does not establish.

```
PAIRING = "Revision/pairing/reports/python-pairing.json"
not_established = read_report(PAIRING)["not_established"]  # a list of sentences
for number, sentence in enumerate(not_established, 1):
    say(f"{number:2d}. {sentence}")
check_reproduces(len(not_established) == 12
                 and not_established[0].startswith("No creation process"),
                 "the pairing record lists 12 things it does not establish, "
                 "the first: no creation process",
                 f"{PAIRING}, key not_established")
```

The Python pairing report holds, under its key `not_established`, a list of sentences; the loop prints them numbered from 1 (Out [11]). The check requires twelve sentences, the first beginning with No creation process. In plain words, the twelve say: nothing in the equations creates a universe or a pair; no rate, probability or amplitude is derived; no conservation law forces pairing, and a single universe is an equally valid solution; the zero total of a T1 pair is an identity for one field configuration and its image, not a cancellation between two independently quantised universes; T2 does not reverse the energy-momentum tensor; the Z2 mirror is ASSUMED; the back-reaction on gravity is not part of the theorems; nothing forces the partner to exist; T1 pairs (m, λ) with $(-m, -\lambda)$, not with $(-m, \lambda)$; a positive-norm quantum state space is not established by the theorems; the edge $z = \pi/2$ is a degenerate surface of the metric with no derived junction condition; and the Kohn-Sham level T3 is proved separately, with its own hypotheses.

In [12], how a fingerprint reacts to a change.

```
def text_fingerprint(text):
    """The sha256 fingerprint of a text (encoded as UTF-8 bytes)."""
    return hashlib.sha256(text.encode("utf-8")).hexdigest()
```

`text.encode("utf-8")` turns the text into its bytes, `hashlib.sha256` computes the fingerprint of the bytes, and `.hexdigest()` writes it as 64 hexadecimal characters.

```
for text in ("Universes in Pairs", "Universes in pairs"):
    digest = text_fingerprint(text)
    say(f"{text}:")
    say(f"    {digest}")
```

Two texts that differ only in the capital or small letter p. Out [12] shows their fingerprints: they have nothing visible in common.

```
SENTENCE = ("The rule above every other rule of this book is honesty: it never "
            "writes proved for a statement that is not proved.")
```

```
original = text_fingerprint(SENTENCE)
changed_characters = []  # for each position: how many of the 64 characters change
for position in range(len(SENTENCE)):
    letter = SENTENCE[position]
    altered = SENTENCE[:position] + chr(ord(letter) + 1) + SENTENCE[position + 1:]
    new = text_fingerprint(altered)
    changed_characters.append(sum(1 for a, b in zip(original, new) if a != b))
counts = np.array(changed_characters)
```

A sentence of 115 characters and its fingerprint. For every position, `ord(letter)` is the number of the character in the computer's alphabet (for example 97 for a), `chr(... + 1)` is the next character (b), and `SENTENCE[:position] + ... + SENTENCE[position + 1:]` is the sentence with that one character replaced (`[:position]` is the part before it, `[position + 1:]` the part after it). The fingerprint of the altered sentence is compared with the original character by character (`zip` pairs the two strings), and the number of differing characters is stored. `counts` is the array of the 115 numbers.

```
report("characters of the sentence", len(SENTENCE))
report("changed characters of the fingerprint: smallest, mean, largest",
       f"{counts.min()}, {counts.mean():.2f}, {counts.max()}")
```

Out [12]: 115 characters; the smallest number of changed characters is 54, the mean 60.03, the largest 64. The mean is what Section 0.18 derived for a random string, 60.

```
values, how_often = np.unique(counts, return_counts=True)  # each count, how often
fig, ax = plt.subplots()
ax.bar(values, how_often, width=0.8, color="#2a78d6", edgecolor="white",
       linewidth=1.5, label="one-character changes of the sentence")
ax.axvline(60, color="black", linewidth=1.2, linestyle=":",
           label="expected for a random fingerprint: 60")
ax.set_xlim(-1, 65)
```

`np.unique(..., return_counts=True)` returns the different values that occur and how often each occurs: a **histogram**. The bars are drawn at those values; `ax.axvline(60, ...)` draws a dotted vertical line at 60; the horizontal axis shows the whole range from 0 to 64, so that the empty left part is visible.

```
# "\n" inside a string starts a new line of the text.
ax.text(3, 0.55 * how_often.max(), "a fingerprint that changed only a little\n"
        "would give a bar on this side: none did", color="#52514e", fontsize=9)
ax.set_xlabel("number of the 64 characters of the fingerprint that change")
ax.set_ylabel("number of changed sentences")
ax.set_title("Change one character, and the fingerprint changes completely")
ax.legend(loc="upper left")
```

A note written into the empty left part of the picture, the labels, the title and the legend.

```
save_figure(fig, "fingerprints",
            r"How much a sha256 fingerprint changes when one character of a text "
```

```
            r"changes: for each of the 115 characters of one sentence, the "
            r"character was replaced by the next one and the number of the 64 "
            r"hexadecimal characters of the fingerprint that changed was counted; "
            r"horizontal axis that number (0 to 64), vertical axis how many of the "
            r"115 altered sentences gave it. Every change altered between "
            f"{counts.min()} and {counts.max()} of the 64 characters, on average "
            f"{counts.mean():.2f}, as for a random string (dotted line at 60): none "
            f"of the {len(counts)} one-character changes left the fingerprint "
            r"nearly the same.")
check(counts.min() > 32 and abs(counts.mean() - 60.0) < 1.0,
      f"all {len(counts)} one-character changes alter more than half of the "
      "fingerprint")
```

The figure `00c_4_fingerprints.png`; its caption takes the smallest, the mean and the largest count from the computation (54, 60.03 and 64) and states only what was measured: none of these 115 changes left the fingerprint nearly the same. The check requires that every change alters more than 32 of the 64 characters, that is more than half of them (`>` is "greater than"), and that the mean lies within 1 of 60. What Figure 00c.4 shows: all bars stand close to the dotted line at 60, and the left half of the picture is empty: no one-character change left a fingerprint nearly unchanged.

In [13], the fingerprints recorded by the reports.

```
def file_fingerprint(path):
    """The sha256 fingerprint of the bytes of the repository file path."""
    return hashlib.sha256(repository_file(path).read_bytes()).hexdigest()
```

As `text_fingerprint`, but for the bytes of a file of the repository (`read_bytes` reads them unchanged).

```
RECORDED = []  # (report, file, recorded fingerprint)
GKD = "Revision/gkd_lovelock/results/wolfram-gkd-report.json"
gkd = read_report(GKD)
for path, value in {**gkd["inputSha256"], **gkd["sourceSha256"]}.items():
    RECORDED.append((GKD, path, value))
LOVELOCK = "Revision/gkd_lovelock/results/python-lovelock-report.json"
for name, value in read_report(LOVELOCK)["inputsSha256"].items():
    RECORDED.append((LOVELOCK, "Revision/gkd_lovelock/results/" + name, value))
```

The list `RECORDED` collects groups of three: the report, the file and the fingerprint the report recorded for it. The Wolfram report of GKD and the Lovelock tensors stores two dictionaries from file paths to fingerprints; `{**a, **b}` makes one dictionary of both, and all 15 entries are collected. The Python Lovelock report stores 2 more, under file names without the folder, which is added in front.

```
IN_DETAILS = [  # (report, check, the file whose fingerprint the detail holds)
    ("ks-theory-wolfram.json", "fixture_input", "algebra/gammas.json"),
    ("ks-theory-python.json", "fixture_input", "algebra/reports/python-gammas.json"),
    ("ks-reference.json", "theory_input_coefficients", "kohn_sham/ks-theory.json"),
    ("ks-rust-solver.json", "theory_input_coefficients", "kohn_sham/ks-theory.json"),
    ("ks-rust-solver.json", "gamma_fixture_numeric", "algebra/gammas.json"),
    ("ks-rust-solver.json", "thermo_mu_vs_40digit_roots",
```

```
     "kohn_sham/solver/tools/mermin-roots-40digit.json"),
    ("ks-crosscheck.json", "problem_definition_identical",
     "kohn_sham/ks-theory.json"),
]
```

Seven more fingerprints are written inside the detail texts of checks of five Kohn-Sham reports; this list names, for each, the report, the check and the file.

```
for name, check_name, path in IN_DETAILS:
    report_path = "Revision/kohn_sham/reports/" + name
    detail = next(entry["detail"] for entry in read_report(report_path)["checks"]
                  if entry["name"] == check_name)
    value = re.search(r"\(sha256 ([0-9a-f]{16,64})\)", detail).group(1)
    RECORDED.append((report_path, "Revision/" + path, value))
```

For each, the detail of the named check is read, and the regular expression finds the fingerprint in it: `\(` and `\)` are the round brackets themselves (a backslash makes a special character ordinary), `[0-9a-f]` is one hexadecimal character, and `{16,64}` means 16 to 64 of them. `re.search` finds the first match, and `.group(1)` is the part in the inner brackets, the fingerprint (complete, or only its first 16 characters).

```
changed = []  # files whose fingerprint today differs from the recorded one
for report_path, path, value in RECORDED:
    same = file_fingerprint(path).startswith(value)  # a full or shortened value
    if not same:
        changed.append(path)
    status = "same" if same else "CHANGED"
    short_path = path.removeprefix("Revision/")  # the path without Revision/
    report_name = report_path.rsplit("/", 1)[1]  # the file name of the report
    say(f"{status:7} {short_path:52} {report_name}")
```

For each of the 24, the fingerprint of today's file is computed and must begin with the recorded value (`startswith` accepts a shortened value, and a complete value only if the two are equal). One line per fingerprint is printed: the 24 lines of Out [13], all reading same.

```
recorded_gammas = next(value for report_path, path, value in RECORDED
                       if report_path.endswith("ks-theory-wolfram.json"))
today_gammas = file_fingerprint("Revision/algebra/gammas.json")
say("Revision/algebra/gammas.json, recorded in ks-theory-wolfram.json and today:")
say(f"    {recorded_gammas}")
say(f"    {today_gammas}")
```

One example printed in full: the fingerprint of the file of the gammas as recorded by the Wolfram Kohn-Sham verifier, and as computed today; the two lines of 64 characters in Out [13] are identical.

```
report("recorded fingerprints compared", len(RECORDED))
check_reproduces(len(RECORDED) == 24 and changed == [],
                 "the 24 recorded fingerprints equal the files of today",
                 f"{GKD}, keys inputSha256 and sourceSha256, and five further reports")
```

The check requires 24 recorded fingerprints and no changed file. So these reports read exactly today's versions of these 24 files. (The record holds further fingerprints, for example in the key `inputs` of some reports; this notebook does not compare them.)

In [14], the last check.

```
figure_names = ["00c_1_checks_by_report.png", "00c_2_two_verifiers.png",
                "00c_3_ledger.png", "00c_4_fingerprints.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "the four figure files of this notebook exist")
all_checks_passed()
```

As in Notebook 00b: the four figure files must exist, and the last line prints ALL 18 CHECKS PASSED (notebook 00c): one check each in In [2], In [8], In [11], In [12], In [13] and In [14], two in In [3], three in In [5], three in In [6] and four in In [9].

0.22 Why every run gives the same bytes

Section 0.9 promised that every notebook of the book, run a second time, gives exactly the same bytes: the same printed text, the same pictures, the same files. The Revision record makes the same promise for its long computations. This section explains why such a promise can be kept at all, and what has to be done to keep it. It also explains why two *different* computations of the same number, for example two solvers, never agree exactly, and why their comparison needs a tolerance.

A computer is deterministic. Given the same program and the same input, it performs the same steps and gets the same result. Two runs of a careless notebook can still print different text, for five reasons: (1) it prints the time or the date; (2) it uses random numbers without a fixed starting point; (3) it prints the names of a set, or the files of a folder, in an order that can change from run to run; (4) it adds numbers in an order that depends on the computer, and the order changes the last digits of a sum; (5) it writes files with the line ends of the operating system. The notebooks of the book avoid all five. We now look at each, beginning with the way a computer stores numbers, because reason (4) comes from there.

Binary fractions. We write numbers in the decimal system, with the ten digits 0 to 9 and powers of 10. A computer writes them in the **binary** system, with the two digits 0 and 1 (each one a **bit**) and powers of 2: binary 101 means $1 \cdot 4 + 0 \cdot 2 + 1 \cdot 1 = 5$, and binary 0.11 means $1 \cdot \frac{1}{2} + 1 \cdot \frac{1}{4} = \frac{3}{4}$. A binary fraction with finitely many digits is a whole number divided by a power of 2. The number $0.1 = 1/10$ is not of this kind. Suppose it were, $1/10 = n/2^k$ with whole numbers n and k:

$$2^k = 10\,n$$

(multiply both sides by $10 \cdot 2^k$),

$$2^{k-1} = 5\,n$$

(divide both sides by 2, using $10 = 2 \cdot 5$). Then 5 would divide a power of 2, which is impossible, because the only prime number that divides a power of 2 is 2 itself (every whole number is a product

of prime numbers in exactly one way; this school fact is used here without proof). So the binary expansion of 1/10 never ends, just as the decimal expansion $1/3 = 0.333\ldots$ never ends, and the computer has to cut it off.

Floating-point numbers. Python's numbers with a fraction part (the type `float`, and numpy's `float64`) are **floating-point numbers**: each is a whole number m of exactly 53 binary digits, that is $2^{52} \le m < 2^{53}$, times a power of two, $x = m \cdot 2^e$ (and the same with a minus sign; zero is stored separately). The 53 binary digits correspond to about 16 decimal digits, since $2^{53} = 9007199254740992$ has 16 digits. A number that is not of this form is replaced by the nearest one that is: this is **rounding**. If it lies exactly halfway between two neighbours, the rule is to take the neighbour whose m is even (**round half to even**).

Which power of 2. The size of a stored number fixes its power of 2. Take $x = m \cdot 2^e$ with $2^{52} \le m < 2^{53}$, and multiply both inequalities by 2^e:

$$2^{52+e} \le x < 2^{53+e}$$

(multiplying both sides of an inequality by the positive number 2^e keeps it true, and $2^{52} \cdot 2^e = 2^{52+e}$ by the law of exponents). Now suppose that x lies between 2^k and 2^{k+1} for a whole number k, that is $2^k \le x < 2^{k+1}$. Then

$$52 + e = k, \quad \text{that is} \quad e = k - 52$$

(the intervals from 2^j to 2^{j+1}, one for each whole number j, do not overlap, so x lies in exactly one of them; the line above and the assumption both name that interval, so $52 + e = k$; then subtract 52 on both sides). We call this the **storage rule**: a number between 2^k and 2^{k+1} is stored as $m \cdot 2^{k-52}$ with a 53-digit m.

How 0.1 is stored. The number 0.1 lies between $2^{-4} = 0.0625$ and $2^{-3} = 0.125$; so, by the storage rule with $k = -4$, it must be written as $m \cdot 2^{-4-52} = m \cdot 2^{-56}$ with a 53-digit m:

$$m = 0.1 \cdot 2^{56} = 7205759403792793.6$$

(the condition $x = m \cdot 2^{-56}$ solved for m; $2^{56} = 72057594037927936$),

$$m \approx 7205759403792794$$

(rounding to the nearest whole number; it lies between $2^{52} = 4503599627370496$ and 2^{53}, as it must),

$$0.1 \approx \frac{7205759403792794}{2^{56}} = \frac{3602879701896397}{2^{55}} = 0.1000000000000000055511\ldots$$

(the numerator is even, so numerator and denominator can be divided by 2). The stored number is larger than 1/10 by about 5.6×10^{-18}. Notebook 00d prints exactly this fraction and all its decimal digits.

Why $0.1 + 0.2$ is not 0.3. Doubling changes only the power of 2, so 0.2 is stored exactly twice the stored 0.1:

$$0.2 \approx \frac{3602879701896397}{2^{54}} = \frac{7205759403792794}{2^{55}}$$

(multiply the stored 0.1 by 2, then write it over 2^{55} by multiplying numerator and denominator by 2). The number 0.3 lies between 2^{-2} and 2^{-1}, so, by the storage rule with $k = -2$, it is stored as $m \cdot 2^{-2-52} = m \cdot 2^{-54}$ with $m = 0.3 \cdot 2^{54} = 5404319552844595.2$, rounded:

$$0.3 \approx \frac{5404319552844595}{2^{54}}$$

(the same steps as for 0.1). The sum of the two stored numbers is

$$\frac{3602879701896397}{2^{55}} + \frac{7205759403792794}{2^{55}} = \frac{10808639105689191}{2^{55}}$$

(fractions with the same denominator are added by adding their numerators). This sum lies between 2^{-2} and 2^{-1}, so, by the storage rule with $k = -2$ again, it must be stored as $m \cdot 2^{-54}$, with

$$m = \frac{10808639105689191}{2} = 5404319552844595.5$$

(the sum written over 2^{54}: divide the numerator by 2). This lies exactly halfway between 5404319552844595 and 5404319552844596, and round half to even chooses the even one:

$$0.1 + 0.2 \approx \frac{5404319552844596}{2^{54}}$$

(round half to even). Comparing with the stored 0.3, the numerators differ by 1, so

$$(0.1 + 0.2) - 0.3 = \frac{1}{2^{54}} = 2^{-54} = 5.55 \times 10^{-17}$$

(subtraction of fractions with the same denominator). Python therefore prints $0.1 + 0.2$ as 0.30000000000000004, and the question whether $0.1 + 0.2$ equals 0.3 is answered False. Status: PROVED (by the exact arithmetic above); Notebook 00d checks it.

Machine epsilon and the gaps between numbers. The number 1 is stored with $m = 2^{52}$ and $e = -52$; the next larger stored number has $m = 2^{52} + 1$, so it is $1 + 2^{-52}$. The gap

$$\epsilon = 2^{-52} = 2.22 \times 10^{-16}$$

is called the **machine epsilon**. The number $1 + \epsilon/2 = 1 + 2^{-53}$ lies exactly halfway between 1 and $1 + \epsilon$; round half to even picks 1 (its $m = 2^{52}$ is even), so $1 + 2^{-53}$ is stored as 1. More generally, every stored number x between 2^k and 2^{k+1} (with $2^k \le x < 2^{k+1}$) has the power 2^{k-52} (the storage rule), so the gap to the next stored number, whose m is larger by 1, is 2^{k-52}. Dividing by x:

$$\frac{\text{gap}}{x} = \frac{2^{k-52}}{x} \le \frac{2^{k-52}}{2^k} = 2^{-52} = \epsilon$$

(a fraction becomes larger or stays equal when its denominator is replaced by a smaller or equal one, here $x \geq 2^k$), and

$$\frac{\text{gap}}{x} > \frac{2^{k-52}}{2^{k+1}} = 2^{-53} = \frac{\epsilon}{2}$$

(the same rule with $x < 2^{k+1}$). So every stored number carries the same relative accuracy, between $\epsilon/2$ and ϵ, about 16 significant decimal digits, whatever its size. A difference of one gap is called one **unit in the last place**, one **ulp**.

The order of a sum changes the last digits. Every addition rounds its result. Rounding is deterministic, but it depends on the order of the operations. The smallest example:

$$(1 + 2^{-53}) + 2^{-53} = 1 + 2^{-53} = 1$$

(the bracket is computed first; it is the halfway case above and is rounded to 1; then the same happens again), while

$$1 + (2^{-53} + 2^{-53}) = 1 + 2^{-52}$$

(the bracket is computed first: $2^{-53} + 2^{-53} = 2 \cdot 2^{-53} = 2^{-52}$ exactly, because doubling changes only the power of 2; and $1 + 2^{-52}$ is a stored number). The same three numbers, added in two orders, give two different stored results. In a long sum the effect grows. Notebook 00d adds the million numbers $1/k^2$, $k = 1, \ldots, 10^6$, **forwards** (the largest first) and **backwards** (the smallest first). Forwards, every small term is added to a running total of about 1.6 and is rounded to the gap of that total; backwards, small terms are added to small totals, which loses less. Measured against the exactly rounded sum, the forward sum is wrong by up to 196 ulps and the backward sum by at most 1 ulp; numpy's own way of adding, in pairs and pairs of pairs, by at most 3 ulps (COMPUTED, Notebook 00d). Different computers, or the same computer using several processor cores, may add in different orders; this is why the book always adds in a fixed order.

The error of the method is a different thing. The infinite sum $1 + 1/4 + 1/9 + \cdots$ is $\pi^2/6$ (a theorem of Euler, 1734, used here without proof). Stopping after N terms leaves out the tail $\sum_{k>N} 1/k^2$, and this is not a rounding error but an error of the method. Its size follows from comparing each term with an integral. The function $1/x^2$ decreases, so on the interval from $k-1$ to k it is larger than its value at the right end:

$$\frac{1}{k^2} < \int_{k-1}^{k} \frac{dx}{x^2}$$

(the area under a decreasing curve over an interval of length 1 is larger than the curve's smallest value there, $1/k^2$), and on the interval from k to $k+1$ it is smaller than its value at the left end:

$$\frac{1}{k^2} > \int_{k}^{k+1} \frac{dx}{x^2}$$

(the area is smaller than the largest value, $1/k^2$). Adding these inequalities for $k = N+1, N+2, \ldots$ joins the intervals into one:

$$\int_{N+1}^{\infty} \frac{dx}{x^2} < \sum_{k>N} \frac{1}{k^2} < \int_{N}^{\infty} \frac{dx}{x^2}$$

(sums of inequalities, and integrals over adjacent intervals add up to the integral over their union), and since $\int_a^\infty dx/x^2 = [-1/x]_a^\infty = 1/a$,

$$\frac{1}{N+1} < \frac{\pi^2}{6} - \sum_{k=1}^{N} \frac{1}{k^2} < \frac{1}{N}$$

(the fundamental theorem of calculus with the antiderivative $-1/x$ of $1/x^2$, whose value goes to 0 as x grows). For $N = 10^6$ the method error lies between 9.99999×10^{-7} and 10^{-6}; Notebook 00d measures 9.999995×10^{-7}, more than 10^7 times larger than even the largest rounding difference of the sums (196 ulps of about 2.2×10^{-16} each, that is about 4×10^{-14}).

Tolerances. Two runs of the same program in the same order agree byte for byte. Two *different* computations of the same quantity, such as two solvers, or one solver with two step sizes, agree only up to rounding and up to the errors of their methods. Such a comparison uses a **tolerance**: the largest difference that it accepts as agreement. The tolerance must be fixed *before* the comparison is made; a tolerance chosen after seeing the difference would prove nothing. The Revision record's Kohn-Sham solver was run with its canonical settings and again with refined settings (twice as many integration steps, tighter tolerances of its own, and one equation solved in another, exactly equivalent form that rounds along another path). The tolerances fixed in advance were 10^{-8} for energies, levels and thermodynamic quantities and 10^{-6} for profiles and derivatives. The eight measured largest differences are below their tolerances by factors (**margins**) between 4.7 and 7692 (COMPUTED: `Revision/kohn_sham/reports/ks-rust-determinism.json`; the measured values are quoted by `Revision/kohn_sham/reports/ks-crosscheck.json`, key `rust_matrix_wide_uncertainties`). The eight comparisons are these eight checks of the determinism report:

- `refined_ground_energies`: the ground-state energies;
- `refined_ground_homo_lumo_gap`: the gaps between levels;
- `refined_eigenvalues`: all Kohn-Sham levels;
- `refined_delta_scf`: the excitation energies;
- `refined_profiles`: the profiles;
- `refined_adiabatic_derivatives`: the adiabatic derivatives;
- `refined_thermodynamics`: the thermodynamic quantities;
- `refined_heat_capacity`: the heat capacity.

In the report the check `refined_mermin_root_path` stands between the last two; it is not a comparison with a tolerance but the negative control described next.

A negative control. A **negative control** is a test that must detect a known error; if it does not, the test is useless. The record contains one that teaches a general lesson. An earlier version

of the solver found the chemical potential μ (Chapter 13) with a method that was wrong by up to about 8×10^{-10} in units of the mass m in three thermal states, and it used that method in *both* runs. Both runs made the same rounding error, so their difference was tiny and hid the error. The present refined run finds μ along another rounding path, and its difference from the old result shows the error in full (`Revision/kohn_sham/reports/ks-rust-determinism.json`, check `refined_mermin_root_path`). Two computations that round the same way can agree with each other and both be wrong: a comparison is only as good as the independence of the two computations.

Seeds. A random-number generator of a computer is a formula that produces, step by step, numbers that look random. It starts from a number called the **seed**, and the same seed always gives the same sequence. The notebooks of the book use random numbers only from a generator with a fixed seed, so that every run draws the same numbers.

The order of a set. A Python **set** is an unordered collection of different things, written like `{"x1", "x2"}`. When Python prints a set, the order of its members depends on their **hash values**, numbers computed from the names with a secret key that Python chooses anew every time it starts, unless the **environment variable** `PYTHONHASHSEED` (a named setting that a program receives when it starts) fixes the key. The build of a notebook sets it to 0 and the check run to 1 (Section 0.9), so that a notebook that printed a set in its stored order would fail the check. The notebooks therefore sort every set before printing it.

Line ends. A text file ends each line with special bytes. Linux and macOS use one byte, LF (line feed, the number 10); Windows traditionally uses two, CR LF (carriage return 13, then line feed 10). The same two lines of text written with LF and with CR LF are different bytes, of different lengths and with different fingerprints. The book and the Revision record write every file with LF, on every operating system.

Fingerprints of the results. The two Kohn-Sham solvers of the record wrote, next to their result files, a **manifest**: a file that lists every result file with its sha256 fingerprint (Section 0.18). The record also ran each solver a second time and compared every file of the two runs byte for byte (`Revision/kohn_sham/reports/ks-rust-determinism.json`, check `repeat_byte_identical`; `Revision/kohn_sham/reports/ks-crosscheck.json`, check `reference_repeat_byte_identical`).

Example: what could make two runs differ. Notebook 00d shows each of these facts with a small experiment and reproduces the corresponding checks of the record: it prints how 0.1 is stored and checks the two facts derived above; draws the gaps between stored numbers; adds the million numbers $1/k^2$ in three orders; reads the eight tolerances of the Kohn-Sham solver with the measured differences and the negative control, and draws them; makes random walks with fixed seeds; runs Python twelve times with twelve hash seeds and prints the order of a set each time; shows the bytes of LF and CR LF line ends and confirms that no result file of the record has CR LF line ends; and computes 582 fingerprints and compares them with the two manifests. It draws six figures and ends with ALL 22 CHECKS PASSED (notebook 00d).

0.23 How to run Notebook 00d

Step 1. What this notebook does and what it needs.

Notebook 00d (Why every run gives the same bytes: rounding, order, seeds and line ends) is the file `Revision/textbook/notebooks/00d_reproducible_runs.ipynb` of the repository Dirac_claude.

It shows with small experiments why the notebooks of the textbook print the same numbers and write the same files every time they run: how the computer rounds decimal numbers, why the order of a sum changes its last digits (so that checks allow a tolerance), how a seed fixes random numbers, why names are sorted before they are printed, and why every file is written with the same line ends. It reproduces the tolerance, line-end, fingerprint and repeat checks of the Revision Kohn-Sham record (eight measured differences below their tolerances, a negative control that shows how one shared rounding path hid an error, 584 result files of two solvers without CR LF line ends, 582 recorded sha256 fingerprints equal to the files of today, two repeat runs byte for byte) and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 00d_reproducible_runs.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00d_reproducible_runs.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 00d_reproducible_runs.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/00d.captions.json`
- `Revision/textbook/figures/00d_1_float_spacing.png`
- `Revision/textbook/figures/00d_2_summation_order.png`
- `Revision/textbook/figures/00d_3_tolerances.png`
- `Revision/textbook/figures/00d_4_shared_rounding.png`
- `Revision/textbook/figures/00d_5_seeded_walks.png`
- `Revision/textbook/figures/00d_6_set_orders.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of this notebook exist
ALL 22 CHECKS PASSED (notebook 00d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/00d_reproducible_runs.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 00d_reproducible_runs.ipynb
python -m nbconvert --execute --inplace 00d_reproducible_runs.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "AssertionError: check failed" for a check about the files of the folder Revision/kohn_sham (their number, their line ends or their fingerprints): a file of the Revision record was changed, added or converted after the repository was downloaded. The first command below, run in the repository folder, lists every changed or added file; the second restores a changed file (write the file name that the first command printed instead of FILE); delete a file that the first command lists as untracked.

```
git status
git restore FILE
```

- "CalledProcessError" in the section about the order of a set of names: the notebook could not start Python a second time. Close JupyterLab, activate the environment again, start JupyterLab again from the same terminal and run the notebook again.

0.24 Notebook 00d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/00d_reproducible_runs.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Every notebook of this book is run twice by the book's checking tool, and the
second run must reproduce the first one exactly, byte for byte: the same printed
text, the same pictures, the same files. The Revision record does the same with
its long computations: its solvers of the Kohn-Sham equations were run a second
time and their result files compared byte for byte. This notebook shows, with
small experiments, what could make two runs differ and how the book prevents it.
It

- shows how the computer stores the number 0.1, and why 0.1 + 0.2 is not exactly
  0.3;
- draws the gaps between neighbouring numbers of the computer;
- adds the same numbers in two different orders and draws how the results differ
  in their last digits, which is why checks compare numbers with a tolerance;
- reads the tolerances of the Revision record's Kohn-Sham solver and the
  differences that were measured, and draws them;
- reads the record's negative control, which shows how two runs that round the
  same way hid an error, and draws it;
- shows how a seed makes random numbers repeat exactly;
- runs Python twelve times and shows that the order of a set of names changes from
  run to run, while the sorted order does not;
- shows that line ends change the bytes of a file, counts the result files of the
  Revision record and confirms that none has the line ends of Windows;
- computes the sha256 fingerprints of 582 result files, compares them with the
  fingerprints written down in the record, and reads the record's comparisons of
  two runs of each solver;
- draws six teaching plots and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook
```

Step 1. What this notebook does and what it needs.

Notebook 00d (Why every run gives the same bytes: rounding, order, seeds and line ends) is the file ‘Revision/textbook/notebooks/00d_reproducible_runs.ipynb‘ of the repository Dirac_claude. It shows with small experiments why the notebooks of the textbook print the same numbers and write the same files every time they run: how the computer rounds decimal numbers, why the order of a sum changes its last digits (so that checks allow a tolerance), how a seed fixes random numbers, why names are sorted before they are printed, and why every file is written with the same line ends. It reproduces the tolerance, line-end, fingerprint and repeat checks of the Revision Kohn-Sham record (eight measured differences below their tolerances, a negative control that shows how one shared rounding path hid an error, 584 result files of two solvers without CR LF line ends, 582 recorded sha256 fingerprints equal to the files of today, two repeat runs byte for byte) and draws six teaching plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 00d_reproducible_runs.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 15 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.

**Step 6. Or run the notebook without a browser (headless).**
```

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 00d_reproducible_runs.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 00d_reproducible_runs.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/00d.captions.json‘
- ‘Revision/textbook/figures/00d_1_float_spacing.png‘
- ‘Revision/textbook/figures/00d_2_summation_order.png‘
- ‘Revision/textbook/figures/00d_3_tolerances.png‘
- ‘Revision/textbook/figures/00d_4_shared_rounding.png‘
- ‘Revision/textbook/figures/00d_5_seeded_walks.png‘
- ‘Revision/textbook/figures/00d_6_set_orders.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS the six figure files of this notebook exist
ALL 22 CHECKS PASSED (notebook 00d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/00d_reproducible_runs.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 00d_reproducible_runs.ipynb
python -m nbconvert --execute --inplace 00d_reproducible_runs.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "AssertionError: check failed" for a check about the files of the folder Revision/kohn_sham (their number, their line ends or their fingerprints): a file of the Revision record was changed, added or converted after the repository was downloaded. The first command below, run in the repository folder, lists every changed or added file; the second restores a changed file (write the file name that the first command printed instead of FILE); delete a file that the first command lists as untracked.

```
git status
git restore FILE
```

- "CalledProcessError" in the section about the order of a set of names: the notebook could not start Python a second time. Close JupyterLab, activate the environment again, start JupyterLab again from the same terminal and run the notebook again.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 00d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 00d (Why every run gives the same bytes: rounding, order, seeds and line ends)
# is the file Revision/textbook/notebooks/00d_reproducible_runs.ipynb of the repository
# Dirac_claude. It shows with small experiments why the notebooks of the textbook print
# the same numbers and write the same files every time they run: how the computer rounds
# decimal numbers, why the order of a sum changes its last digits (so that checks allow a
# tolerance), how a seed fixes random numbers, why names are sorted before they are
# printed, and why every file is written with the same line ends. It reproduces the
# tolerance, line-end, fingerprint and repeat checks of the Revision Kohn-Sham record
# (eight measured differences below their tolerances, a negative control that shows how
# one shared rounding path hid an error, 584 result files of two solvers without CR LF
# line ends, 582 recorded sha256 fingerprints equal to the files of today, two repeat
# runs byte for byte) and draws six teaching plots. It needs a computer with Windows 11,
# macOS or Linux, an internet connection for the installation, the program Git, and
# Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages
# at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
# jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
# 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
```

```
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
```

```
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 00d_reproducible_runs.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 00d_reproducible_runs.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
```

```
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 00d_reproducible_runs.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/00d.captions.json
# - Revision/textbook/figures/00d_1_float_spacing.png
# - Revision/textbook/figures/00d_2_summation_order.png
# - Revision/textbook/figures/00d_3_tolerances.png
# - Revision/textbook/figures/00d_4_shared_rounding.png
# - Revision/textbook/figures/00d_5_seeded_walks.png
# - Revision/textbook/figures/00d_6_set_orders.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS the six figure files of this notebook exist
#     ALL 22 CHECKS PASSED (notebook 00d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/00d_reproducible_runs.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
```

```
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 00d_reproducible_runs.ipynb
#     python -m nbconvert --execute --inplace 00d_reproducible_runs.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "AssertionError: check failed" for a check about the files of the folder
#   Revision/kohn_sham (their number, their line ends or their fingerprints): a file of
#   the Revision record was changed, added or converted after the repository was
#   downloaded. The first command below, run in the repository folder, lists every
#   changed or added file; the second restores a changed file (write the file name that
#   the first command printed instead of FILE); delete a file that the first command
#   lists as untracked.
#     git status
#     git restore FILE
# - "CalledProcessError" in the section about the order of a set of names: the notebook
#   could not start Python a second time. Close JupyterLab, activate the environment
#   again, start JupyterLab again from the same terminal and run the notebook again.
#
# ------------------------------------------------------------------------------------

Text cell:

```
## 3. The words used in this notebook
```

```
- **Bit, byte**: a bit is one binary digit, 0 or 1; a byte is 8 bits, a whole
  number from 0 to 255. Every file is a sequence of bytes.
- **Binary**: the way of writing numbers with the two digits 0 and 1, in powers of
  2 instead of powers of 10: binary 101 is $4 + 0 + 1 = 5$, and binary 0.11 is
  $1/2 + 1/4 = 3/4$.
- **Floating-point number**: the way the computer stores a number with a fraction
  part: a whole number of at most 53 binary digits times a power of 2. Python's
  `float` and numpy's `float64` are such numbers. They have about 16 significant
  decimal digits.
- **Rounding**: replacing a number by the nearest floating-point number. It happens
  after every addition, multiplication and division.
- **Gap, unit in the last place (ulp)**: the distance from a floating-point number
  to the next larger one. A difference of one ulp is the smallest possible change
  of a stored number.
- **Machine epsilon** $\epsilon$: the gap between 1 and the next larger
  floating-point number, $\epsilon = 2^{-52} \approx 2.22 \times 10^{-16}$.
- **Tolerance**: the largest difference between two numbers that a check accepts
  as agreement.
- **Random-number generator, seed**: a program that produces numbers that look
  random. It starts from a number called the *seed*; the same seed always gives the
  same sequence.
- **Random walk**: a path that takes a step of $+1$ or $-1$ at random, again and
  again.
- **Set**: an unordered collection of different things, written `{"x1", "x2"}` in
  Python. Python keeps the names of a set in an order decided by their *hash
  values*: numbers computed from the names with a secret key that Python chooses
  anew each time it starts, unless the *environment variable* PYTHONHASHSEED fixes
  the key.
- **Environment variable**: a named setting that a program receives from the
  computer when it starts.
- **Line end**: the bytes that end a line of a text file. Linux and macOS use one
  byte, LF (line feed, the number 10); Windows traditionally uses two, CR LF
  (carriage return 13, then line feed 10).
- **Fingerprint (sha256)**: 64 hexadecimal characters computed from the bytes of a
  file; a file that differs in a single byte gives a completely different
  fingerprint. **Hexadecimal**: the digits 0 to 9 and the letters a to f.
- **Manifest**: a file that lists other files with their fingerprints.
- **Byte-identical**: two files with exactly the same bytes.
- **Subprocess**: a program that another program starts and whose printed output it
  reads.
```

```
## 4. The physical and mathematical situation

A computer is deterministic: given the same program and the same input, it does the
same steps and gets the same result. Yet two runs of a careless notebook can print
different text, for five reasons:

1. it prints the time or the date;
2. it uses random numbers without a fixed seed;
3. it prints the names of a set, or of the files of a folder, in an order that can
   change from run to run;
```

```
4. it adds numbers in an order that depends on the computer (for example on the
   number of processor cores working together), and the order changes the last
   digits of a sum;
5. it writes files with the line ends of the operating system.

The notebooks of the book avoid all five: they print no times, use fixed seeds,
sort names before printing them, add in a fixed order, and write every file with
LF line ends. Where two *different* computations of the same quantity are compared,
for example two solvers or two step sizes, the results agree only up to rounding
and up to the errors of the methods; such a comparison uses a tolerance that is
fixed before the comparison is made.

Why does rounding exist at all? A decimal fraction such as $0.1 = 1/10$ has a power
of 10 below the fraction line. The computer stores binary fractions, which have a
power of 2 below the fraction line. Since $10 = 2 \cdot 5$, the factor 5 cannot be
removed, and $1/10$ is not a binary fraction: its binary expansion
$0.000110011001100\ldots$ never ends, just as $1/3 = 0.333\ldots$ never ends in
decimal. The computer keeps 53 significant binary digits and rounds the rest away;
it stores 0.1 as the nearest binary fraction,
$$0.1 \approx \frac{3602879701896397}{2^{55}} = 0.1000000000000000055511\ldots$$
Every further operation rounds its result again to 53 binary digits. Rounding is
deterministic (the same operation on the same numbers always gives the same
result), but it depends on the order of the operations: in general
$(a + b) + c$ and $a + (b + c)$ round differently.
```

Text cell:

```
## 5. How the computer stores 0.1

The next cell imports two modules of Python itself. `Fraction(x)` writes the
floating-point number $x$ as the exact fraction that the computer stores, and
`Decimal(x)` writes all its decimal digits. The cell prints both for 0.1, prints
$0.1 + 0.2$ with every digit that Python needs to identify the stored number
(`!r` inside the braces of an f-string asks for this), and checks two facts: 0.1 is
stored as $3602879701896397 / 2^{55}$, and $0.1 + 0.2$ differs from $0.3$ by
$2^{-54} \approx 5.55 \times 10^{-17}$.

The cell also defines the helper `check_reproduces`, used later for checks that
reproduce a Revision record: it first calls `sys.stdout.flush()`, which sends all
printed text that is still waiting, and then calls `check` with the record.
(Jupyter sends printed text in pieces; flushing first keeps the PASS line and the
line `reproduces ...` below it in one piece, so that the book's tools read them
together.)
```

In [2]:

```
import sys  # sys.stdout is the channel through which the notebook prints
from decimal import Decimal  # the exact decimal digits of a stored number
from fractions import Fraction  # a stored number as an exact fraction

import numpy as np  # arrays of numbers
```

```
def check_reproduces(condition, name, record):
    """check(condition, name, record=record), after sending the waiting output."""
    sys.stdout.flush()  # send every printed line that is still waiting
    check(condition, name, record=record)

stored = Fraction(0.1)  # the fraction that the computer really stores for 0.1
say(f"0.1 is stored as the fraction {stored}")
say(f"    = {Decimal(0.1)}")
say(f"0.1 + 0.2 = {0.1 + 0.2!r}")
say(f"0.1 + 0.2 == 0.3 is {0.1 + 0.2 == 0.3}")  # == asks: exactly equal?
difference = (0.1 + 0.2) - 0.3
report("(0.1 + 0.2) - 0.3", repr(difference))
check(stored == Fraction(3602879701896397, 2 ** 55),
      "0.1 is stored as 3602879701896397 / 2^55, not exactly as 1/10")
check(0.1 + 0.2 != 0.3 and difference == 2.0 ** -54,
      "0.1 + 0.2 differs from 0.3 by 2^-54 = 5.55e-17, one rounding step")
```

PASS 0.1 + 0.2 differs from 0.3 by 2^-54 = 5.55e-17, one rounding step
```

Text cell:

```
The next cell asks numpy for the machine epsilon $\epsilon$ of 64-bit
floating-point numbers, the gap between 1 and the next larger stored number. It
checks that $\epsilon = 2^{-52}$, that $1 + \epsilon$ is stored as a number larger
than 1, and that $1 + \epsilon/2$, which lies exactly halfway between 1 and
$1 + \epsilon$, is rounded back to 1. (A number exactly halfway is rounded to the
neighbour whose last binary digit is 0, which here is 1.)
```

In [3]:

```
epsilon = float(np.finfo(np.float64).eps)  # the gap between 1 and the next number
report("machine epsilon", repr(epsilon))
say(f"1 + epsilon     == 1 is {1.0 + epsilon == 1.0}")
say(f"1 + epsilon / 2 == 1 is {1.0 + epsilon / 2 == 1.0}")
check(epsilon == 2.0 ** -52 and 1.0 + epsilon > 1.0 and 1.0 + epsilon / 2 == 1.0,
      "machine epsilon is 2^-52: 1 + 2^-52 is stored, 1 + 2^-53 rounds back to 1")
```

Out [3]:

```
RESULT machine epsilon = 2.220446049250313e-16
1 + epsilon     == 1 is False
1 + epsilon / 2 == 1 is True
PASS machine epsilon is 2^-52: 1 + 2^-52 is stored, 1 + 2^-53 rounds back to 1
```

Text cell:

```
## 6. The gaps between neighbouring numbers

The gap between neighbouring floating-point numbers is not the same everywhere: it
grows with the size of the numbers. Between $2^{k}$ and $2^{k+1}$ all stored
numbers have the same gap $2^{k - 52}$, and the gap doubles at every power of 2. So
for every $x$ the gap lies between $\epsilon x / 2$ and $\epsilon x$: every stored
number is accurate to about 16 significant digits, whatever its size.

The next cell computes the gap with `np.spacing(x)` at 3000 values of $x$ from
$10^{-3}$ to $10^{6}$ (`np.logspace(-3, 6, 3000)` makes numbers equally spaced on
a logarithmic axis), draws it on logarithmic axes together with the two lines
$\epsilon x$ and $\epsilon x / 2$, prints the gaps at 1, 1000 and $10^{6}$, and
checks that the gap lies between the two lines at all 3000 points.
```

In [4]:

```
BLUE, ORANGE, AQUA, YELLOW = "#2a78d6", "#eb6834", "#1baf7a", "#eda100"
x_values = np.logspace(-3.0, 6.0, 3000)  # 3000 numbers from 0.001 to 1000000
gaps = np.spacing(x_values)  # the gap from each number to the next larger one
for x in (1.0, 1000.0, 1.0e6):
    say(f"gap above {x:>9g}: {np.spacing(x):.3e}")

fig, ax = plt.subplots()
# drawstyle="steps-post" draws each value as a flat step until the next x.

```
## 7. The order of a sum changes the last digits
```

```
We add the numbers $1, 1/4, 1/9, \ldots, 1/N^2$, that is $1/k^2$ for
$k = 1, \ldots, N$, in two orders:

- **forwards**: starting with the largest number 1. The running total is about
  1.6 from the start, so every small number is added to a large total, and each
  addition rounds to the gap of that total;
- **backwards**: starting with the smallest number $1/N^2$. The running total grows
  slowly, and small numbers are added to small totals, which loses less.

The reference is `math.fsum`, which adds the stored numbers exactly and rounds only
once at the end (the *exactly rounded* sum). The difference of each sum from it is
measured in ulps: the difference divided by the gap `np.spacing` of the exact sum.
`np.add.accumulate(terms)` adds the numbers of an array one after the other,
starting with the first, and returns every running total, so `forward[N - 1]` is
the forward sum of the first $N$ numbers. `terms[:N][::-1]` is the first $N$
numbers in reverse order. A third way, numpy's `np.sum`, adds in pairs, then pairs
of pairs, and so on (*pairwise summation*), which also loses little.

The next cell does this for 31 values of $N$ from 10 to $10^{6}$, prints the four
sums for $N = 10^{6}$ with all their digits, and prints how far the sum of $10^{6}$
numbers lies below the limit of the infinite sum, $\pi^2/6$. That last difference,
about $1/N = 10^{-6}$, is not a rounding error: it is the error of the *method*
(stopping after $N$ numbers), and it is more than $10^{7}$ times larger than the
largest rounding difference.
```

In [5]:

```
import math  # math.fsum: the exactly rounded sum; math.pi

N_MAX = 10 ** 6
k = np.arange(1, N_MAX + 1, dtype=np.float64)  # 1, 2, ..., 1000000 as floats
terms = 1.0 / (k * k)  # the numbers 1/k^2
forward = np.add.accumulate(terms)  # all forward running totals
# 31 values of N, equally spaced on a logarithmic axis from 10 to 10^6.
n_values = np.unique(np.round(np.logspace(1.0, 6.0, 31)).astype(int))
ulps = {"forward": [], "backward": [], "pairwise": []}  # the errors in ulps

## 8. Why checks allow a tolerance: the Revision record

The Revision record's Kohn-Sham solver, a Rust program, was run with its canonical
settings and again with *refined* settings: twice as many steps of its
Runge-Kutta integrator, root and self-consistency tolerances ten times smaller, and
one equation (the condition that fixes the chemical potential $\mu$) solved in a
different but exactly equivalent form, which rounds along a different path. The
differences between the two runs measure the error of the canonical run. Before the
comparison, tolerances were fixed: $10^{-8}$ for energies, levels and thermodynamic
quantities, $10^{-6}$ for profiles and derivatives.

The report Revision/kohn_sham/reports/ks-rust-determinism.json records eight such
comparisons, each with its tolerance at the end of its detail text, and the
cross-check report Revision/kohn_sham/reports/ks-crosscheck.json quotes the eight
measured largest differences as numbers under the key
`rust_matrix_wide_uncertainties`. The next cell reads both, finds each measured
number (written with four significant digits) in the detail of its check, reads the
tolerance with the pattern `tolerance (\S+)` of the module `re` (`\S+` means one or
more characters that are not blanks; the brackets mark the part to return), and
prints a table with the *margin*, the tolerance divided by the measured
difference. The names of the eight quantities are explained in the Kohn-Sham
chapters; here only their sizes matter.

Text cell:

The record also teaches why the refined run had to round along a different path. An earlier version of the solver found μ with a third method, a *direct count*, and used it in BOTH runs. In three thermal states that method was wrong by up to about $8 \times 10^{-10}\,m$, but both runs made the same rounding error, so the difference between the runs (the *former measure*) was tiny and hid the error. The present refined run finds μ along another rounding path, and its difference from the old result (the *present measure*) shows the error in full. The check ‘refined_mermin_root_path‘ of the same report records this as a *negative control* (a test that must detect a known error) in its detail text, one entry per state.

The next cell reads these entries with a regular expression: ‘re.findall‘ returns, for every place where the pattern matches, the parts in brackets (the name of the state and three numbers). It prints them as a table and checks, as the record states, that in every state the former measure stays below half of the error while the present measure is at least half of it. Two computations that make the same rounding error agree with each other and can still both be wrong: a comparison is only as good as the independence of the two computations.

In [9]:

```
root_path = determinism_checks["refined_mermin_root_path"]  # the record's check
CONTROL = (r"(N\w+): direct-count error (\S+) m \(refined run \S+\), "
```

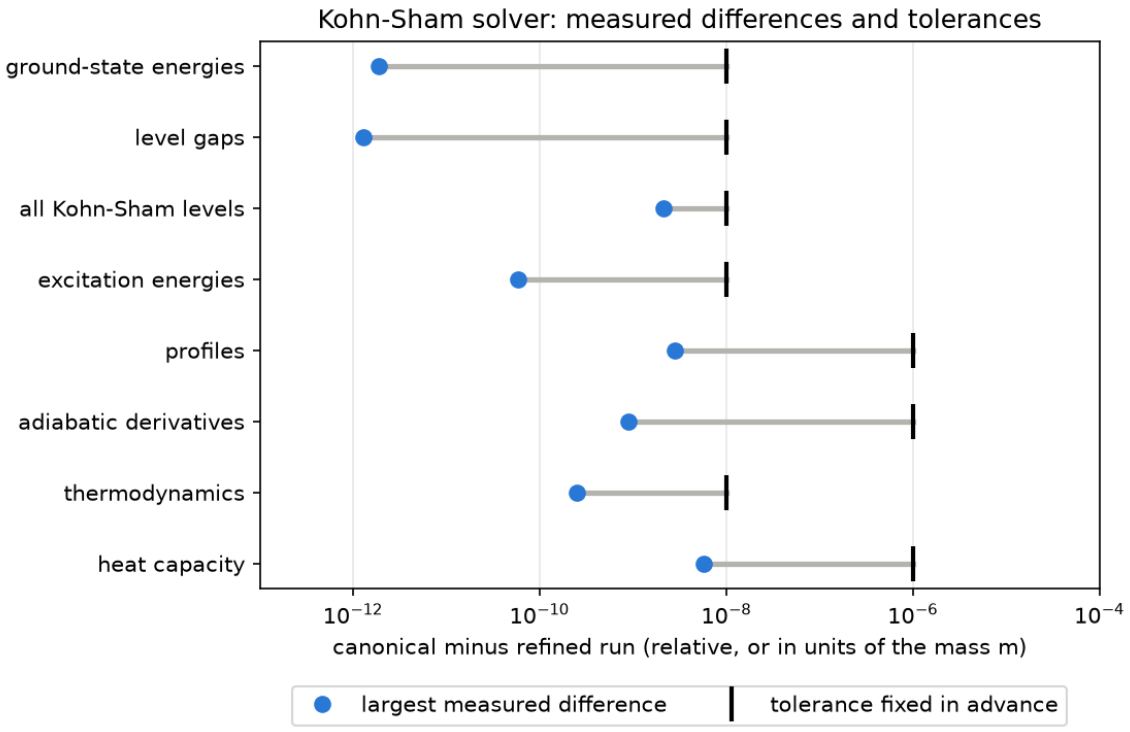

Figure 13: The eight comparisons between the canonical and the refined run of the Revision record's Kohn-Sham solver (one row each): the largest measured difference (blue dot) and the tolerance fixed before the comparison (black bar), on a logarithmic horizontal axis (relative differences, or level differences in units of the mass m). Every dot lies to the left of its bar: the measured differences are between 4.7 and 7692 times smaller than their tolerances. The grey line from a dot to its bar is this margin. ```
## 9. Random numbers that repeat: seeds

‘np.random.default_rng(seed)‘ makes a random-number generator that starts from the
given seed. The next cell makes three generators, two with the seed 12345 and one
with the seed 2026, lets each produce 400 random steps of $+1$ or $-1$
(‘choice([-1, 1], size=400)‘ picks 400 times from the list $[-1, 1]$), and adds the
steps up into random walks with ‘np.cumsum‘ (the running totals). It prints the
first ten steps of each, draws the three walks, and checks that the two walks with
the same seed are identical while the third differs.
```

In [11]:

```
walks = {}  # a label -> the 401 positions of the walk (it starts at 0)

```
## 10. The order of a set of names

The next cell starts Python twelve times as a subprocess, each time with another
```

```
value 0, 1, ..., 11 of the environment variable PYTHONHASHSEED, and lets it print
the eight names $x_0, \ldots, x_7$ of a set. ‘sys.executable‘ is the Python program
that runs this notebook; ‘-c‘ tells it to run the program text that follows;
the names are given to that program as its arguments ‘sys.argv[1:]‘, and
‘print(*names)‘ prints them separated by blanks. ‘dict(os.environ,
PYTHONHASHSEED=...)‘ is a copy of the environment variables with one of them set.
The cell runs the seed 0 a second time, collects the orders, and checks three
statements: the same seed gives the same order; the twelve seeds give different
orders; and sorted with ‘sorted‘, every order becomes $x_0, \ldots, x_7$.

This is why no notebook of the book prints a set without sorting it first: the
checking tool runs every notebook a second time with another hash seed, and an
unsorted set would print its names in another order.
```

In [12]:

lines "x1 x2" and "x3 x4" as bytes, once with LF line ends and once with CR LF line
ends (‘"\n"‘ is LF, ‘"\r\n"‘ is CR LF; ‘.encode("utf-8")‘ turns a text into
bytes), prints the bytes as numbers and their sha256 fingerprints, and checks that
the two versions have different lengths and different fingerprints. A program that
compares files byte for byte therefore needs one fixed kind of line end; the book
and the Revision record use LF everywhere. (The repository’s file .gitattributes
tells git to store and deliver every file unchanged, so that a computer with
Windows receives the same LF line ends.)
```

In [14]:

```
import hashlib  # computes sha256 fingerprints

TEXT = "x1 x2\nx3 x4\n"  # two lines, each ended by a line end
with_lf = TEXT.encode("utf-8")  # LF line ends: the byte 10
with_crlf = TEXT.replace("\n", "\r\n").encode("utf-8")  # CR LF: the bytes 13, 10
for label, data in (("LF   ", with_lf), ("CR LF", with_crlf)):
    say(f"{label} {len(data):2d} bytes: {list(data)}")
    say(f"      sha256 {hashlib.sha256(data).hexdigest()}")
check(len(with_crlf) == len(with_lf) + 2
      and hashlib.sha256(with_lf).digest() != hashlib.sha256(with_crlf).digest(),
      "the same two lines with LF and with CR LF line ends are different bytes")
```

Out [14]:

```
LF    12 bytes: [120, 49, 32, 120, 50, 10, 120, 51, 32, 120, 52, 10]
      sha256 dfcf8f120dfb5a9b8d784c7b038aa4cff5ed0b74c5809b5d51f81f763b30bf59
CR LF 14 bytes: [120, 49, 32, 120, 50, 13, 10, 120, 51, 32, 120, 52, 13, 10]
      sha256 c8b93d4c3f40882e9d91457a270e93ff4ea184e5616806b7e1b6d3ac753b52ab
PASS the same two lines with LF and with CR LF line ends are different bytes
```

Text cell:

```
The next cell looks at the result files of the Revision record’s two Kohn-Sham
solvers: the Rust solver (the folder Revision/kohn_sham/results) and the
independent Python reference solver (the folder Revision/kohn_sham/reference/
results). For each folder it counts the files, adds up their sizes in bytes and
counts the files that contain the two bytes CR LF. The two checks require that no
file has CR LF line ends, as the record’s checks ‘outputs_lf_only‘ (Rust) and
‘reference_outputs_lf_only‘ (reference) found when the solvers ran.
‘folder.rglob("*")‘ lists everything in a folder and in all its sub-folders;
‘sorted‘ puts the list in a fixed order.
```

In [15]:

Text cell:

12. Fingerprints of the result files

Each of the two result folders holds a manifest, a file manifest.json that lists every other file of the folder with its sha256 fingerprint: the Rust solver's manifest gives for each file its path, its size and its fingerprint; the reference solver's manifest gives for each path its fingerprint. The next cell computes the fingerprint of every listed file as it is today, compares it with the listed one, and checks that every file of each folder except the manifest itself is listed. When all agree, the files of today are exactly, byte for byte, the files that the solvers wrote.

The record also ran each solver a second time and compared every file of the two runs: the Rust solver in the check ‘repeat_byte_identical‘ of the report ks-rust-determinism.json ("244 files (... bytes) compared"), the reference solver in the check ‘reference_repeat_byte_identical‘ of the cross-check report. The last two checks of the cell confirm that the record found no differing file and that it compared as many files (and, for the Rust solver, as many bytes) as the folders hold today.

In [16]:

PASS the six figure files of this notebook exist
ALL 22 CHECKS PASSED (notebook 00d)
```

Text cell:

```
## 14. What this notebook showed

- The computer stores numbers as binary fractions with 53 significant binary
  digits: 0.1 is stored as $3602879701896397/2^{55}$, and $0.1 + 0.2$ differs from
  $0.3$ by one rounding step, $2^{-54}$. The gap between neighbouring stored
  numbers grows with their size and always lies between $\epsilon x/2$ and
  $\epsilon x$, $\epsilon = 2^{-52}$.
- Rounding is deterministic, but it depends on the order of the operations: the
  same million numbers added forwards and backwards give sums that differ by
  about 200 units in the last place, a relative difference of a few times
  $10^{-14}$. This is why every comparison of two different computations uses a
  tolerance, fixed in advance.
- The Revision record's Kohn-Sham solver was compared with a refined run of itself:
  all eight measured differences lie below the tolerances that were fixed in
  advance (the margins are printed in section 8). The record's negative control
  shows that two runs with the same rounding path hid errors of the chemical
  potential up to about $8 \times 10^{-10}\,m$, which is why the refined run now
  rounds along a different path.
- A fixed seed makes random numbers repeat exactly; the order of a set of names
  changes with the hash seed, while the sorted order does not; LF and CR LF line
```

```
  ends make the same text into different bytes.
- The result files of the record's two Kohn-Sham solvers have only LF line ends,
  and the 582 fingerprints of their two manifests equal the files of today: the
  stored results are exactly the ones the solvers wrote. A second run of each
  solver gave the same files byte for byte.
```

0.25 Line-by-line walk-through of Notebook 00d

The notebook has seventeen code cells, In [1] to In [17]. This section explains every line of each of them.

In [1], the set-up cell. It is the set-up cell of Notebook 00a, word for word, except that its comment lines hold the run instructions of Notebook 00d (Section 0.23) and the line `NOTEBOOK_ID = "00d"` names this notebook. Every line of its code is explained in Section 0.13. It prints Set-up of notebook 00d complete: repository folder found, helpers defined.

In [2], how the computer stores 0.1.

```
import sys  # sys.stdout is the channel through which the notebook prints
from decimal import Decimal  # the exact decimal digits of a stored number
from fractions import Fraction  # a stored number as an exact fraction

import numpy as np  # arrays of numbers
```

Two modules of Python itself that look inside a stored number: `Fraction(x)` gives the exact fraction that the computer stores for the floating-point number `x`, and `Decimal(x)` all its decimal digits. Then `sys` and numpy, as before.

```
def check_reproduces(condition, name, record):
    """check(condition, name, record=record), after sending the waiting output."""
    sys.stdout.flush()  # send every printed line that is still waiting
    check(condition, name, record=record)
```

The helper for checks that reproduce a Revision record, explained in Section 0.17 (In [2] of Notebook 00b).

```
stored = Fraction(0.1)  # the fraction that the computer really stores for 0.1
say(f"0.1 is stored as the fraction {stored}")
say(f"    = {Decimal(0.1)}")
say(f"0.1 + 0.2 = {0.1 + 0.2!r}")
say(f"0.1 + 0.2 == 0.3 is {0.1 + 0.2 == 0.3}")  # == asks: exactly equal?
```

The first two lines of Out [2] print the stored fraction, 3602879701896397/36028797018963968 (the denominator is 2^{55}), and its 55 decimal digits after the point, exactly the result of Section 0.22. `!r` inside the braces prints a number with as many digits as Python needs to identify the stored number uniquely: 0.30000000000000004. The fourth line asks whether $0.1 + 0.2$ is exactly equal to 0.3: False.

```
difference = (0.1 + 0.2) - 0.3
report("(0.1 + 0.2) - 0.3", repr(difference))
check(stored == Fraction(3602879701896397, 2 ** 55),
      "0.1 is stored as 3602879701896397 / 2^55, not exactly as 1/10")
check(0.1 + 0.2 != 0.3 and difference == 2.0 ** -54,
      "0.1 + 0.2 differs from 0.3 by 2^-54 = 5.55e-17, one rounding step")
```

The difference is printed with `repr` (the same as `!r`): 5.551115123125783e-17, which means $5.551115123125783 \times 10^{-17}$. The two checks confirm the two results derived by hand in Section 0.22: the stored 0.1 is $3602879701896397/2^{55}$, and $(0.1 + 0.2) - 0.3$ is exactly 2^{-54} (`!=` means "is not equal to").

In [3], the machine epsilon.

```
epsilon = float(np.finfo(np.float64).eps)  # the gap between 1 and the next number
report("machine epsilon", repr(epsilon))
say(f"1 + epsilon     == 1 is {1.0 + epsilon == 1.0}")
say(f"1 + epsilon / 2 == 1 is {1.0 + epsilon / 2 == 1.0}")
check(epsilon == 2.0 ** -52 and 1.0 + epsilon > 1.0 and 1.0 + epsilon / 2 == 1.0,
      "machine epsilon is 2^-52: 1 + 2^-52 is stored, 1 + 2^-53 rounds back to 1")
```

`np.finfo(np.float64)` describes numpy's 64-bit floating-point numbers, and its `.eps` is the machine epsilon, printed as 2.220446049250313e-16. Then $1 + \epsilon$ is not equal to 1 (False), while $1 + \epsilon/2$ is rounded back to 1 (True), the halfway case of Section 0.22. The check confirms all three facts.

In [4], the gaps between neighbouring numbers.

```
BLUE, ORANGE, AQUA, YELLOW = "#2a78d6", "#eb6834", "#1baf7a", "#eda100"
x_values = np.logspace(-3.0, 6.0, 3000)  # 3000 numbers from 0.001 to 1000000
gaps = np.spacing(x_values)  # the gap from each number to the next larger one
for x in (1.0, 1000.0, 1.0e6):
    say(f"gap above {x:>9g}: {np.spacing(x):.3e}")
```

Four colours. `np.logspace(-3.0, 6.0, 3000)` makes 3000 numbers from 10^{-3} to 10^{6} whose logarithms are equally spaced, so that they spread evenly over a logarithmic axis. `np.spacing(x)` is the gap from x to the next larger stored number. The loop prints the gaps at 1, 1000 and 10^6: 2.220×10^{-16}, 1.137×10^{-13} and 1.164×10^{-10} (Out [4]). Each is about ϵ times the number: 1000 lies between $2^9 = 512$ and 2^{10}, so its gap is $2^{9-52} = 2^{-43} = 1.137 \times 10^{-13}$.

```
fig, ax = plt.subplots()
# drawstyle="steps-post" draws each value as a flat step until the next x.
ax.plot(x_values, gaps, color=BLUE, linewidth=1.5, drawstyle="steps-post",
        label="gap to the next stored number")
ax.plot(x_values, epsilon * x_values, color="black", linestyle="--",
        linewidth=1.0, label=r"$\epsilon x$")
ax.plot(x_values, epsilon * x_values / 2, color="black", linestyle=":",
        linewidth=1.0, label=r"$\epsilon x / 2$")
ax.set_xscale("log")  # logarithmic horizontal axis
ax.set_yscale("log")  # logarithmic vertical axis
ax.set_xlabel(r"the number $x$")
```

```
ax.set_ylabel("gap to the next stored number")
ax.set_title("The gaps between neighbouring floating-point numbers")
ax.legend(loc="upper left")
```

The gaps are drawn as a staircase (each value as a flat step), together with the two straight lines ϵx (dashed) and $\epsilon x/2$ (dotted) that Section 0.22 derived as the upper and lower bounds; both axes are logarithmic.

```
save_figure(fig, "float_spacing",
            r"The gap between a floating-point number $x$ and the next larger "
            r"stored number (blue staircase) for $x$ from $10^{-3}$ to $10^{6}$, on "
            r"logarithmic axes (both pure numbers), with the lines $\epsilon x$ "
            r"(dashed) and $\epsilon x/2$ (dotted), $\epsilon = 2^{-52}$. The gap is "
            r"constant between two powers of 2 and doubles at each of them, so it "
            r"always lies between the two lines: every stored number carries about "
            r"16 significant digits, whatever its size.")
ratios = gaps / x_values  # the gap relative to the number
check(bool(np.all(ratios > epsilon / 2) and np.all(ratios <= epsilon))
      and np.spacing(1.0) == epsilon,
      "the gap lies between eps x / 2 and eps x at all 3000 points")
```

The figure `00d_1_float_spacing.png`, and the check of the bounds of Section 0.22 at all 3000 points: `np.all` is true when the comparison holds for every entry, and `bool` makes a plain truth value of it. What Figure 00d.1 shows: a staircase that climbs over nine powers of ten while staying between the two parallel lines; each step is flat between two powers of 2 and jumps up by a factor 2 at each of them.

In [5], one sum in three orders.

```
import math  # math.fsum: the exactly rounded sum; math.pi

N_MAX = 10 ** 6
k = np.arange(1, N_MAX + 1, dtype=np.float64)  # 1, 2, ..., 1000000 as floats
terms = 1.0 / (k * k)  # the numbers 1/k^2
forward = np.add.accumulate(terms)  # all forward running totals
```

The module `math` of Python provides `math.fsum`, which adds stored numbers exactly and rounds only once, at the end (the **exactly rounded** sum), and π. `np.arange(1, N_MAX + 1, ...)` is the array 1, 2, ..., 10^6 (the end is not included, hence the +1), as floating-point numbers; `terms` holds the million numbers $1/k^2$. `np.add.accumulate` adds them one after the other, starting with the first and largest, and returns every running total: `forward[n - 1]` is the forward sum of the first `n` terms.

```
# 31 values of N, equally spaced on a logarithmic axis from 10 to 10^6.
n_values = np.unique(np.round(np.logspace(1.0, 6.0, 31)).astype(int))
ulps = {"forward": [], "backward": [], "pairwise": []}  # the errors in ulps
```

31 numbers of terms from 10 to 10^6, rounded to whole numbers (`np.round`, then `.astype(int)`); `np.unique` sorts them and removes repetitions. The dictionary `ulps` will hold the three lists of errors.

```
for n in n_values:
    exact = math.fsum(terms[:n])  # the exactly rounded sum of the first n numbers
    gap = np.spacing(exact)  # one ulp of the exact sum
    backward = np.add.accumulate(terms[:n][::-1])[-1]  # smallest number first
    ulps["forward"].append(float((forward[n - 1] - exact) / gap))
    ulps["backward"].append(float((backward - exact) / gap))
    ulps["pairwise"].append(float((np.sum(terms[:n]) - exact) / gap))
```

For each number of terms `n`: the exactly rounded sum of the first `n` terms (`terms[:n]`); one ulp of it; the backward sum, which adds the reversed list (`[::-1]`) and keeps the last running total (`[-1]`); and the errors of the three sums, each divided by the ulp, so that they are measured in ulps. `np.sum` adds in pairs, then pairs of pairs, and so on (**pairwise summation**).

```
# The three sums of all 10^6 numbers, as plain Python floats (float(...)).
forward_million = float(forward[-1])
backward_million = float(np.add.accumulate(terms[::-1])[-1])
pairwise_million = float(np.sum(terms))
exact_million = math.fsum(terms)
say(f"forward  sum of 10^6 numbers: {forward_million!r}")
say(f"backward sum of 10^6 numbers: {backward_million!r}")
say(f"pairwise sum of 10^6 numbers: {pairwise_million!r}")
say(f"exactly rounded sum         : {exact_million!r}")
```

The four sums of all million terms, printed with every digit that identifies them: the forward sum 1.64493306684877, the backward and the pairwise sum 1.6449330668487263, and the exactly rounded sum 1.6449330668487265 (Out [5]). Forwards and backwards, the same numbers give different last digits.

```
worst_forward = max(abs(u) for u in ulps["forward"])  # the largest size of error
worst_backward = max(abs(u) for u in ulps["backward"])
worst_pairwise = max(abs(u) for u in ulps["pairwise"])
report("largest forward error in ulps", f"{worst_forward:.0f}")
report("largest backward error in ulps", f"{worst_backward:.0f}")
report("largest pairwise error in ulps", f"{worst_pairwise:.0f}")
report("pi^2/6 minus the exact sum of 10^6 numbers",
       f"{math.pi ** 2 / 6 - exact_million:.6e}")
```

The largest size of each error over the 31 values of N: 196 ulps forwards, 1 ulp backwards, 3 ulps pairwise. The last RESULT line is the error of the method, $\pi^2/6$ minus the sum, 9.999995×10^{-7}, inside the bounds $1/(N+1)$ and $1/N$ derived in Section 0.22.

In [6], the three errors drawn.

```
fig, ax = plt.subplots()
ax.plot(n_values, ulps["forward"], "o-", color=BLUE, markersize=4,
        label="forwards (largest number first)")
ax.plot(n_values, ulps["backward"], "s-", color=ORANGE, markersize=4,
        label="backwards (smallest number first)")
ax.plot(n_values, ulps["pairwise"], "^:", color=AQUA, markersize=4,
        label="pairwise (numpy's np.sum)")
```

```
ax.axhline(0.0, color="black", linewidth=0.8)  # the exactly rounded sum
ax.set_xscale("log")
ax.set_xlabel(r"number of terms $N$ of the sum $1 + 1/4 + \cdots + 1/N^2$")
ax.set_ylabel("error in units of the last place (ulps)")
ax.set_title("The same numbers added in different orders")
ax.legend(loc="upper left")
```

The three lists of errors against N on a logarithmic horizontal axis: `"o-"` draws circles joined by lines, `"s-"` squares, `"^:"` triangles joined by a dotted line. `ax.axhline(0.0, ...)` draws a horizontal line at 0, the exactly rounded sum.

```
save_figure(fig, "summation_order",
            r"The rounding error of the sum $1 + 1/4 + 1/9 + \cdots + 1/N^2$ in "
            r"units of the last place (vertical axis, ulps, the gap between "
            r"neighbouring stored numbers at the sum) against the number of terms "
            r"$N$ from 10 to $10^{6}$ (horizontal axis, logarithmic), measured from "
            r"the exactly rounded sum: forwards with the largest term first (blue "
            r"circles), backwards with the smallest term first (orange squares), "
            r"and pairwise as numpy adds (aqua triangles). The forward error grows "
            f"to {worst_forward:.0f} ulps, a relative error of a few times "
            r"$10^{-14}$; the backward error stays within "
            f"{worst_backward:.0f} ulp and the pairwise error within "
            f"{worst_pairwise:.0f} ulps. Same numbers, different order, different "
            r"last digits.")
```

The figure `00d_2_summation_order.png`; its caption takes the three worst errors from the computation. What Figure 00d.2 shows: the blue forward errors wander away from zero as N grows, to almost 200 ulps, while the orange and aqua errors stay on the line at 0 within a few ulps.

```
relative = max(abs(s - exact_million) for s in
               (forward_million, backward_million, pairwise_million)) / exact_million
report("largest relative difference of the three sums of 10^6 numbers",
       f"{relative:.2e}")
check(forward_million != backward_million,
      "forwards and backwards, the sums of the 10^6 numbers differ in the last digits")
check(worst_backward <= 1.0,
      "the backward sum is within one ulp of the exactly rounded sum for every N")
check(relative < 1e-13,
      "the three sums agree to a relative 1e-13: a tolerance of 1e-12 accepts all")
```

The largest distance of the three sums from the exactly rounded sum, divided by the sum (a **relative** difference): 2.65×10^{-14}. Three checks: the forward and the backward sum are different stored numbers; the backward sum is never more than 1 ulp off; and all three agree to a relative 10^{-13}, so a check with a tolerance of 10^{-12} would accept each of them.

In [7], the tolerances of the Revision record.

```
import re  # finds patterns in texts ("regular expressions")
```

```
def read_json(path):
    """The content of the JSON file path of the repository (dictionaries, lists)."""
    return json.loads(repository_file(path).read_text(encoding="utf-8"))
```

The module of regular expressions (explained in Section 0.21, In [6]) and a function that reads a JSON file of the repository.

```
DETERMINISM = "Revision/kohn_sham/reports/ks-rust-determinism.json"
CROSS = "Revision/kohn_sham/reports/ks-crosscheck.json"
determinism_checks = {entry["name"]: entry for entry in read_json(DETERMINISM)["checks"]}
measured = read_json(CROSS)["rust_matrix_wide_uncertainties"]  # name -> difference
```

The determinism report of the Kohn-Sham solver and the cross-check report. `{entry["name"]: entry for entry in ...}` is a **dictionary comprehension**: it makes a dictionary from each check's name to the check, so that a check can be looked up by name. `measured` is a dictionary from the name of each of the eight comparisons to its measured largest difference, as the cross-check quotes it.

```
SHORT_NAMES = {  # the check names of the record -> short names for the table
    "refined_ground_energies": "ground-state energies",
    "refined_ground_homo_lumo_gap": "level gaps",
    "refined_eigenvalues": "all Kohn-Sham levels",
    "refined_delta_scf": "excitation energies",
    "refined_profiles": "profiles",
    "refined_adiabatic_derivatives": "adiabatic derivatives",
    "refined_thermodynamics": "thermodynamics",
    "refined_heat_capacity": "heat capacity",
}
```

The eight checks of the comparison between the canonical and the refined run, each with a short name for the table (the quantities are explained in Chapters 14 and 15; here only their sizes matter).

```
tolerances, quoted, verdicts = {}, {}, {}
say("quantity                measured   tolerance   margin")
for name, short in SHORT_NAMES.items():
    detail = determinism_checks[name]["detail"]
    verdicts[name] = determinism_checks[name]["verdict"]
    tolerances[name] = float(re.findall(r"tolerance (\S+)", detail)[-1])
    quoted[name] = f"{measured[name]:.3e}" in detail  # the same number in both files
    margin = tolerances[name] / measured[name]
    say(f"{short:22} {measured[name]:9.3e}   {tolerances[name]:9.0e}   {margin:7.1f}")
```

Three empty dictionaries, and a table header. For each comparison: the detail text and the verdict of the record's check; the tolerance, found with the pattern `tolerance (\S+)` (`\S+` is one or more characters that are not blanks, so it catches the number after the word tolerance; `[-1]` takes the last match, and `float` turns the text into a number); whether the measured number, written with four significant digits (`.3e`), occurs in the detail text too, so that both files state the same number; and the **margin**, the tolerance divided by the measured difference. The table of Out [7] shows, for example, the ground-state energies: measured 1.901×10^{-12}, tolerance 10^{-8}, margin 5260.4; the smallest margin, 4.7, belongs to all Kohn-Sham levels (2.135×10^{-9} against 10^{-8}).

```
smallest = min(tolerances[n] / measured[n] for n in SHORT_NAMES)
report("smallest margin (tolerance / measured difference)", f"{smallest:.1f}")
check_reproduces(
    sorted(measured) == sorted(SHORT_NAMES) and all(quoted.values())
    and all(verdicts[n] == "PASS" and measured[n] < tolerances[n] for n in SHORT_NAMES),
    "each of the eight measured differences of the record is below its tolerance",
    f"{DETERMINISM}, checks " + ", ".join(SHORT_NAMES))
```

The smallest margin is printed. The check requires that the cross-check quotes exactly these eight comparisons (`sorted` of a dictionary gives its sorted keys), that each measured number appears in its check's detail, and that each check passed with the measured difference below the tolerance. Its record names the eight checks one by one: `", ".join(SHORT_NAMES)` joins the keys of the dictionary, in their order, into one string with a comma and a blank between neighbours. (In the report the check `refined_mermin_root_path` stands between the last two of them; it is not a comparison with a tolerance but the negative control of In [9].) Out [7] ends with the PASS line and the record line, which `say` breaks into four lines.

In [8], the tolerances drawn.

```
fig, ax = plt.subplots(figsize=(7.0, 4.6))
rows = np.arange(len(SHORT_NAMES))[::-1]  # the first quantity at the top
for row, name in zip(rows, SHORT_NAMES):
    ax.plot([measured[name], tolerances[name]], [row, row], color="#b5b3ad",
            linewidth=2.5)  # the margin
```

One row per comparison, the first at the top (as in Section 0.21, In [7]). In each row a thick grey line runs from the measured difference to the tolerance: on a logarithmic axis its length is the logarithm of the margin.

```
ax.plot([measured[n] for n in SHORT_NAMES], rows, "o", color=BLUE, markersize=7,
        label="largest measured difference")
ax.plot([tolerances[n] for n in SHORT_NAMES], rows, "|", color="black",
        markersize=16, markeredgewidth=2.0, label="tolerance fixed in advance")
ax.set_xscale("log")
ax.set_xlim(1e-13, 1e-4)
ax.set_yticks(rows, labels=list(SHORT_NAMES.values()))
ax.grid(False, axis="y")
ax.set_xlabel("canonical minus refined run (relative, or in units of the mass m)")
ax.set_title("Kohn-Sham solver: measured differences and tolerances")
# The legend below the picture, in two columns, so that it covers no row.
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.16), ncol=2)
```

A blue dot at each measured difference and a black vertical bar (the marker `"|"`) at each tolerance; a logarithmic axis from 10^{-13} to 10^{-4}; the short names label the rows; the legend is placed below the picture (`bbox_to_anchor=(0.5, -0.16)`, measured in units of the picture's size) in two columns (`ncol=2`).

```
margins = [tolerances[n] / measured[n] for n in SHORT_NAMES]  # tolerance / measured
save_figure(fig, "tolerances",
```

```
        r"The eight comparisons between the canonical and the refined run of "
        r"the Revision record's Kohn-Sham solver (one row each): the largest "
        r"measured difference (blue dot) and the tolerance fixed before the "
        r"comparison (black bar), on a logarithmic horizontal axis (relative "
        r"differences, or level differences in units of the mass $m$). Every "
        r"dot lies to the left of its bar: the measured differences are "
        f"between {min(margins):.1f} and {max(margins):.0f} times smaller "
        r"than their tolerances. The grey line from a dot to its bar is this "
        r"margin.")
```

The figure `00d_3_tolerances.png`, whose caption quotes the smallest and the largest margin, 4.7 and 7692. What Figure 00d.3 shows: every blue dot lies to the left of its black bar, most of them by two to four powers of ten; the closest pair is that of all Kohn-Sham levels.

In [9], the negative control.

```
root_path = determinism_checks["refined_mermin_root_path"]  # the record's check
CONTROL = (r"(N\w+): direct-count error (\S+) m \(refined run \S+\), "
           r"former measure (\S+), present measure against it (\S+),")
```

The record's check `refined_mermin_root_path` and a regular expression that finds its entries for the three states. `\w+` is one or more letters, digits or underscores (the name of a state, such as N8_lam0_a00_T10), `\S+` a number, and `\(` and `\)` are round brackets themselves; the four bracketed parts are the name of the state, the error of the old method, the **former measure** (the difference between the two runs when both used the old method) and the **present measure** (the difference seen by the present refined run).

```
control = []  # (state, error of the old root, former measure, present measure)
for state, error, former, present in re.findall(CONTROL, root_path["detail"]):
    control.append((state, abs(float(error)), float(former), float(present)))
say("state              old method error   former measure   present measure")
for state, error, former, present in control:
    say(f"{state:17} {error:12.3e} m   {former:14.3e}   {present:15.3e}")
```

`re.findall` returns, for every match, the four bracketed parts; the numbers are turned into floating-point numbers (the error with `abs`, its size). The table of Out [9] has three rows: the largest error of the old method, $8.267 \times 10^{-10}\,m$ in the state N8_lamm1_a00_T10, was seen by the former comparison as a difference of only 5.829×10^{-16}, and by the present comparison as 8.271×10^{-10}.

```
largest_hidden = max(error for _, error, _, _ in control)
report("largest error that one shared rounding path hid", f"{largest_hidden:.3e}", "m")
check_reproduces(
    root_path["verdict"] == "PASS" and len(control) == 3
    and all(former < error / 2 <= present for _, error, former, present in control),
    f"one shared rounding path hid errors up to {largest_hidden:.1e} m; "
    "two paths show them",
    f"{DETERMINISM}, check refined_mermin_root_path")
```

The largest hidden error is printed with the unit m. The check states, as the record does, that in each of the three states the former measure is below half of the error (it hid it), while the

present measure is at least half of it (it shows it): a chain comparison `a < b <= c` holds when both comparisons hold.

In [10], the negative control drawn.

```
fig, ax = plt.subplots(figsize=(7.0, 4.0))
rows = np.arange(len(control))[::-1]  # the first state at the top
height = 0.26  # three bars in each row
errors = [error for _, error, _, _ in control]
formers = [former for _, _, former, _ in control]
presents = [present for _, _, _, present in control]
# How many times smaller the former measure is than the error, state by state.
hidden_ratios = [error / former for error, former in zip(errors, formers)]
```

One row per state, three bars in each; the three columns of the table as three lists; and, for the caption, how many times smaller the former measure was than the error in each state.

```
ax.barh(rows + height, errors, height, color=ORANGE,
        label="error of the old method")
ax.barh(rows, formers, height, color="#b5b3ad",
        label="former comparison (one rounding path in both runs)")
ax.barh(rows - height, presents, height, color=BLUE,
        label="present comparison (two rounding paths)")
ax.set_xscale("log")
ax.set_xlim(1e-17, 1e-8)
ax.set_yticks(rows, labels=[state for state, _, _, _ in control])
ax.grid(False, axis="y")
ax.set_xlabel(r"size of the difference in $\mu$ (units of the mass m)")
ax.set_title("A comparison that rounds the same way twice sees nothing")
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.18), ncol=1)
```

The three bars of each state, orange above, grey in the middle and blue below, on a logarithmic axis from 10^{-17} to 10^{-8}; the states label the rows, and the legend stands below the picture.

```
save_figure(fig, "shared_rounding",
            r"The negative control of the Revision record's Kohn-Sham solver for "
            r"the three thermal states named on the vertical axis: the error of the "
            r"old method for the chemical potential $\mu$ (orange), the difference "
            r"between the two runs when both used that method, and so shared its "
            r"rounding (grey), and the difference seen by the present refined run, "
            r"which rounds along another path (blue); horizontal axis the size of "
            r"the difference in units of the mass $m$, logarithmic. The grey bars "
            f"are between {min(hidden_ratios):.0f} and "
            f"{max(hidden_ratios) / 1e6:.1f} million "
            r"times shorter than the orange ones: two runs with the same rounding "
            f"hid errors up to {largest_hidden:.1e} "
            r"$m$, which the blue bars show in full.")
```

The figure `00d_4_shared_rounding.png`; its caption computes how much shorter the grey bars are. What Figure 00d.4 shows: in each state the orange and the blue bar have almost the same length

(the present comparison sees the whole error), while the grey bar is between 93 and 1.4 million times shorter, as the caption computes from the table of Out [9] (the former comparison saw almost nothing). This is the lesson of the negative control of Section 0.22.

In [11], random walks with seeds.

```
walks = {}  # a label -> the 401 positions of the walk (it starts at 0)
for label, seed in (("seed 12345, first run", 12345),
                    ("seed 12345, second run", 12345), ("seed 2026", 2026)):
    generator = np.random.default_rng(seed)  # a new generator from this seed
    steps = generator.choice([-1, 1], size=400)  # 400 random steps of +1 or -1
    walks[label] = np.concatenate([[0], np.cumsum(steps)])  # positions 0 ... 400
    first = " ".join(f"{s:+d}" for s in steps[:10])  # e.g. "+1 -1 +1 ..."
    say(f"{label:23} first steps: {first}")
```

Three new random-number generators, two from the seed 12345 and one from the seed 2026. `generator.choice([-1, 1], size=400)` picks 400 times at random from the list $[-1, 1]$: the steps of a **random walk**. `np.cumsum` gives the running totals, the positions after each step, and `np.concatenate([[0], ...])` puts the starting position 0 in front. The first ten steps of each walk are printed (Out [11]): the two walks of the seed 12345 begin with the same ten steps, the third with others.

```
fig, ax = plt.subplots()
step_numbers = np.arange(401)
ax.plot(step_numbers, walks["seed 12345, first run"], color=BLUE, linewidth=3.0,
        label="seed 12345, first run")
ax.plot(step_numbers, walks["seed 12345, second run"], color=YELLOW, linewidth=1.2,
        linestyle="--", label="seed 12345, second run (lies on the first)")
ax.plot(step_numbers, walks["seed 2026"], color=ORANGE, linewidth=1.5,
        label="seed 2026")
ax.set_xlabel("step number")
ax.set_ylabel("position (sum of the steps)")
ax.set_title("Random walks: the same seed gives the same walk")
# The legend below the picture, so that it covers no part of the walks.
ax.legend(loc="upper center", bbox_to_anchor=(0.5, -0.16), ncol=1)
```

The three walks: the first thick and blue, the second thin, dashed and yellow, so that it is visible on top of the first, the third orange.

```
save_figure(fig, "seeded_walks",
            r"Three random walks of 400 steps of $+1$ or $-1$ (horizontal axis the "
            r"step number, vertical axis the position, the sum of the steps so far; "
            r"pure numbers). The thick blue walk and the dashed yellow walk come from "
            r"two separate generators started with the same seed 12345: they are "
            r"identical, step for step, so the yellow line lies on the blue one. "
            r"The orange walk, from the seed 2026, is different. A fixed seed makes "
            r"random numbers repeat exactly in every run.")
check(np.array_equal(walks["seed 12345, first run"], walks["seed 12345, second run"]),
      "two generators with the same seed give the same 400 steps")
check(not np.array_equal(walks["seed 12345, first run"], walks["seed 2026"]),
      "a generator with another seed gives other steps")
```

The figure `00d_5_seeded_walks.png` and two checks: `np.array_equal` is true when two arrays have the same shape and the same entries. What Figure 00d.5 shows: the yellow dashed walk runs exactly inside the thick blue one for all 400 steps, while the orange walk goes its own way.

In [12], the order of a set.

```
import subprocess  # starts another program and reads what it prints

NAMES = ["x0", "x1", "x2", "x3", "x4", "x5", "x6", "x7"]
PROGRAM = "import sys; print(*set(sys.argv[1:]))"  # print the names of a set
```

`subprocess` starts other programs. `PROGRAM` is a complete little Python program in one line: it makes a set of the names it receives as its arguments (`sys.argv` is the list of the arguments of a program, and `[1:]` leaves out the first entry, the program's own name) and prints them separated by blanks (`print(*...)` prints the members one after the other).

```
def set_order(seed):
    """The order in which a new Python with PYTHONHASHSEED = seed prints the set."""
    environment = dict(os.environ, PYTHONHASHSEED=str(seed))
    completed = subprocess.run([sys.executable, "-c", PROGRAM, *NAMES],
                               capture_output=True, text=True, env=environment,
                               check=True)  # check=True: stop if Python failed
    return completed.stdout.split()  # the printed names, in their printed order
```

`dict(os.environ, PYTHONHASHSEED=str(seed))` is a copy of the environment variables of the notebook with one of them set to the given hash seed. `subprocess.run` starts a new Python (`sys.executable` is the Python program that runs this notebook) with the option `-c`, which tells it to run the program text that follows, and the eight names as arguments; the new Python receives the copied environment (`env=`). Its printed line is collected and cut at the blanks into the list of the names in their printed order.

```
orders = [set_order(seed) for seed in range(12)]  # the seeds 0, 1, ..., 11
for seed, order in enumerate(orders):
    printed = " ".join(order)  # the eight names separated by blanks
    say(f"PYTHONHASHSEED={seed:<2}  {printed}")
in_order = " ".join(sorted(orders[0]))  # sorted: x0 x1 ... x7
say(f"sorted              {in_order}")
different = len({tuple(order) for order in orders})  # the number of distinct orders
report("distinct orders among the 12 runs", different)
```

Twelve runs with the hash seeds 0 to 11; the order of each is printed (the first twelve lines of Out [12]), then the sorted order. `{tuple(order) for order in orders}` is a set of the twelve orders (a list cannot be a member of a set, a **tuple** can); equal orders count once, so its size is the number of distinct orders: 12, every run printed another order.

```
check(set_order(0) == orders[0], "the same hash seed gives the same order")
check(different >= 2, "different hash seeds give different orders of the same set")
check(all(sorted(order) == NAMES for order in orders),
      "sorted, the names come in the same order x0 ... x7 in every run")
```

Three checks: a thirteenth run with the seed 0 repeats the order of the first; at least two of the orders differ; and every order, sorted, is $x_0, \ldots, x_7$. This is why the notebooks sort before they print.

In [13], the twelve orders as a picture.

```
table = orders + [sorted(orders[0])]  # 13 rows of 8 names: 12 runs and the sorted
# Each name replaced by its number in NAMES: x0 -> 0, x1 -> 1, ..., x7 -> 7.
numbers = np.array([[NAMES.index(name) for name in row] for row in table])
colours = matplotlib.colormaps["viridis"].resampled(8)  # 8 colours, violet to yellow
```

The twelve orders and, as a thirteenth row, the sorted order. `NAMES.index(name)` is the position of a name in the list `NAMES`, so each name becomes a number from 0 to 7, and `numbers` is a table of 13 rows and 8 columns. The colour map viridis, cut into 8 colours from dark violet to yellow, gives each name its colour.

```
fig, ax = plt.subplots(figsize=(7.0, 6.0))
# vmin and vmax put each of the numbers 0 ... 7 in the middle of its own colour.
ax.imshow(numbers, cmap=colours, vmin=-0.5, vmax=7.5, aspect="auto")
for row in range(numbers.shape[0]):
    for column in range(8):
        # white letters on the dark colours, black ones on the light colours
        ink = "white" if numbers[row, column] < 5 else "black"
        ax.text(column, row, table[row][column], ha="center", va="center",
                color=ink, fontsize=9)
```

The table drawn as coloured squares (as in Section 0.17, In [3]); `aspect="auto"` lets the squares stretch to fill the figure, and `numbers.shape[0]` is the number of rows, 13. Each square gets the name written into it.

```
ax.axhline(11.5, color="white", linewidth=4.0)  # a gap before the sorted row
ax.set_xticks(range(8), labels=[str(place) for place in range(1, 9)])
ax.set_yticks(range(13),
              labels=[f"PYTHONHASHSEED={seed}" for seed in range(12)] + ["sorted"])
ax.grid(False)
ax.set_xlabel("place in the printed order")
ax.set_title("The same set of eight names, printed by twelve runs of Python")
```

A thick white line separates the sorted row from the twelve runs; the columns are labelled with the places 1 to 8 and the rows with the hash seeds and the word sorted.

```
save_figure(fig, "set_orders",
            r"The order in which twelve separate runs of Python print the same set "
            r"of the eight names $x_0, \ldots, x_7$ (one row per run, labelled by "
            r"its hash seed PYTHONHASHSEED from 0 to 11; horizontal axis the place 1 "
            r"to 8 in the printed order; each square coloured by its name, from "
            r"dark violet for $x_0$ to yellow for $x_7$). Every run prints another "
            r"order, so the rows are scrambled differently; the bottom row, the "
            r"sorted order, is the same in every run.")
```

The figure `00d_6_set_orders.png`. What Figure 00d.6 shows: twelve rows of scrambled colours, no two alike, above one row in which the colours run in order from violet to yellow.

In [14], line ends.

```
import hashlib  # computes sha256 fingerprints

TEXT = "x1 x2\nx3 x4\n"  # two lines, each ended by a line end
with_lf = TEXT.encode("utf-8")  # LF line ends: the byte 10
with_crlf = TEXT.replace("\n", "\r\n").encode("utf-8")  # CR LF: the bytes 13, 10
```

In a Python string, `\n` is the line end LF and `\r` the carriage return CR. The same two lines are made into bytes once with LF and once with CR LF (`replace` puts `\r\n` for every `\n`).

```
for label, data in (("LF   ", with_lf), ("CR LF", with_crlf)):
    say(f"{label} {len(data):2d} bytes: {list(data)}")
    say(f"      sha256 {hashlib.sha256(data).hexdigest()}")
check(len(with_crlf) == len(with_lf) + 2
      and hashlib.sha256(with_lf).digest() != hashlib.sha256(with_crlf).digest(),
      "the same two lines with LF and with CR LF line ends are different bytes")
```

`list(data)` writes the bytes as numbers: the letter x is 120, the digits 1 to 4 are 49 to 52, the blank is 32, LF is 10 and CR is 13. Out [14] shows 12 bytes with LF and 14 with CR LF, and two completely different fingerprints. The check confirms the two extra bytes and the different fingerprints (`.digest()` is the fingerprint as bytes instead of characters).

In [15], the line ends of the record's result files.

```
def files_below(folder):
    """The files in the repository folder and its sub-folders, in sorted order."""
    return sorted(p for p in repository_file(folder).rglob("*") if p.is_file())
```

All files in a folder and its sub-folders (`rglob("*")` lists everything, `is_file` keeps the files), in sorted order.

```
RUST_RESULTS = "Revision/kohn_sham/results"
REFERENCE_RESULTS = "Revision/kohn_sham/reference/results"
rust_files = files_below(RUST_RESULTS)
rust_crlf = sum(1 for p in rust_files if b"\r\n" in p.read_bytes())
reference_files = files_below(REFERENCE_RESULTS)
reference_crlf = sum(1 for p in reference_files if b"\r\n" in p.read_bytes())
```

The result folders of the Rust solver and of the Python reference solver. For each, the files are listed and the files that contain the two bytes CR LF are counted (`b"\r\n"` is a **bytes** literal, and `in` searches for it in the bytes of the file).

```
report("Rust result files", len(rust_files))
report("size of the Rust result files", sum(p.stat().st_size for p in rust_files),
```

```
       "bytes")
report("Rust result files with CR LF line ends", rust_crlf)
report("reference result files", len(reference_files))
report("size of the reference result files",
       sum(p.stat().st_size for p in reference_files), "bytes")
report("reference result files with CR LF line ends", reference_crlf)
```

The numbers of files, their total sizes (`p.stat().st_size` is the size of a file in bytes) and the numbers of files with CR LF: Out [15] reports 244 Rust result files with 5857843 bytes and 340 reference result files, none with CR LF line ends.

```
lf_rust = determinism_checks["outputs_lf_only"]  # the record's check (Rust)
check_reproduces(
    rust_crlf == 0 and lf_rust["verdict"] == "PASS"
    and "(offending: none)" in lf_rust["detail"],
    f"none of the {len(rust_files)} Rust result files has CR LF line ends",
    f"{DETERMINISM}, check outputs_lf_only")
cross_checks = {entry["name"]: entry for entry in read_json(CROSS)["checks"]}
lf_reference = cross_checks["reference_outputs_lf_only"]  # the record's check
stated = f"{len(reference_files)} reference result files; files with CRLF: none"
check_reproduces(
    reference_crlf == 0 and lf_reference["verdict"] == "PASS"
    and stated in lf_reference["detail"],
    f"none of the {len(reference_files)} reference result files has CR LF line ends",
    f"{CROSS}, check reference_outputs_lf_only")
```

Two checks, one per solver: today no file has CR LF line ends, and the record's own check found the same when the solver ran (its detail says that no file offended, or states the number of reference files and that none had CRLF).

In [16], the fingerprints of the result files.

```
def file_fingerprint(path):
    """The sha256 fingerprint of the bytes of the file path."""
    return hashlib.sha256(path.read_bytes()).hexdigest()

def relative_names(files, folder):
    """The paths of files relative to the repository folder, written with /."""
    root = repository_file(folder)
    return sorted(p.relative_to(root).as_posix() for p in files)
```

The fingerprint of a file (as in Section 0.21, In [13], but for a path that is already complete), and the sorted names of files relative to a folder, written with `/`. (The docstring says "the repository folder"; the names are relative to the folder `folder`, which is what the manifests list.)

```
# The Rust manifest: a list of entries {"path": ..., "bytes": ..., "sha256": ...}.
rust_manifest = read_json(f"{RUST_RESULTS}/manifest.json")["files"]
rust_listed = {entry["path"]: entry for entry in rust_manifest}  # path -> entry
rust_wrong = []  # the listed files whose size or fingerprint differs today
```

```
for path, entry in rust_listed.items():
    today = repository_file(f"{RUST_RESULTS}/{path}")  # the file as it is today
    same_size = today.stat().st_size == entry["bytes"]
    if not same_size or file_fingerprint(today) != entry["sha256"]:
        rust_wrong.append(path)
```

The Rust solver's manifest lists, for every result file, its path, its size and its fingerprint. For each listed file, today's size and today's fingerprint are compared with the listed ones; a file that differs in either is noted.

```
# The reference manifest: a dictionary path -> fingerprint.
reference_manifest = read_json(f"{REFERENCE_RESULTS}/manifest.json")["files"]
reference_wrong = []
for path, value in reference_manifest.items():
    today = repository_file(f"{REFERENCE_RESULTS}/{path}")
    if file_fingerprint(today) != value:
        reference_wrong.append(path)
```

The reference solver's manifest is a dictionary from each path to its fingerprint; the comparison is the same.

```
report("Rust results: fingerprints compared", len(rust_listed))
report("Rust results: files that differ", len(rust_wrong))
report("reference results: fingerprints compared", len(reference_manifest))
report("reference results: files that differ", len(reference_wrong))
report("fingerprints compared in all", len(rust_listed) + len(reference_manifest))
```

Out [16] reports 243 Rust and 339 reference fingerprints compared, 582 in all, and no file that differs. (Each folder holds one more file, its manifest, which cannot list its own fingerprint.)

```
rust_others = [n for n in relative_names(rust_files, RUST_RESULTS)
               if n != "manifest.json"]
reference_others = [n for n in relative_names(reference_files, REFERENCE_RESULTS)
                    if n != "manifest.json"]
check(rust_wrong == [] and sorted(rust_listed) == rust_others,
      f"the {len(rust_listed)} fingerprints of the Rust manifest equal today's files")
```

The files of each folder except the manifest. The check requires that no listed Rust file differs and that the manifest lists exactly the files of the folder: none is missing, none is extra.

```
manifest_check = cross_checks["reference_manifest"]
stated = f"lists {len(reference_manifest)} files with SHA-256"  # the record's words
check_reproduces(
    reference_wrong == [] and sorted(reference_manifest) == reference_others
    and manifest_check["verdict"] == "PASS" and stated in manifest_check["detail"],
    f"the {len(reference_manifest)} fingerprints of the reference manifest equal "
    "today's files",
    f"{CROSS}, check reference_manifest")
```

The same for the reference folder, together with the record's own check `reference_manifest`, whose detail must state the same number of listed files.

```
rust_repeat = determinism_checks["repeat_byte_identical"]  # the Rust second run
# The part of its detail that counts, e.g. "244 files (5857843 bytes) compared, ...".
found = re.search(r"(\d+) files \((\d+) bytes\) compared, same file set: (\w+), "
                  r"differing files: (\w+)", rust_repeat["detail"])
say(f"the record (Rust): {found.group(0)}")
rust_bytes = sum(p.stat().st_size for p in rust_files)  # the bytes of today
check_reproduces(
    rust_repeat["verdict"] == "PASS"
    and (int(found.group(1)), int(found.group(2))) == (len(rust_files), rust_bytes)
    and found.group(3) == "True" and found.group(4) == "none",
    f"a second run of the Rust solver gave the same {len(rust_files)} files "
    f"({rust_bytes} bytes)",
    f"{DETERMINISM}, check repeat_byte_identical")
```

The record's comparison of a second run of the Rust solver with the first. The regular expression picks out four parts of its detail: the number of files, the number of bytes, whether the two runs wrote the same set of files, and the differing files. `found.group(0)` is the whole matched text, printed in Out [16]: 244 files (5857843 bytes) compared, same file set: True, differing files: none. The check requires that the record compared as many files and bytes as the folder holds today, with the same file set and no differing file.

```
repeat = cross_checks["reference_repeat_byte_identical"]  # the reference second run
# The part of its detail that counts the files, e.g. "340 result files, same ...".
found = re.search(r"(\d+) result files, same file set: (\w+), differing files: (\w+)",
                  repeat["detail"])
say(f"the record (reference): {found.group(0)}")
check_reproduces(
    repeat["verdict"] == "PASS" and int(found.group(1)) == len(reference_files)
    and found.group(2) == "True" and found.group(3) == "none",
    f"a second run of the reference solver gave the same {len(reference_files)} "
    "files, byte for byte",
    f"{CROSS}, check reference_repeat_byte_identical")
```

The same for the reference solver: 340 result files, the same file set, no differing file. Out [16] ends with this PASS line and its record.

In [17], the last check.

```
figure_names = ["00d_1_float_spacing.png", "00d_2_summation_order.png",
                "00d_3_tolerances.png", "00d_4_shared_rounding.png",
                "00d_5_seeded_walks.png", "00d_6_set_orders.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "the six figure files of this notebook exist")
all_checks_passed()
```

The six figure files must exist; the last line prints ALL 22 CHECKS PASSED (notebook 00d): two checks in In [2], one in In [3], one in In [4], three in In [6], one in In [7], one in In [9], two in In [11], three in In [12], one in In [14], two in In [15], four in In [16] and one in In [17].

0.26 What we proved, what we computed, what we assumed

This chapter is mostly a map; the few results it derives are elementary, but each is derived line by line and checked by a notebook.

PROVED in this chapter (by school algebra and one-variable calculus):

- the tangent line of $y = x^2$ at $x = 1$ is $y = 2x - 1$, and it lies below the parabola because $x^2 - (2x - 1) = (x - 1)^2 \geq 0$; and $e^t e^{-t} = 1$ for every t (Section 0.10);
- the signs of the eight entries of the author's metric are $(+, +, +, +, -, -, -, -)$ at every point of the patch $0 < z < \pi/2$, for every a_4 and every $b_4 > 0$, so the signature is (4,4) (Section 0.14, Fact 1);
- the length factors are $\cot z$ for x_0, $e^{a_4} \sin^{1/6} z$ for x_1, x_2, x_3, 1 for x_4 and $b_4^{1/2} e^{-a_4} \sin^{1/6} z$ for x_5, x_6, x_7 (Fact 2); along the history $a_4 = AHx_4$, $b_4 = 1$ the extra-time factors obey $df_5/dx_4 = -AHf_5$ (exponential deflation) and the space factors $df_1/dx_4 = +AHf_1$ (exponential inflation), and $f_1 f_5 = b_4^{1/2} \sin^{1/3} z$ contains no a_4 in every history (Fact 3);
- $\det g = b_4^3 \cos^2 z$ and the volume factor $\sqrt{|\det g|} = b_4^{3/2} \cos z$, for every function a_4: the inflation and the deflation cancel in the volume, which changes in time only through b_4 (Fact 4; also by the exact symbolic checks `sqrt_det_g` and `sqrt_abs_det_g_is_cos_z`, and at $b_4 = 1$ `sqrt_det_g_is_cos_z` and `sqrt_det_g_equals_cos_z`, of the Revision reports listed at the end of Fact 4);
- the expected number of changed characters of a random 64-character hexadecimal fingerprint is $64 \cdot 15/16 = 60$ (Section 0.18);
- $1/10$ has no finite binary expansion; the computer stores 0.1 as $3602879701896397/2^{55}$ and computes $0.1 + 0.2$ as $5404319552844596/2^{54}$, which exceeds the stored 0.3 by 2^{-54}; the machine epsilon is 2^{-52}, and the gap between neighbouring stored numbers lies between $\epsilon x/2$ and ϵx; $(1 + 2^{-53}) + 2^{-53} \neq 1 + (2^{-53} + 2^{-53})$ in floating-point arithmetic; and $1/(N + 1) < \pi^2/6 - \sum_{k \leq N} 1/k^2 < 1/N$ (Section 0.22).

The chapter also states, without proof, the theorems that later chapters prove: T1, T2, Q, T3 and C1 (Section 0.2; Chapters 18 to 20) and the exact local conservation law of the U(1) charge (the total charge is constant only under the ASSUMED no-flux condition at the edge $z = \pi/2$) and the charge-conjugation matrices $\mathcal{C}_+ = C$ and $\mathcal{C}_- = \Gamma C$ (Chapters 5 and 21). Their status, PROVED, is that of the Revision record, given in the ledger with the reports that verify them.

COMPUTED by the notebooks (each number in the cell named; where a Revision record is reproduced, the record file and its check):

- Notebook 00a: the installed versions (In [2] to In [4]); the determinant -2.000000000000 (In [5]); the derivative $2 \sin x \cos x$ (In [6]); 30 digits of π (In [7]); the tangent line and the two exponentials at 401 points each (In [8], In [9]).
- Notebook 00b: the names and the signs of the coordinates (In [2]; reproduces `Revision /algebra/reports/wolfram-algebra.json`, check `eta_in_author_order`); the eight entries

of the metric with b_4 (In [4]; reproduces `Revision/metric_b4/results/wolfram-metric-b4-report.json`, check `metric_equals_author_Out101`) and at $b_4 = 1$ (In [4]; reproduces `Revision/theory/reports/python-field-theory.json`, check `metric_from_vielbein_equals_SPEC`); no wrong sign at 14457 points (In [5]); $\det g = b_4^3 \cos^2 z$ (In [6]; reproduces `Revision/theory/reports/wolfram-field-theory-b4.json`, check `sqrt_det_g`) and $\det g = \cos^2 z$ at $b_4 = 1$ (In [6]; reproduces `Revision/theory/reports/wolfram-field-theory.json`, check `sqrt_det_g_is_cos_z`); $e^3 = 20.0855$ and $e^{-3} = 0.049787$ (In [7]); the table of the length factors at $z = \pi/4$, $b_4 = 1$ with the product 0.7071 (In [8]; reproduces `Revision/field_equations_a4/reports/wolfram-a4-report.json`, check `sqrt_abs_det_g_is_cos_z`); the volume factor equal to $\cos z$ within 1.0×10^{-15} at 200 points for three values of a_4 at $b_4 = 1$ (In [9]; reproduces `Revision/theory/reports/python-field-theory.json`, check `sqrt_det_g_equals_cos_z`), and equal to $2^{3/2} \cos z$ within 2.7×10^{-15} at $a_4 = 1$, $b_4 = 2$ (In [9]; reproduces `Revision/theory/reports/wolfram-field-theory-b4.json`, check `sqrt_det_g`).

- Notebook 00c: 12 of 12 checks of the charge-conjugation report (In [2]); the statements $\mathcal{C}_+ = C$, $\mathcal{C}_- = \Gamma C$ and $J = 0$ for a real field, word for word in the details of that report (In [3]; checks `charge_conjugation_matrix_plus`, `charge_conjugation_matrix_minus` and `real_fields_charge_conjugation`); the local conservation law of the charge, and the report's own statement that a constant total charge is not established (In [3]; check `u1_noether_matrix_identity`); the 51 reports of the record, all found by the search, no check FAIL (1352 PASS and 5 NOT-AVAILABLE of 1357 checks in the run of 2026-10-14; the counts follow the record), and each report's own totals equal to the counted ones (In [5]); the 49 counts of the table of `Revision/README.md`, the 3 counts quoted by `Revision/kohn_sham/reports/ks-crosscheck.json`, check `inputs_all_pass`, and the 13 of 13 quoted by `Revision/dark_sector/dirac16complex/outputs/eos-summary.json`, key `checks` (In [6]); the ledger with 11 PROVED, 3 COMPUTED, 1 ASSUMED, 2 HYPOTHESIS and 3 OPEN rows, every report in exactly one row, and only row 7 with checks that are not PASS, its five NOT-AVAILABLE comparisons (In [9]); the twelve sentences of `Revision/pairing/reports/python-pairing.json`, key `not_established` (In [11]); 54 to 64 changed characters, mean 60.03, for one-character changes (In [12]); 24 recorded fingerprints equal to today's files (In [13]).
- Notebook 00d: the forward, backward and pairwise errors of 196, 1 and 3 ulps, and the method error 9.999995×10^{-7} (In [5]); the relative difference 2.65×10^{-14} of the three sums (In [6]); the eight measured differences of the Kohn-Sham solver below their tolerances with the margins 4.7 to 7692 (In [7]; reproduces `Revision/kohn_sham/reports/ks-rust-determinism.json`, its eight comparison checks named in Section 0.22, from `refined_ground_energies` to `refined_heat_capacity` without the negative control `refined_mermin_root_path`); the negative control with a hidden error up to 8.267×10^{-10} in units of m (In [9]; check `refined_mermin_root_path` of the same report); 12 distinct set orders for 12 hash seeds (In [12]); no CR LF line end in the 244 Rust and the 340 reference result files (In [15]; checks `outputs_lf_only` and `reference_outputs_lf_only`); 582 manifest fingerprints equal to today's files, and the record's repeat runs of both solvers byte-identical (In [16]; checks `reference_manifest`, `repeat_byte_identical` and `reference_repeat_byte_identical`).

ASSUMED (used, not derived here):

- the conventions of Section 0.5: the author's names and roles of the coordinates, the signs η, units with the speed of light and Planck's constant equal to 1;

- the author's metric itself (Section 0.14), and the history $a_4 = AHx_4$ where it is used, a prescribed background (`Revision/field_equations_a4/reports/ks-source-conditions.json`, check `ks_history_is_a_prescribed_background`);
- the Z2 mirror at the edge $z = \pi/2$ of the hidden direction, in T2 and T3;
- the Kohn-Sham approximation (the stationary-slice ansatz, the Hartree term and the exchange of a uniform gas without correlation, mean-field states, the chosen condition at the tip), in T3 and in every Kohn-Sham result (rows 8, 9, 12 and 13 of the ledger, Section 0.18);
- school facts used without proof: the determinant of a diagonal matrix is the product of its diagonal entries (proved in Chapter 1); every whole number is a product of primes in exactly one way; Euler's sum $\pi^2/6$; the rules of the floating-point arithmetic (53 binary digits, round half to even), which are a property of the computer;
- that a change of a single byte changes the sha256 fingerprint completely, beyond the 115 cases that Notebook 00c measures, and that nobody can construct two different files with the same sha256 fingerprint (both believed, not proved; Section 0.18).

HYPOTHESIS and OPEN. The chapter adds no hypothesis of its own; it records the two HYPOTHESIS rows of the ledger (a time-varying dark sector from the fields, investigated but not established; a partner universe of opposite charge) and the three OPEN rows (that the total charge of one universe stays constant, which needs the ASSUMED no-flux condition at the brane; that the big bang creates universes in pairs, which the equations do not prove; and what produces the excess of matter over antimatter, which the theory as built does not produce). The PROVED row 2 names one OPEN part in its note: for a self-coupling $\lambda \neq 0$ the operator form of the energy-momentum tensor for the field on a whole slice of space is OPEN (it is proved only in a finite model of one set of 16 modes), and the field-equations record of Chapter 12 ASSUMES it.

0.27 Exercises

Exercise 1. Give each statement one of the five labels and one sentence of reason. (a) The author's metric has the signature (4,4). (b) The ground-state energies of the canonical and the refined run of the Revision record's Kohn-Sham solver differ by at most 1.901×10^{-12} (relative). (c) The metric function grows in proportion to the time, $a_4 = AHx_4$, in the Kohn-Sham chapters. (d) Our universe has a partner universe of opposite charge. (e) At the big bang, a pair of universes of masses $+M$ and $-M$ was created.

Answer. (a) PROVED: Fact 1 of Section 0.14 derives the signs $(+,+,+,+,-,-,-,-)$ at every point of the patch by school algebra, and the Wolfram verifier checks them (`eta_in_author_order`). (The metric itself is ASSUMED, as the author's input; given the metric, its signature is proved.) (b) COMPUTED: it is a number measured by comparing two numerical runs (`Revision/kohn_sham/reports/ks-rust-determinism.json`, check `refined_ground_energies`), reproducible but not exact. (c) ASSUMED: it is a prescribed background; the computed Kohn-Sham states cannot be its source (row 10 of the ledger). (d) HYPOTHESIS: T1 proves that every solution with mass $+m$ has an image with mass $-m$ and opposite charge, but not that such an image exists alongside our universe (row 17). (e) OPEN as a question of this book: the author proposed it, but no equation of the record describes the creation of anything, so it is not proved (row 19).

Exercise 2. Notebook 00a checks that Python is version 3.12 or newer by comparing the pairs $(3, 12)$ and (major, minor). Would the pair $(4, 0)$ pass? Would $(3, 9)$?

Answer. Pairs are compared like words in a dictionary: first the first numbers, and only when they are equal the second numbers. $(4, 0)$: the first numbers are 4 and 3, and 4 is larger, so $(4, 0) \geq (3, 12)$ and the check passes (the second numbers are not compared). $(3, 9)$: the first numbers are equal, so the second numbers decide; 9 is smaller than 12, so $(3, 9) < (3, 12)$ and the check fails. (Comparing the versions as decimal numbers would be wrong: 3.9 is larger than 3.12 as a decimal number, but version 9 comes before version 12.)

Exercise 3. Compute the eight length factors of the author's metric at the hidden coordinate $z = \pi/6$, at $a_4 = \ln 2$ (so that $e^{a_4} = 2$) and $b_4 = 1$, and show that their product is $\cos(\pi/6) = \sqrt{3}/2$.

Answer. $\sin(\pi/6) = 1/2$, so $\sin^{1/6}(\pi/6) = (1/2)^{1/6} = 2^{-1/6}$; $\cot(\pi/6) = \cos(\pi/6)/\sin(\pi/6) = (\sqrt{3}/2)/(1/2) = \sqrt{3}$. By Fact 2 of Section 0.14 with $b_4 = 1$: $f_0 = \sqrt{3} = 1.7321$; $f_1 = f_2 = f_3 = 2 \cdot 2^{-1/6} = 2^{5/6} = 1.7818$; $f_4 = 1$; $f_5 = f_6 = f_7 = \frac{1}{2} \cdot 2^{-1/6} = 2^{-7/6} = 0.4454$. The product is $\sqrt{3} \cdot (2^{5/6})^3 \cdot 1 \cdot (2^{-7/6})^3 = 2^{5/2} \cdot 2^{-7/2} \cdot \sqrt{3} = 2^{-1}\sqrt{3} = \sqrt{3}/2$ (power rule, then the law of exponents $2^{5/2-7/2} = 2^{-1}$), which is $\cos(\pi/6)$, as Fact 4 says for every a_4.

Exercise 4. Along the history $a_4 = AHx_4$ with $A = 1$, $H = 1$ and $b_4 = 1$, after how much time x_4 has the length factor of an extra time fallen to half its value at $x_4 = 0$? After how much time has it fallen to one thousandth? What has the factor of ordinary space done in the same time?

Answer. By Fact 3, $f_5(x_4) = e^{-x_4} \sin^{1/6} z$, so $f_5(x_4)/f_5(0) = e^{-x_4}$. Half: $e^{-x_4} = 1/2$, so $-x_4 = \ln(1/2) = -\ln 2$ (take the natural logarithm of both sides), and $x_4 = \ln 2 = 0.6931$. One thousandth: $x_4 = \ln 1000 = 6.9078$. In the same times the factor of ordinary space, $e^{x_4} \sin^{1/6} z$, has grown by the factors 2 and 1000, since $e^{x_4} = 1/e^{-x_4}$. Every interval of length $\ln 2$ halves the extra-time factor again: this is what exponential deflation means.

Exercise 5. Is $0.5 + 0.25 == 0.75$ true in Python? Explain with the stored fractions why the answer differs from that for $0.1 + 0.2 == 0.3$.

Answer. True. The numbers $0.5 = 1/2$, $0.25 = 1/4$ and $0.75 = 3/4$ are binary fractions with a few digits (binary 0.1, 0.01 and 0.11), so each is stored exactly, without rounding. Their exact sum, $1/2 + 1/4 = 3/4$, is again a stored number, so the addition does not round either, and the result is exactly the stored 0.75. In Section 0.22, by contrast, 0.1, 0.2 and 0.3 are all rounded when they are stored, and the sum is rounded once more; the roundings do not cancel, and the result misses the stored 0.3 by 2^{-54}.

Exercise 6. Above $2^{53} = 9007199254740992$ the gap between neighbouring stored numbers is 2. In floating-point arithmetic, compute $(2^{53} + 1) + 1$ and $2^{53} + (1 + 1)$.

Answer. 2^{53} is stored with $m = 2^{52}$ and the power 2^1, so the stored numbers just above it are $2^{53} + 2$, $2^{53} + 4$, and so on, with $m = 2^{52} + 1$, $2^{52} + 2$, and so on. First order: $2^{53} + 1$ lies exactly halfway between 2^{53} (with the even $m = 2^{52}$) and $2^{53} + 2$ (with the odd $m = 2^{52} + 1$); round half to even gives 2^{53}. Adding 1 again gives the same halfway case and again $2^{53} = 9007199254740992$. Second order: $1 + 1 = 2$ exactly, and $2^{53} + 2 = 9007199254740994$ is a stored number. The two orders differ by 2, the gap at that size: the same three numbers added in two orders give two different results, as in Section 0.22.

Exercise 7. Notebook 00c compares some fingerprints of which the report recorded only the first 16 hexadecimal characters. If fingerprints behave like random strings, what is the probability that a

different file has a fingerprint that begins with the same 16 characters?

Answer. Each of the 16 characters agrees with probability 1/16, and for a random string the 16 agreements are independent, so the probability is $(1/16)^{16} = 16^{-16} = (2^4)^{-16} = 2^{-64}$ (the power rule). Since $2^{10} = 1024 \approx 10^3$, $2^{-64} = 2^{-4} \cdot 2^{-60} \approx \frac{1}{16} \cdot 10^{-18}$; exactly, $2^{-64} = 5.42 \times 10^{-20}$. Even a shortened fingerprint ties a report to its file beyond any reasonable doubt.

Exercise 8. Theorem T1 is PROVED, and it says that a universe with mass $+m$ and its T1 image with mass $-m$ have opposite charges, so that together they have the total charge zero. (a) Why does this not prove that the big bang creates universes in pairs? (b) Name one calculation that would be needed in addition.

Answer. (a) T1 is a map between solution sets: if a configuration of the field is a solution of the equations with (m, λ), then its image under Γ is a solution of the equations with $(-m, -\lambda)$. It says which configurations are allowed, not which configurations occur, when, or how often; a single universe with mass $+m$ is an equally valid solution without its partner. The zero total holds for classical fields; at the quantum level the image is the same quantum system written in other variables, and two independently quantised universes do not cancel (Q). The same situation is familiar from ordinary physics: the conservation of energy, momentum and charge allows two energetic photons to turn into an electron and a positron, but whether this happens, and how often, is computed from the dynamics of the particles, not from the conservation laws. (b) A dynamical calculation: for example a quantum amplitude, or a probability per unit time, for a transition from a state without universes to a state with the pair, or a solution of the coupled equations of the fields and of gravity that evolves from an initial state into the pair. None of these is derived in the Revision record, which is why the ledger labels the statement OPEN (`Revision/pairing/reports/python-pairing.json`, key `not_established`, sentences 1 and 2).

1 Mathematics from zero I: numbers, complex numbers, vectors, matrices, indices, determinants, the generalized Kronecker delta

This chapter builds, from school algebra, every piece of algebra that the rest of the course uses: exact and rounded numbers, powers and the exponential function, complex numbers, vectors and matrices, determinants, index notation with the summation convention, eigenvalues and the signature of a metric, and the generalized Kronecker delta with which the field equations of gravity are written. Every idea is put to work in a Jupyter notebook, and every notebook is applied to the objects of the author's theory as soon as possible.

1.1 What this chapter is for

Why so much algebra. The theory of this course lives in a universe with eight directions. The author names them $x_0, \ldots, x_7$: a hidden space direction x_0, the three directions x_1, x_2, x_3 of ordinary space, the time x_4, and three further time-like directions x_5, x_6, x_7, called the **extra times**. The geometry of this universe is described by the author's **metric**, a list of eight expressions, one for each direction, which says how long a small step along that direction is (the word is explained fully in Sections 1.5 and 1.29):

$$g = \mathrm{diag}(\,\cot^2 z,\ e^{2a_4}s,\ e^{2a_4}s,\ e^{2a_4}s,\ -1,\ -b_4e^{-2a_4}s,\ -b_4e^{-2a_4}s,\ -b_4e^{-2a_4}s),$$

with $s = \sin^{1/3} z$ and $z = 6Hx_0$. Here H is a positive constant of the author's, z lies between 0 and $\pi/2$, and a_4 and b_4 are functions of the time x_4, b_4 positive (b_4 is the author's change of 2026-10-14; $b_4 = 1$ gives the metric used before, and the backgrounds of the book take $b_4 = 1$, as the Revision record does); as a_4 grows, the entries of space grow like e^{2a_4} and the entries of the three extra times shrink like e^{-2a_4}: space inflates and the extra times **deflate exponentially**. To read this one line you need powers, roots, the exponential function, the trigonometric functions and the idea of a list of numbers with a sign attached to each entry. The fields of the theory have sixteen complex components at every point, and they are acted on by eight real 16×16 matrices, the **gamma matrices**. To compute with them you need complex numbers, matrices and their products, determinants, eigenvalues, and a compact notation, index notation, in which one short line stands for dozens of equations. Finally the field equations of gravity in eight dimensions (Chapter 11) are written with the **generalized Kronecker delta**, a determinant of zeros and ones. This chapter teaches all of it.

The seven notebooks. The chapter has seven worked examples, each a complete Jupyter notebook, taken in this order:

notebook	topic	sections
01f	whole numbers, fractions, real and floating-point numbers, powers, exponential, logarithm	Sections 1.2 to 1.9
01b	complex numbers, Euler's formula, rotations, boosts, oscillation and growth	Sections 1.10 to 1.17
01a	vectors, matrices, permutations, determinants, the gamma matrices and the metric	Sections 1.18 to 1.25
01e	index notation, the summation convention, the frame metric, the Clifford relation	Sections 1.26 to 1.33
01g	eigenvalues, eigenvectors, the signature (4,4), Sylvester's law	Sections 1.34 to 1.41
01c	the generalized Kronecker delta, its proof, its counts, its contractions	Sections 1.42 to 1.48
01d	binary numbers, a pseudo-random generator, the record's tests of the generalized delta reproduced exactly	Sections 1.49 to 1.54

The letters were given to the notebooks when they were made; the chapter takes them in the order in which the ideas build on each other, so that every notion is introduced before a notebook uses it.

Each notebook appears in three parts: a section "How to run Notebook 01x", which gives the complete instructions for running it on Windows, macOS or Linux; a section "Notebook 01x: complete text", which prints every cell, everything it printed and every figure it drew; and a section "Line-by-line walk-through of Notebook 01x", which explains every line of every code cell. The first code cell of every notebook, the **set-up cell**, is the same in all notebooks except for the notebook's name; it is explained line by line once, in Section 1.9, and the later walk-throughs refer back to that explanation.

Counting from 1 and from 0. In mathematics the rows and columns of a table are usually numbered $1, 2, 3, \ldots$; the author numbers the coordinates from 0, x_0 to x_7. The programming language Python numbers the entries of a list $0, 1, 2, \ldots$. So the coordinate x_k is entry k of a Python list (x_0 is entry 0 and x_7 entry 7), while the entry in row 1 and column 1 of a matrix `A` is `A[0, 0]`. Every walk-through says which numbering a line uses.

The labels of every statement. Every result in this chapter carries one of the labels of the book: PROVED (an exact derivation is written out here, line by line, and a notebook checks it), COMPUTED (a number found by a notebook, with the cell that prints it), ASSUMED (a standard fact used without proof here, said so where it is used). When a notebook reproduces a number of the **Revision record** (the folder Revision of the repository, in which every computation of the author's theory is done and checked), the text names the record file and the check, exactly as the notebook's PASS line does. The labels HYPOTHESIS (a scenario that is stated, not derived) and OPEN (a question that no record answers yet), used later in the book, do not occur in this chapter. Nothing in this chapter concerns pair creation or matter and antimatter; those questions are treated, with the exact scope of what is proved, in Chapters 18 to 21.

1.2 Whole numbers and fractions, exactly

Whole numbers. The **whole numbers** (or **integers**) are $\ldots, -2, -1, 0, 1, 2, \ldots$. Python computes with them exactly, however many digits they have: $2^{100} = 1267650600228229401496703205376$ has 31 digits, and every one of them is right. Another large whole number that the course meets is

$$16! = 1 \cdot 2 \cdot 3 \cdots 16 = 20922789888000,$$

the number of terms of the determinant of a 16×16 matrix (Section 1.21). The symbol $n!$, read "n factorial", is the product of the whole numbers from 1 to n, with $0! = 1$.

Fractions. A **fraction** (or **rational number**) is a quotient p/q of two whole numbers with $q \neq 0$. The same fraction has many spellings, $1/2 = 2/4 = 3/6$, because multiplying numerator and denominator by the same number does not change the quotient. The spelling is in **lowest terms** when p and q have no common factor larger than 1. The **greatest common divisor** $\gcd(p, q)$ is the largest whole number that divides both; dividing p and q by it gives the lowest terms. For 84/126:

$$84 = 2 \cdot 42, \qquad 126 = 3 \cdot 42, \qquad \text{so} \qquad \frac{84}{126} = \frac{84/42}{126/42} = \frac{2}{3}$$

(the first two equations factor out 42, which is $\gcd(84, 126)$ because 2 and 3 have no common factor; the third divides numerator and denominator by 42). Two fractions are added by bringing them to

a common denominator:

$$\frac{1}{3}+\frac{1}{6}=\frac{2}{6}+\frac{1}{6}=\frac{3}{6}=\frac{1}{2}$$

(first 1/3 is written with the denominator 6 by multiplying numerator and denominator by 2; then the numerators are added over the common denominator; then the common factor 3 of 3 and 6 is cancelled). Python's module `fractions` computes with fractions exactly in this way, and Notebook 01f, In [2], checks these three examples.

Long division. The decimal digits of a fraction p/q with $0<p<q$ are produced by the school method of long division. Start with the **remainder** $r=p$. At every step multiply the remainder by 10; the whole part of the division of $10r$ by q is the next digit, and what is left over is the new remainder. For 1/7:

$$10=1\cdot 7+3,\quad 30=4\cdot 7+2,\quad 20=2\cdot 7+6,\quad 60=8\cdot 7+4,\quad 40=5\cdot 7+5,\quad 50=7\cdot 7+1.$$

The digits are 1, 4, 2, 8, 5, 7, and the last remainder is 1, the remainder we started with. From here everything repeats, so $1/7=0.142857142857\ldots$, written 0.(142857): the block in brackets repeats for ever. The length of the repeating block is the **period**; for 1/7 it is 6.

Theorem (PROVED). The decimal digits of a fraction p/q either end or, from some place on, repeat a block of at most $q-1$ digits. *Proof.* Every remainder is one of the numbers $0,1,\ldots,q-1$, because a remainder after division by q is smaller than q. If a remainder is 0, the division ends: every further digit is 0. Otherwise every remainder is one of the $q-1$ numbers $1,\ldots,q-1$. Among the first q remainders two must therefore be equal (there are only $q-1$ different values for q remainders). Each step computes the next digit and remainder from the present remainder alone, so as soon as a remainder comes back, the digits from there on repeat the digits after its first appearance. The block between two equal remainders is at most $q-1$ steps long.

From the digits back to the fraction (PROVED). Let $x=0.(c_1\ldots c_m)$ be a repeating block of m digits, and let C be the whole number with the digits $c_1\ldots c_m$. Then

$$10^m x=c_1\ldots c_m.(c_1\ldots c_m)=C+x$$

(multiplying by 10^m moves the decimal point m places to the right, so the first block stands before the point and the same repeating digits follow it),

$$10^m x-x=C,\qquad x=\frac{C}{10^m-1}$$

(subtract x from both sides; then take out the factor x and divide by 10^m-1). For example $0.(142857)=142857/999999=1/7$, because $7\cdot 142857=999999$. If k digits $d_1\ldots d_k$ (the whole number D) come before the repeating block, they are worth $D/10^k$, and the block is shifted k places further right, which divides its value by 10^k:

$$0.d_1\ldots d_k(c_1\ldots c_m)=\frac{D}{10^k}+\frac{C}{10^k(10^m-1)}.$$

For example $5/12 = 0.41(6)$: $D = 41$, $k = 2$, $C = 6$, $m = 1$, and $41/100 + 6/(100 \cdot 9) = 369/900 + 6/900 = 375/900 = 5/12$. Notebook 01f, In [3], writes long division as a Python function and checks this formula on six fractions.

Which fractions end (PROVED, using one ASSUMED fact). A fraction p/q in lowest terms has a decimal expansion that ends exactly when q has no prime factor other than 2 and 5, that is $q = 2^a 5^b$. (A **prime number** is a whole number larger than 1 that only 1 and itself divide.) *Proof.* If $q = 2^a 5^b$ and k is the larger of a and b, then $10^k = 2^k 5^k$ is a multiple of q, say $10^k = qt$, and $p/q = pt/10^k$: a whole number divided by 10^k, which has at most k digits after the point. Conversely, if the digits end after k places, then $p/q = N/10^k$ for a whole number N, so $p \cdot 10^k = Nq$; q divides $p \cdot 10^k$ and has no common factor with p, so it divides $10^k = 2^k 5^k$, and its prime factors are among 2 and 5. The last step uses the uniqueness of the factorisation of a whole number into primes, a standard theorem of arithmetic that we use without proof (ASSUMED). Notebook 01f, In [4], computes the period of $1/q$ for every q from 2 to 300 and checks the theorem and the bound $q - 1$; 23 denominators reach the full period $q - 1$, the first of them 7, 17, 19, 23, 29, 47, 59, 61, 97 (COMPUTED).

1.3 Real numbers: the square root of 2 is not a fraction

The number line contains numbers that are not fractions. The most famous is $\sqrt{2}$, the positive number whose square is 2, the length of the diagonal of a square with side 1.

Theorem (PROVED). No fraction p/q has $(p/q)^2 = 2$. *Proof by contradiction.* Suppose p/q is in lowest terms and $p^2/q^2 = 2$. Then:

- $p^2 = 2q^2$ (multiply both sides by q^2), so p^2 is even;
- p is even, because the square of an odd number is odd: $(2k+1)^2 = 4k^2+4k+1 = 2(2k^2+2k)+1$ (multiply out; then take out the factor 2 from the first two terms); so $p = 2r$ for a whole number r;
- $(2r)^2 = 2q^2$, that is $4r^2 = 2q^2$, that is $q^2 = 2r^2$ (insert $p = 2r$; then divide by 2), so q^2 is even and, by the same argument, q is even;
- so 2 divides both p and q, and p/q was not in lowest terms after all.

The assumption led to a contradiction, so it is false: $\sqrt{2}$ is not a fraction. A number that is not a fraction is called **irrational**; its decimal digits never end and never repeat (by the formula of Section 1.2, a number whose digits end or repeat is a fraction). The **real numbers** are all the numbers of the number line, fractions and irrational numbers together.

Fractions that come close (PROVED). Start with $1/1$ and make new fractions by the rule $p' = p + 2q$, $q' = p + q$: this gives $3/2$, $7/5$, $17/12$, $41/29$, $99/70$, and so on. For each of them $p^2 - 2q^2$ is $+1$ or -1:

$$p'^2 - 2q'^2 = (p + 2q)^2 - 2(p + q)^2 = p^2 + 4pq + 4q^2 - 2p^2 - 4pq - 2q^2 = -(p^2 - 2q^2)$$

(insert the rule; multiply out both squares, $(u+v)^2 = u^2+2uv+v^2$; collect the terms: $4pq-4pq = 0$, $p^2 - 2p^2 = -p^2$, $4q^2 - 2q^2 = 2q^2$). Every step changes the sign, and $1^2 - 2 \cdot 1^2 = -1$, so the values are $-1, +1, -1, \ldots$. How far is p/q from $\sqrt{2}$? Multiply the difference by $p + q\sqrt{2}$:

$$\Big(\frac{p}{q}-\sqrt{2}\Big)(p+q\sqrt{2}) = \frac{p^2+pq\sqrt{2}-pq\sqrt{2}-2q^2}{q} = \frac{p^2-2q^2}{q}, \qquad \text{so} \qquad \frac{p}{q}-\sqrt{2} = \frac{p^2-2q^2}{q(p+q\sqrt{2})}$$

(multiply out the product; the middle terms cancel; then divide by $p+q\sqrt{2}$). With $p^2-2q^2=\pm1$ and $p \approx q\sqrt{2}$ the size of the error is about $1/(q\cdot 2q\sqrt{2}) = 1/(2\sqrt{2}\,q^2) \approx 0.35355/q^2$. Notebook 01f, In [5], computes twelve of these fractions with 50-digit arithmetic: for $19601/13860$ the error is 1.84×10^{-9}, and the error times q^2 is 0.353553 (COMPUTED). It also checks with exact whole numbers that $p^2=2q^2$ has no solution with $q \le 10000$.

Bisection. A real number can be pinned down by fractions alone. Because $1^2<2<2^2$, $\sqrt{2}$ lies between 1 and 2. Take the middle m of the interval: if $m^2<2$, the root lies in the right half, otherwise in the left half. Each step halves the width of the interval while both ends stay exact fractions; after 60 steps the width is $2^{-60} \approx 8.7\times10^{-19}$. This is **bisection**. Notebook 01f, In [6], finds $1.4142135623730950483 < \sqrt{2} < 1.4142135623730950492$ in this way (COMPUTED).

1.4 Floating-point numbers, rounding and cancellation

How a computer stores a real number. A computer does not store real numbers with infinitely many digits. It stores a **floating-point number**: a whole number m of at most 53 binary digits (**bits**, the digits 0 and 1 of the base-2 system) times a power of two, $m\cdot 2^k$. Python's `float` and numpy's arrays use these numbers. A fraction whose denominator is a power of 2, such as $0.5=1/2$ or $0.375=3/8$, is stored exactly. A fraction such as $0.1=1/10$, whose denominator contains the prime factor 5, has an endless expansion in base 2 (by the argument of Section 1.2 with 2 in place of 10), so it is **rounded** to the nearest floating-point number. Notebook 01f, In [7], reads out the stored value: 0.1 is stored as 3602879701896397/36028797018963968, a fraction with the denominator 2^{55}, slightly larger than $1/10$. That is why $0.1+0.2$ prints as 0.30000000000000004 and is not equal to the stored 0.3.

Machine epsilon. The step from 1 to the next floating-point number is

$$\varepsilon = 2^{-52} \approx 2.220446049250313\times10^{-16},$$

called **machine epsilon**. So $1+\varepsilon$ is stored, but $1+\varepsilon/2$ lies halfway and is rounded back to 1. Above $2^{53}=9007199254740992$ the step between neighbouring floating-point numbers is 2, so the odd number $2^{53}+1$ cannot be stored at all: it is rounded to 2^{53}.

The step at every size (PROVED). Write a positive number as $x=f\cdot 2^e$ with $\frac{1}{2}\le f<1$ (every positive number can be written so, by choosing the power of two). The 53 bits of m then cover the factor f, whose last bit is worth 2^{-53}; so the step to the next floating-point number is $2^{-53}\cdot 2^e = 2^{e-53}$. Divided by x:

$$\frac{2^{e-53}}{f\cdot 2^e} = \frac{2^{-53}}{f}, \qquad \text{and} \qquad \tfrac{1}{2}\le f<1 \;\Rightarrow\; 2^{-53} < \frac{2^{-53}}{f} \le 2^{-52}$$

(cancel 2^e; then divide the inequalities for f into 2^{-53}, which reverses them). So the **relative** step always lies between $\varepsilon/2$ and ε: floating-point numbers have about 16 significant decimal digits at

every size, and rounding a number to the nearest one changes it by at most $\varepsilon/2$ of its size. Notebook 01f, In [7], checks the formula 2^{e-53} at 2301 numbers from 10^{-3} to 10^{20}, and In [8] draws the step.

Cancellation. The function $f(x) = (1-\cos x)/x^2$ tends to $\frac{1}{2}$ as x tends to 0 (because $\cos x \approx 1-x^2/2$ for small x, a fact of calculus, the Taylor series of the cosine, ASSUMED here and confirmed by sympy in Notebook 01f, In [9]). Computed as written, it fails for small x. The computer's value of $\cos x$ is a floating-point number near 1, so it is wrong by up to the spacing of the floating-point numbers there, of the size of ε; the subtraction $1-\cos x$ keeps this absolute error, while the true value $x^2/2$ is tiny. The relative error of the result is therefore of the size

$$\frac{\varepsilon}{x^2/2} = \frac{2\varepsilon}{x^2}$$

(absolute error divided by the size of the true value; the dashed line of Figure 01f.4). For $x = 10^{-8}$ the true value of $\cos x$ is $1 - 5\times10^{-17}$, which is nearer to 1 than to the floating-point number just below 1 (which is $1 - 2^{-53} \approx 1 - 1.1\times10^{-16}$), so $\cos x$ is rounded to exactly 1 and the formula returns 0: every digit is lost. This loss of digits when two nearly equal numbers are subtracted is called **cancellation**.

The cure: rewrite the formula (PROVED). From the addition theorem $\cos(2y) = \cos^2 y - \sin^2 y$ and $\cos^2 y = 1 - \sin^2 y$:

$$\cos(2y) = 1 - \sin^2 y - \sin^2 y = 1 - 2\sin^2 y, \qquad \text{so with } y = x/2: \qquad 1 - \cos x = 2\sin^2(x/2)$$

(insert the second identity into the first; collect; then put $y = x/2$ and move terms across). Hence $f(x) = 2\sin^2(x/2)/x^2$, a formula without a subtraction. Notebook 01f, In [9], compares both formulas with 50-digit arithmetic at 361 values of x from 10^{-9} to 1: the rewritten formula has the largest relative error 4.4×10^{-16}, the formula as written 1.0, that is 100 per cent (COMPUTED). Whenever a later notebook of the course rewrites a formula before computing it, this is the reason.

1.5 Powers, roots, the exponential function and the logarithm

The laws of powers. For positive numbers a, b and any real numbers p, q:

$$a^p a^q = a^{p+q}, \qquad (a^p)^q = a^{pq}, \qquad (ab)^p = a^p b^p, \qquad a^{-p} = \frac{1}{a^p}, \qquad \sqrt{a} = a^{1/2}, \qquad a^{1/n} = \sqrt[n]{a}.$$

These are school algebra (ASSUMED here; Notebook 01f, In [10], confirms them with sympy for symbols declared positive). They need positive bases. For a negative number the law $(a^p)^q = a^{pq}$ can fail: $\sqrt{(-2)^2} = \sqrt{4} = 2$, not -2. In general $\sqrt{y^2} = |y|$, the **absolute value** of y (y without its sign).

A worked example (PROVED). For $s > 0$ and real a:

$$\frac{1}{\sqrt{s^{1/3}/e^{2a}}} = \Big(\frac{s^{1/3}}{e^{2a}}\Big)^{-1/2} = \frac{(s^{1/3})^{-1/2}}{(e^{2a})^{-1/2}} = \frac{s^{-1/6}}{e^{-a}} = \frac{e^a}{s^{1/6}}$$

(the root is the power $1/2$ and one over it the power $-1/2$; the power of a quotient is the quotient of the powers; $(a^p)^q = a^{pq}$ twice, with $\frac{1}{3}\cdot(-\frac{1}{2}) = -\frac{1}{6}$ and $2\cdot(-\frac{1}{2}) = -1$; one over e^{-a} is e^a and $s^{-1/6}$ is one over $s^{1/6}$).

The length factors of the author's metric (PROVED). The metric g of Section 1.1 is **diagonal**: it has one entry $g_{\mu\mu}$ for each direction x_μ ($\mu = 0,\dots,7$), and the squared length of a small step dx_μ along that one direction is $g_{\mu\mu}\,dx_\mu^2$. A negative entry marks a **time-like** direction (x_4 to x_7), a positive entry a **space-like** one (x_0, x_1, x_2, x_3). The **length factor** of a direction is $\sqrt{|g_{\mu\mu}|}$: the length of the step is the factor times $|dx_\mu|$. For $0 < z < \pi/2$ both $\sin z$ and $\cos z$ are positive, so the laws of powers apply and give

$$\sqrt{\cot^2 z} = \cot z, \qquad \sqrt{e^{2a_4}\sin^{1/3} z} = e^{a_4}\sin^{1/6} z, \qquad \sqrt{1} = 1,$$
$$\sqrt{b_4 e^{-2a_4}\sin^{1/3} z} = b_4^{1/2} e^{-a_4}\sin^{1/6} z$$

(the root of a product is the product of the roots; $\sqrt{e^{2a_4}} = e^{a_4}$ and $\sqrt{\sin^{1/3} z} = \sin^{1/6} z$ by $(a^p)^q = a^{pq}$; $\sqrt{b_4} = b_4^{1/2}$; $\cot z > 0$). The hidden direction has the factor $\cot z$; the three space directions have $e^{a_4}\sin^{1/6} z$, which grows as a_4 grows; the time has 1; the three extra times have $b_4^{1/2}e^{-a_4}\sin^{1/6} z$, which shrinks exponentially when b_4 is constant. The product of all eight factors is

$$\cot z\cdot(e^{a_4}\sin^{1/6} z)^3\cdot 1\cdot(b_4^{1/2}e^{-a_4}\sin^{1/6} z)^3 = b_4^{3/2}\,e^{3a_4-3a_4}\,\sin^{6/6} z\,\cot z = b_4^{3/2}\sin z\cot z = b_4^{3/2}\cos z$$

(collect the powers of b_4, of e and of $\sin z$ with $a^p a^q = a^{p+q}$: $3\cdot\frac{1}{2} = \frac{3}{2}$, $3a_4 - 3a_4 = 0$ and $6\cdot\frac{1}{6} = 1$; then $\cot z = \cos z/\sin z$). The growth of space and the deflation of the extra times cancel exactly in the product, for every value of a_4; at $b_4 = 1$ the product is $\cos z$. The Revision record stores this product as `sqrtAbsDetG` $= b_4^{3/2}\sin z\cot z$ in `Revision/gkd_lovelock/results/curvature.json` and checks it in `python-lovelock-report.json`, check `sqrt_abs_det_g`; Notebook 01f, In [11], reads the metric from the record and reproduces both. (Section 1.21 shows that this product is the square root of the size of the determinant of g.)

The number e. The number $e = 2.71828\dots$ is the limit of $(1 + 1/n)^n$ for ever larger n: the growth of one unit of money in a year at the interest rate of 100 per cent, paid in n equal parts. How fast is the limit reached? With the natural logarithm ln (defined below) and the series $\ln(1+u) = u - u^2/2 + u^3/3 - \dots$ for small u (a Taylor series of calculus, ASSUMED here):

$$\ln\Big(1+\frac{1}{n}\Big)^n = n\ln\Big(1+\frac{1}{n}\Big) = n\Big(\frac{1}{n} - \frac{1}{2n^2} + \dots\Big) = 1 - \frac{1}{2n} + \dots$$

(the logarithm of a power is the power times the logarithm; insert the series with $u = 1/n$; multiply out), so

$$\Big(1+\frac{1}{n}\Big)^n = e^{1-1/(2n)+\dots} = e\cdot e^{-1/(2n)+\dots} \approx e\Big(1-\frac{1}{2n}\Big), \qquad e - \Big(1+\frac{1}{n}\Big)^n \approx \frac{e}{2n}$$

(undo the logarithm with the exponential; split the power with $a^{p+q} = a^p a^q$; use $e^{-u} \approx 1 - u$ for small u; subtract from e). Notebook 01f, In [12], confirms the law $e/(2n)$ within 1 per cent for every

$n = 10^3, \ldots, 10^{16}$ with 50-digit arithmetic. With floating-point numbers the limit breaks down: $1 + 1/n$ is rounded by up to $\varepsilon/2$ of its size, and raising to the power n multiplies this relative error by about n (because $(1+\delta)^n \approx 1 + n\delta$ for small δ). For $n = 10^9$ the computed error is 2.2×10^{-7} instead of 1.36×10^{-9}, and for $n = 10^{16}$ the number $1 + 10^{-16}$ is rounded to exactly 1, so the result is $1^n = 1$ and the error is $e - 1 = 1.7$ (COMPUTED, Notebook 01f, In [12]; Figure 01f.5).

The exponential function and the logarithm. The **exponential function** e^t is defined for every real t, is always positive and grows; its inverse is the **natural logarithm** $\ln x$, defined for $x > 0$: $\ln(e^t) = t$ and $e^{\ln x} = x$. The logarithm turns products into sums (PROVED):

$$e^{\ln x + \ln y} = e^{\ln x}\, e^{\ln y} = xy \qquad \Rightarrow \qquad \ln(xy) = \ln x + \ln y$$

(the law $a^{p+q} = a^p a^q$ with $a = e$; then take the logarithm of both sides). For the author's metric this means: when a_4 grows by $\ln 2 \approx 0.693$ (and b_4 stays constant), the space factor e^{a_4} doubles and the extra-time factor halves,

$$e^{-(a_4 + \ln 2)} = e^{-a_4}\, e^{-\ln 2} = e^{-a_4} \cdot \frac{1}{2}$$

(the law of powers; then $e^{-\ln 2} = 1/e^{\ln 2} = 1/2$). A growth of a_4 by 1 multiplies e^{a_4} by e, one **e-fold**. To shrink the extra times by a factor 1000, a_4 must grow by $\ln 1000 = 6.9078$ (COMPUTED, Notebook 01f, In [12]). On a **logarithmic axis**, on which each equal step multiplies by the same factor, both e^{a_4} and e^{-a_4} are straight lines, one rising and one falling equally fast (Figure 01f.6).

1.6 Example: numbers, rounding and the length factors of the author's metric

Notebook 01f puts Sections 1.2 to 1.5 to work. It computes exactly with whole numbers and fractions; writes long division as a program and plots the periods of $1/q$; proves and checks that $\sqrt{2}$ is not a fraction and pins it down by bisection and by the fractions p/q with $p^2 - 2q^2 = \pm 1$; shows how floating-point numbers are spaced, why $0.1 + 0.2 \neq 0.3$ in a computer, and how cancellation destroys a formula and how rewriting cures it; checks the laws of powers and applies them to the author's metric as stored in the Revision record; and builds e as a limit and draws the growth e^{a_4} of space and the exponential deflation e^{-a_4} of the extra times. It ends with the line ALL 26 CHECKS PASSED (notebook 01f).

1.7 How to run Notebook 01f

Step 1. What this notebook does and what it needs.

Notebook 01f (Numbers: fractions, real numbers, floating point and powers) is the file `Revision/textbook/notebooks/01f_numbers_and_powers.ipynb` of the repository Dirac_claude. It computes exactly with whole numbers and fractions, turns fractions into repeating decimals by long division, proves and checks that the square root of 2 is not a fraction and pins it down by halving intervals and by its best fractions, shows how a computer stores real numbers as floating-point numbers and what rounding and cancellation do, checks the laws of powers and roots and uses them to turn the author's metric into the length factors of the eight directions, whose product is the square root of the size of its determinant recorded in the Revision record, and builds the exponential

function and the logarithm with the growth of space and the exponential deflation of the three extra times on logarithmic axes. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
```

```
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01f_numbers_and_powers.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01f_numbers_and_powers.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01f_numbers_and_powers.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01f.captions.json`
- `Revision/textbook/figures/01f_1_decimal_periods.png`
- `Revision/textbook/figures/01f_2_square_root_of_two.png`
- `Revision/textbook/figures/01f_3_float_spacing.png`
- `Revision/textbook/figures/01f_4_cancellation.png`
- `Revision/textbook/figures/01f_5_limit_for_e.png`
- `Revision/textbook/figures/01f_6_growth_and_deflation.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 26 CHECKS PASSED (notebook 01f)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01f_numbers_and_powers.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01f_numbers_and_powers.ipynb
python -m nbconvert --execute --inplace 01f_numbers_and_powers.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

1.8 Notebook 01f: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01f_numbers_and_powers.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook builds the numbers that the course computes with, from whole
numbers to the floating-point numbers of a computer, and the powers, roots,
exponentials and logarithms that the author's metric is made of. It

- computes exactly with whole numbers and fractions;
- turns fractions into decimals by long division and shows that their digits
  always end or repeat (with a plot of the length of the repeating part);
- proves that $\sqrt 2$ is not a fraction, pins it down between fractions by
  halving an interval, and finds the best fractions near it;
- shows how a computer stores a real number (a *floating-point number*), why
  $0.1 + 0.2$ is not exactly $0.3$ in a computer, how far apart neighbouring
  floating-point numbers are, and how a careless formula loses all its digits
  (*cancellation*);
- checks the laws of powers and roots, and uses them to turn the diagonal of
  the author's metric into the eight length factors, whose product is the square
  root of the size of the determinant stored in the Revision record;
- builds the number $e$ and the exponential function as a limit, and shows the
  growth $e^{a_4}$ of space and the exponential deflation $e^{-a_4}$ of the
  three extra times on ordinary and on logarithmic axes.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01f (Numbers: fractions, real numbers, floating point and powers) is the file
‘Revision/textbook/notebooks/01f_numbers_and_powers.ipynb‘ of the repository
Dirac_claude. It computes exactly with whole numbers and fractions, turns fractions into
repeating decimals by long division, proves and checks that the square root of 2 is not a
fraction and pins it down by halving intervals and by its best fractions, shows how a
computer stores real numbers as floating-point numbers and what rounding and cancellation
do, checks the laws of powers and roots and uses them to turn the author's metric into
the length factors of the eight directions, whose product is the square root of the size
of its determinant recorded in the Revision record, and builds the exponential function
and the logarithm with the growth of space and the exponential deflation of the three
extra times on logarithmic axes. It needs a computer with Windows 11, macOS or Linux, an
internet connection for the installation, the program Git, and Python 3.12 or newer (the
notebooks were built with Python 3.14.5) with these packages at exactly these versions:
numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program
that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.
```

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git

pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 01f_numbers_and_powers.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 01f_numbers_and_powers.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01f_numbers_and_powers.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01f.captions.json‘
- ‘Revision/textbook/figures/01f_1_decimal_periods.png‘
- ‘Revision/textbook/figures/01f_2_square_root_of_two.png‘
- ‘Revision/textbook/figures/01f_3_float_spacing.png‘
- ‘Revision/textbook/figures/01f_4_cancellation.png‘
- ‘Revision/textbook/figures/01f_5_limit_for_e.png‘
- ‘Revision/textbook/figures/01f_6_growth_and_deflation.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it

runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 26 CHECKS PASSED (notebook 01f)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01f_numbers_and_powers.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
  python -m jupyterlab 01f_numbers_and_powers.ipynb
  python -m nbconvert --execute --inplace 01f_numbers_and_powers.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues

and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01f (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01f (Numbers: fractions, real numbers, floating point and powers) is the file
# Revision/textbook/notebooks/01f_numbers_and_powers.ipynb of the repository
# Dirac_claude. It computes exactly with whole numbers and fractions, turns fractions
# into repeating decimals by long division, proves and checks that the square root of 2
# is not a fraction and pins it down by halving intervals and by its best fractions,
# shows how a computer stores real numbers as floating-point numbers and what rounding
# and cancellation do, checks the laws of powers and roots and uses them to turn the
# author's metric into the length factors of the eight directions, whose product is the
# square root of the size of its determinant recorded in the Revision record, and builds
# the exponential function and the logarithm with the growth of space and the exponential
# deflation of the three extra times on logarithmic axes. It needs a computer with
# Windows 11, macOS or Linux, an internet connection for the installation, the program
# Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these
# packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib
# 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and
# nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
```

```
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01f_numbers_and_powers.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
```

```
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01f_numbers_and_powers.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01f_numbers_and_powers.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01f.captions.json
# - Revision/textbook/figures/01f_1_decimal_periods.png
# - Revision/textbook/figures/01f_2_square_root_of_two.png
# - Revision/textbook/figures/01f_3_float_spacing.png
# - Revision/textbook/figures/01f_4_cancellation.png
# - Revision/textbook/figures/01f_5_limit_for_e.png
# - Revision/textbook/figures/01f_6_growth_and_deflation.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 26 CHECKS PASSED (notebook 01f)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
```

```
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01f_numbers_and_powers.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01f_numbers_and_powers.ipynb
#     python -m nbconvert --execute --inplace 01f_numbers_and_powers.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the
#   notebook reads Revision records of the repository; your copy of the repository is
#   incomplete. Download it again with git clone and open the notebook inside the new
#   copy.
#
# ------------------------------------------------------------------------------------

Text cell:

```
## 3. The words used in this notebook

- **Whole numbers** (integers): $\dots, -2, -1, 0, 1, 2, \dots$. Python computes
  with them exactly, however large they are.
- **Fraction** (rational number): $p/q$ with whole numbers $p$ and $q \neq 0$.
  It is in **lowest terms** when $p$ and $q$ have no common factor larger than 1.
  Python's `fractions.Fraction` computes with fractions exactly.
- **Greatest common divisor** $\gcd(p, q)$: the largest whole number that
  divides both $p$ and $q$ (`math.gcd`).
- **Long division**: the school method that produces the decimal digits of
  $p/q$ one after the other from the remainders.
- **Repeating decimal**: a decimal whose digits repeat a block for ever, written
  with the block in brackets: $1/7 = 0.(142857)$. The block's length is the
  **period**.
- **Prime number**: a whole number larger than 1 that only 1 and itself divide.
- **Real number**: a number on the number line; it may need infinitely many
  digits that do not repeat, like $\sqrt 2$ or $\pi$. Such a number is
  **irrational** (not a fraction).
- **Bisection**: halving an interval that contains the number again and again,
  keeping the half that still contains it.
- **Floating-point number**: the way a computer stores a real number: a whole
  number of 53 binary digits (bits) times a power of 2. Neighbouring
  floating-point numbers are a small step apart, so most real numbers are
  **rounded** to the nearest one.
- **Machine epsilon** $\varepsilon = 2^{-52} \approx 2.2 \times 10^{-16}$: the
  step from 1 to the next floating-point number.
- **Relative error**: $|$computed $-$ exact$|$ divided by $|$exact$|$.
- **Cancellation**: the loss of digits when two nearly equal numbers are
  subtracted.
- **Power** $a^p$ and **root** $a^{1/n}$; the **laws of powers**
  $a^p a^q = a^{p+q}$, $(a^p)^q = a^{pq}$, $(ab)^p = a^p b^p$,
  $a^{-p} = 1/a^p$ for positive $a, b$.
- **Absolute value** $|x|$: $x$ without its sign; $\sqrt{x^2} = |x|$.
- **Exponential function** $e^x$ and **natural logarithm** $\ln x$, which
  undoes it: $\ln(e^x) = x$. The number $e = 2.71828\dots$.
- **e-fold**: a growth by the factor $e$; a growth of $a_4$ by $\ln 2 \approx
  0.693$ doubles $e^{a_4}$ and halves $e^{-a_4}$.
- **Logarithmic axis**: an axis on which each step multiplies by 10, so that
  an exponential function is a straight line.
- **mpmath**: a Python package that computes with as many decimal digits as
  requested (here 50).

## 4. The physical and mathematical situation
```

```
The author's metric of the primordial gravitational field is the diagonal
matrix

$$g = \mathrm{diag}\big(\cot^2 z, e^{2a_4} s, e^{2a_4} s, e^{2a_4} s, -1,
-b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s\big),\quad
s = \sin^{1/3} z,\ z = 6 H x_0,\ 0 < z < \pi/2,$$

with a function $a_4(x_4)$ and a positive function $b_4(x_4)$ of the time
($b_4 = 1$ in the background of the Revision record). Its entries are built
from powers ($\sin^{1/3} z$ is the cube root of $\sin z$), exponentials
($e^{2a_4}$) and a trigonometric function. A length along a coordinate is the
square root of the size of its metric entry: along $x_1, x_2, x_3$ (space) it is
$e^{a_4}\sin^{1/6} z$, which grows as $a_4$ grows, and along the three extra
times $x_5, x_6, x_7$ it is $b_4^{1/2} e^{-a_4}\sin^{1/6} z$, which shrinks: for
constant $b_4$ the extra times deflate exponentially.
The time $x_4$ has the factor 1 and the hidden direction $x_0$ the factor
$\cot z$. To compute with these expressions correctly one needs the laws of
powers, roots, exponentials and logarithms, and one needs to know when a
computer computes exactly (whole numbers, fractions, sympy's symbols) and when
it rounds (floating-point numbers). Both are built here from zero.
```

Text cell:

```
## 5. Whole numbers and fractions, exactly

Python's whole numbers have no size limit: $2^{100}$ has 31 digits, and every
one of them is right. Fractions are exact too: `fractions.Fraction(1, 3)` is
the number $1/3$ itself, not a rounded decimal. The next cell computes

- $2^{100}$ and $16! = 20{,}922{,}789{,}888{,}000$ exactly;
- $\tfrac13 + \tfrac16 = \tfrac26 + \tfrac16 = \tfrac36 = \tfrac12$ (bring both
  to the common denominator 6, add the numerators, cancel the common factor 3);
- $\tfrac{84}{126}$ in lowest terms: $\gcd(84, 126) = 42$, so
  $\tfrac{84}{126} = \tfrac{84/42}{126/42} = \tfrac23$.
```

## 6. Fractions as decimals: the digits end or repeat

Long division of $p$ by $q$ (with $0 < p < q$) works with remainders: multiply
the remainder by 10, the whole part of the division by $q$ is the next digit,
and what is left is the new remainder. For $1/7$: $10 = 1 \cdot 7 + 3$ (digit
1, remainder 3), $30 = 4 \cdot 7 + 2$ (digit 4, remainder 2), then digits
2, 8, 5, 7 with remainders 6, 4, 5, 1, and the remainder 1 is where we
started: from here the digits repeat, $1/7 = 0.(142857)$.

Why the digits must end or repeat: a remainder is one of $0, 1, \dots, q - 1$.
If it becomes 0 the division ends. Otherwise it is one of the $q - 1$ numbers
$1, \dots, q - 1$, so after at most $q - 1$ steps a remainder comes back, and
from then on everything repeats. So the period is at most $q - 1$.

The digits can be turned back into the fraction: if the digits $d_1 \dots d_k$
come first and then the block $c_1 \dots c_m$ repeats, the number is

$$\frac{D}{10^k} + \frac{C}{10^k(10^m - 1)},$$

where $D$ and $C$ are the whole numbers with the digits $d_1 \dots d_k$ and
$c_1 \dots c_m$ (because $0.(c_1 \dots c_m) = C/10^m + C/10^{2m} + \dots =
C/(10^m - 1)$, a geometric series). The next cell defines ‘decimal_digits‘,
prints six examples and checks that the digits give the fractions back.
```

In [3]:

```

## 7. Real numbers: the square root of 2 is not a fraction

**Claim.** No fraction $p/q$ has $(p/q)^2 = 2$. **Proof** by contradiction,
```

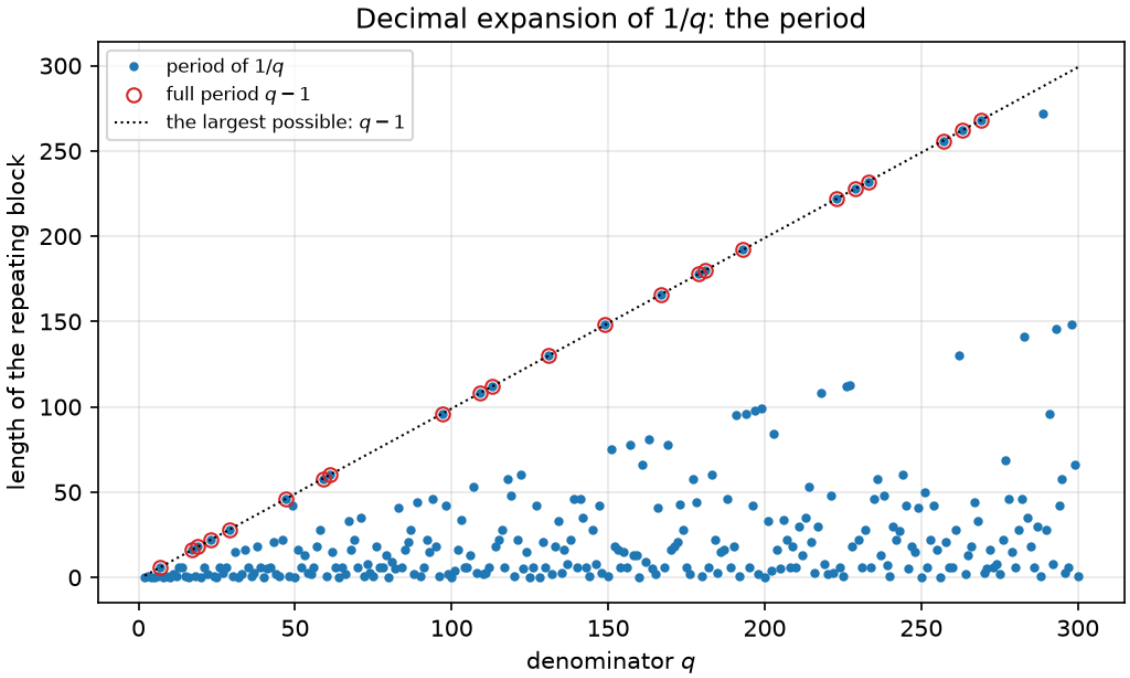

Figure 17: The length of the repeating block (the period) of the decimal digits of $1/q$ for every denominator $q = 2$ to 300 (blue dots); horizontal axis q, vertical axis the period (a whole number). Dots at 0 are the denominators $q = 2^a 5^b$, whose decimals end. No dot lies above the dotted line $q - 1$, because long division has only $q - 1$ nonzero remainders; the red circles are the primes that reach it. (Notebook 01f, figure 1.)

```
line by line. Suppose $p/q$ is in lowest terms and $p^2/q^2 = 2$. Then

- $p^2 = 2q^2$ (multiply by $q^2$), so $p^2$ is even;
- then $p$ is even (the square of an odd number $2k + 1$ is
  $4k^2 + 4k + 1$, which is odd), so $p = 2r$ for a whole number $r$;
- then $4r^2 = 2q^2$, that is $q^2 = 2r^2$, so $q$ is even as well;
- so 2 divides both $p$ and $q$, and $p/q$ was not in lowest terms: a
  contradiction. Hence $\sqrt 2$ is not a fraction: it is irrational.

The best one can do is to come close. The fractions $p/q$ made by the rule
$p' = p + 2q$, $q' = p + q$ from $1/1$ ($3/2$, $7/5$, $17/12$, $41/29$, ...)
have $p^2 - 2q^2 = \pm 1$, alternating in sign: indeed

$$p'^2 - 2q'^2 = (p + 2q)^2 - 2(p + q)^2 = p^2 + 4pq + 4q^2 - 2p^2 - 4pq - 2q^2
= -(p^2 - 2q^2)$$

(multiply out both squares, then collect the terms). So $p^2/q^2 = 2 \pm
1/q^2$ comes ever closer to 2 without reaching it, and
$p/q - \sqrt 2 = (p^2 - 2q^2)/(q(p + q\sqrt 2))$ (multiply numerator and
denominator by $p + q\sqrt 2$), whose size is about $1/(2\sqrt 2\, q^2)$.

The next cell checks with exact whole numbers that $p^2 = 2q^2$ has no
solution with $q \leq 10{,}000$, lists 12 of these fractions with
$p^2 - 2q^2$ and the error (computed with mpmath at 50 digits), and checks
that error $\cdot\, q^2$ approaches $1/(2\sqrt 2) = 0.35355\dots$
```

## 8. Floating-point numbers

A computer stores a real number as a **floating-point number**: a whole number
$m$ of at most 53 bits times a power of two, $m \cdot 2^k$. Fractions whose
denominator is a power of 2, such as $0.5 = 1/2$, are stored exactly; others,
such as $0.1 = 1/10$, are rounded to the nearest such number. That is why
$0.1 + 0.2$ is not exactly $0.3$ in a computer. The next cell shows:

- $0.1 + 0.2$ as Python prints it, and the exact fraction that is stored for
  $0.1$ (`fractions.Fraction(0.1)` reads it out): its denominator is $2^{55}$;
- machine epsilon $\varepsilon = 2^{-52}$: $1 + \varepsilon$ is the next
  floating-point number after 1, and $1 + \varepsilon/2$ is rounded back to 1;
- above $2^{53}$ not even every whole number can be stored:
  $2^{53} + 1$ is rounded to $2^{53}$;
- the step from a number $x$ to the next floating-point number
  (`np.spacing`): writing $x = f \cdot 2^e$ with $\tfrac12 \leq f < 1$
  (`np.frexp` finds $f$ and $e$), the step is exactly $2^{e - 53}$; so it is
  about $\varepsilon x$: the *relative* precision is the same at every size.

## 9. Rounding and cancellation

The function $f(x) = (1 - \cos x)/x^2$ tends to $\tfrac12$ as $x$ tends to 0.
Computed as written, it fails for small $x$: $\cos x$ is very close to 1, its
rounding error is about $\varepsilon$, and the subtraction $1 - \cos x$ keeps
this error while the true value $1 - \cos x \approx x^2/2$ is tiny. The
relative error is then about $\varepsilon/(x^2/2)$; for $x = 10^{-8}$,
$\cos x$ is rounded to exactly 1 and the result is 0, all digits lost. This
is **cancellation**.

The cure is to rewrite the formula without the subtraction. The half-angle
formula $\cos(2y) = 1 - 2\sin^2 y$ (from $\cos(2y) = \cos^2 y - \sin^2 y$ and
$\cos^2 y = 1 - \sin^2 y$) with $y = x/2$ gives
$1 - \cos x = 2\sin^2(x/2)$, so

$$f(x) = \frac{2\sin^2(x/2)}{x^2},$$

which has no subtraction. The next cell checks the limit and the identity with
sympy, computes both formulas at 361 values of $x$ from $10^{-9}$ to 1,
compares them with mpmath at 50 digits, and plots the relative errors.
```

## 10. Powers and roots: the length factors of the author's metric

For positive $a, b$ and any real $p, q$ the laws of powers are

$$a^p a^q = a^{p+q},\quad (a^p)^q = a^{pq},\quad (ab)^p = a^p b^p,\quad
a^{-p} = \frac{1}{a^p},\quad \sqrt a = a^{1/2}.$$

They need $a, b > 0$. For a negative number they can fail:
$\sqrt{(-2)^2} = \sqrt 4 = 2$, not $-2$; in general $\sqrt{x^2} = |x|$.

A worked example with $s > 0$ and real $a$:

$$\frac{1}{\sqrt{s^{1/3}/e^{2a}}} = \Big(\frac{s^{1/3}}{e^{2a}}\Big)^{-1/2}
= \frac{(s^{1/3})^{-1/2}}{(e^{2a})^{-1/2}} = \frac{s^{-1/6}}{e^{-a}}
= \frac{e^{a}}{s^{1/6}}$$

(the root is the power $1/2$ and one over it the power $-1/2$; the power of a
quotient is the quotient of the powers; $(a^p)^q = a^{pq}$ twice; one over
$e^{-a}$ is $e^a$).

**The length factors.** The length of a small step $dx$ along one coordinate
is $\sqrt{|g_{\mu\mu}|}\,dx$. For $0 < z < \pi/2$ both $\sin z$ and $\cos z$
are positive, so the laws apply:

$$\sqrt{\cot^2 z} = \cot z,\quad \sqrt{e^{2a_4}\sin^{1/3} z} = e^{a_4}\sin^{1/6} z,
\quad \sqrt{1} = 1,\quad
\sqrt{b_4 e^{-2a_4}\sin^{1/3} z} = b_4^{1/2} e^{-a_4}\sin^{1/6} z,$$

and their product over the eight directions is

$$\cot z \cdot (e^{a_4}\sin^{1/6} z)^3 \cdot 1 \cdot (b_4^{1/2} e^{-a_4}\sin^{1/6} z)^3
= b_4^{3/2}\, e^{3a_4 - 3a_4}\,\sin^{6/6} z\,\cot z = b_4^{3/2} \sin z \cot z
= b_4^{3/2} \cos z,$$

the record's `sqrtAbsDetG` ($b_4^{3/2} \sin z \cot z$; $\cos z$ at $b_4 = 1$).
The next cell checks the laws and the example with sympy (with symbols declared
positive or real), then reads the metric from the record with the symbols
$S = \sin z$ and $C = \cos z$ (both positive, $\cot z = C/S$) and $b_4$
(positive), takes the square root of the size of every entry (the sign of entry
$\mu$ is $\eta_{\mu\mu}$ of the frame metric), and checks the eight factors and
their product.

## 11. The exponential function, the logarithm and logarithmic axes

The number $e$ is the limit of $(1 + 1/n)^n$ for ever larger $n$ (the growth of
1 unit of money at the interest rate 100 per cent per year, paid in $n$ parts).
The error $e - (1 + 1/n)^n$ is about $e/(2n)$ for large $n$. With 50-digit
```

```
arithmetic this is what one sees. With floating-point numbers the formula
breaks down for large $n$: $1 + 1/n$ is rounded (by up to $\varepsilon/2$),
and the power $n$ multiplies that rounding error by about $n$; for
$n = 10^{16}$, $1 + 1/n$ is rounded to exactly 1, and $1^n = 1$.

The logarithm undoes the exponential, $\ln(e^t) = t$, and turns products into
sums, $\ln(xy) = \ln x + \ln y$ for positive $x, y$ (because
$e^{\ln x + \ln y} = e^{\ln x}e^{\ln y} = xy$). In the author's metric the
length factors contain $e^{a_4}$ (space) and $e^{-a_4}$ (extra times). When
$a_4$ grows by $\ln 2 \approx 0.693$, $e^{a_4}$ doubles and
$e^{-a_4}$ halves: $e^{-(a_4 + \ln 2)} = e^{-a_4} e^{-\ln 2} = e^{-a_4}/2$. To
shrink the extra times by a factor 1000, $a_4$ must grow by
$\ln 1000 \approx 6.91$.

The next cell computes the errors for $n = 1, 10, \dots, 10^{16}$ both ways,
checks the $e/(2n)$ law (within 1 per cent for $n \geq 1000$) and the
breakdown of the floating-point version, and checks the laws of the logarithm.
```

```

Text cell:

```
## 13. What this notebook showed

- Whole numbers and fractions are computed exactly by Python ($2^{100}$, $16!$,
  $1/3 + 1/6 = 1/2$, $84/126 = 2/3$).
- The decimal digits of a fraction end or repeat, with a period of at most
```

```
  $q - 1$; they end exactly when $q = 2^a 5^b$.
- $\sqrt 2$ is not a fraction (proved); bisection pins it between exact
  fractions to $2^{-60}$, and the fractions $1/1, 3/2, 7/5, \dots$ with
  $p^2 - 2q^2 = \pm 1$ approach it with errors close to $1/(2\sqrt2\,q^2)$.
- A computer stores real numbers as floating-point numbers with a relative
  precision of about $\varepsilon = 2^{-52}$: $0.1 + 0.2 \neq 0.3$, and above
  $2^{53}$ whole numbers are skipped. Subtracting nearly equal numbers loses
  digits (cancellation); rewriting $1 - \cos x$ as $2\sin^2(x/2)$ cures it.
- The laws of powers hold for positive bases, and $\sqrt{y^2} = |y|$. Applied
  to the author's metric of the Revision record they give the length factors
  $\cot z$ (hidden direction), $e^{a_4}\sin^{1/6} z$ (space), 1 (time) and
  $b_4^{1/2} e^{-a_4}\sin^{1/6} z$ (the exponentially deflating extra times),
  whose product is $b_4^{3/2} \cos z$, the record's $\sqrt{|\det g|}$, for every
  $a_4$ ($\cos z$ at $b_4 = 1$).
- $e$ is the limit of $(1 + 1/n)^n$, with the error $e/(2n)$; floating point
  breaks this limit for $n$ beyond about $10^8$. A growth of $a_4$ by $\ln 2$
  doubles $e^{a_4}$ and halves $e^{-a_4}$; on a logarithmic axis both are
  straight lines.
```

1.9 Line-by-line walk-through of Notebook 01f

The notebook has fourteen code cells, In [1] to In [14]. This section explains every line of every one of them, in order. A line that starts with `#` is a **comment**: Python skips it; it is there for the reader. A comment may also stand at the end of a line of code, after the sign `#`. Where a quoted cell ends with a long figure caption, the remaining lines of the caption are replaced here by `...`); every caption is printed in full under its figure in Section 1.8.

In [1], the set-up cell. Its first part repeats the complete run instructions of Section 1.7 as comment lines, so that the notebook file carries its own instructions. The code starts below the line of `=` signs that reads THE SET-UP. This code is the same in every notebook of the book except for one line, the notebook's name. It is explained here once; the walk-throughs of the other six notebooks of this chapter refer back to this explanation.

```
import json  # reads and writes JSON files (text files that hold names and numbers)
import os  # reads the environment variable TEXTBOOK_OUTPUT_ROOT (explained below)
import textwrap  # breaks long printed text into lines of at most 89 characters
from pathlib import Path  # file and folder paths that work on Windows, macOS and Linux
```

`import` loads a **module** (a part of Python or of an installed package) so that the code can use it. `json` reads and writes the text format JSON, in which the Revision record stores its results as names and values; `os` gives access to the computer's environment; `textwrap` breaks long text into lines; `from pathlib import Path` takes the single name `Path` out of the module `pathlib`. A `Path` is the address of a file or folder, written the same way on every operating system.

```
import matplotlib  # the plotting package
import matplotlib.pyplot as plt  # its drawing functions, called plt by convention
from IPython.display import Image, display  # shows a saved picture below a cell
```

These lines load the plotting package matplotlib, its drawing functions under the short name `plt`,

and the two functions `Image` and `display` of IPython (the part of Jupyter that runs Python code), which show a picture file below a cell.

```
NOTEBOOK_ID = "01f"  # this notebook: chapter 01, example f
```

A **variable** is a name for a value. This line gives the name `NOTEBOOK_ID` to the **string** (a text in quotes) `"01f"`. It is the only line of the set-up code that differs between notebooks; the figure files and the captions file are named after it.

```
def find_repository_root():
    """Return the repository folder (Dirac_claude).

    Jupyter runs a notebook in the folder that holds it.  Starting there, go up one
    folder at a time until a folder contains Revision/textbook/requirements.txt (the
    list of the book's packages); that folder is the repository."""
    here = Path.cwd().resolve()  # the folder in which this notebook runs
    for folder in [here, *here.parents]:  # this folder, its parent, its grandparent ...
        if (folder / "Revision" / "textbook" / "requirements.txt").is_file():
            return folder
    raise FileNotFoundError(
        "The repository folder was not found: open this notebook inside the folder "
        "Revision/textbook/notebooks of the repository Dirac_claude")
```

`def` defines a **function**: a named piece of code that runs when it is called. The text in triple quotes under the `def` line is its **docstring**, a description for the reader. `Path.cwd()` is the folder in which the notebook runs, and `.resolve()` writes it as a complete address. `here.parents` is the parent folder, its parent, and so on up to the top of the disk; `[here, *here.parents]` is the list that starts with `here` and continues with all of them (the star unpacks the parents into the list). The `for` loop takes the folders of this list one after the other. The operator `/` joins a folder and a name into a longer path, and `.is_file()` is true when that file exists. The first folder that contains `Revision/textbook/requirements.txt` is the repository, and `return` hands it back. If no folder qualifies, `raise` stops the notebook with a `FileNotFoundError` whose message says what to do.

```
# The repository folder.  It is never printed: it differs from computer to computer,
# and the printed output of a notebook must not.
REPO = find_repository_root()
# Every file is WRITTEN below OUTPUT_ROOT.  OUTPUT_ROOT is the repository folder unless
# the environment variable TEXTBOOK_OUTPUT_ROOT names another folder; the book's
# checking tool sets it, so that a check run writes into a scratch folder instead.
OUTPUT_ROOT = Path(os.environ.get("TEXTBOOK_OUTPUT_ROOT", str(REPO)))
```

The first code line calls the function and names its result `REPO`. The second chooses the folder below which the notebook writes its files. `os.environ` holds the **environment variables** of the running program (named texts that a program receives from the computer); `.get(name, default)` returns the value of `TEXTBOOK_OUTPUT_ROOT` if it is set and the default `str(REPO)` (the repository folder as a string) otherwise. When you run the notebook the variable is not set, so the files go into the repository; the book's checking tool sets it to a scratch folder, so that a check never changes the repository.

```
def repository_file(relative):
    """The path of the repository file relative, for READING (a Revision record)."""
    return REPO / relative

def output_file(relative):
    """The path at which to WRITE the repository file relative (its folder is made)."""
    path = OUTPUT_ROOT / relative
    path.parent.mkdir(parents=True, exist_ok=True)
    return path
```

`repository_file("Revision/...")` gives the full path of a file of the repository, for reading. `output_file("Revision/...")` gives the full path at which to write a file; `path.parent.mkdir(parents=True, exist_ok=True)` first creates the folder that will hold it, together with any missing folder above it, and does nothing if the folder exists.

```
def say(text):
    """Print text in lines of at most 89 characters (the width of a page of the book)."""
    print(textwrap.fill(str(text), width=89, subsequent_indent="    "))
```

`say` prints a text in lines of at most 89 characters, so that every printed line fits the width of a page of the book; `textwrap.fill` breaks the text at blanks, and every line after the first starts with four blanks. `str(text)` turns any value into a string first.

```
matplotlib.rcdefaults()  # ignore personal matplotlib settings: same figures everywhere
plt.rcParams.update({"figure.figsize": (7.0, 4.2), "font.size": 10.0,
                     "axes.grid": True, "grid.alpha": 0.3})
```

matplotlib reads personal settings from a file on your computer if you have one; `matplotlib.rcdefaults()` returns to the built-in settings, so that the figures are the same on every computer. `plt.rcParams.update({...})` then sets four settings for every figure: its size (7.0 inches wide, 4.2 inches high), the size of its letters (10 points), and a faint grid behind the curves (`grid.alpha` 0.3: 30 per cent opaque). The braces `{...}` make a **dictionary**: pairs of a key and a value, written `key: value`.

```
FIGURE_FOLDER = "Revision/textbook/figures"  # where the figures are saved
CAPTION_FILE = f"{FIGURE_FOLDER}/{NOTEBOOK_ID}.captions.json"  # their captions
FIGURE_NUMBERS = {}  # figure name -> its number k (file name <id>_<k>_<name>.png)
CAPTIONS = {}  # figure file name -> caption, written to CAPTION_FILE after every figure
# Start with an empty captions file ({} is an empty JSON dictionary); save_figure fills
# it.  newline="\n" writes the same line ends on Windows, macOS and Linux.
output_file(CAPTION_FILE).write_text("{}\n", encoding="utf-8", newline="\n")
```

A string that starts with `f` is an **f-string**: every name in braces is replaced by its value, so `CAPTION_FILE` is `"Revision/textbook/figures/01f.captions.json"`. `FIGURE_NUMBERS` and `CAPTIONS` start as empty dictionaries. The last line writes the text `{}` and a line end into the captions file: an empty list of captions, which `save_figure` fills. `encoding="utf-8"` fixes how the letters are stored as bytes.

```
def save_figure(fig, name, caption):
    """Save the figure fig as Revision/textbook/figures/<id>_<k>_<name>.png, record its
    caption in CAPTION_FILE, show the saved picture below the cell and close the figure.
    k counts the figures of the notebook 1, 2, 3, ...; a cell run again keeps its k."""
    number = FIGURE_NUMBERS.setdefault(name, len(FIGURE_NUMBERS) + 1)
    file_name = f"{NOTEBOOK_ID}_{number}_{name}.png"
    relative = f"{FIGURE_FOLDER}/{file_name}"
    # dpi=150: 150 dots per inch.  bbox_inches="tight": cut away the empty margin.
    # metadata={"Software": None}: no program name is stored in the PNG file, so that
    # every run writes exactly the same bytes.
    fig.savefig(output_file(relative), dpi=150, bbox_inches="tight",
                metadata={"Software": None})
    plt.close(fig)  # forget the figure, so that Jupyter does not draw it a second time
    CAPTIONS[file_name] = caption
    output_file(CAPTION_FILE).write_text(
        json.dumps(CAPTIONS, indent=1, sort_keys=True) + "\n", encoding="utf-8",
        newline="\n")
    display(Image(filename=str(output_file(relative))),
            metadata={"textbook_figure": file_name})  # the saved picture itself
    say(f"Figure {NOTEBOOK_ID}.{number} saved as {relative}")
```

This function saves a figure and shows it. `setdefault(name, value)` returns the number already stored for this figure name, or stores and returns `len(FIGURE_NUMBERS) + 1` (one more than the number of figures so far) for a new name; so the figures are numbered 1, 2, 3, ... and a cell run twice keeps the number of its figure. The file name is the notebook's name, the number and the figure's name, for example `01f_1_decimal_periods.png`. `fig.savefig` writes the picture as a PNG file with 150 dots per inch, cuts away the empty margin and stores no program name in the file, so that two runs write exactly the same bytes. `plt.close(fig)` removes the figure from memory, because Jupyter would otherwise draw it a second time at the end of the cell. The caption is stored in `CAPTIONS`, and the whole dictionary is written into the captions file (`json.dumps` turns it into JSON text with one entry per line, the keys sorted). `display(Image(...))` shows the saved picture below the cell; the `metadata` entry tells the book's tools which file the picture is. The last line prints where the figure was saved, for example `Figure 01f.1 saved as Revision/textbook/figures/01f_1_decimal_periods.png`.

```
PASSED = []  # the names of the checks that passed, in order

def check(condition, name, record=None):
    """A check.  If condition is False, stop with an AssertionError that names the
    check (an if statement is used instead of assert, because python -O would skip an
    assert).  Otherwise print "PASS <name>" and, when the check reproduces a Revision
    record, a second line naming the record file and its check."""
    if not condition:
        raise AssertionError(f"check failed: {name}")
    PASSED.append(name)
    say(f"PASS {name}")
    if record is not None:
        say(f"     reproduces {record}")
```

`PASSED` is an empty **list** (an ordered collection, written with square brackets). `check` is the function behind every check of the book. `condition` is a statement that is either true (`True`) or false (`False`).

If it is false, `raise AssertionError(...)` stops the notebook with an error that names the check. (Python's own statement `assert` would do the same, but Python started with the option that optimises the code skips every `assert`; an `if` statement is never skipped.) If it is true, the name is appended to `PASSED` and the line PASS followed by the name is printed. `record=None` makes the third argument optional: a check that reproduces a number of the Revision record passes the record's file and check name, and `check` prints them on a second line that starts with reproduces.

```
def report(label, value, unit=""):
    """Print a key number as a line "RESULT <label> = <value> <unit>"."""
    say(f"RESULT {label} = {value}" + (f" {unit}" if unit else ""))

def all_checks_passed():
    """Print the last line of the notebook: how many checks passed."""
    print(f"ALL {len(PASSED)} CHECKS PASSED (notebook {NOTEBOOK_ID})")

say(f"Set-up of notebook {NOTEBOOK_ID} complete: repository folder found, helpers "
    "defined.")
```

`report` prints a key number as a line that starts with RESULT; `(f" {unit}" if unit else "")` adds a blank and the unit when a unit is given and nothing otherwise. `all_checks_passed` prints the last line of every notebook; `len(PASSED)` is the number of checks that passed. The last statement prints the one output line of In [1]: Set-up of notebook 01f complete: repository folder found, helpers defined. (Two strings written next to each other, as here on two lines, are joined by Python into one.)

In [2], whole numbers and fractions.

```
import fractions  # exact fractions p/q
import math  # factorial, gcd, isqrt, e, log

import mpmath  # numbers with many digits
import numpy as np  # arrays of floating-point numbers
import sympy as sp  # exact algebra with symbols
```

The module `fractions` (part of Python) computes with exact fractions; `math` holds functions of single numbers: `math.factorial`, `math.gcd` (the greatest common divisor), `math.isqrt` (the whole part of a square root, computed exactly), the number `math.e` and the logarithm `math.log`. The package mpmath computes with as many decimal digits as requested; numpy (short name `np`) computes with **arrays**, lists of floating-point numbers on which arithmetic acts entry by entry; sympy (short name `sp`) does exact algebra with symbols.

```
big = 2 ** 100
say(f"2^100 = {big} ({len(str(big))} digits)")
say(f"16! = {math.factorial(16)}")
check(big == 1267650600228229401496703205376 and len(str(big)) == 31
      and math.factorial(16) == 20922789888000,
      "2^100 and 16! are computed exactly")
```

In Python ** means "to the power", so 2 ** 100 is 2^{100}. str(big) writes the number as a string of digits and len(...) counts them. The check compares both numbers with their exact values, digit for digit (the operator == tests equality, and requires both conditions). Output: 2^100 = 1267650600228229401496703205376 (31 digits), 16! = 20922789888000, and the PASS line.

```
third, sixth = fractions.Fraction(1, 3), fractions.Fraction(1, 6)
say(f"1/3 + 1/6 = {third + sixth}")
check(third + sixth == fractions.Fraction(1, 2), "1/3 + 1/6 = 1/2 exactly")
```

fractions.Fraction(1, 3) is the exact number 1/3; the first line names two fractions at once (Python assigns the values on the right to the names on the left in order). Their sum is computed exactly as in Section 1.2 and printed as 1/2; the check confirms it.

```
reduced = fractions.Fraction(84, 126)  # Fraction always cancels common factors
say(f"gcd(84, 126) = {math.gcd(84, 126)}, 84/126 = {reduced}")
check(math.gcd(84, 126) == 42 and reduced == fractions.Fraction(2, 3)
      and (reduced.numerator, reduced.denominator) == (2, 3),
      "84/126 = 2/3 in lowest terms, with gcd(84, 126) = 42")
```

A Fraction is always stored in lowest terms, so Fraction(84, 126) becomes 2/3; .numerator and .denominator read its two parts. The check confirms $\gcd(84, 126) = 42$ and the lowest terms of Section 1.2. Output: gcd(84, 126) = 42, 84/126 = 2/3 and the PASS line.

In [3], long division.

```
def decimal_digits(p, q):
    """The decimal digits of p/q (0 < p < q) by long division: the digits before
    the repeating block, and the repeating block (empty if the division ends)."""
    digits = []
    first_seen = {}  # remainder -> the place of the digit it produced first
    remainder = p
    while remainder != 0 and remainder not in first_seen:
        first_seen[remainder] = len(digits)
        remainder *= 10
        digits.append(remainder // q)  # the next digit
        remainder %= q  # what is left
    if remainder == 0:
        return digits, []
    start = first_seen[remainder]  # the remainder came back: the digits repeat
    return digits[:start], digits[start:]
```

This is long division exactly as in Section 1.2. digits collects the digits; the dictionary first_se en remembers, for each remainder met so far, the place of the digit that it produced. The while loop runs as long as its condition is true: the remainder is not 0 (!= means "is not equal to") and has not been seen before. Inside, the present remainder is recorded with its place, multiplied by 10 (remainder *= 10 is short for remainder = remainder * 10), the whole part of the division by q (//, division without the remainder) is appended as the next digit, and remainder %= q keeps what is left (% gives the remainder of a division). When the loop stops, either the remainder is 0 (the division has ended, and the function returns the digits and an empty block []), or a remainder

has come back; then the digits from its first place on repeat. `digits[:start]` is the part of the list before place `start`, `digits[start:]` the part from there on. The function returns both lists.

```
def from_digits(head, block):
    """The fraction with the digits head followed by block repeated for ever."""
    k, m = len(head), len(block)
    D = int("".join(map(str, head)) or "0")
    value = fractions.Fraction(D, 10 ** k)
    if block:
        C = int("".join(map(str, block)))
        value += fractions.Fraction(C, 10 ** k * (10 ** m - 1))
    return value
```

This function turns the digits back into the fraction with the formula $D/10^k + C/(10^k(10^m - 1))$ of Section 1.2. `map(str, head)` turns every digit into a one-letter string, `"".join(...)` glues them into one string, and `int(...)` reads it as the whole number D; when there are no digits before the block, the empty string is replaced by `"0"` (`or` takes its right side when the left side is empty). `if block:` is true when the block is not empty; then the block's whole number C is made the same way and its value is added.

```
all_back = True
for p, q in [(1, 4), (1, 3), (1, 6), (1, 7), (5, 12), (1, 97)]:
    head, block = decimal_digits(p, q)
    head_text = "".join(map(str, head))
    block_text = "(" + "".join(map(str, block)) + ")" if block else ""
    text = "0." + head_text + block_text
    if len(text) > 40:  # 1/97 has a block of 96 digits: show its length only
        text = f"0.({len(block)} repeating digits)"
    say(f"{p}/{q} = {text}, period {len(block)}")
    all_back &= from_digits(head, block) == fractions.Fraction(p, q)
check(decimal_digits(1, 7) == ([], [1, 4, 2, 8, 5, 7]) and all_back,
      "1/7 = 0.(142857), and the digits of all six examples give the fractions back")
```

The loop takes six fractions. For each it computes the digits, writes them as text with the repeating block in brackets (`... if block else ""`: the bracketed block when there is one, nothing otherwise), and prints the result with its period, the length of the block. For 1/97 the text would be too long for a line, so only the length 96 is printed. `all_back &= ...` is short for `all_back = all_back and ...`: it stays true only if every fraction is recovered from its digits. The check also compares the digits of 1/7 with the hand calculation. Output: $1/4 = 0.25$ (period 0), $1/3 = 0.(3)$, $1/6 = 0.1(6)$, $1/7 = 0.(142857)$ (period 6), $5/12 = 0.41(6)$, 1/97 with 96 repeating digits, and the PASS line.

In [4], which fractions end, and the plot of the periods.

```
def only_twos_and_fives(q):
    """True if q has no prime factor other than 2 and 5."""
    for factor in (2, 5):
        while q % factor == 0:
            q //= factor
    return q == 1
```

The function divides q by 2 as long as it can (`q % factor == 0`: the remainder is 0), then by 5 as long as it can; `q //= factor` is short for `q = q // factor`. If 1 is left, q had no other prime factor.

```
qs = list(range(2, 301))
periods = [len(decimal_digits(1, q)[1]) for q in qs]
check(all((period == 0) == only_twos_and_fives(q) for q, period in zip(qs, periods))
      and all(period <= q - 1 for q, period in zip(qs, periods)),
      "1/q ends exactly when q = 2^a 5^b, and the period is at most q - 1 "
      "(q = 2 to 300)")
```

`range(2, 301)` counts from 2 up to 300 (the end 301 is not included), and `list(...)` makes it a list. The second line is a **list comprehension**: for every q it computes the digits of $1/q$, takes the block (entry `[1]` of the pair returned by `decimal_digits`) and its length. `zip(qs, periods)` pairs each q with its period. `all(...)` is true when the condition holds for every pair: the period is 0 exactly when $q = 2^a 5^b$ (the theorem of Section 1.2), and it never exceeds $q - 1$.

```
full = [q for q, period in zip(qs, periods) if period == q - 1]
say(f"q with the full period q - 1: {full[:12]} ... ({len(full)} of them)")
```

`full` collects the denominators with the largest possible period $q - 1$; the line prints the first twelve (`full[:12]`) and their number: 7, 17, 19, 23, 29, 47, 59, 61, 97, 109, 113, 131, ... (23 of them).

```
fig, ax = plt.subplots(figsize=(8.0, 4.4))
ax.plot(qs, periods, ".", color="tab:blue", label="period of $1/q$")
ax.plot(full, [q - 1 for q in full], "o", color="tab:red", fillstyle="none",
        label="full period $q - 1$")
ax.plot([2, 300], [1, 299], "k:", lw=1, label="the largest possible: $q - 1$")
ax.set_xlabel("denominator $q$")
ax.set_ylabel("length of the repeating block")
ax.set_title("Decimal expansion of $1/q$: the period")
ax.legend(loc="upper left", fontsize=8);
save_figure(fig, "decimal_periods",
            "The length of the repeating block (the period) of the decimal digits "
            ...)
```

`plt.subplots(figsize=(8.0, 4.4))` makes a new figure `fig`, 8 inches wide and 4.4 high, with one pair of axes `ax`. `ax.plot(xs, ys, style)` draws the points with these coordinates: `"."` small dots (the periods), `"o"` with `fillstyle="none"` open red circles (the full periods), and `"k:"` a black (`k`) dotted (`:`) line of width 1 (`lw=1`) from $(2, 1)$ to $(300, 299)$, the line $q - 1$. `label=` names a curve in the legend; text between dollar signs is typeset as mathematics. The next three lines label the axes and set the title; `ax.legend(...)` draws the legend in the upper left corner with small letters. The semicolon at the end of that line keeps Jupyter from printing the value of the line (a description of the legend with a memory address, which would differ from run to run). `save_figure` saves Figure 01f.1 with its caption. What Figure 01f.1 shows: every dot lies on or below the dotted line, the dots at 0 are the denominators $2^a 5^b$, and the red circles are the primes that reach the bound $q - 1$.

In [5], the square root of 2 is not a fraction; fractions that come close.

```
# isqrt(n) is the whole part of the square root of n, computed exactly:
no_solution = all(math.isqrt(2 * q * q) ** 2 != 2 * q * q for q in range(1, 10001))
check(no_solution, "p^2 = 2 q^2 has no solution in whole numbers with q <= 10000")
```

If $p^2 = 2q^2$ had a solution, p would be the whole number isqrt$(2q^2)$ and its square would equal $2q^2$. The line tests this for every q from 1 to 10000 with exact whole numbers and finds no solution, as the proof of Section 1.3 says.

```
mpmath.mp.dps = 50  # 50 significant digits
root2 = mpmath.sqrt(2)
convergents = [(1, 1)]
while len(convergents) < 12:
    p, q = convergents[-1]
    convergents.append((p + 2 * q, p + q))  # the rule p' = p + 2q, q' = p + q
```

`mpmath.mp.dps = 50` makes mpmath compute with 50 significant decimal digits (`dps`: decimal places), so `root2` is $\sqrt{2}$ to 50 digits. The list `convergents` starts with the pair $(1, 1)$; the loop takes the last pair (`[-1]` is the last entry of a list), applies the rule of Section 1.3 and appends the new pair, until there are 12 pairs.

```
for p, q in convergents:
    error = abs(mpmath.mpf(p) / q - root2)
    say(f"{p}/{q}: p^2 - 2 q^2 = {p * p - 2 * q * q:+d}, error "
        f"{mpmath.nstr(error, 3)}, error q^2 = {mpmath.nstr(error * q * q, 6)}")
```

For each fraction, `mpmath.mpf(p)` makes p an mpmath number, so that p/q is computed to 50 digits; `abs` is the absolute value. The printed line gives $p^2 - 2q^2$ with its sign (`:+d` prints a whole number with a sign), the error with 3 significant digits (`mpmath.nstr(x, 3)`) and the error times q^2 with 6. The output shows the signs $-1, +1, -1, \ldots$ and the error times q^2 settling at 0.353553 from 577/408 on.

```
signs = [p * p - 2 * q * q for p, q in convergents]
check(signs == [(-1) ** (k + 1) for k in range(12)],
      "p^2 - 2 q^2 = -1, +1, -1, ... for the 12 fractions")
p, q = convergents[-1]
limit_value = 1 / (2 * root2)
check(abs(abs(mpmath.mpf(p) / q - root2) * q * q - limit_value) < mpmath.mpf("1e-6"),
      "the error of p/q times q^2 approaches 1/(2 sqrt 2) = 0.35355")
```

The first check compares the list of the values $p^2 - 2q^2$ with $(-1)^{k+1}$ for $k = 0, \ldots, 11$, that is $-1, +1, -1, \ldots$, as derived in Section 1.3. The second takes the last fraction, 19601/13860, and checks that its error times q^2 differs from $1/(2\sqrt{2}) = 0.35355\ldots$ by less than 10^{-6} (`mpmath.mpf("1e-6")` is 10^{-6} as an mpmath number).

In [6], bisection, and the best fractions with each denominator.

```
low, high = fractions.Fraction(1), fractions.Fraction(2)  # 1^2 < 2 < 2^2
widths = [high - low]
```

```
for step in range(60):
    middle = (low + high) / 2
    if middle * middle < 2:
        low = middle  # the root is in the right half
    else:
        high = middle  # the root is in the left half
    widths.append(high - low)
```

This is bisection as described in Section 1.3, with exact fractions: the interval starts as $[1, 2]$; each of the 60 passes computes the middle, keeps the half that contains $\sqrt{2}$ (`if ... else` runs the first block when the condition is true and the second otherwise), and records the new width.

```
low_mp = mpmath.mpf(low.numerator) / low.denominator
high_mp = mpmath.mpf(high.numerator) / high.denominator
say(f"after 60 halvings: {mpmath.nstr(low_mp, 20)} < sqrt 2 < "
    f"{mpmath.nstr(high_mp, 20)}")
say(f"sqrt 2 with 30 digits: {mpmath.nstr(root2, 30)}")
check(low * low < 2 < high * high and high - low == fractions.Fraction(1, 2 ** 60)
      and low_mp < root2 < high_mp,
      "60 halvings: exact fractions low < sqrt 2 < high with high - low = 2^(-60)")
```

The two ends are turned into 50-digit numbers and printed with 20 significant digits, and $\sqrt{2}$ itself with 30 digits:

```
after 60 halvings: 1.4142135623730950483 < sqrt 2 < 1.4142135623730950492
sqrt 2 with 30 digits: 1.41421356237309504880168872421
```

Python allows chained comparisons, `a < b < c`, meaning $a < b$ and $b < c$. The check confirms with exact fractions that $\text{low}^2 < 2 < \text{high}^2$ and that the width is exactly 2^{-60}, and with 50-digit numbers that $\sqrt{2}$ lies between the ends.

```
denominators = np.arange(1, 1001)
best_p = np.rint(denominators * np.sqrt(2.0))  # the nearest numerator for each q
best_error = np.abs(best_p / denominators - np.sqrt(2.0))
```

`np.arange(1, 1001)` is the array of the whole numbers 1 to 1000. For each denominator q the best numerator is the whole number nearest to $q\sqrt{2}$ (`np.rint` rounds to the nearest whole number), and `best_error` is the array of the 1000 errors $|p/q - \sqrt{2}|$, computed in floating point (good enough for a picture).

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.3))
left.semilogy(range(61), [float(w) for w in widths], "o-", ms=3)
left.set_xlabel("number of halvings")
left.set_ylabel("width of the interval (logarithmic scale)")
left.set_title("bisection: $\\sqrt{2}$ between two fractions")
```

`plt.subplots(1, 2, ...)` makes a figure with two pairs of axes side by side, named `left` and `right`. `semilogy` draws with a logarithmic vertical axis; the widths (turned into floating-point

numbers with `float`) are drawn against the step number as dots joined by lines (`"o-"`, marker size `ms=3`). In a string in Python a backslash has a special meaning, so the LaTeX command `\sqrt` is written with two backslashes.

```
right.loglog(denominators, best_error, ".", ms=3, color="0.6",
             label="best $p/q$ for each $q$")
conv_q = [q for _, q in convergents if q <= 1000]
conv_error = [float(abs(mpmath.mpf(p) / q - root2)) for p, q in convergents
              if q <= 1000]
right.loglog(conv_q, conv_error, "o", color="tab:red",
             label="$1/1, 3/2, 7/5, 17/12, \\dots$")
right.loglog(denominators, 1 / (2 * np.sqrt(2.0) * denominators ** 2.0), "k--",
             lw=1, label="$1/(2\\sqrt{2}\\,q^2)$")
right.set_xlabel("denominator $q$")
right.set_ylabel("error $|p/q - \\sqrt{2}|$")
right.set_title("the best fractions near $\\sqrt{2}$")
right.legend(fontsize=8, loc="lower left")
fig.tight_layout()
save_figure(fig, "square_root_of_two",
            "Left: the width of the interval between two fractions that contains "
            ...)
```

On the right panel, `loglog` makes both axes logarithmic. The 1000 best errors are drawn as grey dots (`color="0.6"` is a grey of brightness 60 per cent); the fractions of In [5] with $q \le 1000$ (the name `_` marks a value that is not used) as red circles; and the line $1/(2\sqrt{2}\,q^2)$ as a black dashed line (the style string made of the letter k and two hyphens). `fig.tight_layout()` arranges the two panels so that their labels do not overlap. What Figure 01f.2 shows: on the left a straight falling line (each step halves the width); on the right no error is zero, and the red fractions lie on the dashed line, as close to $\sqrt{2}$ as $1/q^2$ allows.

In [7], floating-point numbers.

```
total = 0.1 + 0.2
stored = fractions.Fraction(0.1)  # the exact value of the floating-point number 0.1
say(f"0.1 + 0.2 = {total:.17f} (17 digits), and 0.3 = {0.3:.17f}")
say(f"0.1 is stored as {stored.numerator}/{stored.denominator}")
check(total != 0.3 and stored != fractions.Fraction(1, 10)
      and stored.denominator == 2 ** 55,
      "0.1 + 0.2 is not 0.3 in floating point, and 0.1 is stored as a fraction "
      "with the denominator 2^55")
```

`fractions.Fraction(0.1)` reads the exact value of the floating-point number that Python stores for 0.1. `{total:.17f}` prints a number with 17 digits after the point. Output: 0.1 + 0.2 = 0.30000000000000004 and 0.3 = 0.29999999999999999 (the stored values, as Section 1.4 explains), and 0.1 is stored as 3602879701896397/36028797018963968, whose denominator is 2^{55}. The check confirms all three statements.

```
eps = float(np.finfo(float).eps)  # machine epsilon
say(f"machine epsilon = {eps!r} = 2^-52: {eps == 2.0 ** -52}")
check(eps == 2.0 ** -52 and 1.0 + eps != 1.0 and 1.0 + eps / 2 == 1.0,
```

```
      "1 + eps is the next number after 1; 1 + eps/2 is rounded back to 1")
check(float(2 ** 53 + 1) == float(2 ** 53) and float(2 ** 53 - 1) != float(2 ** 53),
      "2^53 + 1 cannot be stored: it is rounded to 2^53")
```

`np.finfo(float).eps` is machine epsilon as numpy knows it; `{eps!r}` prints it with all its digits, 2.220446049250313e-16 (the letter e followed by a number means "times ten to the power": `e-16` is 10^{-16}), and the comparison with `2.0 ** -52` prints True. The first check is the statement of Section 1.4 about $1 + \varepsilon$ and $1 + \varepsilon/2$. The second converts the exact whole numbers $2^{53} + 1$ and $2^{53} - 1$ to floating point (`float(...)`): the first is rounded to 2^{53}, the second is stored exactly.

```
xs = np.logspace(-3, 20, 2301)  # 2301 numbers from 0.001 to 10^20
fraction_part, exponent = np.frexp(xs)  # xs = fraction_part * 2^exponent
predicted = np.ldexp(1.0, exponent - 53)  # 2^(exponent - 53)
check(bool(np.all(np.spacing(xs) == predicted))
      and bool(np.all(np.spacing(xs) <= eps * xs)),
      "the step after x is 2^(e - 53), never more than eps x (2301 values of x)")
```

`np.logspace(-3, 20, 2301)` makes 2301 numbers from 10^{-3} to 10^{20} that are equally spaced on a logarithmic axis. `np.frexp` writes each as $f \cdot 2^e$ with $\frac{1}{2} \le f < 1$ and returns the arrays of f and e; `np.ldexp(1.0, e - 53)` computes $1 \cdot 2^{e-53}$, the step predicted in Section 1.4. `np.spacing(x)` is the actual distance from x to the next floating-point number. The check requires the two to agree exactly at all 2301 numbers, and the step never to exceed εx. (`np.all` is numpy's version of `all`; `bool(...)` turns its answer into a plain True or False.)

In [8], the picture of the spacing.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.4))
big_x = np.logspace(48, 57, 2000, base=2.0)  # from 2^48 to 2^57
left.loglog(big_x, np.spacing(big_x), color="tab:blue", lw=1.5, base=2,
            label="step to the next floating-point number")
left.axvline(2.0 ** 53, color="tab:red", lw=1, label="$x = 2^{53}$")
left.axhline(1.0, color="tab:red", ls=":", lw=1, label="step 1")
left.set_xlabel("number $x$ (logarithmic axis, base 2)")
left.set_ylabel("step size (logarithmic axis, base 2)")
left.set_title("the step doubles at every power of 2")
left.legend(fontsize=8, loc="upper left")
```

The left panel uses 2000 numbers from 2^{48} to 2^{57} (`base=2.0`: equally spaced on a logarithmic axis of base 2) and draws the step against x with both axes logarithmic in base 2. `axvline` draws a vertical line at $x = 2^{53}$, `axhline` a horizontal dotted line (`ls=":"`) at the step 1.

```
right.semilogx(xs, np.spacing(xs) / xs, color="tab:blue", lw=1,
               label="step divided by $x$")
right.axhline(eps, color="black", ls="--", lw=1, label="$\\varepsilon = 2^{-52}$")
right.axhline(eps / 2, color="black", ls=":", lw=1, label="$\\varepsilon/2$")
right.set_ylim(0.0, 1.35 * eps)
right.set_xlabel("number $x$")
right.set_ylabel("relative step")
right.set_title("the relative step is the same at every size")
```

```
right.legend(fontsize=8, loc="lower right")
fig.tight_layout()
save_figure(fig, "float_spacing",
            "How far apart floating-point numbers are. Left: the distance from a "
            ...)
```

The right panel draws the relative step, step divided by x, for the 2301 numbers of In [7] with a logarithmic horizontal axis (`semilogx`), and the two horizontal lines ε (dashed) and $\varepsilon/2$ (dotted). `set_ylim` fixes the vertical range from 0 to $1.35\,\varepsilon$. What Figure 01f.3 shows: on the left a staircase that doubles at every power of 2 and reaches the step 2 right of $x = 2^{53}$; on the right a sawtooth that always stays between $\varepsilon/2$ and ε, the bounds proved in Section 1.4.

In [9], cancellation and its cure.

```
x = sp.Symbol("x", positive=True)
limit_at_zero = sp.limit((1 - sp.cos(x)) / x ** 2, x, 0)
say(f"sympy: the limit of (1 - cos x)/x^2 at x = 0 is {limit_at_zero}")
check(limit_at_zero == sp.Rational(1, 2)
      and sp.simplify(1 - sp.cos(x) - 2 * sp.sin(x / 2) ** 2) == 0,
      "the limit is 1/2, and 1 - cos x = 2 sin(x/2)^2 exactly")
```

`sp.Symbol("x", positive=True)` makes a sympy symbol, a letter that stands for any positive number. `sp.limit(f, x, 0)` computes the limit of the expression as x tends to 0 exactly: $1/2$ (`sp.Rational(1, 2)` is sympy's exact fraction). `sp.simplify(...) == 0` asks sympy to prove that $1 - \cos x - 2\sin^2(x/2)$ is zero for every x: the identity derived in Section 1.4.

```
x_values = np.logspace(-9, 0, 361)
naive = (1 - np.cos(x_values)) / x_values ** 2
stable = 2 * np.sin(x_values / 2) ** 2 / x_values ** 2
mpmath.mp.dps = 50
exact = np.array([float((1 - mpmath.cos(mpmath.mpf(v))) / mpmath.mpf(v) ** 2)
                  for v in x_values.tolist()])  # mpf(v) is the stored value of v
error_naive = np.abs(naive - exact) / exact
error_stable = np.abs(stable - exact) / exact
```

361 values of x from 10^{-9} to 1. `naive` is the formula as written, `stable` the rewritten one, both in floating point. `exact` computes the same function with 50 digits for each value (`x_values.tolist()` turns the array into a plain list; `mpmath.mpf(v)` takes the stored floating-point value exactly, so that all three use the same x) and rounds the result to a floating-point number. The last two lines are the relative errors.

```
report("largest relative error of 2 sin(x/2)^2/x^2", f"{error_stable.max():.1e}")
report("largest relative error of (1 - cos x)/x^2", f"{error_naive.max():.1e}")
check(float(error_stable.max()) < 1e-15,
      "the rewritten formula is correct to 1e-15 at all 361 values of x")
check((1 - math.cos(1e-8)) / 1e-8 ** 2 == 0.0
      and float(error_naive[x_values <= 1e-4].max()) > 1e-3,
      "the formula as written gives 0 at x = 1e-8: cancellation destroyed every digit")
```

The two RESULT lines print the largest relative errors with two significant digits (`.1e`: one digit after the point, in the e-notation): 4.4e-16 for the rewritten formula and 1.0e+00 for the formula as written. The first check requires the rewritten formula to be right to 10^{-15} everywhere. The second confirms that the formula as written gives exactly 0 at $x = 10^{-8}$ (`1e-8` is 10^{-8}) and that its error exceeds 10^{-3} somewhere among the values $x \le 10^{-4}$ (`error_naive[x_values <= 1e-4]` keeps only the errors at these values).

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
floor = 1e-18  # an error 0 is drawn at the bottom of the axis
ax.loglog(x_values, np.maximum(error_naive, floor), ".", ms=3, color="tab:red",
          label="$(1 - \\cos x)/x^2$ as written")
ax.loglog(x_values, np.maximum(error_stable, floor), ".", ms=3, color="tab:blue",
          label="$2\\sin^2(x/2)/x^2$")
ax.loglog(x_values, 2 * eps / x_values ** 2, "k--", lw=1,
          label="$2\\varepsilon/x^2$")
ax.set_ylim(0.5 * floor, 10.0)
ax.set_xlabel("$x$")
ax.set_ylabel("relative error")
ax.set_title("Cancellation and its cure")
ax.legend(fontsize=8, loc="upper right");
save_figure(fig, "cancellation",
            "The relative error of two formulas for $(1 - \\cos x)/x^2$ against $x$ "
            ...)
```

A logarithmic axis cannot show the value 0, so `np.maximum(error, floor)` replaces every error below 10^{-18} by 10^{-18}, which puts exact results at the bottom of the axis. The two error curves and the estimate $2\varepsilon/x^2$ of Section 1.4 are drawn on logarithmic axes. What Figure 01f.4 shows: the red dots follow the dashed line upwards as x shrinks and reach an error of 100 per cent below about $x = 10^{-8}$; the blue dots stay at the rounding level of about 10^{-16}.

In [10], the laws of powers.

```
a, b = sp.symbols("a b", positive=True)
p_sym, q_sym = sp.symbols("p q", real=True)
laws = [a ** p_sym * a ** q_sym - a ** (p_sym + q_sym),
        (a ** p_sym) ** q_sym - a ** (p_sym * q_sym),
        (a * b) ** p_sym - a ** p_sym * b ** p_sym,
        a ** (-p_sym) - 1 / a ** p_sym,
        sp.sqrt(a) - a ** sp.Rational(1, 2)]
check(all(sp.simplify(law) == 0 for law in laws),
      "the five laws of powers hold for positive a, b and real p, q")
```

`sp.symbols("a b", positive=True)` makes two symbols for positive numbers, the next line two for real numbers. Each entry of the list `laws` is the difference of the two sides of one law of Section 1.5; the check asks sympy to simplify each difference to 0. Because sympy knows that a and b are positive, it may use the laws; it would refuse for symbols of unknown sign.

```
y = sp.Symbol("y", real=True)  # a real number of either sign
say(f"sympy: sqrt(y^2) = {sp.sqrt(y ** 2)}; numbers: sqrt((-2)^2) = "
    f"{((-2.0) ** 2) ** 0.5}")
```

```
check(sp.sqrt(y ** 2) == sp.Abs(y) and ((-2.0) ** 2) ** 0.5 == 2.0,
      "sqrt(y^2) = |y|: for negative numbers the law (a^p)^q = a^(pq) fails")
```

For a real symbol of either sign sympy writes $\sqrt{y^2}$ as `Abs(y)`, the absolute value; the number example computes $((-2)^2)^{1/2} = 2$, not $(-2)^{2 \cdot 1/2} = -2$. Output: sympy: sqrt(y^2) = Abs(y); numbers: sqrt((-2)^2) = 2.0, and the PASS line.

```
s_pos, a_real = sp.Symbol("s", positive=True), sp.Symbol("a", real=True)
example = 1 / sp.sqrt(s_pos ** sp.Rational(1, 3) / sp.exp(2 * a_real))
check(sp.simplify(example - sp.exp(a_real) / s_pos ** sp.Rational(1, 6)) == 0,
      "1/sqrt(s^(1/3)/e^(2a)) = e^a/s^(1/6)")
```

The worked example of Section 1.5, with $s > 0$ and real a; `sp.exp` is the exponential function. sympy confirms the result $e^a / s^{1/6}$.

In [11], the length factors of the author's metric, from the record.

```
S, C = sp.symbols("S C", positive=True)  # S = sin z, C = cos z, both > 0
a4 = sp.Symbol("a4", real=True)  # the value of a4(x4) at one time
b4 = sp.Symbol("b4", positive=True)  # the value of b4(x4) at one time
```

Two positive symbols stand for $\sin z$ and $\cos z$ (both are positive for $0 < z < \pi/2$), a real symbol for the value of a_4 at one time, and a positive symbol for the value of b_4 at one time.

```
def from_record(text):
    """The record's Mathematica text as sympy, with sin z = S and cot z = C/S."""
    text = text.replace("a4[x4]", "a4").replace("b4[x4]", "b4")
    text = text.replace("Sin[6*H*x0]", "S")
    text = text.replace("Cot[6*H*x0]", "(C/S)").replace("^", "**")
    return sp.sympify(text, locals={"a4": a4, "b4": b4, "S": S, "C": C, "E": sp.E})
```

The Revision record stores the metric as text in the notation of the program Mathematica, for example `E^(2*a4[x4])*Sin[6*H*x0]^(1/3)`. `from_record` translates such a text into a sympy expression: `.replace(old, new)` replaces every occurrence of a piece of text, here the function values `a4[x4]` and `b4[x4]` by the symbol names `a4` and `b4`, $\sin(6Hx_0)$ by `S`, $\cot(6Hx_0)$ by `(C/S)`, and Mathematica's power sign `^` by Python's `**`. `sp.sympify` then reads the text as a sympy expression; `locals` tells it which symbol each name means (`E` is the number e).

```
curvature = json.loads(repository_file("Revision/gkd_lovelock/results/curvature.json")
                       .read_text(encoding="utf-8"))
eta = json.loads(repository_file("Revision/algebra/gammas.json")
                 .read_text(encoding="utf-8"))["eta"]  # +1 or -1 for x0 ... x7
metric = [from_record(text) for text in curvature["metricDiagonal"]]
sizes = [eta[mu] * metric[mu] for mu in range(8)]  # |g_mu mu| = eta_mu mu g_mu mu
check(all(size.is_positive for size in sizes),
      "every entry of the metric has the sign of eta: eta_mu mu g_mu mu > 0")
```

`read_text` reads a file of the repository as text, and `json.loads` turns the JSON text into a Python dictionary. From the record file `curvature.json` the cell takes the list `metricDiagonal` (the eight diagonal entries as texts, in the order $x_0, \ldots, x_7$); from `gammas.json` it takes the list `eta` of the signs $+1$ or -1 of the eight directions (the **frame metric**, Section 1.27). `metric` is the list of the eight entries as sympy expressions. Multiplying each entry by its sign gives its size $|g_{\mu\mu}|$; the check asks sympy whether each size is positive (`.is_positive`), which it can decide because S, C, b_4 and $e^{\pm 2a_4}$ are positive.

```
factors = [sp.sqrt(size) for size in sizes]  # the length factors
# the author's order x0, x1, ..., x7
expected = ([C / S] + [sp.exp(a4) * S ** sp.Rational(1, 6)] * 3 + [sp.Integer(1)]
            + [sp.sqrt(b4) * sp.exp(-a4) * S ** sp.Rational(1, 6)] * 3)
for mu in range(8):
    say(f"x{mu}: g = {metric[mu]}, length factor {factors[mu]}")
check(len(factors) == 8 and
      all(sp.simplify(f - e) == 0 for f, e in zip(factors, expected)),
      "the length factors: cot z = C/S for x0, e^a4 S^(1/6) for x1 to x3, 1 for x4, "
      "b4^(1/2) e^(-a4) S^(1/6) for x5 to x7")
```

`factors` are the eight square roots. `expected` is the list of Section 1.5 in the author's order: $\cot z = C/S$ for x_0, three times the space factor, 1 for the time, three times the extra-time factor (a list multiplied by 3 repeats its entry three times, and `+` joins lists). The loop prints, for each direction x_μ (Python's index `mu` is the author's index, both counting from 0), the entry and its factor; sympy writes e^{a_4} as `exp(a4)`, $S^{1/6}$ as `S**(1/6)` and $b_4^{1/2}$ as `sqrt(b4)`. The check confirms that there are eight factors and that each equals the expected one.

```
product = sp.simplify(sp.Mul(*factors))
record_root = sp.simplify(from_record(curvature["sqrtAbsDetG"]))
say(f"product of the eight factors = {product}; the record's sqrtAbsDetG = "
    f"{record_root}")
lovelock_report = json.loads(repository_file(
    "Revision/gkd_lovelock/results/python-lovelock-report.json")
    .read_text(encoding="utf-8"))
root_verdict = {c["name"]: c["verdict"]
                for c in lovelock_report["checks"]}["sqrt_abs_det_g"]
check(sp.simplify(product - b4 ** sp.Rational(3, 2) * C) == 0
      and sp.simplify(record_root - b4 ** sp.Rational(3, 2) * C) == 0
      and root_verdict == "PASS",
      "the product of the length factors is b4^(3/2) cos z, the record's "
      "sqrt|det g| = b4^(3/2) sin z cot z, for every a4",
      record="Revision/gkd_lovelock/results/curvature.json, sqrtAbsDetG; "
             "python-lovelock-report.json, check sqrt_abs_det_g")
```

`sp.Mul(*factors)` multiplies the eight factors (the star hands the list's entries to `Mul` one by one), and `simplify` reduces the product to `C*b4**(3/2)`, that is $b_4^{3/2}\cos z$, as derived in Section 1.5. The record's text `Sin[6*H*x0]*Cot[6*H*x0]*b4[x4]^(3/2)` becomes $S \cdot (C/S) \cdot b_4^{3/2} = b_4^{3/2} C$ as well. The report `python-lovelock-report.json` holds a list of checks, each with a name and a verdict; the **dictionary comprehension** `{c["name"]: c["verdict"] for c in ...}` makes a dictionary from names to verdicts, and `["sqrt_abs_det_g"]` looks up the verdict of the record's

check, PASS. The check requires that both differences from $b_4^{3/2}C$ simplify to 0 and that the verdict is PASS; it reproduces the record and prints the two record names.

In [12], the limit that defines e, and the logarithm.

```
mpmath.mp.dps = 50
n_values = [10 ** k for k in range(17)]
error_exact = [abs((1 + mpmath.mpf(1) / n) ** n - mpmath.e) for n in n_values]
error_float = [abs((1.0 + 1.0 / n) ** n - math.e) for n in n_values]
for k in (0, 3, 6, 9, 12, 16):
    say(f"n = 10^{k:2d}: 50 digits: error {mpmath.nstr(error_exact[k], 3):>8}; "
        f"floating point: error {error_float[k]:.1e}")
```

`n_values` are $1, 10, 100, \ldots, 10^{16}$. For each the error of $(1 + 1/n)^n$ is computed twice: with 50 digits (`mpmath.e` is e to 50 digits) and with floating-point numbers (`math.e` is e as a float). Six of them are printed; `{k:2d}` prints k in two places and `{...:>8}` puts the text at the right end of 8 places, so that the columns line up. Output: with 50 digits the errors 0.718, 0.00136, 1.36e-6, 1.36e-9, 1.36e-12, 1.36e-16; in floating point 7.2e-01, 1.4e-03, 1.4e-06, 2.2e-07, 2.4e-04, 1.7e+00.

```
ratios = [error_exact[k] * n_values[k] / (mpmath.e / 2) for k in range(3, 17)]
check(all(abs(r - 1) < mpmath.mpf("0.01") for r in ratios),
      "50 digits: the error of (1 + 1/n)^n is e/(2n) within 1 per cent for n >= 1000")
check(error_float[16] == math.e - 1 and error_float[16] > 1e3 * error_float[6],
      "floating point: for n = 10^16, 1 + 1/n is rounded to 1, and the error grows "
      "to e - 1")
```

Each ratio divides the error by the estimate $e/(2n)$ of Section 1.5; the first check requires every ratio for $n \geq 1000$ to be within 1 per cent of 1. The second confirms that for $n = 10^{16}$ the floating-point error is exactly $e - 1$ (the result was $1^n = 1$) and that it is more than 1000 times the error at $n = 10^6$.

```
t_sym = sp.Symbol("t", real=True)
u, w = sp.symbols("u w", positive=True)
check(sp.log(sp.exp(t_sym)) == t_sym
      and sp.expand_log(sp.log(u * w)) == sp.log(u) + sp.log(w)
      and sp.simplify(sp.exp(-(a4 + sp.log(2))) - sp.exp(-a4) / 2) == 0,
      "ln(e^t) = t, ln(u w) = ln u + ln w, and e^(-(a4 + ln 2)) = e^(-a4)/2")
report("growth of a4 that shrinks the extra times by a factor 1000",
       f"{math.log(1000):.4f}")
```

`sp.log` is the natural logarithm. The check confirms the three laws of Section 1.5; `sp.expand_log` splits the logarithm of a product of positive symbols into a sum. The RESULT line prints $\ln 1000 = 6.9078$ (`.4f`: four digits after the point).

In [13], the figures of e and of growth and deflation.

```
fig, ax = plt.subplots(figsize=(8.0, 4.6))
ax.loglog(n_values, [float(e) for e in error_exact], "o-", color="tab:blue",
          label="50-digit arithmetic")
```

```
ax.loglog(n_values, error_float, "s-", color="tab:red", ms=5,
          label="floating point")
ax.loglog(n_values, [math.e / (2 * n) for n in n_values], "k--", lw=1,
          label="$e/(2n)$")
ax.set_xlabel("$n$")
ax.set_ylabel("error $|(1 + 1/n)^n - e|$")
ax.set_title("The limit that defines $e$")
ax.legend(fontsize=8, loc="lower left");
save_figure(fig, "limit_for_e",
            "The error of $(1 + 1/n)^n$ as an approximation of $e$ for $n = 1$ to "
            ...)
```

The two error lists of In [12] are drawn against n on logarithmic axes, the 50-digit errors as blue circles joined by lines, the floating-point errors as red squares (`"s-"`), together with the estimate $e/(2n)$ as a dashed line. What Figure 01f.5 shows: the blue points lie on the dashed line all the way to 10^{16}; the red points follow it only up to about $n = 10^8$, then rise again, because the rounding error multiplied by n takes over.

```
a4_values = np.linspace(0.0, 4.0, 401)
marks = np.log(2.0) * np.arange(6)  # a4 = 0, ln 2, 2 ln 2, ..., 5 ln 2
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.3))
for ax in (left, right):
    ax.plot(a4_values, np.exp(a4_values), color="tab:red",
            label="$e^{a_4}$: space $x_1, x_2, x_3$")
    ax.plot(a4_values, np.exp(-a4_values), color="tab:blue",
            label="$e^{-a_4}$: extra times $x_5, x_6, x_7$")
    ax.plot(marks, np.exp(marks), "o", color="tab:red", ms=4)
    ax.plot(marks, np.exp(-marks), "o", color="tab:blue", ms=4)
    ax.set_xlabel("$a_4$")
```

`np.linspace(0.0, 4.0, 401)` makes 401 equally spaced values of a_4 from 0 to 4. `marks` are the six values $0, \ln 2, \ldots, 5 \ln 2$ (`np.log` is the natural logarithm). The loop draws the same four things on both panels: the curves e^{a_4} (red, the factor of space) and e^{-a_4} (blue, the factor of the extra times), and dots at the marks, where the factors have doubled or halved once more.

```
left.set_ylabel("factor (ordinary axis)")
left.set_title("ordinary vertical axis")
left.legend(fontsize=8, loc="upper left")
right.set_yscale("log")
right.set_ylabel("factor (logarithmic axis)")
right.set_title("logarithmic vertical axis: straight lines")
for k in range(1, 6):
    right.text(marks[k], np.exp(-marks[k]) * 0.55, f"$2^{{-{k}}}$", ha="center",
               fontsize=8, color="tab:blue")
fig.tight_layout()
save_figure(fig, "growth_and_deflation",
            "The factors $e^{a_4}$ (red), which multiply the lengths along the three "
            ...)
```

The left panel keeps an ordinary vertical axis; the right panel gets a logarithmic one (`set_yscale("log")`). `right.text(x, y, text)` writes a label below each blue dot: $2^{-1}, \ldots, 2^{-5}$ (in an

f-string, double braces `{{` and `}}` stand for single braces in the text, so that LaTeX receives `2^{-1}`; `ha="center"` centres the text on the point). What Figure 01f.6 shows: on the ordinary axis one curve shoots up and the other creeps towards 0; on the logarithmic axis both are straight lines with opposite slopes, and the blue dots halve at every step $\ln 2$: the extra times deflate exponentially as a_4 grows.

In [14], the last check.

```
figure_names = ["01f_1_decimal_periods.png", "01f_2_square_root_of_two.png",
                "01f_3_float_spacing.png", "01f_4_cancellation.png",
                "01f_5_limit_for_e.png", "01f_6_growth_and_deflation.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

The list holds the names of the six figure files; the check confirms that each exists in the folder `Revision/textbook/figures` (below the output folder). `all_checks_passed()` prints the last line, ALL 26 CHECKS PASSED (notebook 01f). The 26 checks are: 3 in In [2], 1 in In [3], 1 in In [4], 3 in In [5], 1 in In [6], 4 in In [7], 3 in In [9], 3 in In [10], 3 in In [11], 3 in In [12] and 1 in In [14].

1.10 Complex numbers: the rules of arithmetic

Why a new kind of number. The equation $x^2 = -1$ has no solution among the real numbers, because the square of a real number is never negative. Yet the course needs such a solution everywhere. The fields of the author's theory have sixteen components at every point, and these components are **complex numbers** (for the field dirac16complex they are complex **anticommuting** quantities: two of them, a and b, obey $ab = -ba$ instead of $ab = ba$; they are introduced in Chapter 7; for the field dirac16complex00 they are ordinary complex numbers). A wave that oscillates in the time x_4 is written with a factor $e^{-i\varepsilon x_4}$, and whether such a wave stays bounded or grows without limit is decided by a complex number. This section builds the complex numbers from school algebra; Sections 1.11 to 1.13 add the exponential function, rotations and boosts.

Definition. We introduce a new number i, the **imaginary unit**, with the single property

$$i^2 = -1,$$

and we compute with it by the ordinary rules of algebra (sums and products may be re-ordered and multiplied out as usual). A **complex number** is a number $z = a + ib$ with two real numbers a and b. The number $a = \operatorname{Re} z$ is its **real part** and $b = \operatorname{Im} z$ its **imaginary part**. Two complex numbers are equal when both their real parts and their imaginary parts are equal. A real number a is the complex number $a + i0$; a number ib with real part 0 is called **purely imaginary**. Python writes the imaginary unit as `1j` (the letter `j` right after a number), and sympy as `I`.

Sum and product (PROVED). Sums are taken part by part: $(a+ib)+(c+id) = (a+c)+i(b+d)$ (collect the real terms and the terms with i). The product follows from multiplying out:

$$(a + ib)(c + id) = ac + iad + ibc + i^2bd$$

(every term of the first bracket times every term of the second: the distributive law),

$$= ac + i(ad + bc) - bd$$

(replace i^2 by -1, and take out the factor i from the two middle terms),

$$= (ac - bd) + i(ad + bc)$$

(group the two real terms). For example

$$(1 + 2i)(3 - i) = 3 - i + 6i - 2i^2 = 3 + 5i + 2 = 5 + 5i$$

(multiply out; collect $-i + 6i = 5i$ and replace $-2i^2$ by $+2$; add $3 + 2$). The formula for the product does not change when (a, b) and (c, d) are exchanged ($ac-bd$ and $ad+bc$ stay the same), so $zw = wz$: complex numbers **commute**. (Matrices, in Section 1.18, will not.)

The conjugate and the modulus (PROVED). The **complex conjugate** of $z = a + ib$ is $z^* = a - ib$: the sign of the imaginary part is changed and nothing else. Then

$$zz^* = (a + ib)(a - ib) = a^2 - iab + iab - i^2b^2 = a^2 + b^2$$

(multiply out; the two middle terms cancel, and $-i^2b^2 = +b^2$). This is a real number and never negative. Its positive square root $|z| = \sqrt{a^2 + b^2}$ is the **modulus** (or size) of z. A number $z \neq 0$ can be divided by: multiplying numerator and denominator of a quotient by the conjugate of the denominator makes the denominator real,

$$\frac{1 + 2i}{3 - i} = \frac{(1 + 2i)(3 + i)}{(3 - i)(3 + i)} = \frac{3 + i + 6i + 2i^2}{9 + 1} = \frac{1 + 7i}{10}$$

(multiply numerator and denominator by $3 + i$, which does not change the quotient; multiply out both, the denominator with $zz^* = a^2 + b^2$; then $3 + 2i^2 = 1$).

Three rules (PROVED). For all complex $z = a + ib$ and $w = c + id$:

1. $(zw)^* = z^*w^*$. Proof: by the product rule $zw = (ac - bd) + i(ad + bc)$, so $(zw)^* = (ac - bd) - i(ad + bc)$; and $z^*w^* = (a - ib)(c - id) = ac - iad - ibc + i^2bd = (ac - bd) - i(ad + bc)$ (multiply out; $i^2 = -1$; group). The two results are equal.
2. $zz^* = a^2 + b^2 = |z|^2$ (shown above).
3. $|zw| = |z|\,|w|$. Proof: $|zw|^2 = (zw)(zw)^*$ (rule 2 for the number zw) $= zw\,z^*w^*$ (rule 1) $= (zz^*)(ww^*)$ (complex numbers commute) $= |z|^2|w|^2$ (rule 2 twice); then take the positive square root of both sides.

Notebook 01b, In [2] and In [3], checks the examples with exact sympy arithmetic and the three rules with sympy symbols that stand for any real numbers a, b, c, d.

The complex plane. The complex number $z = a + ib$ is drawn as the point (a, b) of a plane, or as the arrow from the origin to that point: the horizontal axis carries the real part, the vertical axis the imaginary part. The modulus $|z|$ is the length of the arrow (Pythagoras). Adding two complex numbers adds the arrows: put the arrow of w at the tip of the arrow of z. The conjugate z^* is the mirror image of z in the real axis. Multiplying by i turns an arrow by a right angle:

$$i(a + ib) = ia + i^2 b = -b + ia$$

(multiply out; $i^2 = -1$), so the point (a, b) goes to the point $(-b, a)$, which has the same length $\sqrt{b^2 + a^2}$ and lies a quarter turn further counterclockwise. For $z = 1 + 2i$ this is $iz = -2 + i$. Figure 01b.1 draws these arrows.

1.11 The exponential series and Euler's formula

The exponential series. From calculus we take the series of the exponential function (Chapter 2 derives it from Taylor's theorem; here it is ASSUMED):

$$e^x = \sum_{k=0}^{\infty} \frac{x^k}{k!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots .$$

A **series** is an endless sum $t_0 + t_1 + t_2 + \cdots$; its **partial sum** $S_N = t_0 + \cdots + t_N$ adds the terms up to number N, and the series **converges** to a number S when the error $|S_N - S|$ becomes as small as we like for large N. In the same way (also ASSUMED from calculus) the sine and the cosine are

$$\cos\theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \cdots , \qquad \sin\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \cdots ,$$

with θ in **radians** (the angle measured as the length of the arc on the circle of radius 1; π radians are 180 degrees).

Euler's formula (PROVED from the assumed series). We define $e^{i\theta}$ for a real θ by putting $x = i\theta$ into the exponential series. The powers of i repeat with period 4:

$$i^0 = 1, \quad i^1 = i, \quad i^2 = -1, \quad i^3 = i^2\, i = -i, \quad i^4 = (i^2)^2 = 1,$$

(each power is the previous one times i, with $i^2 = -1$), and then $1, i, -1, -i$ again. So in $(i\theta)^k/k! = i^k\theta^k/k!$ the even terms $k = 2m$ carry $i^{2m} = (i^2)^m = (-1)^m$ and the odd terms $k = 2m + 1$ carry $i^{2m+1} = i\,(-1)^m$:

$$e^{i\theta} = \Big(1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \cdots\Big) + i\Big(\theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \cdots\Big)$$

(the terms of the series sorted into the even ones and the odd ones, the factor i of the odd ones taken out),

$$e^{i\theta} = \cos\theta + i\sin\theta$$

(the two brackets are the series of the cosine and the sine). This is **Euler's formula**. Notebook 01b, In [5], adds the terms one by one for $\theta = 2$: after 21 terms ($N = 20$) the partial sum differs from $\cos 2 + i \sin 2$ by 4.1×10^{-14} (COMPUTED); In [7] repeats the formula with 50-digit arithmetic.

How fast the series converges (PROVED). For $\theta \geq 0$:

$$|S_N - e^{i\theta}| = \Big| \sum_{k \geq N+1} \frac{(i\theta)^k}{k!} \Big| \leq \sum_{k \geq N+1} \frac{\theta^k}{k!}$$

(the full series minus the partial sum is the sum of the terms left out; the size of a sum is at most the sum of the sizes of its terms, a fact about complex numbers called the triangle inequality, ASSUMED here; and $|i^k| = 1$). Write $k = N + 1 + m$ with $m = 0, 1, 2, \ldots$. Since

$$(N + 1 + m)! = (N + 1)! \cdot (N + 2)(N + 3) \cdots (N + 1 + m) \geq (N + 1)!\, m!$$

(the factorial split after the factor $N + 1$; each of the m remaining factors $N + 1 + j$ is at least j, so their product is at least $1 \cdot 2 \cdots m = m!$), every term obeys

$$\frac{\theta^{N+1+m}}{(N + 1 + m)!} \leq \frac{\theta^{N+1}}{(N + 1)!} \cdot \frac{\theta^m}{m!}$$

(a larger denominator gives a smaller fraction; $\theta^{N+1+m} = \theta^{N+1}\theta^m$). Adding over m and using $\sum_m \theta^m/m! = e^\theta$:

$$|S_N - e^{i\theta}| \leq e^\theta \, \frac{\theta^{N+1}}{(N + 1)!}.$$

For $\theta = 2$ and $N = 20$ the bound is $e^2\, 2^{21}/21! \approx 3.0 \times 10^{-13}$, and the error found, 4.1×10^{-14}, lies below it. For large N the error is about the size of the first term left out, $\theta^{N+1}/(N + 1)!$, because each later term is smaller than the one before by the factor $\theta/(k + 1)$, which is small once k is much larger than θ. Going from N to $N + 1$ the first term left out changes from $\theta^{N+1}/(N + 1)!$ to $\theta^{N+2}/(N + 2)!$, a factor

$$\frac{\theta^{N+2}/(N + 2)!}{\theta^{N+1}/(N + 1)!} = \frac{\theta}{N + 2}$$

(divide the powers and the factorials; $(N + 2)! = (N + 2)\,(N + 1)!$). Notebook 01b, In [6], finds this factor within 10 per cent for $N = 10$ to 19 (COMPUTED; Figure 01b.2).

The law of exponents (PROVED). For real angles α and β:

$$e^{i\alpha} e^{i\beta} = (\cos\alpha + i \sin\alpha)(\cos\beta + i \sin\beta)$$

(Euler's formula twice),

$$= \cos\alpha \cos\beta + i \cos\alpha \sin\beta + i \sin\alpha \cos\beta + i^2 \sin\alpha \sin\beta$$

(multiply out),

$$= (\cos\alpha\cos\beta - \sin\alpha\sin\beta) + i(\sin\alpha\cos\beta + \cos\alpha\sin\beta)$$

($i^2 = -1$; group the real and the imaginary terms),

$$= \cos(\alpha+\beta) + i\sin(\alpha+\beta) = e^{i(\alpha+\beta)}$$

(the addition theorems $\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta$ and $\sin(\alpha+\beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta$ of school trigonometry, ASSUMED; then Euler's formula backwards). So the rule $e^p e^q = e^{p+q}$ of real exponents (Section 1.5) holds for imaginary exponents too, which is why the notation $e^{i\theta}$ is justified. For a general complex exponent we define $e^{x+iy} = e^x e^{iy}$ with real x and y; then $e^z e^w = e^{z+w}$ for all complex z and w, by the two laws of exponents. Notebook 01b, In [7], proves the law with sympy for symbols α and β.

Three consequences (PROVED). First, $|e^{i\theta}|^2 = \cos^2\theta + \sin^2\theta = 1$ (the modulus of $a+ib$ with $a = \cos\theta$, $b = \sin\theta$; then $\cos^2 + \sin^2 = 1$): the number $e^{i\theta}$ lies on the circle of radius 1, the **unit circle**, at the angle θ. Second,

$$(e^{i\theta})^* = \cos\theta - i\sin\theta = \cos(-\theta) + i\sin(-\theta) = e^{-i\theta}$$

(conjugate; the cosine does not change and the sine changes sign when the angle changes sign; Euler's formula for the angle $-\theta$). Third, $e^{i\pi} = \cos\pi + i\sin\pi = -1 + 0i = -1$. Notebook 01b, In [7], computes $e^{i\pi}$ with 50 significant digits: the real part is -1 and an imaginary part of size 1.0×10^{-51} is left over, because the number π itself is stored with 50 digits, not because the formula fails (COMPUTED).

The polar form. Every complex number $z \neq 0$ can be written as $z = re^{i\varphi}$ with $r = |z|$ and a real angle φ, its **argument** (or **phase angle**): the point $(a/r, b/r)$ lies on the unit circle, so it is $(\cos\varphi, \sin\varphi)$ for some angle φ (school trigonometry, ASSUMED), and then $z = r(\cos\varphi + i\sin\varphi) = re^{i\varphi}$. Python's `cmath.phase(z)` returns the argument.

1.12 Multiplication turns the plane; the real matrix of a complex number

Multiplication is a turn and a stretch (PROVED). Let $u = re^{i\alpha}$ and let $p = \rho e^{i\varphi}$ be any point of the plane. Then

$$u\,p = r\rho\, e^{i\alpha} e^{i\varphi} = r\rho\, e^{i(\alpha+\varphi)}$$

(re-order the factors, which commute; the law of exponents). So multiplying every point of the plane by u multiplies every length by r and adds α to every angle: it turns the plane about the origin by the angle α and stretches it by r. For $r = 1$ it is a pure **rotation**, which keeps every length. A rotation never mirrors a figure: Figure 01b.3 shows the letter F turned by 60 and by 150 degrees and turned back a quarter while shrunk to 0.6; it is never seen in its mirror image.

Matrices of size 2 by 2. To write the same turn without complex numbers we need a tool that the next part of the chapter develops fully (Sections 1.18 to 1.20), here only for tables of four

numbers. A **2 × 2 matrix** is a table of four numbers in two rows and two columns. It acts on a pair of numbers (x, y), written as a column, by "row times column":

$$\begin{pmatrix} p & q \\ r & s \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} px + qy \\ rx + sy \end{pmatrix}$$

(the first row (p, q) is multiplied entry by entry with the column (x, y) and added, and so is the second row). The **product** MN of two such matrices is the matrix that acts like "first N, then M"; its entry in row i and column k is row i of M times column k of N, entry by entry, added. The **identity matrix** I has the rows $(1, 0)$ and $(0, 1)$ and leaves every pair unchanged. The **determinant** of the matrix with rows (a, b) and (c, d) is the number $ad - bc$. The **transpose** M^T exchanges rows and columns: the rows of M^T are the columns of M.

The matrix of a complex number (PROVED). Multiplying $x + iy$ by $a + ib$ gives, by the product rule of Section 1.10 with $c = x$ and $d = y$,

$$(a + ib)(x + iy) = (ax - by) + i(bx + ay),$$

and written for the pair (x, y) this is

$$\begin{pmatrix} a & -b \\ b & a \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ax - by \\ bx + ay \end{pmatrix}$$

(row times column: $a \cdot x + (-b) \cdot y$ and $b \cdot x + a \cdot y$). So every complex number $a + ib$ has a real matrix $M(a + ib)$ with the rows $(a, -b)$ and (b, a). Multiplying the matrices is the same as multiplying the numbers:

$$M(a + ib)\, M(c + id) = \begin{pmatrix} a & -b \\ b & a \end{pmatrix} \begin{pmatrix} c & -d \\ d & c \end{pmatrix} = \begin{pmatrix} ac - bd & -ad - bc \\ bc + ad & -bd + ac \end{pmatrix}$$

(row times column for each of the four entries),

$$= \begin{pmatrix} ac - bd & -(ad + bc) \\ ad + bc & ac - bd \end{pmatrix} = M\big((ac - bd) + i(ad + bc)\big) = M\big((a + ib)(c + id)\big)$$

(re-order and take out the sign; this is the pattern of M with real part $ac - bd$ and imaginary part $ad + bc$; the product rule of Section 1.10). The number 1 has the matrix $M(1) = I$, and the number i has the matrix

$$J = M(i) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad JJ = \begin{pmatrix} 0 \cdot 0 + (-1) \cdot 1 & 0 \cdot (-1) + (-1) \cdot 0 \\ 1 \cdot 0 + 0 \cdot 1 & 1 \cdot (-1) + 0 \cdot 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = -I$$

(row times column). A *real* matrix squares to minus the identity: it plays the role of the number i. This is the first appearance of an idea that runs through the whole course: the author's gamma

matrices are real, and real matrices whose squares are $-I$ do the work that the imaginary unit does elsewhere. The determinant of $M(a+ib)$ is $a\cdot a-(-b)\cdot b=a^2+b^2=|a+ib|^2$.

The rotation matrix (PROVED). The matrix of $e^{i\alpha}=\cos\alpha+i\sin\alpha$ is the **rotation matrix**

$$R(\alpha)=M(e^{i\alpha})=\begin{pmatrix}\cos\alpha & -\sin\alpha\\ \sin\alpha & \cos\alpha\end{pmatrix}.$$

It inherits three properties. (a) $R(\alpha)R(\beta)=M(e^{i\alpha})M(e^{i\beta})=M(e^{i\alpha}e^{i\beta})=M(e^{i(\alpha+\beta)})=R(\alpha+\beta)$ (the product rule of the matrices M; the law of exponents): two turns make one turn by the sum of the angles. (b) $\det R(\alpha)=\cos^2\alpha+\sin^2\alpha=1$ (the determinant of M is the squared modulus, here $|e^{i\alpha}|^2=1$). (c) $R(\alpha)^TR(\alpha)=I$:

$$\begin{pmatrix}\cos\alpha & \sin\alpha\\ -\sin\alpha & \cos\alpha\end{pmatrix}\begin{pmatrix}\cos\alpha & -\sin\alpha\\ \sin\alpha & \cos\alpha\end{pmatrix}=\begin{pmatrix}\cos^2\alpha+\sin^2\alpha & -\cos\alpha\sin\alpha+\sin\alpha\cos\alpha\\ -\sin\alpha\cos\alpha+\cos\alpha\sin\alpha & \sin^2\alpha+\cos^2\alpha\end{pmatrix}=I$$

(the transpose has the columns of R as rows; row times column; then $\cos^2+\sin^2=1$ and the mixed terms cancel). Property (c) says that R keeps the squared length x^2+y^2; directly, with $c=\cos\alpha$ and $s=\sin\alpha$,

$$(cx-sy)^2+(sx+cy)^2=c^2x^2-2csxy+s^2y^2+s^2x^2+2scxy+c^2y^2=(c^2+s^2)(x^2+y^2)=x^2+y^2$$

(the squares of the two components of $R(x,y)$, multiplied out with $(u\pm v)^2=u^2\pm2uv+v^2$; the mixed terms cancel; collect; $c^2+s^2=1$). Notebook 01b, In [9], checks all of this exactly and checks that $R(\pi/3)$ moves the corners of the letter F exactly as multiplication by $e^{i\pi/3}$ does.

The roots of unity (PROVED). For a whole number $n\geq1$ the n numbers

$$z_k=e^{2\pi ik/n},\qquad k=0,1,\ldots,n-1,$$

satisfy $z_k^n=e^{2\pi ik}=\cos(2\pi k)+i\sin(2\pi k)=1$ (the law of exponents applied n times adds the angle $2\pi k/n$ to itself n times; Euler's formula; a whole number of full turns). They are the **roots of unity** of order n, the corners of a regular polygon with n sides on the unit circle. For $n\geq2$ their sum $S=z_0+\cdots+z_{n-1}$ is 0:

$$z_1S=z_1z_0+z_1z_1+\cdots+z_1z_{n-1}=z_1+z_2+\cdots+z_{n-1}+z_0=S$$

(multiply out; $z_1z_k=e^{2\pi i(k+1)/n}=z_{k+1}$ by the law of exponents, and $z_1z_{n-1}=e^{2\pi i}=1=z_0$, so the same numbers appear in another order). Hence $(z_1-1)S=0$, and since $z_1\neq1$ for $n\geq2$, $S=0$ (divide by the nonzero number z_1-1). The eight eighth roots are 1, $\frac{\sqrt2}{2}+\frac{\sqrt2}{2}i$, i, $-\frac{\sqrt2}{2}+\frac{\sqrt2}{2}i$, -1, $-\frac{\sqrt2}{2}-\frac{\sqrt2}{2}i$, $-i$, $\frac{\sqrt2}{2}-\frac{\sqrt2}{2}i$ (from $\cos(\pi/4)=\sin(\pi/4)=\sqrt2/2$). Notebook 01b, In [10], checks this for $n=3$ and $n=8$ and draws the two polygons (Figure 01b.4).

Conjugation and real numbers (PROVED). Conjugation changes the sign of the imaginary part and nothing else. Hence: a real number, whose imaginary part is 0, is its own conjugate,

$x^* = x$; a list of real numbers does not change at all when every entry is conjugated; conjugating twice gives back the original number, $(z^*)^* = z$; and $(e^{i\alpha})^* = e^{-i\alpha}$, so conjugation turns a rotation into the opposite rotation. The first of these facts has a consequence that the course uses again and again. The author's gamma matrices are real, and fields with real components occur throughout the course. On a real field, complex conjugation does nothing at all. So a conjugation that is to change a real field cannot be plain complex conjugation: it must act through a matrix on the sixteen components. Chapter 5 derives the two charge-conjugation matrices of the theory and shows that only one of them changes a real field. Notebook 01b, In [11], checks the four statements.

1.13 Boosts, hyperbolic functions, oscillation and growth

Hyperbolic functions. The **hyperbolic cosine** and **hyperbolic sine** are

$$\cosh\varphi = \frac{e^{\varphi} + e^{-\varphi}}{2}, \qquad \sinh\varphi = \frac{e^{\varphi} - e^{-\varphi}}{2}.$$

They obey (PROVED):

$$\cosh^2\varphi = \frac{e^{2\varphi} + 2 + e^{-2\varphi}}{4}, \qquad \sinh^2\varphi = \frac{e^{2\varphi} - 2 + e^{-2\varphi}}{4}$$

(square the definitions with $(u \pm v)^2 = u^2 \pm 2uv + v^2$, using $e^{\varphi}e^{-\varphi} = e^0 = 1$ and $(e^{\varphi})^2 = e^{2\varphi}$), so

$$\cosh^2\varphi - \sinh^2\varphi = \frac{2 - (-2)}{4} = 1$$

(subtract; the terms $e^{\pm 2\varphi}$ cancel). Adding and subtracting the two definitions gives

$$\cosh\varphi + \sinh\varphi = e^{\varphi}, \qquad \cosh\varphi - \sinh\varphi = e^{-\varphi}.$$

The addition theorems of cosh and sinh (PROVED). With $c_1 = \cosh\varphi_1$ and so on,

$$\cosh\varphi_1\cosh\varphi_2 + \sinh\varphi_1\sinh\varphi_2 = \frac{(e^{\varphi_1} + e^{-\varphi_1})(e^{\varphi_2} + e^{-\varphi_2}) + (e^{\varphi_1} - e^{-\varphi_1})(e^{\varphi_2} - e^{-\varphi_2})}{4}$$

(the definitions inserted; both products have the denominator $2 \cdot 2$),

$$= \frac{2e^{\varphi_1+\varphi_2} + 2e^{-\varphi_1-\varphi_2}}{4} = \cosh(\varphi_1 + \varphi_2)$$

(multiplied out, the mixed terms $e^{\varphi_1-\varphi_2}$ and $e^{-\varphi_1+\varphi_2}$ appear once with $+$ and once with $-$ and cancel, while $e^{\varphi_1+\varphi_2}$ and $e^{-\varphi_1-\varphi_2}$ appear twice; then the definition of cosh). In the same way, $\sinh\varphi_1\cosh\varphi_2 + \cosh\varphi_1\sinh\varphi_2 = \sinh(\varphi_1 + \varphi_2)$: multiplied out, the products give $(e^{\varphi_1+\varphi_2} + e^{\varphi_1-\varphi_2} - e^{-\varphi_1+\varphi_2} - e^{-\varphi_1-\varphi_2}) + (e^{\varphi_1+\varphi_2} - e^{\varphi_1-\varphi_2} + e^{-\varphi_1+\varphi_2} - e^{-\varphi_1-\varphi_2})$ over 4, and the mixed terms cancel again.

Rotations and boosts. In the author's spacetime there are directions of two kinds: four **space-like** ones, x_0, x_1, x_2, x_3, and four **time-like** ones, x_4, x_5, x_6, x_7 (Section 1.5; Section 1.27 makes the words exact). A transformation that mixes two directions of the same kind is a rotation, which keeps $x^2 + y^2$. A transformation that mixes a time-like coordinate t with a space-like coordinate x (for example x_4 with x_0) keeps instead the difference $x^2 - t^2$; it is a **boost**:

$$\begin{pmatrix} t' \\ x' \end{pmatrix} = \Lambda(\varphi) \begin{pmatrix} t \\ x \end{pmatrix}, \qquad \Lambda(\varphi) = \begin{pmatrix} \cosh\varphi & \sinh\varphi \\ \sinh\varphi & \cosh\varphi \end{pmatrix}.$$

The number φ is the **rapidity** of the boost. Three properties (PROVED). (a) It keeps $-t^2 + x^2$: with $c = \cosh\varphi$ and $s = \sinh\varphi$, $t' = ct + sx$ and $x' = st + cx$ (row times column), and

$$-t'^2 + x'^2 = -(c^2t^2 + 2cstx + s^2x^2) + (s^2t^2 + 2sctx + c^2x^2) = -(c^2 - s^2)t^2 + (c^2 - s^2)x^2 = -t^2 + x^2$$

(square with $(u+v)^2 = u^2 + 2uv + v^2$; the mixed terms cancel; collect; $c^2 - s^2 = 1$). With the **frame metric** of this pair, $\eta = \mathrm{diag}(-1, +1)$ (the diagonal matrix with -1 for the time-like t and $+1$ for the space-like x), this statement is written $\Lambda^T \eta \Lambda = \eta$; Section 1.27 explains this way of writing it. Its determinant is $c^2 - s^2 = 1$. (b) Rapidities add: $\Lambda(\varphi_1)\Lambda(\varphi_2) = \Lambda(\varphi_1 + \varphi_2)$; row times column gives the entries $c_1c_2 + s_1s_2$ and $s_1c_2 + c_1s_2$ (each twice), which are $\cosh(\varphi_1 + \varphi_2)$ and $\sinh(\varphi_1 + \varphi_2)$ by the addition theorems. (c) The two **light-like** directions $(t, x) = (1, 1)$ and $(1, -1)$, on which $-t^2 + x^2 = 0$, are only stretched:

$$\Lambda(\varphi) \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} c+s \\ s+c \end{pmatrix} = e^{\varphi} \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \qquad \Lambda(\varphi) \begin{pmatrix} 1 \\ -1 \end{pmatrix} = \begin{pmatrix} c-s \\ s-c \end{pmatrix} = e^{-\varphi} \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

(row times column; then $c \pm s = e^{\pm\varphi}$). A boost stretches one light-like direction by the growing exponential e^{φ} and shrinks the other by the decaying exponential $e^{-\varphi}$; the product of the two factors is 1. The lengths along space and along the extra times in the author's metric carry the factors e^{a_4} and e^{-a_4}, a pattern of the same form; only the form is the same, because a_4 is a function of the time x_4 and not the rapidity of a boost. Where a rotation moves a point around a circle $x^2 + y^2 = 1$, a boost moves it along a **hyperbola** $t^2 - x^2 = 1$ that never crosses the light-like lines $t = \pm x$ (Figure 01b.5). Notebook 01b, In [12] and In [13], checks (a) to (c) exactly and in numbers.

Oscillation and growth (PROVED). For a real number ε, the **frequency**, the wave

$$e^{-i\varepsilon t} = \cos(\varepsilon t) - i\sin(\varepsilon t)$$

(Euler's formula with the angle $-\varepsilon t$; the cosine is even, the sine odd) has the modulus 1 at every time t: its real and imaginary parts oscillate, and it stays bounded. If the frequency is imaginary, $\varepsilon = i\gamma$ with a real γ, the same formula gives

$$e^{-i\varepsilon t} = e^{-i(i\gamma)t} = e^{-i^2\gamma t} = e^{\gamma t}$$

(insert $\varepsilon = i\gamma$; $i \cdot i = i^2$; $-i^2 = 1$): no oscillation at all, but exponential growth for $\gamma > 0$ and exponential decay for $\gamma < 0$. A complex frequency $\varepsilon = 2 + 0.3i$ gives

$$e^{-i(2+0.3i)t} = e^{-2it-0.3i^2t} = e^{0.3t}e^{-2it}$$

(multiply out the exponent; $-0.3i^2 = 0.3$; split the exponential with $e^{z+w} = e^z e^w$): an oscillation whose size $e^{0.3t}$ grows. An imaginary part of a frequency is the mathematical sign of an **instability**; Chapter 8 meets it in the waves along the extra times. Notebook 01b, In [14], checks the three cases at 501 times and draws them (Figure 01b.6).

1.14 Example: complex numbers, rotations and boosts

Notebook 01b puts Sections 1.10 to 1.13 to work. It computes with complex numbers in Python and exactly with sympy and checks the rules of the conjugate and the modulus for all complex numbers; draws complex numbers as arrows; adds up the exponential series at $i\theta$ term by term and measures how fast it reaches $\cos\theta + i\sin\theta$; confirms $e^{i\pi} = -1$ to 50 digits and proves the law of exponents; turns the letter F by multiplication and by the rotation matrix; checks $J^2 = -I$ and the rules of the rotation matrices; draws the roots of unity; checks that conjugation leaves real numbers unchanged; compares rotations, which keep circles, with boosts, which keep hyperbolas; and shows that a real frequency gives an oscillation and an imaginary one exponential growth. Every check is exact (sympy) or numerical with a stated tolerance; nothing in this notebook comes from the Revision record, and it reads no file. It ends with the line ALL 34 CHECKS PASSED (notebook 01b).

1.15 How to run Notebook 01b

Step 1. What this notebook does and what it needs.

Notebook 01b (Complex numbers, rotations and boosts) is the file `Revision/textbook/notebooks/01b_complex_rotations.ipynb` of the repository Dirac_claude. It computes with complex numbers in Python and exactly with sympy, draws them as arrows in the plane, adds up the series of the exponential function to show Euler's formula and how fast the series converges, shows that multiplying by a complex number of modulus 1 rotates the plane and that the same rotation is a real 2 by 2 matrix, draws the roots of unity, shows that conjugation leaves real numbers unchanged, compares rotations, which keep x squared plus y squared, with boosts, which keep x squared minus t squared, and shows that a real frequency gives an oscillation while an imaginary frequency gives exponential growth. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at

the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01b_complex_rotations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01b_complex_rotations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01b_complex_rotations.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01b.captions.json`

- `Revision/textbook/figures/01b_1_complex_plane.png`
- `Revision/textbook/figures/01b_2_euler_series.png`
- `Revision/textbook/figures/01b_3_rotation_by_multiplication.png`
- `Revision/textbook/figures/01b_4_roots_of_unity.png`
- `Revision/textbook/figures/01b_5_rotations_and_boosts.png`
- `Revision/textbook/figures/01b_6_oscillation_and_growth.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 34 CHECKS PASSED (notebook 01b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01b_complex_rotations.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".

- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01b_complex_rotations.ipynb
python -m nbconvert --execute --inplace 01b_complex_rotations.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

1.16 Notebook 01b: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01b_complex_rotations.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook builds the complex numbers from zero and connects them with
rotations of the plane. It

- adds, multiplies and divides complex numbers in Python and exactly with
  sympy, and checks the rules of the modulus and of the conjugate;
- draws complex numbers as arrows in the plane;
- adds up the series $\sum_k (i\theta)^k / k!$ term by term and shows that it
  reaches $\cos\theta + i \sin\theta$ (Euler's formula), with a plot of how fast
  the error shrinks;
- shows that multiplying by $e^{i\alpha}$ rotates every point of the plane by the
  angle $\alpha$, and that the same rotation is a real $2 \times 2$ matrix; the
  real matrix $J$ that represents $i$ satisfies $J^2 = -I$;
- draws the roots of unity, the $n$ numbers with $z^n = 1$;
```

```
- shows that conjugation leaves every real number unchanged;
- compares rotations, which keep $x^2 + y^2$, with *boosts*, which keep
  $x^2 - t^2$ (one time-like and one space-like direction);
- shows that $e^{-i\varepsilon t}$ oscillates with modulus 1 when the frequency
  $\varepsilon$ is real, and grows exponentially when $\varepsilon$ is imaginary.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01b (Complex numbers, rotations and boosts) is the file
‘Revision/textbook/notebooks/01b_complex_rotations.ipynb‘ of the repository Dirac_claude.
It computes with complex numbers in Python and exactly with sympy, draws them as arrows
in the plane, adds up the series of the exponential function to show Euler’s formula and
how fast the series converges, shows that multiplying by a complex number of modulus 1
rotates the plane and that the same rotation is a real 2 by 2 matrix, draws the roots of
unity, shows that conjugation leaves real numbers unchanged, compares rotations, which
keep x squared plus y squared, with boosts, which keep x squared minus t squared, and
shows that a real frequency gives an oscillation while an imaginary frequency gives
exponential growth. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy,
sympy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and
runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):
```

```
    sudo apt update
    sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01b_complex_rotations.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its

left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01b_complex_rotations.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01b_complex_rotations.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01b.captions.json‘
- ‘Revision/textbook/figures/01b_1_complex_plane.png‘
- ‘Revision/textbook/figures/01b_2_euler_series.png‘
- ‘Revision/textbook/figures/01b_3_rotation_by_multiplication.png‘
- ‘Revision/textbook/figures/01b_4_roots_of_unity.png‘
- ‘Revision/textbook/figures/01b_5_rotations_and_boosts.png‘
- ‘Revision/textbook/figures/01b_6_oscillation_and_growth.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 34 CHECKS PASSED (notebook 01b)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01b_complex_rotations.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 01b_complex_rotations.ipynb
      python -m nbconvert --execute --inplace 01b_complex_rotations.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01b (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
```

```
#
# Notebook 01b (Complex numbers, rotations and boosts) is the file
# Revision/textbook/notebooks/01b_complex_rotations.ipynb of the repository Dirac_claude.
# It computes with complex numbers in Python and exactly with sympy, draws them as arrows
# in the plane, adds up the series of the exponential function to show Euler's formula
# and how fast the series converges, shows that multiplying by a complex number of
# modulus 1 rotates the plane and that the same rotation is a real 2 by 2 matrix, draws
# the roots of unity, shows that conjugation leaves real numbers unchanged, compares
# rotations, which keep x squared plus y squared, with boosts, which keep x squared minus
# t squared, and shows that a real frequency gives an oscillation while an imaginary
# frequency gives exponential growth. It needs a computer with Windows 11, macOS or
# Linux, an internet connection for the installation, the program Git, and Python 3.12 or
# newer (the notebooks were built with Python 3.14.5) with these packages at exactly
# these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, sympy, mpmath and matplotlib; the other packages run
# Jupyter, the program that shows and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
```

```
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in

```

```
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01b_complex_rotations.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01b_complex_rotations.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01b_complex_rotations.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
```

```
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01b.captions.json
# - Revision/textbook/figures/01b_1_complex_plane.png
# - Revision/textbook/figures/01b_2_euler_series.png
# - Revision/textbook/figures/01b_3_rotation_by_multiplication.png
# - Revision/textbook/figures/01b_4_roots_of_unity.png
# - Revision/textbook/figures/01b_5_rotations_and_boosts.png
# - Revision/textbook/figures/01b_6_oscillation_and_growth.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 34 CHECKS PASSED (notebook 01b)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01b_complex_rotations.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
```

```
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01b_complex_rotations.ipynb
#     python -m nbconvert --execute --inplace 01b_complex_rotations.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Imaginary unit** $i$: a new number with $i^2 = -1$. Python writes it ‘1j‘,
  sympy writes it ‘I‘.
- **Complex number**: $z = a + ib$ with real numbers $a$ (the **real part**,
  $\mathrm{Re}\,z$) and $b$ (the **imaginary part**, $\mathrm{Im}\,z$).
- **Complex plane**: the plane in which $z = a + ib$ is the point (or the arrow
  from the origin to the point) $(a, b)$; horizontal axis $\mathrm{Re}$,
  vertical axis $\mathrm{Im}$.
- **Modulus** $|z| = \sqrt{a^2 + b^2}$: the length of the arrow.
- **Argument** (or **phase angle**): the angle between the arrow and the positive
  real axis, measured counterclockwise in radians ($\pi$ radians $= 180$
  degrees).
- **Conjugate** $z^* = a - ib$: the mirror image of $z$ in the real axis.
- **Series, partial sum**: an infinite sum $t_0 + t_1 + t_2 + \cdots$; its
  partial sum $S_N$ adds the terms $t_0$ to $t_N$. The series **converges** to a
  number $S$ when the error $|S_N - S|$ becomes as small as we like for large $N$.
- **Factorial** $k! = 1 \cdot 2 \cdots k$, with $0! = 1$.
```

```
- **Euler's formula**: $e^{i\theta} = \cos\theta + i \sin\theta$ for real
  $\theta$.
- **Polar form**: $z = r e^{i\varphi}$ with $r = |z|$ and $\varphi$ the argument.
- **Rotation**: turning the plane about the origin by an angle; it keeps every
  length. The **rotation matrix** of the angle $\alpha$ has the rows
  $(\cos\alpha, -\sin\alpha)$ and $(\sin\alpha, \cos\alpha)$.
- **Hyperbolic functions**: $\cosh\varphi = (e^{\varphi} + e^{-\varphi})/2$ and
  $\sinh\varphi = (e^{\varphi} - e^{-\varphi})/2$; they satisfy
  $\cosh^2\varphi - \sinh^2\varphi = 1$.
- **Boost**: the matrix with rows $(\cosh\varphi, \sinh\varphi)$ and
  $(\sinh\varphi, \cosh\varphi)$ acting on a pair $(t, x)$ of a time-like and a
  space-like coordinate; it keeps $x^2 - t^2$. The number $\varphi$ is its
  **rapidity**.
- **Root of unity**: a complex number $z$ with $z^n = 1$ for a whole number
  $n \geq 1$.
- **Frequency**: the number $\varepsilon$ in $e^{-i\varepsilon t}$; for real
  $\varepsilon$ the real and imaginary parts oscillate like $\cos$ and $\sin$.
- **mpmath**: a Python package that computes with as many decimal digits as
  requested (here 50).
```

Text cell:

```
## 4. The physical and mathematical situation

The fields of the author's theory have 16 *complex* components at every point of
spacetime (for the field dirac16complex they are complex anticommuting quantities,
for which $ab = -ba$ instead of $ab = ba$; for dirac16complex00 they are ordinary
complex numbers), and a wave that oscillates in the
time $x_4$ is written with factors like $e^{-i\varepsilon x_4}$. The author's
gamma matrices, on the other hand, are *real*. This notebook shows
how the two fit together: a real $2 \times 2$ matrix $J$ with $J^2 = -I$ behaves
exactly like the number $i$, and multiplying by a complex number of modulus 1 is
the same as rotating with a real matrix.

Euler's formula $e^{i\theta} = \cos\theta + i\sin\theta$ comes from the series of
the exponential function, $e^x = \sum_{k=0}^\infty x^k/k!$, with $x = i\theta$:
the powers of $i$ repeat as $1, i, -1, -i, 1, \dots$, so the even terms build the
series of $\cos\theta$ and the odd terms $i$ times the series of $\sin\theta$.

The author's spacetime has four space-like directions ($x_0, x_1, x_2, x_3$,
where the frame metric $\eta$ has $+1$) and four time-like ones ($x_4$ to $x_7$,
where $\eta$ has $-1$). A transformation that mixes two directions of the same
kind is a rotation, which keeps $x^2 + y^2$; one that mixes a time-like with a
space-like direction is a boost, which keeps $x^2 - t^2$ and is built from
$\cosh$ and $\sinh$ instead of $\cos$ and $\sin$. A boost stretches one light-like
direction ($x = t$) by $e^{\varphi}$ and shrinks the other ($x = -t$) by
$e^{-\varphi}$: a growing and a shrinking exponential whose product is 1. The
lengths of space and of the extra times in the author's metric carry the factors
$e^{a_4}$ and $e^{-a_4}$, a pattern of the same form (only the form is the
same: $a_4$ is a function of the time, not a rapidity).

Finally, the frequency $\varepsilon$ of a wave decides its fate: if $\varepsilon$
is real, $|e^{-i\varepsilon t}| = 1$ for all times; if $\varepsilon = i\gamma$ is
```

```
imaginary, $e^{-i\varepsilon t} = e^{\gamma t}$ grows (or shrinks) exponentially.
An imaginary frequency is the mathematical sign of an instability.
```

Text cell:

```
## 5. Complex numbers in Python and in sympy

The next cell computes with $z = 1 + 2i$ and $w = 3 - i$ in two ways. Python's
own complex numbers (written `1 + 2j`) are floating-point numbers. sympy's `I` is
the exact imaginary unit, so sympy gives exact results:

$(1 + 2i)(3 - i) = 3 - i + 6i - 2i^2 = 3 + 5i + 2 = 5 + 5i$, and
$\frac{1 + 2i}{3 - i} = \frac{(1 + 2i)(3 + i)}{(3 - i)(3 + i)} =
\frac{3 + i + 6i + 2i^2}{9 + 1} = \frac{1 + 7i}{10}$ (multiplying numerator and
denominator by the conjugate $3 + i$ of the denominator makes the denominator
real).
```

In [2]:

```
import cmath  # functions of complex numbers: phase (the argument), exp
import math  # cos, sin, exp, factorial of real numbers

import mpmath  # numbers with as many digits as we ask for
import numpy as np  # arrays of numbers
import sympy as sp  # exact arithmetic

z = 1 + 2j  # Python writes the imaginary unit as j, right after a number
w = 3 - 1j
say(f"Python: z = {z}, w = {w}, z + w = {z + w}, z w = {z * w}")
I = sp.I  # sympy's exact imaginary unit
z_exact = 1 + 2 * I
w_exact = 3 - I
product = sp.expand(z_exact * w_exact)  # multiply out, with I**2 = -1
quotient = sp.simplify(z_exact / w_exact)
say(f"sympy: z w = {product}, z / w = {quotient}")
check(I ** 2 == -1, "i^2 = -1")
check(product == 5 + 5 * I and complex(product) == z * w, "(1 + 2i)(3 - i) = 5 + 5i")
check(sp.simplify(quotient - (1 + 7 * I) / 10) == 0, "(1 + 2i)/(3 - i) = (1 + 7i)/10")
```

Out [2]:

```
Python: z = (1+2j), w = (3-1j), z + w = (4+1j), z w = (5+5j)
sympy: z w = 5 + 5*I, z / w = 1/10 + 7*I/10
PASS i^2 = -1
PASS (1 + 2i)(3 - i) = 5 + 5i
PASS (1 + 2i)/(3 - i) = (1 + 7i)/10
```

Text cell:

```
The next cell checks the rules of the conjugate and the modulus for *all*
complex numbers $z = a + ib$ and $w = c + id$, with sympy symbols $a, b, c, d$
that stand for any real numbers:

- $(zw)^* = z^* w^*$: conjugating a product conjugates each factor;
- $z z^* = a^2 + b^2 = |z|^2$, a real number that is never negative;
- $|zw|^2 = |z|^2 |w|^2$, hence $|zw| = |z|\,|w|$: lengths multiply.
```

In [3]:

```
a, b, c, d = sp.symbols("a b c d", real=True)  # any real numbers
zz = a + b * I
ww = c + d * I
check(sp.expand(sp.conjugate(zz * ww) - sp.conjugate(zz) * sp.conjugate(ww)) == 0,
      "(z w)* = z* w* for all complex z and w")
check(sp.expand(zz * sp.conjugate(zz)) == a ** 2 + b ** 2,
      "z z* = a^2 + b^2 = |z|^2 for every z = a + i b")
check(sp.expand(zz * ww * sp.conjugate(zz * ww)
                - (a ** 2 + b ** 2) * (c ** 2 + d ** 2)) == 0,
      "|z w|^2 = |z|^2 |w|^2 for all complex z and w")
say(f"|z| = {sp.Abs(z_exact)}, |w| = {sp.Abs(w_exact)}, "
    f"|z w| = {sp.Abs(product)}")
```

Out [3]:

```
PASS (z w)* = z* w* for all complex z and w
PASS z z* = a^2 + b^2 = |z|^2 for every z = a + i b
PASS |z w|^2 = |z|^2 |w|^2 for all complex z and w
|z| = sqrt(5), |w| = sqrt(10), |z w| = 5*sqrt(2)
```

Text cell:

```
## 6. Complex numbers as arrows

The next cell draws $z = 1 + 2i$, $w = 3 - i$, their sum $z + w = 4 + i$ (the
diagonal of the parallelogram spanned by $z$ and $w$: put the arrow $w$ at the
tip of $z$), the conjugate $z^* = 1 - 2i$ (the mirror image in the real axis) and
$iz = -2 + i$, which is $z$ turned by a right angle. The helper ‘arrow‘ draws a
complex number as an arrow from a starting point. The check confirms that $iz$
has the same length as $z$ and an argument larger by $\pi/2$ (‘cmath.phase‘ gives
the argument).
```

In [4]:

```
def arrow(ax, number, color, label, start=0j, style="-"):
    """Draw the complex number as an arrow from start to start + number."""
    tip = start + number
    ax.annotate("", xy=(tip.real, tip.imag), xytext=(start.real, start.imag),

## 7. Euler's formula from the exponential series

The exponential series at $x = i\theta$ is
$\sum_{k=0}^\infty (i\theta)^k / k!$. Its terms can be made one from the other:
the term number $k+1$ is the term number $k$ times $i\theta/(k+1)$. The next cell
adds the terms for $\theta = 2$ one by one and keeps the partial sums
$S_0, S_1, \dots, S_{20}$ and their errors $|S_N - (\cos 2 + i \sin 2)|$.

How big can the error be? The error is the sum of the terms left out after $S_N$,
and the size of a sum is at most the sum of the sizes of its terms. These terms
have the sizes $\theta^k/k!$ for $k \geq N + 1$, and
$\frac{\theta^{N+1+m}}{(N+1+m)!} \leq \frac{\theta^{N+1}}{(N+1)!} \cdot
\frac{\theta^m}{m!}$ (because $(N+1+m)!$ is at least $(N+1)! \, m!$); adding over
$m = 0, 1, 2, \dots$ and using $\sum_m \theta^m/m! = e^\theta$ gives the bound
```

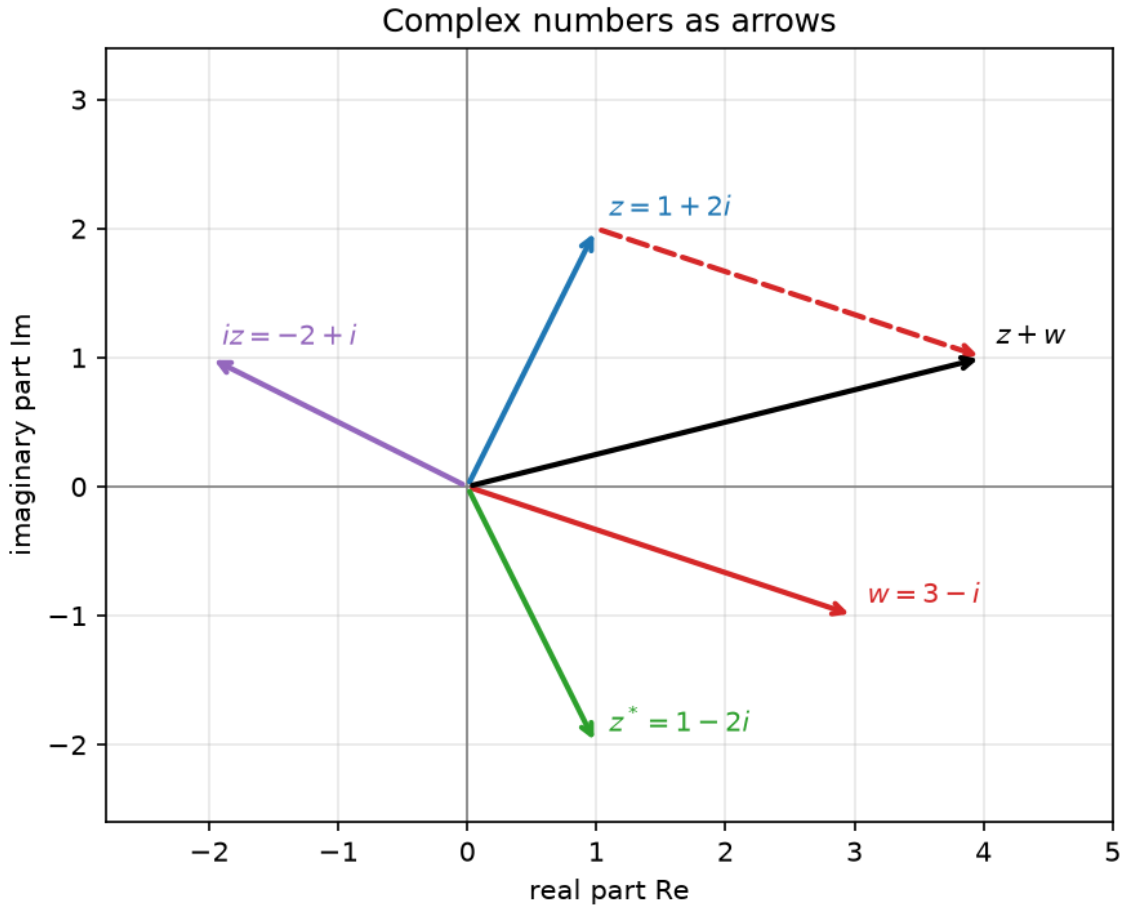

Figure 23: Complex numbers as arrows in the complex plane; horizontal axis the real part, vertical axis the imaginary part (pure numbers). Blue $z = 1 + 2i$, red $w = 3 - i$ (dashed: the same arrow moved to the tip of z), black their sum $z + w = 4 + i$, green the conjugate $z^* = 1 - 2i$ (the mirror image of z in the real axis) and purple $iz = -2 + i$, which is z turned counterclockwise by a right angle. (Notebook 01b, figure 1.)

```
$|S_N - e^{i\theta}| \leq e^\theta \, \theta^{N+1}/(N+1)!$. The cell checks the
error against this bound for every $N$, and checks that after 21 terms the error
is below $10^{-12}$.
```

```

Text cell:

```
The next cell draws the partial sums $S_0, \dots, S_{10}$ as points of the complex
plane joined in order (they spiral in towards the point $e^{2i}$ on the unit
circle), and on the right the error against $N$ on a logarithmic scale, together
with the bound of the previous cell. For large $N$ the error is about the size of
the first term left out, $\theta^{N+1}/(N+1)!$, so going from $N$ to $N + 1$
multiplies it by about $\theta/(N+2)$: the error shrinks faster and faster. The
cell checks this for $N = 10$ to 19 (agreement within 10 per cent).

## 8. Multiplying by a complex number rotates and stretches

Write $u = r e^{i\alpha}$ and a point of the plane as $p = \rho e^{i\varphi}$.
Then $up = r\rho \, e^{i(\alpha + \varphi)}$ by the law of exponents: the length
is multiplied by $r$ and the angle increased by $\alpha$. For $r = 1$ the
multiplication is a pure rotation.

The next cell draws the outline of the letter F (chosen because its mirror image
looks different, so a mirror would be noticed), and its images under
multiplication by $e^{i\pi/3}$ (60 degrees), $e^{5i\pi/6}$ (150 degrees) and
$0.6\,e^{-i\pi/2}$ (a quarter turn clockwise and a shrinking to 0.6). It checks
that the rotations keep the distance of every corner from the origin and turn
its angle by exactly $\alpha$.
```

In [8]:

```

## 9. The same rotation as a real 2 x 2 matrix

Multiplying $x + iy$ by $a + ib$ gives $(ax - by) + i(bx + ay)$. Written for the
pair $(x, y)$ this is the matrix product
```

```
$$\begin{pmatrix} a & -b \\ b & a \end{pmatrix}
\begin{pmatrix} x \\ y \end{pmatrix} =
\begin{pmatrix} ax - by \\ bx + ay \end{pmatrix}.$$

So every complex number $a + ib$ has a real matrix $M(a + ib)$ with the rows
$(a, -b)$ and $(b, a)$. The number 1 has the identity matrix and $i$ has the
matrix $J$ with rows $(0, -1)$ and $(1, 0)$. The next cell checks, exactly with
sympy, that

- $J^2 = -I$: a *real* matrix plays the role of $i$;
- $M(z) M(w) = M(zw)$ for all $z$ and $w$: multiplying matrices is the same as
  multiplying the numbers;
- $\det M(a + ib) = a^2 + b^2 = |z|^2$;
- the rotation matrix $R(\alpha) = M(e^{i\alpha})$ obeys
  $R(\alpha) R(\beta) = R(\alpha + \beta)$, $\det R(\alpha) = 1$ and
  $R(\alpha)^T R(\alpha) = I$ (so it keeps $x^2 + y^2$).

It also checks in numbers that rotating the corners of the letter F with
$R(\pi/3)$ gives the same points as multiplying them by $e^{i\pi/3}$.
```

In [9]:

```

## 10. The roots of unity

The numbers $z_k = e^{2\pi i k/n}$, $k = 0, 1, \dots, n-1$, satisfy
$z_k^n = e^{2\pi i k} = 1$: they are the $n$ roots of unity. They are the corners
of a regular polygon with $n$ sides on the unit circle, and their sum is 0 (the
sum is unchanged when every $z_k$ is multiplied by $z_1$, which only re-orders
them; a number that does not change when multiplied by $z_1 \neq 1$ must be 0).

The next cell checks this in numbers for $n = 3$ and $n = 8$, writes the eight
eighth roots exactly with sympy (‘expand_complex‘ writes a number as real part
plus $i$ times imaginary part), checks their eighth powers and their sum exactly,
and draws both polygons.
```

In [10]:

```

## 11. Conjugation and real numbers

Conjugation changes the sign of the imaginary part and nothing else. So a real
number, which has imaginary part 0, is its own conjugate: $x^* = x$; and a list
of real numbers is not changed at all by conjugating every entry. Conjugating
twice gives back the original number, and the conjugate of $e^{i\alpha}$ is
$e^{-i\alpha}$: conjugation turns a rotation into the opposite rotation.
```

```
This simple fact matters later in the course: the author's gamma matrices are
real, and for real quantities conjugation does nothing at all. So a conjugation
that is meant to change a real field cannot be plain complex conjugation: it
must act through a *matrix* on the field's components. The next cell checks the
four statements with numpy (`.conj()` conjugates every entry of an array).
```

In [11]:

```
v_real = np.array([0.5, -2.0, 3.0])  # a list of real numbers
v_complex = np.array([1 + 2j, -1j, 4.0])  # a list with imaginary parts
check((v_real.conj() == v_real).all(),
      "conjugation leaves a list of real numbers unchanged")
check(not (v_complex.conj() == v_complex).all(),
      "conjugation changes a list whose imaginary parts are not all 0")
check((v_complex.conj().conj() == v_complex).all(),

## 12. Rotations and boosts

A rotation mixes two directions of the same kind and keeps $x^2 + y^2$. A boost
mixes a time-like coordinate $t$ with a space-like coordinate $x$:

$$\begin{pmatrix} t' \\ x' \end{pmatrix} =
\begin{pmatrix} \cosh\varphi & \sinh\varphi \\ \sinh\varphi & \cosh\varphi
\end{pmatrix} \begin{pmatrix} t \\ x \end{pmatrix}.$$

With the frame metric of this pair, $\eta = \mathrm{diag}(-1, +1)$ ($t$ is
time-like, $x$ space-like, as $x_4$ and $x_0$ in the author's coordinates), the
boost $\Lambda$ satisfies $\Lambda^T \eta \Lambda = \eta$, which says that
$-t'^2 + x'^2 = -t^2 + x^2$; it follows from $\cosh^2 - \sinh^2 = 1$. The next
cell checks exactly with sympy:

- $\Lambda^T \eta \Lambda = \eta$ and $\det \Lambda = 1$;
- rapidities add: $\Lambda(\varphi_1) \Lambda(\varphi_2) = \Lambda(\varphi_1 +
  \varphi_2)$ (the addition theorems of $\cosh$ and $\sinh$);
- the two light-like directions $(t, x) = (1, 1)$ and $(1, -1)$ are only
  stretched: $\Lambda (1, 1) = e^{\varphi} (1, 1)$ and
  $\Lambda (1, -1) = e^{-\varphi} (1, -1)$, because
  $\cosh\varphi \pm \sinh\varphi = e^{\pm\varphi}$.
```

In [12]:

```
phi, phi1, phi2 = sp.symbols("phi phi1 phi2", real=True)

def boost(rapidity):
    """The boost matrix acting on the pair (t, x)."""
    return sp.Matrix([[sp.cosh(rapidity), sp.sinh(rapidity)],
                      [sp.sinh(rapidity), sp.cosh(rapidity)]])

eta_tx = sp.diag(-1, 1)  # t time-like (-1), x space-like (+1)

## 13. Oscillation and growth

For a real frequency $\varepsilon$ the wave $e^{-i\varepsilon t} =
```

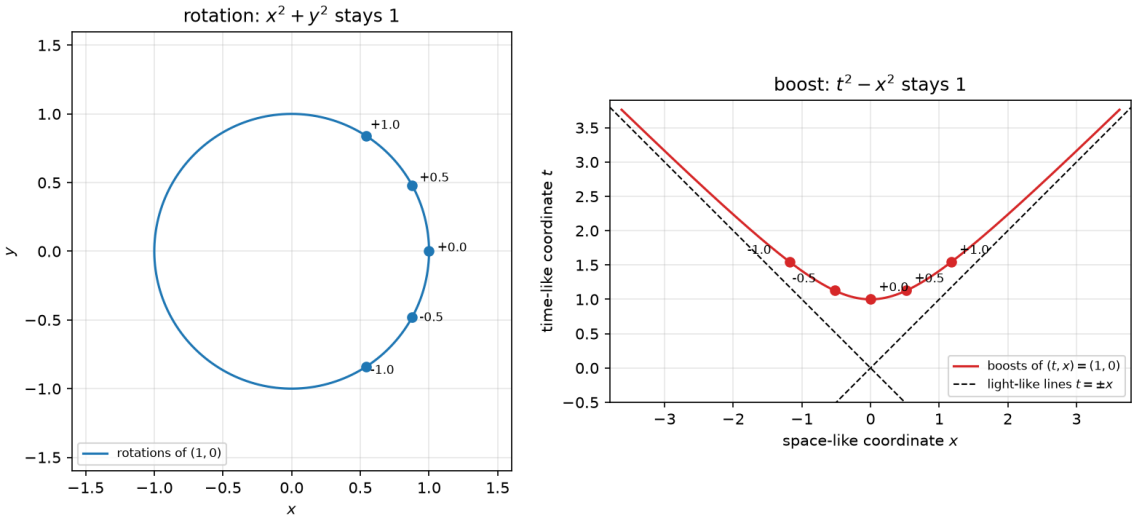

Figure 27: Left: the point $(1, 0)$ rotated by all angles from 0 to 2π (blue circle $x^2 + y^2 = 1$; the dots are the angles -1 to 1 in steps of 0.5); axes x and y. Right: the event $(t, x) = (1, 0)$ boosted with rapidities from -2 to 2 (red hyperbola $t^2 - x^2 = 1$; the dots are the rapidities -1 to 1 in steps of 0.5) and the light-like lines $t = \pm x$ (dashed); horizontal axis the space-like x, vertical axis the time-like t (pure numbers). A rotation keeps a circle, a boost keeps a hyperbola. (Notebook 01b, figure 5.)

```
\cos(\varepsilon t) - i \sin(\varepsilon t)$ has modulus 1 at all times: its real
and imaginary parts oscillate. For an imaginary frequency $\varepsilon = i\gamma$
($\gamma$ real) the same formula gives $e^{-i(i\gamma)t} = e^{\gamma t}$: no
oscillation, but exponential growth for $\gamma > 0$ (and decay for
$\gamma < 0$). A complex frequency $\varepsilon = 2 + 0.3i$ gives
$e^{-i\varepsilon t} = e^{0.3t} e^{-2it}$: an oscillation whose size grows like
$e^{0.3t}$.

The next cell checks these three statements at 501 times from 0 to 10 and draws
them.
```

## 15. What this notebook showed

- Complex numbers $a + ib$ obey the ordinary rules of algebra with $i^2 = -1$;
  $(zw)^* = z^* w^*$, $zz^* = |z|^2$ and $|zw| = |z|\,|w|$ hold for all of them
  (proved with sympy symbols).
- The exponential series at $i\theta$ converges to $\cos\theta + i\sin\theta$
  (Euler's formula); after 21 terms the error at $\theta = 2$ is below
  $10^{-12}$, and every error lies below the bound
  $e^\theta \theta^{N+1}/(N+1)!$; mpmath confirms $e^{i\pi} = -1$ to 50 digits.
- Multiplying by $e^{i\alpha}$ rotates the plane by $\alpha$; the same rotation
  is the real matrix $R(\alpha)$, and the real matrix $J$ of $i$ has $J^2 = -I$.
- The $n$ roots of unity are the corners of a regular polygon and add up to 0.
- Conjugation leaves real numbers, and lists of real numbers, unchanged.
- Rotations keep $x^2 + y^2$; boosts, which mix a time-like and a space-like
  direction, keep $x^2 - t^2$, add their rapidities, and stretch the two
  light-like directions by $e^{\varphi}$ and $e^{-\varphi}$.
- A real frequency gives an oscillation of constant size; an imaginary frequency
  gives exponential growth or decay.
```

1.17 Line-by-line walk-through of Notebook 01b

The notebook has fifteen code cells, In [1] to In [15]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.16 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.15. Its code is, line for line, the set-up code of Notebook 01f explained in Section 1.9, with the single difference `NOTEBOOK_ID = "01b"`, so that the figures are named `01b_1_complex_plane.png` and so on and the captions file is `Revision/textbook/figures/01b.captions.json`. It prints one line, Set-up of notebook 01b complete: repository folder found, helpers defined.

In [2], complex numbers in Python and in sympy.

```
import cmath  # functions of complex numbers: phase (the argument), exp
import math  # cos, sin, exp, factorial of real numbers

import mpmath  # numbers with as many digits as we ask for
import numpy as np  # arrays of numbers
import sympy as sp  # exact arithmetic
```

The module `cmath` (part of Python) holds the functions of complex numbers, among them `cmath.phase`, the argument of Section 1.11; `math` holds the same functions for real numbers. mpmath, numpy and sympy were introduced in Section 1.9.

```
z = 1 + 2j  # Python writes the imaginary unit as j, right after a number
w = 3 - 1j
say(f"Python: z = {z}, w = {w}, z + w = {z + w}, z w = {z * w}")
```

`2j` is Python's spelling of $2i$, so `z` is $1 + 2i$ and `w` is $3 - i$ (`1j` is i; a lone `j` would be a variable name). These are floating-point complex numbers: two floating-point numbers, the real and the imaginary part. The line prints `Python:  z = (1+2j), w = (3-1j), z + w = (4+1j), z w = (5+5j)`: Python writes a complex number in brackets.

```
I = sp.I  # sympy's exact imaginary unit
z_exact = 1 + 2 * I
w_exact = 3 - I
product = sp.expand(z_exact * w_exact)  # multiply out, with I**2 = -1
quotient = sp.simplify(z_exact / w_exact)
say(f"sympy: z w = {product}, z / w = {quotient}")
```

`sp.I` is sympy's exact imaginary unit; the name `I` is given to it. `z_exact` and `w_exact` are the same two numbers in exact form. `sp.expand` multiplies out a product (and replaces i^2 by -1); `sp.simplify` brings the quotient into its simplest form, which for a complex number is real part plus imaginary part. Output: `sympy:  z w = 5 + 5*I, z / w = 1/10 + 7*I/10`, the results of Section 1.10.

```
check(I ** 2 == -1, "i^2 = -1")
check(product == 5 + 5 * I and complex(product) == z * w, "(1 + 2i)(3 - i) = 5 + 5i")
check(sp.simplify(quotient - (1 + 7 * I) / 10) == 0, "(1 + 2i)/(3 - i) = (1 + 7i)/10")
```

Three checks. The first confirms that sympy's unit squares to -1. The second compares the exact product with $5 + 5i$ and also with Python's floating-point product (`complex(...)` turns the exact number into a Python complex number). The third confirms the quotient by showing that its difference from $(1 + 7i)/10$ simplifies to 0. Three PASS lines.

In [3], the rules of the conjugate and the modulus, for all complex numbers.

```
a, b, c, d = sp.symbols("a b c d", real=True)  # any real numbers
zz = a + b * I
ww = c + d * I
```

Four sympy symbols for real numbers; `zz` $= a + ib$ and `ww` $= c + id$ stand for any two complex numbers.

```
check(sp.expand(sp.conjugate(zz * ww) - sp.conjugate(zz) * sp.conjugate(ww)) == 0,
      "(z w)* = z* w* for all complex z and w")
check(sp.expand(zz * sp.conjugate(zz)) == a ** 2 + b ** 2,
      "z z* = a^2 + b^2 = |z|^2 for every z = a + i b")
check(sp.expand(zz * ww * sp.conjugate(zz * ww)
                - (a ** 2 + b ** 2) * (c ** 2 + d ** 2)) == 0,
      "|z w|^2 = |z|^2 |w|^2 for all complex z and w")
```

`sp.conjugate` forms the conjugate. Each check multiplies out the difference of the two sides of one of the three rules of Section 1.10 and requires 0. Because the symbols stand for all real numbers, these are proofs, not tests of examples. Three PASS lines.

```
say(f"|z| = {sp.Abs(z_exact)}, |w| = {sp.Abs(w_exact)}, "
    f"|z w| = {sp.Abs(product)}")
```

`sp.Abs` is the modulus. Output: `|z| = sqrt(5), |w| = sqrt(10), |z w| = 5*sqrt(2)`, and indeed $\sqrt{5} \cdot \sqrt{10} = \sqrt{50} = 5\sqrt{2}$, rule 3.

In [4], complex numbers as arrows.

```
def arrow(ax, number, color, label, start=0j, style="-"):
    """Draw the complex number as an arrow from start to start + number."""
    tip = start + number
    ax.annotate("", xy=(tip.real, tip.imag), xytext=(start.real, start.imag),
                arrowprops={"arrowstyle": "->", "color": color, "lw": 2,
                            "linestyle": style})
    ax.text(tip.real + 0.1, tip.imag + 0.1, label, color=color)
```

A helper that draws a complex number as an arrow. The arguments after the first ones have default values (`start=0j`: the arrow starts at the origin unless another start is given; `style="-"`: a solid line). `.real` and `.imag` are the real and imaginary parts of a Python complex number. `ax.annotate("", xy=..., xytext=...)` draws an arrow without text from the point `xytext` to the point `xy`; the dictionary `arrowprops` sets its look (an arrow head, the colour, the line width 2 and the line style). `ax.text` writes the label a little to the right of and above the tip.

```
fig, ax = plt.subplots(figsize=(7.0, 5.2))
arrow(ax, z, "tab:blue", "$z = 1 + 2i$")
arrow(ax, w, "tab:red", "$w = 3 - i$")
arrow(ax, w, "tab:red", "", start=z, style="--")  # w moved to the tip of z
arrow(ax, z + w, "black", "$z + w$")
arrow(ax, z.conjugate(), "tab:green", "$z^* = 1 - 2i$")
arrow(ax, 1j * z, "tab:purple", "$iz = -2 + i$")
```

A figure with one pair of axes, then six arrows: z, w, the arrow w again starting at the tip of z (dashed, `style` set to a string of two hyphens), their sum, the conjugate (`.conjugate()` is Python's conjugate) and iz.

```
ax.axhline(0, color="0.5", lw=0.8)  # the real axis
ax.axvline(0, color="0.5", lw=0.8)  # the imaginary axis
ax.set_xlim(-2.8, 5.0)
ax.set_ylim(-2.6, 3.4)
ax.set_aspect("equal")
ax.set_xlabel("real part Re")
ax.set_ylabel("imaginary part Im")
ax.set_title("Complex numbers as arrows")
save_figure(fig, "complex_plane",
            "Complex numbers as arrows in the complex plane; horizontal axis the "
            ...)
```

The two grey lines are the real and the imaginary axis. `set_xlim` and `set_ylim` fix the ranges; `set_aspect("equal")` makes one unit equally long on both axes, so that right angles look right. The labels, the title and `save_figure` follow. What Figure 01b.1 shows: the sum $z + w$ is the diagonal of the parallelogram spanned by z and w; z^* is z mirrored in the real axis; iz is z turned by a right angle.

```
turn = cmath.phase(1j * z) - cmath.phase(z)  # difference of the two arguments
check(abs(abs(1j * z) - abs(z)) < 1e-15 and abs(turn - math.pi / 2) < 1e-12,
      "multiplying by i keeps the length and turns by pi/2")
```

`cmath.phase` gives the argument in radians; `turn` is how much larger the argument of iz is than that of z. `abs` of a Python complex number is its modulus. The check requires the same length to 10^{-15} and a turn of $\pi/2$ to 10^{-12}, the statement of Section 1.10. The output is the figure line and the PASS line.

In [5], Euler's formula from the exponential series.

```
theta = 2.0
target = complex(math.cos(theta), math.sin(theta))  # cos(theta) + i sin(theta)
partial_sums = []
total = 0j
term = 1 + 0j  # the term number 0: (i theta)^0 / 0! = 1
```

The angle $\theta = 2$; `target` is $\cos 2 + i \sin 2$ as a Python complex number (`complex(x, y)` is $x + iy$). The list `partial_sums` will hold $S_0, \ldots, S_{20}$; `total` starts at 0 and `term` at the term number 0, which is 1.

```
for k in range(21):
    total += term
    partial_sums.append(total)  # S_k
    term = term * 1j * theta / (k + 1)  # the next term
errors = [abs(s - target) for s in partial_sums]
```

The loop runs for $k = 0$ to 20: it adds the current term, stores the partial sum S_k, and makes the next term from the current one, $(i\theta)^{k+1}/(k+1)! = \frac{(i\theta)^k}{k!} \cdot \frac{i\theta}{k+1}$ (one more factor $i\theta$ and one more factor $k+1$ in the factorial). Making each term from the previous one avoids computing large powers and factorials. `errors` holds the 21 errors $|S_N - e^{2i}|$.

```
bounds = [math.exp(theta) * theta ** (n + 1) / math.factorial(n + 1)
          for n in range(21)]
for n in (0, 1, 2, 5, 10, 15, 20):
    say(f"N = {n:2d}: S_N = {partial_sums[n].real:+.12f} {partial_sums[n].imag:+.12f} i,"
        f" error {errors[n]:.1e}")
say(f"cos 2 + i sin 2 = {target.real:+.12f} {target.imag:+.12f} i")
```

`bounds` holds the bound $e^\theta \theta^{N+1}/(N+1)!$ of Section 1.11 for $N = 0$ to 20. Seven partial sums are printed with 12 digits after the point and a sign (`:+.12f`), with their errors. The output shows $S_0 = 1$, $S_1 = 1 + 2i$, $S_2 = -1 + 2i$, and then the partial sums settling: $S_{20} = -0.416146836547 + 0.909297426826\,i$, equal in all printed digits to $\cos 2 + i \sin 2$, with the error 4.1×10^{-14}; the errors are 1.7, 1.8, 1.2, 0.086, 5.1×10^{-5}, 3.1×10^{-9}, 4.1×10^{-14}. The first errors do not shrink, because for $k < \theta$ the terms still grow.

```
check(all(e <= b + 1e-15 for e, b in zip(errors, bounds)),
      "the error of every partial sum is below e^theta theta^(N+1)/(N+1)!")
report("error of the series for e^(2i) after 21 terms", f"{errors[20]:.1e}")
check(errors[20] < 1e-12, "21 terms of the series give cos 2 + i sin 2 to 1e-12")
```

The first check compares every error with its bound (the extra 10^{-15} allows for the rounding of the floating-point numbers themselves). The RESULT line prints 4.1×10^{-14}, and the last check requires it to be below 10^{-12}. Two PASS lines.

In [6], the picture of the series.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.6))
circle = np.exp(1j * np.linspace(0.0, 2.0 * np.pi, 400))  # the unit circle
left.plot(circle.real, circle.imag, color="0.7", lw=1, label="unit circle")
```

Two panels side by side. `np.linspace(0.0, 2.0 * np.pi, 400)` gives 400 angles from 0 to 2π; `np.exp(1j * ...)` turns them into the points $e^{i\theta}$ of the unit circle (numpy computes complex exponentials entry by entry); `.real` and `.imag` of a numpy array are the arrays of the real and imaginary parts. The circle is drawn in light grey.

```
first = np.array(partial_sums[:11])
left.plot(first.real, first.imag, "o-", color="tab:blue",
          label="partial sums $S_0, \\dots, S_{10}$")
```

```
for n in range(5):  # number the first five points
    left.text(first[n].real + 0.06, first[n].imag + 0.06, f"$S_{n}$")
left.plot([target.real], [target.imag], "*", color="tab:red", ms=14,
          label="$e^{2i} = \\cos 2 + i \\sin 2$")
```

The first eleven partial sums as an array, drawn as points joined in order; the first five are labelled S_0 to S_4; the target e^{2i} is a large red star (`"*"`, marker size 14).

```
left.set_aspect("equal")
left.set_xlabel("real part")
left.set_ylabel("imaginary part")
left.set_title("Partial sums of the series of $e^{2i}$")
left.legend(loc="lower left", fontsize=8)
right.semilogy(range(21), errors, "o-", label="error $|S_N - e^{2i}|$")
right.semilogy(range(21), bounds, "--", label="bound $e^2 \\, 2^{N+1}/(N+1)!$")
right.set_xlabel("number $N$ of the last term")
right.set_ylabel("error (logarithmic scale)")
right.set_title("How fast the series converges")
right.legend()
fig.tight_layout()
save_figure(fig, "euler_series",
            "Left: the partial sums $S_N = \\sum_{k=0}^{N} (2i)^k/k!$ for $N = 0$ to "
            ...)
```

Labels for the left panel; on the right the 21 errors and the 21 bounds against N with a logarithmic vertical axis (`semilogy`), the bound dashed (the style string of two hyphens). What Figure 01b.2 shows: on the left the partial sums turn around the origin and close in on the star; on the right the errors fall ever faster and stay below the dashed bound.

```
step_ratios = [errors[n + 1] / errors[n] for n in range(10, 20)]
check(all(abs(ratio - theta / (n + 2)) < 0.1 * theta / (n + 2)
          for ratio, n in zip(step_ratios, range(10, 20))),
      "from N to N + 1 the error is multiplied by about theta/(N + 2) (N = 10 to 19)")
```

`step_ratios` are the ten ratios of the error at $N+1$ to the error at N for $N = 10$ to 19; the check requires each to lie within 10 per cent of $\theta/(N+2)$, the factor derived in Section 1.11. One PASS line.

In [7], 50 digits and the law of exponents.

```
mpmath.mp.dps = 50  # work with 50 significant digits
i_mp = mpmath.mpc(0, 1)  # the imaginary unit as an mpmath number
euler_gap = abs(mpmath.exp(i_mp * 2) - (mpmath.cos(2) + i_mp * mpmath.sin(2)))
pi_gap = abs(mpmath.exp(i_mp * mpmath.pi) + 1)
e_i_pi = mpmath.exp(i_mp * mpmath.pi)
```

`mpmath.mpc(0, 1)` is the complex number $0 + 1i$ in mpmath, computed with 50 digits. `euler_gap` is the size of $e^{2i} - (\cos 2 + i \sin 2)$, `pi_gap` the size of $e^{i\pi} + 1$, and `e_i_pi` the number $e^{i\pi}$ itself.

```
# pi itself is stored with 50 digits, so a tiny imaginary part of about 1e-51 is
# left over: the rounding of pi, not a failure of the formula.
say(f"e^(i pi): real part {mpmath.nstr(e_i_pi.real, 30)}, imaginary part of size "
    f"{mpmath.nstr(abs(e_i_pi.imag), 2)}")
check(euler_gap < mpmath.mpf("1e-45") and pi_gap < mpmath.mpf("1e-45"),
      "mpmath, 50 digits: e^(2i) = cos 2 + i sin 2 and e^(i pi) = -1")
```

The comment explains the leftover imaginary part. The line prints e^(i pi): real part -1.0, imaginary part of size 1.0e-51 (`mpmath.nstr` writes a number with the given count of significant digits and drops needless zeros, so -1 appears as -1.0). The check requires both gaps to be below 10^{-45}.

```
alpha, beta = sp.symbols("alpha beta", real=True)
left_side = sp.expand((sp.cos(alpha) + I * sp.sin(alpha))
                      * (sp.cos(beta) + I * sp.sin(beta)))
right_side = sp.expand(sp.expand_trig(sp.cos(alpha + beta) + I * sp.sin(alpha + beta)))
check(sp.expand(left_side - right_side) == 0,
      "sympy: e^(i alpha) e^(i beta) = e^(i (alpha + beta)) for all real angles")
```

The proof of the law of exponents of Section 1.11 with sympy: `left_side` is $(\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)$ multiplied out; `sp.expand_trig` writes $\cos(\alpha+\beta)$ and $\sin(\alpha+\beta)$ with the addition theorems, and `right_side` is the result multiplied out. Their difference is 0 for all angles. The cell prints two PASS lines.

In [8], multiplication turns the letter F.

```
letter_f = np.array([0, 2j, 1.2 + 2j, 1.2 + 1.6j, 0.4 + 1.6j, 0.4 + 1.1j, 1.0 + 1.1j,
                     1.0 + 0.7j, 0.4 + 0.7j, 0.4, 0]) + (0.3 + 0.2j)  # corners
```

The eleven corners of the outline of a letter F as complex numbers (the last one repeats the first, to close the outline); adding $0.3 + 0.2i$ to the array shifts every corner a little away from the origin, so that no corner is the origin itself.

```
factors = [(1, "original", "black"),
           (np.exp(1j * np.pi / 3), "times $e^{i\\pi/3}$", "tab:blue"),
           (np.exp(5j * np.pi / 6), "times $e^{5i\\pi/6}$", "tab:red"),
           (0.6 * np.exp(-1j * np.pi / 2), "times $0.6\\,e^{-i\\pi/2}$", "tab:green")]
```

Four factors with their labels and colours: 1 (the original), $e^{i\pi/3}$ (a turn by 60 degrees), $e^{5i\pi/6}$ (150 degrees) and $0.6\,e^{-i\pi/2}$ (a quarter turn clockwise and a shrinking to 0.6).

```
fig, ax = plt.subplots(figsize=(8.4, 6.0))
for factor, label, color in factors:
    image = factor * letter_f  # every corner multiplied by the factor
    ax.fill(image.real, image.imag, color=color, alpha=0.35, label=label)
    ax.plot(image.real, image.imag, color=color, lw=1)
ax.plot([0], [0], "k+", ms=12)  # the origin, the centre of the rotations
```

For each factor every corner is multiplied (numpy multiplies an array entry by entry), and `ax.fill` paints the inside of the outline, 35 per cent opaque (`alpha=0.35`), while `ax.plot` draws its edge. A black cross marks the origin.

```
ax.set_aspect("equal")
ax.set_xlabel("real part")
ax.set_ylabel("imaginary part")
ax.set_title("Multiplication by a complex number")
ax.legend(loc="center left", bbox_to_anchor=(1.02, 0.5), fontsize=9)
save_figure(fig, "rotation_by_multiplication",
            "The letter F (black) and its images after multiplying every corner by "
            ...)
```

The legend is placed outside the axes, to the right (`bbox_to_anchor=(1.02, 0.5)` names a point just right of the axes at half their height). What Figure 01b.3 shows: four copies of the letter, turned about the origin and once shrunk, never mirrored.

```
rotations_ok = True
for alpha_value in (np.pi / 3, 5 * np.pi / 6):
    image = np.exp(1j * alpha_value) * letter_f
    rotations_ok &= bool(np.max(np.abs(np.abs(image) - np.abs(letter_f))) < 1e-14)
    turned = np.angle(image / letter_f)  # the change of every angle
    rotations_ok &= bool(np.max(np.abs(turned - alpha_value)) < 1e-12)
check(rotations_ok, "multiplying by e^(i alpha) keeps lengths and adds alpha to "
      "every angle")
```

For the two pure rotations: `np.abs` of a complex array is the array of the moduli, so the first condition requires every corner to keep its distance from the origin; `np.angle(image / letter_f)` is the argument of the quotient of each image corner and its original, which is the change of its angle, and the second condition requires it to be α. One PASS line.

In [9], the same turns as real 2 × 2 matrices.

```
def M(re_part, im_part):
    """The real 2 x 2 matrix of the complex number re_part + i im_part."""
    return sp.Matrix([[re_part, -im_part], [im_part, re_part]])

J = M(0, 1)  # the matrix of i
check(J * J == -sp.eye(2), "J J = -I: the real matrix J behaves like i")
```

`sp.Matrix([[...], [...]])` makes a sympy matrix from the list of its rows; `M` builds the matrix with the rows $(a, -b)$ and (b, a) of Section 1.12. `J` is the matrix of i; `*` between sympy matrices is the matrix product, and `sp.eye(2)` is the 2×2 identity. The check is $J^2 = -I$.

```
zw_re, zw_im = a * c - b * d, a * d + b * c  # z w = (ac - bd) + i (ad + bc)
check((M(a, b) * M(c, d) - M(zw_re, zw_im)).expand() == sp.zeros(2, 2),
      "M(z) M(w) = M(z w) for all complex z and w")
check(sp.expand(M(a, b).det()) == a ** 2 + b ** 2, "det M(a + i b) = a^2 + b^2")
```

With the real symbols a, b, c, d of In [3]: the real and imaginary parts of zw; then the product rule $M(z)M(w) = M(zw)$ (`sp.zeros(2, 2)` is the 2×2 matrix of zeros) and the determinant $a^2 + b^2$ (`.det()` is sympy's determinant), both for all values of the symbols.

```
def R(angle):
    """The rotation matrix of the angle: the matrix of e^(i angle)."""
    return M(sp.cos(angle), sp.sin(angle))

product_rule = (R(alpha) * R(beta) - R(alpha + beta)).applyfunc(sp.expand_trig)
check(product_rule.expand() == sp.zeros(2, 2), "R(alpha) R(beta) = R(alpha + beta)")
```

`R` builds the rotation matrix. `.applyfunc(f)` applies the function `f` to every entry of a matrix; here `sp.expand_trig` writes the entries of $R(\alpha+\beta)$ with the addition theorems, and after multiplying out every entry of the difference is 0: two turns make one.

```
check(sp.simplify(R(alpha).det()) == 1 and
      (R(alpha).T * R(alpha)).applyfunc(sp.simplify) == sp.eye(2),
      "det R(alpha) = 1 and R(alpha)^T R(alpha) = I")
```

`.T` is the transpose. The check is properties (b) and (c) of Section 1.12.

```
rotation = np.array(R(sp.pi / 3).evalf(), dtype=float)  # R(pi/3) as numbers
corners = np.array([letter_f.real, letter_f.imag])  # 2 rows: x and y of each corner
by_matrix = rotation @ corners
by_number = np.exp(1j * np.pi / 3) * letter_f
check(np.max(np.abs(by_matrix[0] + 1j * by_matrix[1] - by_number)) < 1e-14,
      "the rotation matrix R(pi/3) moves the corners exactly like e^(i pi/3)")
```

`.evalf()` turns the exact matrix $R(\pi/3)$ into decimal numbers, and `np.array(..., dtype=floa t)` into a numpy array of floating-point numbers. `corners` is a table with two rows, the x and the y coordinates of the eleven corners; `rotation @ corners` multiplies the matrix with every column at once (`@` is numpy's matrix product; Section 1.18 treats it in full). `by_matrix[0] + 1j * by_matrix[1]` turns the two rows back into complex numbers, which must agree with the corners multiplied by $e^{i\pi/3}$ to 10^{-14}. The cell prints six PASS lines.

In [10], the roots of unity.

```
for n in (3, 8):
    roots = np.exp(2j * np.pi * np.arange(n) / n)  # e^(2 pi i k/n), k = 0 ... n-1
    check(np.max(np.abs(roots ** n - 1)) < 1e-12 and abs(roots.sum()) < 1e-12,
          f"the {n} roots of unity of order {n}: z^{n} = 1 and their sum is 0")
```

For $n = 3$ and $n = 8$: `np.arange(n)` is $0, \ldots, n-1$, so `roots` holds the n roots of unity; the check requires every n-th power to be 1 and the sum to be 0, both to 10^{-12}. Two PASS lines, whose texts contain the value of `n` (an f-string).

```
eighth = [sp.expand_complex(sp.exp(2 * sp.pi * I * k / 8)) for k in range(8)]
say("the eighth roots of unity, exactly: " + ", ".join(str(r) for r in eighth))
check(all(sp.simplify(r ** 8 - 1) == 0 for r in eighth) and
      sp.simplify(sum(eighth)) == 0,
      "sympy: each exact eighth root has eighth power 1, and they add up to 0")
```

The eight roots exactly: `sp.expand_complex` writes $e^{2\pi ik/8}$ as real part plus i times imaginary part. They are printed (`", ".join(...)` joins the texts with a comma and a blank): `1, sqrt(2)/2 + sqrt(2)*I/2, I`, and so on, the list of Section 1.12. The check proves the two properties exactly.

```
fig, axes = plt.subplots(1, 2, figsize=(10.0, 4.8))
for ax, n in zip(axes, (3, 8)):
    roots = np.exp(2j * np.pi * np.arange(n + 1) / n)  # the first root again at the end
    ax.plot(circle.real, circle.imag, color="0.75", lw=1)
    ax.plot(roots.real, roots.imag, "o-", color="tab:blue")
    for k in range(n):
        arrow(ax, roots[k], "tab:blue", f"$z_{k}$")
```

Two panels, one for $n = 3$ and one for $n = 8$. With `np.arange(n + 1)` the list ends with the first root again ($k = n$ gives $e^{2\pi i} = 1$), so that the line through the points closes the polygon. The unit circle of In [6] is drawn in grey, the polygon in blue, and each root as a labelled arrow from the origin, with the helper of In [4].

```
    ax.set_aspect("equal")
    ax.set_xlim(-1.45, 1.45)
    ax.set_ylim(-1.35, 1.35)
    ax.set_xlabel("real part")
    ax.set_ylabel("imaginary part")
    ax.set_title(f"the {n} roots of $z^{n} = 1$")
fig.tight_layout()
save_figure(fig, "roots_of_unity",
            "The roots of unity $z_k = e^{2\\pi i k/n}$ for $n = 3$ (left) and "
            ...)
```

Equal scales, ranges, labels and a title on each panel; then the figure is saved. What Figure 01b.4 shows: a regular triangle and a regular octagon inscribed in the unit circle; the arrows of each picture add up to zero, as proved in Section 1.12. The cell prints three PASS lines, the exact roots and the figure line.

In [11], conjugation and real numbers.

```
v_real = np.array([0.5, -2.0, 3.0])  # a list of real numbers
v_complex = np.array([1 + 2j, -1j, 4.0])  # a list with imaginary parts
check((v_real.conj() == v_real).all(),
      "conjugation leaves a list of real numbers unchanged")
check(not (v_complex.conj() == v_complex).all(),
      "conjugation changes a list whose imaginary parts are not all 0")
check((v_complex.conj().conj() == v_complex).all(),
      "conjugating twice gives back the original list")
check(abs(np.exp(0.7j).conjugate() - np.exp(-0.7j)) < 1e-15,
      "the conjugate of e^(i alpha) is e^(-i alpha)")
```

`.conj()` conjugates every entry of a numpy array; `==` between two arrays compares entry by entry, and `.all()` is true when every comparison is true. The four checks are the four statements of Section 1.12: a real list is unchanged; a list with imaginary parts changes (`not` turns true into false and back); conjugating twice restores the list; and $(e^{0.7i})^* = e^{-0.7i}$. Four PASS lines.

In [12], boosts, exactly.

```
phi, phi1, phi2 = sp.symbols("phi phi1 phi2", real=True)

def boost(rapidity):
    """The boost matrix acting on the pair (t, x)."""
    return sp.Matrix([[sp.cosh(rapidity), sp.sinh(rapidity)],
                      [sp.sinh(rapidity), sp.cosh(rapidity)]])
```

Three real symbols for rapidities, and a function that builds the boost $\Lambda(\varphi)$ of Section 1.13.

```
eta_tx = sp.diag(-1, 1)  # t time-like (-1), x space-like (+1)
L = boost(phi)
check((L.T * eta_tx * L - eta_tx).applyfunc(sp.simplify) == sp.zeros(2, 2) and
      sp.simplify(L.det()) == 1,
      "a boost keeps -t^2 + x^2 (Lambda^T eta Lambda = eta) and has det 1")
```

`sp.diag(-1, 1)` is the diagonal matrix $\eta = \mathrm{diag}(-1, +1)$. The check computes $\Lambda^T \eta \Lambda - \eta$, simplifies every entry (sympy knows $\cosh^2 - \sinh^2 = 1$) and requires the zero matrix, and requires $\det \Lambda = 1$: property (a).

```
added = (boost(phi1) * boost(phi2) - boost(phi1 + phi2)).applyfunc(sp.expand_trig)
check(added.expand() == sp.zeros(2, 2), "rapidities add: boost(phi1) boost(phi2) = "
      "boost(phi1 + phi2)")
```

Property (b): `expand_trig` also knows the addition theorems of cosh and sinh.

```
light_plus = (L * sp.Matrix([1, 1]) - sp.exp(phi) * sp.Matrix([1, 1]))
light_minus = (L * sp.Matrix([1, -1]) - sp.exp(-phi) * sp.Matrix([1, -1]))
# rewrite(sp.exp) writes cosh and sinh with exponentials, then simplify:
check(light_plus.applyfunc(lambda e: sp.simplify(e.rewrite(sp.exp)))
      == sp.zeros(2, 1) and
      light_minus.applyfunc(lambda e: sp.simplify(e.rewrite(sp.exp)))
      == sp.zeros(2, 1),
      "the light-like directions are stretched by e^phi and by e^(-phi)")
```

Property (c): `sp.Matrix([1, 1])` is the column $(1, 1)$. `light_plus` is $\Lambda(1,1) - e^{\varphi}(1,1)$ and `light_minus` is $\Lambda(1,-1) - e^{-\varphi}(1,-1)$. A `lambda e: ...` is a function without a name, written in one line: it takes an entry `e`, rewrites cosh and sinh with exponentials (their definitions) and simplifies. Both differences must be zero columns (`sp.zeros(2, 1)`). The cell prints three PASS lines.

In [13], circles and hyperbolas.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 5.0))
angles = np.linspace(0.0, 2.0 * np.pi, 400)
left.plot(np.cos(angles), np.sin(angles), color="tab:blue",
```

```
          label="rotations of $(1, 0)$")
marks = np.array([-1.0, -0.5, 0.0, 0.5, 1.0])
left.plot(np.cos(marks), np.sin(marks), "o", color="tab:blue")
for value in marks:
    left.text(1.06 * np.cos(value), 1.06 * np.sin(value), f"{value:+.1f}", fontsize=8)
```

The point $(1, 0)$ turned by an angle α is $R(\alpha)(1, 0) = (\cos\alpha, \sin\alpha)$; for 400 angles from 0 to 2π these points make the circle. Five angles $-1, -0.5, 0, 0.5, 1$ are marked with dots and labelled just outside the circle (the factor 1.06 moves the label outwards).

```
left.set_aspect("equal")
left.set_xlim(-1.6, 1.6)
left.set_ylim(-1.6, 1.6)
left.set_xlabel("$x$")
left.set_ylabel("$y$")
left.set_title("rotation: $x^2 + y^2$ stays 1")
left.legend(loc="lower left", fontsize=8)
```

Equal scales, ranges, labels, title and legend of the left panel.

```
rapidities = np.linspace(-2.0, 2.0, 400)
right.plot(np.sinh(rapidities), np.cosh(rapidities), color="tab:red",
           label="boosts of $(t, x) = (1, 0)$")
right.plot(np.sinh(marks), np.cosh(marks), "o", color="tab:red")
```

The event $(t, x) = (1, 0)$ boosted with rapidity φ is $\Lambda(\varphi)(1, 0) = (\cosh\varphi, \sinh\varphi)$; it is drawn with $x = \sinh\varphi$ on the horizontal and $t = \cosh\varphi$ on the vertical axis, for 400 rapidities from -2 to 2, with dots at the five marked rapidities.

```
for value in marks:  # labels left of the points on the left half, right otherwise
    shift = 0.12 if value >= 0 else -0.62
    right.text(np.sinh(value) + shift, np.cosh(value) + 0.12, f"{value:+.1f}",
               fontsize=8)
```

The labels of the dots are put to the right of the points on the right half and to the left on the left half, so that they do not cover the curve (`a if condition else b` takes `a` when the condition holds and `b` otherwise).

```
edge = np.linspace(-3.8, 3.8, 2)
right.plot(edge, edge, "k--", lw=1, label="light-like lines $t = \\pm x$")
right.plot(edge, -edge, "k--", lw=1)
```

`edge` holds the two numbers -3.8 and 3.8; the two dashed black lines through $(-3.8, -3.8)$, $(3.8, 3.8)$ and through $(-3.8, 3.8)$, $(3.8, -3.8)$ are the light-like lines $t = x$ and $t = -x$.

```
right.set_aspect("equal")
right.set_xlim(-3.8, 3.8)
```

```
right.set_ylim(-0.5, 3.9)
right.set_xlabel("space-like coordinate $x$")
right.set_ylabel("time-like coordinate $t$")
right.set_title("boost: $t^2 - x^2$ stays 1")
right.legend(loc="lower right", fontsize=8)
fig.tight_layout()
save_figure(fig, "rotations_and_boosts",
            "Left: the point $(1, 0)$ rotated by all angles from 0 to $2\\pi$ "
            ...)
```

Scales, ranges, labels and legend of the right panel, then the figure. What Figure 01b.5 shows: the rotated point runs around a circle; the boosted event runs along the upper branch of the hyperbola $t^2 - x^2 = 1$, which comes ever closer to the dashed light-like lines but never crosses them.

```
on_hyperbola = np.cosh(rapidities) ** 2 - np.sinh(rapidities) ** 2
check(np.max(np.abs(on_hyperbola - 1)) < 1e-12,
      "numbers: cosh^2 - sinh^2 = 1 at 400 rapidities from -2 to 2")
```

The check computes $\cosh^2\varphi - \sinh^2\varphi$ at the 400 rapidities and requires 1 to 10^{-12}. One PASS line.

In [14], oscillation and growth.

```
t = np.linspace(0.0, 10.0, 501)
wave = np.exp(-1j * 2.0 * t)  # real frequency 2
growing = np.exp(-1j * (0.3j) * t)  # imaginary frequency 0.3 i
decaying = np.exp(-1j * (-0.3j) * t)  # imaginary frequency -0.3 i
mixed = np.exp(-1j * (2.0 + 0.3j) * t)  # complex frequency 2 + 0.3 i
```

501 times from 0 to 10, and the wave $e^{-i\varepsilon t}$ for the four frequencies of Section 1.13: 2, $0.3i$, $-0.3i$ and $2 + 0.3i$.

```
check(np.max(np.abs(np.abs(wave) - 1.0)) < 1e-14,
      "real frequency: |e^(-i eps t)| = 1 at every time")
check(np.max(np.abs(growing - np.exp(0.3 * t))) < 1e-12 * np.exp(3.0),
      "imaginary frequency 0.3 i: e^(-i eps t) = e^(0.3 t), real and growing")
check(np.max(np.abs(np.abs(mixed) - np.exp(0.3 * t))) < 1e-12 * np.exp(3.0),
      "complex frequency 2 + 0.3 i: the size of the wave is e^(0.3 t)")
```

The three statements of Section 1.13: modulus 1 for the real frequency; $e^{0.3t}$ for the imaginary one; size $e^{0.3t}$ for the complex one. The tolerance $10^{-12}e^3$ is relative to the largest value $e^{0.3\cdot 10} = e^3 \approx 20$. Three PASS lines.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.4))
left.plot(t, wave.real, label="real part $\\cos 2t$")
left.plot(t, wave.imag, "--", label="imaginary part $-\\sin 2t$")
left.plot(t, np.abs(wave), color="black", lw=2, label="modulus $= 1$")
left.set_xlabel("time $t$")
left.set_ylabel("value")
left.set_title("real frequency $\\varepsilon = 2$")
left.set_ylim(-1.75, 1.3)  # room below the curves for the legend
left.legend(loc="lower center", ncol=3, fontsize=8)
```

The left panel: the real part, the imaginary part (dashed) and the modulus (thick black) of the wave with the real frequency 2. The vertical range leaves room below the curves for a legend in three columns (`ncol=3`).

```
right.plot(t, growing.real, color="tab:red", lw=2,
           label="$\\varepsilon = 0.3i$: $e^{0.3t}$")
right.plot(t, decaying.real, color="tab:blue", lw=2,
           label="$\\varepsilon = -0.3i$: $e^{-0.3t}$")
right.plot(t, mixed.real, color="tab:green",
           label="$\\varepsilon = 2 + 0.3i$: real part")
right.plot(t, -np.exp(0.3 * t), ":", color="tab:red")  # the lower envelope
right.set_xlabel("time $t$")
right.set_ylabel("value")
right.set_title("imaginary and complex frequencies")
right.legend(loc="upper left", fontsize=8)
fig.tight_layout()
save_figure(fig, "oscillation_and_growth",
            "Left: the wave $e^{-i\\varepsilon t}$ with the real frequency "
            ...)
```

The right panel: the growing and the decaying wave (both real), the real part of the wave with the complex frequency, and the dotted red curve $-e^{0.3t}$, which with the solid red curve $e^{0.3t}$ encloses the growing oscillation. What Figure 01b.6 shows: on the left a steady oscillation of constant size; on the right one curve growing, one decaying, and an oscillation whose swings grow between $\pm e^{0.3t}$.

In [15], the last check.

```
figure_names = ["01b_1_complex_plane.png", "01b_2_euler_series.png",
                "01b_3_rotation_by_multiplication.png", "01b_4_roots_of_unity.png",
                "01b_5_rotations_and_boosts.png", "01b_6_oscillation_and_growth.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

As in Notebook 01f: the six figure files must exist, and the last line is printed, ALL 34 CHECKS PASSED (notebook 01b). The 34 checks are: 3 in In [2], 3 in In [3], 1 in In [4], 2 in In [5], 1 in In [6], 2 in In [7], 1 in In [8], 6 in In [9], 3 in In [10], 4 in In [11], 3 in In [12], 1 in In [13], 3 in In [14] and 1 in In [15].

1.18 Vectors and matrices; the matrix product

Vectors. A **vector** is an ordered list of numbers, such as $v = (1, 2, 0)$; the numbers are its **components**, and v has three of them. The fields of the course have sixteen components at every point, so at each point a field is a vector with sixteen components. Vectors with the same number of components are added component by component, and a vector is multiplied by a number c by multiplying every component:

$$(v + w)_i = v_i + w_i, \qquad (cv)_i = c\, v_i.$$

The **dot product** of two vectors with n components is the number

$$v \cdot w = \sum_{i=1}^{n} v_i w_i = v_1 w_1 + v_2 w_2 + \cdots + v_n w_n.$$

The symbol $\sum$ (the capital Greek letter sigma) abbreviates a sum: $\sum_{i=1}^{n} t_i$ means $t_1 + t_2 + \cdots + t_n$, and the letter i under it, the **index** of the sum, runs through the whole numbers from 1 to n. For $v = (1, 2, 0)$ and $w = (0, 1, 1)$: $v + w = (1, 3, 1)$, $3v = (3, 6, 0)$ and $v \cdot w = 1 \cdot 0 + 2 \cdot 1 + 0 \cdot 1 = 2$.

Matrices. A **matrix** with m rows and n columns, an $m \times n$ matrix, is a rectangular table of numbers A_{ij}: the first index $i = 1, \ldots, m$ numbers the row (counted downwards), the second $j = 1, \ldots, n$ the column (counted to the right). It is **square** if $m = n$. Python counts from 0, so the entry A_{23} in row 2 and column 3 is `A[1, 2]` in Python. A vector with n components may be written as a column, an $n \times 1$ matrix.

Matrix times vector. An $m \times n$ matrix A turns a vector v with n components into a vector Av with m components:

$$(Av)_i = \sum_{j=1}^{n} A_{ij} v_j,$$

component i of Av is row i of A times v, entry by entry, added up (the rule of Section 1.12 for 2×2 matrices). For the 3×3 matrix A with the rows $(1, 2, 0)$, $(0, 1, 1)$, $(1, 3, 1)$ and $v = (1, 2, 0)$:

$$Av = \begin{pmatrix} 1 \cdot 1 + 2 \cdot 2 + 0 \cdot 0 \\ 0 \cdot 1 + 1 \cdot 2 + 1 \cdot 0 \\ 1 \cdot 1 + 3 \cdot 2 + 1 \cdot 0 \end{pmatrix} = \begin{pmatrix} 5 \\ 2 \\ 7 \end{pmatrix}$$

(each row times the column v). The map $v \mapsto Av$ is **linear**: $A(v + w) = Av + Aw$ and $A(cv) = c\,Av$, because $\sum_j A_{ij}(v_j + w_j) = \sum_j A_{ij} v_j + \sum_j A_{ij} w_j$ and $\sum_j A_{ij}(c v_j) = c \sum_j A_{ij} v_j$ (multiply out inside the sum; a common factor comes out of a sum).

The matrix product (PROVED). The product of an $m \times n$ matrix A and an $n \times p$ matrix B is the $m \times p$ matrix

$$(AB)_{ik} = \sum_{j=1}^{n} A_{ij} B_{jk},$$

entry (i, k) is row i of A times column k of B. It is made so that $(AB)v = A(Bv)$ for every vector v:

$$\big(A(Bv)\big)_i = \sum_j A_{ij} (Bv)_j = \sum_j A_{ij} \sum_k B_{jk} v_k = \sum_k \Big(\sum_j A_{ij} B_{jk} \Big) v_k = \big((AB)v\big)_i$$

(the rule of matrix times vector, twice; the factor A_{ij} moved into the inner sum and the two sums exchanged, which only re-orders the terms of a finite sum; the definition of AB). With the matrix A above and B with the rows $(0, 1, 0)$, $(1, 0, 2)$, $(0, 1, 1)$:

$$AB = \begin{pmatrix} 2 & 1 & 4 \\ 1 & 1 & 3 \\ 3 & 2 & 7 \end{pmatrix}, \qquad BA = \begin{pmatrix} 0 & 1 & 1 \\ 3 & 8 & 2 \\ 1 & 4 & 2 \end{pmatrix}$$

(for example the entry in row 1, column 3 of AB is $1 \cdot 0 + 2 \cdot 2 + 0 \cdot 1 = 4$, and that of BA is $0 \cdot 0 + 1 \cdot 1 + 0 \cdot 1 = 1$). The two products differ: **matrix multiplication is not commutative**, $AB \neq BA$ in general. The order of the factors matters in every matrix formula of the course. The product is, however, **associative**, $(AB)C = A(BC)$, because both sides have the entries $\sum_j \sum_k A_{ij}B_{jk}C_{kl}$, and **distributive**, $A(B + C) = AB + AC$ (multiply out inside the sum).

The summation convention, a first look. In $(AB)_{ik} = \sum_j A_{ij}B_{jk}$ the index j appears twice in the product and is summed; i and k appear once and are not summed. The course writes such sums without the sign $\sum$: an index that appears twice in one product is summed over all its values. So $A_{ij}B_{jk}$ means $\sum_j A_{ij}B_{jk}$. A summed index is called a **dummy** index (its name does not matter: $A_{ij}B_{jk} = A_{il}B_{lk}$), an index that is not summed a **free** index (the formula holds for each of its values). numpy's function `einsum` reads this convention literally: `np.einsum("ij,jk->ik", A, B)` says "the first factor has the indices i, j, the second j, k; j appears twice and is summed; the result has the indices i, k". Section 1.26 develops the convention fully, with upper and lower indices.

Identity, transpose and trace (PROVED). The **identity matrix** I is the square matrix with 1 on the diagonal and 0 elsewhere; its entries are the **Kronecker delta**, $\delta_{ij} = 1$ if $i = j$ and 0 otherwise, and $IA = AI = A$. The **transpose** A^T has the rows and columns exchanged, $(A^T)_{ij} = A_{ji}$. The transpose of a product is the product of the transposes in the opposite order:

$$\left((AB)^T\right)_{ki} = (AB)_{ik} = \sum_j A_{ij}B_{jk} = \sum_j (B^T)_{kj}(A^T)_{ji} = (B^T A^T)_{ki}$$

(the definition of the transpose; the matrix product; each factor written with its transpose, re-ordered, since numbers commute; the matrix product of B^T and A^T). The **trace** of a square matrix is the sum of its diagonal entries, $\operatorname{tr} A = \sum_i A_{ii}$. Although $AB \neq BA$, the two products have the same trace:

$$\operatorname{tr}(AB) = \sum_i \sum_j A_{ij}B_{ji} = \sum_j \sum_i B_{ji}A_{ij} = \operatorname{tr}(BA)$$

(the diagonal entries of AB, added; the order of the two sums and of the two factors exchanged; the diagonal entries of BA, added). In the example both traces are 10 ($2 + 1 + 7$ and $0 + 8 + 2$). Notebook 01a, In [2] to In [5], computes all of this three ways (with loops, with `einsum`, with numpy's operator `@`) and draws the four matrices as **heat maps**, pictures in which every entry is a coloured square (Figure 01a.1).

1.19 Permutations and their signs

Permutations. A **permutation** of n objects is a re-ordering of them. We take the objects to be the numbers $0, 1, \ldots, n-1$ (as Python does; the book's formulas use $1, \ldots, n$, which changes nothing): a permutation σ is the list $(\sigma(0), \sigma(1), \ldots, \sigma(n-1))$ that contains each number exactly once. There are $n! = 1 \cdot 2 \cdots n$ permutations: the first place can hold any of the n numbers, the

second any of the $n-1$ that are left, and so on, down to 1 choice for the last place, and the numbers of choices multiply.

Inversions and the sign. An **inversion** of a permutation is a pair of places $i < j$ whose entries stand in the wrong order, $\sigma(i) > \sigma(j)$. The **sign** of the permutation is

$$\operatorname{sign}(\sigma) = (-1)^{\text{number of inversions}},$$

$+1$ for an **even** and -1 for an **odd** permutation. The six permutations of $0, 1, 2$:

permutation	**inversions (pairs of entries in the wrong order)**	**number**	**sign**
(0, 1, 2)	none	0	$+1$
(0, 2, 1)	(2, 1)	1	-1
(1, 0, 2)	(1, 0)	1	-1
(1, 2, 0)	(1, 0), (2, 0)	2	$+1$
(2, 0, 1)	(2, 0), (2, 1)	2	$+1$
(2, 1, 0)	(2, 1), (2, 0), (1, 0)	3	-1

Theorem: an exchange flips the sign (PROVED). Exchanging the entries at two places of a permutation changes its sign. *Proof, step 1: neighbouring places.* Exchange the entries at the places k and $k+1$. A pair of places that contains neither k nor $k+1$ keeps its two entries and its order. For a place p outside the two, the two pairs (p, k) and $(p, k+1)$ compare the entry at p with the same two entries before and after the exchange, only in the other order of the pairs, so together they contain the same number of inversions. The pair $(k, k+1)$ itself was an inversion exactly when it is not one after the exchange. So the number of inversions changes by exactly 1, and the sign flips. *Step 2: any two places $i < j$.* Move the entry at place i to the right by $j-i$ exchanges of neighbours, until it stands at place j; the entry that stood at place j is now at place $j-1$. Move that entry to the left by $j-i-1$ exchanges of neighbours, until it stands at place i. Every other entry is back at its place, and the two entries have traded places. That took $(j-i)+(j-i-1) = 2(j-i)-1$ exchanges of neighbours, an odd number; by step 1 each flips the sign, and an odd number of flips is a flip.

Half of the permutations are even (PROVED). For $n \geq 2$, exchanging the first two entries turns every even permutation into an odd one and every odd one into an even one (the theorem), and doing it twice gives back the original permutation. So it pairs the even permutations with the odd ones one to one, and there are $n!/2$ of each. Notebook 01a, In [6] and In [7], lists the six permutations of three objects with their inversions and checks the three statements (the count $n!$, half of them even, every exchange flips the sign) for every permutation of $n = 1$ to 6 objects.

The inverse permutation has the same sign (PROVED). The **inverse** σ^{-1} undoes σ: $\sigma^{-1}(b) = i$ when $\sigma(i) = b$. If the places $i < j$ form an inversion of σ, put $a = \sigma(j)$ and $b = \sigma(i)$; then $a < b$ and $\sigma^{-1}(a) = j > i = \sigma^{-1}(b)$, so (a, b) is an inversion of σ^{-1}; and every inversion of σ^{-1} comes back to one of σ in this way. So both have the same number of inversions and the same sign.

Permutation matrices. The **permutation matrix** P_σ has a 1 in row i and column $\sigma(i)$ for every i, and 0 elsewhere: exactly one 1 in every row and in every column. A **signed permutation**

matrix may have -1 instead of 1 in some of these places. Figure 01a.2 shows the 24 permutation matrices of 4 objects.

1.20 Determinants: the Leibniz formula and its six rules

Definition. The **determinant** of a square $n \times n$ matrix A is the number

$$\det A = \sum_{\sigma} \operatorname{sign}(\sigma)\, A_{1\sigma(1)} A_{2\sigma(2)} \cdots A_{n\sigma(n)},$$

the sum over all $n!$ permutations σ of $1, \ldots, n$ (the **Leibniz formula**). Each term takes exactly one entry from every row i, namely the one in column $\sigma(i)$, so it also takes exactly one entry from every column. For $n = 2$ the permutations $(1, 2)$ (sign $+1$) and $(2, 1)$ (sign -1) give

$$\det \begin{pmatrix} a & b \\ c & d \end{pmatrix} = ad - bc,$$

the formula of Section 1.12. For $n = 3$ the six permutations of the table of Section 1.19 (counted from 1 instead of 0) give

$$\det A = A_{11}A_{22}A_{33} + A_{12}A_{23}A_{31} + A_{13}A_{21}A_{32} - A_{12}A_{21}A_{33} - A_{11}A_{23}A_{32} - A_{13}A_{22}A_{31}.$$

For the matrix A of Section 1.18 the six terms are $1 + 2 + 0 - 0 - 3 - 0 = 0$: the determinant vanishes, and indeed the third row $(1, 3, 1)$ is the sum of the first two.

Three special matrices (PROVED). (a) A **diagonal** matrix, whose entries off the diagonal are 0: every permutation other than the identity takes some entry off the diagonal, so only the term of the identity survives, and $\det \operatorname{diag}(d_1, \ldots, d_n) = d_1 d_2 \cdots d_n$. (b) A permutation matrix P_σ: a term of a permutation $\tau \neq \sigma$ contains an entry $(i, \tau(i))$ with $\tau(i) \neq \sigma(i)$, which is 0; so only the term of σ survives, and it is $\operatorname{sign}(\sigma) \cdot 1 \cdots 1$: $\det P_\sigma = \operatorname{sign}(\sigma)$. (c) A signed permutation matrix with the nonzero entries $s_1, \ldots, s_n = \pm 1$ in the places of σ: by the same argument

$$\det = \operatorname{sign}(\sigma)\, s_1 s_2 \cdots s_n.$$

The six rules of determinants. Write M for an $n \times n$ matrix.

Rule 1. $\det(MN) = \det M \det N$. For 2×2 matrices this is a direct computation (PROVED): with M of rows $(a, b), (c, d)$ and N of rows $(e, f), (g, h)$, MN has the rows $(ae + bg, af + bh)$ and $(ce + dg, cf + dh)$, and

$$\det(MN) = (ae + bg)(cf + dh) - (af + bh)(ce + dg)$$

(the 2×2 formula),

$$= aecf + aedh + bgcf + bgdh - afce - afdg - bhce - bhdg$$

(multiply out), in which $aecf$ cancels $afce$ and $bgdh$ cancels $bhdg$, leaving $adeh+bcfg-adfg-bceh = ad(eh-fg)-bc(eh-fg) = (ad-bc)(eh-fg)$ (re-order the factors; take out the common factors). For every n the rule is a standard theorem of algebra, ASSUMED here; Notebook 01a, In [11], checks it exactly for two 4×4 matrices.

Rule 2. $\det(M^T) = \det M$ (PROVED). The term of σ in $\det M^T$ is $\operatorname{sign}(\sigma)\prod_i (M^T)_{i\sigma(i)} = \operatorname{sign}(\sigma)\prod_i M_{\sigma(i)i}$. Re-ordering the factors by their row $j = \sigma(i)$ writes the product as $\prod_j M_{j\sigma^{-1}(j)}$, the term of σ^{-1} in $\det M$, and $\operatorname{sign}(\sigma^{-1}) = \operatorname{sign}(\sigma)$ (Section 1.19). As σ runs through all permutations, so does σ^{-1}, so the two sums have the same terms.

Rule 3. Exchanging two rows changes the sign (PROVED). Let M' be M with the rows r and s exchanged. The term of σ in $\det M'$ has the factors $M'_{r\sigma(r)} = M_{s\sigma(r)}$ and $M'_{s\sigma(s)} = M_{r\sigma(s)}$, so its product of entries is that of the permutation τ that equals σ with the entries at the places r and s exchanged; and $\operatorname{sign}(\tau) = -\operatorname{sign}(\sigma)$ (the theorem of Section 1.19). As σ runs through all permutations so does τ, so every term of $\det M$ appears in $\det M'$ with the opposite sign: $\det M' = -\det M$.

Rule 4. A matrix with two equal rows has determinant 0 (PROVED): exchanging the two equal rows changes nothing, yet by rule 3 it changes the sign, so $D = -D$, and $D = 0$.

Rule 5. Multiplying one row by a number c multiplies the determinant by c (PROVED): every term contains exactly one entry of that row, so every term is multiplied by c.

Rule 6. Adding c times row s to row r (with $s \neq r$) does not change the determinant (PROVED). Every term contains exactly one entry of row r, which is now $M_{r\sigma(r)} + c\,M_{s\sigma(r)}$; multiplying out, the determinant splits into $\det M$ plus c times the determinant of M with row r replaced by row s; that matrix has two equal rows, so the second part is 0 by rule 4.

Determinants and inverses. A square matrix M is **invertible** if there is a matrix M^{-1} with $MM^{-1} = M^{-1}M = I$; then the equation $Mv = w$ can be undone, $v = M^{-1}w$. For a 2×2 matrix with $ad - bc \neq 0$ the inverse is

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} = \frac{1}{ad-bc}\begin{pmatrix} d & -b \\ -c & a \end{pmatrix},$$

as multiplying out shows: the product of the two matrices has the entries $ad - bc$, $-ab + ba = 0$, $cd - dc = 0$ and $-cb + da$, so it is $(ad - bc)I$, and dividing by $ad - bc$ gives I. For every n it is a standard theorem that M is invertible exactly when $\det M \neq 0$ (ASSUMED here; one half follows from rule 1: if M^{-1} exists, $\det M \det M^{-1} = \det I = 1$, so $\det M \neq 0$). The determinant is the one number that says whether a matrix can be undone.

1.21 What a determinant measures, what it costs, and two matrices of the course

A signed area (PROVED). A 2×2 matrix M with rows (a, b) and (c, d) moves the corners $(0,0)$, $(1,0)$, $(1,1)$, $(0,1)$ of the unit square to the corners $(0,0)$, (a,c), $(a+b, c+d)$, (b,d) of a parallelogram: the images $Me_1 = (a,c)$ and $Me_2 = (b,d)$ of $e_1 = (1,0)$ and $e_2 = (0,1)$ are the two columns of M. The **signed area** of a polygon with the corners $(x_1, y_1), \ldots, (x_K, y_K)$, listed in order, is given by the **shoelace formula**

$$\tfrac{1}{2}\sum_{k=1}^{K}\left(x_k y_{k+1} - x_{k+1} y_k\right) \qquad (\text{with } x_{K+1} = x_1,\ y_{K+1} = y_1),$$

which equals the area when the corners are listed counterclockwise and minus the area when they are listed clockwise (a standard fact of plane geometry, ASSUMED here). For the parallelogram the four terms of the sum are

$$0 \cdot c - a \cdot 0 = 0, \quad a(c+d) - (a+b)c = ad - bc, \quad (a+b)d - b(c+d) = ad - bc, \quad b \cdot 0 - 0 \cdot d = 0$$

(insert the corners in order; multiply out; ac and bd cancel), so the signed area is $\frac{1}{2} \cdot 2(ad - bc) = \det M$. The size of the determinant is the factor by which M multiplies areas, and its sign says whether the order of the corners is kept ($\det M > 0$) or reversed, that is, whether the picture is mirrored ($\det M < 0$). A determinant 0 flattens the square onto a line, and such a matrix cannot be undone. Notebook 01a, In [12], checks this for three examples and 1000 random matrices (Figure 01a.3).

What a determinant costs. The Leibniz formula has $n!$ terms, each a product of n entries. For the 16×16 gamma matrices of the course that would be

$$16! = 20922789888000$$

terms. Computers therefore use **elimination**: by rule 6 one may subtract multiples of rows from other rows without changing the determinant, and doing so step by step makes every entry below the diagonal zero, which needs about $n^3/3$ multiplications. For a matrix with zeros below the diagonal (a **triangular** matrix) only the term of the identity survives in the Leibniz formula, because every other permutation σ has some row i with $\sigma(i) < i$ (the numbers $\sigma(i) - i$ add up to 0 and are not all 0, so one of them is negative), and the entry $A_{i\sigma(i)}$ below the diagonal is 0. So the determinant of the triangular matrix is the product of its diagonal. For $n = 16$ elimination needs about $16^3/3 \approx 1365$ steps instead of 2.1×10^{13} terms (Figure 01a.4).

The gamma matrices of the Revision record. The file `Revision/algebra/gammas.json` of the Revision record holds the eight real 16×16 gamma matrices $\gamma^{(x_0)}, \ldots, \gamma^{(x_7)}$ of the author's theory, one for each coordinate, rebuilt in the record from the author's own formulas (Chapter 4 builds them step by step), and the diagonal of the frame metric $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \ldots, x_7$. The record states, in its report `Revision/algebra/reports/python-algebra.json`, check `reality_signed_permutations`, that every gamma matrix is a real signed permutation matrix, and in its check `clifford_relation` that $\gamma^a \gamma^b + \gamma^b \gamma^a = 2\eta^{ab} I$; with equal indices this says $(\gamma^a)^2 = \eta_{aa} I$: $+I$ for the space-like directions x_0, x_1, x_2, x_3 and $-I$ for the time-like directions $x_4, \ldots, x_7$. Two consequences for the determinant (PROVED): by rule 1, $(\det \gamma^a)^2 = \det\left((\gamma^a)^2\right) = \det(\pm I) = (\pm 1)^{16} = 1$, so $\det \gamma^a = \pm 1$; and by the formula (c) for signed permutation matrices it is $\mathrm{sign}(\sigma)$ times the product of the sixteen signs, a computation of 16 numbers and one permutation instead of 16! terms. Notebook 01a, In [14] and In [15], reads the matrices, reproduces the two record checks and finds $\det \gamma^a = +1$ for all eight (COMPUTED): the permutation of each is even, and each has an even number of entries -1 (eight for $\gamma^{(x_1)}$ to $\gamma^{(x_7)}$, none for $\gamma^{(x_0)}$).

The determinant of the author's metric (PROVED). The author's metric (Section 1.1) is diagonal, so by (a) its determinant is the product of its eight diagonal entries:

$$\det g = \cot^2 z \cdot \big(e^{2a_4} s\big)^3 \cdot (-1) \cdot \big(-\, b_4 e^{-2a_4} s\big)^3$$

(the determinant of a diagonal matrix; the three equal space entries give a cube, and so do the three equal extra-time entries),

$$= \cot^2 z \cdot e^{6a_4} s^3 \cdot (-1) \cdot (-1)\, b_4^3 e^{-6a_4} s^3$$

(the power of a product is the product of the powers, $(e^{2a_4})^3 = e^{6a_4}$, $(b_4 e^{-2a_4})^3 = b_4^3 e^{-6a_4}$, and $(-x)^3 = -x^3$),

$$= b_4^3\, e^{6a_4 - 6a_4}\, s^6\, \cot^2 z = b_4^3 \sin^2 z\, \frac{\cos^2 z}{\sin^2 z} = b_4^3 \cos^2 z$$

(the two signs give $(-1)(-1) = +1$ and the powers of e are collected with $a^p a^q = a^{p+q}$; then $e^0 = 1$, $s^6 = (\sin^{1/3} z)^6 = \sin^2 z$ and $\cot z = \cos z / \sin z$; cancel $\sin^2 z$). The growth e^{6a_4} of the three space directions and the shrinking e^{-6a_4} of the three exponentially deflating extra times cancel exactly, for every value of a_4; only the factor b_4^3 of the extra times is left. The sign is + because the metric has four negative entries, an even number. Since $\cos z > 0$ for $0 < z < \pi/2$ and $b_4 > 0$,

$$\sqrt{|\det g|} = b_4^{3/2} \cos z = b_4^{3/2} \sin z \cot z,$$

and this is the product of the eight length factors of Section 1.5 (the square root of a product of positive numbers is the product of their square roots, and $|\det g| = \prod_\mu |g_{\mu\mu}|$); at $b_4 = 1$ it is $\cos z$. The record stores it as `sqrtAbsDetG` $= b_4^{3/2} \sin z \cot z$ in `Revision/gkd_lovelock/results/curvature.json` and checks it in `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `sqrt_abs_det_g`; Notebook 01a, In [17] and In [18], reproduces both, exactly with sympy and in numbers at 900 points (Figure 01a.6).

1.22 Example: matrices, permutations and determinants

Notebook 01a puts Sections 1.18 to 1.21 to work. It computes the dot product, matrix times vector and the matrix product with loops, with `einsum` and with `@`, and shows with heat maps that $AB \neq BA$; lists the permutations of 3 objects with their inversions and signs, checks the exchange theorem for every permutation of up to 6 objects and draws the 24 permutation matrices of 4 objects; writes the Leibniz formula as a Python function and compares it with sympy and numpy; checks the six rules; draws signed areas; plots the cost of the Leibniz formula against elimination; reads the eight gamma matrices from the Revision record and checks that they are signed permutation matrices with determinant 1 whose squares are $\pm I$; and reads the author's metric from the record and proves that its determinant is $b_4^3 \cos^2 z$ for every a_4. It ends with the line ALL 30 CHECKS PASSED (notebook 01a).

1.23 How to run Notebook 01a

Step 1. What this notebook does and what it needs.

Notebook 01a (Matrices, permutations and determinants) is the file `Revision/textbook/notebooks/01a_matrices_determinants.ipynb` of the repository Dirac_claude. It multiplies matrices in three ways (with loops, with the summation convention through numpy einsum, and with the operator @) and shows with heat maps that the order of the factors matters, lists the permutations of up to four objects with their signs, computes determinants with the Leibniz formula and compares them with numpy and sympy, checks the rules of determinants and draws their meaning as a signed area, reads the real 16 by 16 gamma matrices and the frame metric of the author's coordinates x0 to x7 from the Revision record and checks that every gamma matrix is a signed permutation matrix with determinant 1, and proves with sympy that the determinant of the author's metric is the square of cos(6 H x0) for every value of a4. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01a_matrices_determinants.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01a_matrices_determinants.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01a_matrices_determinants.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01a.captions.json`
- `Revision/textbook/figures/01a_1_matrix_product.png`
- `Revision/textbook/figures/01a_2_permutation_matrices.png`
- `Revision/textbook/figures/01a_3_area_and_determinant.png`
- `Revision/textbook/figures/01a_4_determinant_cost.png`
- `Revision/textbook/figures/01a_5_gamma_matrices.png`
- `Revision/textbook/figures/01a_6_metric_and_determinant.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 30 CHECKS PASSED (notebook 01a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01a_matrices_determinants.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01a_matrices_determinants.ipynb
python -m nbconvert --execute --inplace 01a_matrices_determinants.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the notebook reads two Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

1.24 Notebook 01a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01a_matrices_determinants.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

This notebook builds, from zero, the tools that every later notebook uses to
handle lists of numbers: vectors, matrices, permutations and determinants. It

- multiplies a matrix with a vector and two matrices with each other in three
  ways (with loops, with the summation convention, with numpy's operator `@`)
  and shows with heat maps that $AB$ and $BA$ are in general different;
- lists the permutations (re-orderings) of 3 and of 4 objects, counts their
  inversions and gives each its sign $+1$ or $-1$;
- computes determinants with the Leibniz formula, written by hand in Python,
  and compares the results with the programs numpy and sympy;
- checks six rules of determinants, and draws what a $2 \times 2$ determinant
  means: the signed area of a parallelogram;
- explains with a plot why computers do not use the Leibniz formula for big
  matrices;
- reads the eight real $16 \times 16$ gamma matrices of the author's theory from
  the Revision record and checks that each one is a *signed permutation matrix*
  whose determinant is 1;
- reads the author's metric from the Revision record and proves with sympy that
  its determinant is $b_4^3 \cos^2 z$ with $z = 6 H x_0$, whatever the value of
  $a_4$.

Every check prints a line that starts with PASS; where a check repeats a result
of the Revision record, a second line names the record file and its check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01a (Matrices, permutations and determinants) is the file
`Revision/textbook/notebooks/01a_matrices_determinants.ipynb` of the repository
Dirac_claude. It multiplies matrices in three ways (with loops, with the summation
convention through numpy einsum, and with the operator @) and shows with heat maps that
the order of the factors matters, lists the permutations of up to four objects with their
signs, computes determinants with the Leibniz formula and compares them with numpy and
sympy, checks the rules of determinants and draws their meaning as a signed area, reads
the real 16 by 16 gamma matrices and the frame metric of the author's coordinates x0 to
x7 from the Revision record and checks that every gamma matrix is a signed permutation
```

matrix with determinant 1, and proves with sympy that the determinant of the author's metric is the square of cos(6 H x0) for every value of a4. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01a_matrices_determinants.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01a_matrices_determinants.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01a_matrices_determinants.ipynb‘ (in the same folder, without running the cells again) to

read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01a.captions.json‘
- ‘Revision/textbook/figures/01a_1_matrix_product.png‘
- ‘Revision/textbook/figures/01a_2_permutation_matrices.png‘
- ‘Revision/textbook/figures/01a_3_area_and_determinant.png‘
- ‘Revision/textbook/figures/01a_4_determinant_cost.png‘
- ‘Revision/textbook/figures/01a_5_gamma_matrices.png‘
- ‘Revision/textbook/figures/01a_6_metric_and_determinant.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 30 CHECKS PASSED (notebook 01a)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01a_matrices_determinants.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt

  install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 01a_matrices_determinants.ipynb
      python -m nbconvert --execute --inplace 01a_matrices_determinants.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the notebook reads two Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01a (Matrices, permutations and determinants) is the file
# Revision/textbook/notebooks/01a_matrices_determinants.ipynb of the repository
# Dirac_claude. It multiplies matrices in three ways (with loops, with the summation
# convention through numpy einsum, and with the operator @) and shows with heat maps that
# the order of the factors matters, lists the permutations of up to four objects with
# their signs, computes determinants with the Leibniz formula and compares them with
# numpy and sympy, checks the rules of determinants and draws their meaning as a signed
# area, reads the real 16 by 16 gamma matrices and the frame metric of the author's
# coordinates x0 to x7 from the Revision record and checks that every gamma matrix is a
# signed permutation matrix with determinant 1, and proves with sympy that the
# determinant of the author's metric is the square of cos(6 H x0) for every value of a4.
# It needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
```

```
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
```

```
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
```

```
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01a_matrices_determinants.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01a_matrices_determinants.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01a_matrices_determinants.ipynb (in the same folder, without running the cells again)
# to read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01a.captions.json
# - Revision/textbook/figures/01a_1_matrix_product.png
# - Revision/textbook/figures/01a_2_permutation_matrices.png
# - Revision/textbook/figures/01a_3_area_and_determinant.png
# - Revision/textbook/figures/01a_4_determinant_cost.png
# - Revision/textbook/figures/01a_5_gamma_matrices.png
# - Revision/textbook/figures/01a_6_metric_and_determinant.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
```

```
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 30 CHECKS PASSED (notebook 01a)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01a_matrices_determinants.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01a_matrices_determinants.ipynb
#     python -m nbconvert --execute --inplace 01a_matrices_determinants.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the
#   notebook reads two Revision records of the repository; your copy of the repository is
```

```
#   incomplete. Download it again with git clone and open the notebook inside the new
#   copy.
#

## 3. The words used in this notebook

- **Vector**: an ordered list of numbers, such as $v = (1, 2, 0)$. The numbers
  are its **components**; $v$ has 3 components.
- **Matrix**: a rectangular table of numbers with rows (across) and columns
  (down). $A_{ij}$ is the **entry** in row $i$ and column $j$. A matrix with $m$
  rows and $n$ columns is an $m \times n$ matrix; it is **square** if $m = n$.
- **Index**: a letter such as $i$, $j$ or $k$ that numbers the components of a
  vector or the rows and columns of a matrix. In mathematics rows and columns
  are numbered $1, 2, 3, \dots$; Python numbers them $0, 1, 2, \dots$, so the
  entry $A_{11}$ (row 1, column 1) is `A[0, 0]` in Python.
- **Matrix product**: $(AB)_{ik} = \sum_j A_{ij} B_{jk}$: entry $(i, k)$ of $AB$
  is row $i$ of $A$ times column $k$ of $B$, entry by entry, added up.
- **Summation convention**: an index that appears twice in one product is summed
  over all its values without writing $\sum$; so $A_{ij} B_{jk}$ means
  $\sum_j A_{ij} B_{jk}$. A summed index is a **dummy** index (its name does not
  matter); an index that is not summed is a **free** index. In the physics of the
  course one of the two equal indices is written up and one down, as in
  $v^\mu w_\mu = \sum_\mu v^\mu w_\mu$; for the entries of plain tables of
  numbers, as in this notebook, both are written down.
- **einsum**: numpy's function that evaluates a product written with the
  summation convention, for example `np.einsum("ij,jk->ik", A, B)`.
- **Identity matrix** $I$: the square matrix with 1 on the diagonal and 0
  elsewhere. Its entries are the **Kronecker delta** $\delta_{ij}$, which is 1
  when $i = j$ and 0 otherwise.
- **Transpose** $A^T$: the matrix with rows and columns exchanged,
  $(A^T)_{ij} = A_{ji}$.
- **Permutation**: a re-ordering of the numbers $0, 1, \dots, n-1$ (or of any $n$
  different objects). There are $n! = 1 \cdot 2 \cdots n$ of them.
- **Inversion**: a pair of places in a permutation whose two entries stand in the
```

```
  wrong order (the larger one first).
- **Sign** of a permutation: $+1$ if it has an even number of inversions (an
  **even** permutation), $-1$ if odd.
- **Permutation matrix**: the matrix with exactly one 1 in every row and every
  column and 0 elsewhere; row $i$ has its 1 in column $\sigma(i)$ for a
  permutation $\sigma$. A **signed permutation matrix** may have $-1$ instead of
  $1$ in some of these places.
- **Determinant** $\det A$ of a square matrix (Leibniz formula):
  $\det A = \sum_\sigma \mathrm{sign}(\sigma) A_{1\sigma(1)} A_{2\sigma(2)}
  \cdots A_{n\sigma(n)}$, the sum over all $n!$ permutations $\sigma$.
- **Heat map**: a picture of a matrix in which every entry is a coloured square
  (here red for positive, white for zero, blue for negative entries).
- **Floating-point number**: the way a computer stores a real number, with about
  16 significant digits, so results can be off in the last digits. **Exact**
  arithmetic (sympy) keeps whole numbers, fractions and symbols without rounding.
- **Metric** $g$: the table of numbers that turns small coordinate steps
  $dx_0, \dots, dx_7$ into a squared length,
  $ds^2 = g_{00} dx_0^2 + \dots + g_{77} dx_7^2$ for a diagonal metric; here it is
  a diagonal $8 \times 8$ matrix (only the diagonal entries $g_{00}, \dots,
  g_{77}$ are not zero), and a negative entry marks a time-like direction.
- **Revision record**: the files of the folder Revision of the repository, in
  which every result of the author's theory is computed and checked.
```

```
## 4. The physical and mathematical situation

The theory of this course works with matrices everywhere. Its spacetime has
eight coordinates, which the author calls $x_0, \dots, x_7$: $x_1, x_2, x_3$ are
ordinary space, $x_4$ is the time, $x_5, x_6, x_7$ are three extra times whose
lengths deflate exponentially as $a_4$ grows, and $x_0$ is a hidden space
direction. The author's metric is the diagonal matrix

$$g = \mathrm{diag}\big(\cot^2 z, e^{2a_4} s, e^{2a_4} s, e^{2a_4} s, -1,
-b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s\big),\quad
s = \sin^{1/3} z,\ z = 6 H x_0,$$

with $0 < z < \pi/2$, a positive constant $H$, a function $a_4(x_4)$ of the
time and a positive function $b_4(x_4)$ of the time (the author's metric of
2026-10-14; with $b_4 = 1$ it is the earlier metric). The simpler *frame metric*
$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ keeps only the signs: $+1$
for the space-like directions $x_0, x_1, x_2, x_3$ and $-1$ for the time-like
directions $x_4, x_5, x_6, x_7$. The fields of the theory have 16 components, and
the eight *gamma matrices* that act on them are real $16 \times 16$ matrices.

The determinant is the one number that tells whether a square matrix can be
undone (inverted): it can exactly when $\det A \neq 0$. For a diagonal matrix
only one term of the Leibniz formula survives (all others contain an entry off
the diagonal, which is 0), so the determinant is the product of the diagonal
entries. For the author's metric this product is

$$\det g = \cot^2 z \cdot (e^{2a_4} s)^3 \cdot (-1) \cdot (-b_4 e^{-2a_4} s)^3
= b_4^3 e^{6a_4} e^{-6a_4} s^6 \cot^2 z
```

```
= b_4^3 \sin^2 z \, \frac{\cos^2 z}{\sin^2 z} = b_4^3 \cos^2 z,$$

because $(-1) \cdot (-1)^3 = +1$, $e^{6a_4} e^{-6a_4} = e^0 = 1$,
$s^6 = (\sin^{1/3} z)^6 = \sin^2 z$ and $\cot z = \cos z / \sin z$. The growth
$e^{6a_4}$ of the three space directions is cancelled exactly by the shrinking
$e^{-6a_4}$ of the three extra times; only the factor $b_4^3$ of the three extra
times is left. The last part of the notebook checks this with sympy, starting
from the metric as it is stored in the Revision record.
```

Text cell:

```
## 5. Vectors and matrices in Python

The next cell loads the packages, makes two vectors $v = (1, 2, 0)$ and
$w = (0, 1, 1)$ as numpy arrays, adds them, multiplies $v$ by 3, and computes
the **dot product** $v \cdot w = \sum_i v_i w_i = 1 \cdot 0 + 2 \cdot 1 + 0
\cdot 1 = 2$ twice: once as a written-out sum and once with numpy's `@`.
`tolist()` turns an array into a plain Python list for printing.
```

In [2]:

```
import itertools  # all orderings (permutations) of a list
import math  # factorials

import numpy as np  # arrays of numbers: vectors and matrices
import sympy as sp  # exact arithmetic with whole numbers, fractions and symbols

v = np.array([1, 2, 0])  # a vector with 3 components
w = np.array([0, 1, 1])
say(f"v = {v.tolist()}, w = {w.tolist()}")
say(f"v + w = {(v + w).tolist()}, 3 v = {(3 * v).tolist()}")
# The dot product as a sum over the index i = 0, 1, 2 (Python counts from 0):
dot_by_hand = sum(int(v[i]) * int(w[i]) for i in range(3))
say(f"v . w by the sum = {dot_by_hand}, with numpy's @ = {int(v @ w)}")
check(dot_by_hand == int(v @ w) == 2, "the dot product of v and w is 2")
```

Out [2]:

```
v = [1, 2, 0], w = [0, 1, 1]
v + w = [1, 3, 1], 3 v = [3, 6, 0]
v . w by the sum = 2, with numpy's @ = 2
PASS the dot product of v and w is 2
```

Text cell:

```
The next cell makes the $3 \times 3$ matrix $A$ with rows $(1, 2, 0)$,
$(0, 1, 1)$ and $(1, 3, 1)$ and multiplies it with the vector $v$ by the rule
$(Av)_i = \sum_j A_{ij} v_j$, written as a loop, and with numpy's `A @ v`. Row 1
gives $1 \cdot 1 + 2 \cdot 2 + 0 \cdot 0 = 5$, row 2 gives
$0 + 2 + 0 = 2$, row 3 gives $1 + 6 + 0 = 7$.
```

In [3]:

```
A = np.array([[1, 2, 0],
              [0, 1, 1],
              [1, 3, 1]])  # three rows, each a list of three entries
say(f"A has {A.shape[0]} rows and {A.shape[1]} columns")
# Python counts rows and columns from 0: A[1, 2] is row 2, column 3 of A.
say(f"the entry in row 2, column 3 of A is A[1, 2] = {A[1, 2]}")
# (A v)_i = sum over j of A_ij v_j, one number for each row i:
Av_by_hand = [sum(int(A[i, j]) * int(v[j]) for j in range(3)) for i in range(3)]
say(f"A v by the sum = {Av_by_hand}, with numpy = {(A @ v).tolist()}")
check(Av_by_hand == (A @ v).tolist() == [5, 2, 7],
      "A v computed with the sum rule is (5, 2, 7), the same as numpy's A @ v")
```

Out [3]:

```
A has 3 rows and 3 columns
the entry in row 2, column 3 of A is A[1, 2] = 1
A v by the sum = [5, 2, 7], with numpy = [5, 2, 7]
PASS A v computed with the sum rule is (5, 2, 7), the same as numpy's A @ v
```

Text cell:

```
## 6. The matrix product, three ways

The next cell multiplies $A$ with a second matrix $B$ in three ways and checks
that they agree:

1. three nested loops that add $A_{ij} B_{jk}$ over the dummy index $j$ for every
   pair of free indices $(i, k)$;
2. `np.einsum("ij,jk->ik", A, B)`: the text `"ij,jk->ik"` is the summation
   convention itself. It says: the first factor has the indices $i, j$, the
   second $j, k$; the index $j$ appears twice, so it is summed; the result has
   the indices $i, k$;
3. numpy's operator `A @ B`.

Then it computes $BA$ and checks that it differs from $AB$: the order of the
factors of a matrix product matters. It also checks the transpose rule
$(AB)^T = B^T A^T$ (`.T` is numpy's transpose) and that the trace (the sum of
the diagonal entries, `np.trace`) of $AB$ and of $BA$ is the same.
```

In [4]:

```
B = np.array([[0, 1, 0],
              [1, 0, 2],
              [0, 1, 1]])
n = 3
AB_loops = np.zeros((n, n), dtype=int)  # a 3 x 3 matrix of zeros to fill in
for i in range(n):  # the row of the product (a free index)
    for k in range(n):  # the column of the product (a free index)
```

```
        for j in range(n):  # the summed (dummy) index
            AB_loops[i, k] += A[i, j] * B[j, k]
AB_einsum = np.einsum("ij,jk->ik", A, B)  # j appears twice: it is summed
AB = A @ B
BA = B @ A
say(f"A B = {AB.tolist()}")
say(f"B A = {BA.tolist()}")
check((AB_loops == AB).all() and (AB_einsum == AB).all(),
      "loops, einsum and @ give the same product A B")
check(not (AB == BA).all(), "A B is not equal to B A: the order matters")
check(((A @ B).T == B.T @ A.T).all(), "the transpose rule (A B)^T = B^T A^T")
check(np.trace(AB) == np.trace(BA), "A B and B A have the same trace")
```

Out [4]:

```
A B = [[2, 1, 4], [1, 1, 3], [3, 2, 7]]
B A = [[0, 1, 1], [3, 8, 2], [1, 4, 2]]
PASS loops, einsum and @ give the same product A B
PASS A B is not equal to B A: the order matters
PASS the transpose rule (A B)^T = B^T A^T
PASS A B and B A have the same trace
```

Text cell:

```
The next cell defines a small drawing helper, ‘heat_map‘, used for every picture
of a matrix in this notebook, and draws $A$, $B$, $AB$ and $BA$. Each entry is a
coloured square (red positive, white zero, blue negative) with its value written
in it. ‘plt.subplots(1, 4)‘ makes a figure with 4 drawing areas (*axes*) side by
side; ‘save_figure‘ saves the picture, shows it below the cell and records its
caption.
```

In [5]:

```
def heat_map(ax, matrix, title, labels=None, annotate=True, digits=0,
             skip_zeros=False):
    """Draw matrix on the axes ax: every entry a coloured square, red for
    positive, white for zero, blue for negative entries; when annotate is True
    the value is written in its square with the given number of digits (not
    for the zero entries when skip_zeros is True)."""
    m = np.asarray(matrix, dtype=float)
    limit = max(1.0, float(np.abs(m).max()))  # colours run from -limit to +limit
    image = ax.imshow(m, cmap="RdBu_r", vmin=-limit, vmax=limit)
    ax.set_title(title)

## 7. Permutations and their signs

A permutation of $0, 1, \dots, n-1$ is the same list in another order. An
**inversion** is a pair of places $i < j$ where the entry at place $i$ is larger
than the entry at place $j$. The sign is $(-1)^{\text{number of inversions}}$.

The next cell defines the functions ‘inversions‘ and ‘sign‘ and prints the six
permutations of $0, 1, 2$ (Python’s ‘itertools.permutations‘ lists them) with
```

```
their inversions and signs. For example $(1, 2, 0)$ has the inversions
$(1, 0)$ and $(2, 0)$, two of them, so its sign is $+1$; $(0, 2, 1)$ has one
inversion, $(2, 1)$, so its sign is $-1$.
```

In [6]:

```
def inversions(order):
    """The number of pairs of places i < j whose entries stand in the wrong order."""
    return sum(1 for i in range(len(order)) for j in range(i + 1, len(order))
               if order[i] > order[j])

def sign(order):
    """+1 for an even number of inversions, -1 for an odd number."""
    return 1 if inversions(order) % 2 == 0 else -1

for order in itertools.permutations(range(3)):  # all 6 orderings of 0, 1, 2
    say(f"permutation {order}: number of inversions {inversions(order)}, "
        f"sign {sign(order):+d}")
signs_of_three = [sign(order) for order in itertools.permutations(range(3))]
check(signs_of_three.count(1) == 3 and signs_of_three.count(-1) == 3,
      "of the 6 permutations of 3 objects, 3 are even and 3 are odd")
```

Out [6]:

```
permutation (0, 1, 2): number of inversions 0, sign +1
permutation (0, 2, 1): number of inversions 1, sign -1
permutation (1, 0, 2): number of inversions 1, sign -1
permutation (1, 2, 0): number of inversions 2, sign +1
permutation (2, 0, 1): number of inversions 2, sign +1
permutation (2, 1, 0): number of inversions 3, sign -1
PASS of the 6 permutations of 3 objects, 3 are even and 3 are odd
```

Text cell:

```
The next cell checks three facts for every $n$ from 1 to 6:

- there are $n!$ permutations (`math.factorial(n)`);
- for $n \geq 2$ exactly half of them are even;
- exchanging the entries at two places of a permutation always changes its sign
  (checked for every permutation of $n$ objects and every pair of places).

The third fact is the reason why a determinant changes sign when two rows are
exchanged (section 9 of this notebook).
```

In [7]:

```
swap_rule_holds = True
for n in range(1, 7):
```

```
    orders = list(itertools.permutations(range(n)))

```
## 8. The determinant by the Leibniz formula
```

```
The Leibniz formula takes, for every permutation $\sigma$, one entry from every
row $i$, namely the one in column $\sigma(i)$, multiplies them, attaches the sign
of $\sigma$, and adds the $n!$ results:

$$\det A = \sum_\sigma \mathrm{sign}(\sigma) A_{1\sigma(1)} \cdots
A_{n\sigma(n)}.$$

For $n = 2$ the two permutations $(1, 2)$ (sign $+1$) and $(2, 1)$ (sign $-1$)
give $\det A = A_{11} A_{22} - A_{12} A_{21}$, the familiar $ad - bc$.

The next cell writes this formula as the Python function ‘leibniz_det‘ and
tests it: with sympy symbols for a general $2 \times 2$ matrix (result
$ad - bc$); on the matrix $A$ of section 5 (whose third row is the sum of the
first two, so its determinant must be 0); and on the permutation matrices of 4
objects, whose determinant must be the sign of the permutation (only the term of
$\sigma$ itself is not zero, and it equals $\mathrm{sign}(\sigma) \cdot 1$).
```

In [9]:

```
def leibniz_det(M):
    """The determinant of the square matrix M (a list of rows, a numpy array or a
    sympy Matrix) by the Leibniz formula: for every permutation, the sign times
    one entry from every row, row i giving the entry in column order[i]."""

PASS Leibniz, sympy and numpy agree on 7 random integer matrices
```

Text cell:

```
## 9. The rules of determinants

The next cell checks, exactly with sympy, six rules on two random $4 \times 4$
integer matrices $M$ and $N$:

1. $\det(MN) = \det M \cdot \det N$ (the determinant of a product);
2. $\det(M^T) = \det M$;
3. exchanging two rows changes the sign of the determinant: after the exchange,
   the term of a permutation $\sigma$ has the same product of entries as the term
   of the permutation with the entries $\sigma(r)$ and $\sigma(s)$ of the two
   rows $r, s$ exchanged, whose sign is opposite (section 7); so all products
   come back with opposite signs;
```

```
4. a matrix with two equal rows has determinant 0 (exchanging the two equal rows
   changes nothing, yet by rule 3 changes the sign: $D = -D$, so $D = 0$);
5. multiplying one row by a number $c$ multiplies the determinant by $c$ (every
   term contains exactly one entry of that row);
6. adding $c$ times row $s$ to row $r$ does not change the determinant: every
   term contains exactly one entry of row $r$, so the determinant splits into
   $\det M$ plus $c$ times the determinant of $M$ with row $r$ replaced by row
   $s$, which has two equal rows and is 0 by rule 4.

It also checks that the determinant of a diagonal matrix is the product of its
diagonal entries.

## 10. What a determinant measures: a signed area

A $2 \times 2$ matrix $M$ moves every point $(x, y)$ of the plane to
$M (x, y)$. The unit square with corners $(0,0)$, $(1,0)$, $(1,1)$, $(0,1)$ goes
```

```
to the parallelogram with corners $(0,0)$, $M e_1$, $M e_1 + M e_2$, $M e_2$,
where $e_1 = (1, 0)$, $e_2 = (0, 1)$ and $M e_1$, $M e_2$ are the two columns of
$M$. Its area is $|\det M|$; the sign of $\det M$ says whether the order of the
corners is kept (counterclockwise, $\det M > 0$) or reversed ($\det M < 0$).

The next cell measures the *signed area* of each image with the shoelace formula
$\tfrac12 \sum_k (x_k y_{k+1} - x_{k+1} y_k)$ (the sum over the corners in order,
the last one followed by the first), which is positive for corners in
counterclockwise order, checks that it equals $\det M$ for three example
matrices and for 1000 random ones, and draws the three examples: determinant
$2$ (area doubled), $-1.5$ (area 1.5, orientation reversed) and $0$ (the square
is flattened onto a line).
```

In [12]:

```
def signed_area(corners):
    """The shoelace formula: positive for corners listed counterclockwise."""

## 11. Why computers do not use the Leibniz formula for big matrices

The Leibniz formula has $n!$ terms. Elimination (subtracting multiples of rows
until the matrix is triangular, which by rule 6 does not change the
determinant; then the determinant is the product of the diagonal) needs about
$n^3/3$ multiplications. The next cell prints and plots both numbers for
$n = 1$ to $16$. For the $16 \times 16$ gamma matrices of the theory the Leibniz
formula would have $16!$ = 20,922,789,888,000 terms. The vertical axis is
logarithmic: each step up multiplies by 10.
```

In [13]:

```
sizes = np.arange(1, 17)
leibniz_terms = np.array([math.factorial(int(k)) for k in sizes], dtype=float)
elimination_steps = sizes.astype(float) ** 3 / 3
report("number of terms of the Leibniz formula for n = 16", math.factorial(16))
check(math.factorial(16) == 20922789888000, "16! = 20 922 789 888 000")

## 12. Matrices of the course: the gamma matrices of the Revision record

The file Revision/algebra/gammas.json of the Revision record holds the eight real
$16 \times 16$ gamma matrices $\gamma^{(x_0)}, \dots, \gamma^{(x_7)}$ of the
author's theory (one for each coordinate, rebuilt in the Revision record from the
author's formulas) and the diagonal of the frame metric $\eta$. The next cell
reads the file (a JSON file: text that holds lists and numbers) and checks what
the record states in its check
`reality_signed_permutations`: every entry is $-1$, $0$ or $1$, and every row and
every column has exactly one entry that is not zero. Such a *signed permutation
matrix* is a permutation matrix with some 1s replaced by $-1$.
```

In [14]:

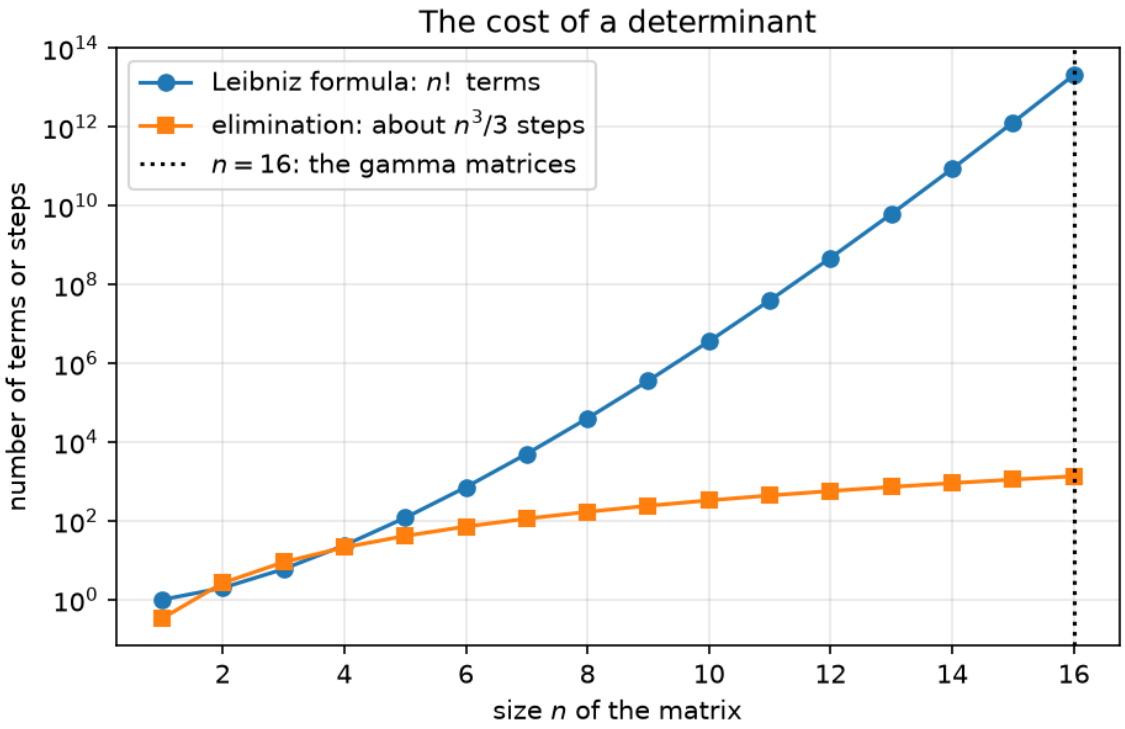

Figure 32: The number of terms $n!$ of the Leibniz formula (circles) and the number of steps $n^3/3$ of elimination (squares) for an $n \times n$ matrix, $n = 1$ to 16; horizontal axis n, vertical axis the count on a logarithmic scale. Up to $n = 4$ the two are similar; for $n = 16$ the Leibniz formula has about 2.1×10^{13} terms against about 1365 steps of elimination. (Notebook 01a, figure 4.)

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
names = record["coordinates"]  # ["x0", "x1", ..., "x7"]
eta = record["eta"]  # the diagonal of the frame metric, in the order x0 ... x7
gamma = [np.array(matrix, dtype=int) for matrix in record["gamma"]]
say(f"coordinates: {names}")
say(f"diagonal of eta: {eta}")
signed_permutation = True
for g_a in gamma:
    signed_permutation &= set(np.unique(g_a).tolist()) <= {-1, 0, 1}
    signed_permutation &= ((g_a != 0).sum(axis=1) == 1).all()  # one per row
    signed_permutation &= ((g_a != 0).sum(axis=0) == 1).all()  # one per column

Out [14]:

```
coordinates: ['x0', 'x1', 'x2', 'x3', 'x4', 'x5', 'x6', 'x7']
diagonal of eta: [1, 1, 1, 1, -1, -1, -1, -1]
PASS the record holds eight 16 x 16 gamma matrices
PASS every gamma matrix is a real signed permutation matrix
     reproduces Revision/algebra/reports/python-algebra.json, check
    reality_signed_permutations
```

Text cell:

```
For a signed permutation matrix only one term of the Leibniz formula is not zero:
the term of the permutation $\sigma$ whose entries $\gamma_{i\sigma(i)}$ are the
nonzero ones. So $\det \gamma = \mathrm{sign}(\sigma) \cdot s_1 s_2 \cdots s_{16}$,
where $s_i = \pm 1$ are the signs of these entries. This needs 16 numbers and one
permutation instead of $16!$ terms.

The next cell computes the determinant of each gamma matrix this way, compares it
with sympy's exact determinant and with numpy's, and checks that each gamma
matrix squared is $\eta_{aa}$ times the $16 \times 16$ identity matrix: $+I$ for
the space-like directions $x_0, x_1, x_2, x_3$ and $-I$ for the time-like
directions $x_4, \dots, x_7$ (this is the part with equal indices of the
relation $\gamma^a \gamma^b + \gamma^b \gamma^a = 2 \eta^{ab} I$ that the gamma
matrices obey).

## 13. The author's metric and its determinant

The file Revision/gkd_lovelock/results/curvature.json of the Revision record
stores the diagonal of the author's metric as text in the notation of the
program Mathematica, for example 'E^(2*a4[x4])*Sin[6*H*x0]^(1/3)' for
$e^{2a_4(x_4)} \sin^{1/3}(6 H x_0)$ and
'-E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*b4[x4]' for
$-b_4(x_4) e^{-2a_4(x_4)} \sin^{1/3}(6 H x_0)$, and the square root of the size
of its determinant as 'Sin[6*H*x0]*Cot[6*H*x0]*b4[x4]^(3/2)'.

The next cell types the metric exactly as in section 4 of this notebook, with
sympy symbols $a_4$ (the value of $a_4(x_4)$ at one time, any real number),
$b_4$ (the value of $b_4(x_4)$ at one time, a positive number) and
$z = 6 H x_0$ (a positive number), translates the record's text into sympy (the
function 'from_record' replaces the Mathematica names by sympy names), and checks:

- the record's diagonal equals the typed one, entry by entry;
- the product of the diagonal entries, $\det g$, simplifies to $b_4^3 \cos^2 z$
  (no $a_4$ is left);
- the record's $b_4^{3/2} \sin z \cot z$ equals $b_4^{3/2} \cos z$, whose square
  is $\det g$.
```

ALL 30 CHECKS PASSED (notebook 01a)
```

Text cell:

```
## 15. What this notebook showed

- A matrix product $(AB)_{ik} = A_{ij} B_{jk}$ (summation convention: $j$ is
  summed) can be computed with loops, with ‘einsum‘ or with ‘@‘; the three agree,
  and $AB \neq BA$ in general, while $(AB)^T = B^T A^T$ and the traces of $AB$
  and $BA$ are equal.
- A permutation of $n$ objects has a sign $\pm 1$ given by its number of
  inversions; half of the $n!$ permutations are even ($n \geq 2$), and
  exchanging two entries flips the sign.
- The Leibniz formula, written by hand, gives the same determinants as sympy and
  numpy; determinants obey the six rules of section 9 and measure signed areas.
  For big matrices the Leibniz formula is far too long ($16! \approx 2 \times
  10^{13}$ terms), but for a signed permutation matrix only one term survives.
- The eight gamma matrices of the Revision record are real signed permutation
  matrices with determinant 1; each squares to $+I$ (space-like directions
  $x_0, x_1, x_2, x_3$) or $-I$ (time-like directions $x_4, \dots, x_7$).
- The determinant of the author’s metric is $\det g = b_4^3 \cos^2(6 H x_0)$ for
  every value of $a_4$: the growth $e^{6a_4}$ of the three space directions and
  the shrinking $e^{-6a_4}$ of the three extra times cancel exactly, and $b_4$
  enters only as the factor $b_4^3$. This repeats the Revision record’s check
  ‘sqrt_abs_det_g‘.
```

1.25 Line-by-line walk-through of Notebook 01a

The notebook has nineteen code cells, In [1] to In [19]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.24 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.23. Its code is, line for line, the set-up code of Notebook 01f explained in Section 1.9, with the single difference `NOTEBOOK_ID = "01a"`. It prints Set-up of notebook 01a complete: repository folder found, helpers defined.

In [2], vectors.

```
import itertools  # all orderings (permutations) of a list
import math  # factorials

import numpy as np  # arrays of numbers: vectors and matrices
import sympy as sp  # exact arithmetic with whole numbers, fractions and symbols
```

`itertools` (part of Python) produces, among other things, all permutations of a list (`itertools.permutations`); `math` gives the factorial `math.factorial` and the product `math.prod`; numpy and sympy as before.

```
v = np.array([1, 2, 0])  # a vector with 3 components
w = np.array([0, 1, 1])
say(f"v = {v.tolist()}, w = {w.tolist()}")
say(f"v + w = {(v + w).tolist()}, 3 v = {(3 * v).tolist()}")
```

`np.array([1, 2, 0])` makes a numpy array, here of whole numbers. `+` adds two arrays entry by entry and `3 * v` multiplies every entry: exactly the rules of Section 1.18. `.tolist()` turns an array into a plain Python list for printing. Output: v = [1, 2, 0], w = [0, 1, 1] and v + w = [1, 3, 1], 3 v = [3, 6, 0].

```
# The dot product as a sum over the index i = 0, 1, 2 (Python counts from 0):
dot_by_hand = sum(int(v[i]) * int(w[i]) for i in range(3))
say(f"v . w by the sum = {dot_by_hand}, with numpy's @ = {int(v @ w)}")
check(dot_by_hand == int(v @ w) == 2, "the dot product of v and w is 2")
```

`sum(... for i in range(3))` adds the products $v_i w_i$ for $i = 0, 1, 2$ (Python's numbering of the components 1, 2, 3); `int(...)` turns a numpy number into a plain Python whole number. For two vectors, numpy's operator `@` is the dot product. Both give 2, and the check confirms it. Output: v . w by the sum = 2, with numpy's @ = 2, and the PASS line.

In [3], matrix times vector.

```
A = np.array([[1, 2, 0],
              [0, 1, 1],
              [1, 3, 1]])  # three rows, each a list of three entries
say(f"A has {A.shape[0]} rows and {A.shape[1]} columns")
# Python counts rows and columns from 0: A[1, 2] is row 2, column 3 of A.
say(f"the entry in row 2, column 3 of A is A[1, 2] = {A[1, 2]}")
```

A matrix is an array of rows. `A.shape` is the pair (number of rows, number of columns). The second line prints the entry $A_{23} = 1$ under its Python name `A[1, 2]`.

```
# (A v)_i = sum over j of A_ij v_j, one number for each row i:
Av_by_hand = [sum(int(A[i, j]) * int(v[j]) for j in range(3)) for i in range(3)]
say(f"A v by the sum = {Av_by_hand}, with numpy = {(A @ v).tolist()}")
check(Av_by_hand == (A @ v).tolist() == [5, 2, 7],
      "A v computed with the sum rule is (5, 2, 7), the same as numpy's A @ v")
```

The list comprehension computes, for each row i, the sum over j of $A_{ij} v_j$: the rule of Section 1.18. `A @ v` is numpy's matrix times vector. Both give $(5, 2, 7)$. Output: A has 3 rows and 3 columns, the entry line, A v by the sum = [5, 2, 7], with numpy = [5, 2, 7], and the PASS line.

In [4], the matrix product, three ways.

```
B = np.array([[0, 1, 0],
              [1, 0, 2],
              [0, 1, 1]])
n = 3
AB_loops = np.zeros((n, n), dtype=int)  # a 3 x 3 matrix of zeros to fill in
for i in range(n):  # the row of the product (a free index)
    for k in range(n):  # the column of the product (a free index)
        for j in range(n):  # the summed (dummy) index
            AB_loops[i, k] += A[i, j] * B[j, k]
```

The second matrix B of Section 1.18. `np.zeros((n, n), dtype=int)` is a 3×3 array of whole-number zeros. The three nested loops compute $(AB)_{ik} = \sum_j A_{ij}B_{jk}$: the two outer loops run over the free indices i and k, the inner loop adds the terms of the dummy index j (`+=` adds to the entry).

```
AB_einsum = np.einsum("ij,jk->ik", A, B)  # j appears twice: it is summed
AB = A @ B
BA = B @ A
say(f"A B = {AB.tolist()}")
say(f"B A = {BA.tolist()}")
```

The same product with `einsum` (the summation convention of Section 1.18) and with `@`; then BA. Output: A B = [[2, 1, 4], [1, 1, 3], [3, 2, 7]] and B A = [[0, 1, 1], [3, 8, 2], [1, 4, 2]], the matrices of Section 1.18.

```
check((AB_loops == AB).all() and (AB_einsum == AB).all(),
      "loops, einsum and @ give the same product A B")
check(not (AB == BA).all(), "A B is not equal to B A: the order matters")
check(((A @ B).T == B.T @ A.T).all(), "the transpose rule (A B)^T = B^T A^T")
check(np.trace(AB) == np.trace(BA), "A B and B A have the same trace")
```

Four checks: the three ways agree entry by entry; $AB \neq BA$; the transpose rule (`.T` is numpy's transpose); equal traces (`np.trace`). Four PASS lines.

In [5], heat maps.

```
def heat_map(ax, matrix, title, labels=None, annotate=True, digits=0,
             skip_zeros=False):
    """Draw matrix on the axes ax: every entry a coloured square, red for
    positive, white for zero, blue for negative entries; when annotate is True
    the value is written in its square with the given number of digits (not
    for the zero entries when skip_zeros is True)."""
    m = np.asarray(matrix, dtype=float)
    limit = max(1.0, float(np.abs(m).max()))  # colours run from -limit to +limit
    image = ax.imshow(m, cmap="RdBu_r", vmin=-limit, vmax=limit)
```

A drawing helper used for every matrix picture of this notebook. `np.asarray(..., dtype=float)` makes a floating-point array of any table. `limit` is the largest size of an entry (at least 1). `ax.imsho w` draws the table as coloured squares; the **colour map** `"RdBu_r"` runs from blue through white to red, and `vmin=-limit, vmax=limit` puts white exactly at 0, so that red means positive and blue negative.

```
    ax.set_title(title)
    ax.grid(False)  # no grid lines across the coloured squares
    if labels is None:  # number rows and columns 1, 2, 3, ... as in mathematics
        labels = [str(k + 1) for k in range(m.shape[0])]
    ax.set_xticks(range(m.shape[1]), labels[:m.shape[1]])
    ax.set_yticks(range(m.shape[0]), labels[:m.shape[0]])
```

The title; no grid lines; if no labels are given, rows and columns are labelled 1, 2, 3, ... as in mathematics (Python's square number k gets the label $k + 1$); `set_xticks` and `set_yticks` put the labels under the columns and beside the rows.

```
    if annotate:
        for i in range(m.shape[0]):
            for j in range(m.shape[1]):
                if skip_zeros and m[i, j] == 0:
                    continue
                # white writing on dark squares, black writing on light ones
                ink = "white" if abs(m[i, j]) > 0.6 * limit else "black"
                ax.text(j, i, f"{m[i, j]:.{digits}f}", ha="center", va="center",
                        color=ink)
    return image
```

When `annotate` is true, the value of every entry is written in the middle of its square (`ha` and `va`: horizontal and vertical alignment), with `digits` digits after the point (the format inside the braces is itself built from `digits`); `continue` skips a zero entry when `skip_zeros` is true. Dark squares get white writing. The helper returns the picture, so that a colour bar can be added later.

```
fig, axes = plt.subplots(1, 4, figsize=(11.0, 3.2))
for ax, matrix, title in zip(axes, [A, B, AB, BA], ["A", "B", "A B", "B A"]):
    heat_map(ax, matrix, title)
fig.tight_layout()
save_figure(fig, "matrix_product",
            "Heat maps of the $3 \\times 3$ matrices $A$, $B$ and of their products "
            ...)
```

Four panels in a row, one heat map in each. What Figure 01a.1 shows: AB and BA have different entries, for example 4 and 1 in row 1, column 3.

In [6], permutations and their signs.

```
def inversions(order):
    """The number of pairs of places i < j whose entries stand in the wrong order."""
    return sum(1 for i in range(len(order)) for j in range(i + 1, len(order))
               if order[i] > order[j])

def sign(order):
    """+1 for an even number of inversions, -1 for an odd number."""
    return 1 if inversions(order) % 2 == 0 else -1
```

`inversions` counts the pairs of places $i < j$ (the inner range starts at $i + 1$) with `order[i] > order[j]`: it adds 1 for each such pair. `sign` returns $+1$ when that number is even (its remainder after division by 2 is 0) and -1 otherwise: the definition of Section 1.19.

```
for order in itertools.permutations(range(3)):  # all 6 orderings of 0, 1, 2
    say(f"permutation {order}: number of inversions {inversions(order)}, "
```

```
        f"sign {sign(order):+d}")
signs_of_three = [sign(order) for order in itertools.permutations(range(3))]
check(signs_of_three.count(1) == 3 and signs_of_three.count(-1) == 3,
      "of the 6 permutations of 3 objects, 3 are even and 3 are odd")
```

`itertools.permutations(range(3))` produces the six orderings of 0, 1, 2 as tuples (lists in round brackets). The loop prints each with its inversions and sign; the output is the table of Section 1.19. `.count(1)` counts the entries equal to 1. The check: three even, three odd.

In [7], the exchange theorem for up to 6 objects.

```
swap_rule_holds = True
for n in range(1, 7):
    orders = list(itertools.permutations(range(n)))
    even = sum(1 for order in orders if sign(order) == 1)
    say(f"n = {n}: n! = {len(orders):3d} permutations; even {even:3d}, "
        f"odd {len(orders) - even:3d}")
    swap_rule_holds &= len(orders) == math.factorial(n)
    swap_rule_holds &= (n == 1 or 2 * even == len(orders))
```

For $n = 1$ to 6: all permutations, the number of even ones, and a printed line; then two conditions are added to `swap_rule_holds` with `&=` (it stays true only if every condition holds): there are $n!$ permutations, and (for $n \geq 2$) exactly half are even. The output lines read n = 1: n! = 1 permutations; even 1, odd 0 up to n = 6: n! = 720 permutations; even 360, odd 360.

```
    for order in orders:
        for i in range(n):
            for j in range(i + 1, n):
                swapped = list(order)
                swapped[i], swapped[j] = swapped[j], swapped[i]  # exchange two
                swap_rule_holds &= sign(swapped) == -sign(order)
check(swap_rule_holds, "n! permutations, half of them even (n >= 2), and every "
      "exchange of two entries flips the sign (n = 1 to 6)")
```

For every permutation and every pair of places $i < j$: a copy of the permutation with the two entries exchanged (`a, b = b, a` exchanges two values in Python) must have the opposite sign. With n up to 6 this tests every exchange of every permutation, the theorem of Section 1.19. One PASS line.

In [8], the permutation matrices of 4 objects.

```
def permutation_matrix(order):
    """The matrix with a 1 in row i, column order[i], and 0 elsewhere."""
    P = np.zeros((len(order), len(order)), dtype=int)
    for i, column in enumerate(order):
        P[i, column] = 1
    return P
```

`enumerate(order)` gives the pairs (place, entry), so row `i` gets a 1 in column `order[i]`: the permutation matrix of Section 1.19.

```
fig, axes = plt.subplots(4, 6, figsize=(10.0, 7.4))
for ax, order in zip(axes.flat, itertools.permutations(range(4))):
    # Grey squares for the 1s; the title gives the permutation and its sign.
    ax.imshow(permutation_matrix(order), cmap="Greys", vmin=0, vmax=1.4)
    ax.set_title(f"{order}  {sign(order):+d}", fontsize=8)
    ax.set_xticks([])
    ax.set_yticks([])
fig.tight_layout()
save_figure(fig, "permutation_matrices",
            "The 24 permutation matrices of 4 objects; each small picture is a "
            ...)
```

A grid of 4 rows and 6 columns of small axes for the $4! = 24$ permutations; `axes.flat` runs through them one after the other. Each matrix is drawn with the grey colour map (`vmax=1.4` makes the 1s dark grey rather than black); the title gives the permutation and its sign; `set_xticks([])` removes the tick labels. What Figure 01a.2 shows: twelve signs $+1$ and twelve -1; the first picture is the identity; exchanging two rows of any picture gives a picture with the opposite sign.

In [9], the Leibniz formula in Python.

```
def leibniz_det(M):
    """The determinant of the square matrix M (a list of rows, a numpy array or a
    sympy Matrix) by the Leibniz formula: for every permutation, the sign times
    one entry from every row, row i giving the entry in column order[i]."""
    rows = [list(row) for row in (M.tolist() if hasattr(M, "tolist") else M)]
    total = 0
    for order in itertools.permutations(range(len(rows))):
        term = sign(order)
        for i in range(len(rows)):
            term = term * rows[i][order[i]]
        total = total + term
    return total
```

The Leibniz formula of Section 1.20, literally. First the matrix is turned into a list of rows, whatever it is (`hasattr(M, "tolist")` asks whether `M` can turn itself into a list, as numpy arrays and sympy matrices can). Then, for every permutation, the term starts as the sign and is multiplied by the entry of row `i` in column `order[i]` for every row; the terms are added. Because Python and sympy add and multiply whole numbers and symbols exactly, the result is exact.

```
a, b, c, d = sp.symbols("a b c d")  # four symbols: letters for any numbers
det_2 = leibniz_det([[a, b], [c, d]])
say(f"det of the 2 x 2 matrix with rows (a, b) and (c, d) = {det_2}")
check(sp.expand(det_2 - (a * d - b * c)) == 0, "Leibniz for 2 x 2: a d - b c")
```

With four symbols the formula gives `a*d - b*c`, the formula $ad - bc$.

```
say(f"det A = {leibniz_det(A)} (row 3 of A is row 1 plus row 2)")
check(leibniz_det(A) == 0, "det A = 0 because the rows of A are dependent")
check(all(leibniz_det(permutation_matrix(order)) == sign(order)
          for order in itertools.permutations(range(4))),
      "the determinant of every permutation matrix of 4 objects is its sign")
```

$\det A = 0$, as computed in Section 1.20, and $\det P_\sigma = \text{sign}(\sigma)$ for all 24 permutations of 4 objects, rule (b) of Section 1.20. Output: the two lines and three PASS lines.

In [10], three ways of computing a determinant.

```
generator = np.random.default_rng(12345)  # random numbers with a fixed seed
all_agree = True
for n in range(1, 8):
    M = generator.integers(-5, 6, size=(n, n))  # whole numbers -5 ... 5
    exact = leibniz_det(M)
    by_sympy = sp.Matrix(M.tolist()).det()
    by_numpy = np.linalg.det(M)  # a floating-point number
```

`np.random.default_rng(12345)` makes a **random-number generator** with the fixed starting number (**seed**) 12345, so that every run on every computer gets the same numbers. `generato r.integers(-5, 6, size=(n, n))` draws an $n \times n$ table of whole numbers from -5 to 5 (the end 6 is not included). For $n = 1$ to 7 the determinant is computed three ways: by `leibniz_det`, by sympy (exact, by elimination) and by numpy's `np.linalg.det` (floating point, by elimination).

```
    say(f"n = {n}: Leibniz {exact}, sympy {by_sympy}, numpy {by_numpy:.6f} "
        f"(n! = {math.factorial(n)} Leibniz terms)")
    all_agree &= exact == by_sympy and abs(by_numpy - exact) < 1e-6 * max(1, abs(exact))
check(all_agree, "Leibniz, sympy and numpy agree on 7 random integer matrices")
```

Each line prints the three results and the number of Leibniz terms; the exact two must agree exactly, numpy's to a millionth of the size of the result. Output: the determinants 2, 15, -35, -24, 730, 15445 and 60109 for $n = 1$ to 7, the same three times each, with 1 to 5040 Leibniz terms; then the PASS line.

In [11], the six rules.

```
M = sp.Matrix(generator.integers(-5, 6, size=(4, 4)).tolist())
N = sp.Matrix(generator.integers(-5, 6, size=(4, 4)).tolist())
say(f"det M = {M.det()}, det N = {N.det()}, det(M N) = {(M * N).det()}")
check((M * N).det() == M.det() * N.det(), "rule 1: det(M N) = det M det N")
check(M.T.det() == M.det(), "rule 2: det of the transpose = det")
```

Two random 4×4 integer matrices as exact sympy matrices (the generator continues where In [10] stopped). Output: det M = -192, det N = 128, det(M N) = -24576, and indeed $-192 \cdot 128 = -24576$. Rules 1 and 2 are checked exactly.

```
swapped = M.copy()
swapped.row_swap(0, 2)  # exchange rows 1 and 3
check(swapped.det() == -M.det(), "rule 3: exchanging two rows flips the sign")
twin = M.copy()
twin[3, :] = M[1, :]  # make row 4 equal to row 2
check(twin.det() == 0, "rule 4: two equal rows give determinant 0")
```

`.copy()` makes an independent copy, so that `M` itself stays unchanged. `row_swap(0, 2)` exchanges rows 1 and 3 (Python's 0 and 2): rule 3. `twin[3, :] = M[1, :]` replaces row 4 by row 2 (`[3, :]` means row 3 in Python's numbering, all columns): rule 4.

```
scaled = M.copy()
scaled[1, :] = 7 * M[1, :]  # multiply row 2 by 7
check(scaled.det() == 7 * M.det(), "rule 5: a row times 7 multiplies det by 7")
added = M.copy()
added[0, :] = M[0, :] + 5 * M[3, :]  # row 1 plus 5 times row 4
check(added.det() == M.det(), "rule 6: adding a multiple of a row keeps det")
D = sp.diag(2, -3, 5, 7)
check(D.det() == 2 * (-3) * 5 * 7, "a diagonal matrix: det = product of the diagonal")
```

Rule 5 (row 2 times 7), rule 6 (5 times row 4 added to row 1), and rule (a) for the diagonal matrix $\mathrm{diag}(2, -3, 5, 7)$. The cell prints seven PASS lines.

In [12], signed areas.

```
def signed_area(corners):
    """The shoelace formula: positive for corners listed counterclockwise."""
    total = 0.0
    for k in range(len(corners)):
        x1, y1 = corners[k]
        x2, y2 = corners[(k + 1) % len(corners)]  # % len: after the last, the first
        total += x1 * y2 - x2 * y1
    return total / 2
```

The shoelace formula of Section 1.21. For each corner k the next corner is number $(k + 1)$ modulo the number of corners, so that the last corner is followed by the first (the remainder `%` turns K into 0).

```
square = np.array([[0, 0], [1, 0], [1, 1], [0, 1]], dtype=float)  # counterclockwise
examples = [np.array([[2.0, 1.0], [1.0, 1.5]]),
            np.array([[1.0, 2.0], [1.0, 0.5]]),
            np.array([[1.0, 2.0], [0.5, 1.0]])]
fig, axes = plt.subplots(1, 3, figsize=(11.0, 3.9))
```

The unit square as four rows (corners) in counterclockwise order, three example matrices with the determinants $2 \cdot 1.5 - 1 \cdot 1 = 2$, $1 \cdot 0.5 - 2 \cdot 1 = -1.5$ and $1 \cdot 1 - 2 \cdot 0.5 = 0$, and a figure with three panels.

```
for ax, Mx in zip(axes, examples):
    image = square @ Mx.T  # each corner (a row) multiplied by the matrix
    ax.fill(square[:, 0], square[:, 1], color="0.85", label="unit square")
    ax.fill(image[:, 0], image[:, 1], color="tab:orange", alpha=0.5,
            label="its image")
```

For each matrix: `square @ Mx.T` multiplies every corner by the matrix (a corner is a row here, and a row r times M^T is the transpose of M times the column r, by the transpose rule). `square[:, 0]` is the column of the x values, `square[:, 1]` that of the y values. The square is filled light grey, its image orange and half transparent.

```
    ax.annotate("", xy=Mx[:, 0], xytext=(0, 0),
                arrowprops={"arrowstyle": "->", "color": "tab:blue", "lw": 2})
    ax.annotate("", xy=Mx[:, 1], xytext=(0, 0),
                arrowprops={"arrowstyle": "->", "color": "tab:red", "lw": 2})
    ax.text(*(Mx[:, 0] * 1.05), "$M e_1$", color="tab:blue")
    ax.text(*(Mx[:, 1] * 1.05), "$M e_2$", color="tab:red")
```

The two columns of the matrix, Me_1 and Me_2, as a blue and a red arrow from the origin, each labelled a little beyond its tip (the star hands the two coordinates of the point to `ax.text` as its first two arguments).

```
    ax.set_title(f"det M = {np.linalg.det(Mx):+.2f}, area {signed_area(image):+.2f}")
    ax.set_aspect("equal")
    ax.set_xlim(-0.3, 3.4)
    ax.set_ylim(-0.3, 2.9)
    ax.set_xlabel("$x$")
    ax.set_ylabel("$y$")
    ax.legend(loc="upper left", fontsize=8)
fig.tight_layout()
save_figure(fig, "area_and_determinant",
            "The unit square (grey) and its image (orange) under three $2 \\times 2$ "
            ...)
```

The title of each panel shows the determinant and the signed area of the image, which agree. What Figure 01a.3 shows: the area doubled (left); an area 1.5 with the two arrows in exchanged order, a mirrored picture (middle); the square flattened onto a line (right).

```
areas_match = all(abs(signed_area(square @ Mx.T) - np.linalg.det(Mx)) < 1e-12
                  for Mx in examples)
random_matrices = generator.normal(size=(1000, 2, 2))  # 1000 random 2 x 2 matrices
areas_match &= all(abs(signed_area(square @ Mx.T) - np.linalg.det(Mx)) < 1e-12
                   for Mx in random_matrices)
check(areas_match, "the signed area of the image of the unit square is det M "
      "(3 examples and 1000 random matrices)")
```

The signed area must equal the determinant to 10^{-12} for the three examples and for 1000 random 2×2 matrices (`generator.normal` draws **normal random numbers**, numbers around 0 with the bell-shaped distribution; `size=(1000, 2, 2)` gives 1000 matrices). One PASS line.

In [13], the cost of a determinant.

```
sizes = np.arange(1, 17)
leibniz_terms = np.array([math.factorial(int(k)) for k in sizes], dtype=float)
elimination_steps = sizes.astype(float) ** 3 / 3
report("number of terms of the Leibniz formula for n = 16", math.factorial(16))
check(math.factorial(16) == 20922789888000, "16! = 20 922 789 888 000")
```

For $n = 1$ to 16: the $n!$ terms of the Leibniz formula and the $n^3/3$ steps of elimination (`astype(float)` turns the whole numbers into floating-point numbers). The RESULT line prints 20922789888000, and the check compares it with 16! written out.

```
fig, ax = plt.subplots()
ax.semilogy(sizes, leibniz_terms, "o-", label="Leibniz formula: $n!$ terms")
ax.semilogy(sizes, elimination_steps, "s-", label="elimination: about $n^3/3$ steps")
ax.axvline(16, color="black", ls=":", label="$n = 16$: the gamma matrices")
ax.set_xlabel("size $n$ of the matrix")
ax.set_ylabel("number of terms or steps")
ax.set_title("The cost of a determinant")
ax.legend();
```

Both counts against n with a logarithmic vertical axis, and a dotted vertical line at $n = 16$. The semicolon after `ax.legend()` keeps Jupyter from printing the value of the line (Section 1.9).

```
# The two counts for n = 16, rounded, for the caption: 2.1e13 and 1365.
mantissa, exponent = f"{leibniz_terms[-1]:.1e}".split("e")
save_figure(fig, "determinant_cost",
            "The number of terms $n!$ of the Leibniz formula (circles) and the "
            ...
            f"$n = 16$ the Leibniz formula has about ${mantissa} \\times "
            f"10^{{{int(exponent)}}}$ terms against about "
            f"{elimination_steps[-1]:.0f} steps of elimination.")
```

The caption quotes the count for $n = 16$ as computed, not typed: `f"{x:.1e}"` writes 16! as the text 2.1e+13, and `.split("e")` cuts it at the letter e into the **mantissa** 2.1 and the **exponent** +13 (both are still texts). The line `...` stands for three ordinary text lines of the caption; the last three lines are f-strings, and Python joins all the pieces into one caption. In the first of them `{mantissa}` inserts the text 2.1, and `\\times` becomes the LaTeX command `\times`, the multiplication sign (in a Python string a backslash has a special meaning, so one backslash is written as two, Section 1.9). In the second, `10^{{{int(exponent)}}}` reads from the left: `10^`, then `{{`, which stands for one literal brace `{` (a single brace would start an insertion, Section 1.9), then the insertion `{int(exponent)}`, then `}}`, one literal `}`. `int(exponent)` turns the text +13 into the whole number 13 (it drops the plus sign; for a text such as -06 it would also drop the leading zero). So LaTeX receives `10^{13}` and prints 10^{13}: the braces hold the whole exponent, and without them only the first digit would be raised. In the third, `{elimination_steps[-1]:.0f}` inserts the last entry of the elimination counts, $16^3/3 = 1365.33\ldots$, with no digits after the point (`.0f`): 1365. The caption therefore ends "about 2.1×10^{13} terms against about 1365 steps of elimination.". What Figure 01a.4 shows: up to $n = 4$ the two counts are similar; then $n!$ grows far faster than $n^3/3$.

In [14], the gamma matrices of the record.

```
record = json.loads(repository_file("Revision/algebra/gammas.json")
                    .read_text(encoding="utf-8"))
names = record["coordinates"]  # ["x0", "x1", ..., "x7"]
eta = record["eta"]  # the diagonal of the frame metric, in the order x0 ... x7
gamma = [np.array(matrix, dtype=int) for matrix in record["gamma"]]
say(f"coordinates: {names}")
say(f"diagonal of eta: {eta}")
```

The record file is read as text and turned into a Python dictionary (`json.loads`, Section 1.9). Its entry `coordinates` holds the names x0 to x7, `eta` the diagonal of η, and `gamma` the eight matrices,

each a list of 16 rows; they become numpy arrays of whole numbers. Output: coordinates: ['x0', 'x1', 'x2', 'x3', 'x4', 'x5', 'x6', 'x7'] and diagonal of eta: [1, 1, 1, 1, -1, -1, -1, -1].

```
signed_permutation = True
for g_a in gamma:
    signed_permutation &= set(np.unique(g_a).tolist()) <= {-1, 0, 1}
    signed_permutation &= ((g_a != 0).sum(axis=1) == 1).all()  # one per row
    signed_permutation &= ((g_a != 0).sum(axis=0) == 1).all()  # one per column
```

For each matrix three conditions: `np.unique` lists the different entries, and `set(...) <= {-1, 0, 1}` asks whether they are among $-1, 0, 1$ (`<=` between sets means "is contained in"); `(g_a != 0)` is a table of True and False, and `.sum(axis=1)` counts the True values in each row (`axis=0`: in each column), which must be 1 everywhere. Together: a signed permutation matrix.

```
check(len(gamma) == 8 and all(g_a.shape == (16, 16) for g_a in gamma),
      "the record holds eight 16 x 16 gamma matrices")
check(signed_permutation, "every gamma matrix is a real signed permutation matrix",
      record="Revision/algebra/reports/python-algebra.json, "
             "check reality_signed_permutations")
```

Two checks: eight matrices of size 16×16, and the signed-permutation property; the second reproduces the record's check `reality_signed_permutations`, so `check` prints a second line naming it. Two PASS lines.

In [15], determinants and squares of the gamma matrices.

```
identity16 = np.eye(16, dtype=int)  # the 16 x 16 identity matrix
all_det_one = True
squares_right = True
for name, eta_aa, g_a in zip(names, eta, gamma):
    order = [int(np.flatnonzero(row)[0]) for row in g_a]  # column of each nonzero
    signs = [int(g_a[i, order[i]]) for i in range(16)]  # the nonzero entries
    det_by_structure = sign(order) * math.prod(signs)
```

`np.eye(16, dtype=int)` is the 16×16 identity. For each matrix: `np.flatnonzero(row)` lists the places of the nonzero entries of a row, and the first (only) one is its column, so `order` is the permutation σ; `signs` are the sixteen nonzero entries s_i; and the determinant is $\operatorname{sign}(\sigma)\, s_1 \cdots s_{16}$ by formula (c) of Section 1.20 (`math.prod` multiplies the entries of a list).

```
    det_exact = sp.Matrix(g_a.tolist()).det()
    det_numpy = np.linalg.det(g_a)
    say(f"gamma^({name}): eta {eta_aa:+d}, {signs.count(-1)} entries -1, "
        f"permutation sign {sign(order):+d}, det {det_by_structure:+d}, "
        f"sympy {det_exact}, numpy {det_numpy:.3f}")
    all_det_one &= det_by_structure == det_exact == 1 and abs(det_numpy - 1) < 1e-9
    squares_right &= (g_a @ g_a == eta_aa * identity16).all()
```

The same determinant exactly with sympy and in floating point with numpy; a line per matrix; then the two conditions: all three determinants equal 1, and $\gamma^a\gamma^a = \eta_{aa} I$. The output reads, for

$\gamma^{(x_0)}$ (the first line), 0 entries -1, permutation sign +1, det +1, sympy 1, numpy 1.000, and for $\gamma^{(x_1)}$ to $\gamma^{(x_7)}$ 8 entries -1 with the same determinants.

```
check(all_det_one, "every gamma matrix has determinant 1 (three ways)")
check(squares_right, "gamma^a gamma^a = eta_aa times the identity for every a",
      record="Revision/algebra/reports/python-algebra.json, check "
             "clifford_relation (its 8 relations with equal indices)")
```

Two PASS lines; the second reproduces the part of the record's check `clifford_relation` with equal indices.

In [16], heat maps of two gamma matrices.

```
fig, axes = plt.subplots(1, 3, figsize=(11.0, 4.0))
ticks = [str(k) for k in range(1, 17)]
pictures = [(gamma[1], "$\\gamma^{(x_1)}$"), (gamma[4], "$\\gamma^{(x_4)}$"),
            (gamma[4] @ gamma[4], "$\\gamma^{(x_4)} \\gamma^{(x_4)} = -I$")]
for ax, (matrix, title) in zip(axes, pictures):
    image = heat_map(ax, matrix, title, labels=ticks, annotate=False)
    ax.tick_params(labelsize=6)
```

Three panels: $\gamma^{(x_1)}$ (Python's `gamma[1]`: the list `gamma` holds the matrices in the author's order $x_0, \ldots, x_7$, so the index of $\gamma^{(x_k)}$ is k), $\gamma^{(x_4)}$ (`gamma[4]`) and its square, drawn with the helper of In [5] without written values; the row and column labels 1 to 16 are made small.

```
fig.colorbar(image, ax=axes, shrink=0.75, label="entry", ticks=[-1, 0, 1])
save_figure(fig, "gamma_matrices",
            "Heat maps of two of the eight real $16 \\times 16$ gamma matrices of "
            ...)
```

`fig.colorbar` adds a bar that explains the colours, shared by the three panels (`ax=axes`), 75 per cent as tall as them, with the marks -1, 0, 1. What Figure 01a.5 shows: in every row and every column of a gamma matrix exactly one coloured square; the square of the time-like $\gamma^{(x_4)}$ has blue squares (-1) on the diagonal and nothing else: $-I$.

In [17], the author's metric and its determinant, from the record.

```
a4 = sp.Symbol("a4", real=True)  # the value of the function a4(x4) at one time
b4 = sp.Symbol("b4", positive=True)  # the value of the function b4(x4) at one time
z = sp.Symbol("z", positive=True)  # z = 6 H x0, between 0 and pi/2
s = sp.sin(z) ** sp.Rational(1, 3)  # sin(z) to the power 1/3
g_typed = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * s] * 3 + [sp.Integer(-1)]
           + [-b4 * sp.exp(-2 * a4) * s] * 3)  # the author's order x0, x1, ..., x7
```

Symbols for the value of a_4 (any real number), for the value of b_4 (positive) and for z (positive), $s = \sin^{1/3} z$, and the author's metric typed as the list of its eight diagonal entries in the author's order $x_0, \ldots, x_7$, as in Section 1.1 (`sp.Integer(-1)` is the exact whole number -1).

```
curvature = json.loads(repository_file("Revision/gkd_lovelock/results/curvature.json")
                       .read_text(encoding="utf-8"))

def from_record(text):
    """The record's Mathematica text as a sympy expression."""
    text = text.replace("a4[x4]", "a4").replace("b4[x4]", "b4")
    text = text.replace("Sin[6*H*x0]", "sin(z)")
    text = text.replace("Cot[6*H*x0]", "cot(z)").replace("^", "**")
    return sp.sympify(text, locals={"a4": a4, "b4": b4, "z": z, "E": sp.E})
```

The record file, and the translation of its Mathematica texts into sympy, as in Notebook 01f, In [11] (Section 1.9), except that here $\sin(6Hx_0)$ becomes `sin(z)` and $\cot(6Hx_0)$ becomes `cot(z)` with the symbol z.

```
g_record = [from_record(text) for text in curvature["metricDiagonal"]]
check(len(g_record) == 8 and
      all(sp.simplify(x - y) == 0 for x, y in zip(g_record, g_typed)),
      "the record's metric diagonal equals the author's metric typed here")
det_g = sp.Mul(*g_typed)  # the product of the 8 diagonal entries
say(f"product of the diagonal entries, as sympy writes it: {det_g}")
```

The record's eight entries are compared one by one with the typed ones (and there must be eight). `det_g` is the product of the diagonal, the determinant by rule (a). Output: sympy writes it `b4**3*si n(z)**2*cot(z)**2`, already without a_4.

```
check(sp.simplify(det_g - b4 ** 3 * sp.cos(z) ** 2) == 0,
      "det g = b4^3 cos(z)^2 for every a4: the e^(6 a4) of space and the e^(-6 a4) "
      "of the extra times cancel",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "sqrt_abs_det_g")
root_record = from_record(curvature["sqrtAbsDetG"])
say(f"the record's square root of |det g|: {root_record}")
check(sp.simplify(root_record - b4 ** sp.Rational(3, 2) * sp.cos(z)) == 0 and
      sp.simplify(root_record ** 2 - det_g) == 0,
      "the record's sqrtAbsDetG = b4^(3/2) sin z cot z = b4^(3/2) cos z, and its "
      "square is det g",
      record="Revision/gkd_lovelock/results/curvature.json, sqrtAbsDetG")
```

The check $\det g = b_4^3 \cos^2 z$ (Section 1.21), which reproduces the record's check `sqrt_abs_det_g`; then the record's `sqrtAbsDetG`, printed as `b4**(3/2)*sin(z)*cot(z)`, which must simplify to $b_4^{3/2} \cos z$ and square to $\det g$. Three PASS lines, two with a second line naming the record.

In [18], the metric in numbers.

```
metric_numbers = sp.lambdify((a4, b4, z), g_typed, "numpy")  # a4, b4, z -> 8 numbers
z_values = np.linspace(0.01, np.pi / 2 - 0.01, 300)  # inside (0, pi/2)
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.6))
g_point = np.diag(np.array(metric_numbers(0.5, 1.0, 0.9), dtype=float))
coordinate_labels = [f"$x_{k}$" for k in range(8)]  # x with subscripts 0 ... 7
```

```
heat_map(left, g_point, "metric $g$ at $a_4 = 0.5$, $b_4 = 1$, $z = 0.9$",
         labels=coordinate_labels, digits=2, skip_zeros=True)
left.tick_params(labelsize=8)
```

`sp.lambdify` turns the exact list of formulas into a fast numpy function of a_4, b_4 and z that returns the eight numbers. `z_values` are 300 values inside $(0, \pi/2)$. On the left, the 8×8 metric at $a_4 = 0.5$, $b_4 = 1$, $z = 0.9$ (`np.diag` of a list builds the diagonal matrix) is drawn as a heat map with the coordinate names x_0 to x_7 as labels and two digits, the zero entries left blank.

```
largest_error = 0.0
for a4_value, b4_value, style in [(-1.0, 1.0, "-"), (0.0, 0.5, "--"), (1.0, 2.0, ":")]:
    dets = np.array([np.linalg.det(np.diag(np.array(metric_numbers(a4_value, b4_value,
                                                                   zv), dtype=float)))
                     for zv in z_values]) / b4_value ** 3
    largest_error = max(largest_error, float(np.max(np.abs(dets - np.cos(z_values)
                                                           ** 2))))
    right.plot(z_values, dets, style, lw=2,
               label=f"det g / $b_4^3$, $a_4 = {a4_value:+.0f}$, $b_4 = {b4_value:g}$")
```

For the three pairs $(a_4, b_4) = (-1, 1)$, $(0, 0.5)$ and $(1, 2)$ (solid, dashed and dotted lines): at each of the 300 values of z the 8×8 matrix is built and its determinant computed by numpy's elimination, then divided by b_4^3; `largest_error` keeps the largest difference from $\cos^2 z$; the 300 values are drawn against z.

```
right.plot(z_values, np.cos(z_values) ** 2, color="black", lw=0.8,
           label="$\\cos^2 z$")
right.set_xlabel("$z = 6 H x_0$")
right.set_ylabel("$\\det g / b_4^3$")
right.set_title("$\\det g / b_4^3$ does not depend on $a_4$")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "metric_and_determinant",
            "Left: heat map of the author's $8 \\times 8$ metric at $a_4 = 0.5$, "
            ...)
```

The curve $\cos^2 z$ as a thin black line, labels, a legend in a small font, and the figure. What Figure 01a.6 shows: on the left only the diagonal is coloured, red for x_0, x_1, x_2, x_3 and blue for x_4 to x_7; on the right the three curves of $\det g / b_4^3$ and $\cos^2 z$ lie on top of each other.

```
report("largest difference between det g / b4^3 and cos(z)^2 at 900 points",
       f"{largest_error:.1e}")
check(largest_error < 1e-12, "numpy: det g = b4^3 cos(z)^2 at 300 values of z for "
      "each of (a4, b4) = (-1, 1), (0, 0.5), (1, 2)")
```

The RESULT line prints 2.9×10^{-15}, rounding errors only, and the check requires less than 10^{-12} (COMPUTED).

In [19], the last check.

```
figure_names = ["01a_1_matrix_product.png", "01a_2_permutation_matrices.png",
                "01a_3_area_and_determinant.png", "01a_4_determinant_cost.png",
                "01a_5_gamma_matrices.png", "01a_6_metric_and_determinant.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

The six figure files must exist; the last line is ALL 30 CHECKS PASSED (notebook 01a). The 30 checks are: 1 in In [2], 1 in In [3], 4 in In [4], 1 in In [6], 1 in In [7], 3 in In [9], 1 in In [10], 7 in In [11], 1 in In [12], 1 in In [13], 2 in In [14], 2 in In [15], 3 in In [17], 1 in In [18] and 1 in In [19].

1.26 Index notation and the summation convention

Why indices. Every formula of the theory involves the eight coordinates at once. The field equation of the Revision record, $\gamma^\mu D_\mu \Psi = (m + U'(S))\Psi$ (Chapter 7), is a sum of eight terms, one for each coordinate; the Clifford relation of the gamma matrices is one line that stands for 64 equations between 16×16 matrices. **Index notation** writes such formulas compactly: a letter stands for each of the coordinates, and a rule says which letters are summed.

Indices and their positions. An **index** is a letter that stands for any one of the eight coordinates $x_0, \ldots, x_7$. The course uses the Latin letters a, b, c, d for the directions of the frame (the eight directions with the frame metric η, below) and the Greek letters μ, ν, λ for the coordinates themselves; both run over the eight values 0 to 7, the numbers of the author's coordinates. A vector v has the components $v^0, \ldots, v^7$, written with an **upper index**: the component of v along x_3 is v^3, which Python stores as `v[3]` (the author and Python both count from 0). An upper index is a label, not a power: v^3 is a component, and its square is written $(v^3)^2$. A second list of eight numbers that belongs to the same vector, $v_0, \ldots, v_7$, carries a **lower index**; Section 1.27 says how one list is made from the other. In index formulas the coordinates themselves are written x^μ with an upper index, and a small step along them dx^μ; the author's names $x_0, \ldots, x_7$ denote the same coordinates (the lower number is part of the name, as in Section 1.1), and the index of a coordinate is never lowered with a metric.

Free and dummy indices. Take a table $M^a{}_b$ (row a, column b) and a vector v^b. In

$$w^a = M^a{}_b v^b = \sum_b M^a{}_b v^b$$

the index a is **free**: it appears once in every term, and the formula holds for each of its values, one equation for each a. The index b is a **dummy**: it appears twice in one term, once up and once down, and it is summed over all its values. The **summation convention** (introduced by Einstein) is the rule that such a repeated pair is summed without writing $\sum$. A dummy index may be renamed, $M^a{}_b v^b = M^a{}_c v^c$, because the name of the letter in a sum does not change its value; a free index may not. In a correct equation every term has the same free indices in the same positions. A formula with k free indices over eight coordinates stands for 8^k equations: 1, 8, 64, 512 for $k = 0, 1, 2, 3$.

An example (PROVED by arithmetic). With the table M of rows $(1, 2, 0)$, $(0, 1, 1)$, $(1, 3, 1)$ and $v = (2, -1, 3)$ (three index values only, to keep it small):

$$w^1 = 1\cdot 2 + 2\cdot(-1) + 0\cdot 3 = 0, \quad w^2 = 0\cdot 2 + 1\cdot(-1) + 1\cdot 3 = 2, \quad w^3 = 1\cdot 2 + 3\cdot(-1) + 1\cdot 3 = 2$$

(for each free value a, the sum over the dummy b). Two numbers without any free index: the **trace** $M^a{}_a = M^1{}_1 + M^2{}_2 + M^3{}_3 = 1+1+1 = 3$, and, with $u_a = (1,0,2)$, the number $u_a M^a{}_b v^b = u_a w^a = 1\cdot 0 + 0\cdot 2 + 2\cdot 2 = 4$ (two dummy pairs, summed; first over b, which gives w^a, then over a). Setting an upper and a lower index equal and summing over it is called a **contraction**; it removes two free indices.

The Kronecker delta. With one upper and one lower index, $\delta^a{}_b$ (also written δ^a_b) is 1 if $a = b$ and 0 otherwise; as a table it is the identity matrix. Three rules (PROVED):

$$\delta^a{}_b v^b = v^a, \qquad \delta^a{}_b\, \delta^b{}_c = \delta^a{}_c, \qquad \delta^a{}_a = 8$$

(in $\sum_b \delta^a{}_b v^b$ only the term $b = a$ is not zero, and it is $1\cdot v^a$; the second rule is the first with the vector replaced by the column c of δ; the third adds $\delta^0{}_0 + \cdots + \delta^7{}_7 = 1 + \cdots + 1$, eight ones). Contracting with δ renames an index.

1.27 The frame metric: lowering, raising and squared lengths

The frame metric. The **frame metric** of the author's spacetime is the diagonal table

$$\eta_{ab} = \mathrm{diag}(+1,+1,+1,+1,-1,-1,-1,-1) \quad \text{in the order } x_0,\ldots,x_7.$$

It records only which directions are space-like (+1: the hidden x_0 and x_1, x_2, x_3) and which are time-like (−1: the time x_4 and the three extra times x_5, x_6, x_7). The Revision record stores it in `Revision/algebra/gammas.json` and states it in the report `Revision/algebra/reports/python-algebra.json`, check `coordinate_map`. Its inverse, written with upper indices η^{ab}, is the diagonal table of the inverse entries, $1/(+1) = +1$ and $1/(-1) = -1$: the same entries. Hence (PROVED)

$$\eta^{ab}\eta_{bc} = \delta^a{}_c$$

(the product of two diagonal tables is the diagonal table of the products of their entries, and each product is $(\pm 1)(\pm 1) = 1$).

Lowering and raising (PROVED). The lower list of a vector is made with η:

$$v_a = \eta_{ab} v^b = \eta_{aa} v^a \quad \text{(no sum in the last expression)}$$

(only the term $b = a$ of the sum survives, because η is diagonal). So **lowering** an index keeps the four space-like components and changes the sign of the four time-like ones: for $v^a = (1,2,\ldots,8)$ (that is $v^0 = 1, v^1 = 2, \ldots, v^7 = 8$), $v_a = (1,2,3,4,-5,-6,-7,-8)$. **Raising** with η^{ab} undoes it: $\eta^{ab} v_b = \eta^{ab}\eta_{bc} v^c = \delta^a{}_c v^c = v^a$ (insert the lowered list; the inverse rule; the delta renames).

The squared length. The **squared length** of a vector is

$$Q(v) = \eta_{ab} v^a v^b = v^a v_a = (v^0)^2 + (v^1)^2 + (v^2)^2 + (v^3)^2 - (v^4)^2 - (v^5)^2 - (v^6)^2 - (v^7)^2$$

(the sum over b is the lowered list; in the double sum only the terms $a = b$ survive because η is diagonal). A vector $v \neq 0$ is **space-like** if $Q(v) > 0$, **time-like** if $Q(v) < 0$ and **light-like** (or **null**) if $Q(v) = 0$. Five examples (PROVED by arithmetic): the unit vector along x_1 has $Q = +1$ (space-like); the unit vector along x_5 has $Q = -1$ (time-like); their sum has $Q = 1 - 1 = 0$ (light-like although it is not zero); $(1, 1, \ldots, 1)$ has $Q = 4 - 4 = 0$ (light-like); and $v = (1, 2, \ldots, 8)$ has

$$Q = (1 + 4 + 9 + 16) - (25 + 36 + 49 + 64) = 30 - 174 = -144$$

(the squares of the space-like components v^0, v^1, v^2, v^3 minus those of the time-like components $v^4, \ldots, v^7$): time-like. The **signature** of η is $(4, 4)$: four entries $+1$ and four entries -1 (Section 1.36 gives the general definition). The boost of Section 1.13 keeps the squared length of the pair (t, x) with $\eta = \mathrm{diag}(-1, +1)$; written with tables, the squared length of Λv is $(\Lambda v)^T \eta (\Lambda v) = v^T (\Lambda^T \eta \Lambda) v$ (the transpose rule of Section 1.18), so $\Lambda^T \eta \Lambda = \eta$ says that it equals $v^T \eta v$ for every v.

Half of all random vectors are space-like (PROVED, with one ASSUMED fact of probability). Draw the eight components of a vector as independent **normal random numbers** (numbers around 0 whose histogram is the bell curve $e^{-x^2/2}/\sqrt{2\pi}$). Exchange its four space-like components (v^0, v^1, v^2, v^3) with its four time-like components (v^4, v^5, v^6, v^7). The new vector v' has

$$Q(v') = (v^4)^2 + (v^5)^2 + (v^6)^2 + (v^7)^2 - (v^0)^2 - (v^1)^2 - (v^2)^2 - (v^3)^2 = -Q(v)$$

(every square that was added is now subtracted and every square that was subtracted is now added). Because all eight components are drawn in the same way, the exchanged vector is exactly as likely as the original one; so $Q > 0$ and $Q < 0$ are equally likely, and $Q = 0$ exactly has probability 0 (ASSUMED from probability theory). Therefore, **in the signature (4,4) exactly half of all random vectors are space-like.** In ordinary spacetime with three space directions and one time, signature (3,1), $Q = (v^1)^2 + (v^2)^2 + (v^3)^2 - (v^4)^2$ adds three squares and subtracts one, and most random vectors are space-like; integral calculus (not shown here, ASSUMED) gives the fraction $1/2 + 1/\pi \approx 0.818$. Notebook 01e, In [6], draws 200,000 random vectors and measures the fractions 0.5011 and 0.8177 (COMPUTED). A measured fraction p from N tries is expected to scatter around the true value by about one **standard deviation** $\sqrt{p(1-p)/N}$ (ASSUMED from probability), here $\sqrt{0.25/200000} \approx 0.0011$ for the first; both measurements lie within 4 standard deviations of $1/2$ and of $1/2 + 1/\pi$ (Figure 01e.2).

1.28 Symmetric and antisymmetric arrays; commutators; the Clifford relation

The symmetric and the antisymmetric part. A square array is **symmetric** if $S_{ab} = S_{ba}$ and **antisymmetric** if $A_{ab} = -A_{ba}$; the diagonal of an antisymmetric array is 0, because $A_{aa} = -A_{aa}$ forces $A_{aa} = 0$. Every square array is the sum of a symmetric and an antisymmetric part:

$$M_{ab} = S_{ab} + A_{ab}, \qquad S_{ab} = \tfrac{1}{2}(M_{ab} + M_{ba}), \qquad A_{ab} = \tfrac{1}{2}(M_{ab} - M_{ba})$$

(adding the two parts gives back M_{ab}, because the terms M_{ba} cancel; exchanging a and b leaves S unchanged and changes the sign of A).

Theorem (PROVED). If $S_{ab} = S_{ba}$ and $A^{ab} = -A^{ba}$, then $S_{ab}A^{ab} = 0$. *Proof*, line by line:

$$S_{ab}A^{ab} = S_{ba}A^{ba}$$

(both sides are the same double sum over all pairs; only the names of the two dummy indices were exchanged, which does not change a sum),

$$S_{ba}A^{ba} = S_{ab}\,(-A^{ab})$$

(the symmetry of S and the antisymmetry of A), so $S_{ab}A^{ab} = -S_{ab}A^{ab}$, and a number that equals its own negative is 0. In words: the term (a, b) and the term (b, a) cancel, and the diagonal terms are 0. Raising both indices keeps an array antisymmetric: $A^{ab} = \eta^{ac}\eta^{bd}A_{cd}$, and $A^{ba} = \eta^{bc}\eta^{ad}A_{cd} = \eta^{ac}\eta^{bd}A_{dc} = -\eta^{ac}\eta^{bd}A_{cd} = -A^{ab}$ (the definition with a and b exchanged; the dummies c and d renamed into each other and the factors re-ordered; the antisymmetry of A_{cd}).

A consequence used again and again (PROVED). For a vector with ordinary (**commuting**) components, $v^a v^b = v^b v^a$ is symmetric in a and b, so by the theorem $v^a v^b A_{ab} = 0$ for every antisymmetric A, and $v^a v^b M_{ab} = v^a v^b S_{ab}$: only the symmetric part of an array counts in a squared expression. Later in the course (Chapter 7) the components of the field dirac16complex **anticommute**, $\theta_a\theta_b = -\theta_b\theta_a$; then the products are antisymmetric, and only the antisymmetric part of an array counts.

Commutators and anticommutators. For two square matrices P and R the **commutator** and the **anticommutator** are

$$[P, R] = PR - RP, \qquad \{P, R\} = PR + RP.$$

They split a product into two parts, $PR = \frac{1}{2}[P, R] + \frac{1}{2}\{P, R\}$ (the two halves add up to $\frac{1}{2}(PR - RP + PR + RP) = PR$), and directly from the definitions $[R, P] = -[P, R]$ and $\{R, P\} = \{P, R\}$. P and R **commute** if $[P, R] = 0$ and **anticommute** if $\{P, R\} = 0$, that is $PR = -RP$.

The Clifford relation. The eight gamma matrices of the Revision record obey

$$\gamma^a\gamma^b + \gamma^b\gamma^a = 2\eta^{ab}I \qquad (a, b = x_0, \ldots, x_7),$$

the **Clifford relation**. Chapter 4 derives it, and the Revision record checks it in the check `clifford_relation` of its report `Revision/algebra/reports/python-algebra.json`. With two free indices it stands for $8 \cdot 8 = 64$ matrix equations. For $a = b$ it says $(\gamma^a)^2 = \eta^{aa}I$, $+I$ for a space-like and $-I$ for a time-like direction (Section 1.21). For $a \neq b$ it says $\{\gamma^a, \gamma^b\} = 0$: different gamma matrices anticommute, and their commutator is $[\gamma^a, \gamma^b] = \gamma^a\gamma^b - \gamma^b\gamma^a = 2\gamma^a\gamma^b$. The product of two signed permutation matrices is again a signed permutation matrix (each row of the product picks one row of the second factor, with a sign), so this commutator has exactly 16 nonzero entries, ± 2.

Symmetric and antisymmetric gamma matrices (PROVED). A real matrix O with $O^T O = I$ is called **orthogonal**; then $O^T = O^{-1}$. Every signed permutation matrix is orthogonal: the entry (j, k) of $O^T O$ is $\sum_i O_{ij}O_{ik}$, the "dot product" of the columns j and k; for $j = k$ it is the square of the one nonzero entry ± 1 of the column, which is 1; for $j \neq k$ the nonzero entries of the two columns lie in different rows (a row holds only one nonzero entry), so every product $O_{ij}O_{ik}$ is 0.

For a gamma matrix, $(\gamma^a)^2 = \eta^{aa} I$ says $\gamma^a(\eta^{aa}\gamma^a) = I$ (multiply by the number $\eta^{aa} = \pm 1$, whose square is 1), so $(\gamma^a)^{-1} = \eta^{aa}\gamma^a$. Together:

$$(\gamma^a)^T = (\gamma^a)^{-1} = \eta_{aa}\gamma^a \quad \text{(no sum)},$$

the gamma matrices of the space-like directions x_0, x_1, x_2, x_3 are **symmetric** and those of the time-like directions $x_4, \ldots, x_7$ are **antisymmetric**. The record states this in its check `symmetry_pattern`.

Three contractions (PROVED). Lowering the index of the gamma matrices gives $\gamma_a = \eta_{ab}\gamma^b$, which is $+\gamma^a$ for a space-like and $-\gamma^a$ for a time-like direction. *First*, $\gamma^a\gamma_a = 8I$:

$$\gamma^a\gamma_a = \sum_a \gamma^a \eta_{ab}\gamma^b = \sum_a \eta_{aa}(\gamma^a)^2$$

(insert γ_a; only $b = a$ survives because η is diagonal),

$$\sum_a \eta_{aa}(\gamma^a)^2 = \sum_a \eta_{aa}\eta^{aa} I = \sum_a 1 \cdot I = 8I$$

(the Clifford relation with $a = b$; then $\eta_{aa}\eta^{aa} = (\pm 1)^2 = 1$ for each of the eight values of a). Each time-like direction contributes $(\gamma^a)^2 = -I$, but its $\eta_{aa} = -1$ turns the contribution into $+I$. *Second*, $\gamma^a\gamma^b\gamma_a = -6\gamma^b$. First lower one index of the Clifford relation: multiplying $\gamma^b\gamma^c + \gamma^c\gamma^b = 2\eta^{bc}I$ by η_{ca} and summing over c gives

$$\gamma^b\gamma_a + \gamma_a\gamma^b = 2\delta^b{}_a I, \qquad \text{that is} \qquad \gamma^b\gamma_a = -\gamma_a\gamma^b + 2\delta^b{}_a I$$

($\gamma^c\eta_{ca} = \gamma_a$ by the definition of lowering, and $\eta^{bc}\eta_{ca} = \delta^b{}_a$; then move one term to the other side). Then

$$\gamma^a\gamma^b\gamma_a = \gamma^a\big(-\gamma_a\gamma^b + 2\delta^b{}_a I\big) = -(\gamma^a\gamma_a)\gamma^b + 2\gamma^b = -8\gamma^b + 2\gamma^b = -6\gamma^b$$

(insert the lowered relation; multiply out, where $\gamma^a\delta^b{}_a = \gamma^b$ because only $a = b$ survives; the first contraction; collect). In n dimensions the same steps give $(2-n)\gamma^b$. *Third*, $\mathrm{tr}(\gamma^a\gamma^b) = 16\eta^{ab}$: since $\mathrm{tr}(\gamma^a\gamma^b) = \mathrm{tr}(\gamma^b\gamma^a)$ (Section 1.18), $\mathrm{tr}(\gamma^a\gamma^b) = \frac{1}{2}\mathrm{tr}(\gamma^a\gamma^b + \gamma^b\gamma^a) = \frac{1}{2}\cdot 2\eta^{ab}\,\mathrm{tr}\,I = 16\eta^{ab}$ (the average of two equal numbers; the Clifford relation; $\mathrm{tr}\,I = 16$ for the 16×16 identity). Notebook 01e, In [10] to In [13], checks all of this with the matrices of the record (Figures 01e.4 and 01e.5).

1.29 The author's metric in index notation

The metric and its inverse. The author's metric $g_{\mu\nu}$ is the diagonal table of Section 1.1, with the entries $g_{00} = \cot^2 z$, $g_{11} = g_{22} = g_{33} = e^{2a_4}s$, $g_{44} = -1$ and $g_{55} = g_{66} = g_{77} = -b_4 e^{-2a_4}s$, where $s = \sin^{1/3} z$ and $z = 6Hx_0$; the record stores it in `Revision/gkd_lovelock/results/curvature.json`, key `metricDiagonal`. Its inverse $g^{\mu\nu}$ is the diagonal table with the entries $g^{\mu\mu} = 1/g_{\mu\mu}$, and $g^{\mu\nu}g_{\nu\lambda} = \delta^\mu{}_\lambda$ (PROVED: the product of two diagonal tables, with $(1/g_{\mu\mu})\,g_{\mu\mu} = 1$); the record

checks it in `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `metric_inverse`. The metric lowers and raises coordinate indices as η does for frame indices: $dx_\mu = g_{\mu\nu}dx^\nu$.

The line element (PROVED). The squared length of a small step dx^μ in the coordinates is the **line element**

$$ds^2 = g_{\mu\nu}\,dx^\mu dx^\nu = \sum_\mu g_{\mu\mu}\,(dx^\mu)^2 = dx^\mu dx_\mu$$

(a double sum, in which only the terms $\nu = \mu$ survive because g is diagonal; the sum over ν is the lowered list). For the step with the same small size ϵ in all eight coordinates, $dx^\mu = \epsilon$:

$$ds^2 = \epsilon^2\big(\cot^2 z + 3e^{2a_4}s - 1 - 3b_4e^{-2a_4}s\big)$$

(the eight diagonal entries, each times ϵ^2: the hidden direction, three equal space entries, the time, three equal extra-time entries). From here on take $b_4 = 1$, the background of the Revision record:

$$= \epsilon^2\big(3s\,(e^{2a_4} - e^{-2a_4}) - 1 + \cot^2 z\big) = \epsilon^2\big(6s\sinh(2a_4) - 1 + \cot^2 z\big)$$

(insert $b_4 = 1$ and take out the common factor $3s$; then $e^x - e^{-x} = 2\sinh x$ with $x = 2a_4$, the definition of Section 1.13). As a_4 grows, the term of the three space directions grows like e^{2a_4} and the term of the three exponentially deflating extra times shrinks towards 0 like e^{-2a_4}.

Where the step changes its kind (PROVED). Take $b_4 = 1$. For fixed z, ds^2 grows when a_4 grows, because $6s > 0$ and sinh is an increasing function (its derivative cosh is positive; the derivative of $6s\sinh(2a_4)$ with respect to a_4 is $12s\cosh(2a_4) > 0$). Since sinh takes every real value exactly once, its inverse function arcsinh exists, and $ds^2 = 0$ exactly at

$$a_4^*(z) = \tfrac{1}{2}\operatorname{arcsinh}\Big(\frac{1 - \cot^2 z}{6s}\Big)$$

(set $ds^2 = 0$; solve for $\sinh(2a_4) = (1 - \cot^2 z)/(6s)$; apply arcsinh; divide by 2). For $a_4 < a_4^*(z)$ the step is time-like, for $a_4 > a_4^*(z)$ space-like: as space inflates and the extra times deflate, the same coordinate step turns from time-like to space-like. Notebook 01e, In [14] and In [15], checks the formula exactly and the sign change on a grid of 301×300 points (Figure 01e.6; COMPUTED).

1.30 Example: index notation in the author's spacetime

Notebook 01e puts Sections 1.26 to 1.29 to work. It computes sums with free and dummy indices with loops and with `einsum`; reads η from the Revision record, lowers and raises an index and checks $\eta^{ab}\eta_{bc} = \delta^a{}_c$ and $\delta^a{}_a = 8$; sorts vectors into space-like, time-like and light-like ones and measures with 200,000 random vectors that half of them are space-like in the signature (4,4) but about 82 per cent in the signature (3,1); checks the theorem on symmetric and antisymmetric arrays exactly with whole numbers; checks all 64 Clifford relations of the record's gamma matrices, their symmetry pattern and the three contractions; and writes the author's line element as a sum over indices and shows how the inflation of space and the deflation of the extra times change it. It ends with the line ALL 25 CHECKS PASSED (notebook 01e).

1.31 How to run Notebook 01e

Step 1. What this notebook does and what it needs.

Notebook 01e (Index notation, the summation convention and the metric) is the file `Revision /textbook/notebooks/01e_index_notation.ipynb` of the repository Dirac_claude. It teaches free and dummy indices and the summation convention with numpy einsum, reads the frame metric eta of the author's coordinates x0 to x7 from the Revision record, lowers and raises indices with it, sorts vectors into space-like, time-like and light-like ones in the signature (4,4) and compares random vectors with those of ordinary four-dimensional spacetime, proves that a symmetric array contracted with an antisymmetric one gives zero, checks the Clifford relation of the eight real gamma matrices of the Revision record as one index formula for all 64 pairs, derives and checks the contractions gamma^a gamma_a = 8 and gamma^a gamma^b gamma_a = -6 gamma^b, and writes the squared length of a coordinate step in the author's metric, whose three extra times deflate exponentially, as a sum over indices, with heat maps and plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
```

```
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01e_index_notation.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a

number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01e_index_notation.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01e_index_notation.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01e.captions.json`
- `Revision/textbook/figures/01e_1_eta_and_delta.png`
- `Revision/textbook/figures/01e_2_squared_lengths.png`
- `Revision/textbook/figures/01e_3_symmetric_antisymmetric.png`
- `Revision/textbook/figures/01e_4_clifford_tables.png`
- `Revision/textbook/figures/01e_5_gamma_contractions.png`
- `Revision/textbook/figures/01e_6_step_length.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 25 CHECKS PASSED (notebook 01e)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01e_index_notation.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01e_index_notation.ipynb
python -m nbconvert --execute --inplace 01e_index_notation.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

1.32 Notebook 01e: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01e_index_notation.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

Every formula of the course is written in *index notation*: a letter such as $a$
or $\mu$ stands for each of the eight coordinates $x_0, \dots, x_7$ of the
author's spacetime, and a letter that appears twice is summed. This notebook
teaches that notation from zero and uses it on the objects of the theory. It

- shows free and dummy indices and the summation convention with numpy's
  function `einsum`, which reads the convention literally;
- reads the frame metric $\eta$ from the Revision record, lowers and raises
  indices with it, and checks $\eta^{ab}\eta_{bc} = \delta^a_c$ and
  $\delta^a_a = 8$;
- computes squared lengths $\eta_{ab} v^a v^b$ and sorts vectors into
  space-like, time-like and light-like ones; with four space-like and four
  time-like directions exactly half of all random vectors are space-like, unlike
  in ordinary four-dimensional spacetime;
- proves that a symmetric array contracted with an antisymmetric one gives 0;
- checks the Clifford relation $\gamma^a \gamma^b + \gamma^b \gamma^a =
  2\eta^{ab} I$ of the eight real gamma matrices of the Revision record: one
  index formula that stands for 64 matrix equations;
- derives and checks the contractions $\gamma^a \gamma_a = 8 I$ and
  $\gamma^a \gamma^b \gamma_a = -6 \gamma^b$;
- writes the squared length of a small coordinate step in the author's metric
  as a sum over indices, and shows how the growth of space and the exponential
  deflation of the three extra times change it.

Every check prints a line that starts with PASS; where a check repeats a result
of the Revision record, a second line names the record file and its check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01e (Index notation, the summation convention and the metric) is the file
`Revision/textbook/notebooks/01e_index_notation.ipynb` of the repository Dirac_claude. It
teaches free and dummy indices and the summation convention with numpy einsum, reads the
frame metric eta of the author's coordinates x0 to x7 from the Revision record, lowers
and raises indices with it, sorts vectors into space-like, time-like and light-like ones
in the signature (4,4) and compares random vectors with those of ordinary
```

four-dimensional spacetime, proves that a symmetric array contracted with an antisymmetric one gives zero, checks the Clifford relation of the eight real gamma matrices of the Revision record as one index formula for all 64 pairs, derives and checks the contractions gamma^a gamma_a = 8 and gamma^a gamma^b gamma_a = -6 gamma^b, and writes the squared length of a coordinate step in the author's metric, whose three extra times deflate exponentially, as a sum over indices, with heat maps and plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of

‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
```

```
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 01e_index_notation.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 15 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
Down, or press Ctrl+C twice in the terminal.

**Step 6. Or run the notebook without a browser (headless).**

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 01e_index_notation.ipynb

This runs every cell from the top to the bottom and saves the results into the notebook
```

file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01e_index_notation.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01e.captions.json‘
- ‘Revision/textbook/figures/01e_1_eta_and_delta.png‘
- ‘Revision/textbook/figures/01e_2_squared_lengths.png‘
- ‘Revision/textbook/figures/01e_3_symmetric_antisymmetric.png‘
- ‘Revision/textbook/figures/01e_4_clifford_tables.png‘
- ‘Revision/textbook/figures/01e_5_gamma_contractions.png‘
- ‘Revision/textbook/figures/01e_6_step_length.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 25 CHECKS PASSED (notebook 01e)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01e_index_notation.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use

  ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 01e_index_notation.ipynb
      python -m nbconvert --execute --inplace 01e_index_notation.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01e (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01e (Index notation, the summation convention and the metric) is the file
# Revision/textbook/notebooks/01e_index_notation.ipynb of the repository Dirac_claude. It
# teaches free and dummy indices and the summation convention with numpy einsum, reads
# the frame metric eta of the author's coordinates x0 to x7 from the Revision record,
# lowers and raises indices with it, sorts vectors into space-like, time-like and
# light-like ones in the signature (4,4) and compares random vectors with those of
# ordinary four-dimensional spacetime, proves that a symmetric array contracted with an
# antisymmetric one gives zero, checks the Clifford relation of the eight real gamma
# matrices of the Revision record as one index formula for all 64 pairs, derives and
# checks the contractions gamma^a gamma_a = 8 and gamma^a gamma^b gamma_a = -6 gamma^b,
# and writes the squared length of a coordinate step in the author's metric, whose three
# extra times deflate exponentially, as a sum over indices, with heat maps and plots. It
# needs a computer with Windows 11, macOS or Linux, an internet connection for the
# installation, the program Git, and Python 3.12 or newer (the notebooks were built with
```

```
# Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#

# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
```

```
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
```

```
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01e_index_notation.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01e_index_notation.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01e_index_notation.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01e.captions.json
# - Revision/textbook/figures/01e_1_eta_and_delta.png
# - Revision/textbook/figures/01e_2_squared_lengths.png
# - Revision/textbook/figures/01e_3_symmetric_antisymmetric.png
# - Revision/textbook/figures/01e_4_clifford_tables.png
# - Revision/textbook/figures/01e_5_gamma_contractions.png
# - Revision/textbook/figures/01e_6_step_length.png
#
```

```
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 25 CHECKS PASSED (notebook 01e)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01e_index_notation.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01e_index_notation.ipynb
#     python -m nbconvert --execute --inplace 01e_index_notation.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
```

```
#   a result.
# - "FileNotFoundError" for a file below Revision/algebra or Revision/gkd_lovelock: the
#   notebook reads Revision records of the repository; your copy of the repository is
#   incomplete. Download it again with git clone and open the notebook inside the new
#   copy.
#

## 3. The words used in this notebook

- **Index**: a letter ($a, b, c, d$ or $\mu, \nu, \lambda$) that stands for one
  of the eight coordinates $x_0, \dots, x_7$; the component of a vector $v$
  along $x_3$ is written $v^3$. Python numbers the same components 0 to 7 in
  the same order, so $v^3$ is `v[3]`.
- **Upper and lower index**: $v^a$ and $v_a$ are two lists of eight numbers
  that belong to the same vector (section 6 says how one is made from the
  other). An upper index is a label, not a power: $v^3$ is a component, and its
  square is written $(v^3)^2$.
- **Free index**: an index that appears once in every term of a formula; the
  formula holds for each of its values, so a formula with $k$ free indices over
  8 coordinates stands for $8^k$ equations.
- **Dummy index**: an index that appears twice in one term, once up and once
  down; it is summed over all its values. Its name does not matter.
- **Summation convention** (Einstein's): the rule that a repeated index is
  summed without writing $\sum$: $v^a w_a = \sum_{a} v^a w_a$.
- **einsum**: numpy's function that evaluates such a sum from a text that lists
  the indices of every factor, for example `np.einsum("ab,b->a", M, v)`.
- **Contraction**: setting an upper and a lower index equal and summing over
  it, as in $\delta^a_a$ or $v^a w_a$.
- **Kronecker delta** $\delta^a_b$: 1 if $a = b$ and 0 otherwise; as a table it
  is the identity matrix $I$.
- **Frame metric** $\eta_{ab}$: the diagonal table
  $\mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order $x_0, \dots,
  x_7$; $\eta^{ab}$ (upper indices) is its inverse.
- **Lowering and raising**: $v_a = \eta_{ab} v^b$ and $v^a = \eta^{ab} v_b$.
```

```
- **Squared length** $Q(v) = \eta_{ab} v^a v^b$. A vector $v \neq 0$ is
  **space-like** if $Q > 0$, **time-like** if $Q < 0$ and **light-like** (or
  **null**) if $Q = 0$.
- **Signature** (4,4): $\eta$ has four entries $+1$ and four entries $-1$.
- **Symmetric** array: $S_{ab} = S_{ba}$; **antisymmetric** array:
  $A_{ab} = -A_{ba}$ (its diagonal is 0).
- **Commutator** $[P, R] = PR - RP$; **anticommutator** $\{P, R\} = PR + RP$.
- **Gamma matrices** $\gamma^a$: the eight real $16 \times 16$ matrices of the
  author's theory, one for each coordinate, stored in the Revision record; they
  obey the **Clifford relation** $\{\gamma^a, \gamma^b\} = 2\eta^{ab} I$.
- **Orthogonal matrix**: a real matrix $O$ with $O^T O = I$, so $O^T = O^{-1}$.
- **Trace** $\mathrm{tr}\,M$: the sum of the diagonal entries of a matrix; it
  obeys $\mathrm{tr}(PR) = \mathrm{tr}(RP)$.
- **Metric** $g_{\mu\nu}$ and **line element**: the author's metric turns a
  small coordinate step $dx^\mu$ into the squared length
  $ds^2 = g_{\mu\nu} dx^\mu dx^\nu$.
- **Normal random numbers**: random numbers whose histogram is the bell curve
  $e^{-x^2/2}/\sqrt{2\pi}$; numpy's `normal` draws them.
- **Histogram**: bars that show how many numbers fall into each interval.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's spacetime has eight coordinates: $x_1, x_2, x_3$ are ordinary
space, $x_4$ is the time, $x_5, x_6, x_7$ are three extra times, and $x_0$ is a
hidden space direction. The *frame metric*

$$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$$

records only which directions are space-like ($+1$: $x_0, x_1, x_2, x_3$) and
which are time-like ($-1$: $x_4, \dots, x_7$). The full *metric* of the
primordial gravitational field is

$$g = \mathrm{diag}\big(\cot^2 z, e^{2a_4} s, e^{2a_4} s, e^{2a_4} s, -1,
-b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s\big),\quad
s = \sin^{1/3} z,\ z = 6 H x_0,$$

with a positive constant $H$, $0 < z < \pi/2$, a function $a_4(x_4)$ and a
positive function $b_4(x_4)$ of the time ($b_4 = 1$ in the background of the
Revision record): as $a_4$ grows, the lengths along $x_1, x_2, x_3$ grow like
$e^{a_4}$ and the lengths along the three extra times shrink like
$b_4^{1/2} e^{-a_4}$, that is, for constant $b_4$ they deflate exponentially.

Each equation of the theory is an index formula. For example the field
equation of the Revision record, $\gamma^\mu D_\mu \Psi = (m + U'(S))\Psi$, is a
sum over $\mu$ of eight terms, and the Clifford relation
$\gamma^a \gamma^b + \gamma^b \gamma^a = 2\eta^{ab} I$ is one line that stands
for $8 \cdot 8 = 64$ equations between $16 \times 16$ matrices. Reading and
checking such formulas is the skill this notebook trains.
```

Text cell:

```
## 5. Free and dummy indices

The next cell works with a $3 \times 3$ table $M^a{}_b$ (row $a$, column $b$) and
the vector $v^b = (2, -1, 3)$. In

$$w^a = M^a{}_b v^b = \sum_{b} M^a{}_b v^b$$

the index $a$ is free (one equation for each $a$) and $b$ is a dummy (summed).
The cell computes $w$ three ways: with loops; with
`np.einsum("ab,b->a", M, v)`, whose text says "the first factor has the indices
$a, b$, the second $b$; $b$ appears twice, so it is summed; the result keeps
$a$"; and with the dummy renamed to $c$, which changes nothing. Row 1 gives
$1 \cdot 2 + 2 \cdot (-1) + 0 \cdot 3 = 0$, row 2 gives $0 - 1 + 3 = 2$, row 3
gives $2 - 3 + 3 = 2$.

It then computes two numbers without any free index: the trace
$M^a{}_a = 1 + 1 + 1 = 3$ (a contraction of the two indices of one table) and
$u_a M^a{}_b v^b$ for $u_a = (1, 0, 2)$, which has two dummy indices; since
$M^a{}_b v^b = (0, 2, 2)$, it is $1 \cdot 0 + 0 \cdot 2 + 2 \cdot 2 = 4$.
Finally it prints how many equations a formula with 0 to 3 free indices over
the eight coordinates stands for.
```

In [2]:

```
import itertools  # all pairs (a, b) of indices
import math  # pi and square roots of plain numbers

import numpy as np  # arrays and einsum
import sympy as sp  # exact algebra with symbols

M = np.array([[1, 2, 0],
              [0, 1, 1],
              [1, 3, 1]])  # the entries M^a_b: row a, column b
v = np.array([2, -1, 3])  # the components v^b
u = np.array([1, 0, 2])  # the components u_a of a second vector
# w^a = M^a_b v^b: the free index a is kept, the dummy index b is summed.
w_loops = [sum(int(M[a, b]) * int(v[b]) for b in range(3)) for a in range(3)]
w_einsum = np.einsum("ab,b->a", M, v)  # "b" appears twice: it is summed
w_renamed = np.einsum("ac,c->a", M, v)  # the dummy renamed to c: the same sum
say(f"w = M v by loops {w_loops}, by einsum {w_einsum.tolist()}, with the dummy "

0 free indices over the 8 coordinates: 8^0 = 1 equation
1 free indices over the 8 coordinates: 8^1 = 8 equations
2 free indices over the 8 coordinates: 8^2 = 64 equations
3 free indices over the 8 coordinates: 8^3 = 512 equations
```

Text cell:

```
## 6. The frame metric: lowering and raising an index

The next cell reads the coordinate names and the diagonal of $\eta$ from the
Revision record file Revision/algebra/gammas.json, and the record's report
Revision/algebra/reports/python-algebra.json, whose check `coordinate_map`
states $\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$. Then:

- $\eta_{ab}$ is the diagonal matrix with these entries. Its inverse
  $\eta^{ab}$ is the diagonal matrix of the inverses $1/(+1) = +1$ and
  $1/(-1) = -1$: the same entries.
- $\eta^{ab}\eta_{bc}$ (free indices $a$ up and $c$ down, dummy $b$) must be
  $\delta^a_c$, and contracting the two indices of $\delta$ counts the
  coordinates: $\delta^a_a = 1 + 1 + \dots + 1 = 8$.
- Lowering the index of $v^a = (1, 2, \dots, 8)$ gives
  $v_a = \eta_{ab} v^b$; because $\eta$ is diagonal, only the term $b = a$ of
  the sum survives, $v_a = \eta_{aa} v^a$ (no sum here): the four time-like
  components $x_4, \dots, x_7$ change sign. Raising again,
  $\eta^{ab} v_b$, gives back $v^a$, because $\eta^{ab}\eta_{bc} = \delta^a_c$.

The cell after it defines the helper `heat_map`, which draws a table as
coloured squares (red positive, white zero, blue negative), and draws
$\eta_{ab}$, $\delta^a_c$ and the two lists $v^a$ and $v_a$.

## 7. Squared lengths in the signature (4,4)

The squared length of a vector is

$$Q(v) = \eta_{ab} v^a v^b = v^a v_a = (v^0)^2 + (v^1)^2 + (v^2)^2 + (v^3)^2
- (v^4)^2 - (v^5)^2 - (v^6)^2 - (v^7)^2,$$

where the second form uses $v_a = \eta_{ab} v^b$, and the third writes out the
sum (only the terms $a = b$ survive because $\eta$ is diagonal). The next cell
defines `squared_length`, which evaluates $\eta_{ab} v^a v^b$ for many vectors
at once (`einsum("na,ab,nb->n", ...)`: $n$ numbers the vectors and is kept;
$a$ and $b$ are summed), and sorts five examples:

- the unit vector along $x_1$: $Q = +1$, space-like;
- the unit vector along $x_5$: $Q = -1$, time-like;
- their sum: $Q = 1 - 1 = 0$, light-like although it is not zero;
- $(1, 1, \dots, 1)$: $Q = 4 - 4 = 0$, light-like as well;
- $v^a = (1, 2, \dots, 8)$: $Q = 1 + 4 + 9 + 16 - 25 - 36 - 49 - 64 = -144$,
  time-like.

It checks the sorting and that $\eta_{ab} v^a v^b$ equals $v^a v_a$ for the last
example (the list $v_a$ of section 6).
```

In [5]:

```
def squared_length(vectors, metric_diagonal):
    """eta_ab v^a v^b for every row v of the array vectors (a and b are summed;
    the index n, which numbers the rows, is kept)."""

PASS the five examples are sorted correctly, and eta_ab v^a v^b = v^a v_a = -144
```

Text cell:

```
How many vectors are space-like? Draw the eight components of a vector as
independent normal random numbers. Exchange its four space-like components
$(v^0, v^1, v^2, v^3)$ with its four time-like components
$(v^4, v^5, v^6, v^7)$: the new vector $v'$ has

$$Q(v') = (v^4)^2 + (v^5)^2 + (v^6)^2 + (v^7)^2 - (v^0)^2 - (v^1)^2 - (v^2)^2
- (v^3)^2 = -Q(v),$$

because every square that was added is now subtracted and every square that
was subtracted is now added. The exchanged vector is exactly as likely as the
original one (all eight components are drawn the same way), so $Q > 0$ and
$Q < 0$ are equally likely, and $Q = 0$ exactly has probability 0: **in the
signature (4,4) exactly half of all random vectors are space-like.** In
ordinary spacetime with one time and three space directions, signature
(3,1), $Q = (v^1)^2 + (v^2)^2 + (v^3)^2 - (v^4)^2$ has three squares added
and one subtracted, and most random vectors are space-like; integral calculus
(not shown here) gives the fraction $1/2 + 1/\pi \approx 0.818$.

The next cell draws 200,000 random vectors (seed 12345), checks the exchange
rule on every one of them, measures both fractions and compares them with
$1/2$ and $1/2 + 1/\pi$, allowing 4 standard deviations
$\sqrt{p(1-p)/N}$ of a measured fraction $p$ from $N$ tries.

## 8. A symmetric array contracted with an antisymmetric one gives zero

Every square array $M_{ab}$ is a sum of a symmetric and an antisymmetric part:

$$M_{ab} = S_{ab} + A_{ab},\qquad S_{ab} = \tfrac12 (M_{ab} + M_{ba}),\qquad
A_{ab} = \tfrac12 (M_{ab} - M_{ba}).$$

Adding the two parts gives back $M_{ab}$ (the terms $M_{ba}$ cancel);
exchanging $a$ and $b$ leaves $S$ unchanged and changes the sign of $A$.

**Claim.** If $S_{ab} = S_{ba}$ and $A^{ab} = -A^{ba}$, then
$S_{ab} A^{ab} = 0$. **Proof**, line by line:

$$S_{ab} A^{ab} = S_{ba} A^{ba}$$

(both sides are the same sum over all pairs; the names of the two summed
indices were exchanged, which does not change a sum),

$$S_{ba} A^{ba} = S_{ab} \, (-A^{ab})$$

(the symmetry of $S$ and the antisymmetry of $A$), so
$S_{ab} A^{ab} = -S_{ab} A^{ab}$, and a number that equals its own negative is
0. In words: the term $(a, b)$ and the term $(b, a)$ cancel, and the diagonal
terms are 0.

Raising both indices keeps an array antisymmetric:
```

```
$A^{ab} = \eta^{ac}\eta^{bd} A_{cd}$, and
$A^{ba} = \eta^{bc}\eta^{ad} A_{cd} = \eta^{ad}\eta^{bc} A_{cd}$; renaming the
dummies $c \leftrightarrow d$ gives $\eta^{ac}\eta^{bd} A_{dc} =
-\eta^{ac}\eta^{bd} A_{cd} = -A^{ab}$.

A consequence used again and again: for a vector with ordinary (commuting)
components, $v^a v^b$ is symmetric in $a$ and $b$, so
$v^a v^b A_{ab} = 0$ and $v^a v^b M_{ab} = v^a v^b S_{ab}$: only the
symmetric part of an array counts in a squared expression. (Later in the course
the components of the field dirac16complex *anticommute*; then the opposite
holds, and only the antisymmetric part counts.)

The next cell checks all of this exactly, with whole numbers: it works with
$2S$ and $2A$, so that no fraction appears.
```

## 9. Commutators, anticommutators and the Clifford relation
```

```
For two square matrices $P$ and $R$ the commutator $[P, R] = PR - RP$ and the
anticommutator $\{P, R\} = PR + RP$ split the product into two parts:

$$PR = \tfrac12 [P, R] + \tfrac12 \{P, R\},$$

because the two halves add up to $\tfrac12 (PR - RP + PR + RP) = PR$; and
$[R, P] = -[P, R]$, $\{R, P\} = \{P, R\}$ directly from the definitions.

The eight gamma matrices obey the Clifford relation

$$\gamma^a \gamma^b + \gamma^b \gamma^a = 2\eta^{ab} I \qquad (a, b = x_0, \dots,
x_7).$$

It has two free indices, so it stands for 64 matrix equations: for $a = b$ it
says $(\gamma^a)^2 = \eta^{aa} I$ ($+I$ for a space-like and $-I$ for a time-like
direction); for $a \neq b$ it says that $\gamma^a$ and $\gamma^b$
anticommute, $\gamma^a \gamma^b = -\gamma^b \gamma^a$, so their commutator is
$2\gamma^a\gamma^b$.

A second fact follows from it. Each gamma matrix of the record is a signed
permutation matrix, so it is orthogonal: $(\gamma^a)^T \gamma^a = I$, that is
$(\gamma^a)^T = (\gamma^a)^{-1}$. And $(\gamma^a)^2 = \eta^{aa} I$ says
$(\gamma^a)^{-1} = \eta^{aa}\gamma^a$ (because $\eta^{aa} = \pm 1$ is its own
inverse). Together: $(\gamma^a)^T = \eta_{aa}\gamma^a$ (no sum; $\eta_{aa} =
\eta^{aa}$): the gamma matrices of the space-like directions are symmetric and
those of the time-like directions antisymmetric. The record's check
'symmetry_pattern' states exactly this.

The next cell checks the commutator rules on two random matrices, then reads the
gamma matrices from the record, checks all 64 anticommutators exactly, keeps the
number $c_{ab}$ in $\{\gamma^a, \gamma^b\} = c_{ab} I$ and the number of
nonzero entries of each commutator, and checks orthogonality and the symmetry
pattern.

## 10. Contractions with the gamma matrices

Lowering the index of the gamma matrices gives $\gamma_a = \eta_{ab}\gamma^b$,
which is $+\gamma^a$ for a space-like and $-\gamma^a$ for a time-like
direction. Two contractions follow from the Clifford relation alone.

**First:** $\gamma^a \gamma_a = 8 I$. Line by line:

$$\gamma^a \gamma_a = \sum_a \gamma^a \eta_{ab} \gamma^b
= \sum_a \eta_{aa} (\gamma^a)^2$$

(only $b = a$ survives because $\eta$ is diagonal),
```

```
$$\sum_a \eta_{aa} (\gamma^a)^2 = \sum_a \eta_{aa} \eta^{aa} I$$

(the Clifford relation with $a = b$: $2(\gamma^a)^2 = 2\eta^{aa} I$),

$$\sum_a \eta_{aa}\eta^{aa} I = \sum_a 1 \cdot I = 8 I$$

($\eta_{aa}\eta^{aa} = (\pm 1)^2 = 1$ for each of the 8 values of $a$). Each
time-like direction contributes $(\gamma^a)^2 = -I$, but its $\eta_{aa} = -1$
turns the contribution into $+I$.

**Second:** $\gamma^a \gamma^b \gamma_a = -6\gamma^b$. First lower one index of
the Clifford relation: multiplying $\gamma^b\gamma^c + \gamma^c\gamma^b =
2\eta^{bc} I$ by $\eta_{ca}$ and summing over $c$ gives
$\gamma^b\gamma_a + \gamma_a\gamma^b = 2\delta^b_a I$, that is
$\gamma^b\gamma_a = -\gamma_a\gamma^b + 2\delta^b_a I$. Then

$$\gamma^a \gamma^b \gamma_a = \gamma^a\big(-\gamma_a\gamma^b + 2\delta^b_a
I\big) = -(\gamma^a\gamma_a)\gamma^b + 2\gamma^b = -8\gamma^b + 2\gamma^b =
-6\gamma^b$$

(the bracket was multiplied out; $\gamma^a\delta^b_a = \gamma^b$ because only
$a = b$ survives; the first contraction was used). In $n$ dimensions the same
steps give $(2 - n)\gamma^b$.

**Third:** $\mathrm{tr}(\gamma^a\gamma^b) = 16\eta^{ab}$, because
$\mathrm{tr}(\gamma^a\gamma^b) = \mathrm{tr}(\gamma^b\gamma^a)$, so
$\mathrm{tr}(\gamma^a\gamma^b) = \tfrac12\mathrm{tr}(\{\gamma^a, \gamma^b\}) =
\tfrac12 \cdot 2\eta^{ab} \cdot \mathrm{tr}\,I = 16\eta^{ab}$.

The next cell checks the three results with the matrices of the record.
```

## 11. The author's metric in index notation

The Revision record file Revision/gkd_lovelock/results/curvature.json stores
the diagonal of the author's metric as text in the notation of the program
Mathematica, for example 'E^(2*a4[x4])*Sin[6*H*x0]^(1/3)' and
'-E^(-2*a4[x4])*Sin[6*H*x0]^(1/3)*b4[x4]'. The next cell turns the text into
sympy expressions (with the symbols $a_4$, $b_4$ and $z = 6 H x_0$) and checks
them against the metric of section 4. Then:

- the inverse metric of a diagonal metric is diagonal with the inverse entries,
  $g^{\mu\mu} = 1/g_{\mu\mu}$, and $g^{\mu\nu} g_{\nu\lambda} =
  \delta^\mu_\lambda$; the record's report python-lovelock-report.json checks
  this in its check 'metric_inverse';
- the squared length of a small step $dx^\mu$ is the double sum
  $ds^2 = g_{\mu\nu} dx^\mu dx^\nu$, in which only the terms $\nu = \mu$
  survive: $ds^2 = \sum_\mu g_{\mu\mu} (dx^\mu)^2$;
- for the step with the same small size $\epsilon$ in all eight coordinates,
  $dx^\mu = \epsilon$, this is

$$ds^2 = \epsilon^2\big(3e^{2a_4}s - 1 - 3b_4e^{-2a_4}s + \cot^2 z\big),$$

and at $b_4 = 1$, the background of the Revision record,
```

```
$$ds^2 = \epsilon^2\big(6 s \sinh(2a_4) - 1 + \cot^2 z\big),$$

because $e^{x} - e^{-x} = 2\sinh x$ with $x = 2a_4$; and lowering the index,
$dx_\mu = g_{\mu\nu} dx^\nu$, gives the same number as $dx^\mu dx_\mu$.

The cell checks all three statements exactly (in units with $\epsilon = 1$).

```
The rest of this section takes $b_4 = 1$. For each $z$, $ds^2$ grows when $a_4$
grows ($\sinh$ is an increasing function and $6s > 0$), from very negative values
(time-like steps) to very positive ones (space-like steps). It is zero where
$6 s \sinh(2a_4) = 1 - \cot^2 z$, that is at

$$a_4^{\ast}(z) = \tfrac12\,\mathrm{arcsinh}\!\left(\frac{1 - \cot^2 z}{6 s}\right),$$

where $\mathrm{arcsinh}$ undoes $\sinh$. The next cell evaluates $ds^2$ on a
grid of 301 values of $a_4$ from $-1.5$ to $1.5$ and 300 values of $z$, checks
that it grows with $a_4$ on every row of the grid and that its sign changes
exactly at $a_4^{\ast}(z)$, and draws two pictures: the sign map with the curve
$a_4^{\ast}(z)$, and at $z = 0.9$ the four kinds of terms of the sum against
$a_4$: the growing term of the three space directions, the constant term of
the time, the shrinking term of the three deflating extra times, and the
constant term of the hidden direction.
```

In [15]:

```
ds2_numbers = sp.lambdify((a4, z), closed_form, "numpy")  # a formula -> a function
a4_values = np.linspace(-1.5, 1.5, 301)
z_values = np.linspace(0.15, np.pi / 2 - 0.005, 300)

```
PASS all 6 figure files of this notebook exist
ALL 25 CHECKS PASSED (notebook 01e)
```

Text cell:

```
## 13. What this notebook showed
```

```
- An index that appears once in every term is free (the formula holds for each
  of its values: $8^k$ equations for $k$ free indices); an index that appears
  twice is a dummy and is summed (the summation convention). numpy's 'einsum'
  evaluates such sums from the list of indices; renaming a dummy changes
  nothing.
- The frame metric of the Revision record is $\eta =
  \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$; $\eta^{ab}$ has the same
  entries, $\eta^{ab}\eta_{bc} = \delta^a_c$ and $\delta^a_a = 8$. Lowering an
  index flips the signs of the four time-like components $x_4, \dots, x_7$.
- The squared length $\eta_{ab}v^a v^b = v^a v_a$ sorts vectors into
  space-like, time-like and light-like ones; in the signature (4,4) exchanging
  the space-like and the time-like components turns $Q$ into $-Q$, so exactly
  half of all random vectors are space-like (measured: 0.50), while in ordinary
  spacetime about 82 per cent are.
- A symmetric array contracted with an antisymmetric one gives 0; so only the
  symmetric part of an array counts in $v^a v^b M_{ab}$ for commuting
  components.
- The eight gamma matrices of the Revision record obey
  $\{\gamma^a, \gamma^b\} = 2\eta^{ab} I$ for all 64 pairs; they are orthogonal,
  symmetric for the space-like and antisymmetric for the time-like directions;
  and $\gamma^a\gamma_a = 8I$, $\gamma^a\gamma^b\gamma_a = -6\gamma^b$,
  $\mathrm{tr}(\gamma^a\gamma^b) = 16\eta^{ab}$, derived line by line and
  checked.
- In the author's metric the step $dx^\mu = \epsilon$ has
  $ds^2 = \epsilon^2(3e^{2a_4}s - 1 - 3b_4e^{-2a_4}s + \cot^2 z)$, which is
  $\epsilon^2(6 s\sinh(2a_4) - 1 + \cot^2 z)$ at $b_4 = 1$; as $a_4$ grows, the term
  of the three space directions grows like $e^{2a_4}$ and the term of the
  three exponentially deflating extra times shrinks like $e^{-2a_4}$, and the
  step turns from time-like to space-like at $a_4^{\ast}(z)$.
```

1.33 Line-by-line walk-through of Notebook 01e

The notebook has sixteen code cells, In [1] to In [16]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.32 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.31; its code is the set-up code explained in Section 1.9, with `NOTEBOOK_ID = "01e"`. It prints Set-up of notebook 01e complete: repository folder found, helpers defined.

In [2], free and dummy indices.

```
import itertools  # all pairs (a, b) of indices
import math  # pi and square roots of plain numbers

import numpy as np  # arrays and einsum
import sympy as sp  # exact algebra with symbols
```

The modules of this notebook: `itertools.product` will produce all pairs of indices, `math` gives π and square roots of single numbers.

```
M = np.array([[1, 2, 0],
              [0, 1, 1],
```

```
              [1, 3, 1]])  # the entries M^a_b: row a, column b
v = np.array([2, -1, 3])  # the components v^b
u = np.array([1, 0, 2])  # the components u_a of a second vector
```

The table $M^a{}_b$, the vector v^b and the lower list u_a of the example of Section 1.26.

```
# w^a = M^a_b v^b: the free index a is kept, the dummy index b is summed.
w_loops = [sum(int(M[a, b]) * int(v[b]) for b in range(3)) for a in range(3)]
w_einsum = np.einsum("ab,b->a", M, v)  # "b" appears twice: it is summed
w_renamed = np.einsum("ac,c->a", M, v)  # the dummy renamed to c: the same sum
```

w^a three ways: with loops (for each free value a, the sum over the dummy b); with `einsum`, whose text `"ab,b->a"` lists the indices of each factor and of the result (the letter b appears in both factors and not in the result, so it is summed); and with the dummy renamed to c.

```
say(f"w = M v by loops {w_loops}, by einsum {w_einsum.tolist()}, with the dummy "
    f"renamed {w_renamed.tolist()}")
check(w_loops == w_einsum.tolist() == w_renamed.tolist() == (M @ v).tolist()
      == [0, 2, 2],
      "loops, einsum and @ give w = (0, 2, 2); renaming the dummy changes nothing")
```

The three results are printed, each `[0, 2, 2]`, and checked against each other, against `M @ v` and against the hand calculation.

```
trace = int(np.einsum("aa->", M))  # M^a_a: the repeated index a is summed
full = int(np.einsum("a,ab,b->", u, M, v))  # u_a M^a_b v^b: two dummies, no free
say(f"M^a_a = {trace}, u_a M^a_b v^b = {full}")
check(trace == int(np.trace(M)) == 3 and full == int(u @ M @ v) == 4,
      "the trace M^a_a = 3 and the number u_a M^a_b v^b = 4")
```

`"aa->"` contracts the two indices of one table: the trace. `"a,ab,b->"` contracts two pairs and keeps no index (nothing after the arrow): a single number. Output: `M^a_a = 3, u_a M^a_b v^b = 4`, and the PASS line.

```
for free in range(4):
    word = "equation" if free == 0 else "equations"  # 8^0 = 1 equation
    say(f"{free} free indices over the 8 coordinates: 8^{free} = {8 ** free} {word}")
```

Four lines: a formula with 0, 1, 2, 3 free indices stands for 1, 8, 64, 512 equations (the singular "equation" for 1). The cell prints two PASS lines in all.

In [3], the frame metric from the record.

```
algebra = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
names = algebra["coordinates"]  # ["x0", "x1", ..., "x7"]
eta_diagonal = algebra["eta"]  # the diagonal of eta in the order x0 ... x7
```

The record file of the gamma matrices, read as in Notebook 01a; its coordinate names and the diagonal of η.

```
algebra_report = json.loads(repository_file(
    "Revision/algebra/reports/python-algebra.json").read_text(encoding="utf-8"))
verdicts = {c["name"]: c["verdict"] for c in algebra_report["checks"]}
map_verdict = verdicts["coordinate_map"]  # "pass" in the record
say(f"coordinates {names}")
say(f"diagonal of eta {eta_diagonal}; record check coordinate_map: {map_verdict}")
```

The record's report: its list of checks is turned into a dictionary from the check names to their verdicts (this report writes the verdict in small letters, `pass`). Output: the eight names, the diagonal `[1, 1, 1, 1, -1, -1, -1, -1]` and the record's verdict pass.

```
check(eta_diagonal == [1, 1, 1, 1, -1, -1, -1, -1]
      and verdicts["coordinate_map"] == "pass",
      "eta = diag(+1, +1, +1, +1, -1, -1, -1, -1) in the order x0 ... x7",
      record="Revision/algebra/reports/python-algebra.json, check coordinate_map")
```

The diagonal of Section 1.27 and the record's verdict; this check reproduces the record's check `coordinate_map`.

```
eta_lower = np.diag(eta_diagonal)  # eta_ab as an 8 x 8 matrix
eta_upper = np.diag([1 // e for e in eta_diagonal])  # eta^ab: 1/(+1) = 1, 1/(-1) = -1
delta = np.einsum("ab,bc->ac", eta_upper, eta_lower)  # eta^ab eta_bc
check((delta == np.eye(8, dtype=int)).all() and int(np.einsum("aa->", delta)) == 8,
      "eta^ab eta_bc = delta^a_c, and the contraction delta^a_a = 8")
```

η_{ab} and η^{ab} as 8×8 tables; the inverse entries are computed with the whole-number division `//`, which gives $1//1 = 1$ and $1//(-1) = -1$ exactly. The contraction $\eta^{ab}\eta_{bc}$ must be the identity, and $\delta^a{}_a$ must be 8.

```
v_up = np.arange(1, 9)  # v^a = 1, 2, ..., 8
v_down = np.einsum("ab,b->a", eta_lower, v_up)  # v_a = eta_ab v^b
v_back = np.einsum("ab,b->a", eta_upper, v_down)  # eta^ab v_b
flipped = [names[a] for a in range(8) if v_down[a] != v_up[a]]
say(f"v^a = {v_up.tolist()}")
say(f"v_a = {v_down.tolist()}; the components that changed sign: {flipped}")
check(flipped == ["x4", "x5", "x6", "x7"] and (v_back == v_up).all(),
      "lowering flips the signs of the time-like x4 ... x7; raising undoes it")
```

$v^a = (1, \ldots, 8)$, lowered and raised again with `einsum`; `flipped` lists the names of the components that changed. Output: `v_a = [1, 2, 3, 4, -5, -6, -7, -8]`, the changed components x4 to x7, and the PASS line; the cell prints three PASS lines in all.

In [4], the first heat maps.

```
labels = [f"$x_{k}$" for k in range(8)]  # x with the subscripts 0 ... 7
```

```
def heat_map(ax, matrix, title, ticks=labels, annotate=True, size=7.0):
    """Draw matrix on the axes ax: red positive, white zero, blue negative; with
    annotate the value is written in its square (%g: no needless digits)."""
    m = np.asarray(matrix, dtype=float)
    limit = max(1.0, float(np.abs(m).max()))  # colours from -limit to +limit
    ax.imshow(m, cmap="RdBu_r", vmin=-limit, vmax=limit)
    ax.grid(False)  # no grid lines across the coloured squares
    ax.set_xticks(range(m.shape[1]), ticks[:m.shape[1]], fontsize=7)
    ax.set_yticks(range(m.shape[0]), ticks[:m.shape[0]], fontsize=7)
    ax.set_title(title, fontsize=10)
```

The labels $x_0, \ldots, x_7$ for the axes, and a heat-map helper like the one of Notebook 01a (Section 1.25), with the coordinate names as default labels (`ticks=labels`) and an adjustable size of the written values.

```
    if annotate:
        for i in range(m.shape[0]):
            for j in range(m.shape[1]):
                ink = "white" if abs(m[i, j]) > 0.6 * limit else "black"
                ax.text(j, i, f"{m[i, j]:g}", ha="center", va="center",
                        fontsize=size, color=ink)
```

The value of every entry is written in its square with the format `:g`, which drops needless digits (1.0 is written 1).

```
fig, axes = plt.subplots(1, 3, figsize=(12.0, 4.0))
heat_map(axes[0], eta_lower, "$\\eta_{ab}$ (row $a$, column $b$)")
heat_map(axes[1], delta, "$\\eta^{ab}\\eta_{bc} = \\delta^a_c$ (row $a$, column $c$)")
positions = np.arange(8)
axes[2].bar(positions - 0.2, v_up, width=0.4, label="$v^a$ (upper index)")
axes[2].bar(positions + 0.2, v_down, width=0.4, label="$v_a = \\eta_{ab} v^b$")
```

Three panels: the heat maps of η_{ab} and of $\eta^{ab}\eta_{bc}$, and a bar chart of the two lists v^a and v_a side by side (`ax.bar(positions, heights, width=...)` draws bars; shifting the positions by ∓ 0.2 puts the two bars of each coordinate next to each other).

```
axes[2].axhline(0, color="black", lw=0.8)
axes[2].set_xticks(positions, labels)
axes[2].set_ylabel("component")
axes[2].set_title("lowering the index of $v$", fontsize=10)
axes[2].legend(fontsize=8, loc="lower left")
fig.tight_layout()
save_figure(fig, "eta_and_delta",
            "Left: the frame metric $\\eta_{ab}$ of the author's coordinates as a "
            ...)
```

A zero line, labels and the figure. What Figure 01e.1 shows: η red $(+1)$ for x_0, x_1, x_2, x_3 and blue (-1) for x_4 to x_7; the contraction is the identity; the orange bars of v_a point down exactly at the four time-like coordinates.

In [5], squared lengths of five vectors.

```
def squared_length(vectors, metric_diagonal):
    """eta_ab v^a v^b for every row v of the array vectors (a and b are summed;
    the index n, which numbers the rows, is kept)."""
    metric = np.diag(metric_diagonal)
    return np.einsum("na,ab,nb->n", vectors, metric, vectors)
```

$Q(v) = \eta_{ab} v^a v^b$ for many vectors at once: the array `vectors` has one vector per row, numbered by `n`; in `"na,ab,nb->n"` the letters a and b appear twice and are summed, while n is kept, so the result is one number per vector.

```
unit = np.eye(8, dtype=int)  # row k is the unit vector along x_k
examples = {"e(x1)": unit[1], "e(x5)": unit[5], "e(x1) + e(x5)": unit[1] + unit[5],
            "(1, 1, 1, 1, 1, 1, 1, 1)": np.ones(8, dtype=int),
            "(1, 2, 3, 4, 5, 6, 7, 8)": v_up}
kinds = []
```

The rows of the identity are the unit vectors, row k along x_k (the author's index and Python's agree); the dictionary holds the five examples of Section 1.27 with their names (`np.ones(8)` is the vector of eight ones).

```
for name, vector in examples.items():
    q = int(squared_length(vector[None, :], eta_diagonal)[0])  # one row
    kind = "space-like" if q > 0 else ("time-like" if q < 0 else "light-like")
    kinds.append(kind)
    q_text = f"{q:+d}" if q != 0 else "0"  # a sign in front of nonzero values only
    say(f"v = {name}: eta_ab v^a v^b = {q_text}, {kind}")
```

For each example: `vector[None, :]` makes the vector a table with one row, as `squared_length` expects, and `[0]` takes the one result. The kind follows from the sign of Q (two nested `a if condition else b`). Output: +1 space-like, -1 time-like, 0 light-like, 0 light-like, -144 time-like.

```
check(kinds == ["space-like", "time-like", "light-like", "light-like", "time-like"]
      and int(squared_length(v_up[None, :], eta_diagonal)[0]) == int(v_up @ v_down)
      == -144,
      "the five examples are sorted correctly, and eta_ab v^a v^b = v^a v_a = -144")
```

The sorting, and $\eta_{ab} v^a v^b = v^a v_a = -144$ for the last example, with the lowered list of In [3]. One PASS line.

In [6], how many vectors are space-like.

```
generator = np.random.default_rng(12345)  # random numbers with a fixed seed
samples = generator.normal(size=(200000, 8))  # 200,000 vectors of 8 components
q44 = squared_length(samples, eta_diagonal)  # signature (4,4)
space_part, time_part = [0, 1, 2, 3], [4, 5, 6, 7]  # x0 x1 x2 x3, and x4 ... x7
exchanged = samples.copy()
exchanged[:, space_part] = samples[:, time_part]  # time components -> space slots
exchanged[:, time_part] = samples[:, space_part]  # space components -> time slots
```

200,000 vectors of eight normal random numbers (seed 12345) and their squared lengths. `space_part` and `time_part` are Python's places of the space-like components $v^0, \ldots, v^3$ and of the time-like components $v^4, \ldots, v^7$. `exchanged` is a copy in which the four time-like components are written into the space-like places and the four space-like ones into the time-like places (`[:, space_part]` selects these columns in every row).

```
check(np.allclose(squared_length(exchanged, eta_diagonal), -q44, rtol=0, atol=1e-9),
      "exchanging the space-like and the time-like components turns Q into -Q "
      "(all 200000 vectors)")
```

The exchange rule $Q(v') = -Q(v)$ of Section 1.27 for every one of the vectors (`np.allclose` compares two arrays entry by entry with the stated tolerances: `rtol=0`, no relative tolerance, `atol=1e-9`, an absolute one of 10^{-9}).

```
fraction44 = float(np.mean(q44 > 0))  # the fraction of space-like vectors
q31 = squared_length(samples[:, :4], [1, 1, 1, -1])  # 3 space, 1 time direction
fraction31 = float(np.mean(q31 > 0))
exact31 = 0.5 + 1 / math.pi
sd44 = math.sqrt(0.5 * 0.5 / 200000)  # one standard deviation of a fraction
sd31 = math.sqrt(exact31 * (1 - exact31) / 200000)
```

`np.mean(q44 > 0)` is the mean of a table of True (counted as 1) and False (0): the fraction of space-like vectors. For the signature (3,1) the first four components of each vector are used with the metric $\mathrm{diag}(1, 1, 1, -1)$. `exact31` is $1/2 + 1/\pi$, and `sd44`, `sd31` are the standard deviations $\sqrt{p(1-p)/N}$ of Section 1.27.

```
report("fraction of space-like random vectors, signature (4,4)", f"{fraction44:.4f}")
report("fraction of space-like random vectors, signature (3,1)", f"{fraction31:.4f}")
check(abs(fraction44 - 0.5) < 4 * sd44,
      "signature (4,4): half of the random vectors are space-like")
check(abs(fraction31 - exact31) < 4 * sd31,
      "signature (3,1): the fraction is 1/2 + 1/pi = 0.818 (within 4 standard "
      "deviations)")
```

The RESULT lines print 0.5011 and 0.8177; the checks require each to lie within 4 standard deviations of its expected value. The cell prints three PASS lines.

In [7], the two histograms.

```
fig, axes = plt.subplots(1, 2, figsize=(11.0, 4.2), sharey=True)
bins = np.linspace(-15.0, 15.0, 121)  # 120 intervals of width 0.25
for ax, values, fraction, title, color in (
        (axes[0], q44, fraction44, "signature (4,4): 4 space-like, 4 time-like",
         "tab:purple"),
        (axes[1], q31, fraction31, "signature (3,1): 3 space-like, 1 time-like",
         "tab:green")):
    ax.hist(values, bins=bins, density=True, color=color, alpha=0.75)
    ax.axvline(0.0, color="black", lw=1)
```

Two panels with a shared vertical axis (`sharey=True`). The 121 edges `bins` cut the range -15 to 15 into 120 intervals; `ax.hist` counts how many values fall into each interval and draws the counts as bars, scaled (`density=True`) so that the bars show the fraction of vectors per unit of Q. A black line marks $Q = 0$.

```
    ax.text(0.97, 0.95, f"space-like: {fraction:.3f}", transform=ax.transAxes,
            ha="right", va="top")
    ax.text(0.03, 0.95, f"time-like: {1 - fraction:.3f}", transform=ax.transAxes,
            ha="left", va="top")
    ax.set_xlabel("squared length $Q = \\eta_{ab} v^a v^b$")
    ax.set_title(title, fontsize=10)
axes[0].set_ylabel("fraction of vectors per unit of $Q$")
fig.tight_layout()
save_figure(fig, "squared_lengths",
            "Histograms of the squared length $Q = \\eta_{ab} v^a v^b$ of 200,000 "
            ...)
```

The measured fractions are written into the upper corners (`transform=ax.transAxes` measures the position in fractions of the panel, 0 to 1, instead of in data units). What Figure 01e.2 shows: on the left a histogram that is the same on both sides of 0 (half space-like, half time-like); on the right one that leans to the positive side (82 per cent space-like).

In [8], symmetric times antisymmetric, exactly.

```
M8 = generator.integers(-5, 6, size=(8, 8))  # a random 8 x 8 array, entries -5 ... 5
S2 = M8 + M8.T  # twice the symmetric part
A2 = M8 - M8.T  # twice the antisymmetric part
check((S2 == S2.T).all() and (A2 == -A2.T).all() and (S2 + A2 == 2 * M8).all(),
      "M = S + A with S = (M + M^T)/2 symmetric and A = (M - M^T)/2 antisymmetric")
```

A random 8×8 array of whole numbers. The cell works with $2S$ and $2A$, which are whole numbers, so that every computation is exact. The check: $2S$ is symmetric, $2A$ antisymmetric, and $2S + 2A = 2M$.

```
A2_up = np.einsum("ac,bd,cd->ab", eta_upper, eta_upper, A2)  # A^ab (times 2)
terms = S2 * A2_up  # the 64 terms S_ab A^ab (times 4), before the sum
total = int(np.einsum("ab,ab->", S2, A2_up))  # the full contraction (times 4)
say(f"4 S_ab A^ab = {total}; the largest single term is "
    f"{int(np.abs(terms).max())}")
```

$A^{ab} = \eta^{ac}\eta^{bd}A_{cd}$ (both indices raised; `einsum` with two summed pairs), the 64 single products $S_{ab}A^{ab}$ (`*` between arrays multiplies entry by entry) and their sum. Output: `4 S_ab A^ab = 0; the largest single term is 24`: the terms are not zero, but they cancel in pairs.

```
check((A2_up == -A2_up.T).all() and (terms == -terms.T).all() and total == 0,
      "A^ab is antisymmetric, the terms (a, b) and (b, a) cancel, S_ab A^ab = 0")
```

The three statements of Section 1.28: raising keeps antisymmetry; the term (a, b) is minus the term (b, a); the sum is 0.

```
all_zero = True
for _ in range(100):  # 100 more random pairs of arrays
    X = generator.integers(-9, 10, size=(8, 8))
    Y = generator.integers(-9, 10, size=(8, 8))
    all_zero &= int(np.einsum("ab,ac,bd,cd->", X + X.T, eta_upper, eta_upper,
                              Y - Y.T)) == 0
check(all_zero, "S_ab A^ab = 0 for 100 more random pairs of arrays")
```

The theorem for 100 more random pairs: $X + X^T$ is symmetric, $Y - Y^T$ antisymmetric, and the contraction with both indices of the second raised is computed in one `einsum` (the loop variable `_` is not used).

```
squares_ok = True
for _ in range(100):  # 100 random vectors with whole-number components
    w8 = generator.integers(-9, 10, size=8)
    squares_ok &= int(np.einsum("a,b,ab->", w8, w8, A2)) == 0
    squares_ok &= (int(np.einsum("a,b,ab->", w8, w8, 2 * M8))
                   == int(np.einsum("a,b,ab->", w8, w8, S2)))
check(squares_ok, "v^a v^b A_ab = 0 and v^a v^b M_ab = v^a v^b S_ab (100 random "
      "vectors with commuting components)")
```

The consequence for commuting components: for 100 random vectors $v^a v^b A_{ab} = 0$ and $v^a v^b (2M_{ab}) = v^a v^b (2S_{ab})$. The cell prints four PASS lines.

In [9], the picture of the cancellation.

```
fig, axes = plt.subplots(1, 4, figsize=(13.0, 3.7))
heat_map(axes[0], M8, "$M_{ab}$", size=6.0)
heat_map(axes[1], S2 / 2, "symmetric part $S_{ab}$", size=5.5)
heat_map(axes[2], A2 / 2, "antisymmetric part $A_{ab}$", size=5.5)
heat_map(axes[3], terms / 4, "terms $S_{ab} A^{ab}$ (sum 0)", annotate=False)
fig.tight_layout()
save_figure(fig, "symmetric_antisymmetric",
            "A random $8 \\times 8$ array $M_{ab}$ of whole numbers (left), its "
            ...)
```

Four heat maps: M, S, A (the doubled arrays divided by 2) and the 64 terms (divided by 4), the last without written values. What Figure 01e.3 shows: S looks the same mirrored in the diagonal; A changes colour under the mirror and has a white diagonal; in the right panel every coloured square has a square of the opposite colour at its mirror place.

In [10], commutators and the Clifford relation of the record.

```
P = generator.integers(-3, 4, size=(4, 4))
R = generator.integers(-3, 4, size=(4, 4))
commutator = P @ R - R @ P
anticommutator = P @ R + R @ P
check((2 * (P @ R) == commutator + anticommutator).all()
      and (R @ P - P @ R == -commutator).all()
      and (R @ P + P @ R == anticommutator).all(),
      "P R = [P, R]/2 + {P, R}/2, [R, P] = -[P, R] and {R, P} = {P, R}")
```

Two random 4×4 integer matrices, their commutator and anticommutator, and the three rules of Section 1.28 (the first written as $2PR = [P, R] + \{P, R\}$ to stay with whole numbers).

```
gamma = [np.array(matrix, dtype=int) for matrix in algebra["gamma"]]  # gamma^a
identity16 = np.eye(16, dtype=int)
anti_table = np.zeros((8, 8), dtype=int)  # {gamma^a, gamma^b} = anti_table[a, b] I
commutator_size = np.zeros((8, 8), dtype=int)  # nonzero entries of the commutator
clifford_holds = True
```

The eight gamma matrices of the record; two 8×8 tables to be filled: the number c_{ab} in $\{\gamma^a, \gamma^b\} = c_{ab} I$, and the number of nonzero entries of each commutator.

```
for a, b in itertools.product(range(8), repeat=2):  # all 64 ordered pairs
    anti = gamma[a] @ gamma[b] + gamma[b] @ gamma[a]
    anti_table[a, b] = anti[0, 0]  # the number in front of I
    clifford_holds &= bool((anti == 2 * eta_upper[a, b] * identity16).all())
    commutator_size[a, b] = np.count_nonzero(gamma[a] @ gamma[b]
                                             - gamma[b] @ gamma[a])
```

`itertools.product(range(8), repeat=2)` produces all 64 ordered pairs (a, b). For each: the anticommutator; its top-left entry (if it is $c_{ab} I$, every diagonal entry is c_{ab}); the exact comparison with $2\eta^{ab} I$; and `np.count_nonzero` of the commutator.

```
check(clifford_holds and verdicts["clifford_relation"] == "pass",
      "{gamma^a, gamma^b} = 2 eta^ab I for all 64 ordered pairs (a, b)",
      record="Revision/algebra/reports/python-algebra.json, check "
             "clifford_relation")
```

All 64 relations hold, and the record's verdict is pass: this reproduces the record's check `clifford_relation`.

```
orthogonal = all((g.T @ g == identity16).all() for g in gamma)
transpose_sign = [1 if (g.T == g).all() else (-1 if (g.T == -g).all() else 0)
                  for g in gamma]  # +1 symmetric, -1 antisymmetric
say("symmetric: " + ", ".join(names[a] for a in range(8) if transpose_sign[a] == 1)
    + "; antisymmetric: "
    + ", ".join(names[a] for a in range(8) if transpose_sign[a] == -1))
```

Each gamma matrix is tested for $O^T O = I$, and `transpose_sign` records $+1$ for a symmetric matrix, -1 for an antisymmetric one (and 0 for neither, which does not occur). Output: symmetric: x0, x1, x2, x3; antisymmetric: x4, x5, x6, x7.

```
check(orthogonal and transpose_sign == eta_diagonal
      and verdicts["symmetry_pattern"] == "pass",
      "each gamma^a is orthogonal and (gamma^a)^T = eta_aa gamma^a: symmetric "
      "for x0, x1, x2, x3, antisymmetric for x4 ... x7",
      record="Revision/algebra/reports/python-algebra.json, check "
             "symmetry_pattern")
```

The theorem $(\gamma^a)^T = \eta_{aa}\gamma^a$ of Section 1.28 (the list of signs equals the diagonal of η), reproducing the record's check `symmetry_pattern`. The cell prints three PASS lines.

In [11], the Clifford tables as pictures.

```
fig, axes = plt.subplots(1, 3, figsize=(12.5, 4.0),
                         gridspec_kw={"width_ratios": [1, 1, 1.2]})
heat_map(axes[0], anti_table, "$\\{\\gamma^a, \\gamma^b\\} = c_{ab} I$: $c_{ab}$")
heat_map(axes[1], commutator_size,
         "nonzero entries of $[\\gamma^a, \\gamma^b]$", size=6.0)
```

Three panels, the third a little wider (`width_ratios`). The table c_{ab} and the table of commutator sizes as heat maps.

```
axes[2].bar(positions - 0.2, transpose_sign, width=0.4, color="tab:blue",
            label="$s_a$ in $(\\gamma^a)^T = s_a \\gamma^a$")
axes[2].bar(positions + 0.2, eta_diagonal, width=0.4, color="tab:orange",
            label="$\\eta_{aa}$")
axes[2].axhline(0, color="black", lw=0.8)
axes[2].set_xticks(positions, labels)
axes[2].set_ylim(-1.6, 1.6)
axes[2].set_title("symmetric ($+1$) or antisymmetric ($-1$)", fontsize=10)
axes[2].legend(fontsize=8, loc="lower left")
fig.tight_layout()
save_figure(fig, "clifford_tables",
            "The Clifford relation of the eight real $16 \\times 16$ gamma matrices "
            ...)
```

The third panel draws, for each coordinate, the transpose sign next to η_{aa}. What Figure 01e.4 shows: c_{ab} is ± 2 on the diagonal and 0 elsewhere; every commutator of two different gamma matrices has 16 nonzero entries and the diagonal (a matrix with itself) has none; the blue and orange bars are equal for every coordinate.

In [12], the three contractions.

```
gamma_lower = [sum(eta_lower[a, b] * gamma[b] for b in range(8)) for a in range(8)]
contraction = sum(gamma[a] @ gamma_lower[a] for a in range(8))  # gamma^a gamma_a
check((contraction == 8 * identity16).all(), "gamma^a gamma_a = 8 I")
```

$\gamma_a = \eta_{ab}\gamma^b$ as a list of eight matrices (the sum over b written out), then $\gamma^a\gamma_a$ (the sum over a) and the first contraction, $8I$.

```
lowered_ok = all((gamma[b] @ gamma_lower[a] + gamma_lower[a] @ gamma[b]
                  == 2 * int(a == b) * identity16).all()
                 for a, b in itertools.product(range(8), repeat=2))
sandwich = [sum(gamma[a] @ gamma[b] @ gamma_lower[a] for a in range(8))
            for b in range(8)]  # gamma^a gamma^b gamma_a for each b
```

`lowered_ok` tests the lowered Clifford relation $\gamma^b\gamma_a + \gamma_a\gamma^b = 2\delta^b{}_a I$ for all 64 pairs (`int(a == b)` is 1 for equal indices and 0 otherwise: the Kronecker delta). `sandwich` holds $\gamma^a\gamma^b\gamma_a$ for each b.

```
factors = [int(sandwich[b][np.nonzero(gamma[b])][0]
               // gamma[b][np.nonzero(gamma[b])][0]) for b in range(8)]
say(f"gamma^a gamma^b gamma_a = c gamma^b with c = {factors} for b = x0 ... x7")
check(lowered_ok and all((sandwich[b] == -6 * gamma[b]).all() for b in range(8)),
      "gamma^b gamma_a + gamma_a gamma^b = 2 delta^b_a I, and gamma^a gamma^b "
      "gamma_a = -6 gamma^b for every b")
```

To find the factor c in $\gamma^a\gamma^b\gamma_a = c\,\gamma^b$, the first nonzero entry of γ^b (`np.nonzero` gives the places of the nonzero entries) and the entry of the sandwich at the same place are divided. Output: c = [-6, -6, -6, -6, -6, -6, -6, -6]. The check requires the lowered relation and the exact equality with $-6\gamma^b$.

```
traces = np.array([[int(np.trace(gamma[a] @ gamma[b])) for b in range(8)]
                   for a in range(8)])
check((traces == 16 * eta_upper).all(), "tr(gamma^a gamma^b) = 16 eta^ab")
```

The table of the 64 traces must be $16\eta^{ab}$, the third contraction. The cell prints three PASS lines.

In [13], the contractions as pictures.

```
square_sign = [int(np.trace(g @ g)) // 16 for g in gamma]  # (gamma^a)^2 = +-I
term_sign = [eta_diagonal[a] * square_sign[a] for a in range(8)]  # eta_aa (gamma^a)^2
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
```

The sign of $(\gamma^a)^2 = \pm I$ is read from its trace (± 16, divided by 16), and `term_sign` is the sign of the term $\eta_{aa}(\gamma^a)^2$ of the first contraction.

```
left.bar(positions - 0.27, square_sign, width=0.27, color="tab:blue",
         label="$(\\gamma^a)^2 = \\pm I$: the sign")
left.bar(positions, eta_diagonal, width=0.27, color="tab:orange",
         label="$\\eta_{aa}$")
left.bar(positions + 0.27, term_sign, width=0.27, color="tab:green",
         label="term $\\eta_{aa}(\\gamma^a)^2 = +I$")
left.plot(positions, np.cumsum(term_sign) / 8, "k.--", lw=1,
          label="running sum / 8")
```

Three bars per coordinate: the sign of the square, η_{aa} and their product; and the **running sum** of the terms (`np.cumsum` adds the entries one after the other: 1, 2, ..., 8), divided by 8, as a dashed black line with dots (the style string made of a dot and two hyphens).

```
left.axhline(0, color="black", lw=0.8)
left.set_xticks(positions, labels)
left.set_ylim(-1.5, 1.9)
left.set_title("$\\gamma^a\\gamma_a$: eight terms, each $+I$, sum $8I$",
               fontsize=10)
left.legend(fontsize=7, loc="lower left", ncol=2)
```

Zero line, labels, range, title and a two-column legend.

```
right.plot(positions, factors, "o", color="tab:red", ms=9,
           label="$c$ in $\\gamma^a\\gamma^b\\gamma_a = c\\,\\gamma^b$")
right.axhline(2 - 8, color="black", ls=":", label="$2 - n$ for $n = 8$")
right.set_xticks(positions, [f"$b = x_{k}$" for k in range(8)], fontsize=8)
right.set_ylim(-8.0, 0.5)
right.set_ylabel("factor $c$")
right.set_title("$\\gamma^a\\gamma^b\\gamma_a = -6\\gamma^b$ for every $b$",
                fontsize=10)
right.legend(fontsize=8, loc="upper right")
fig.tight_layout()
save_figure(fig, "gamma_contractions",
            "Left: the contraction $\\gamma^a\\gamma_a$ term by term for $a = x_0$ "
            ...)
```

On the right the eight factors c as red dots and the dotted line $2 - n = -6$. What Figure 01e.5 shows: the blue and orange bars are both negative exactly for x_4 to x_7, so every green bar is $+1$ and the running sum climbs to 1 (that is, $8I$); all eight red dots sit on the line -6.

In [14], the author's metric in index notation.

```
a4 = sp.Symbol("a4", real=True)  # the value of a4(x4) at one time
b4 = sp.Symbol("b4", positive=True)  # the value of b4(x4) at one time
z = sp.Symbol("z", positive=True)  # z = 6 H x0, between 0 and pi/2
s = sp.sin(z) ** sp.Rational(1, 3)
g_typed = ([sp.cot(z) ** 2] + [sp.exp(2 * a4) * s] * 3 + [sp.Integer(-1)]
           + [-b4 * sp.exp(-2 * a4) * s] * 3)  # the author's order x0, x1, ..., x7
curvature = json.loads(repository_file("Revision/gkd_lovelock/results/curvature.json")
                       .read_text(encoding="utf-8"))
```

The symbols, the typed metric and the record file, exactly as in Notebook 01a, In [17] (Section 1.25).

```
def from_record(text):
    """The record's Mathematica text as a sympy expression."""
    text = text.replace("a4[x4]", "a4").replace("b4[x4]", "b4")
    text = text.replace("Sin[6*H*x0]", "sin(z)")
    text = text.replace("Cot[6*H*x0]", "cot(z)").replace("^", "**")
    return sp.sympify(text, locals={"a4": a4, "b4": b4, "z": z, "E": sp.E})

g_record = [from_record(text) for text in curvature["metricDiagonal"]]
check(len(g_record) == 8 and
      all(sp.simplify(x - y) == 0 for x, y in zip(g_record, g_typed)),
      "the record's metric diagonal is the author's metric of section 4",
      record="Revision/gkd_lovelock/results/curvature.json, metricDiagonal")
```

The same translation function and the comparison with the typed metric (the "section 4" of the check's name is section 4 of the notebook, which states the metric); this check reproduces the record's key `metricDiagonal`.

```
g_lower = sp.diag(*g_record)  # g_mu nu
g_upper = sp.diag(*[1 / entry for entry in g_record])  # g^mu nu
lovelock_report = json.loads(repository_file(
    "Revision/gkd_lovelock/results/python-lovelock-report.json")
    .read_text(encoding="utf-8"))
lovelock_verdicts = {c["name"]: c["verdict"] for c in lovelock_report["checks"]}
```

$g_{\mu\nu}$ and $g^{\mu\nu}$ as diagonal sympy matrices (the star hands the eight entries to `sp.diag` one by one), and the verdicts of the record's report (this one writes them in capitals, PASS).

```
check((g_upper * g_lower).applyfunc(sp.simplify) == sp.eye(8)
      and lovelock_verdicts["metric_inverse"] == "PASS",
      "g^mu nu g_nu lambda = delta^mu_lambda",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "metric_inverse")
```

$g^{\mu\nu}g_{\nu\lambda} = \delta^{\mu}{}_{\lambda}$, reproducing the record's check `metric_inverse`.

```
step = sp.Matrix([1] * 8)  # dx^mu = 1 for every mu (units with epsilon = 1)
ds2 = (step.T * g_lower * step)[0, 0]  # g_mu nu dx^mu dx^nu
step_lower = g_lower * step  # dx_mu = g_mu nu dx^nu
ds2_contracted = (step.T * step_lower)[0, 0]  # dx^mu dx_mu
general_form = 3 * sp.exp(2 * a4) * s - 1 - 3 * b4 * sp.exp(-2 * a4) * s + sp.cot(z) ** 2
closed_form = 6 * s * sp.sinh(2 * a4) - 1 + sp.cot(z) ** 2  # at b4 = 1
say(f"ds^2 for dx^mu = 1: {ds2}")
```

The step $dx^{\mu} = 1$ (that is, $\epsilon = 1$) as a column of eight ones. `step.T * g_lower * step` is the row times the table times the column, a 1×1 matrix whose one entry `[0, 0]` is $g_{\mu\nu}dx^{\mu}dx^{\nu}$. The lowered step and the contraction $dx^{\mu}dx_{\mu}$; the general form and, at $b_4 = 1$, the closed form of Section 1.29. Output: `-3*b4*exp(-2*a4)*sin(z)**(1/3) + 3*exp(2*a4)*sin(z)**(1/3) + cot(z)**2 - 1`, the first line of the derivation (sympy chooses its own order of the terms).

```
check(sp.expand(ds2 - general_form) == 0
      and sp.expand((ds2.subs(b4, 1) - closed_form).rewrite(sp.exp)) == 0
      and sp.expand(ds2_contracted - ds2) == 0,
      "ds^2 = 3 e^(2 a4) s - 1 - 3 b4 e^(-2 a4) s + cot(z)^2 for the step dx^mu = 1, "
      "= 6 s sinh(2 a4) - 1 + cot(z)^2 at b4 = 1, and dx^mu dx_mu gives the same")
```

The difference from the general form multiplies out to 0; at $b_4 = 1$ (`.subs(b4, 1)`) the difference from the closed form, with sinh written as exponentials, multiplies out to 0 as well; and both ways of contracting agree. The cell prints three PASS lines.

In [15], where the step changes its kind.

```
ds2_numbers = sp.lambdify((a4, z), closed_form, "numpy")  # a formula -> a function
a4_values = np.linspace(-1.5, 1.5, 301)
z_values = np.linspace(0.15, np.pi / 2 - 0.005, 300)
A4_grid, Z_grid = np.meshgrid(a4_values, z_values)  # rows: z, columns: a4
values = ds2_numbers(A4_grid, Z_grid)
```

The closed form at $b_4 = 1$ as a numpy function; 301 values of a_4 and 300 values of z. `np.meshgrid` makes two tables of the same shape, one holding a_4 and one holding z at every grid point (a row for each z, a column for each a_4), so that `values` holds ds^2/ϵ^2 at all $301 \cdot 300$ points.

```
threshold = 0.5 * np.arcsinh((1 - 1 / np.tan(z_values) ** 2)
                             / (6 * np.sin(z_values) ** (1 / 3)))
check(bool((np.diff(values, axis=1) > 0).all()),
      "on every row of the grid, ds^2 grows as a4 grows")
away = np.abs(A4_grid - threshold[:, None]) > 1e-9  # leave out points on the curve
check(bool(((values > 0) == (A4_grid > threshold[:, None]))[away].all()),
      "ds^2 > 0 exactly to the right of the curve a4*(z)")
```

`threshold` is $a_4^*(z)$ for each z ($\cot z = 1/\tan z$). `np.diff(values, axis=1)` takes the differences of neighbours along each row; all positive means that ds^2 grows with a_4. `threshold[:, None]` turns the list into a column so that it is compared with every column of the grid; at every point not within 10^{-9} of the curve, $ds^2 > 0$ must hold exactly when $a_4 > a_4^*(z)$. Two PASS lines.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.5, 4.5))
image = left.imshow(np.tanh(values), origin="lower", aspect="auto", cmap="RdBu_r",
                    vmin=-1, vmax=1, extent=(a4_values[0], a4_values[-1],
                                             z_values[0], z_values[-1]))
left.plot(threshold, z_values, color="black", lw=1.5, label="$ds^2 = 0$")
left.set_xlim(a4_values[0], a4_values[-1])
left.grid(False)  # no grid lines across the coloured map
```

The left panel shows the whole grid as a coloured map. tanh squeezes every value into the range -1 to 1 while keeping its sign, so that red means space-like and blue time-like. `origin="lower"` puts the first row at the bottom, `extent` gives the map the coordinates of a_4 and z, and `aspect="auto"` lets it fill the panel. The black curve is $a_4^*(z)$.

```
left.text(0.75, 0.4, "space-like\n$ds^2 > 0$", ha="center", color="white")
left.text(-0.9, 1.2, "time-like\n$ds^2 < 0$", ha="center", color="white")
left.set_xlabel("$a_4$")
left.set_ylabel("$z = 6 H x_0$")
left.set_title("sign of $ds^2$ for the step $dx^\\mu = \\epsilon$", fontsize=10)
left.legend(loc="upper right", fontsize=8)
fig.colorbar(image, ax=left, label="$\\tanh(ds^2/\\epsilon^2)$")
```

Two white labels (`\n` in a string starts a new line), the axis labels, the title, the legend and a colour bar.

```
z_fixed = 0.9
s_fixed = np.sin(z_fixed) ** (1 / 3)
space_term = 3 * np.exp(2 * a4_values) * s_fixed  # x1, x2, x3
extra_term = -3 * np.exp(-2 * a4_values) * s_fixed  # x5, x6, x7 (deflating)
hidden_term = np.full_like(a4_values, 1 / np.tan(z_fixed) ** 2)  # x0
```

On the right, at $z = 0.9$, the four kinds of terms of the sum against a_4: the three space directions, the three deflating extra times, and the hidden direction (`np.full_like` makes an array of the same length filled with one value).

```
right.plot(a4_values, space_term, color="tab:red", label="space $x_1, x_2, x_3$")
right.plot(a4_values, np.full_like(a4_values, -1.0), color="tab:gray",
           label="time $x_4$")
right.plot(a4_values, extra_term, color="tab:blue",
           label="extra times $x_5, x_6, x_7$")
right.plot(a4_values, hidden_term, color="tab:green", label="hidden $x_0$")
right.plot(a4_values, space_term - 1 + extra_term + hidden_term, "k", lw=2.5,
           label="sum $ds^2/\\epsilon^2$")
```

The four terms (the time term is the constant -1) and their sum as a thick black line.

```
right.axhline(0, color="black", lw=0.8)
right.set_ylim(-12, 12)
right.set_xlabel("$a_4$")
right.set_ylabel("contribution to $ds^2/\\epsilon^2$")
right.set_title(f"the terms of $g_{{\\mu\\nu}} dx^\\mu dx^\\nu$ at $z = {z_fixed}$",
                fontsize=10)
right.legend(fontsize=8, loc="lower right")
fig.tight_layout()
save_figure(fig, "step_length",
            "The squared length $ds^2 = g_{\\mu\\nu} dx^\\mu dx^\\nu$ of the "
            ...)
```

The title is an f-string, so the braces of the LaTeX subscript are doubled. What Figure 01e.6 shows: on the left a blue (time-like) region to the left of the black curve and a red (space-like) region to its right; on the right the red space term climbing, the blue extra-time term rising from very negative values towards 0 as the extra times deflate, and the black sum crossing zero.

In [16], the last check.

```
figure_names = ["01e_1_eta_and_delta.png", "01e_2_squared_lengths.png",
                "01e_3_symmetric_antisymmetric.png", "01e_4_clifford_tables.png",
                "01e_5_gamma_contractions.png", "01e_6_step_length.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

The last line is ALL 25 CHECKS PASSED (notebook 01e). The 25 checks are: 2 in In [2], 3 in In [3], 1 in In [5], 3 in In [6], 4 in In [8], 3 in In [10], 3 in In [12], 3 in In [14], 2 in In [15] and 1 in In [16].

1.34 Eigenvalues and eigenvectors; the characteristic polynomial

Directions that are only stretched. A square matrix M usually turns a vector into a vector that points somewhere else. A few special directions are only stretched (or shrunk, or reversed):

$$Mv = \lambda v, \qquad v \neq 0.$$

The number λ (the Greek letter lambda) is an **eigenvalue** of M and v an **eigenvector** belonging to it. Any multiple cv with $c \neq 0$ is an eigenvector too ($M(cv) = cMv = c\lambda v = \lambda(cv)$), so only the direction of v matters. The list of all eigenvalues is the **spectrum** of M. Eigenvalues are everywhere in the course: the signature (4,4) of the author's spacetime is a count of positive and negative eigenvalues of its metric (Section 1.36); the gamma matrices are known by their eigenvalues (Section 1.37); and the energies of quantum states are eigenvalues (Chapters 10, 14 and 15).

Why a determinant decides. $Mv = \lambda v$ can be written

$$(M - \lambda I)v = 0$$

(move $\lambda v = \lambda I v$ to the left side and take out v). If $\det(M - \lambda I) \neq 0$, the matrix $M - \lambda I$ can be undone (Section 1.20), and undoing it on both sides gives $v = 0$: no eigenvector. Conversely, if $\det(M - \lambda I) = 0$, the equation has a solution $v \neq 0$ (a standard theorem of linear algebra, ASSUMED). So the eigenvalues are exactly the numbers with

$$p(\lambda) = \det(M - \lambda I) = 0.$$

p is the **characteristic polynomial** of M. By the Leibniz formula every term of $\det(M - \lambda I)$ is a product of n entries, of which at most n (the diagonal ones) contain λ; so p is a **polynomial** (a sum of powers of λ with number coefficients) of degree n. A **root** of a polynomial is a number at which it is 0. The **fundamental theorem of algebra** (ASSUMED) says that a polynomial of degree n has exactly n roots $\lambda_1, \ldots, \lambda_n$ when complex numbers are allowed and a repeated root is counted as often as it appears, its **multiplicity**. So an $n \times n$ matrix has n eigenvalues, some of which may be complex or repeated.

The eigenvalues add up to the trace and multiply to the determinant (PROVED). A polynomial of degree n whose highest term is $(-\lambda)^n$ and whose roots are $\lambda_1, \ldots, \lambda_n$ is

$$p(\lambda) = (\lambda_1 - \lambda)(\lambda_2 - \lambda)\cdots(\lambda_n - \lambda)$$

(the factored form; the highest term of $\det(M - \lambda I)$ is the product of the n diagonal terms $-\lambda$, which is $(-\lambda)^n$). Setting $\lambda = 0$:

$$p(0) = \det M = \lambda_1 \lambda_2 \cdots \lambda_n$$

(at $\lambda = 0$ the matrix $M - \lambda I$ is M): the determinant is the **product** of the eigenvalues. Multiplying out the factored form, the terms with λ^{n-1} take $-\lambda$ from all brackets but one and λ_i from that one, so they add up to $(-1)^{n-1}(\lambda_1 + \cdots + \lambda_n)\lambda^{n-1}$. In the Leibniz formula only the product of the diagonal entries, $(M_{11} - \lambda)\cdots(M_{nn} - \lambda)$, contains λ^{n-1} (every other term misses at least two diagonal entries, so it has at most $n - 2$ factors with λ), and in the same way its λ^{n-1} terms are $(-1)^{n-1}(M_{11} + \cdots + M_{nn})\lambda^{n-1}$. Comparing the two: the **sum** of the eigenvalues is the trace.

A 2×2 example by hand (PROVED). Take M with the rows $(2, 1)$ and $(1, 2)$. Line by line:

$$\det(M - \lambda I) = (2 - \lambda)(2 - \lambda) - 1 \cdot 1$$

(the determinant $ad - bc$ of the matrix with the rows $(2-\lambda, 1)$ and $(1, 2-\lambda)$),

$$= \lambda^2 - 4\lambda + 4 - 1 = \lambda^2 - 4\lambda + 3 = (\lambda - 1)(\lambda - 3)$$

(multiply out; collect; two numbers whose product is 3 and whose sum is 4). So the eigenvalues are 1 and 3. For $\lambda = 3$ the equation $(M - 3I)v = 0$ has the rows $-v_1 + v_2 = 0$ and $v_1 - v_2 = 0$, which say the same, so $v = (1, 1)$; for $\lambda = 1$ it reads $v_1 + v_2 = 0$, so $v = (1, -1)$. Check: $3 + 1 = 4 = \operatorname{tr} M$ and $3 \cdot 1 = 3 = 2 \cdot 2 - 1 \cdot 1 = \det M$.

What the example means (PROVED). Take the vectors of length 1, $x = (\cos t, \sin t)$, which run around the unit circle as the angle t runs from 0 to 2π. Their images are $Mx = (2\cos t + \sin t, \cos t + 2\sin t)$, with the squared length

$$(2\cos t + \sin t)^2 + (\cos t + 2\sin t)^2 = 4\cos^2 t + 4\cos t \sin t + \sin^2 t + \cos^2 t + 4\cos t \sin t + 4\sin^2 t$$

(multiply out both squares with $(u + v)^2 = u^2 + 2uv + v^2$),

$$= 5\cos^2 t + 5\sin^2 t + 8\cos t \sin t = 5 + 8\cos t \sin t = 5 + 4\sin 2t$$

(collect; $\cos^2 t + \sin^2 t = 1$; the double-angle formula $2\sin t \cos t = \sin 2t$ of school trigonometry, ASSUMED). It is largest, $5 + 4 = 9$, where $\sin 2t = 1$, at $t = \pi/4$, the direction $(1, 1)/\sqrt{2}$; and smallest, $5 - 4 = 1$, at $t = -\pi/4$, the direction $(1, -1)/\sqrt{2}$. So the unit circle becomes an **ellipse** whose longest and shortest half-axes have the lengths $\sqrt{9} = 3$ and $\sqrt{1} = 1$, the two eigenvalues, and lie along the two eigenvectors (Figure 01g.1).

The chain matrix of size 3 (PROVED). The 3×3 **chain matrix** T_3 has 2 on the diagonal, -1 just above and just below it, and 0 elsewhere. With the six-term formula of Section 1.20 (the entries $a_{11} = a_{22} = a_{33} = 2 - \lambda$, $a_{12} = a_{21} = a_{23} = a_{32} = -1$, $a_{13} = a_{31} = 0$):

$$\det(T_3 - \lambda I) = (2-\lambda)^3 + 0 + 0 - (-1)(-1)(2-\lambda) - (2-\lambda)(-1)(-1) - 0$$

(the six terms in the order of Section 1.20; the second, third and sixth contain a_{13} or a_{31}, which are 0),

$$= (2-\lambda)^3 - 2(2-\lambda) = (2-\lambda)\left[(2-\lambda)^2 - 2\right]$$

(collect the two equal terms; take out the factor $2 - \lambda$). The roots are $\lambda = 2$ and $(2-\lambda)^2 = 2$, that is $\lambda = 2 \pm \sqrt{2}$. Multiplied out, $p(\lambda) = -\lambda^3 + 6\lambda^2 - 10\lambda + 4$ (from $(2-\lambda)^3 = 8 - 12\lambda + 6\lambda^2 - \lambda^3$ and $-2(2-\lambda) = -4 + 2\lambda$). The sum of the roots is $6 = \operatorname{tr} T_3$, and their product is $(2-\sqrt{2}) \cdot 2 \cdot (2+\sqrt{2}) = 2(4-2) = 4 = p(0) = \det T_3$ (Figure 01g.2).

1.35 The chain matrix of any size; rotations and boosts; conjugate pairs

The chain matrix T_n (PROVED). Row j of $T_n v$ is $-v_{j-1} + 2v_j - v_{j+1}$, where we put $v_0 = v_{n+1} = 0$ (the first and the last row have only one neighbour; a missing neighbour counts as 0). Try $v_j = \sin(j\theta)$ for an angle θ:

$$\sin((j-1)\theta) + \sin((j+1)\theta) = 2\sin(j\theta)\cos\theta$$

(the addition theorems $\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y$ with $x = j\theta$ and $y = \theta$, added; the terms $\cos x \sin y$ cancel), so

$$-v_{j-1} + 2v_j - v_{j+1} = 2\sin(j\theta) - 2\sin(j\theta)\cos\theta = (2 - 2\cos\theta)\sin(j\theta)$$

(insert; take out the common factor). This is λv_j with $\lambda = 2 - 2\cos\theta$, provided the two end conditions hold. The start $v_0 = \sin 0 = 0$ holds for every θ. The end $v_{n+1} = \sin((n+1)\theta) = 0$ holds when $(n+1)\theta$ is a whole multiple of π, $\theta = k\pi/(n+1)$. For $k = 1, \ldots, n$ this gives n different eigenvalues

$$\lambda_k = 2 - 2\cos\frac{k\pi}{n+1}, \qquad k = 1, \ldots, n$$

(different because the cosine decreases between 0 and π), with the eigenvectors $v_j = \sin(jk\pi/(n+1))$: sine waves sampled at the points $j = 1, \ldots, n$, with k half waves along the chain. For $n = 3$ they are $2 - 2\cos(\pi/4) = 2 - \sqrt{2}$, $2 - 2\cos(\pi/2) = 2$ and $2 - 2\cos(3\pi/4) = 2 + \sqrt{2}$, as found above. This matrix comes back whenever a second derivative is computed on a grid of points (Chapter 2): then the sine waves are the shapes of a vibrating string or of a quantum particle in a box. Notebook 01g, In [5], checks the formula for $n = 10$: numpy's eigenvalues differ from it by at most 8.9×10^{-16} (COMPUTED; Figure 01g.3).

Rotations have complex eigenvalues (PROVED). The rotation matrix $R(\alpha)$ of Section 1.12 turns every vector, so for $0 < \alpha < \pi$ no real direction is kept. Its characteristic polynomial is

$$(\cos\alpha - \lambda)^2 + \sin^2\alpha = \lambda^2 - 2\cos\alpha\,\lambda + 1$$

(the determinant $ad - bc$ of the matrix with the rows $(\cos\alpha - \lambda, -\sin\alpha)$ and $(\sin\alpha, \cos\alpha - \lambda)$; multiply out and use $\cos^2\alpha + \sin^2\alpha = 1$). By the formula for the roots of a quadratic $\lambda^2 + p\lambda + q$, $\lambda = -p/2 \pm \sqrt{p^2/4 - q}$ (school algebra, ASSUMED),

$$\lambda = \cos\alpha \pm \sqrt{\cos^2\alpha - 1} = \cos\alpha \pm \sqrt{-\sin^2\alpha} = \cos\alpha \pm i\sin\alpha = e^{\pm i\alpha}$$

(insert $p = -2\cos\alpha$, $q = 1$; $\cos^2 - 1 = -\sin^2$; a square root of $-x^2$ is ix, because $(ix)^2 = -x^2$; Euler's formula): two complex numbers of modulus 1. The eigenvectors are $(1, \mp i)$: $R(\alpha)(1, -i) = (\cos\alpha + i\sin\alpha, \sin\alpha - i\cos\alpha) = e^{i\alpha}(1, -i)$, because $e^{i\alpha} \cdot (-i) = -i\cos\alpha + \sin\alpha$ (row times column; multiply out). For $\alpha = \pi/2$, R is the matrix J of Section 1.12, whose eigenvalues are $\pm i$: the real matrix that plays the role of i has the eigenvalues $\pm i$.

Boosts have real eigenvalues. The boost $\Lambda(\varphi)$ of Section 1.13 has the characteristic polynomial $(\cosh\varphi - \lambda)^2 - \sinh^2\varphi = \lambda^2 - 2\cosh\varphi\,\lambda + 1$ (now with $\cosh^2 - \sinh^2 = 1$), whose roots are $\cosh\varphi \pm \sqrt{\cosh^2\varphi - 1} = \cosh\varphi \pm \sinh\varphi = e^{\pm\varphi}$ (for $\varphi \geq 0$, where $\sinh\varphi \geq 0$), with the eigenvectors $(1, \pm 1)$, the two light-like directions found in Section 1.13 (PROVED). Their product is 1 (Figure 01g.4).

Complex eigenvalues of a real matrix come in pairs (PROVED). If M is real and $Mv = \lambda v$, conjugating every entry gives $M^*v^* = \lambda^* v^*$, and $M^* = M$; so $Mv^* = \lambda^* v^*$: λ^* is an eigenvalue too, with the eigenvector v^*. Notebook 01g, In [6], checks this on 200 random real 5×5 matrices.

1.36 Symmetric and Hermitian matrices; the signature and Sylvester's law

Words. The **conjugate transpose** of a matrix is $M^\dagger = (M^*)^T$: conjugate every entry, then exchange rows and columns; for a column v, $v^\dagger$ is the row of the conjugated components, and $v^\dagger v = \sum_i |v_i|^2$, which is positive for $v \neq 0$. Like the transpose it reverses products, $(AB)^\dagger = B^\dagger A^\dagger$ (the conjugate of a product of matrices is the product of the conjugates, entry by entry, by rule 1 of Section 1.10; then the transpose rule of Section 1.18). A matrix is **Hermitian** if $H^\dagger = H$; a real Hermitian matrix is a symmetric matrix. The **length** of a real vector is $|v| = \sqrt{v_1^2 + \cdots + v_n^2}$; two real vectors are **perpendicular** (or orthogonal) if $u^T w = \sum_i u_i w_i = 0$.

Theorem 1: a symmetric matrix has only real eigenvalues (PROVED). Let S be real and symmetric, and $Sv = \lambda v$ with a column $v \neq 0$ that may be complex.

- Conjugate and transpose both sides: $v^\dagger S^\dagger = \lambda^* v^\dagger$ (the product rule of †; a number only gets conjugated), and $S^\dagger = S$ because S is real ($S^* = S$) and symmetric ($S^T = S$); so $v^\dagger S = \lambda^* v^\dagger$.
- Multiply $Sv = \lambda v$ from the left by $v^\dagger$: $v^\dagger S v = \lambda\, v^\dagger v$.
- Multiply $v^\dagger S = \lambda^* v^\dagger$ from the right by v: $v^\dagger S v = \lambda^*\, v^\dagger v$.
- Subtract the two lines: $0 = (\lambda - \lambda^*)\, v^\dagger v$.
- $v^\dagger v = |v_1|^2 + \cdots + |v_n|^2 > 0$, so $\lambda - \lambda^* = 0$: λ equals its conjugate, so it is real.

The same lines, with $S^\dagger = S$ as the only property used, prove it for a complex Hermitian matrix.

Theorem 2: eigenvectors with different eigenvalues are perpendicular (PROVED). Let $Su = \lambda u$ and $Sw = \mu w$ with $\lambda \neq \mu$ (real vectors, real eigenvalues). Then $u^T S w = \mu\, u^T w$ (insert Sw), and also $u^T S w = (S^T u)^T w = (Su)^T w = \lambda\, u^T w$ (the transpose rule; $S^T = S$; insert Su). Subtracting: $(\lambda - \mu)\, u^T w = 0$, so $u^T w = 0$.

The spectral theorem (ASSUMED). A standard theorem of linear algebra, used here without proof, says that also when eigenvalues repeat, a real symmetric $n \times n$ matrix has n perpendicular eigenvectors of length 1, and that, with these eigenvectors as the columns of a matrix O,

$$S = O \Lambda O^T, \qquad O^T O = I,$$

with the eigenvalues on the diagonal of the diagonal matrix Λ (O is orthogonal, Section 1.28). One can see that both sides do the same to every eigenvector: $O^T u_i = e_i$, the i-th unit vector, because the columns of O are perpendicular and of length 1; so $O \Lambda O^T u_i = O \Lambda e_i = \lambda_i O e_i = \lambda_i u_i = S u_i$. Notebook 01g, In [8], checks this for 300 random symmetric 8×8 matrices $S = A + A^T$: every eigenvalue is real (the largest imaginary part found by the general eigenvalue program is 0.0) and $O \Lambda O^T = S$ to 10^{-12}; the 300 non-symmetric matrices A have 67.7 per cent complex eigenvalues (COMPUTED; Figure 01g.5).

The quadratic form and the signature. A symmetric matrix S defines the **quadratic form** $Q(v) = v^T S v = S_{ab} v^a v^b$; for the frame metric it is the squared length of Section 1.27. In the eigenvector coordinates $v = Ow$:

$$Q = (Ow)^T S(Ow) = w^T (O^T S O) w = w^T \Lambda w = \lambda_1 w_1^2 + \cdots + \lambda_n w_n^2$$

(insert; the transpose rule $(Ow)^T = w^T O^T$; $O^T S O = O^T O \Lambda O^T O = \Lambda$; a diagonal matrix in a quadratic form gives a sum of squares). So the **signature** (p, q) of a symmetric matrix, the numbers of its positive and its negative eigenvalues, says in how many perpendicular directions Q is positive and in how many it is negative. An eigenvalue 0 would be a direction in which Q vanishes; the metrics of the course have none (their determinants, the products of the eigenvalues, are not 0).

Sylvester's law of inertia (PROVED from one ASSUMED fact). A change of coordinates $v = Pw$ with an invertible matrix P gives $Q = w^T (P^T S P) w$: the matrix of the form becomes $P^T S P$. Its eigenvalues are different, but its signature is the same. We use one fact of linear algebra without proof (ASSUMED): more than n vectors with n components are **linearly dependent**, that is, some combination $c_1 u_1 + c_2 u_2 + \cdots$ with numbers c_i not all 0 gives the zero vector. *Proof.* Let S have p positive eigenvalues with perpendicular unit eigenvectors $u_1, \ldots, u_p$, and let $S' = P^T S P$ have p' positive eigenvalues; suppose $p' < p$.

- On every combination $x = \sum_i c_i u_i$ with not all $c_i = 0$: $Q(x) = \sum_i \sum_j c_i c_j \, u_i^T S u_j = \sum_i \lambda_i c_i^2 > 0$ (multiply out; $S u_j = \lambda_j u_j$ and $u_i^T u_j = \delta_{ij}$ by Theorem 2 and the length 1; every $\lambda_i > 0$).
- Let $u'_1, \ldots, u'_{n-p'}$ be perpendicular unit eigenvectors of S' with eigenvalues ≤ 0. On every combination $y = \sum_k d_k u'_k$: $y^T S' y = \sum_k \lambda'_k d_k^2 \leq 0$ (the same computation), and $y^T S' y = (Py)^T S (Py) = Q(Py)$ (the definition of S'; the transpose rule).
- The $p + (n - p') > n$ vectors $u_1, \ldots, u_p, Pu'_1, \ldots, Pu'_{n-p'}$ are linearly dependent: $\sum_i c_i u_i + \sum_k d_k P u'_k = 0$ with numbers not all 0. Put $x = \sum_i c_i u_i$ and $y = -\sum_k d_k u'_k$, so $x = Py$. If all c_i were 0, then $P \sum_k d_k u'_k = 0$, hence $\sum_k d_k u'_k = 0$ (P can be undone), hence all $d_k = 0$ (multiply by u'^T_l and use the perpendicularity); so some $c_i \neq 0$.
- Then $Q(x) > 0$ by the first line, but $Q(x) = Q(Py) \leq 0$ by the second: impossible.

So $p' \geq p$. The same argument with the roles exchanged ($S = (P^{-1})^T S' P^{-1}$) gives $p \geq p'$, and the argument for $-S$ counts the negative eigenvalues. So **the signature is a property of the form, not of the coordinates used to describe it.** Notebook 01g, In [10], checks the law on 2000 random matrices P: every $P^T \eta P$ has the signature (4,4), with eigenvalues of sizes from 1.4×10^{-8} to 37.0, all far enough from 0 that rounding cannot change their signs (COMPUTED; Figure 01g.6, left).

The signature of the author's spacetime (PROVED). The eigenvalues of a diagonal matrix are its diagonal entries (each unit vector e_i is an eigenvector: $D e_i = d_i e_i$). So η has the eigenvalues $+1$ (four times) and -1 (four times): the signature (4,4) (record `Revision/algebra/reports/python-algebra.json`, check `coordinate_map`, which states η). The author's metric g has the eigenvalues $\cot^2 z > 0$, $e^{2a_4} s > 0$ (three times), -1 and $-b_4 e^{-2a_4} s < 0$ (three times), for every a_4, every $b_4 > 0$ and every $0 < z < \pi/2$: again four positive and four negative. As a_4 grows (with b_4 constant) the three extra-time eigenvalues $-b_4 e^{-2a_4} s$ shrink towards 0, the exponential deflation of the extra

times, but they never change sign; and their product with the others is $\det g = b_4^3 \cos^2 z > 0$ (Section 1.21). Notebook 01g, In [11], checks the signs at $3 \times 61 \times 50 = 9150$ grid points (a_4, z, b_4) and the product to 10^{-12} (COMPUTED; Figure 01g.6, right, drawn at $b_4 = 1$).

1.37 The eigenvalues of the gamma matrices and of B; power iteration

The gamma matrices (PROVED). The gamma matrices obey $(\gamma^a)^2 = \eta^{aa} I$ (Section 1.28). If $\gamma^a v = \lambda v$ with $v \neq 0$, then

$$(\gamma^a)^2 v = \gamma^a(\lambda v) = \lambda\, \gamma^a v = \lambda^2 v$$

(apply γ^a twice; a number can be moved in front of a matrix), and also $(\gamma^a)^2 v = \eta^{aa} v$. So $\lambda^2 = \eta^{aa}$: $\lambda = \pm 1$ for the space-like directions x_0, x_1, x_2, x_3 and $\lambda = \pm i$ for the time-like directions $x_4, \ldots, x_7$. How many of each? The trace of a gamma matrix is 0: for any $b \neq a$,

$$\operatorname{tr} \gamma^a = \eta^{bb} \operatorname{tr}(\gamma^b \gamma^b \gamma^a) = \eta^{bb} \operatorname{tr}(\gamma^b \gamma^a \gamma^b) = -\eta^{bb} \operatorname{tr}(\gamma^b \gamma^b \gamma^a) = -\operatorname{tr} \gamma^a$$

(insert $\eta^{bb}(\gamma^b)^2 = \eta^{bb}\eta^{bb} I = I$; the trace does not change when the first factor is moved to the end, $\operatorname{tr}(XY) = \operatorname{tr}(YX)$ with $X = \gamma^b$; the anticommutation $\gamma^a \gamma^b = -\gamma^b \gamma^a$ for $a \neq b$; the first step backwards), and a number equal to its own negative is 0. The trace is the sum of the 16 eigenvalues (Section 1.34), so $+1$ and -1 (or $+i$ and $-i$) occur 8 times each, and the characteristic polynomial is $(\lambda - 1)^8(\lambda + 1)^8 = (\lambda^2 - 1)^8$ for a space-like and $(\lambda - i)^8(\lambda + i)^8 = (\lambda^2 + 1)^8$ for a time-like direction, in one formula $(\lambda^2 - \eta_{aa})^8$. (sympy's `charpoly` computes $\det(\lambda I - M)$, which for a 16×16 matrix equals $\det(M - \lambda I)$, because changing the sign of all 16 rows multiplies the determinant by $(-1)^{16} = 1$, rule 5 of Section 1.20.) Notebook 01g, In [13], checks this exactly for the eight matrices of the record (Figure 01g.7, left).

The gamma matrix of a vector (PROVED). For a vector v the matrix $\gamma(v) = v_a \gamma^a$ (with $v_a = \eta_{ab} v^b$) squares to

$$\gamma(v)^2 = v_a v_b\, \gamma^a \gamma^b = \tfrac{1}{2} v_a v_b (\gamma^a \gamma^b + \gamma^b \gamma^a) = v_a v_b\, \eta^{ab} I = Q(v)\, I$$

(multiply out the two sums; the numbers $v_a v_b$ are symmetric in a and b, so only the symmetric part of $\gamma^a \gamma^b$ counts, by the argument of Section 1.28 applied entry by entry; the Clifford relation; $v_a v_b \eta^{ab} = v_a v^a = Q(v)$). So, as above, its eigenvalues are $\pm\sqrt{Q(v)}$: real for a space-like, imaginary for a time-like v (eight of each sign, because $\operatorname{tr} \gamma(v) = v_a \operatorname{tr} \gamma^a = 0$). For a light-like $v \neq 0$, $\gamma(v)$ is not the zero matrix, because $\operatorname{tr}(\gamma(v)\gamma^b) = v_a \operatorname{tr}(\gamma^a \gamma^b) = 16\, v_a \eta^{ab} = 16\, v^b$ (the third contraction of Section 1.28; raising the index) is not 0 for a component $v^b \neq 0$; but $\gamma(v)^2 = 0$: a matrix with a power equal to 0 is called **nilpotent**, and all its eigenvalues are 0 ($\lambda^2 v = \gamma(v)^2 v = 0$ gives $\lambda = 0$); its characteristic polynomial is λ^{16}. Notebook 01g, In [14], checks $\gamma(v)^2 = Q(v) I$ exactly for four examples and 100 random vectors (Figure 01g.7, right).

The Hermitian matrix B and its signature (8,8). The Revision record stores, in `Revision /algebra/gammas.json`, the real matrix $C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ and the matrix $B = -i\, C \gamma^{(x_4)}$. B is complex: its real part is 0 and its imaginary part is a real 16×16 matrix of entries -1, 0, 1. In the theory of the course B gives the charge density $J^{(x_4)} = \Psi^\dagger B \Psi$ of the fields (Chapters 7 and 10). Its properties:

- B is Hermitian. For a matrix iA with real A, $(iA)^\dagger = i^* A^T = -iA^T$ (conjugate the number i; a real matrix only gets transposed), so $(iA)^\dagger = iA$ means $A^T = -A$: B is Hermitian exactly when its imaginary part is antisymmetric. By Theorem 1 its eigenvalues are real.
- $B^2 = I$, so, as for the gamma matrices, every eigenvalue has $\lambda^2 = 1$: $\lambda = \pm 1$.
- $\operatorname{tr} B = 0$, so $+1$ and -1 occur 8 times each: the signature (8,8), and the characteristic polynomial is $(\lambda - 1)^8(\lambda + 1)^8$.

The record checks these properties twice: in its algebra report `Revision/algebra/reports/python-algebra.json`, in the check named `B_hermitian_involution_signature`, and in its theory report `Revision/theory/reports/python-field-theory.json`, in the check named `B_properties`. Notebook 01g, In [16], reproduces them exactly from the record's matrices (PROVED by exact computation; Figure 01g.8). Because half of the eigenvalues of B are negative, the charge $\Psi^\dagger B \Psi$ can be positive or negative: the record calls it an **indefinite** form, and its quantisation entry reads "B Hermitian, B^2 = 1, signature (8,8): indefinite (Krein) state space". A **Krein space** is a space of states whose product of two states, built with B as in $\Psi^\dagger B \Psi$, takes the place of the dot product, so that a state can have a negative "squared length" (the dot product of an ordinary vector with itself is never negative); Chapter 10 explains what this means for the quantised field.

Power iteration (PROVED). A computer does not find eigenvalues as the roots of $\det(M - \lambda I)$ (that polynomial is very sensitive to rounding for large matrices); it transforms the matrix step by step. The simplest such method is **power iteration**. Write a starting vector as a sum of eigenvectors, $x_0 = c_1 u_1 + c_2 u_2 + \cdots$, with $|\lambda_1| > |\lambda_2| \geq \cdots$ and $c_1 \neq 0$. Multiplying by M k times gives

$$M^k x_0 = c_1 \lambda_1^k u_1 + c_2 \lambda_2^k u_2 + \cdots = \lambda_1^k \Big(c_1 u_1 + c_2 \Big(\frac{\lambda_2}{\lambda_1}\Big)^k u_2 + \cdots \Big)$$

(each eigenvector is only multiplied by its eigenvalue, once per step; then λ_1^k is taken out). The ratios $(\lambda_j/\lambda_1)^k$ shrink to 0, so the direction of $M^k x_0$ approaches u_1, and the leftover error shrinks by the factor $|\lambda_2/\lambda_1|$ in each step. Rescaling the vector to length 1 after each step keeps its numbers from growing without changing its direction. For the matrix M of Section 1.34 the factor is $1/3$; for T_3 it is

$$\frac{2}{2+\sqrt{2}} = \frac{2(2-\sqrt{2})}{(2+\sqrt{2})(2-\sqrt{2})} = \frac{2(2-\sqrt{2})}{2} = 2 - \sqrt{2} \approx 0.586$$

(multiply numerator and denominator by $2 - \sqrt{2}$; $(2+\sqrt{2})(2-\sqrt{2}) = 4 - 2$). Notebook 01g, In [18], measures 0.333333 and 0.585786 to 0.585789 (COMPUTED; Figure 01g.9).

1.38 Example: eigenvalues, eigenvectors and the signature (4,4)

Notebook 01g puts Sections 1.34 to 1.37 to work. It finds the eigenvalues of a 2×2 matrix by hand and with sympy and numpy and draws how the matrix turns the unit circle into an ellipse; computes the characteristic polynomial of the chain matrix and checks its exact eigenvalues and sine-wave eigenvectors; checks the complex eigenvalues of rotations and the real eigenvalues of

boosts; checks on random matrices that symmetric matrices have real eigenvalues and perpendicular eigenvectors; reads η and the author's metric from the Revision record, counts their positive and negative eigenvalues and checks Sylvester's law on 2000 random coordinate changes; derives and checks the eigenvalues of the eight gamma matrices and of $\gamma(v)$; finds the signature (8,8) of the record's matrix B; and runs power iteration. It ends with the line ALL 30 CHECKS PASSED (notebook 01g).

1.39 How to run Notebook 01g

Step 1. What this notebook does and what it needs.

Notebook 01g (Eigenvalues, eigenvectors and the signature (4,4)) is the file `Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb` of the repository Dirac_claude. It finds eigenvalues and eigenvectors by hand and with sympy and numpy, derives the characteristic polynomial and the rules that the eigenvalues add up to the trace and multiply to the determinant, solves the chain matrix of a grid exactly (sine-shaped eigenvectors), shows that real rotations have complex eigenvalues and boosts real ones, proves that symmetric and Hermitian matrices have real eigenvalues, counts the positive and negative eigenvalues of the frame metric and of the author's metric (the signature (4,4)) and checks that a change of coordinates never changes these counts (Sylvester's law of inertia), derives the eigenvalues of the eight real gamma matrices of the Revision record and of the Hermitian matrix B with its signature (8,8), and shows how a computer finds an eigenvalue by power iteration. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01g_eigenvalues_signature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01g_eigenvalues_signature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01g_eigenvalues_signature.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01g.captions.json`
- `Revision/textbook/figures/01g_1_circle_to_ellipse.png`
- `Revision/textbook/figures/01g_2_characteristic_polynomial.png`
- `Revision/textbook/figures/01g_3_chain_matrix.png`
- `Revision/textbook/figures/01g_4_rotation_and_boost.png`
- `Revision/textbook/figures/01g_5_random_spectra.png`
- `Revision/textbook/figures/01g_6_signature.png`
- `Revision/textbook/figures/01g_7_gamma_eigenvalues.png`
- `Revision/textbook/figures/01g_8_hermitian_b.png`
- `Revision/textbook/figures/01g_9_power_iteration.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which

is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 9 figure files of this notebook exist
ALL 30 CHECKS PASSED (notebook 01g)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01g_eigenvalues_signature.ipynb
python -m nbconvert --execute --inplace 01g_eigenvalues_signature.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock, Revision/algebra or Revision/theory: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

1.40 Notebook 01g: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A square matrix $M$ usually turns a vector into a vector that points somewhere
else. A few special directions are only stretched: $M v = \lambda v$. The
number $\lambda$ is an **eigenvalue** and $v$ an **eigenvector**. Eigenvalues
are everywhere in the course: the signature (4,4) of the author's spacetime is a
count of positive and negative eigenvalues of its metric, the gamma matrices
are known by their eigenvalues, and energies of quantum states are
eigenvalues. This notebook

- finds the eigenvalues and eigenvectors of a $2 \times 2$ matrix by hand and
  draws how the matrix turns the unit circle into an ellipse;
- derives the *characteristic polynomial* $\det(M - \lambda I)$ and the rules
  "the eigenvalues add up to the trace and multiply to the determinant";
- solves exactly the *chain matrix* (2 on the diagonal, $-1$ next to it), whose
  eigenvectors are sampled sine waves;
- shows that real rotation matrices have complex eigenvalues $e^{\pm i\alpha}$,
  while boosts have real ones $e^{\pm\varphi}$;
- proves that symmetric (and Hermitian) matrices have real eigenvalues and
  perpendicular eigenvectors, and checks it on random matrices;
- counts the positive and negative eigenvalues of the frame metric $\eta$ and of
  the author's metric $g$ (the signature (4,4)) and checks that no change of
  coordinates changes these counts (Sylvester's law of inertia);
- derives the eigenvalues of the eight real gamma matrices of the Revision
  record ($\pm 1$ or $\pm i$, eight times each) and of the matrix
```

```
  $\gamma(v) = v_a \gamma^a$ of a vector, which are $\pm\sqrt{Q(v)}$;
- finds the eigenvalues of the Hermitian matrix $B$ of the record, $+1$ and
  $-1$ eight times each: the signature (8,8);
- shows how a computer finds an eigenvalue by *power iteration*.

Every check prints a line that starts with PASS; where a check repeats a result
of the Revision record, a second line names the record file and its check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01g (Eigenvalues, eigenvectors and the signature (4,4)) is the file
‘Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb‘ of the repository
Dirac_claude. It finds eigenvalues and eigenvectors by hand and with sympy and numpy,
derives the characteristic polynomial and the rules that the eigenvalues add up to the
trace and multiply to the determinant, solves the chain matrix of a grid exactly
(sine-shaped eigenvectors), shows that real rotations have complex eigenvalues and boosts
real ones, proves that symmetric and Hermitian matrices have real eigenvalues, counts the
positive and negative eigenvalues of the frame metric and of the author's metric (the
signature (4,4)) and checks that a change of coordinates never changes these counts
(Sylvester's law of inertia), derives the eigenvalues of the eight real gamma matrices of
the Revision record and of the Hermitian matrix B with its signature (8,8), and shows how
a computer finds an eigenvalue by power iteration. It needs a computer with Windows 11,
macOS or Linux, an internet connection for the installation, the program Git, and Python
3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at
exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0,
jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert
7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run
Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
```

two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01g_eigenvalues_signature.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 15 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01g_eigenvalues_signature.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01g_eigenvalues_signature.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01g.captions.json‘
- ‘Revision/textbook/figures/01g_1_circle_to_ellipse.png‘
- ‘Revision/textbook/figures/01g_2_characteristic_polynomial.png‘
- ‘Revision/textbook/figures/01g_3_chain_matrix.png‘
- ‘Revision/textbook/figures/01g_4_rotation_and_boost.png‘
- ‘Revision/textbook/figures/01g_5_random_spectra.png‘
- ‘Revision/textbook/figures/01g_6_signature.png‘
- ‘Revision/textbook/figures/01g_7_gamma_eigenvalues.png‘
- ‘Revision/textbook/figures/01g_8_hermitian_b.png‘
- ‘Revision/textbook/figures/01g_9_power_iteration.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the

notebook (the output of its last code cell) you must see exactly these lines:

```
    PASS all 9 figure files of this notebook exist
    ALL 30 CHECKS PASSED (notebook 01g)
```

and the notebook must show 9 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
      python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

  ```
      python -m jupyterlab 01g_eigenvalues_signature.ipynb
      python -m nbconvert --execute --inplace 01g_eigenvalues_signature.ipynb
  ```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock, Revision/algebra or Revision/theory: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.

The first code cell below (the set-up cell) repeats these instructions as comments; then

it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01g (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01g (Eigenvalues, eigenvectors and the signature (4,4)) is the file
# Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb of the repository
# Dirac_claude. It finds eigenvalues and eigenvectors by hand and with sympy and numpy,
# derives the characteristic polynomial and the rules that the eigenvalues add up to the
# trace and multiply to the determinant, solves the chain matrix of a grid exactly
# (sine-shaped eigenvectors), shows that real rotations have complex eigenvalues and
# boosts real ones, proves that symmetric and Hermitian matrices have real eigenvalues,
# counts the positive and negative eigenvalues of the frame metric and of the author's
# metric (the signature (4,4)) and checks that a change of coordinates never changes
# these counts (Sylvester's law of inertia), derives the eigenvalues of the eight real
# gamma matrices of the Revision record and of the Hermitian matrix B with its signature
# (8,8), and shows how a computer finds an eigenvalue by power iteration. It needs a
# computer with Windows 11, macOS or Linux, an internet connection for the installation,
# the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
# with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
# matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
# and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the
# other packages run Jupyter, the program that shows and runs notebooks. It does not need
# Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
```

```
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
```

```
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01g_eigenvalues_signature.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 15
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
```

```
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01g_eigenvalues_signature.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01g_eigenvalues_signature.ipynb (in the same folder, without running the cells again)
# to read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01g.captions.json
# - Revision/textbook/figures/01g_1_circle_to_ellipse.png
# - Revision/textbook/figures/01g_2_characteristic_polynomial.png
# - Revision/textbook/figures/01g_3_chain_matrix.png
# - Revision/textbook/figures/01g_4_rotation_and_boost.png
# - Revision/textbook/figures/01g_5_random_spectra.png
# - Revision/textbook/figures/01g_6_signature.png
# - Revision/textbook/figures/01g_7_gamma_eigenvalues.png
# - Revision/textbook/figures/01g_8_hermitian_b.png
# - Revision/textbook/figures/01g_9_power_iteration.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 9 figure files of this notebook exist
#     ALL 30 CHECKS PASSED (notebook 01g)
#
# and the notebook must show 9 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
```

```
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01g_eigenvalues_signature.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01g_eigenvalues_signature.ipynb
#     python -m nbconvert --execute --inplace 01g_eigenvalues_signature.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below Revision/gkd_lovelock, Revision/algebra or
#   Revision/theory: the notebook reads Revision records of the repository; your copy of
#   the repository is incomplete. Download it again with git clone and open the notebook
#   inside the new copy.
#

## 3. The words used in this notebook

- **Eigenvalue, eigenvector**: a number $\lambda$ and a vector $v \neq 0$ with
  $M v = \lambda v$ for a square matrix $M$. Any multiple $c v$ ($c \neq 0$) is
  an eigenvector too, so only the *direction* of $v$ matters.
- **Spectrum**: the list of all eigenvalues of a matrix.
- **Characteristic polynomial**: $p(\lambda) = \det(M - \lambda I)$, a
  polynomial in $\lambda$ whose roots are the eigenvalues.
- **Root** (or zero) of a polynomial: a number where it is 0. A root that
  appears $k$ times in the factorised polynomial has **multiplicity** $k$.
- **Trace** $\mathrm{tr}\,M$: the sum of the diagonal entries.
- **Determinant** $\det M$: the number of notebook 01a; $\det M \neq 0$ exactly
  when $M$ can be undone (inverted).
- **Length** (norm) of a vector, $|v| = \sqrt{v_1^2 + \dots + v_n^2}$; a **unit
  vector** has length 1.
- **Perpendicular** (orthogonal) vectors: $u^T w = \sum_i u_i w_i = 0$.
- **Symmetric matrix**: $S^T = S$. **Orthogonal matrix**: $O^T O = I$; its
  columns are perpendicular unit vectors.
- **Complex conjugate** $z^*$ and **conjugate transpose**
  $M^\dagger = (M^*)^T$ (conjugate every entry, then exchange rows and
  columns); for a column $v$, $v^\dagger v = \sum_i |v_i|^2$.
- **Hermitian matrix**: $H^\dagger = H$; a real Hermitian matrix is a
  symmetric matrix.
- **Quadratic form** of a symmetric matrix $S$: the number
  $Q(v) = v^T S v = S_{ab} v^a v^b$.
- **Signature** $(p, q)$ of a symmetric matrix: $p$ eigenvalues are positive
  and $q$ negative (the rest are 0).
- **Sylvester's law of inertia**: the matrices $S$ and $P^T S P$ ($P$
  invertible) have the same signature.
- **Light-like** vector: $v \neq 0$ with $Q(v) = 0$ (notebook 01e).
- **Nilpotent matrix**: a matrix $N \neq 0$ with $N^k = 0$ for some power $k$;
  all its eigenvalues are 0.
- **Power iteration**: multiply a vector by $M$ again and again and rescale it
  to length 1; it turns towards the eigenvector of the eigenvalue of largest
  size.
```

```
## 4. The physical and mathematical situation

**Why a determinant decides.** $M v = \lambda v$ can be written
$(M - \lambda I) v = 0$ (move $\lambda v = \lambda I v$ to the left side). If
$\det(M - \lambda I) \neq 0$, the matrix $M - \lambda I$ can be undone, and
undoing it on both sides gives $v = 0$: no eigenvector. So eigenvalues are
exactly the numbers with

$$p(\lambda) = \det(M - \lambda I) = 0.$$

By the Leibniz formula every term of $\det(M - \lambda I)$ is a product of $n$
entries, and at most $n$ of them contain $\lambda$; so $p$ is a polynomial of
```

```
degree $n$. A theorem of algebra (the *fundamental theorem of algebra*) says
that such a polynomial has exactly $n$ roots $\lambda_1, \dots, \lambda_n$ when
complex numbers are allowed and a repeated root is counted as often as its
multiplicity says; so an $n \times n$ matrix has $n$ eigenvalues, some of which
may be complex or repeated.

**Trace and determinant.** A polynomial of degree $n$ whose highest term is
$(-\lambda)^n$ and whose roots are $\lambda_1, \dots, \lambda_n$ is

$$p(\lambda) = (\lambda_1 - \lambda)(\lambda_2 - \lambda)\cdots(\lambda_n -
\lambda).$$

Setting $\lambda = 0$ gives $p(0) = \det M = \lambda_1 \lambda_2 \cdots
\lambda_n$: the determinant is the **product** of the eigenvalues. Multiplying
out, the terms with $\lambda^{n-1}$ are
$(-1)^{n-1}(\lambda_1 + \dots + \lambda_n)\lambda^{n-1}$. In the Leibniz
formula only the product of the diagonal entries,
$(M_{11} - \lambda)\cdots(M_{nn} - \lambda)$, contains $\lambda^{n-1}$ (every
other term misses at least two diagonal entries), and its $\lambda^{n-1}$ terms
are $(-1)^{n-1}(M_{11} + \dots + M_{nn})\lambda^{n-1}$. Comparing: the
**sum** of the eigenvalues is the trace.

**The course.** The author's spacetime has the frame metric
$\eta = \mathrm{diag}(+1, +1, +1, +1, -1, -1, -1, -1)$ in the order
$x_0, \dots, x_7$ ($x_1, x_2, x_3$ space, $x_4$ time, $x_5, x_6, x_7$ the
three extra times, $x_0$ the hidden direction) and the metric

$$g = \mathrm{diag}\big(\cot^2 z, e^{2a_4} s, e^{2a_4} s, e^{2a_4} s, -1,
-b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s, -b_4 e^{-2a_4} s\big),\quad
s = \sin^{1/3} z,\ z = 6 H x_0,$$

with a function $a_4(x_4)$ and a positive function $b_4(x_4)$ of the time
($b_4 = 1$ in the background of the Revision record), whose extra-time entries
shrink like $e^{-2a_4}$ as $a_4$ grows (for constant $b_4$): the extra
times deflate exponentially. "Signature (4,4)" means: four positive and four
negative eigenvalues. The eight real $16 \times 16$ gamma matrices obey
$(\gamma^a)^2 = \eta^{aa} I$, which fixes their eigenvalues; and the matrix
$B = -i C \gamma^{(x_4)}$ of the record, which gives the charge density of
the fields of the theory, is Hermitian with eigenvalues $+1$ and $-1$.
```

Text cell:

```
## 5. A 2 x 2 example by hand

Take $M$ with the rows $(2, 1)$ and $(1, 2)$. Line by line:

$$\det(M - \lambda I) = (2 - \lambda)(2 - \lambda) - 1 \cdot 1$$

(the $2 \times 2$ determinant $ad - bc$ of the matrix with rows
$(2 - \lambda, 1)$ and $(1, 2 - \lambda)$),

$$= \lambda^2 - 4\lambda + 4 - 1 = \lambda^2 - 4\lambda + 3$$
```

```
(multiply out), $= (\lambda - 1)(\lambda - 3)$ (two numbers with product 3 and
sum 4). So the eigenvalues are 1 and 3. For $\lambda = 3$ the equation
$(M - 3I)v = 0$ reads $-v_1 + v_2 = 0$ (both rows say the same), so
$v = (1, 1)$; for $\lambda = 1$ it reads $v_1 + v_2 = 0$, so $v = (1, -1)$.
Check: $3 + 1 = 4 = \mathrm{tr}\,M$ and $3 \cdot 1 = 3 = 4 - 1 = \det M$.

The next cell repeats this with sympy (‘factor‘ writes a polynomial as a
product, ‘solve‘ finds its roots), checks $M v = \lambda v$ for both
eigenvectors, and compares with numpy’s ‘eigh‘ (the eigenvalue program for
symmetric matrices; it returns the eigenvalues from the smallest up and the
eigenvectors, of length 1, as the columns of a matrix).
```

```

Text cell:

```
The next cell shows the meaning of the result. It takes 721 points on the unit
circle (all vectors of length 1), multiplies each by $M$ and draws the image,
an ellipse. The two eigenvector directions $(1, 1)/\sqrt 2$ and
$(1, -1)/\sqrt 2$ are drawn with their images: they keep their direction and
are stretched by 3 and by 1. The vector $u = (1, 0)$ is drawn as well: its
image $M u = (2, 1)$ points in another direction. The cell checks that the
longest and the shortest image have the lengths 3 and 1, the two eigenvalues
(for a symmetric matrix the ellipse's half-axes are the eigenvalues' sizes).
```

In [3]:

## 6. The characteristic polynomial and the chain matrix

The next cell takes the $3 \times 3$ *chain matrix* $T_3$ with 2 on the
diagonal and $-1$ just above and just below it. Its characteristic polynomial,
multiplied out by sympy, is $-\lambda^3 + 6\lambda^2 - 10\lambda + 4 =
-(\lambda - 2)(\lambda^2 - 4\lambda + 2)$, with the roots $2$ and
$2 \pm \sqrt 2$ (the quadratic formula: $\lambda = 2 \pm \sqrt{4 - 2}$). The
cell checks the roots, the sum rule ($6 = \mathrm{tr}\,T_3$) and the product
rule ($(2 - \sqrt 2) \cdot 2 \cdot (2 + \sqrt 2) = 2 \cdot (4 - 2) = 4 =
\det T_3$), and draws $p(\lambda)$ with its three roots.
```

In [4]:

```
T3 = sp.Matrix([[2, -1, 0], [-1, 2, -1], [0, -1, 2]])
p3 = sp.expand((T3 - lam * sp.eye(3)).det())

Text cell:

```
The chain matrix $T_n$ of any size $n$ has an exact solution. Row $j$ of
$T_n v$ is $-v_{j-1} + 2v_j - v_{j+1}$, with $v_0 = v_{n+1} = 0$ (the rows at
the ends have only one neighbour). Try $v_j = \sin(j\theta)$:

$$\sin((j-1)\theta) + \sin((j+1)\theta) = 2\sin(j\theta)\cos\theta$$

(the addition theorems $\sin(x \pm y) = \sin x\cos y \pm \cos x\sin y$ with
$x = j\theta$, $y = \theta$, added: the $\cos x \sin y$ terms cancel), so

$$-v_{j-1} + 2v_j - v_{j+1} = (2 - 2\cos\theta)\sin(j\theta).$$

The start $v_0 = \sin 0 = 0$ holds for every $\theta$; the end
$v_{n+1} = \sin((n+1)\theta) = 0$ holds for $\theta = k\pi/(n+1)$,
$k = 1, \dots, n$. So the eigenvalues are $\lambda_k = 2 - 2\cos(k\pi/(n+1))$
and the eigenvectors are sine waves sampled at the points $j = 1, \dots, n$.
This matrix comes back whenever a second derivative is computed on a grid of
points; then the sine waves are the shapes of a vibrating string or of a
quantum particle in a box. The next cell checks the formula for $n = 10$ with
numpy and draws the first three eigenvectors and all ten eigenvalues.

## 7. Real matrices with complex eigenvalues: rotations and boosts

The rotation matrix $R(\alpha)$ with rows $(\cos\alpha, -\sin\alpha)$ and
$(\sin\alpha, \cos\alpha)$ turns every vector (notebook 01b), so for
```

```
$0 < \alpha < \pi$ no real direction is kept. Its characteristic polynomial is

$$(\cos\alpha - \lambda)^2 + \sin^2\alpha = \lambda^2 - 2\cos\alpha\,\lambda +
1$$

(multiply out and use $\cos^2\alpha + \sin^2\alpha = 1$), with the roots
$\lambda = \cos\alpha \pm \sqrt{\cos^2\alpha - 1} = \cos\alpha \pm
i\sin\alpha = e^{\pm i\alpha}$: complex numbers of modulus 1, with the complex
eigenvectors $(1, \mp i)$. For $\alpha = \pi/2$, $R$ is the matrix $J$ of
notebook 01b with $J^2 = -I$, and its eigenvalues are $\pm i$.

The boost $\Lambda(\varphi)$ with rows $(\cosh\varphi, \sinh\varphi)$ and
$(\sinh\varphi, \cosh\varphi)$ has the characteristic polynomial
$\lambda^2 - 2\cosh\varphi\,\lambda + 1$ (now
$\cosh^2\varphi - \sinh^2\varphi = 1$), with the real roots
$\cosh\varphi \pm \sinh\varphi = e^{\pm\varphi}$ and the eigenvectors
$(1, \pm 1)$, the two light-like directions.

A real matrix can have complex eigenvalues, but they come in pairs: taking the
complex conjugate of $M v = \lambda v$ for a real $M$ gives
$M v^* = \lambda^* v^*$, so $\lambda^*$ is an eigenvalue too. The next cell
checks all of this exactly with sympy (‘expand_complex‘ writes a number as
real part plus $i$ times imaginary part) and draws the eigenvalues.

## 8. Symmetric matrices: real eigenvalues, perpendicular eigenvectors

**Claim 1.** A real symmetric matrix $S$ has only real eigenvalues. **Proof**,
line by line. Let $S v = \lambda v$ with a column $v \neq 0$ that may be
complex.

- Conjugate and transpose both sides: $v^\dagger S^\dagger = \lambda^*
  v^\dagger$, and $S^\dagger = S$ because $S$ is real ($S^* = S$) and
  symmetric ($S^T = S$); so $v^\dagger S = \lambda^* v^\dagger$.
```

```
- Multiply $S v = \lambda v$ from the left by $v^\dagger$:
  $v^\dagger S v = \lambda\, v^\dagger v$.
- Multiply $v^\dagger S = \lambda^* v^\dagger$ from the right by $v$:
  $v^\dagger S v = \lambda^*\, v^\dagger v$.
- Subtract the two lines: $0 = (\lambda - \lambda^*)\, v^\dagger v$.
- $v^\dagger v = |v_1|^2 + \dots + |v_n|^2 > 0$, so $\lambda = \lambda^*$:
  $\lambda$ is real.

The same lines, with $S^\dagger = S$ as the only property used, prove it for a
complex **Hermitian** matrix.

**Claim 2.** Eigenvectors of a symmetric matrix with different eigenvalues are
perpendicular. **Proof.** Let $S u = \lambda u$, $S w = \mu w$, $\lambda \neq
\mu$. Then $u^T S w = \mu\, u^T w$, and also $u^T S w = (S^T u)^T w = (S u)^T w
= \lambda\, u^T w$. Subtracting: $(\lambda - \mu)\, u^T w = 0$, so
$u^T w = 0$.

Hence (and one can show this also when eigenvalues repeat) $S = O \Lambda O^T$,
with the eigenvalues on the diagonal of $\Lambda$ and the eigenvectors as the
columns of an orthogonal matrix $O$. The next cell checks this on 300 random
symmetric $8 \times 8$ matrices $S = A + A^T$ and contrasts them with the 300
non-symmetric matrices $A$, whose eigenvalues are often complex.

## 9. The signature and Sylvester's law of inertia

A symmetric matrix $S$ defines the quadratic form $Q(v) = v^T S v$. For the
frame metric, $Q(v) = \eta_{ab} v^a v^b$ is the squared length of notebook
```

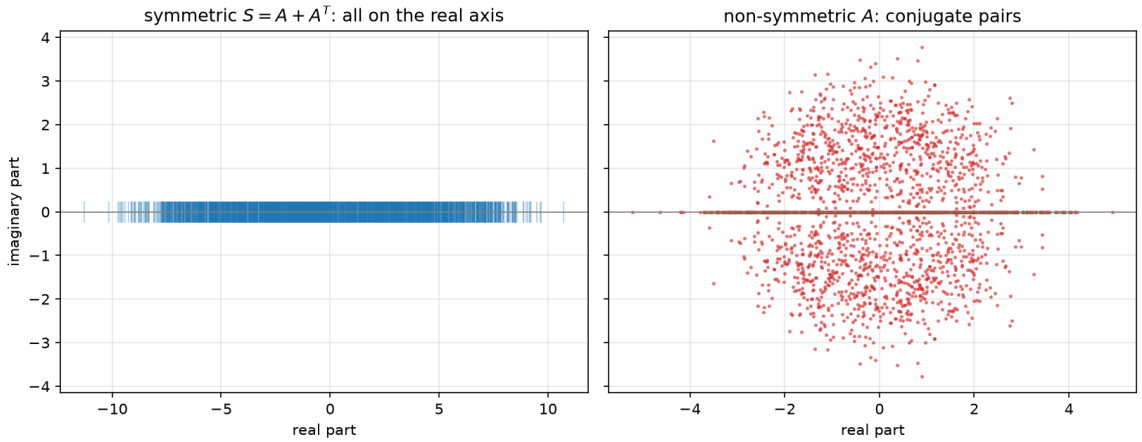

Figure 45: The eigenvalues of 300 random real 8×8 matrices in the complex plane (horizontal axis real part, vertical axis imaginary part, pure numbers). Left: the symmetric matrices $S = A + A^T$; every one of the 2400 eigenvalues lies on the real axis (blue strokes). Right: the non-symmetric matrices A (red dots); many eigenvalues are complex, and the picture is mirror-symmetric in the real axis because complex eigenvalues of a real matrix come in conjugate pairs. (Notebook 01g, figure 5.)

```
01e. In the eigenvector coordinates $v = O w$ (the columns of $O$ are the
eigenvectors of $S$) it becomes $Q = \lambda_1 w_1^2 + \dots + \lambda_n
w_n^2$, because $O^T S O = \Lambda$. So the **signature** $(p, q)$, the
numbers of positive and negative eigenvalues, says in how many perpendicular
directions $Q$ is positive and in how many negative.

A change of coordinates $v = P w$ with an invertible matrix $P$ gives
$Q = w^T (P^T S P) w$: the matrix of the form becomes $P^T S P$. Its
eigenvalues are different, but **Sylvester's law of inertia** says that the
signature is the same. The reason in words: let $S$ have $p$ and $P^T S P$
have $p'$ positive eigenvalues, and suppose $p' < p$. On every nonzero
combination of the $p$ eigenvectors of $S$ with positive eigenvalues,
$Q > 0$. On every combination of the $n - p'$ vectors $P u$, where $u$ runs
through the eigenvectors of $P^T S P$ with eigenvalues $\leq 0$, $Q \leq 0$.
Together these are $p + n - p' > n$ vectors in $n$-dimensional space, so a
nonzero combination of the first kind equals a combination of the second
kind, and on that vector $Q > 0$ and $Q \leq 0$ at once, which is
impossible. So $p' \geq p$; exchanging the roles of the two matrices gives
$p \geq p'$, and the same argument for $-S$ counts the negative eigenvalues.
So the signature (4,4) of the author's spacetime is a property of the
spacetime, not of the coordinates used to describe it.

The next cell reads $\eta$ from the Revision record, finds its eigenvalues
(for a diagonal matrix: its diagonal entries) and its signature, and checks the
law on 2000 random invertible matrices $P$ (it also makes sure that no
eigenvalue is so close to 0 that rounding could change its sign: each must be
larger than 1000 times the rounding error, $2.2 \times 10^{-16}$ times the
largest size). Then it reads the author's metric
from the record and counts the signs of its eigenvalues on a grid of 61 values
of $a_4$ from $-3$ to 3, 50 values of $z$ in $(0, \pi/2)$ and the three values
```

```
$b_4 = 0.5$, 1 and 2; their product must be $\det g = b_4^3 \cos^2 z > 0$.

## 10. The eigenvalues of the gamma matrices

The eight real gamma matrices of the Revision record obey
$(\gamma^a)^2 = \eta^{aa} I$ (the Clifford relation with equal indices). If
$\gamma^a v = \lambda v$, then, line by line,

$$(\gamma^a)^2 v = \gamma^a(\lambda v) = \lambda\,\gamma^a v = \lambda^2 v$$

(apply $\gamma^a$ twice; a number can be moved in front), and also
$(\gamma^a)^2 v = \eta^{aa} v$. So $\lambda^2 = \eta^{aa}$:
$\lambda = \pm 1$ for the space-like directions $x_0, x_1, x_2, x_3$ and
$\lambda = \pm i$ for the time-like directions $x_4, \dots, x_7$.

How many of each? The trace is 0: for any $b \neq a$,
$\mathrm{tr}\,\gamma^a = \eta^{bb}\,\mathrm{tr}(\gamma^b\gamma^b\gamma^a)$
(insert $\eta^{bb}(\gamma^b)^2 = \eta^{bb}\eta^{bb} I = I$),
$= \eta^{bb}\,\mathrm{tr}(\gamma^b\gamma^a\gamma^b)$ (the trace does not
change when the first factor is moved to the end),
$= -\eta^{bb}\,\mathrm{tr}(\gamma^b\gamma^b\gamma^a)$ (the anticommutation
```

```
$\gamma^a\gamma^b = -\gamma^b\gamma^a$), $= -\mathrm{tr}\,\gamma^a$. A number
equal to its own negative is 0. The trace is the sum of the 16 eigenvalues, so
$+1$ and $-1$ (or $+i$ and $-i$) occur 8 times each: the characteristic
polynomial is $(\lambda^2 - \eta^{aa})^8$.

More generally, for any vector $v$ the matrix $\gamma(v) = v_a\gamma^a$ (with
$v_a = \eta_{ab} v^b$) squares to $\gamma(v)^2 = v_a v_b \gamma^a \gamma^b =
\tfrac12 v_a v_b (\gamma^a\gamma^b + \gamma^b\gamma^a) = v_a v_b \eta^{ab} I =
Q(v)\, I$ (only the symmetric part of $\gamma^a\gamma^b$ counts, notebook 01e),
so its eigenvalues are $\pm\sqrt{Q(v)}$: real for a space-like, imaginary for a
time-like and 0 for a light-like $v$. A light-like $v$ gives a *nilpotent*
matrix: $\gamma(v) \neq 0$ but $\gamma(v)^2 = 0$. The next cell checks all of
this with the matrices of the record.

## 11. A Hermitian matrix of the record: B and its signature (8,8)

The record stores the matrix $B = -i\, C\gamma^{(x_4)}$, where
$C = \gamma^{(x_0)}\gamma^{(x_1)}\gamma^{(x_2)}\gamma^{(x_3)}$ is real. $B$ is
```

```
complex: its real part is 0, its imaginary part a real $16 \times 16$ matrix of
entries $-1$, 0, 1. In the theory of the course $B$ gives the charge density
$J^{(x_4)} = \Psi^\dagger B \Psi$ of the fields. Its properties, line by line:

- $B$ is Hermitian ($B^\dagger = B$); for a matrix $iA$ with real $A$ this
  means $(iA)^\dagger = -i A^T = iA$, that is $A^T = -A$: the imaginary part is
  antisymmetric. By section 8 its eigenvalues are real.
- $B^2 = I$, so as in section 10 every eigenvalue has $\lambda^2 = 1$:
  $\lambda = \pm 1$.
- $\mathrm{tr}\,B = 0$, so $+1$ and $-1$ occur 8 times each: the signature
  (8,8), and the characteristic polynomial is $(\lambda - 1)^8(\lambda + 1)^8$.

Because half of the eigenvalues of $B$ are negative, the charge
$\Psi^\dagger B \Psi$ can be positive or negative: the record calls it an
indefinite form, and for the quantised field it leads to an indefinite
(Krein) state space: a space of states whose product of two states, built with
$B$ as in $\Psi^\dagger B \Psi$, takes the place of the dot product, so that a
state can have a negative "squared length" (the dot product of an ordinary
vector with itself is never negative). The next cell checks the four properties
exactly with sympy and with numpy (‘eigh‘ also works for Hermitian matrices; its
eigenvectors are perpendicular in the sense $u^\dagger w = 0$).
```

## 12. How a computer finds an eigenvalue: power iteration

A computer does not find eigenvalues as the roots of $\det(M - \lambda I)$
(that polynomial is very sensitive to rounding for large matrices); it
transforms the matrix step by step. The simplest such method is **power
iteration**. Write a starting vector as a sum of eigenvectors,
$x_0 = c_1 u_1 + c_2 u_2 + \dots$, with $|\lambda_1| > |\lambda_2| \geq \dots$.
Multiplying by $M$ $k$ times gives

$$M^k x_0 = c_1 \lambda_1^k u_1 + c_2 \lambda_2^k u_2 + \dots =
\lambda_1^k\Big(c_1 u_1 + c_2 (\lambda_2/\lambda_1)^k u_2 + \dots\Big)$$

(each eigenvector is only multiplied by its eigenvalue; then $\lambda_1^k$ is
taken out), so the direction approaches $u_1$, and the error shrinks by the
factor $|\lambda_2/\lambda_1|$ in each step. Rescaling to length 1 after each
step keeps the numbers from growing. The next cell runs 40 steps from
$x_0 = (1, 0)$ for the matrix $M$ of section 5 (factor $1/3$) and from
$(1, 0, 0)$ for $T_3$ of section 6 (factor $2/(2 + \sqrt 2) = 2 - \sqrt 2
\approx 0.586$), measures the distance to the true eigenvector and checks the
factor.
```

In [18]:

```
def power_iteration(matrix, start, steps):
    """Multiply by matrix and rescale to length 1, steps times; return the
```

```
    distances to the eigenvector of the largest eigenvalue after each step."""

## 14. What this notebook showed

- The eigenvalues of a square matrix $M$ are the roots of its characteristic
  polynomial $\det(M - \lambda I)$; they add up to the trace and multiply to
  the determinant (derived, and checked for $2 \times 2$ and $3 \times 3$
  examples). An eigenvector keeps its direction; for a symmetric matrix the
  unit circle becomes an ellipse whose half-axes lie along the eigenvectors.
- The chain matrix $T_n$ has the eigenvalues $2 - 2\cos(k\pi/(n+1))$ and sampled
  sine waves as eigenvectors (derived, and checked for $n = 10$).
- Real rotations have the complex eigenvalues $e^{\pm i\alpha}$ (for $J$:
  $\pm i$), boosts the real eigenvalues $e^{\pm\varphi}$ with light-like
  eigenvectors; complex eigenvalues of a real matrix come in conjugate pairs.
- Symmetric and Hermitian matrices have real eigenvalues and perpendicular
  eigenvectors (proved; checked on 300 random matrices).
- The frame metric $\eta$ and the author's metric $g$ have four positive and
  four negative eigenvalues, the signature (4,4), at every point; the deflation
  of the extra times shrinks their eigenvalues towards 0 without changing their
  sign, and the product of the eigenvalues is $\det g = b_4^3 \cos^2 z$. No change of
  coordinates changes the signature (Sylvester's law of inertia, checked on 2000
  random coordinate changes).
- The real gamma matrices of the record have the eigenvalues $\pm 1$
  (space-like directions) or $\pm i$ (time-like directions), eight times each,
  because $(\gamma^a)^2 = \eta^{aa} I$ and $\mathrm{tr}\,\gamma^a = 0$; the
  matrix $\gamma(v) = v_a\gamma^a$ has the eigenvalues $\pm\sqrt{Q(v)}$ and is
  nilpotent for a light-like $v$.
- The Hermitian matrix $B = -iC\gamma^{(x_4)}$ of the record has eight
  eigenvalues $+1$ and eight $-1$: the signature (8,8), which makes the charge
  $\Psi^\dagger B \Psi$ an indefinite form.
- Power iteration finds the eigenvector of the largest eigenvalue; each step
  shrinks the error by $|\lambda_2/\lambda_1|$.
```

1.41 Line-by-line walk-through of Notebook 01g

The notebook has nineteen code cells, In [1] to In [19]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.40 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.39; its code is the set-up code explained in Section 1.9, with `NOTEBOOK_ID = "01g"`. It prints Set-up of notebook 01g complete: repository folder found, helpers defined.

In [2], a 2 × 2 example.

```
import math  # square roots and pi

import numpy as np  # arrays and numerical linear algebra
import sympy as sp  # exact algebra
```

The modules: `math` for square roots and π, numpy for numerical linear algebra (its sub-module `np.linalg` holds the eigenvalue programs), sympy for exact algebra.

```
lam = sp.Symbol("lambda")  # the unknown eigenvalue
M = sp.Matrix([[2, 1], [1, 2]])
char_poly = sp.expand((M - lam * sp.eye(2)).det())  # det(M - lambda I)
say(f"det(M - lambda I) = {char_poly} = {sp.factor(char_poly)}")
```

A symbol for λ (named `lam`, because `lambda` is a reserved word of Python), the matrix M, and its characteristic polynomial $\det(M - \lambda I)$, multiplied out. `sp.factor` writes it as a product. Output: `det(M - lambda I) = lambda**2 - 4*lambda + 3 = (lambda - 3)*(lambda - 1)`.

```
eigenvalues = sorted(sp.solve(char_poly, lam))  # the roots
check(eigenvalues == [1, 3], "the eigenvalues of M are 1 and 3")
v3, v1 = sp.Matrix([1, 1]), sp.Matrix([1, -1])
check(M * v3 == 3 * v3 and M * v1 == 1 * v1,
      "M (1, 1) = 3 (1, 1) and M (1, -1) = 1 (1, -1)")
check(sum(eigenvalues) == M.trace() == 4 and eigenvalues[0] * eigenvalues[1]
      == M.det() == 3, "sum of the eigenvalues = trace = 4, product = det = 3")
```

`sp.solve(p, lam)` returns the roots of p, and `sorted` puts them in increasing order. Three exact checks: the eigenvalues 1 and 3, the two eigenvector equations $Mv = \lambda v$, and the sum and product rules of Section 1.34.

```
values, vectors = np.linalg.eigh(np.array(M.tolist(), dtype=float))
# The sign of an eigenvector is free (v and -v are both eigenvectors), and
# different computers may return either; make the first entry of each column
# positive so that every computer prints the same.
vectors = vectors * np.sign(vectors[0])
```

`np.linalg.eigh` is numpy's eigenvalue program for symmetric (and Hermitian) matrices; it returns the eigenvalues from the smallest up and the eigenvectors, of length 1, as the columns of a matrix. Because v and $-v$ are both eigenvectors, the program may return either; `np.sign(vectors[0])` is the sign of the first entry of each column, and multiplying each column by it makes that entry positive, so that every computer prints the same.

```
say(f"numpy eigh: eigenvalues {values.round(12).tolist()}")
say(f"            eigenvectors (columns) {vectors.round(6).tolist()}")
check(np.allclose(values, [1.0, 3.0], atol=1e-12) and
      abs(abs(vectors[:, 1] @ np.array([1.0, 1.0])) - math.sqrt(2)) < 1e-12,
      "numpy finds the eigenvalues 1, 3 and the direction (1, 1) for 3")
```

The results, rounded (`.round(12)`: 12 digits after the point), printed as `[1.0, 3.0]` and the columns `[[0.707107, 0.707107], [-0.707107, 0.707107]]` (the rows of the matrix are printed; its first column is $(1,-1)/\sqrt{2}$, its second $(1,1)/\sqrt{2}$, and $1/\sqrt{2} = 0.707107$). The check: the eigenvalues, and the second column has the dot product $\pm\sqrt{2}$ with $(1,1)$, so it is $\pm(1,1)/\sqrt{2}$. The cell prints four PASS lines.

In [3], the unit circle becomes an ellipse.

```
angles = np.linspace(0.0, 2.0 * np.pi, 721)  # every half degree
circle = np.array([np.cos(angles), np.sin(angles)])  # 2 rows: x and y
M_numbers = np.array(M.tolist(), dtype=float)
ellipse = M_numbers @ circle  # every point of the circle multiplied by M
lengths = np.sqrt((ellipse ** 2).sum(axis=0))  # length of every image
say(f"longest image {lengths.max():.6f}, shortest image {lengths.min():.6f}")
check(abs(lengths.max() - 3) < 1e-9 and abs(lengths.min() - 1) < 1e-4,
      "the unit circle becomes an ellipse with half-axes 3 and 1")
```

721 points of the unit circle (every half degree) as a table with two rows; their images under M; the length of every image (square the entries, add the two rows with `.sum(axis=0)`, take the root). Output: longest image 3.000000, shortest image 1.000000, the half-axes of Section 1.34. The check uses a tight tolerance for the longest and a looser one, 10^{-4}, for the shortest length; the printed values show that both are met with room to spare.

```
fig, ax = plt.subplots(figsize=(6.6, 6.0))
ax.plot(circle[0], circle[1], color="0.6", label="unit circle")
ax.plot(ellipse[0], ellipse[1], color="black", label="its image under $M$")
arrows = [(np.array([1.0, 1.0]) / math.sqrt(2), "tab:red", "eigenvector, 3"),
          (np.array([1.0, -1.0]) / math.sqrt(2), "tab:blue", "eigenvector, 1"),
          (np.array([1.0, 0.0]), "tab:green", "u = (1, 0)")]
```

The circle in grey and the ellipse in black; a list of three vectors of length 1 with colours and names: the two eigenvectors and $u = (1,0)$.

```
for vector, color, name in arrows:
    image = M_numbers @ vector
    # the image first: thick, dashed and see-through, so that the vector drawn
    # on top of it stays visible where the two coincide
    ax.annotate("", xy=image, xytext=(0, 0),
                arrowprops={"arrowstyle": "->", "color": color, "lw": 5,
                            "linestyle": "--", "alpha": 0.4})
    ax.annotate("", xy=vector, xytext=(0, 0),
                arrowprops={"arrowstyle": "->", "color": color, "lw": 2})
    ax.plot([], [], color=color, lw=2, label=f"{name} (dashed: its image)")
```

For each vector its image is drawn first as a thick, dashed, see-through arrow, then the vector itself as a thin solid arrow on top. `ax.plot([], [], ...)` draws nothing (empty lists) but makes an entry for the legend.

```
ax.set_aspect("equal")
ax.set_xlim(-3.3, 3.3)
```

```
ax.set_ylim(-3.3, 3.3)
ax.set_xlabel("first component")
ax.set_ylabel("second component")
ax.set_title("$M$ with rows (2, 1), (1, 2) acting on the plane")
ax.legend(loc="lower right", fontsize=8)
save_figure(fig, "circle_to_ellipse",
            "The unit circle (grey) and its image under the matrix $M$ with rows "
            ...)
```

What Figure 01g.1 shows: the red eigenvector and its image point the same way, the image three times as long; the blue eigenvector's image lies on top of it (eigenvalue 1); the green u is turned to $(2, 1)$; the ellipse's long axis lies along the red, its short axis along the blue direction.

In [4], the characteristic polynomial of the chain matrix.

```
T3 = sp.Matrix([[2, -1, 0], [-1, 2, -1], [0, -1, 2]])
p3 = sp.expand((T3 - lam * sp.eye(3)).det())
say(f"det(T3 - lambda I) = {p3} = {sp.factor(p3)}")
roots3 = sorted(sp.roots(p3, lam).keys(), key=lambda r: float(r))  # small first
say(f"roots: {roots3}")
```

The chain matrix T_3 and its characteristic polynomial, multiplied out and factored: `-lambda**3 + 6*lambda**2 - 10*lambda + 4 = -(lambda - 2)*(lambda**2 - 4*lambda + 2)`, as derived in Section 1.34. `sp.roots` returns a dictionary from the roots to their multiplicities; its keys are sorted by their numerical value (`key=lambda r: float(r)` tells `sorted` to compare the roots as decimal numbers). Output: `roots: [2 - sqrt(2), 2, sqrt(2) + 2]`.

```
check(roots3 == [2 - sp.sqrt(2), 2, 2 + sp.sqrt(2)],
      "the eigenvalues of T3 are 2 - sqrt 2, 2 and 2 + sqrt 2")
check(sp.simplify(sum(roots3) - T3.trace()) == 0 and
      sp.simplify(roots3[0] * roots3[1] * roots3[2] - T3.det()) == 0,
      "sum of the eigenvalues = trace = 6, product = det = 4")
```

The exact roots and the sum and product rules. Two PASS lines.

```
p3_numbers = sp.lambdify(lam, p3, "numpy")  # the polynomial as a numpy function
grid = np.linspace(-0.2, 4.2, 400)
fig, ax = plt.subplots(figsize=(7.2, 4.2))
ax.plot(grid, p3_numbers(grid), color="black", label="$p(\\lambda)$")
ax.axhline(0.0, color="0.5", lw=0.8)
root_values = [float(r) for r in roots3]
ax.plot(root_values, [0.0, 0.0, 0.0], "o", color="tab:red", ms=8,
        label="roots = eigenvalues")
```

The polynomial as a numpy function, drawn for 400 values of λ from -0.2 to 4.2, a grey zero line, and the three roots as red dots on it.

```
for r_text, r_value in zip(["$2 - \\sqrt{2}$", "$2$", "$2 + \\sqrt{2}$"],
                           root_values):
```

```
    ax.text(r_value, 0.6, r_text, ha="center", color="tab:red")
ax.set_xlabel("$\\lambda$")
ax.set_ylabel("$p(\\lambda) = \\det(T_3 - \\lambda I)$")
ax.set_title("The characteristic polynomial of the chain matrix $T_3$")
ax.set_ylim(-3.0, 5.0)
ax.legend(loc="upper right");
save_figure(fig, "characteristic_polynomial",
            "The characteristic polynomial $p(\\lambda) = \\det(T_3 - \\lambda I) "
            ...)
```

Each root labelled above its dot, axis labels, title, range, legend (with the semicolon of Section 1.9). What Figure 01g.2 shows: the cubic curve crosses zero exactly at $2 - \sqrt{2}$, 2 and $2 + \sqrt{2}$, and meets the vertical axis at $p(0) = 4 = \det T_3$.

In [5], the chain matrix of size 10.

```
n = 10
T = 2 * np.eye(n) - np.eye(n, k=1) - np.eye(n, k=-1)  # k=1: just above the diagonal
values_T, vectors_T = np.linalg.eigh(T)  # eigenvalues from the smallest up
k = np.arange(1, n + 1)
formula = 2 - 2 * np.cos(k * np.pi / (n + 1))
say(f"largest difference eigh - formula: {np.max(np.abs(values_T - formula)):.1e}")
check(np.allclose(values_T, formula, rtol=0, atol=1e-12),
      "T_10 has the eigenvalues 2 - 2 cos(k pi/11), k = 1 ... 10")
```

`np.eye(n, k=1)` has ones just above the diagonal and `k=-1` just below, so `T` is T_{10}. Its eigenvalues from numpy are compared with the formula $2 - 2\cos(k\pi/11)$ of Section 1.35 (which is increasing in k, the same order). Output: largest difference eigh - formula: 8.9e-16.

```
j = np.arange(1, n + 1)  # the points of the chain
sines = np.array([np.sin(j * kk * np.pi / (n + 1)) for kk in k]).T  # columns
sines = sines / np.sqrt((sines ** 2).sum(axis=0))  # length 1
overlaps = np.abs((vectors_T * sines).sum(axis=0))  # |cos of the angle|, column-wise
check(np.allclose(overlaps, 1.0, rtol=0, atol=1e-12),
      "every eigenvector of T_10 is a sampled sine wave sin(j k pi/11)")
```

The sampled sine waves $\sin(jk\pi/11)$, one column for each k (`.T` turns the rows into columns), scaled to length 1. For two vectors of length 1 the dot product is the cosine of the angle between them; it is ± 1 exactly when they point along the same line. `(vectors_T * sines).sum(axis=0)` computes the dot product of each numpy eigenvector with its sine wave, column by column; all ten must be ± 1. Two PASS lines.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.2))
fine = np.linspace(0, n + 1, 400)  # the sine curves between the points
for kk, color in zip((1, 2, 3), ("tab:blue", "tab:orange", "tab:green")):
    column = vectors_T[:, kk - 1] * np.sign(vectors_T[0, kk - 1])  # first entry > 0
    scale = column[0] / math.sin(kk * math.pi / (n + 1))
    left.plot(fine, scale * np.sin(fine * kk * math.pi / (n + 1)), color=color, lw=1)
    left.plot(j, column, "o", color=color, label=f"$k = {kk}$")
```

For the three smallest eigenvalues ($k = 1, 2, 3$): the eigenvector, with the sign chosen so that its first entry is positive, is drawn as dots at the points $j = 1, \ldots, 10$; through them the continuous sine curve, scaled to pass through the first dot (`scale`), drawn at 400 points from 0 to 11.

```
left.axhline(0, color="0.5", lw=0.8)
left.set_xlabel("point $j$ of the chain")
left.set_ylabel("entry $v_j$ of the eigenvector")
left.set_title("the first three eigenvectors of $T_{10}$")
left.legend(fontsize=8)
fine_k = np.linspace(0, n + 1, 400)
right.plot(fine_k, 2 - 2 * np.cos(fine_k * np.pi / (n + 1)), color="black", lw=1,
           label="$2 - 2\\cos(k\\pi/11)$")
right.plot(k, values_T, "o", color="tab:red", label="eigenvalues from numpy")
right.set_xlabel("number $k$")
right.set_ylabel("eigenvalue $\\lambda_k$")
right.set_title("the ten eigenvalues of $T_{10}$")
right.legend(fontsize=8, loc="upper left")
fig.tight_layout()
save_figure(fig, "chain_matrix",
            "The $10 \\times 10$ chain matrix $T_{10}$ (2 on the diagonal, $-1$ "
            ...)
```

Labels of the left panel; on the right the curve $2 - 2\cos(k\pi/11)$ for continuous k and the ten numpy eigenvalues as red dots. What Figure 01g.3 shows: the dots of the eigenvectors lie on half a sine wave ($k = 1$), a full wave ($k = 2$) and one and a half waves ($k = 3$), each vanishing at $j = 0$ and $j = 11$; the ten eigenvalues lie on the cosine curve.

In [6], rotations, boosts and conjugate pairs.

```
alpha, phi = sp.symbols("alpha phi", real=True)
R = sp.Matrix([[sp.cos(alpha), -sp.sin(alpha)], [sp.sin(alpha), sp.cos(alpha)]])
p_rot = sp.expand((R - lam * sp.eye(2)).det())
check(sp.simplify(p_rot - (lam ** 2 - 2 * sp.cos(alpha) * lam + 1)) == 0,
      "det(R - lambda I) = lambda^2 - 2 cos(alpha) lambda + 1")
```

The rotation matrix with a symbolic angle, and its characteristic polynomial, which must simplify to $\lambda^2 - 2\cos\alpha\,\lambda + 1$ (Section 1.35).

```
rot_ok = True
for sign_value in (1, -1):  # the eigenvalue e^(+-i alpha), eigenvector (1, -+i)
    eigen = sp.exp(sign_value * sp.I * alpha)
    vector = sp.Matrix([1, -sign_value * sp.I])
    gap = (R * vector - eigen * vector).applyfunc(
        lambda e: sp.simplify(sp.expand_complex(e)))
    rot_ok &= gap == sp.zeros(2, 1)
check(rot_ok, "R(alpha) (1, -+i) = e^(+-i alpha) (1, -+i) for every angle alpha")
```

For both signs: the eigenvalue $e^{\pm i\alpha}$ and the eigenvector $(1, \mp i)$; `gap` is $Rv - \lambda v$ with every entry written as real part plus i times imaginary part (`expand_complex` uses Euler's formula) and simplified; it must be the zero column, for every angle.

```
J = R.subs(alpha, sp.pi / 2)  # the matrix of i
say(f"J = {J.tolist()}, eigenvalues {sorted(J.eigenvals().keys(), key=str)}")
check(set(J.eigenvals().keys()) == {sp.I, -sp.I}, "the eigenvalues of J are +i, -i")
```

`.subs(alpha, sp.pi / 2)` puts $\alpha = \pi/2$ into the matrix, which gives J. `.eigenvals()` returns sympy's exact eigenvalues as a dictionary (eigenvalue: multiplicity); they are printed sorted by their text (`key=str`), so that the order is the same on every computer. Output: `J = [[0, -1], [1, 0]], eigenvalues [-I, I]`.

```
boost = sp.Matrix([[sp.cosh(phi), sp.sinh(phi)], [sp.sinh(phi), sp.cosh(phi)]])
boost_ok = True
for sign_value in (1, -1):  # the eigenvalue e^(+-phi), eigenvector (1, +-1)
    vector = sp.Matrix([1, sign_value])
    gap = (boost * vector - sp.exp(sign_value * phi) * vector).applyfunc(
        lambda e: sp.simplify(e.rewrite(sp.exp)))
    boost_ok &= gap == sp.zeros(2, 1)
check(boost_ok, "a boost has the real eigenvalues e^(+-phi) with the light-like "
      "eigenvectors (1, +-1)")
```

The boost and its two eigenvalue equations, checked as in Notebook 01b, In [12] (Section 1.17).

```
generator = np.random.default_rng(12345)  # random numbers with a fixed seed
pairs_ok = True
for _ in range(200):  # 200 random real 5 x 5 matrices
    found = np.linalg.eigvals(generator.normal(size=(5, 5)))
    pairs_ok &= np.allclose(np.sort_complex(found), np.sort_complex(found.conj()))
check(pairs_ok, "the complex eigenvalues of 200 random real 5 x 5 matrices come "
      "in conjugate pairs")
```

`np.linalg.eigvals` is numpy's eigenvalue program for any square matrix; it returns complex numbers. For each of 200 random real 5×5 matrices the list of eigenvalues, sorted (`np.sort_complex` sorts by real part, then imaginary part), must equal the sorted list of their conjugates: the conjugate-pair theorem of Section 1.35. The cell prints five PASS lines.

In [7], the eigenvalues of rotations and boosts as pictures.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.6))
circle_line = np.exp(1j * np.linspace(0, 2 * np.pi, 400))
left.plot(circle_line.real, circle_line.imag, color="0.75", lw=1)
colors = plt.cm.viridis(np.linspace(0.0, 0.9, 6))  # six colours from a colour map
```

The unit circle of the complex plane in light grey, and six colours taken from the colour map viridis (`plt.cm.viridis(x)` gives the colour at the position x between 0 and 1).

```
for step, color in zip(range(1, 7), colors):
    angle = step * np.pi / 6
    eig = np.linalg.eigvals(np.array([[np.cos(angle), -np.sin(angle)],
                                      [np.sin(angle), np.cos(angle)]]))
    left.plot(eig.real, eig.imag, "o", color=color, ms=8,
              label=f"$\\alpha = {30 * step}$ degrees")
```

For the angles $\pi/6, 2\pi/6, \ldots, \pi$ (30 to 180 degrees) the two eigenvalues of the rotation matrix, computed by numpy, are drawn in the complex plane.

```
left.annotate("$+i$ (the matrix $J$)", xy=(0, 1), xytext=(0.25, 1.25), fontsize=8,
              arrowprops={"arrowstyle": "->"})
left.set_aspect("equal")
left.set_xlim(-1.5, 1.5)
left.set_ylim(-1.5, 1.5)
left.set_xlabel("real part")
left.set_ylabel("imaginary part")
left.set_title("rotations: $e^{\\pm i\\alpha}$")
left.legend(fontsize=7, loc="lower left")
```

An arrow with a label points at $+i$, the eigenvalue of J (90 degrees); scales, labels, title and legend.

```
rapidity = np.linspace(0.0, 1.5, 200)
right.plot(rapidity, np.exp(rapidity), color="tab:red", label="$e^{\\varphi}$")
right.plot(rapidity, np.exp(-rapidity), color="tab:blue", label="$e^{-\\varphi}$")
right.plot(rapidity, np.exp(rapidity) * np.exp(-rapidity), "k--", lw=1,
           label="their product = 1")
right.set_xlabel("rapidity $\\varphi$")
right.set_ylabel("eigenvalue")
right.set_title("boosts: real eigenvalues $e^{\\pm\\varphi}$")
right.legend(fontsize=8)
fig.tight_layout()
save_figure(fig, "rotation_and_boost",
            "Left: the eigenvalues $e^{\\pm i\\alpha}$ of the real rotation "
            ...)
```

On the right the two eigenvalues of a boost and their product against the rapidity. What Figure 01g.4 shows: on the left each pair of dots lies on the unit circle, mirror-symmetric in the real axis, the pair moving from near 1 (30 degrees) to -1 (180 degrees, where the two coincide); on the right one growing and one decaying exponential whose product stays 1.

In [8], symmetric matrices, on random examples.

```
symmetric_spectra, general_spectra = [], []
largest_imaginary = 0.0
decomposition_error = 0.0
for _ in range(300):
    A = generator.normal(size=(8, 8))  # a random real 8 x 8 matrix
    S = A + A.T  # its symmetric part, doubled
    found = np.linalg.eigvals(S)  # the general program: complex results allowed
    largest_imaginary = max(largest_imaginary, float(np.max(np.abs(found.imag))))
    symmetric_spectra.append(found.real)
    general_spectra.append(np.linalg.eigvals(A))
```

For 300 random 8×8 matrices A: the symmetric matrix $S = A + A^T$, its eigenvalues found by the general program `eigvals`, which would report complex values if there were any, and the largest imaginary part found so far; the real parts are kept for the picture, and so are the eigenvalues of A itself.

```
    w, O = np.linalg.eigh(S)  # eigenvalues w and eigenvectors (columns of O)
    decomposition_error = max(
        decomposition_error,
        float(np.max(np.abs(O.T @ O - np.eye(8)))),  # O^T O = I
        float(np.max(np.abs(O @ np.diag(w) @ O.T - S))))  # O Lambda O^T = S
```

`eigh` gives the eigenvalues `w` and the matrix `O` of eigenvectors; the largest deviation from $O^T O = I$ and from $O\Lambda O^T = S$ (with $\Lambda =$ `np.diag(w)`) is kept: the spectral theorem of Section 1.36.

```
general_all = np.concatenate(general_spectra)
complex_share = float(np.mean(np.abs(general_all.imag) > 1e-9))
say(f"symmetric: largest imaginary part {largest_imaginary:.1e}; "
    f"non-symmetric: share of complex eigenvalues {complex_share:.3f}")
```

`np.concatenate` joins the 300 lists into one of 2400 eigenvalues; `complex_share` is the fraction with an imaginary part larger than 10^{-9}. Output: largest imaginary part 0.0e+00; share of complex eigenvalues 0.677.

```
check(largest_imaginary < 1e-9, "300 random symmetric matrices: every eigenvalue "
      "is real")
check(decomposition_error < 1e-12,
      "S = O Lambda O^T with O^T O = I for all 300 symmetric matrices")
check(complex_share > 0.3, "the non-symmetric matrices have many complex "
      "eigenvalues")
report("share of complex eigenvalues of 300 random 8 x 8 matrices",
       f"{complex_share:.3f}")
```

Three PASS lines and the RESULT line 0.677 (COMPUTED).

In [9], all 2400 eigenvalues of each kind.

```
symmetric_all = np.concatenate(symmetric_spectra)
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.4), sharey=True)
left.plot(symmetric_all, np.zeros_like(symmetric_all), "|", color="tab:blue",
          ms=14, alpha=0.3)
left.set_title("symmetric $S = A + A^T$: all on the real axis")
right.plot(general_all.real, general_all.imag, ".", color="tab:red", ms=3,
           alpha=0.5)
right.set_title("non-symmetric $A$: conjugate pairs")
```

On the left the 2400 real eigenvalues of the symmetric matrices as short vertical strokes (`"|"`) on the real axis (imaginary part 0, `np.zeros_like`); on the right the 2400 eigenvalues of the non-symmetric matrices as small red dots in the complex plane.

```
for ax in (left, right):
    ax.axhline(0.0, color="0.5", lw=0.8)
    ax.set_xlabel("real part")
left.set_ylabel("imaginary part")
fig.tight_layout()
```

```
save_figure(fig, "random_spectra",
            "The eigenvalues of 300 random real $8 \\times 8$ matrices in the "
            ...)
```

What Figure 01g.5 shows: on the left everything lies on the real axis; on the right a cloud of dots that is mirror-symmetric in the real axis, with a band of real eigenvalues on it.

In [10], the signature of eta and Sylvester's law.

```
algebra = json.loads(repository_file("Revision/algebra/gammas.json")
                     .read_text(encoding="utf-8"))
names = algebra["coordinates"]  # ["x0", ..., "x7"]
eta = algebra["eta"]  # the diagonal of the frame metric
eta_matrix = np.diag(np.array(eta, dtype=float))
eta_values = np.linalg.eigvalsh(eta_matrix)  # eigenvalues from the smallest up
signature = (int((eta_values > 0).sum()), int((eta_values < 0).sum()))
say(f"eigenvalues of eta: {eta_values.tolist()}; signature {signature}")
```

η from the record, as an 8×8 matrix; `eigvalsh` returns only the eigenvalues of a symmetric matrix. The signature is the pair of the counts of positive and of negative eigenvalues. Output: eight eigenvalues, four -1.0 and four 1.0, signature (4, 4).

```
algebra_report = json.loads(repository_file(
    "Revision/algebra/reports/python-algebra.json").read_text(encoding="utf-8"))
verdicts = {c["name"]: c["verdict"] for c in algebra_report["checks"]}
check(signature == (4, 4) and verdicts["coordinate_map"] == "pass",
      "eta has 4 positive and 4 negative eigenvalues: the signature (4,4)",
      record="Revision/algebra/reports/python-algebra.json, check coordinate_map")
```

The verdicts of the record's report, and the check of the signature, which reproduces the record's check `coordinate_map`.

```
sylvester_counts = set()
smallest_size, largest_size = np.inf, 0.0
transformed_spectra = []
for trial in range(2000):
    P = generator.normal(size=(8, 8))  # a random matrix (invertible: det != 0)
    changed = np.linalg.eigvalsh(P.T @ eta_matrix @ P)
    sylvester_counts.add((int((changed > 0).sum()), int((changed < 0).sum())))
    smallest_size = min(smallest_size, float(np.min(np.abs(changed))))
    largest_size = max(largest_size, float(np.max(np.abs(changed))))
    if trial < 40:
        transformed_spectra.append(changed)
```

For 2000 random matrices P (a random matrix has a determinant that is not 0, except in cases of probability 0): the eigenvalues of $P^T \eta P$, the signature found (collected in a **set**, which keeps each different value once), and the smallest and largest size of an eigenvalue seen (`np.inf` is infinity, a start value larger than any number). The spectra of the first 40 are kept for the picture.

```
say(f"signatures of P^T eta P found: {sorted(sylvester_counts)}; eigenvalue "
    f"sizes from {smallest_size:.1e} to {largest_size:.1f}")
# Rounding changes an eigenvalue by about 2.2e-16 times the largest size; the
# signs are reliable if the smallest size is far above that.
reliable = smallest_size > 1000 * 2.2e-16 * largest_size
check(sylvester_counts == {(4, 4)} and reliable, "Sylvester: P^T eta P has the "
      "signature (4,4) for all 2000 random P, although its eigenvalues change")
```

Output: signatures found [(4, 4)]; eigenvalue sizes from 1.4e-08 to 37.0. A computed eigenvalue can be off by about machine epsilon (2.2×10^{-16}, Section 1.4) times the largest size; the signs can be trusted if the smallest size is more than 1000 times that, here 1.4×10^{-8} against 8.1×10^{-12}. The check: only the signature (4,4) occurred, and the signs are reliable. Two PASS lines.

In [11], the signature of the author's metric.

```
a4 = sp.Symbol("a4", real=True)  # the value of a4(x4) at one time
b4 = sp.Symbol("b4", positive=True)  # the value of b4(x4) at one time
z = sp.Symbol("z", positive=True)  # z = 6 H x0, between 0 and pi/2
curvature = json.loads(repository_file("Revision/gkd_lovelock/results/curvature.json")
                       .read_text(encoding="utf-8"))

def from_record(text):
    """The record's Mathematica text as a sympy expression."""
    text = text.replace("a4[x4]", "a4").replace("b4[x4]", "b4")
    text = text.replace("Sin[6*H*x0]", "sin(z)")
    text = text.replace("Cot[6*H*x0]", "cot(z)").replace("^", "**")
    return sp.sympify(text, locals={"a4": a4, "b4": b4, "z": z, "E": sp.E})
```

The symbols, the record file and the translation function, exactly as in Notebook 01a, In [17] (Section 1.25).

```
g_record = [from_record(text) for text in curvature["metricDiagonal"]]
# a4, b4, z -> the 8 numbers on the diagonal
metric_numbers = sp.lambdify((a4, b4, z), g_record, "numpy")
signs_ok, product_error, points = True, 0.0, 0
for b4_value in (0.5, 1.0, 2.0):
    for a4_value in np.linspace(-3.0, 3.0, 61):
        for z_value in np.linspace(0.05, np.pi / 2 - 0.05, 50):
            g_values = np.linalg.eigvalsh(np.diag(np.array(
                metric_numbers(a4_value, b4_value, z_value), dtype=float)))
            signs_ok &= ((int((g_values > 0).sum()), int((g_values < 0).sum()))
                         == (4, 4))
            product_error = max(product_error, abs(
                np.prod(g_values) / b4_value ** 3 - np.cos(z_value) ** 2))
            points += 1
```

The record's metric as a numpy function of a_4, b_4 and z; then, for $b_4 = 0.5$, 1 and 2, at 61 values of a_4 from -3 to 3 and 50 values of z inside $(0, \pi/2)$ (9150 points in all, counted in `points`), the eight eigenvalues of the 8×8 metric (computed by numpy, although for a diagonal matrix they are its entries), their signs and the distance of their product (`np.prod`) divided by b_4^3 from $\cos^2 z$.

```
check(signs_ok and points == 9150, "the author's metric has the signature (4,4) "
      "at all 9150 grid points (a4, z, b4)")
lovelock_report = json.loads(repository_file(
    "Revision/gkd_lovelock/results/python-lovelock-report.json")
    .read_text(encoding="utf-8"))
root_verdict = {c["name"]: c["verdict"]
                for c in lovelock_report["checks"]}["sqrt_abs_det_g"]
check(product_error < 1e-12 and root_verdict == "PASS",
      "the product of the eight eigenvalues is det g = b4^3 cos(z)^2 at every grid "
      "point",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "sqrt_abs_det_g")
```

Two checks: the signature at all 9150 points, and the product of the eigenvalues equal to $\det g = b_4^3 \cos^2 z$ to 10^{-12} (relative to b_4^3), together with the record's verdict PASS of the check `sqrt_abs_det_g`. Two PASS lines.

In [12], the picture of the signatures.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.5, 4.6))
for column, spectrum in enumerate(transformed_spectra):
    colors_column = ["tab:red" if value > 0 else "tab:blue" for value in spectrum]
    left.scatter(np.full(8, column + 1), spectrum, c=colors_column, s=12)
left.axhline(0.0, color="black", lw=0.8)
left.set_yscale("symlog", linthresh=0.001)  # linear between -0.001 and 0.001
left.set_xlabel("random matrix $P$ (number)")
left.set_ylabel("eigenvalues of $P^T \\eta P$")
left.set_title("always 4 positive (red) and 4 negative (blue)")
```

On the left, for each of the first 40 matrices P, its eight eigenvalues as a column of dots at the horizontal position $1, \ldots, 40$ (`np.full(8, column + 1)` is a list of eight equal positions; `scatter` draws dots with one colour each, red for positive and blue for negative). The vertical axis is **symmetric logarithmic** (`"symlog"`): linear between -0.001 and 0.001 and logarithmic outside, so that large and small values of both signs fit.

```
a4_line = np.linspace(-3.0, 3.0, 301)
curves = np.array([metric_numbers(value, 1.0, 0.9) for value in a4_line],
                  dtype=float)  # at b4 = 1
styles = [("tab:green", "hidden $x_0$", 0), ("tab:red", "space $x_1, x_2, x_3$", 1),
          ("tab:gray", "time $x_4$", 4), ("tab:blue", "extra times $x_5, x_6, x_7$", 5)]
for color, label, index in styles:
    right.plot(a4_line, curves[:, index], color=color, lw=2, label=label)
```

On the right the eight diagonal entries of the metric (its eigenvalues) at $z = 0.9$ and $b_4 = 1$ for 301 values of a_4, as a table with one column per entry; one curve is drawn for each kind of direction (column 0 for the hidden direction x_0, 1 for space, 4 for the time, 5 for the extra times: the column of x_k is k).

```
right.axhline(0.0, color="black", lw=0.8)
right.set_yscale("symlog", linthresh=0.1)
```

```
right.set_xlabel("$a_4$")
right.set_ylabel("eigenvalues of $g$ at $z = 0.9$")
right.set_title("the signs never change: signature (4,4)")
right.legend(fontsize=8, loc="upper left")
fig.tight_layout()
```

A symmetric logarithmic axis linear between -0.1 and 0.1, labels and legend.

```
# how many of the 320 drawn eigenvalues are smaller than 0.001 in size
tiny = sum(int((np.abs(spectrum) < 0.001).sum()) for spectrum in transformed_spectra)
tiny_text = "the one eigenvalue" if tiny == 1 else f"the {tiny} eigenvalues"
tiny_verb = "sits" if tiny == 1 else "sit"  # singular or plural
save_figure(fig, "signature",
            "Left: the eight eigenvalues of $P^T \\eta P$ for 40 random matrices "
            ...
            f"{tiny_text} smaller than 0.001 in size {tiny_verb} on the zero "
            "line, but none is zero. "
            ...)
```

The caption is written from the data: it counts how many of the $40 \cdot 8 = 320$ drawn eigenvalues are smaller than 0.001 in size (they appear on the zero line of the left panel) and chooses the singular or the plural wording. `tiny == 1` is True when exactly one is that small; `x if condition else y` is a **conditional expression**, which gives `x` when the condition is True and `y` otherwise. So `tiny_text` is "the one eigenvalue" or, for example, "the 3 eigenvalues", and `tiny_verb` is "sits" or "sit". The first `...` stands for three ordinary text lines of the caption; the f-string line inserts `tiny_text` and `tiny_verb` where their names stand in braces. In this run two eigenvalues are that small, and the caption reads "the 2 eigenvalues smaller than 0.001 in size sit on the zero line, but none is zero.". The last `...)` stands for the rest of the caption, about the right panel, which has no insertions. What Figure 01g.6 shows: on the left every column has four red and four blue dots although the values change from column to column; on the right the blue extra-time curve (the three equal extra-time eigenvalues) rises towards 0 as a_4 grows, the deflation, without ever crossing it, while the red space curve grows and the grey and green curves stay constant.

In [13], the eigenvalues of the gamma matrices.

```
gamma = [np.array(matrix, dtype=int) for matrix in algebra["gamma"]]  # gamma^a
polynomials_ok, traces_ok, numeric_ok = True, True, True
for name, eta_aa, g_a in zip(names, eta, gamma):
    poly = sp.Matrix(g_a.tolist()).charpoly(lam).as_expr()  # det(lambda I - g_a)
    polynomials_ok &= sp.expand(poly - (lam ** 2 - eta_aa) ** 8) == 0
    traces_ok &= int(np.trace(g_a)) == 0
    found = np.linalg.eigvals(g_a.astype(float))
```

For each gamma matrix: its exact characteristic polynomial (`charpoly(lam)` gives $\det(\lambda I - \gamma^a)$ as a polynomial object, `.as_expr()` as an ordinary sympy expression), compared with $(\lambda^2 - \eta_{aa})^8$; its trace, which must be 0; and its eigenvalues from numpy.

```
    if eta_aa == 1:  # space-like: +1 and -1, eight times each
        numeric_ok &= bool(np.allclose(np.sort(found.real), [-1] * 8 + [1] * 8)
```

```
                        and np.allclose(found.imag, 0))
    else:  # time-like: +i and -i, eight times each
        numeric_ok &= bool(np.allclose(found.real, 0)
                        and np.allclose(np.sort(found.imag), [-1] * 8 + [1] * 8))
    say(f"gamma^({name}): eta {eta_aa:+d}, trace {int(np.trace(g_a))}, "
        f"characteristic polynomial {sp.factor(poly)}")
```

For a space-like direction the sorted real parts must be eight -1 followed by eight $+1$ (`[-1] * 8 + [1] * 8`) and the imaginary parts 0; for a time-like direction the real parts 0 and the sorted imaginary parts eight -1 and eight $+1$. One line per matrix with its factored polynomial: `(lambda - 1)**8*(lambda + 1)**8` for x0, x1, x2, x3 and `(lambda**2 + 1)**8` for x4 to x7.

```
check(traces_ok and polynomials_ok,
      "every gamma^a has trace 0 and the characteristic polynomial "
      "(lambda^2 - eta_aa)^8", record="Revision/algebra/reports/python-algebra.json, "
      "check clifford_relation (the relations with equal indices)")
check(numeric_ok and verdicts["symmetry_pattern"] == "pass",
      "numpy: +1 and -1 (x0, x1, x2, x3: symmetric matrices) or +i and -i "
      "(x4 ... x7: antisymmetric matrices), 8 times each",
      record="Revision/algebra/reports/python-algebra.json, check symmetry_pattern")
```

Two PASS lines, each with the record check it rests on: the eigenvalues follow from the relations with equal indices of `clifford_relation`, and the symmetric (real eigenvalues) or antisymmetric (imaginary eigenvalues) pattern is the record's `symmetry_pattern`.

In [14], the gamma matrix of a vector.

```
def gamma_of(vector):
    """gamma(v) = v_a gamma^a with v_a = eta_ab v^b (whole numbers)."""
    lowered = [eta[a] * int(vector[a]) for a in range(8)]
    return sum(lowered[a] * gamma[a] for a in range(8))

def squared_length(vector):
    """Q(v) = eta_ab v^a v^b."""
    return sum(eta[a] * int(vector[a]) ** 2 for a in range(8))
```

`gamma_of` lowers the index of the vector and forms $v_a\gamma^a$, a 16×16 matrix of whole numbers; `squared_length` is $Q(v)$, written out for the diagonal η.

```
unit = np.eye(8, dtype=int)
examples = [("e(x1)", unit[1]), ("e(x5)", unit[5]), ("e(x1) + e(x5)", unit[1] + unit[5]),
            ("(1, 2, ..., 8)", np.arange(1, 9))]
example_spectra = {}
squares_ok, nilpotent_ok = True, True
```

The four example vectors of Section 1.27 with their names; a dictionary for their spectra.

```
for label, vector in examples:
    matrix = gamma_of(vector)
```

```
    q = squared_length(vector)
    squares_ok &= bool((matrix @ matrix == q * np.eye(16, dtype=int)).all())
    if q == 0:  # light-like: exact answer from sympy
        poly = sp.Matrix(matrix.tolist()).charpoly(lam).as_expr()
        nilpotent_ok &= poly == lam ** 16 and bool(np.count_nonzero(matrix) > 0)
        example_spectra[label] = np.zeros(16, dtype=complex)
```

For each example: $\gamma(v)$, $Q(v)$, and the exact check $\gamma(v)^2 = Q(v)I$. For the light-like vector the characteristic polynomial is computed exactly; it must be λ^{16}, and the matrix must have nonzero entries: nilpotent, not zero. Its spectrum, sixteen zeros, is stored for the picture. (numpy is not reliable for a nilpotent matrix, whose eigenvectors do not fill the space; the exact computation is.)

```
    else:
        example_spectra[label] = np.linalg.eigvals(matrix.astype(float))
        target = np.sqrt(complex(q))  # sqrt(Q), imaginary for Q < 0
        # count the eigenvalues within 1e-9 of +sqrt(Q) and of -sqrt(Q)
        near_plus = int((np.abs(example_spectra[label] - target) < 1e-9).sum())
        near_minus = int((np.abs(example_spectra[label] + target) < 1e-9).sum())
        squares_ok &= near_plus == 8 and near_minus == 8
    say(f"v = {label}: Q(v) = {q}, gamma(v)^2 = Q(v) I")
```

Otherwise numpy's eigenvalues are compared with $\pm\sqrt{Q}$ (`np.sqrt(complex(q))` is imaginary for a negative Q): exactly eight must lie within 10^{-9} of each. One line per example: Q(v) = 1, -1, 0 and -144.

```
for _ in range(100):  # random vectors with whole-number components -5 ... 5
    vector = generator.integers(-5, 6, size=8)
    matrix = gamma_of(vector)
    squares_ok &= bool((matrix @ matrix
                        == squared_length(vector) * np.eye(16, dtype=int)).all())
check(squares_ok, "gamma(v)^2 = Q(v) I exactly and the eigenvalues are +-sqrt(Q(v)) "
      "(4 examples and 100 random vectors)")
check(nilpotent_ok, "a light-like v gives a nilpotent gamma(v): not zero, square "
      "zero, characteristic polynomial lambda^16")
```

The square rule for 100 random whole-number vectors, exactly; then the two checks. Two PASS lines.

In [15], the eigenvalues as pictures.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.8))
for name, eta_aa, g_a in zip(names, eta, gamma):
    found = np.linalg.eigvals(g_a.astype(float))
    color = "tab:red" if eta_aa == 1 else "tab:blue"
    left.plot(found.real, found.imag, "o", color=color, ms=10, alpha=0.3)
```

On the left the 16 eigenvalues of each gamma matrix in the complex plane, red for space-like and blue for time-like directions, see-through (`alpha=0.3`), so that the many dots on top of each other show as a darker colour.

```
left.text(1.0, 0.18, "$+1$: 8 times\n($x_0, x_1, x_2, x_3$)", ha="center",
          fontsize=8)
left.text(-1.0, 0.18, "$-1$: 8 times", ha="center", fontsize=8)
left.text(0.08, 1.0, "$+i$: 8 times ($x_4 \\dots x_7$)", fontsize=8)
left.text(0.08, -1.05, "$-i$: 8 times", fontsize=8)
left.set_xlim(-1.6, 1.9)
left.set_ylim(-1.5, 1.5)
left.set_title("the eight gamma matrices")
```

Four labels at the four points ± 1, $\pm i$, the ranges and the title.

```
markers = {"e(x1)": ("s", "tab:red"), "e(x5)": ("D", "tab:blue"),
           "e(x1) + e(x5)": ("*", "black"), "(1, 2, ..., 8)": ("o", "tab:purple")}
for label, spectrum in example_spectra.items():
    shape, color = markers[label]
    right.plot(spectrum.real, spectrum.imag, shape, color=color, ms=10,
               label=f"$v$ = {label}, $Q = {squared_length(dict(examples)[label])}$")
right.set_xlim(-3.0, 3.0)
right.set_ylim(-8.0, 8.0)
right.set_title("$\\gamma(v) = v_a \\gamma^a$: eigenvalues $\\pm\\sqrt{Q(v)}$")
right.legend(fontsize=8, loc="lower right")
```

On the right the spectra of the four matrices $\gamma(v)$, each with its own marker shape (square, diamond, star, circle); `dict(examples)[label]` looks up the vector of a name, to print its Q in the legend.

```
for ax in (left, right):
    ax.axhline(0.0, color="0.5", lw=0.8)
    ax.axvline(0.0, color="0.5", lw=0.8)
    ax.set_xlabel("real part")
    ax.set_ylabel("imaginary part")
fig.tight_layout()
save_figure(fig, "gamma_eigenvalues",
            "Eigenvalues in the complex plane (horizontal axis real part, vertical "
            ...)
```

Axes and labels on both panels. What Figure 01g.7 shows: on the left the dots sit only at ± 1 and $\pm i$; on the right ± 1, $\pm i$, a single point at 0 for the light-like vector, and $\pm i\sqrt{48} \approx \pm 6.93i$.

In [16], the Hermitian matrix B of the record.

```
B = sp.Matrix(algebra["B"]["re"]) + sp.I * sp.Matrix(algebra["B"]["im"])
C = sp.Matrix(algebra["C"])
check(B == -sp.I * C * sp.Matrix(algebra["gamma"][4]),
      "the record's B equals -i C gamma^(x4) computed from its C and gamma^(x4)")
```

The record stores B as its real part `re` and its imaginary part `im`; the exact sympy matrix is built from them. C is read as well, and the check confirms $B = -iC\gamma^{(x_4)}$ exactly ($\gamma^{(x_4)}$ is entry 4 of the list, which holds the matrices in the author's order $x_0, \dots, x_7$).

```
poly_B = sp.factor(B.charpoly(lam).as_expr())
real_part_zero = sp.Matrix(algebra["B"]["re"]).is_zero_matrix  # True or False
say(f"B: real part zero {real_part_zero}, trace {B.trace()}, characteristic "
    f"polynomial {poly_B}")
```

The factored characteristic polynomial of B, and whether its real part is the zero matrix. Output:

```
B: real part zero True, trace 0, characteristic polynomial (lambda - 1)**8*(lambda +
    1)**8
```

```
check(B.H == B and B * B == sp.eye(16) and B.trace() == 0
      and sp.expand(poly_B - (lam - 1) ** 8 * (lam + 1) ** 8) == 0,
      "B is Hermitian, B^2 = I, tr B = 0, characteristic polynomial "
      "(lambda - 1)^8 (lambda + 1)^8: the signature (8,8)",
      record="Revision/algebra/reports/python-algebra.json, check "
             "B_hermitian_involution_signature")
```

`B.H` is sympy's conjugate transpose $B^\dagger$. The four properties of Section 1.37, exactly; this reproduces the record's check `B_hermitian_involution_signature`.

```
B_numbers = np.array(B.tolist(), dtype=complex)
values_B, vectors_B = np.linalg.eigh(B_numbers)
unitary_error = float(np.max(np.abs(vectors_B.conj().T @ vectors_B - np.eye(16))))
say(f"numpy eigh: eigenvalues {values_B.round(12).tolist()}")
```

B as a complex numpy array; `eigh` works for Hermitian matrices too. `vectors_B.conj().T` is the conjugate transpose of the eigenvector matrix; its product with the eigenvector matrix must be I (eigenvectors perpendicular in the sense $u^\dagger w = 0$, of length 1). Output: eight -1.0 and eight 1.0.

```
theory = json.loads(repository_file(
    "Revision/theory/reports/python-field-theory.json").read_text(encoding="utf-8"))
theory_verdict = {c["name"]: c["verdict"] for c in theory["checks"]}["B_properties"]
krein_entry = theory["formulas"]["quantisation"]["krein"]  # a sentence of the record
say(f"the record's quantisation entry: {krein_entry}")
```

A second record, the theory report: the verdict of its check `B_properties` and its entry `formulas`, `quantisation`, `krein`, a sentence that is printed: B Hermitian, B^2 = 1, signature (8,8): indefinite (Krein) state space.

```
check(np.allclose(values_B, [-1.0] * 8 + [1.0] * 8, rtol=0, atol=1e-12)
      and unitary_error < 1e-12 and theory_verdict == "pass",
      "numpy: eight eigenvalues -1 and eight +1, perpendicular eigenvectors",
      record="Revision/theory/reports/python-field-theory.json, check B_properties")
```

The numerical eigenvalues, the perpendicular eigenvectors and the record's verdict; this reproduces the check `B_properties`. The cell prints three PASS lines.

In [17], the picture of B.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.6),
                                  gridspec_kw={"width_ratios": [1.1, 1]})
image = left.imshow(B_numbers.imag, cmap="RdBu_r", vmin=-1, vmax=1)
left.grid(False)
ticks = range(0, 16, 3)
left.set_xticks(ticks, [str(t + 1) for t in ticks])
left.set_yticks(ticks, [str(t + 1) for t in ticks])
left.set_xlabel("column")
left.set_ylabel("row")
left.set_title("imaginary part of $B$ (the real part is 0)")
fig.colorbar(image, ax=left, shrink=0.8, ticks=[-1, 0, 1])
```

The imaginary part of B as a heat map, with labels at every third row and column (`range(0, 16, 3)` is 0, 3, 6, 9, 12, 15, labelled 1, 4, 7, 10, 13, 16), and a colour bar.

```
right.bar(np.arange(1, 17), values_B,
          color=["tab:blue" if value < 0 else "tab:red" for value in values_B])
right.axhline(0.0, color="black", lw=0.8)
right.set_xticks(range(1, 17, 3))
right.set_ylim(-1.4, 1.4)
right.set_xlabel("eigenvalue number (from the smallest up)")
right.set_ylabel("eigenvalue of $B$")
right.set_title("eight $-1$ and eight $+1$: signature (8,8)")
fig.tight_layout()
save_figure(fig, "hermitian_b",
            "Left: heat map of the imaginary part of the Hermitian matrix "
            ...)
```

On the right the 16 eigenvalues as bars, blue for negative and red for positive. What Figure 01g.8 shows: on the left a pattern of red and blue squares whose mirror image in the diagonal has the opposite colours (antisymmetric imaginary part); on the right eight bars down and eight up.

In [18], power iteration.

```
def power_iteration(matrix, start, steps):
    """Multiply by matrix and rescale to length 1, steps times; return the
    distances to the eigenvector of the largest eigenvalue after each step."""
    values_m, vectors_m = np.linalg.eigh(matrix)
    top = vectors_m[:, -1]  # the eigenvector of the largest eigenvalue
    x = np.array(start, dtype=float)
    distances = []
```

The function first finds the true answer with `eigh` (the last column belongs to the largest eigenvalue), to measure the error of the iteration; `x` is the starting vector.

```
    for _ in range(steps):
        x = matrix @ x
        x = x / np.sqrt(x @ x)  # rescale to length 1
        aligned = top if x @ top > 0 else -top  # the sign of an eigenvector is free
        distances.append(float(np.sqrt(((x - aligned) ** 2).sum())))
    return np.array(distances), abs(values_m[-2] / values_m[-1])
```

Each step multiplies by the matrix and divides by the length (`x @ x` is the squared length). The true eigenvector is taken with the sign that points the same way as `x`, and the distance between the two is recorded. The function returns the distances and the factor $|\lambda_2/\lambda_1|$ of Section 1.37 (the second-largest eigenvalue divided by the largest).

```
runs = {"M (2 x 2)": power_iteration(M_numbers, [1, 0], 40),
        "T3 (3 x 3)": power_iteration(np.array(T3.tolist(), dtype=float),
                                      [1, 0, 0], 40)}
factors_ok = True
for label, (distances, ratio) in runs.items():
    measured = distances[11:21] / distances[10:20]  # steps 11 to 20
    say(f"{label}: |lambda2/lambda1| = {ratio:.6f}, measured factors "
        f"{measured.min():.6f} to {measured.max():.6f}")
    factors_ok &= bool(np.all(np.abs(measured - ratio) < 1e-3))
check(factors_ok, "power iteration: each step shrinks the error by |lambda2/lambda1|"
      " (1/3 for M, 2 - sqrt 2 for T3)")
```

40 steps for M from $(1, 0)$ and for T_3 from $(1, 0, 0)$. The measured factors are the ratios of consecutive distances for the steps 11 to 20 (`distances[11:21] / distances[10:20]` divides each distance by the one before); they must agree with $|\lambda_2/\lambda_1|$ to 10^{-3}. Output: M (2 x 2): |lambda2/lambda1| = 0.333333, measured factors 0.333333 to 0.333333, and T3 (3 x 3): 0.585786, measured 0.585786 to 0.585789, and the PASS line.

```
fig, ax = plt.subplots(figsize=(7.5, 4.4))
steps_axis = np.arange(1, 41)
for (label, (distances, ratio)), color in zip(runs.items(), ("tab:red", "tab:blue")):
    # a distance 0 (exact agreement) is drawn at 1e-17, the bottom of the axis
    ax.semilogy(steps_axis, np.maximum(distances, 1e-17), "o", color=color, ms=4,
                label=label)
    ax.semilogy(steps_axis, distances[0] * ratio ** (steps_axis - 1), "-",
                color=color, lw=1, label=f"factor {ratio:.3f} per step")
```

For both runs: the 40 distances as dots on a logarithmic axis (a distance that is exactly 0 is drawn at 10^{-17}), and the straight line $|\lambda_2/\lambda_1|^{k-1}$ times the first distance.

```
ax.set_ylim(1e-17, 2.0)
ax.set_xlabel("step $k$")
ax.set_ylabel("distance to the eigenvector")
ax.set_title("Power iteration")
ax.legend(fontsize=8);
save_figure(fig, "power_iteration",
            "Power iteration: the distance between the rescaled vector "
            ...)
```

What Figure 01g.9 shows: the red dots (M) fall fast, by the factor 1/3 per step, along their straight line until, after about 33 steps, they reach the rounding level of floating-point numbers; from there on the distance jumps between about 10^{-16} and exactly 0 (drawn at the bottom). The blue dots (T_3) fall more slowly, by 0.586 per step, along their line, down to about 10^{-9} after 40 steps.

In [19], the last check.

```
figure_names = [f"01g_{k}_{name}.png" for k, name in enumerate(
    ["circle_to_ellipse", "characteristic_polynomial", "chain_matrix",
     "rotation_and_boost", "random_spectra", "signature", "gamma_eigenvalues",
     "hermitian_b", "power_iteration"], start=1)]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 9 figure files of this notebook exist")
all_checks_passed()
```

The nine file names are built from their numbers and names (`enumerate(..., start=1)` numbers the list from 1). The last line is ALL 30 CHECKS PASSED (notebook 01g). The 30 checks are: 4 in In [2], 1 in In [3], 2 in In [4], 2 in In [5], 5 in In [6], 3 in In [8], 2 in In [10], 2 in In [11], 2 in In [13], 2 in In [14], 3 in In [16], 1 in In [18] and 1 in In [19].

1.42 The generalized Kronecker delta: the author's definition and its four cases

Why it matters. In eight dimensions the field equations of gravity that the author's theory uses are the **Lovelock equations** (Chapters 11 and 12). Every one of their terms carries a weight, a number $+1$, -1 or 0, given by one combinatorial tool: the **generalized Kronecker delta**. The Revision record computes these weights with a fast program called GKD; this section defines the tool exactly as the author did and proves the rule that GKD uses.

Words. A **label** is a name of a coordinate, here one of $x_0, \dots, x_7$; the computer often numbers them $0, \dots, 7$. Only the question "are two labels equal?" matters below, so the choice of names changes no result. An **index list** is an ordered list of labels, such as (x_1, x_3, x_3); its **length** is the number of its entries (here 3). The ordinary **Kronecker delta** of two labels, $\delta(a, b)$, is 1 if they are equal and 0 otherwise (Section 1.26 wrote it $\delta^a{}_b$).

The author's definition. The author defined the generalized delta in their Mathematica notebook, in the input cell stored in the file as In[87] (their In[54]); the Revision record quotes the cell verbatim in `Revision/gkd_lovelock/results/PROVENANCE_OF_THE_COMPUTATION.md` and lists it in `Revision/gkd_lovelock/results/notebook-input-cells.txt`. In Mathematica's plain-text spelling (`\[Delta]` is the Greek letter δ):

```
k\[Delta][lower_, upper_] /; Length[lower] == Length[upper] :=
    Det[Outer[delta, lower, upper]]
```

In words: for a lower list $(l_1, \dots, l_p)$ and an upper list $(u_1, \dots, u_p)$ of the same length p (the condition after `/;`; for lists of different lengths the definition does not apply and Mathematica leaves the expression unevaluated), build the $p \times p$ matrix whose entry in row i and column j is $\delta(l_i, u_j)$ (`Outer[delta, lower, upper]`), and take its determinant (`Det`). The book writes

$$\delta^{u_1 \dots u_p}_{l_1 \dots l_p} = \det\left[\delta(l_i, u_j)\right]_{i,j=1,\dots,p}.$$

For one index this is the ordinary Kronecker delta: the 1×1 matrix $(\delta(l_1, u_1))$ has this number as its determinant. For two indices the 2×2 determinant gives (PROVED)

$$\delta^{u_1 u_2}_{l_1 l_2} = \det \begin{pmatrix} \delta(l_1, u_1) & \delta(l_1, u_2) \\ \delta(l_2, u_1) & \delta(l_2, u_2) \end{pmatrix} = \delta(l_1, u_1)\,\delta(l_2, u_2) - \delta(l_1, u_2)\,\delta(l_2, u_1)$$

(the definition with $p = 2$; the formula $ad - bc$).

Theorem: the four cases (PROVED). Let $M_{ij} = \delta(l_i, u_j)$.

- (a) If two lower labels are equal, $l_i = l_k$ with $i \neq k$, then the rows i and k of M are equal, so $\det M = 0$ (rule 4 of Section 1.20).
- (b) If two upper labels are equal, two columns of M are equal; the transpose M^T then has two equal rows, so $\det M = \det M^T = 0$ (rules 2 and 4).
- (c) If some lower label l_i is not among the upper labels, row i of M consists of zeros; every term of the Leibniz formula contains one entry of that row, so $\det M = 0$.
- (d) Otherwise the lower labels are p different labels, all among the upper labels, which are p different labels as well; so both lists hold the same p labels, and the lower list is a re-ordering of the upper one. Each l_i equals exactly one upper label $u_{\sigma(i)}$, and σ is a permutation of $1, \ldots, p$. Row i of M has its only 1 in column $\sigma(i)$: M is the permutation matrix of σ, and $\det M = \text{sign}(\sigma)$ (Section 1.20, rule (b) of the three special matrices).

So the generalized delta is 0 when a label is repeated or missing, and otherwise the sign of the permutation that turns the upper list into the lower one. The Revision program GKD (the Rust file `Revision/gkd_lovelock/code/src/gkd.rs`) computes it in exactly this way, without building a matrix: it costs about p^2 comparisons (to count the inversions of σ) instead of the $p!$ terms of the Leibniz formula. The file states this proof in its opening comment, and its tests compare GKD with a literal determinant.

Examples (PROVED). For the lists of length 3 over the labels x_1, x_2, x_3:

lower list	upper list	case	value
(x_1, x_2, x_3)	(x_1, x_2, x_3)	(d), $\sigma = (1, 2, 3)$, no inversion	$+1$
(x_1, x_2, x_3)	(x_2, x_3, x_1)	(d), $\sigma = (3, 1, 2)$, two inversions	$+1$
(x_1, x_2, x_3)	(x_1, x_3, x_2)	(d), $\sigma = (1, 3, 2)$, one inversion	-1
(x_1, x_1, x_3)	(x_1, x_2, x_3)	(a), a repeated lower label	0
(x_1, x_2, x_4)	(x_1, x_2, x_3)	(c), x_4 missing above	0

(In the second row, $l_1 = x_1$ is the third upper label, so $\sigma(1) = 3$; $l_2 = x_2$ is the first, $\sigma(2) = 1$; $l_3 = x_3$ is the second, $\sigma(3) = 2$; the inversions of $(3, 1, 2)$ are the pairs $(3, 1)$ and $(3, 2)$.) The record lists five examples with the labels 1 to 4 in `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `gkd_examples`: $\delta^{12}_{12} = 1$, $\delta^{21}_{12} = -1$, $\delta^{11}_{11} = 0$, $\delta^{231}_{123} = 1$, $\delta^{124}_{123} = 0$ (written there as `kdelta[{1,2},{2,1}] = -1` and so on, lower list first); two more with the labels 0 to 2, and the refusal of lists of different lengths, in `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, check `definition_unequal_lengths_stay_unevaluated`; and the two values that the Rust program prints for itself, $+1$ for the lists $(0, 1, 2)$, $(1, 2, 0)$ and -1 for $(0, 1)$, $(1, 0)$, in `Revision/gkd_lovelock/results/lovelock-report.json`, field `gkdSelfCheck`. Notebook 01c, In [6], reproduces all of them with both the literal determinant and the fast rule (Figure 01c.1 draws the five matrices of the table).

1.43 Counting the values; nine indices in eight dimensions

Two indices (PROVED). With two indices over the eight labels there are $8^2 = 64$ lower lists and 64 upper lists, so $64 \cdot 64 = 4096$ values. A value is not 0 only in case (d): the upper list holds two different labels (there are $8 \cdot 7 = 56$ such lists: 8 choices for the first label, 7 for the second), and the lower list is the same list (value $+1$) or its reverse (value -1). So there are 56 values $+1$, 56 values -1 and $4096 - 112 = 3984$ zeros (Figure 01c.2).

The number of nonzero values (PROVED). In general, with n labels and lists of length $p \le n$: there are $n(n-1)\cdots(n-p+1) = n!/(n-p)!$ upper lists of p different labels (a **falling factorial**: n choices for the first label, $n-1$ for the second, and so on), and $p!$ re-orderings of each, so

$$N_{\neq 0}(n,p) = \frac{n!}{(n-p)!}\, p! \qquad (p \le n), \qquad N_{\neq 0}(n,p) = 0 \qquad (p > n).$$

For $p \ge 2$ half of the re-orderings are even (Section 1.19), so $+1$ and -1 occur equally often; for $p = 1$ every nonzero value is $+1$. For $n = 8$:

length p	**all pairs** 8^{2p}	**value** $+1$	**value** -1	**value 0**
1	64	8	0	56
2	4096	56	56	3984
3	262144	1008	1008	260128
4	16777216	20160	20160	16736896

(for $p = 3$: $8 \cdot 7 \cdot 6 = 336$ lists times $3! = 6$ re-orderings is 2016, half of it 1008; for $p = 4$: $8 \cdot 7 \cdot 6 \cdot 5 = 1680$ times $4! = 24$ is 40320, half of it 20160; the zeros are the rest). The Revision record compared GKD with the author's definition for every pair of lengths 1, 2 and 3, 266,304 pairs in all, and recorded these counts in `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, field `measurements`, entry `gkdComparison`, with the checks `gkd_equals_kdelta_exhaustive_length_1` to `_3`; its Rust self-test compared all 16,777,216 pairs of length 4 (`Revision/gkd_lovelock/results/gkd-selftest.json`). Notebook 01c, In [8] and In [10], repeats both comparisons, every pair, and gets the same counts and no disagreement (COMPUTED, and the counts PROVED by the formula). The nonzero values become rare as p grows: their fraction $N_{\neq 0}(8,p)/8^{2p}$ falls from $1/8$ at $p = 1$ to $8! \cdot 8!/8^{16} \approx 5.8 \times 10^{-6}$ at $p = 8$ (Figures 01c.3 and 01c.4).

A shortcut for the sign (PROVED, with rule 1 of Section 1.20 for general n, which is ASSUMED). When the lower list L is a re-ordering of the upper list U of p different labels, both are re-orderings of the same sorted list $s_1 < s_2 < \cdots < s_p$. Let P_L be the matrix with the entries $(P_L)_{ik} = \delta(l_i, s_k)$ and P_U the one with $(P_U)_{jk} = \delta(u_j, s_k)$; both are permutation matrices. Then

$$(P_L P_U^T)_{ij} = \sum_k \delta(l_i, s_k)\, \delta(u_j, s_k) = \delta(l_i, u_j) = M_{ij}$$

(the matrix product with the transpose; the sum has one nonzero term, the k with $s_k = l_i$, and that term is 1 exactly when $u_j = s_k = l_i$), so $\det M = \det P_L \det P_U^T = \det P_L \det P_U$ (rules 1 and 2). The permutation of P_L sends place i to the place of l_i in the sorted list, and two places $i < j$ are an inversion of it exactly when $l_i > l_j$; so $\det P_L$ is the sign counted by the inversions of the list L itself, $\mathrm{sign}(L)$, and

$$\delta^U_L = \operatorname{sign}(L)\operatorname{sign}(U).$$

This lets numpy compute millions of values at once (Notebook 01c, In [9]).

Nine indices in eight dimensions (PROVED). A list of 9 labels taken from only 8 must repeat a label, by the **pigeonhole principle**: if more than n objects are put into n boxes, some box gets at least two of them. So case (a) applies and the value is 0, for every one of the 8^{18} pairs of lists of length 9. In the **Lovelock tensors** of the theory (the terms of the Lovelock equations built from the **curvature** of spacetime, the measure of how it is bent, Chapters 3 and 11; a **tensor** is a table of numbers labelled by indices, like the metric of Section 1.29, whose entries change in a fixed way when the coordinates are changed, Chapter 3) the generalized delta appears with $2k+1$ indices, $k = 1, 2, 3, \ldots$; the term $k = 4$ would need 9 indices, so it vanishes identically, and the Lovelock sum of an eight-dimensional spacetime stops at $k = 3$. The record checks this in `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `gkd_nine_indices_in_eight_dimensions_vanish`, and `Revision/gkd_lovelock/results/lovelock-report.json`, check `k4_tensor_vanishes`. With 8 labels a nonzero value is still possible: the list $(x_0, \ldots, x_7)$ against its reverse has $8 \cdot 7/2 = 28$ inversions (every one of the $\binom{8}{2} = 28$ pairs is in the wrong order), an even number, so the value is $+1$.

1.44 Contracting one index; the Lovelock trace factors; the Levi-Civita symbol

The contraction identity (PROVED). Take two lists $A = (a_1, \ldots, a_{p-1})$ and $B = (b_1, \ldots, b_{p-1})$, append the same label c to both, and add over all n values of c. Then

$$\sum_c \delta^{a_1 \ldots a_{p-1} c}_{b_1 \ldots b_{p-1} c} = (n - p + 1)\, \delta^{a_1 \ldots a_{p-1}}_{b_1 \ldots b_{p-1}}.$$

Proof by cases. (i) If A or B repeats a label, every extended list repeats it too: every term is 0 by case (a) or (b), and so is the right side. (ii) If A and B consist of different labels but do not hold the same labels, then for each c: if c is a label of A or of B, an extended list repeats it (term 0); if not, the extended lists hold the labels of A plus c and those of B plus c, which still differ (term 0 by case (c)). The right side is 0 as well. (iii) If B is a re-ordering σ of A: for the $p-1$ values of c that are labels of A, the extended lists repeat c (term 0); for each of the other $n - (p-1)$ values, the extended lists are re-ordered by σ with c left at the last place, and that permutation has the same inversions as σ (the last place is in the right order with every other place), so each such term equals $\operatorname{sign}(\sigma)$. Together: $(n - p + 1)\operatorname{sign}(\sigma)$, which is the right side. For $p = 1$ the lists A and B are empty, and the delta of two empty lists is 1 (the determinant of the empty matrix: the Leibniz formula has one term, the empty product, which is 1); the identity then says $\sum_c \delta^c_c = n$, which is $\delta^a{}_a = 8$ of Section 1.26.

The factors of the Lovelock trace identities (PROVED). The Lovelock tensors of order k are built as

$$P_{(k)}{}^h{}_j = \delta^{h h_1 \ldots h_{2k}}_{j j_1 \ldots j_{2k}}\, R^{j_1 j_2}{}_{h_1 h_2} \cdots R^{j_{2k-1} j_{2k}}{}_{h_{2k-1} h_{2k}}, \qquad L_{(k)} = \delta^{h_1 \ldots h_{2k}}_{j_1 \ldots j_{2k}}\, R^{j_1 j_2}{}_{h_1 h_2} \cdots$$

(summation convention over all repeated indices; R is the curvature of spacetime, whose meaning Chapter 3 explains; here only the generalized delta matters). The delta in $P_{(k)}$ has $p = 2k + 1$

indices. The **trace** $\sum_h P_{(k)}{}^h{}_h$ sets $j = h$ and sums: it contracts the first upper index with the first lower one. Moving these two indices from the front to the end of both lists re-orders the rows and the columns of the matrix M by the same permutation, which multiplies the determinant by its sign twice, that is, not at all (rule 3 of Section 1.20 applied once per exchange, to rows and to columns alike). So the contraction identity applies with $n = 8$ and $p = 2k + 1$:

$$\sum_h P_{(k)}{}^h{}_h = (8 - (2k + 1) + 1)\, L_{(k)} = (8 - 2k)\, L_{(k)},$$

with the factors 6, 4 and 2 for $k = 1, 2, 3$. These are exactly the factors of the record's trace identities: `Revision/gkd_lovelock/results/lovelock-report.json`, checks `k1_trace_identity` to `k3_trace_identity` (their texts read `sum_h P_(1)^h_h = (8 - 2) L_(1)` and so on), and `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, checks `k1_trace_equals_6_L1`, `k2_trace_equals_4_L2`, `k3_trace_equals_2_L3`. Notebook 01c, In [14] and In [15], finds the factor $n - p + 1$ for $n = 8$ and every $p = 1$ to 8, and for $n = 4$ and every $p = 1$ to 4 (COMPUTED; Figure 01c.5).

The Levi-Civita symbol (PROVED). The **Levi-Civita symbol** of n labels is the generalized delta with the upper list $(0, 1, \ldots, n - 1)$, all labels in their natural order:

$$\varepsilon_{i_1 \ldots i_n} = \delta^{0\,1\,\ldots\,n-1}_{i_1 \ldots i_n},$$

by case (d) the sign of the list $(i_1, \ldots, i_n)$ if it is a re-ordering of all n labels, and 0 otherwise. For three labels: $\varepsilon_{012} = \varepsilon_{120} = \varepsilon_{201} = +1$, $\varepsilon_{021} = \varepsilon_{102} = \varepsilon_{210} = -1$, and 0 for every list with a repeated label (Figure 01c.6). The product of two of them, summed over their last $n - p$ indices, is

$$\sum_{c_{p+1}, \ldots, c_n} \varepsilon_{a_1 \ldots a_p c_{p+1} \ldots c_n}\, \varepsilon_{b_1 \ldots b_p c_{p+1} \ldots c_n} = (n - p)!\; \delta^{b_1 \ldots b_p}_{a_1 \ldots a_p}.$$

Proof. For full lists ($p = n$), both sides are the product of the signs of the two lists, or 0: by the sign shortcut of Section 1.43, $\delta^B_A = \operatorname{sign}(A) \operatorname{sign}(B) = \varepsilon_A \varepsilon_B$ when both are re-orderings of all labels, and both sides are 0 otherwise. Then contract the last index $n - p$ times with the contraction identity: the first contraction (of a delta with n indices) gives the factor $n - n + 1 = 1$, the next 2, and the last (of a delta with $p + 1$ indices) $n - p$; the product of the factors is $1 \cdot 2 \cdots (n - p) = (n - p)!$.

The author's second route. The author's notebook builds the generalized delta also from two Levi-Civita tensors, in the input cell In[32] (`delta11 = Simplify[(epsilong[-a, -f, ...] epsilong[b, f, ...])/(8 - 1)!]`): the formula above with $n = 8$, $p = 1$ and the divisor 7!. In the author's notation the second ε carries upper indices, raised with the metric, and the minus signs mark lower indices. For the frame metric η, raising all eight indices of ε multiplies each nonzero entry by the product of the eight diagonal entries of η^{-1} (each label occurs exactly once in a nonzero entry), that is by $\det \eta = (+1)^4(-1)^4 = +1$ (PROVED). The author's `epsilong` is the Levi-Civita tensor of a metric g that the author declares in the cell In[29] with `DefMetric[{4, 4, 0}, ...]`: four positive, four negative and no zero eigenvalues, the signature (4,4). For such a tensor the same step gives the sign of $\det g$ (a fact of tensor calculus, ASSUMED here), which is $(-1)^4 = +1$ as for η (and for the author's metric of the Revision record, $\det g = \cos^2 z > 0$, Section 1.21). In four-dimensional spacetime, with one -1, the same step would give the factor -1. So in the signature (4,4) the author's second route gives the generalized delta with no extra sign;

Notebook 01c, In [17], checks this: for all 64 pairs (a, b) the sums are $5040 = 7!$ for $a = b$ and 0 otherwise, the 8×8 identity $\delta^b{}_a$ after the division by 7! (COMPUTED).

1.45 Example: the generalized Kronecker delta

Notebook 01c puts Sections 1.42 to 1.44 to work. It reads the author's definition and the cells of their notebook from the Revision record; writes the definition in Python literally, as a Leibniz determinant of the matrix `Outer`, and again as the fast rule of GKD; reproduces every example of the record; computes all 4096 values with two indices; compares the literal determinant with the fast rule for every one of the 266,304 pairs of lengths 1 to 3 and the 16,777,216 pairs of length 4, and compares the counts with the record; checks the counting formula and the vanishing with nine indices; finds the contraction factors $n - p + 1$ and the factors 6, 4, 2 of the record's Lovelock trace identities; and checks the Levi-Civita product formula and the author's second route. It ends with the line ALL 28 CHECKS PASSED (notebook 01c).

1.46 How to run Notebook 01c

Step 1. What this notebook does and what it needs.

Notebook 01c (The generalized Kronecker delta as a determinant) is the file `Revision/textbook/notebooks/01c_generalized_delta.ipynb` of the repository Dirac_claude. It reads the author's definition of the generalized Kronecker delta from the Revision record (the determinant of the matrix of ordinary Kronecker deltas of two index lists), writes it in Python twice, literally with the Leibniz determinant and as the fast rule of the Revision program GKD (zero for a repeated or missing index, otherwise the sign of a permutation), reproduces the examples and the exhaustive counts of the Revision record for index lists of length 1 to 4 over the eight coordinates x0 to x7 (16,777,216 pairs for length 4), proves and checks the counting formula for the nonzero values, the vanishing for nine indices in eight dimensions, the two-index formula, the contraction identity that gives the factors 6, 4 and 2 of the Lovelock trace identities, and the product formula of two Levi-Civita symbols that the author's notebook also uses, with heat maps and plots. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then

open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01c_generalized_delta.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01c_generalized_delta.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01c_generalized_delta.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01c.captions.json`
- `Revision/textbook/figures/01c_1_outer_matrices.png`
- `Revision/textbook/figures/01c_2_two_index_table.png`
- `Revision/textbook/figures/01c_3_value_counts.png`
- `Revision/textbook/figures/01c_4_nonzero_fraction.png`
- `Revision/textbook/figures/01c_5_contraction_factor.png`
- `Revision/textbook/figures/01c_6_levi_civita.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 28 CHECKS PASSED (notebook 01c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01c_generalized_delta.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01c_generalized_delta.ipynb
python -m nbconvert --execute --inplace 01c_generalized_delta.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.
- the computer becomes slow during the cell that checks all 16,777,216 pairs: that cell needs about 250 MB of memory and 10 to 30 seconds; close other programs and run the cell again. It works in blocks of 1,048,576 pairs, so it never needs more memory than that.

1.47 Notebook 01c: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01c_generalized_delta.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The field equations of gravity that the author's theory uses (the Lovelock
equations) are built with one combinatorial tool: the **generalized Kronecker
delta**. The author defined it in his Mathematica notebook as the determinant of
a small matrix of zeros and ones; the Revision record computes it with a fast
program called GKD. This notebook

- reads the author's definition from the Revision record and writes it in Python
  literally (a Leibniz determinant), and again as the fast rule of GKD;
- reproduces every example of the record and the record's counts of the values
  $+1$, $-1$ and $0$ for all pairs of index lists of length 1, 2 and 3 over the
  eight coordinates $x_0, \dots, x_7$, and checks all 16,777,216 pairs of length
  4, as the record's self-test did;
- proves and checks a formula for the number of nonzero values, and that nine
  indices in eight dimensions always give 0;
- proves and checks the contraction identity, which explains the factors 6, 4
```

  and 2 that appear in the record's Lovelock trace identities;
- shows that the Levi-Civita symbol is a special generalized delta and checks
  the product formula of two Levi-Civita symbols, the second route of the
  author's notebook.

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01c (The generalized Kronecker delta as a determinant) is the file
‘Revision/textbook/notebooks/01c_generalized_delta.ipynb‘ of the repository Dirac_claude.
It reads the author's definition of the generalized Kronecker delta from the Revision
record (the determinant of the matrix of ordinary Kronecker deltas of two index lists),
writes it in Python twice, literally with the Leibniz determinant and as the fast rule of
the Revision program GKD (zero for a repeated or missing index, otherwise the sign of a
permutation), reproduces the examples and the exhaustive counts of the Revision record
for index lists of length 1 to 4 over the eight coordinates x0 to x7 (16,777,216 pairs
for length 4), proves and checks the counting formula for the nonzero values, the
vanishing for nine indices in eight dimensions, the two-index formula, the contraction
identity that gives the factors 6, 4 and 2 of the Lovelock trace identities, and the
product formula of two Levi-Civita symbols that the author's notebook also uses, with
heat maps and plots. It needs a computer with Windows 11, macOS or Linux, an internet
connection for the installation, the program Git, and Python 3.12 or newer (the notebooks
were built with Python 3.14.5) with these packages at exactly these versions: numpy
2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4,
nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy
and matplotlib; the other packages run Jupyter, the program that shows and runs
notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:
```

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in

this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01c_generalized_delta.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the

address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01c_generalized_delta.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01c_generalized_delta.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01c.captions.json‘
- ‘Revision/textbook/figures/01c_1_outer_matrices.png‘
- ‘Revision/textbook/figures/01c_2_two_index_table.png‘
- ‘Revision/textbook/figures/01c_3_value_counts.png‘
- ‘Revision/textbook/figures/01c_4_nonzero_fraction.png‘
- ‘Revision/textbook/figures/01c_5_contraction_factor.png‘
- ‘Revision/textbook/figures/01c_6_levi_civita.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 28 CHECKS PASSED (notebook 01c)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

      python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01c_generalized_delta.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

      python -m jupyterlab 01c_generalized_delta.ipynb
      python -m nbconvert --execute --inplace 01c_generalized_delta.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the notebook reads Revision records of the repository; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.
- the computer becomes slow during the cell that checks all 16,777,216 pairs: that cell needs about 250 MB of memory and 10 to 30 seconds; close other programs and run the cell again. It works in blocks of 1,048,576 pairs, so it never needs more memory than that.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a

check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01c (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01c (The generalized Kronecker delta as a determinant) is the file
# Revision/textbook/notebooks/01c_generalized_delta.ipynb of the repository Dirac_claude.
# It reads the author’s definition of the generalized Kronecker delta from the Revision
# record (the determinant of the matrix of ordinary Kronecker deltas of two index lists),
# writes it in Python twice, literally with the Leibniz determinant and as the fast rule
# of the Revision program GKD (zero for a repeated or missing index, otherwise the sign
# of a permutation), reproduces the examples and the exhaustive counts of the Revision
# record for index lists of length 1 to 4 over the eight coordinates x0 to x7 (16,777,216
# pairs for length 4), proves and checks the counting formula for the nonzero values, the
# vanishing for nine indices in eight dimensions, the two-index formula, the contraction
# identity that gives the factors 6, 4 and 2 of the Lovelock trace identities, and the
# product formula of two Levi-Civita symbols that the author’s notebook also uses, with
# heat maps and plots. It needs a computer with Windows 11, macOS or Linux, an internet
# connection for the installation, the program Git, and Python 3.12 or newer (the
# notebooks were built with Python 3.14.5) with these packages at exactly these versions:
# numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat
# 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself
# imports numpy and matplotlib; the other packages run Jupyter, the program that shows
# and runs notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
```

```
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
```

```
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01c_generalized_delta.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
```

```
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01c_generalized_delta.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01c_generalized_delta.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01c.captions.json
# - Revision/textbook/figures/01c_1_outer_matrices.png
# - Revision/textbook/figures/01c_2_two_index_table.png
# - Revision/textbook/figures/01c_3_value_counts.png
# - Revision/textbook/figures/01c_4_nonzero_fraction.png
# - Revision/textbook/figures/01c_5_contraction_factor.png
# - Revision/textbook/figures/01c_6_levi_civita.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 28 CHECKS PASSED (notebook 01c)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01c_generalized_delta.ipynb inside the folder
#   Dirac_claude.
```

```
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01c_generalized_delta.ipynb
#     python -m nbconvert --execute --inplace 01c_generalized_delta.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below Revision/gkd_lovelock or Revision/algebra: the
#   notebook reads Revision records of the repository; your copy of the repository is
#   incomplete. Download it again with git clone and open the notebook inside the new
#   copy.
# - the computer becomes slow during the cell that checks all 16,777,216 pairs: that cell
#   needs about 250 MB of memory and 10 to 30 seconds; close other programs and run the
#   cell again. It works in blocks of 1,048,576 pairs, so it never needs more memory than
#   that.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Label**: a name of a coordinate, here $x_0, \dots, x_7$. The computer often
  numbers them $0, \dots, 7$; only the question "are two labels equal?" matters
  below, so the names do not change any result.
- **Index list**: an ordered list of labels, such as $(x_1, x_3, x_3)$; its
  **length** is the number of entries (here 3).
- **Kronecker delta** $\delta(a, b)$: 1 if the labels $a$ and $b$ are equal, 0
  otherwise (also written $\delta^a_b$).
- **Generalized Kronecker delta** of a lower list $(l_1, \dots, l_p)$ and an upper
  list $(u_1, \dots, u_p)$ of the same length $p$: the determinant of the
  $p \times p$ matrix whose entry in row $i$ and column $j$ is
  $\delta(l_i, u_j)$; written $\delta^{u_1 \dots u_p}_{l_1 \dots l_p}$.
- **Outer**: Mathematica's name for the operation that builds that matrix,
  `Outer[delta, lower, upper]`. The author's function is called
  `k\[Delta]` (Mathematica's plain-text spelling of "k" followed by the Greek
  letter delta).
- **GKD**: the Revision record's program (written in the language Rust) that
  computes the generalized delta without a determinant.
- **Permutation, inversion, sign**: a re-ordering of a list; a pair of places in
  the wrong order; $(-1)^{\text{number of inversions}}$.
- **Exhaustive check**: a check of *every* possible case, not of examples.
- **Vectorized computation**: numpy applies one operation to millions of numbers
  in an array at once, much faster than a Python loop.
- **Pigeonhole principle**: if more than $n$ objects are put into $n$ boxes, some
  box gets at least two of them.
- **Contraction**: setting an upper and a lower index equal and adding over all
  values of that index (the summation convention).
- **Levi-Civita symbol** $\varepsilon_{i_1 \dots i_n}$: the sign of the list
  $(i_1, \dots, i_n)$ if it is a re-ordering of all $n$ labels, and 0 otherwise.
- **Falling factorial** $n!/(n-p)! = n (n-1) \cdots (n-p+1)$: the number of ways
  to choose $p$ different labels from $n$ in order (`math.perm(n, p)`).
- **Lovelock tensors**: combinations of the curvature of spacetime that enter the
  field equations of gravity in more than four dimensions; the Revision record
  computes three of them for the author's metric, with GKD as the weight of every
  term.
```

Text cell:

```
## 4. The physical and mathematical situation

The author's Mathematica notebook defines (input cell In[54], stored in the file
as In[87]):

`k\[Delta][lower_, upper_] /; Length[lower] == Length[upper] :=
Det[Outer[delta, lower, upper]]`

In words: for two index lists of equal length, build the matrix
$M_{ij} = \delta(l_i, u_j)$ and take its determinant. For one index this is the
ordinary Kronecker delta. For two indices the $2 \times 2$ determinant gives

$$\delta^{u_1 u_2}_{l_1 l_2} = \delta(l_1, u_1)\,\delta(l_2, u_2)
- \delta(l_1, u_2)\,\delta(l_2, u_1).$$
```

```
The Revision program GKD avoids the determinant with a proof in four cases
(written in the file Revision/gkd_lovelock/code/src/gkd.rs):

- (a) two equal lower labels make two equal rows of $M$, so $\det M = 0$;
- (b) two equal upper labels make two equal columns, so $\det M = 0$;
- (c) a lower label that is not among the upper labels makes a row of zeros, so
  $\det M = 0$;
- (d) otherwise both lists consist of the same $p$ different labels; each $l_i$
  equals exactly one $u_{\sigma(i)}$, $M$ is the permutation matrix of $\sigma$,
  and $\det M = \mathrm{sign}(\sigma)$ (only one term of the Leibniz formula is
  not zero).

In the Lovelock tensors of the author's theory the generalized delta appears with
$2k + 1$ indices, $k = 1, 2, 3$, in the eight dimensions $x_0, \dots, x_7$:
$P_{(k)}{}^h{}_j = \delta^{h h_1 \dots h_{2k}}_{j j_1 \dots j_{2k}}
R^{j_1 j_2}{}_{h_1 h_2} \cdots$ (summation convention). Two facts of this
notebook matter there: with 9 indices ($k = 4$) the delta is always 0, so the
sum stops at $k = 3$; and contracting $h$ with $j$ multiplies by $8 - 2k$, which
is why the record's trace identities read $\sum_h P_{(k)}{}^h{}_h = (8 - 2k)
L_{(k)}$ with the factors 6, 4 and 2.
```

Text cell:

```
## 5. The author's definition, read from the record

The next cell reads two files of the Revision record. The file
PROVENANCE_OF_THE_COMPUTATION.md records the author's definition verbatim, with
the Greek letter $\delta$; this notebook is written in plain ASCII, so the letter
is typed as its code `\u03b4`. The file notebook-input-cells.txt lists the input
cells of the author's notebook, each under the label stored in the file; the cell
finds the definition (In[87]), the first cell of the author's second route
(In[32], a product of two Levi-Civita tensors, section 15 of this notebook) and
the cell that declares the metric $g$ used by that route (In[29]), and prints
them, with the Greek letter written as `\[Delta]`. `re.search` looks for a
pattern in a text; `HoldForm[...]` is how the record wraps every cell.
```

In [2]:

```
import itertools  # all lists of labels, all permutations
import json  # reads the JSON reports of the Revision record
import math  # factorials
import re  # finds patterns in texts

import numpy as np  # arrays: many index lists at once

DELTA = "\u03b4"  # the Greek letter delta, written with its code
definition = ("k" + DELTA + "[lower_, upper_] /; Length[lower] == Length[upper] := "
              "Det[Outer[delta, lower, upper]]")
provenance_path = repository_file("Revision/gkd_lovelock/results/"
                                  "PROVENANCE_OF_THE_COMPUTATION.md")
provenance = provenance_path.read_text(encoding="utf-8")
```

```

```

Text cell:

```
## 6. The generalized Kronecker delta, literally

The next cell writes the author's definition in Python, word for word:

- `kronecker(a, b)` is the ordinary Kronecker delta of two labels;
- `outer_matrix(lower, upper)` is `Outer[delta, lower, upper]`;
- `leibniz_det(rows)` is the determinant by the Leibniz formula; the list of the
  permutations of each size and their signs is computed once and kept in the
  dictionary `SIGNED`, because the same lists are needed millions of times;
- `kdelta_literal(lower, upper)` refuses lists of different lengths (the
  author's definition then stays unevaluated) and otherwise returns the
  determinant.

The labels may be any names: here the strings `"x0"`, ..., `"x7"`.
```

In [3]:

```
def kronecker(a, b):
    """The ordinary Kronecker delta of two labels: 1 if they are equal, else 0."""

## 7. The fast rule of the program GKD

The next cell writes the four cases of the proof as the Python function
‘gkd_rule‘, line by line as the Rust function ‘GKD‘ of the record does it: first
it notes the place of every upper label (and returns 0 at a repeated upper label,
case b); then for every lower label it looks up its place among the upper labels
(returning 0 if it is missing, case c, or if that place was taken already, which
means a repeated lower label, case a); the places form the permutation
$\sigma$, whose sign is the result (case d). It never builds a matrix.

The cell checks that the rule gives the literal values for the five examples, and
that renaming the labels ($x_k$ to $x_{k+1}$, with $x_7$ to $x_0$) changes no value:
only equal or different matters.
```

In [5]:

```
def gkd_rule(lower, upper):
    """The program GKD of Revision/gkd_lovelock/code/src/gkd.rs, in Python."""
    if len(lower) != len(upper):
        raise ValueError("the two index lists must have the same length")
    place = {}  # upper label -> its place 0, 1, ..., p-1
    for j, u_label in enumerate(upper):
        if u_label in place:  # case (b): a repeated upper label
            return 0
        place[u_label] = j
    sigma = []  # sigma[i] = the place of lower[i] among the upper labels
```

```
    for l_label in lower:
        if l_label not in place:  # case (c): a lower label missing above
            return 0
        if place[l_label] in sigma:  # case (a): a repeated lower label
            return 0
        sigma.append(place[l_label])
    return sign(sigma)  # case (d): the sign of the permutation sigma

check(all(gkd_rule(lower, upper) == kdelta_literal(lower, upper)
          for lower, upper, _ in examples),
      "the fast rule gives the literal values for the five examples")

## 8. The examples of the record

The next cell reads three reports of the Revision record and repeats their
examples with both functions:

- python-lovelock-report.json, check ‘gkd_examples‘: five values written as
  ‘kdelta[{1,2},{2,1}] = -1‘ and so on (labels 1, 2, 3, 4); a regular expression
  (‘re.findall‘) picks the two lists and the value out of the text;
- wolfram-gkd-report.json, check ‘definition_unequal_lengths_stay_unevaluated‘:
  the values $-1$ and $+1$ of two examples with labels 0, 1, 2, and the refusal
  of lists of different lengths (our functions raise a ‘ValueError‘);
- lovelock-report.json, field ‘gkdSelfCheck‘: the two values that the Rust
  program printed for the lists $(0, 1, 2), (1, 2, 0)$ and $(0, 1), (1, 0)$.
```

In [6]:

```
def read_report(name):
    """A JSON report of Revision/gkd_lovelock/results as a Python dictionary."""
    path = repository_file(f"Revision/gkd_lovelock/results/{name}")

## 9. Two indices: the 64 by 64 table

With two indices over eight labels there are $8^2 = 64$ lower lists and 64 upper
lists, so $64 \cdot 64 = 4096$ values. The next cell computes all of them, checks
the two-term formula
$\delta^{u_1 u_2}_{l_1 l_2} = \delta(l_1, u_1)\delta(l_2, u_2)
- \delta(l_1, u_2)\delta(l_2, u_1)$ for every one of them, counts the values
$+1$ and $-1$ (each must be 56: a list of two *different* labels, $8 \cdot 7 = 56$
of them, gives $+1$ with itself and $-1$ with its reverse), and draws the table.
From here on the labels are the numbers 0 to 7, the computer's names for
$x_0$ to $x_7$.
```

Text cell:

10. All pairs of index lists of length 1, 2 and 3

The Revision record compared GKD with the author's definition for *every* pair of index lists of length 1, 2 and 3 over the eight labels: $8^2 = 64$, $8^4 = 4096$ and 8^6 = 262,144 pairs, 266,304 in all, and recorded how many values are $+1$, -1 and 0. The next cell does the same with plain Python loops: for every pair it computes the literal determinant and the fast rule, counts disagreements and tallies the values. Then it compares the tallies with the record's `measurements` (the field `gkdComparison` of wolfram-gkd-report.json), and its number of disagreements, 0, with the record's three exhaustive checks, which also report 0 mismatches. It keeps every value in an array for the next section. This cell takes several seconds.

In [8]:

## 11. All 16,777,216 pairs of length 4

For length 4 there are $8^8$ = 16,777,216 pairs, too many for a plain Python
loop. The next cell writes both functions again so that numpy treats a whole
block of pairs at once (one index list per row of an array):

- ‘literal_many‘ builds all the matrices ‘Outer‘ of the block at once (an array of
  True and False of shape pairs $\times p \times p$) and adds the Leibniz terms:
  for each permutation, the term is not zero exactly when all its entries are 1;
- ‘rule_many‘ uses a shortcut for the sign. If the lower list $L$ is a re-ordering
  of the upper list $U$, both are re-orderings of the same sorted list $S$. The
  matrix $M_{ij} = \delta(l_i, u_j)$ is then the product $P_L P_U^T$ of the two
  permutation matrices with $(P_L)_{ik} = \delta(l_i, s_k)$ and
  $(P_U)_{jk} = \delta(u_j, s_k)$ (the sum over $k$ has one nonzero term), so
  $\det M = \det P_L \det P_U = \mathrm{sign}(L)\,\mathrm{sign}(U)$, where
  $\mathrm{sign}(L)$ counts the inversions of the list $L$ itself. The other
  cases give 0: a repeated upper label, or different sorted lists.

Before it is trusted, the cell checks both new functions against the plain values
of section 10 for all 266,304 pairs of length 1, 2 and 3.
```

## 12. How many values are not zero: a formula

A value is not zero exactly in case (d): the upper list consists of $p$
different labels, and the lower list is a re-ordering of it. There are
$n(n-1)\cdots(n-p+1) = n!/(n-p)!$ upper lists of $p$ different labels from $n$
(the first label has $n$ choices, the second $n - 1$, and so on), and $p!$
re-orderings of each. So

$$N_{\neq 0}(n, p) = \frac{n!}{(n-p)!} \, p! \quad (p \leq n), \qquad
N_{\neq 0}(n, p) = 0 \quad (p > n).$$

For $p \geq 2$ half of the re-orderings are even, so $+1$ and $-1$ occur equally
often; for $p = 1$ every nonzero value is $+1$. The next cell checks the formula
against the counts of sections 9 to 11, prints it for $p = 1$ to 9, and plots the
total number of pairs $n^{2p}$ and the nonzero ones for $n = 8$.
```

In [12]:

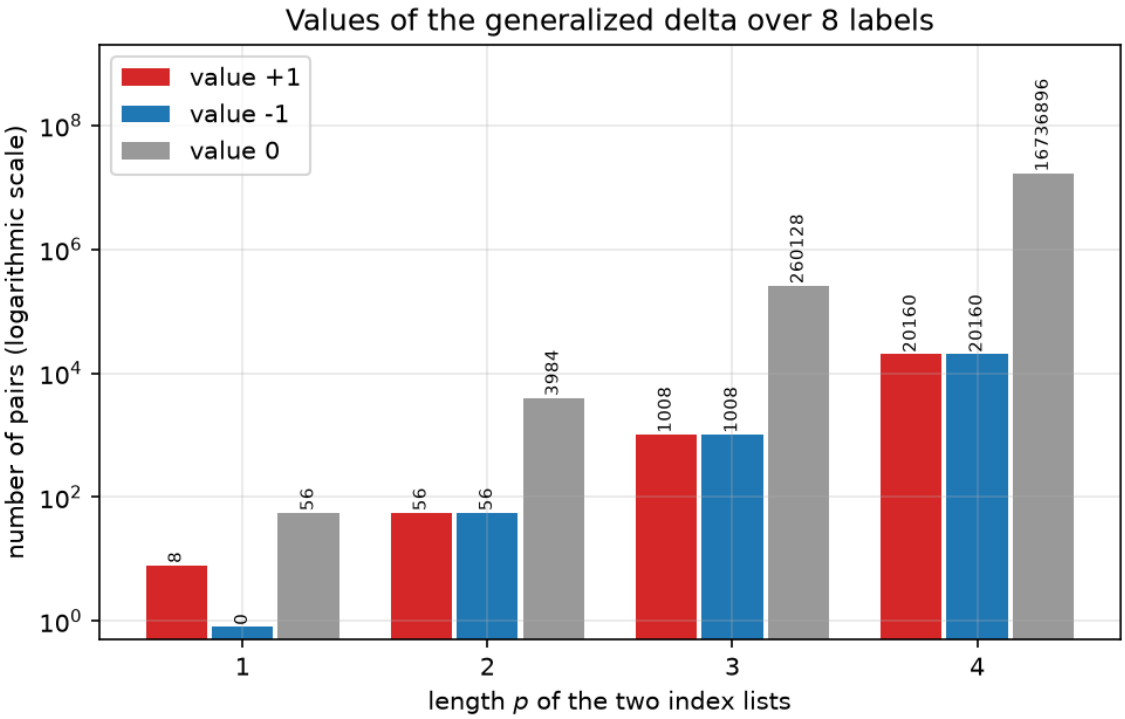

Figure 52: The number of pairs of index lists of length $p = 1$ to 4 over the eight labels x_0 to x_7 for which the generalized delta is $+1$ (red), -1 (blue) and 0 (grey), counted over all 8^{2p} pairs; horizontal axis p, vertical axis the number of pairs on a logarithmic scale, with the exact counts written above the bars (a count 0 is drawn as a short stub). The counts for $p = 1$ to 3 equal those of the Revision record. (Notebook 01c, figure 3.)

## 13. Nine indices in eight dimensions

A list of 9 labels taken from only 8 must repeat a label (pigeonhole principle),
so case (a) or (b) applies and the value is 0, for every one of the $8^{18}$
pairs. This is why the Lovelock sum of the author's theory stops at $k = 3$: the
term $k = 4$ would need $2k + 1 = 9$ indices. The next cell confirms it on 300
pairs of random lists of 9 labels (numpy's random generator with the seed 12345)
and on 300 pairs in which the lower list is a re-ordering of the upper one; here
the literal determinant of the $9 \times 9$ matrix (which would have $9!$ =
362,880 Leibniz terms) is computed with numpy's elimination. With 8 labels a
nonzero value is still possible: the cell prints the value for the list
$(x_0, \dots, x_7)$ against its reverse, which has 28 inversions.
```

In [13]:

```
generator = np.random.default_rng(12345)
nine_all_zero = True
for sample in range(600):
    upper = tuple(int(x) for x in generator.integers(0, 8, size=9))
    if sample % 2 == 0:  # an arbitrary lower list
        lower = tuple(int(x) for x in generator.integers(0, 8, size=9))
    else:  # a re-ordering of the upper list
        lower = tuple(int(x) for x in generator.permutation(np.array(upper)))
```

```

## 14. Contracting one index: the factor $n - p + 1$

Take lists $A = (a_1, \dots, a_{p-1})$ and $B = (b_1, \dots, b_{p-1})$, append the
same label $c$ to both, and add over all $n$ values of $c$. The claim is

$$\sum_{c} \delta^{a_1 \dots a_{p-1} c}_{b_1 \dots b_{p-1} c}
= (n - p + 1)\, \delta^{a_1 \dots a_{p-1}}_{b_1 \dots b_{p-1}}.$$

Proof by cases. If $A$ or $B$ repeats a label, every term repeats it too: all
terms are 0, and so is the right side. If $A$ and $B$ consist of different labels
but are not re-orderings of each other, then for each $c$ the extended lists are
not re-orderings of each other either (if $c$ is among the labels of $A$ or $B$
it is repeated; if not, adding it to both changes nothing): all terms are 0. If
$B$ is a re-ordering $\sigma$ of $A$: for the $p - 1$ values of $c$ that are among
the labels, the extended lists repeat $c$ (term 0); for each of the other
$n - (p - 1)$ values, the extended lists are re-ordered by $\sigma$ with $c$ left
in place, which has the same inversions, so each such term equals
$\mathrm{sign}(\sigma)$. Together: $(n - p + 1)\,\mathrm{sign}(\sigma)$.

The next cell checks this for $n = 8$ and $p = 1$ to 8 (exhaustively up to
$p = 4$, with the block function for $p = 4$; for $p = 5$ to 8 on 4000 random
pairs, half of them re-orderings) and for $n = 4$ and $p = 1$ to 4
(exhaustively). For each $(n, p)$ it records the factor found; for $p = 1$ the
empty lists have the value 1 (the determinant of the empty matrix).
```

## 15. The Levi-Civita symbol and the author's second route

The Levi-Civita symbol $\varepsilon_{i_1 \dots i_n}$ is the generalized delta
with the upper list $(0, 1, \dots, n - 1)$: by case (d) it is the sign of the
list if the list is a re-ordering of all $n$ labels, and 0 otherwise. The
author's notebook builds the generalized delta also from two of them (input cell
In[32]: `epsilong[-a, -f, ...] epsilong[b, f, ...] / (8 - 1)!`). The general
formula is

$$\sum_{c_{p+1}, \dots, c_n} \varepsilon_{a_1 \dots a_p c_{p+1} \dots c_n}\,
\varepsilon_{b_1 \dots b_p c_{p+1} \dots c_n}
= (n - p)!\; \delta^{b_1 \dots b_p}_{a_1 \dots a_p}.$$
```

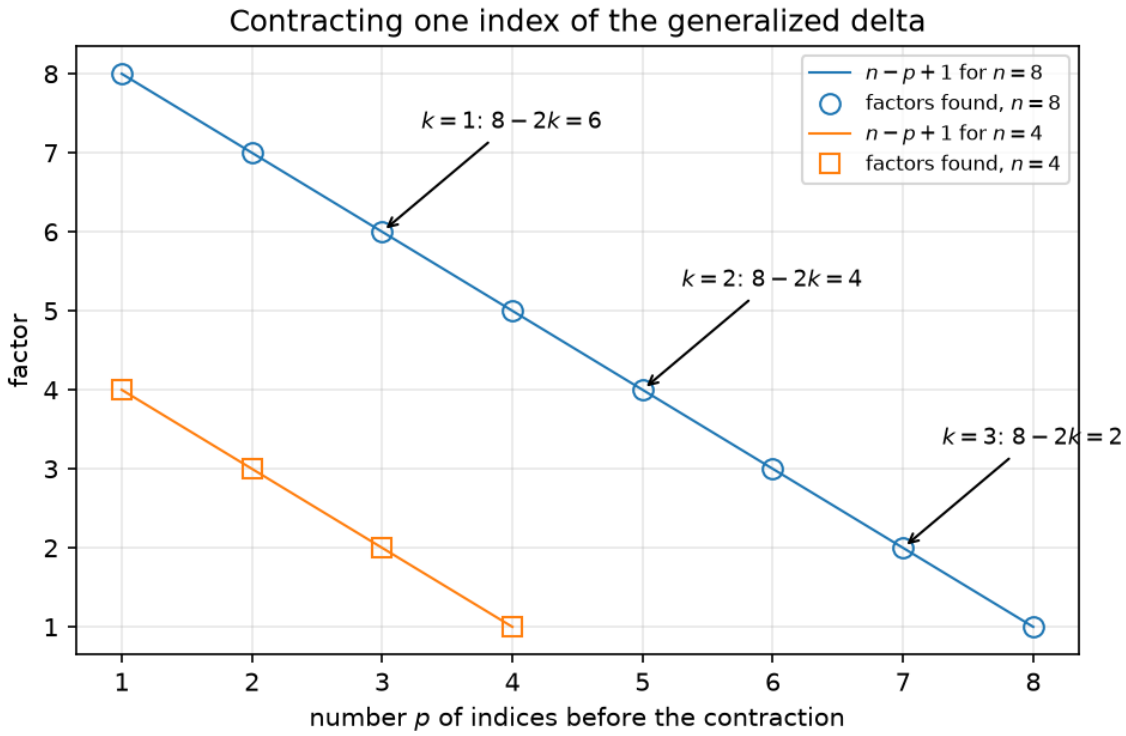

Figure 54: The factor by which contracting one upper with one lower index multiplies the generalized delta with p indices, found by the checks of this notebook (open circles for $n = 8$ labels, open squares for $n = 4$), and the lines $n - p + 1$; horizontal axis p, vertical axis the factor. The arrows mark $p = 2k + 1 = 3, 5, 7$ in eight dimensions, where the factors $8 - 2k = 6, 4, 2$ are those of the Lovelock trace identities of the Revision record. (Notebook 01c, figure 5.)

```
It is the contraction identity of section 14 used $n - p$ times, starting from
$\varepsilon_{a_1 \dots a_n} \varepsilon_{b_1 \dots b_n}
= \delta^{b_1 \dots b_n}_{a_1 \dots a_n}$ (both sides are the product of the
signs of the two lists, or 0), with the factors $1, 2, \dots, n - p$.

In the author's coordinates the second $\varepsilon$ has upper indices, raised
with the metric; raising all $n$ indices of $\varepsilon$ multiplies it by the
product of the diagonal entries of $\eta^{-1}$, which is $\det \eta = +1$ for the
four $+1$ and four $-1$ of $\eta$ (in four-dimensional spacetime, with one $-1$,
the same step gives a factor $-1$). The author's notebook uses the Levi-Civita
tensor 'epsilong' of a metric $g$ that it declares in the cell In[29] with
'DefMetric[{4, 4, 0}, ...]': four positive, four negative and no zero
eigenvalues, the signature (4,4). For that tensor the factor is the sign of
$\det g$, which is $(+1)^4 (-1)^4 = +1$, the same as for $\eta$ (and for the
author's metric of the Revision record, $\det g = \cos^2 z > 0$).
The next cell reads $\eta$ from the Revision record and checks
$\det\eta = +1$; checks the declaration (4, 4, 0) in the cell In[29]; checks
the formula for $n = 4$ and every $p = 0$ to 4 over all lists; and repeats the
author's In[32] for $n = 8$ and $p = 1$: for all 64 pairs $(a, b)$ it adds the
products over all lists $(c_2, \dots, c_8)$ of 7 different labels and divides by
$7! = 5040$; the result must be the $8 \times 8$ identity matrix $\delta^b_a$.
```

Out [19]:

```
PASS all 6 figure files of this notebook exist
ALL 28 CHECKS PASSED (notebook 01c)
```

Text cell:

```
## 17. What this notebook showed

- The author's generalized Kronecker delta, `Det[Outer[delta, lower, upper]]`,
  written literally in Python, equals the fast rule of the Revision program GKD
  (0 for a repeated or missing label, otherwise the sign of a permutation) for
  every pair of index lists of length 1 to 4 over the eight coordinates
  $x_0, \dots, x_7$: 266,304 + 16,777,216 pairs, no disagreement, the same
  result as the record's self-test.
- The counts of $+1$, $-1$ and $0$ (8, 0, 56; 56, 56, 3984; 1008, 1008, 260128;
  20160, 20160, 16736896 for the lengths 1 to 4) agree with the record and with
  the formula $N_{\neq 0} = 8!/(8-p)! \cdot p!$; every example of the record is
  reproduced.
- With 9 indices in 8 dimensions the delta is always 0 (pigeonhole), so the
  Lovelock sum of the theory stops at $k = 3$.
- Contracting one index multiplies by $n - p + 1$; in eight dimensions and with
  $p = 2k + 1$ this is $8 - 2k = 6, 4, 2$, the factors of the record's Lovelock
  trace identities.
- The Levi-Civita symbol is a generalized delta, and the product of two
  Levi-Civita symbols summed over $n - p$ indices is $(n - p)!$ times the
  generalized delta; in the signature (4,4) of the author's metric raising the
  indices adds no sign ($\det\eta = +1$), and the author's second route gives the
  Kronecker delta exactly.
```

1.48 Line-by-line walk-through of Notebook 01c

The notebook has nineteen code cells, In [1] to In [19]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.47 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.46; its code is the set-up code explained in Section 1.9, with `NOTEBOOK_ID = "01c"`. It prints Set-up of notebook 01c complete: repository folder found, helpers defined.

In [2], the author's definition, read from the record.

```
import itertools  # all lists of labels, all permutations
import json  # reads the JSON reports of the Revision record
import math  # factorials
import re  # finds patterns in texts

import numpy as np  # arrays: many index lists at once
```

The modules. `re` (part of Python) finds **patterns** in texts: a pattern, a **regular expression**, describes a piece of text with placeholders, for example `\d+` for "one or more digits" and `(...)` for a part to be taken out.

```
DELTA = "\u03b4"  # the Greek letter delta, written with its code
definition = ("k" + DELTA + "[lower_, upper_] /; Length[lower] == Length[upper] := "
              "Det[Outer[delta, lower, upper]]")
provenance_path = repository_file("Revision/gkd_lovelock/results/"
                                  "PROVENANCE_OF_THE_COMPUTATION.md")
provenance = provenance_path.read_text(encoding="utf-8")
check(definition in provenance, "the record holds the author's definition verbatim",
      record="Revision/gkd_lovelock/results/PROVENANCE_OF_THE_COMPUTATION.md")
```

The notebook is written in plain ASCII, so the Greek letter δ is typed by its code, `\u03b4`. `definition` is the author's definition as one string (two strings next to each other are joined). The record's provenance file is read, and `definition in provenance` asks whether the string occurs in it, letter for letter.

```
input_cells = repository_file("Revision/gkd_lovelock/results/"
                              "notebook-input-cells.txt").read_text(encoding="utf-8")
found = {}
for line in input_cells.splitlines():
    for label in ("In[87]:=", "In[32]:=", "In[29]:="):
        if line.startswith(label):
            found[label] = re.search(r"HoldForm\[(.*)\]", line).group(1)
```

The record's list of the author's input cells has one line per cell, starting with the label stored in the file. For the three labels of interest, the pattern `HoldForm\[(.*)\]` takes out the text between `HoldForm[` and the last `]` of the line (`.*` means "any characters"; the backslash makes the bracket an ordinary character), and `.group(1)` is the part in round brackets.

```
for label in ("In[87]:=", "In[32]:=", "In[29]:="):
    plain_text = found[label].replace(DELTA, "\\[Delta]")  # Mathematica's spelling
    say(f"author's cell {label} {plain_text}")
metric_cell = found["In[29]:="]  # kept for section 15 (the declaration of g)
```

The three cells are printed, with δ written in Mathematica's spelling `\[Delta]`: the definition (In[87]), the first cell of the second route (In[32]) and the declaration of the metric (In[29]), which is kept for In [17].

```
check("Det[Outer[delta, lower, upper]]" in found["In[87]:="] and
      "epsilong" in found["In[32]:="] and "(8 - 1)!" in found["In[32]:="],
```

```
      "the author's notebook defines the delta as a determinant (In[87]) and "
      "also uses a product of two Levi-Civita tensors (In[32])",
      record="Revision/gkd_lovelock/results/notebook-input-cells.txt")
```

The check confirms what the three printed cells show. The cell prints two PASS lines, each with the record it reproduces.

In [3], the generalized delta, literally.

```
def kronecker(a, b):
    """The ordinary Kronecker delta of two labels: 1 if they are equal, else 0."""
    return 1 if a == b else 0

def outer_matrix(lower, upper):
    """Outer[delta, lower, upper]: row i, column j is kronecker(lower[i], upper[j])"""
    return [[kronecker(l_label, u_label) for u_label in upper] for l_label in lower]
```

The ordinary Kronecker delta, and the matrix `Outer` as a list of rows: one row for each lower label, one entry for each upper label.

```
def inversions(order):
    """The number of pairs of places i < j whose entries stand in the wrong order."""
    return sum(1 for i in range(len(order)) for j in range(i + 1, len(order))
               if order[i] > order[j])

def sign(order):
    """+1 for an even number of inversions, -1 for an odd number."""
    return 1 if inversions(order) % 2 == 0 else -1
```

Inversions and sign, as in Notebook 01a, In [6] (Section 1.25).

```
SIGNED = {}  # size n -> list of (permutation, its sign), computed once per size

def signed_permutations(n):
    if n not in SIGNED:
        SIGNED[n] = [(order, sign(order)) for order in itertools.permutations(range(n))]
    return SIGNED[n]
```

The permutations of n objects with their signs are needed millions of times; they are computed once for each size and kept in the dictionary `SIGNED` (`if n not in SIGNED` is true only the first time).

```
def leibniz_det(rows):
    """The Leibniz determinant of a square matrix given as a list of rows."""
    total = 0
    for order, order_sign in signed_permutations(len(rows)):
        term = order_sign
```

```
        for i, column in enumerate(order):
            term *= rows[i][column]
            if term == 0:  # one factor 0 makes the whole term 0: stop early
                break
        total += term
    return total
```

The Leibniz formula as in Notebook 01a, with one saving: as soon as a factor 0 makes a term 0, the inner loop stops (`break`), because the rest of the product cannot change it.

```
def kdelta_literal(lower, upper):
    """The author's k-delta: Det[Outer[delta, lower, upper]] for equal lengths."""
    if len(lower) != len(upper):
        raise ValueError("the two index lists must have the same length")
    return leibniz_det(outer_matrix(lower, upper))
```

The author's definition, word for word: lists of different lengths are refused (Python stops with a `ValueError`, the counterpart of Mathematica leaving the expression unevaluated); otherwise the determinant of `Outer`.

```
def signed(value):
    """A value +1, -1 or 0 as the text "+1", "-1" or "0"."""
    return f"{value:+d}" if value else "0"

same = kdelta_literal(("x1",), ("x1",))  # lists of length 1: ("x1",) has one entry
different = kdelta_literal(("x1",), ("x2",))
say(f"one index: delta(x1, x1) = {same}, delta(x1, x2) = {different}")
check(same == 1 and different == 0,
      "for one index the generalized delta is the ordinary Kronecker delta")
```

A helper that writes a value with its sign (0 without one). Then the case of one index with the labels written as the strings "x1" and "x2" (`("x1",)` is a tuple with one entry; the comma makes it a tuple). Output: one index: delta(x1, x1) = 1, delta(x1, x2) = 0, and the PASS line.

In [4], the five matrices of the table.

```
examples = [(("x1", "x2", "x3"), ("x1", "x2", "x3"), "same lists"),
            (("x1", "x2", "x3"), ("x2", "x3", "x1"), "cyclic turn"),
            (("x1", "x2", "x3"), ("x1", "x3", "x2"), "one exchange"),
            (("x1", "x1", "x3"), ("x1", "x2", "x3"), "repeated lower"),
            (("x1", "x2", "x4"), ("x1", "x2", "x3"), "x4 missing above")]
fig, axes = plt.subplots(1, 5, figsize=(12.0, 3.4))
```

The five pairs of lists of the table of Section 1.42, each with a short description, and five panels.

```
for ax, (lower, upper, what) in zip(axes, examples):
    matrix = np.array(outer_matrix(lower, upper))
    ax.imshow(matrix, cmap="Greys", vmin=0, vmax=1.4)
```

```
    ax.grid(False)
    ax.set_xticks(range(3), [f"${u[0]}_{u[1]}$" for u in upper])  # "x1" -> x_1
    ax.set_yticks(range(3), [f"${l_label[0]}_{l_label[1]}$" for l_label in lower])
    ax.set_xlabel("upper list")
    ax.set_title(f"{what}: det = {signed(kdelta_literal(lower, upper))}", fontsize=9)
```

For each pair the matrix `Outer` is drawn in grey (dark for 1, white for 0); the labels "x1" are written as x_1 (the first character, an underscore for the subscript, the second character); the title gives the determinant.

```
axes[0].set_ylabel("lower list")
fig.tight_layout()
save_figure(fig, "outer_matrices",
            "The matrix Outer of ordinary Kronecker deltas for five pairs of index "
            ...)
values = [kdelta_literal(lower, upper) for lower, upper, _ in examples]
check(values == [1, 1, -1, 0, 0], "the five pictured examples give +1, +1, -1, 0, 0")
```

What Figure 01c.1 shows: the identity matrix (+1); a permutation matrix of a cyclic turn (+1); one with two rows exchanged (−1); two equal rows (0); a white row of zeros (0). The check compares the five values with the table. One PASS line.

In [5], the fast rule of the program GKD.

```
def gkd_rule(lower, upper):
    """The program GKD of Revision/gkd_lovelock/code/src/gkd.rs, in Python."""
    if len(lower) != len(upper):
        raise ValueError("the two index lists must have the same length")
    place = {}  # upper label -> its place 0, 1, ..., p-1
    for j, u_label in enumerate(upper):
        if u_label in place:  # case (b): a repeated upper label
            return 0
        place[u_label] = j
```

The four cases of Section 1.42 as a program, in the order of the Rust function GKD. First every upper label is entered in the dictionary `place` with its place; meeting a label that is already there is case (b), and the function returns 0.

```
    sigma = []  # sigma[i] = the place of lower[i] among the upper labels
    for l_label in lower:
        if l_label not in place:  # case (c): a lower label missing above
            return 0
        if place[l_label] in sigma:  # case (a): a repeated lower label
            return 0
        sigma.append(place[l_label])
    return sign(sigma)  # case (d): the sign of the permutation sigma
```

Then, for every lower label, its place among the upper labels is looked up: a missing label is case (c); a place that was taken already means a repeated lower label, case (a). The places form the permutation σ, and its sign is the value, case (d). No matrix is built.

```
check(all(gkd_rule(lower, upper) == kdelta_literal(lower, upper)
          for lower, upper, _ in examples),
      "the fast rule gives the literal values for the five examples")
renamed = {f"x{k}": f"x{(k + 1) % 8}" for k in range(8)}  # x0->x1, ..., x7->x0
two_lists = list(itertools.product([f"x{k}" for k in range(8)], repeat=2))
check(all(gkd_rule(lo, up) == gkd_rule(tuple(renamed[a] for a in lo),
                                       tuple(renamed[b] for b in up))
          for lo in two_lists for up in two_lists),
      "renaming the labels changes no value (all 4096 pairs of length 2)")
```

The fast rule agrees with the literal determinant on the five examples. Then the labels are renamed, x_k to x_{k+1} and x_7 to x_0 (`(k + 1) % 8`: the remainder of $k+1$ after division by 8, which is 0 for $k = 7$), and all $64 \cdot 64 = 4096$ pairs of lists of length 2 (`itertools.product(..., repeat=2)` gives all lists of two labels) must keep their values: only "equal or different" matters. Two PASS lines.

In [6], the examples of the record.

```
def read_report(name):
    """A JSON report of Revision/gkd_lovelock/results as a Python dictionary."""
    path = repository_file(f"Revision/gkd_lovelock/results/{name}")
    return json.loads(path.read_text(encoding="utf-8"))

def lists_from_text(text):
    """"1,2,3" -> (1, 2, 3)"""
    return tuple(int(part) for part in text.replace(" ", "").split(","))
```

A helper that reads a report of the record, and one that turns a text such as 1,2,3 into the tuple of whole numbers (blanks removed, cut at the commas).

```
python_report = read_report("python-lovelock-report.json")
python_checks = {c["name"]: c for c in python_report["checks"]}
pattern = r"kdelta\[\{([\d,]+)\},\{([\d,]+)\}\] = (-?\d+)"
record_examples = re.findall(pattern, python_checks["gkd_examples"]["detail"])
```

The record's report, its checks as a dictionary by name, and a pattern that matches texts like `kdelta[{1,2},{2,1}] = -1`: the backslashes make the brackets and braces ordinary characters, `([\d,]+)` takes out a run of digits and commas (a list), and `(-?\d+)` a whole number with an optional minus sign. `re.findall` returns all matches in the detail text of the check `gkd_examples`, each as the three parts.

```
for lower_text, upper_text, value in record_examples:
    lower, upper = lists_from_text(lower_text), lists_from_text(upper_text)
    say(f"lower {lower}, upper {upper}: record {signed(int(value))}, literal "
        f"{signed(kdelta_literal(lower, upper))}, rule {signed(gkd_rule(lower, upper))}")
```

Each of the five examples is printed with the record's value, the literal determinant and the fast rule: lower (1, 2), upper (2, 1): record -1, literal -1, rule -1, and so on.

```
check(len(record_examples) == 5 and all(
    kdelta_literal(lists_from_text(lo), lists_from_text(up)) == int(v) ==
    gkd_rule(lists_from_text(lo), lists_from_text(up)) for lo, up, v in record_examples),
    "the five examples of the record", record="Revision/gkd_lovelock/results/"
    "python-lovelock-report.json, check gkd_examples")
```

All five agree, three ways; this reproduces the record's check `gkd_examples`.

```
wolfram_report = read_report("wolfram-gkd-report.json")
wolfram_checks = {c["name"]: c for c in wolfram_report["checks"]}
detail = wolfram_checks["definition_unequal_lengths_stay_unevaluated"]["detail"]
wolfram_pattern = "k" + DELTA + r"\[\{([\d, ]+)\}, \{([\d, ]+)\}\] = ([+-]?\d+)"
wolfram_examples = re.findall(wolfram_pattern, detail)
```

The Wolfram report writes its examples with the Greek letter and blanks, as in `[{0, 1}, {1, 0}] = -1` after $k\delta$; the pattern is adapted accordingly, and finds the two examples with a value (the third list pair of the detail, of unequal lengths, has none).

```
try:
    kdelta_literal((0,), (0, 1))
    refused = False
except ValueError:  # lists of different lengths are refused
    refused = True
check(refused and len(wolfram_examples) == 2 and all(
    kdelta_literal(lists_from_text(lo), lists_from_text(up)) == int(v)
    for lo, up, v in wolfram_examples),
    "lists of different lengths are refused; the two Wolfram examples",
    record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, check "
    "definition_unequal_lengths_stay_unevaluated")
```

`try: ... except ValueError:` runs the first block and, if it stops with a `ValueError`, runs the second block instead of stopping the notebook: lists of the lengths 1 and 2 must be refused. Then the two examples with values; this reproduces the record's check.

```
self_check = read_report("lovelock-report.json")["gkdSelfCheck"]
length3_pair, transposition = self_check["length3Pair"], self_check["transposition"]
say(f"lovelock-report.json gkdSelfCheck: length3Pair = {length3_pair}, "
    f"transposition = {transposition}")
check(self_check["length3Pair"] == gkd_rule((0, 1, 2), (1, 2, 0)) and
      self_check["transposition"] == gkd_rule((0, 1), (1, 0)),
      "the two values printed by the Rust program",
      record="Revision/gkd_lovelock/results/lovelock-report.json, gkdSelfCheck")
```

The two values that the Rust program wrote into its report: length3Pair = 1 and transposition = -1, equal to the fast rule for the lists $(0,1,2)$, $(1,2,0)$ and $(0,1)$, $(1,0)$. The cell prints three PASS lines.

In [7], the 4096 values with two indices.

```
pairs = list(itertools.product(range(8), repeat=2))  # (0, 0), (0, 1), ..., (7, 7)
table = np.array([[gkd_rule(lo, up) for up in pairs] for lo in pairs])  # 64 x 64
```

```
two_term_ok = all(
    gkd_rule(lo, up) == kronecker(lo[0], up[0]) * kronecker(lo[1], up[1])
    - kronecker(lo[0], up[1]) * kronecker(lo[1], up[0])
    for lo in pairs for up in pairs)
check(two_term_ok, "the two-term formula holds for all 4096 pairs of length 2")
```

From here on the labels are the numbers 0 to 7, the computer's names for x_0 to x_7. All 64 lists of length 2; the 64×64 table of values (row: the lower list, column: the upper list); and the two-term formula of Section 1.42 for every entry.

```
say(f"values +1: {(table == 1).sum()}, values -1: {(table == -1).sum()}, "
    f"zeros: {(table == 0).sum()}")
check((table == 1).sum() == 56 and (table == -1).sum() == 56,
      "56 values +1 and 56 values -1 among the 4096")
```

The counts: values +1: 56, values -1: 56, zeros: 3984, as derived in Section 1.43.

```
fig, ax = plt.subplots(figsize=(6.6, 6.2))
image = ax.imshow(table, cmap="RdBu_r", vmin=-1, vmax=1, interpolation="nearest")
ax.grid(False)
ticks = [8 * k for k in range(8)]  # the first pair of each block of 8
ax.set_xticks(ticks, [f"$(x_{k}, x_0)$" for k in range(8)], rotation=90,
              fontsize=7)
ax.set_yticks(ticks, [f"$(x_{k}, x_0)$" for k in range(8)], fontsize=7)
ax.set_xlabel("upper list $(u_1, u_2)$")
ax.set_ylabel("lower list $(l_1, l_2)$")
ax.set_title("all 4096 values of the two-index delta")
fig.colorbar(image, ax=ax, shrink=0.8, ticks=[-1, 0, 1])
save_figure(fig, "two_index_table",
            "All 4096 values of the generalized delta with two indices over the "
            ...)
```

The table as a heat map (`interpolation="nearest"` keeps every entry a sharp square). The lists run in the order $(x_0, x_0), (x_0, x_1), \ldots, (x_7, x_7)$; a tick marks the first list of each block of eight, labelled (x_k, x_0), rotated by 90 degrees below the picture. What Figure 01c.2 shows: 56 red dots on the diagonal (equal lists of two different labels), with 8 white gaps where a list repeats its label, and 56 blue dots where the upper list is the reverse of the lower one. The cell prints two PASS lines.

In [8], every pair of length 1, 2 and 3, with plain loops.

```
comparison = wolfram_report["measurements"]["gkdComparison"]  # one entry per length
recorded = {entry["p"]: entry for entry in comparison}
plain_values = {}  # length p -> array of all values, lower lists in the outer loop
tallies = {}
total_pairs = 0
mismatches = 0
```

The record's table `gkdComparison` (one entry per length, with the counts of $+1$, -1 and 0), made into a dictionary by length; containers for the values, the counts (**tallies**), the number of pairs and of disagreements.

```
for p in (1, 2, 3):
    lists = list(itertools.product(range(8), repeat=p))
    values = []
    for lower in lists:
        for upper in lists:
            fast = gkd_rule(lower, upper)
            mismatches += fast != kdelta_literal(lower, upper)
            values.append(fast)
    plain_values[p] = np.array(values)
    total_pairs += len(values)
```

For $p = 1, 2, 3$: all 8^p lists, and for every pair the fast rule and the literal determinant; `mismatches += fast != ...` adds 1 when the two differ (True counts as 1). The values are kept, lower lists in the outer loop, for In [9].

```
    tally = {v: int((plain_values[p] == v).sum()) for v in (1, -1, 0)}
    tallies[p] = tally
    in_record = (recorded[p]["plusOne"], recorded[p]["minusOne"], recorded[p]["zero"])
    here = (tally[1], tally[-1], tally[0])
    say(f"length {p}: {len(values)} pairs")
    say(f"    counts of (+1, -1, 0): here {here}, record {in_record}")
    check(here == in_record,
          f"length {p}: the counts of +1, -1 and 0 equal the record",
          record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, check "
                 f"gkd_equals_kdelta_exhaustive_length_{p}")
```

The counts of the three values, compared with the record's: for length 3 the output reads here (1008, 1008, 260128), record (1008, 1008, 260128). Each length gives a PASS line that reproduces the record's check of that length.

```
report("pairs of length 1, 2, 3 compared", total_pairs)
exhaustive = [wolfram_checks[f"gkd_equals_kdelta_exhaustive_length_{p}"]
              for p in (1, 2, 3)]  # the record's three exhaustive comparisons
check(total_pairs == 266304 and mismatches == 0 and all(
      c["verdict"] == "PASS" and "(0 mismatches;" in c["detail"] for c in exhaustive),
      "literal determinant = fast rule for all 266304 pairs of length 1, 2, 3",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, checks "
             "gkd_equals_kdelta_exhaustive_length_1 to 3 (0 mismatches)")
```

The RESULT line 266304 ($64 + 4096 + 262144$). `exhaustive` is the list of the record's three checks `gkd_equals_kdelta_exhaustive_length_1`, `_length_2` and `_length_3`, taken from the dictionary `wolfram_checks` of In [6]; the f-string puts the length p at the end of the name. The check requires three things at once: 266,304 pairs; no disagreement between the literal determinant and the fast rule here; and, for each of the three record checks, the verdict PASS and the text `(0 mismatches;` in its detail (`"..." in text` is True when the first text occurs inside the second; `all(...)` is True when the condition holds for every entry of the list). So the notebook's count of disagreements, 0, reproduces the record's count of mismatches between the author's definition and GKD. (The record's sympy verifier ran a different exhaustive comparison on the same 266,304 pairs: the literal determinant against a determinant computed by an independent method, the **cofactor expansion**,

which writes a determinant as a sum over the entries of its first row, each entry times the determinant of the smaller matrix left when its row and column are removed, with the signs $+, -, +, \ldots$ in turn; its check is `gkd_literal_equals_cofactor_expansion` in `python-lovelock-report.json`. It compares two determinant programs, not a determinant with the fast rule, so this notebook does not claim to reproduce it.) The cell takes several seconds and prints four PASS lines.

In [9], many pairs at once.

```
def all_lists(p):
    """Every index list of length p over the labels 0 ... 7, one per row."""
    return np.array(list(itertools.product(range(8), repeat=p)), dtype=np.int8)
```

All 8^p lists of length p as the rows of a numpy array of small whole numbers (`np.int8`: one byte each, enough for 0 to 7).

```
def literal_many(lowers, uppers):
    """The author's definition for many pairs at once (exact whole numbers)."""
    p = lowers.shape[1]
    outer = lowers[:, :, None] == uppers[:, None, :]  # shape (pairs, p, p)
    values = np.zeros(len(lowers), dtype=np.int64)
    rows = np.arange(p)
    for order, order_sign in signed_permutations(p):
        # True where the entries (i, order[i]) of the matrix are all 1
        values += order_sign * outer[:, rows, list(order)].all(axis=1)
    return values
```

The literal determinant for a whole block of pairs: row r of `lowers` and of `uppers` is one pair. `lowers[:, :, None] == uppers[:, None, :]` compares every lower label with every upper label of the same pair at once (numpy **broadcasting**: the inserted axes of length 1 are stretched to match), giving one matrix `Outer` of True and False per pair. For each permutation, `outer[:, rows, list(order)]` picks the entries $(i, \sigma(i))$ of every matrix, `.all(axis=1)` is true when they are all 1 (then the term is ± 1, otherwise 0), and the term's sign is added. This is the Leibniz formula, done for all pairs together.

```
def rule_many(lowers, uppers):
    """The fast rule for many pairs at once."""
    p = lowers.shape[1]
    upper_sorted = np.sort(uppers, axis=1)
    upper_distinct = (np.diff(upper_sorted, axis=1) != 0).all(axis=1)
    same_labels = (np.sort(lowers, axis=1) == upper_sorted).all(axis=1)
```

The fast rule for a block, with the sign shortcut of Section 1.43. Sorting each upper list, `upper_di stinct` is true when no two neighbours of the sorted list are equal (no repeated upper label), and `same_labels` is true when the sorted lower list equals the sorted upper list (the two lists hold the same labels).

```
    first, second = np.triu_indices(p, 1)  # all pairs of places first < second
    inversions_lower = (lowers[:, first] > lowers[:, second]).sum(axis=1)
```

```
    inversions_upper = (uppers[:, first] > uppers[:, second]).sum(axis=1)
    signs = np.where((inversions_lower + inversions_upper) % 2 == 0, 1, -1)
    return np.where(upper_distinct & same_labels, signs, 0)
```

`np.triu_indices(p, 1)` lists all pairs of places $i < j$; the inversions of each lower and each upper list are counted, and $\mathrm{sign}(L)\,\mathrm{sign}(U)$ is $+1$ when their total is even. `np.where(condition, a, b)` takes `a` where the condition holds and `b` elsewhere: the sign where the lists hold the same different labels, 0 otherwise (with distinct upper labels and the same sorted labels, the lower labels are distinct as well, so cases (a), (b) and (c) all give 0).

```
agree = True
for p in (1, 2, 3):
    lists = all_lists(p)
    lowers = np.repeat(lists, len(lists), axis=0)  # each lower list 8^p times
    uppers = np.tile(lists, (len(lists), 1))  # all upper lists, again and again
    agree &= bool((literal_many(lowers, uppers) == plain_values[p]).all())
    agree &= bool((rule_many(lowers, uppers) == plain_values[p]).all())
check(agree, "the block functions agree with the plain ones on all pairs of "
      "length 1, 2, 3")
```

Before the new functions are trusted, they must give the plain values of In [8] for all 266,304 pairs. `np.repeat` repeats each lower list 8^p times and `np.tile` repeats the whole list of upper lists 8^p times, which together produce every pair in the order of In [8] (lower lists in the outer loop). One PASS line.

In [10], all 16,777,216 pairs of length 4.

```
selftest = read_report("gkd-selftest.json")
recorded_selftest = {entry["p"]: entry for entry in selftest["results"]}
lists4 = all_lists(4)  # 4096 lists
tally4 = {1: 0, -1: 0, 0: 0}
mismatches4 = 0
```

The record's self-test report, by length; the 4096 lists of length 4; counters.

```
for start in range(0, 4096, 256):
    lowers = np.repeat(lists4[start:start + 256], 4096, axis=0)
    uppers = np.tile(lists4, (256, 1))
    literal = literal_many(lowers, uppers)
    fast = rule_many(lowers, uppers)
    mismatches4 += int((literal != fast).sum())
    for v in (1, -1, 0):
        tally4[v] += int((fast == v).sum())
tallies[4] = tally4
pairs4 = sum(tally4.values())
```

The $4096 \cdot 4096 = 16{,}777{,}216$ pairs in 16 blocks: each block takes 256 lower lists (`start` runs 0, 256, ..., 3840), each paired with all 4096 upper lists, 1,048,576 pairs per block, few enough to fit in memory. For each block the literal determinant and the fast rule are compared and the values tallied.

```
say(f"length 4: {pairs4} pairs; +1: {tally4[1]}, -1: {tally4[-1]}, 0: {tally4[0]}; "
    f"mismatches {mismatches4}")
report("length 4, counts of the values +1, -1, 0",
       f"{tally4[1]}, {tally4[-1]}, {tally4[0]}")
for p in (1, 2, 3, 4):
    mode, pairs_p, wrong = (recorded_selftest[p]["mode"], recorded_selftest[p]["pairs"],
                            recorded_selftest[p]["mismatches"])
    say(f"record gkd-selftest.json, length {p}: {mode}, {pairs_p} pairs, {wrong} "
        "mismatches")
```

Output: length 4: 16777216 pairs; +1: 20160, -1: 20160, 0: 16736896; mismatches 0, the RESULT line, and four lines of the record's self-test: exhaustive, 64, 4096, 262144 and 16777216 pairs, 0 mismatches each.

```
check(pairs4 == recorded_selftest[4]["pairs"] == 16777216 and
      mismatches4 == recorded_selftest[4]["mismatches"] == 0,
      "all 16777216 pairs of length 4: literal determinant = fast rule",
      record="Revision/gkd_lovelock/results/gkd-selftest.json, length 4 "
             "(exhaustive)")
check(all(recorded_selftest[p]["pairs"] == 8 ** (2 * p) and
          recorded_selftest[p]["mismatches"] == 0 for p in (1, 2, 3)),
      "the record's exhaustive self-tests of length 1, 2, 3 cover 8^(2p) pairs "
      "with no mismatch, as found in section 10",
      record="Revision/gkd_lovelock/results/gkd-selftest.json, lengths 1 to 3")
```

Two PASS lines: the length-4 comparison of the record is reproduced, and the record's lengths 1 to 3 cover every pair (8^{2p}) with no mismatch, as In [8] found (section 10 of the notebook). The cell takes 10 to 30 seconds (COMPUTED).

In [11], the counts as a picture.

```
fig, ax = plt.subplots(figsize=(7.5, 4.4))
lengths = np.arange(1, 5)
for shift, value, color, name in [(-0.27, 1, "tab:red", "value +1"),
                                  (0.0, -1, "tab:blue", "value -1"),
                                  (0.27, 0, "0.6", "value 0")]:
    counts = [max(tallies[p][value], 0.8) for p in lengths]  # 0.8 marks a count 0
    ax.bar(lengths + shift, counts, width=0.25, color=color, label=name)
    for x, count in zip(lengths + shift, counts):
        ax.text(x, count * 1.25, f"{count:.0f}" if count >= 1 else "0",
                ha="center", fontsize=7, rotation=90)
```

Three bars per length: the counts of $+1$, -1 and 0. A logarithmic axis cannot show 0, so a count 0 is drawn as 0.8, a short stub, and labelled "0"; every bar carries its count above it, written vertically (`rotation=90`).

```
ax.set_yscale("log")
ax.set_ylim(0.5, 2e9)
ax.set_xticks(lengths)
ax.set_xlabel("length $p$ of the two index lists")
```

```
ax.set_ylabel("number of pairs (logarithmic scale)")
ax.set_title("Values of the generalized delta over 8 labels")
ax.legend(loc="upper left");
save_figure(fig, "value_counts",
            "The number of pairs of index lists of length $p = 1$ to 4 over the "
            ...)
```

What Figure 01c.3 shows: the grey bars (zeros) tower over the others, more so with every length; the red and blue bars are equal from $p = 2$ on.

In [12], the counting formula.

```
def nonzero_count(n, p):
    """The number of pairs of index lists of length p over n labels with value +-1."""
    return math.perm(n, p) * math.factorial(p) if p <= n else 0
```

The formula of Section 1.43: `math.perm(n, p)` is the falling factorial $n!/(n-p)!$.

```
formula_ok = tallies[1][1] == 8 and tallies[1][-1] == 0
for p in (2, 3, 4):
    formula_ok &= tallies[p][1] == tallies[p][-1] == nonzero_count(8, p) // 2
check(formula_ok, "the counting formula n!/(n-p)! p! gives the counts of lengths 1 to 4")
```

The formula against the counts of In [8] and In [10]: 8 values $+1$ and none -1 for $p = 1$; half of $N_{\neq 0}$ each for $p = 2, 3, 4$.

```
for p in range(1, 10):
    total = 8 ** (2 * p)
    say(f"p = {p}: {total:20d} pairs, {nonzero_count(8, p):11d} not zero, "
        f"fraction {nonzero_count(8, p) / total:.3e}")
```

The table for $p = 1$ to 9: the number of pairs, of nonzero values and their fraction. It ends with p = 8: 281474976710656 pairs, 1625702400 not zero, fraction 5.776e-06, and p = 9: 0 not zero.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.3))
lengths = np.arange(1, 9)
left.semilogy(lengths, [8.0 ** (2 * p) for p in lengths], "s-",
              label="all pairs $8^{2p}$")
left.semilogy(lengths, [nonzero_count(8, p) for p in lengths], "o-",
              label="pairs with value $\\pm 1$")
left.set_xlabel("length $p$")
left.set_ylabel("number of pairs (logarithmic scale)")
left.set_title("for $p = 9$ no pair is left")
left.legend()
```

On the left both numbers for $p = 1$ to 8 on a logarithmic axis.

```
right.semilogy(lengths, [nonzero_count(8, p) / 8.0 ** (2 * p) for p in lengths], "o-",
               color="tab:purple")
right.set_xlabel("length $p$")
right.set_ylabel("fraction of pairs with value $\\pm 1$")
right.set_title("the nonzero values become rare")
fig.tight_layout()
# The fraction for p = 8 written as "5.8 \times 10^{-6}" for the caption:
mantissa, exponent = f"{nonzero_count(8, 8) / 8 ** 16:.1e}".split("e")
save_figure(fig, "nonzero_fraction",
            "Left: the number of all pairs of index lists of length $p$ over 8 "
            ...
            f"$p = 1$ to about ${mantissa} \\times 10^{{{int(exponent)}}}$ at "
            "$p = 8$; horizontal axes the length $p$.")
```

On the right their ratio. As in Notebook 01a, In [13], the fraction for $p = 8$, $1625702400/8^{16} = 5.78\ldots \times 10^{-6}$, is written with one digit after the point as the text 5.8e-06 and split at the letter e into the mantissa 5.8 and the exponent -06. The line `...` stands for four ordinary text lines of the caption. In the f-string line, `{mantissa}` inserts 5.8; `\\times` is one backslash written twice, so LaTeX receives its multiplication sign `\times`; in `10^{{{int(exponent)}}}` the doubled braces `{{` and `}}` stand for one literal brace each, and the insertion between them, `{int(exponent)}`, turns the text -06 into the whole number -6 (the leading zero disappears). So LaTeX receives `10^{-6}`, and the caption reads "to about 5.8×10^{-6} at $p = 8$". The last line is an ordinary text without insertions. What Figure 01c.4 shows: the number of all pairs grows along a straight line on the logarithmic axis, the number of nonzero ones much more slowly, and the fraction falls steadily. The cell prints one PASS line and the table.

In [13], nine indices in eight dimensions.

```
generator = np.random.default_rng(12345)
nine_all_zero = True
for sample in range(600):
    upper = tuple(int(x) for x in generator.integers(0, 8, size=9))
    if sample % 2 == 0:  # an arbitrary lower list
        lower = tuple(int(x) for x in generator.integers(0, 8, size=9))
    else:  # a re-ordering of the upper list
        lower = tuple(int(x) for x in generator.permutation(np.array(upper)))
```

600 random pairs of lists of 9 labels (seed 12345): for even samples an arbitrary lower list, for odd ones a re-ordering of the upper list (`generator.permutation` returns the entries in a random order), the hardest case for the rule.

```
    determinant = np.linalg.det(np.array(outer_matrix(lower, upper), dtype=float))
    nine_all_zero &= gkd_rule(lower, upper) == 0 and abs(determinant) < 1e-9
check(nine_all_zero, "600 pairs of lists of 9 labels from 8: every value is 0",
      record="Revision/gkd_lovelock/results/python-lovelock-report.json, check "
             "gkd_nine_indices_in_eight_dimensions_vanish (with our own random lists)")
```

The literal determinant of the 9×9 matrix is computed by numpy's elimination (the Leibniz formula would have $9! = 362{,}880$ terms); both it and the fast rule must be 0, as the pigeonhole principle says. The record made the same test with its own random lists.

```
eight = tuple(range(8))
reverse = eight[::-1]  # (7, 6, ..., 0)
say(f"8 labels against their reverse: {inversions(reverse)} inversions, value "
    f"{gkd_rule(eight, reverse):+d}")
check(gkd_rule(eight, reverse) == 1 and inversions(reverse) == 28,
      "with 8 labels a nonzero value is possible (the reverse order has 28 "
      "inversions, value +1)")
```

`[::-1]` reverses a list. Output: 8 labels against their reverse: 28 inversions, value +1. The cell prints two PASS lines.

In [14], contracting one index.

```
def contraction_factors(n, p, pairs_of_lists):
    """The set of the ratios sum_c delta(A + c, B + c) / delta(A, B) over the pairs
    with delta(A, B) != 0; returns None if some pair breaks the identity."""
    found_factors = set()
    for lower, upper in pairs_of_lists:
        total = sum(gkd_rule(lower + (c,), upper + (c,)) for c in range(n))
        base = gkd_rule(lower, upper)
```

For each pair of lists A (lower) and B (upper) of length $p-1$: `total` is the sum over the n labels c of the delta of the extended lists (`lower + (c,)` appends c to a tuple), and `base` is the delta of A and B.

```
        if base == 0:
            if total != 0:
                return None
        else:
            found_factors.add(total // base)
            if total != (n - p + 1) * base:
                return None
    return found_factors
```

If the base is 0 the sum must be 0 too; otherwise the ratio is recorded and must be $n-p+1$. A broken pair makes the function return `None` (Python's "nothing"); otherwise it returns the set of ratios found, which must contain one number.

```
factors = {}  # (n, p) -> the factor found
for n in (4, 8):
    for p in range(1, n + 1):
        q = p - 1  # the length of the lists A and B
        if (n == 8 and p <= 3) or n == 4:  # every pair of lists, plain loops
            lists = list(itertools.product(range(n), repeat=q))
            pairs_q = [(lo, up) for lo in lists for up in lists]
```

For $n = 4$ and $n = 8$ and every p: when there are few lists ($n = 8$ with $p \le 3$, or $n = 4$), every pair of lists of length $q = p - 1$ is tested with plain loops. (For $p = 1$ the only list is the empty tuple, whose delta with itself is 1.)

```
        elif n == 8 and p == 4:  # every pair, with the block function
            lists = all_lists(3)
            lowers = np.repeat(lists, len(lists), axis=0)
            uppers = np.tile(lists, (len(lists), 1))
            base = rule_many(lowers, uppers)  # delta(A, B) for all 262144 pairs
            total = sum(rule_many(np.column_stack([lowers, np.full(len(lowers), c)]),
                                  np.column_stack([uppers, np.full(len(uppers), c)]))
                        for c in range(8))  # the sum over c, for all pairs at once
```

For $n = 8$, $p = 4$ all $512 \cdot 512 = 262{,}144$ pairs of lists of length 3 are handled with the block function of In [9]: `np.column_stack` appends a column holding the label c to every list (`np.full(len(lowers), c)` is that column), and the sum over c is taken for all pairs at once.

```
            nonzero = base != 0
            ratios = np.unique(total[nonzero] // base[nonzero])  # base is +1 or -1
            identity_holds = (bool((total[~nonzero] == 0).all()) and len(ratios) == 1
                              and bool((total == (n - p + 1) * base).all()))
            factors[(n, p)] = int(ratios[0]) if identity_holds else None
            continue
```

The same tests as in `contraction_factors`, on arrays: where the base is 0 the sum must be 0 (`~` turns True into False and back), the ratios must be one number, and the identity must hold everywhere. `continue` skips the rest of the loop body for this p.

```
        else:  # random pairs: half re-orderings of different labels, half arbitrary
            pairs_q = []
            for sample in range(4000):
                if sample % 2 == 0:
                    upper = tuple(int(x) for x in generator.permutation(n)[:q])
                    lower = tuple(int(x) for x in generator.permutation(np.array(upper)))
                else:
                    upper = tuple(int(x) for x in generator.integers(0, n, size=q))
                    lower = tuple(int(x) for x in generator.integers(0, n, size=q))
                pairs_q.append((lower, upper))
        found = contraction_factors(n, p, pairs_q)
        factors[(n, p)] = found.pop() if found and len(found) == 1 else None
```

For $n = 8$ and $p = 5$ to 8 there are too many pairs, so 4000 random ones are tested: half of them with q different labels (the first q entries of a random order of all n labels) and a re-ordering of them, where the value is not 0; half arbitrary. Then the function of above is applied, and the one factor found is stored (`found.pop()` takes the element out of the set; `if found and len(found) == 1` guards against `None` and against several factors).

```
say("factors found for n = 8, p = 1 ... 8: "
    + ", ".join(str(factors[(8, p)]) for p in range(1, 9)))
say("factors found for n = 4, p = 1 ... 4: "
    + ", ".join(str(factors[(4, p)]) for p in range(1, 5)))
report("contraction factors for 8 labels, p = 1 to 8",
       ", ".join(str(factors[(8, p)]) for p in range(1, 9)))
check(all(factors[(n, p)] == n - p + 1 for n in (4, 8) for p in range(1, n + 1)),
      "contracting one index multiplies by n - p + 1 (n = 4 and 8, every p)")
```

Output: the factors 8, 7, 6, 5, 4, 3, 2, 1 for $n = 8$ and 4, 3, 2, 1 for $n = 4$, the RESULT line, and the PASS line of the contraction identity of Section 1.44.

In [15], the factors of the record's trace identities.

```
trace_checks = [c for c in wolfram_report["checks"]
                if re.fullmatch(r"k\d_trace_equals_\d_L\d", c["name"])]
named = {}
for c in trace_checks:
    name, verdict = c["name"], c["verdict"]
    k_text, factor_text = re.fullmatch(r"k(\d)_trace_equals_(\d)_L\d", name).groups()
    k = int(k_text)
    named[k] = int(factor_text)
```

The Wolfram report names its trace checks after their factors, for example `k1_trace_equals_6_L1`. `re.fullmatch` requires the whole name to fit the pattern; the second pattern takes out the order k and the factor, and `named` maps k to the factor in the name.

```
    say(f"record check {name}: {verdict}; factor for k = {k}: {factor_text}; "
        f"found here for p = {2 * k + 1}: {factors[(8, 2 * k + 1)]}")
check(named == {1: 6, 2: 4, 3: 2} and
      all(factors[(8, 2 * k + 1)] == named[k] for k in (1, 2, 3)) and
      all(c["verdict"] == "PASS" for c in trace_checks),
      "the factors 8 - 2k = 6, 4, 2 of the Lovelock trace identities",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, checks "
             "k1_trace_equals_6_L1, k2_trace_equals_4_L2, k3_trace_equals_2_L3")
```

For each check the line printed compares the factor in its name with the factor found in In [14] for $p = 2k + 1$: 6 for $p = 3$, 4 for $p = 5$, 2 for $p = 7$. The check reproduces the three record checks. One PASS line.

In [16], the contraction factors as a picture.

```
fig, ax = plt.subplots(figsize=(7.2, 4.4))
for n, marker, color in ((8, "o", "tab:blue"), (4, "s", "tab:orange")):
    p_values = np.arange(1, n + 1)
    ax.plot(p_values, n - p_values + 1, "-", color=color, lw=1,
            label=f"$n - p + 1$ for $n = {n}$")
    ax.plot(p_values, [factors[(n, p)] for p in p_values], marker, color=color,
            ms=8, fillstyle="none", label=f"factors found, $n = {n}$")
```

For $n = 8$ and $n = 4$: the line $n - p + 1$ and the factors found, as open circles or open squares.

```
for k in (1, 2, 3):
    ax.annotate(f"$k = {k}$: $8 - 2k = {8 - 2 * k}$", xy=(2 * k + 1, 8 - 2 * k),
                xytext=(2 * k + 1.3, 8 - 2 * k + 1.3), fontsize=9,
                arrowprops={"arrowstyle": "->", "color": "black"})
ax.set_xlabel("number $p$ of indices before the contraction")
ax.set_ylabel("factor")
ax.set_title("Contracting one index of the generalized delta")
```

```
ax.legend(loc="upper right", fontsize=8);
save_figure(fig, "contraction_factor",
            "The factor by which contracting one upper with one lower index "
            ...)
```

Three arrows mark the Lovelock values. What Figure 01c.5 shows: all symbols on their straight lines, and the arrows at $p = 3, 5, 7$ on the line of $n = 8$ with the factors 6, 4, 2.

In [17], the Levi-Civita symbol and the author's second route.

```
def levi_civita(indices, n):
    """epsilon_(indices): the generalized delta with the upper list 0, 1, ..., n-1."""
    return gkd_rule(tuple(indices), tuple(range(n)))
```

The Levi-Civita symbol as defined in Section 1.44.

```
eta = json.loads(repository_file("Revision/algebra/gammas.json")
                 .read_text(encoding="utf-8"))["eta"]
say(f"diagonal of eta (x0 ... x7) from the record: {eta}; det eta = {math.prod(eta)}")
check(math.prod(eta) == 1, "det eta = +1: raising all 8 indices of epsilon gives no "
      "extra sign in the signature (4,4)")
```

η from the record; its determinant is the product of its diagonal, `math.prod(eta)`, which is 1. Output: the diagonal and det eta = 1, then the PASS line.

```
# (4, 4, 0): 4 positive, 4 negative, 0 zero eigenvalues; sign of det g = (-1)^4
signature = re.search(r"DefMetric\[\{(\d), (\d), (\d)\}", metric_cell)
positive, negative, zero = (int(part) for part in signature.groups())
say(f"the author's metric g: {positive} positive, {negative} negative, {zero} zero "
    f"eigenvalues; sign of det g = (-1)^{negative} = {(-1) ** negative:+d}")
check((positive, negative, zero) == (4, 4, 0) and (-1) ** negative == 1,
      "the author's notebook declares its metric with the signature (4,4), so the "
      "product of two Levi-Civita tensors has the sign +1",
      record="Revision/gkd_lovelock/results/notebook-input-cells.txt, In[29]")
```

From the author's cell In[29], kept in In [2], the pattern takes out the three numbers of `DefMetric[{4, 4, 0}`; `.groups()` returns them as texts, and they are made whole numbers. The sign of $\det g$ is $(-1)^4 = +1$. One PASS line, reproducing the record's cell.

```
formula_ok = True
for p in range(0, 5):  # n = 4, every length p of the lists a and b
    lists = list(itertools.product(range(4), repeat=p))
    for a in lists:
        for b in lists:
            total = sum(levi_civita(a + c, 4) * levi_civita(b + c, 4)
                        for c in itertools.product(range(4), repeat=4 - p))
            formula_ok &= total == math.factorial(4 - p) * gkd_rule(a, b)
check(formula_ok, "n = 4: sum of epsilon epsilon = (n - p)! delta for p = 0 to 4, "
      "all lists")
```

The product formula of Section 1.44 for $n = 4$ and every $p = 0$ to 4: for every pair of lists a, b of length p, the sum over all lists c of length $4 - p$ of $\varepsilon_{ac}\varepsilon_{bc}$ must be $(4 - p)!\,\delta^b_a$.

```
route_sums = np.zeros((8, 8), dtype=np.int64)
for a in range(8):
    others = [label for label in range(8) if label != a]
    for b in range(8):
        # Only lists c of 7 different labels other than a give a nonzero first factor.
        route_sums[a, b] = sum(levi_civita((a,) + c, 8) * levi_civita((b,) + c, 8)
                               for c in itertools.permutations(others))
author_route = route_sums // math.factorial(7)  # divide by 7! = 5040
```

The author's route In[32] for $n = 8$ and $p = 1$. Summing over all 8^7 lists c would be slow, but the first factor $\varepsilon_{ac_2\ldots c_8}$ is 0 unless c consists of the 7 labels other than a in some order; so the sum runs only over the $7! = 5040$ re-orderings of these labels (`itertools.permutations(others)`). Then the sums are divided by 7!.

```
say(f"the sums for a = b are {sorted(set(np.diag(route_sums).tolist()))}, "
    f"for a different from b {sorted(set(route_sums[~np.eye(8, dtype=bool)].tolist()))}")
check((route_sums == math.factorial(7) * np.eye(8, dtype=np.int64)).all(),
      "the author's route In[32]: sum of epsilon epsilon / 7! = delta^b_a, the "
      "8 x 8 identity")
```

The different values found on the diagonal and off it are printed (`set` keeps each value once; `~np.eye(8, dtype=bool)` selects the entries off the diagonal): [5040] and [0]. The check: the sums are 7! times the identity. The cell prints four PASS lines.

In [18], the Levi-Civita symbol as a picture.

```
fig, axes = plt.subplots(1, 4, figsize=(12.0, 3.5),
                         gridspec_kw={"width_ratios": [1, 1, 1, 1.5]})
names3 = ["$x_1$", "$x_2$", "$x_3$"]
for first in range(3):
    ax = axes[first]
    slice_values = np.array([[levi_civita((first, j, k), 3) for k in range(3)]
                             for j in range(3)])
    ax.imshow(slice_values, cmap="RdBu_r", vmin=-1, vmax=1)
    ax.grid(False)
```

Four panels, the last wider. In the first three the Levi-Civita symbol of three labels is drawn as three 3×3 heat maps, one for each first index (row j, column k).

```
    for j in range(3):
        for k in range(3):
            ax.text(k, j, signed(int(slice_values[j, k])), ha="center", va="center",
                    color="white" if slice_values[j, k] else "black")
    ax.set_xticks(range(3), names3)
    ax.set_yticks(range(3), names3)
    ax.set_title(f"$\\varepsilon$ with first index $x_{first + 1}$", fontsize=9)
```

Every square carries its value, white on the coloured squares; labels and a title.

```
image = axes[3].imshow(author_route, cmap="RdBu_r", vmin=-1, vmax=1)
axes[3].grid(False)
eight_names = [f"$x_{k}$" for k in range(8)]
axes[3].set_xticks(range(8), eight_names, fontsize=7)
axes[3].set_yticks(range(8), eight_names, fontsize=7)
axes[3].set_xlabel("$b$")
axes[3].set_ylabel("$a$")
axes[3].set_title("$\\sum \\varepsilon\\varepsilon / 7!$ in 8 dimensions", fontsize=9)
fig.tight_layout()
save_figure(fig, "levi_civita",
            "Left three panels: the Levi-Civita symbol $\\varepsilon_{ijk}$ of the "
            ...)
```

The fourth panel shows the result of the author's route. What Figure 01c.6 shows: in each of the first three panels two nonzero squares, one red and one blue, six in all, the signs of the six orderings; on the right the 8×8 identity matrix.

In [19], the last check.

```
figure_names = ["01c_1_outer_matrices.png", "01c_2_two_index_table.png",
                "01c_3_value_counts.png", "01c_4_nonzero_fraction.png",
                "01c_5_contraction_factor.png", "01c_6_levi_civita.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

The last line is ALL 28 CHECKS PASSED (notebook 01c). The 28 checks are: 2 in In [2], 1 in In [3], 1 in In [4], 2 in In [5], 3 in In [6], 2 in In [7], 4 in In [8], 1 in In [9], 2 in In [10], 1 in In [12], 2 in In [13], 1 in In [14], 1 in In [15], 4 in In [17] and 1 in In [19].

1.49 Binary numbers, bit operations and a pseudo-random generator

Why this section. The Revision record tested its program GKD twice (Section 1.43): a Rust self-test compared GKD with the author's determinant on millions of pairs of index lists, and a Wolfram check received the GKD values of 346,304 pairs from a small Rust program, the **exporter**, and compared them with the author's own definition in Mathematica. Many of these lists were drawn by a **pseudo-random generator**: a fixed formula that turns a number, its **state**, into a new state and an output, again and again; the outputs look random, but they are completely fixed by the first state, the **seed**. Because the formula and the seeds are recorded, the lists can be made again, exactly, and every number of the record can be checked. To do that we need the binary numbers in which the generator computes.

Binary numbers (PROVED). Our numbers are written in base 10: each digit counts a power of 10. In **binary** (base 2) there are only the digits 0 and 1, and each digit, a **bit**, counts a power of 2: the last digit counts $2^0 = 1$, the one before $2^1 = 2$, then $4, 8, 16, \ldots$. The binary digits of a whole number come from repeated division by 2, the remainder method of long division (Section 1.2): for 2026,

$$2026 = 2 \cdot 1013 + 0, \quad 1013 = 2 \cdot 506 + 1, \quad 506 = 2 \cdot 253 + 0, \quad 253 = 2 \cdot 126 + 1, \quad 126 = 2 \cdot 63 + 0,$$

$$63 = 2 \cdot 31 + 1, \quad 31 = 2 \cdot 15 + 1, \quad 15 = 2 \cdot 7 + 1, \quad 7 = 2 \cdot 3 + 1, \quad 3 = 2 \cdot 1 + 1, \quad 1 = 2 \cdot 0 + 1,$$

and the remainders, read from the last to the first, are the binary digits: $2026 = 11111101010$ in binary, 11 binary digits. Check: $1024 + 512 + 256 + 128 + 64 + 32 + 8 + 2 = 2026$ (the powers of 2 at the places of the digits 1). A computer stores whole numbers as a fixed number of bits; 64 bits hold the numbers 0 to $2^{64} - 1 = 18446744073709551615$.

Bytes and negative numbers. A **byte** is 8 bits, a whole number from 0 to 255. A **signed byte** uses the same 8 bits for the numbers -128 to 127: a negative number $-m$ is stored as $256 - m$ (the **two's complement**). So -1 is stored as 255, the eight bits 11111111. The exporter writes the GKD values $+1$, 0, -1 as the bytes 1, 0, 255.

Hexadecimal. Long binary numbers are written more compactly in base 16, **hexadecimal**, with the sixteen digits 0 to 9 and A to F (worth 10 to 15). One hexadecimal digit is exactly 4 bits ($16 = 2^4$). Python writes such a number with the prefix `0x`, for example `0xFF` $= 15 \cdot 16 + 15 = 255$.

The four bit operations (PROVED). The generator uses four operations on the bits of a whole number $x \geq 0$:

- **Shift right** by k places (Python writes it with the operator made of two greater-than signs): the last k bits are dropped. This is whole-number division by 2^k: writing $x = 2^k q + r$ with $0 \leq r < 2^k$, the last k bits of x are the bits of r, and the bits before them are those of q.
- **Shift left** by k places (two less-than signs): k zero bits are appended, which multiplies by 2^k (every bit moves to a place worth 2^k times more).
- **Keeping 64 bits** (`x & MASK`, with `MASK` $= 2^{64} - 1$, sixty-four ones; `&` keeps a bit where both numbers have a 1): the remainder of x divided by 2^{64}. The Rust programs compute with 64-bit numbers, so every result is cut to 64 bits in this way.
- **Exclusive or** (XOR, `x ^ y`): the two numbers are compared bit by bit, and a result bit is 1 when exactly one of the two bits is 1. Applying the same exclusive or twice gives back the number: for single bits, $(a \oplus b) \oplus b = a$ in all four cases ($b = 0$ changes nothing twice; $b = 1$ flips the bit twice), so it holds bit by bit. That is why an XOR step loses nothing.

For the 8-bit number $x = 182 = 10110110$: shifted right by 2 it is $101101 = 45$, and indeed $182 = 4 \cdot 45 + 2$; shifted left by 3 it is $10110110000 = 1456 = 182 \cdot 8$; keeping its last 8 bits gives $10110000 = 176$, and indeed $1456 = 5 \cdot 256 + 176$; and 182 XOR 11110000 flips the first four of the eight bits: $01000110 = 70$.

The generator `xorshift64*`. The Revision programs (the function `compare_random` of `Revision /gkd_lovelock/code/src/gkd.rs` and the exporter of the Wolfram check) use the generator called `xorshift64*` (shift, exclusive or, 64 bits, and a final multiplication, the star). Its state x is a 64-bit number, and one step reads, in Rust:

```
x ^= x >> 12;        x XOR (x shifted right by 12)
x ^= x << 25;        x XOR (x shifted left by 25, cut to 64 bits)
x ^= x >> 27;        x XOR (x shifted right by 27): the new state
output = x * 0x2545F4914F6CDD1D   (cut to 64 bits)
```

(`^=` means "replace by the exclusive or with"). A label from 0 to $n-1$ is the remainder of the output after division by n; the notebook calls this `below(n)`. The exporter starts, for the lists of length p, from the seed `0x243F6A8885A308D3` XOR p; these sixteen hexadecimal digits are the first digits of π after the point, written in base 16 ($\pi = 3.243F6A88\ldots$ in hexadecimal), a number that nobody chose to make a test pass. The Rust self-test starts from (`0x2545F4914F6CDD1D` XOR p) OR 1, where OR 1 sets the last bit to 1. To put a list into a random order the programs use the **Fisher-Yates shuffle**: for i from the last place down to the second, exchange the entry at place i with the entry at a random place from 0 to i.

A test is not a proof. A pseudo-random sample, however large, is evidence, not a proof; the proof that GKD equals the author's determinant is the four-case argument of Section 1.42. What the regenerated lists show is something else, just as important for a record: its numbers are exactly reproducible.

1.50 Fingerprints, the exporter's file and the birthday problem

The sha256 fingerprint. A **sha256 fingerprint** is a 64-digit hexadecimal number computed from the bytes of a file by the method SHA-256. Two different files have different fingerprints for all practical purposes (a property of the method, ASSUMED here), so equal fingerprints mean equal files, byte for byte; and changing a single bit of a file changes its fingerprint completely. The Revision record keeps the fingerprints of the files it used.

The exporter's file (PROVED by arithmetic). The exporter writes, for every pair of index lists, one record of signed bytes: the length p, the p lower labels, the p upper labels and the GKD value, $2p+2$ bytes in all. It writes every pair of the lengths 1, 2 and 3, and 20,000 pseudo-random pairs of each length 4 to 7. So the file has

$$64\cdot 4 + 4096\cdot 6 + 262144\cdot 8 + 20000\,(10+12+14+16) = 256 + 24576 + 2097152 + 1040000 = 3161984$$

bytes (the number of pairs of each length times its record size; multiply out and add). The record states the same size and the file's fingerprint in `Revision/gkd_lovelock/results/wolfram-gkd-report.json`, field `gkdValuesSource`. Notebook 01d, In [8], regenerates all 3,161,984 bytes from the seeds and the recorded source code and finds the recorded fingerprint, `3ddccfa744b3708b` followed by 48 more digits (COMPUTED). It then reproduces every number of the record's table `gkdComparison` (In [9]): for the lengths 1 to 7 the numbers of pairs (64, 4096, 262144 and 20,000 four times; 346,304 in all), the counts of $+1$, -1 and 0, no mismatch between GKD and the author's determinant, and the result of a **negative control**: the same comparison against $-$GKD, a test that must fail, fails exactly at the nonzero values, which shows that the comparison can fail.

The self-test for the lengths 5 to 9. The record's file `Revision/gkd_lovelock/results/gkd-selftest.json` gives, for 200,000 pseudo-random pairs of each length 5 to 9, the numbers of nonzero values, 20538, 7812, 1949, 244 and 0, and no mismatch. Notebook 01d, In [11], regenerates the 1,000,000 pairs and gets exactly these numbers (COMPUTED).

The birthday problem (PROVED). Why these numbers? In the self-test an even sample takes p upper labels with `below(8)` and a re-ordering of them as the lower list; its value is not zero exactly when its p upper labels are all different. Labels drawn one after the other, each with 8 equally likely values, are all different with the probability

$$P(p) = \frac{8}{8} \cdot \frac{7}{8} \cdots \frac{8-p+1}{8} = \frac{8!/(8-p)!}{8^p}$$

(the first label may be anything; the second must avoid it, 7 of 8 values; the third must avoid both, 6 of 8; and so on; independent chances multiply, a rule of probability ASSUMED here). This is the **birthday problem**: the chance that p people have p different birthdays, with 8 "days" instead of 365. For $p = 9$ it is 0, because $8 - 9 + 1 = 0$ (the pigeonhole principle again). An odd sample draws two arbitrary lists; it is nonzero with the probability $q(p) = N_{\neq 0}(8, p)/8^{2p}$ of Section 1.43. For N tries that each succeed with probability q, the number of successes is about Nq, its **expected value**, typically within one **standard deviation** $\sqrt{Nq(1-q)}$ of it (ASSUMED from probability theory). With 100,000 even and 100,000 odd samples the expected number of nonzero values is $100000\,P(p) + 100000\,q(p)$; for $p = 5$:

$$100000 \cdot \frac{8 \cdot 7 \cdot 6 \cdot 5 \cdot 4}{8^5} + 100000 \cdot \frac{806400}{8^{10}} = 100000 \cdot \frac{6720}{32768} + 75.1 = 20507.8 + 75.1 = 20582.9$$

($8^5 = 32768$; $N_{\neq 0}(8, 5) = 6720 \cdot 5! = 806400$ and $8^{10} = 1073741824$), with a standard deviation of about 128; the recorded 20538 lies 0.35 standard deviations below it. Notebook 01d, In [12], makes this comparison for every length 5 to 9 and for the odd samples of the Wolfram check, all within 4 standard deviations (COMPUTED). The classic birthday problem says that among 23 people two share a birthday more often than not: $P_{365}(22) = 0.5243$ and $P_{365}(23) = 0.4927$ (COMPUTED; Figure 01d.6).

1.51 Example: reproducing the record's tests of the generalized delta

Notebook 01d puts Sections 1.49 and 1.50 to work. It writes 2026 in binary and shows how a byte stores -1; applies the four bit operations; writes the generator `xorshift64*` in Python, follows its bits through one step and draws its output; checks that its labels come out about equally often; regenerates the 3,161,984 bytes that the exporter gave the Wolfram check and confirms their size and fingerprint; reproduces every number of the record's table `gkdComparison` and of the Rust self-test for the lengths 5 to 9; and explains the counts with the birthday problem. It ends with the line ALL 19 CHECKS PASSED (notebook 01d).

1.52 How to run Notebook 01d

Step 1. What this notebook does and what it needs.

Notebook 01d (Reproducing the GKD self-tests of the Revision record bit for bit) is the file `Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb` of the repository Dirac_claude. It explains whole numbers in binary, the storage of negative numbers in a byte and the bit operations of the pseudo-random generator xorshift64star used by the Revision programs, re-implements

that generator in Python, regenerates the 3,161,984 bytes of generalized Kronecker delta values that the Rust program GKD gave the Wolfram check of the Revision record and confirms their sha256 fingerprint and every count of that record, repeats the Rust self-test of GKD with 200,000 pseudo-random pairs of index lists for each length 5 to 9 and obtains exactly the recorded numbers of nonzero values, compares every value with the determinant of the author's definition, and explains these numbers with the probability that labels drawn at random are all different (the birthday problem). It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 01d_gkd_record_selftests.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 01d_gkd_record_selftests.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 01d_gkd_record_selftests.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/01d.captions.json`
- `Revision/textbook/figures/01d_1_binary_counting.png`
- `Revision/textbook/figures/01d_2_generator_step.png`
- `Revision/textbook/figures/01d_3_generator_bits.png`
- `Revision/textbook/figures/01d_4_label_histogram.png`
- `Revision/textbook/figures/01d_5_record_counts.png`
- `Revision/textbook/figures/01d_6_birthday_problem.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 19 CHECKS PASSED (notebook 01d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 01d_gkd_record_selftests.ipynb
python -m nbconvert --execute --inplace 01d_gkd_record_selftests.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock: the notebook reads reports of the Revision record; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.
- "AssertionError: check failed: the regenerated values have the size and the sha256 fingerprint of the record": the file wolfram-gkd-report.json of your copy differs from the one the book was built with, or a cell above was changed; download the repository again and run all cells from the top without changing them.

1.53 Notebook 01d: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb`: every cell in order, with the output that the stored, executed

notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

The Revision record checked its program GKD (the generalized Kronecker delta of
notebook 01c) twice: a Rust self-test compared GKD with the author's determinant
on millions of pairs of index lists, and a Wolfram check received the values of
GKD for 346,304 pairs of index lists from a small Rust *exporter* program and
compared them with the author's own definition. Many of these lists were drawn
by a *pseudo-random* generator. Because such a generator is a fixed formula, the
lists can be made again, exactly. This notebook

- explains whole numbers in binary, how a byte stores $-1$, and the three bit
  operations (shift, exclusive or, keeping 64 bits) of the generator
  `xorshift64*` that the Revision programs use;
- writes that generator in Python and shows step by step what it does to the
  bits, and that its output looks random;
- regenerates, in Python, all 3,161,984 bytes that the Rust exporter wrote for
  the Wolfram check, and confirms the size and the sha256 fingerprint recorded in
  the Wolfram report, and every count of that report;
- repeats the Rust self-test for the lengths 5 to 9 (200,000 pairs each) and gets
  exactly the recorded numbers of nonzero values, comparing every value with the
  determinant;
- explains these numbers with the probability that labels drawn at random are
  all different, the "birthday problem".
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 01d (Reproducing the GKD self-tests of the Revision record bit for bit) is the
file `Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb` of the repository
Dirac_claude. It explains whole numbers in binary, the storage of negative numbers in a
byte and the bit operations of the pseudo-random generator xorshift64star used by the
Revision programs, re-implements that generator in Python, regenerates the 3,161,984
bytes of generalized Kronecker delta values that the Rust program GKD gave the Wolfram
check of the Revision record and confirms their sha256 fingerprint and every count of
that record, repeats the Rust self-test of GKD with 200,000 pseudo-random pairs of index
lists for each length 5 to 9 and obtains exactly the recorded numbers of nonzero values,
compares every value with the determinant of the author's definition, and explains these
numbers with the probability that labels drawn at random are all different (the birthday
problem). It needs a computer with Windows 11, macOS or Linux, an internet connection for
the installation, the program Git, and Python 3.12 or newer (the notebooks were built
with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
```

0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, mpmath and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these

lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter lab 01d_gkd_record_selftests.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 30 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
    cd Revision/textbook/notebooks
    jupyter nbconvert --to notebook --execute --inplace 01d_gkd_record_selftests.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 01d_gkd_record_selftests.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/01d.captions.json‘
- ‘Revision/textbook/figures/01d_1_binary_counting.png‘
- ‘Revision/textbook/figures/01d_2_generator_step.png‘
- ‘Revision/textbook/figures/01d_3_generator_bits.png‘
- ‘Revision/textbook/figures/01d_4_label_histogram.png‘
- ‘Revision/textbook/figures/01d_5_record_counts.png‘
- ‘Revision/textbook/figures/01d_6_birthday_problem.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 6 figure files of this notebook exist
ALL 19 CHECKS PASSED (notebook 01d)
```

and the notebook must show 6 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

  ```
  python -m ipykernel install --user --name python3
  ```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs).

Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

```
python -m jupyterlab 01d_gkd_record_selftests.ipynb
python -m nbconvert --execute --inplace 01d_gkd_record_selftests.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.
- "FileNotFoundError" for a file below Revision/gkd_lovelock: the notebook reads reports of the Revision record; your copy of the repository is incomplete. Download it again with git clone and open the notebook inside the new copy.
- "AssertionError: check failed: the regenerated values have the size and the sha256 fingerprint of the record": the file wolfram-gkd-report.json of your copy differs from the one the book was built with, or a cell above was changed; download the repository again and run all cells from the top without changing them.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 01d (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 01d (Reproducing the GKD self-tests of the Revision record bit for bit) is the
# file Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb of the repository
# Dirac_claude. It explains whole numbers in binary, the storage of negative numbers in a
# byte and the bit operations of the pseudo-random generator xorshift64star used by the
# Revision programs, re-implements that generator in Python, regenerates the 3,161,984
# bytes of generalized Kronecker delta values that the Rust program GKD gave the Wolfram
# check of the Revision record and confirms their sha256 fingerprint and every count of
# that record, repeats the Rust self-test of GKD with 200,000 pseudo-random pairs of
# index lists for each length 5 to 9 and obtains exactly the recorded numbers of nonzero
# values, compares every value with the determinant of the author’s definition, and
# explains these numbers with the probability that labels drawn at random are all
# different (the birthday problem). It needs a computer with Windows 11, macOS or Linux,
# an internet connection for the installation, the program Git, and Python 3.12 or newer
# (the notebooks were built with Python 3.14.5) with these packages at exactly these
# versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab
# 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The
# notebook itself imports numpy, mpmath and matplotlib; the other packages run Jupyter,
# the program that shows and runs notebooks. It does not need Rust.
```

```
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
```

```
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
```

```
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 01d_gkd_record_selftests.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 30
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 01d_gkd_record_selftests.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 01d_gkd_record_selftests.ipynb (in the same folder, without running the cells again) to
# read the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/01d.captions.json
# - Revision/textbook/figures/01d_1_binary_counting.png
# - Revision/textbook/figures/01d_2_generator_step.png
# - Revision/textbook/figures/01d_3_generator_bits.png
# - Revision/textbook/figures/01d_4_label_histogram.png
# - Revision/textbook/figures/01d_5_record_counts.png
# - Revision/textbook/figures/01d_6_birthday_problem.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
```

```
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 6 figure files of this notebook exist
#     ALL 19 CHECKS PASSED (notebook 01d)
#
# and the notebook must show 6 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/01d_gkd_record_selftests.ipynb inside the folder
#   Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 01d_gkd_record_selftests.ipynb
#     python -m nbconvert --execute --inplace 01d_gkd_record_selftests.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
# - "FileNotFoundError" for a file below Revision/gkd_lovelock: the notebook reads
#   reports of the Revision record; your copy of the repository is incomplete. Download
#   it again with git clone and open the notebook inside the new copy.
```

```
# - "AssertionError: check failed: the regenerated values have the size and the sha256
#   fingerprint of the record": the file wolfram-gkd-report.json of your copy differs
#   from the one the book was built with, or a cell above was changed; download the
#   repository again and run all cells from the top without changing them.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Binary**: writing a whole number with the two digits 0 and 1; each digit
  (a **bit**) counts a power of 2: $2026 = 1024 + 512 + 256 + 128 + 64 + 32 + 8 +
  2$ is ‘11111101010‘ in binary.
- **Byte**: 8 bits, a whole number from 0 to 255. A **signed byte** uses the same
  8 bits for the numbers $-128$ to $127$: a negative number $-m$ is stored as
  $256 - m$ (the **two’s complement**), so $-1$ is stored as 255, ‘11111111‘.
- **Hexadecimal**: writing a number with the 16 digits ‘0‘–‘9‘ and ‘A‘–‘F‘
  (worth 10 to 15); Python writes such a number with the prefix ‘0x‘. One
  hexadecimal digit is exactly 4 bits.
- **Shift**: ‘x >> k‘ drops the last $k$ bits (the same as dividing by $2^k$ and
  dropping the remainder); ‘x << k‘ appends $k$ zero bits (multiplying by $2^k$).
- **Exclusive or** (‘x ^ y‘, XOR): compares the two numbers bit by bit; a result
  bit is 1 when exactly one of the two bits is 1.
- **Keeping 64 bits** (‘x & MASK‘ with ‘MASK‘ $= 2^{64} - 1$): the remainder of $x$
  divided by $2^{64}$; the Rust programs compute with 64-bit numbers, so every
  result is cut to 64 bits.
- **Pseudo-random generator**: a formula that turns a number (its **state**) into
  a new state and an output, again and again; the outputs look random but are
  completely fixed by the first state, the **seed**.
- ‘xorshift64*‘: the generator of the Revision programs: three shift-and-XOR
  steps on a 64-bit state and a multiplication of the output by a fixed odd
  number.
- **Fisher-Yates shuffle**: a way to put a list into a random order by swapping
  entries one after the other.
- **sha256 fingerprint**: a 64-digit hexadecimal number computed from a file by
  the method SHA-256; two different files have different fingerprints for all
```

```
  practical purposes, so equal fingerprints mean equal files, byte for byte.
- **Exporter**: the small Rust program, held as text inside the Wolfram check
  Revision/gkd_lovelock/verification/verify_lovelock_gkd.wls, that wrote the GKD
  values into a file for the Wolfram check.
- **Expected value, standard deviation**: for $N$ tries that each succeed with
  probability $q$, the number of successes is about $Nq$ (the expected value),
  typically within $\sqrt{Nq(1-q)}$ (one standard deviation) of it.
```

Text cell:

```
## 4. The physical and mathematical situation

The generalized Kronecker delta of two index lists of the same length $p$ over
the eight coordinates $x_0, \dots, x_7$ (labels $0, \dots, 7$ for the computer)
is the determinant of the matrix $M_{ij} = \delta(l_i, u_j)$; the program GKD
computes it as 0 for a repeated or missing label and otherwise as the sign of the
permutation that turns the upper list into the lower one (notebook 01c proves
this). It is the weight of every term of the Lovelock tensors of the author's
theory, so the record tested it hard:

1. the **Rust self-test** (‘lovelock_gkd gkd-selftest‘, file gkd-selftest.json)
   compared GKD with the literal Leibniz determinant for all pairs of lengths 1
   to 4 and for 200,000 pseudo-random pairs of each length 5 to 9;
2. the **Wolfram check** (wolfram-gkd-report.json) had the exporter write, as
   bytes, every pair of lengths 1, 2, 3 and 20,000 pseudo-random pairs of each
   length 4 to 7 with their GKD values, and called the author's own definition
   in Mathematica on every pair.

Both used the generator ‘xorshift64*‘ with stated seeds. This notebook rebuilds
the lists from the seeds and the recorded source code, so it can compare its
results with the record exactly: the same bytes, the same counts. A pseudo-random
sample is not a proof; the proof that GKD equals the determinant is the
four-case argument of notebook 01c. What this notebook shows is that the record's
numbers are exactly reproducible.
```

Text cell:

```
## 5. Whole numbers in binary

The next cell writes 2026 in binary with ‘format(number, "b")‘, adds up the
binary digits times their powers of 2 to get the number back (the last digit
counts $2^0 = 1$, the one before $2^1 = 2$, and so on), prints the largest number
that 64 bits can hold, and shows how a signed byte stores $-1$: as 255, eight
ones. Python's ‘& 0xFF‘ keeps the last 8 bits of a number (0xFF is 255);
‘int.from_bytes(..., signed=True)‘ reads a byte back as a signed number.
```

In [2]:

```
import hashlib  # the sha256 fingerprint
import itertools  # all index lists of a given length
import json  # reads the JSON reports of the record
```

```
import math  # factorials and falling factorials

import mpmath  # numbers with many digits
import numpy as np  # arrays

number = 2026
bits = format(number, "b")  # the binary digits, a text of 0s and 1s
say(f"{number} in binary: {bits} ({len(bits)} binary digits)")
# The last digit counts 2^0, the one before 2^1, ...: reversed() starts at the end.
by_places = sum(int(digit) * 2 ** place for place, digit in enumerate(reversed(bits)))
check(by_places == number == int(bits, 2), "the binary digits of 2026 give back 2026")
say(f"the largest number that 64 bits can hold: 2^64 - 1 = {2 ** 64 - 1}")
stored = (-1) & 0xFF  # the 8 bits that a signed byte uses for -1

## 6. The three bit operations

The next cell applies the operations of the generator to the 8-bit number
$x = 182$ = ‘10110110‘ and prints the bits of each result (‘format(v, "08b")‘
writes a number with at least 8 binary digits):

- ‘x >> 2‘ drops the last two bits: ‘101101‘ = 45, the same as $182 // 4$ (whole
  number division);
- ‘x << 3‘ appends three zero bits: $182 \cdot 8 = 1456$;
- ‘(x << 3) & 0xFF‘ keeps the last 8 bits: the remainder of 1456 divided by 256;
- ‘x ^ 0b11110000‘ flips the first four of the eight bits.

It checks these rules on 1000 random 64-bit numbers too, and that applying the
same exclusive or twice gives back the number, which is why an XOR step loses
nothing.
```

In [4]:

## 7. The generator ‘xorshift64*‘, step by step

One step of the generator, as written in the record’s Rust code (the function
‘compare_random‘ of Revision/gkd_lovelock/code/src/gkd.rs and the exporter in
verify_lovelock_gkd.wls):

1. ‘x ^= x >> 12‘: XOR the state with itself shifted 12 bits to the right;
2. ‘x ^= x << 25‘: XOR with itself shifted 25 bits to the left (Rust keeps 64
   bits, so we write ‘& MASK‘);
3. ‘x ^= x >> 27‘: XOR with itself shifted 27 bits to the right; this is the new
   state;
4. the output is the new state times the odd constant ‘0x2545F4914F6CDD1D‘, cut
   to 64 bits.

The generator’s output ‘below(n)‘, a label from 0 to $n - 1$, is the output’s
remainder after division by $n$. The exporter starts from the seed
‘0x243F6A8885A308D3 XOR p‘ for the length $p$; these 16 hexadecimal digits are
the first digits of $\pi$ after the point, written in base 16 (a number that
nobody chose to make a test pass). The Rust self-test starts from
‘(0x2545F4914F6CDD1D XOR p) OR 1‘ (‘| 1‘ makes the last bit 1).

The next cell writes the generator as a small Python class, checks the digits of
$\pi$ with mpmath, and checks that the same seed always gives the same numbers
while a different seed gives different ones.
```

In [5]:

```

## 9. The GKD values that the Rust exporter gave the Wolfram check

The exporter, whose Rust source is printed inside the Wolfram check
verify_lovelock_gkd.wls, writes one **record** of signed bytes per pair of index
lists: the length $p$, the $p$ lower labels, the $p$ upper labels, and the GKD
value ($+1$, 0, or $-1$ stored as 255). It writes

- for $p = 1, 2, 3$ every pair, in the order of Mathematica's
  `Tuples[Range[0, 7], 2 p]` (all lists of $2p$ labels in dictionary order; the
  first $p$ are the lower list, the last $p$ the upper list), which is the order
  of Python's `itertools.product(range(8), repeat=2 * p)`;
- for $p = 4, 5, 6, 7$ 20,000 pairs from the generator with the seed
  `0x243F6A8885A308D3 XOR p`: an even sample (number 0, 2, 4, ...) takes $p$
  different labels (for $i = 0, \dots, p - 1$ it swaps place $i$ of the list
  $0, \dots, 7$ with place $i$ + `below(8 - i)`) as the upper list, and a
  re-ordering of them (for $i = p - 1$ down to 1 it swaps place $i$ with place
  `below(i + 1)`) as the lower list; an odd sample draws $p$ upper labels and
  then $p$ lower labels with `below(8)`.

The next cell defines the GKD rule (as in notebook 01c), regenerates all records
in this order, and keeps the lists and values for the next sections. Then it
compares the size of the bytes and their sha256 fingerprint with the record's
```

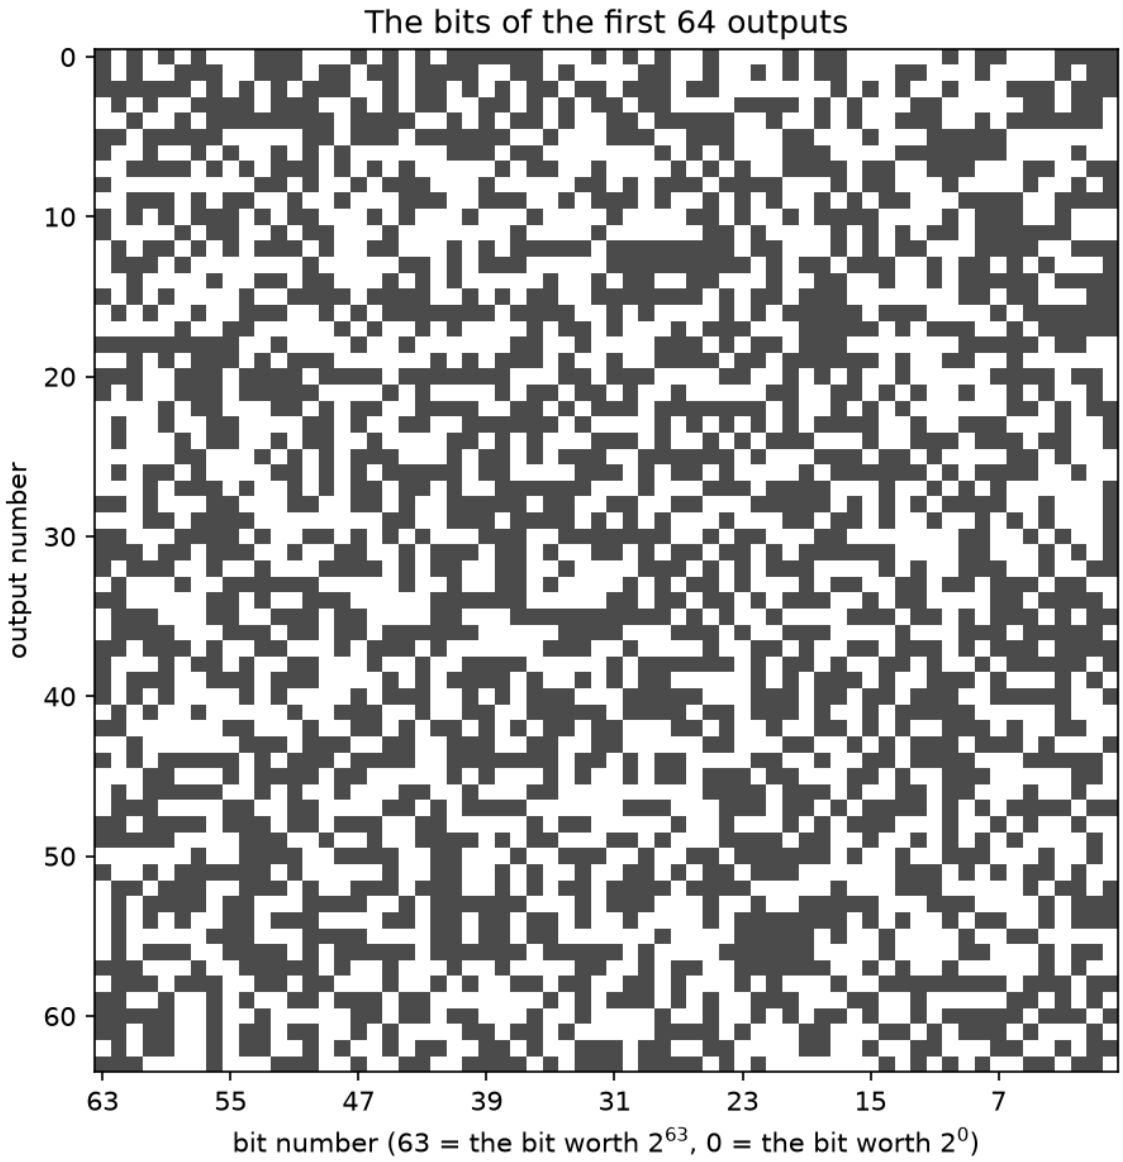

Figure 58: The 64 bits (columns, dark = 1, the highest bit on the left) of the first 64 outputs (rows, the first at the top) of the generator of the record started from the exporter's seed for length 4. No row, column or diagonal pattern is visible: the bits look random, although every one of them is fixed by the seed. (Notebook 01d, figure 3.)

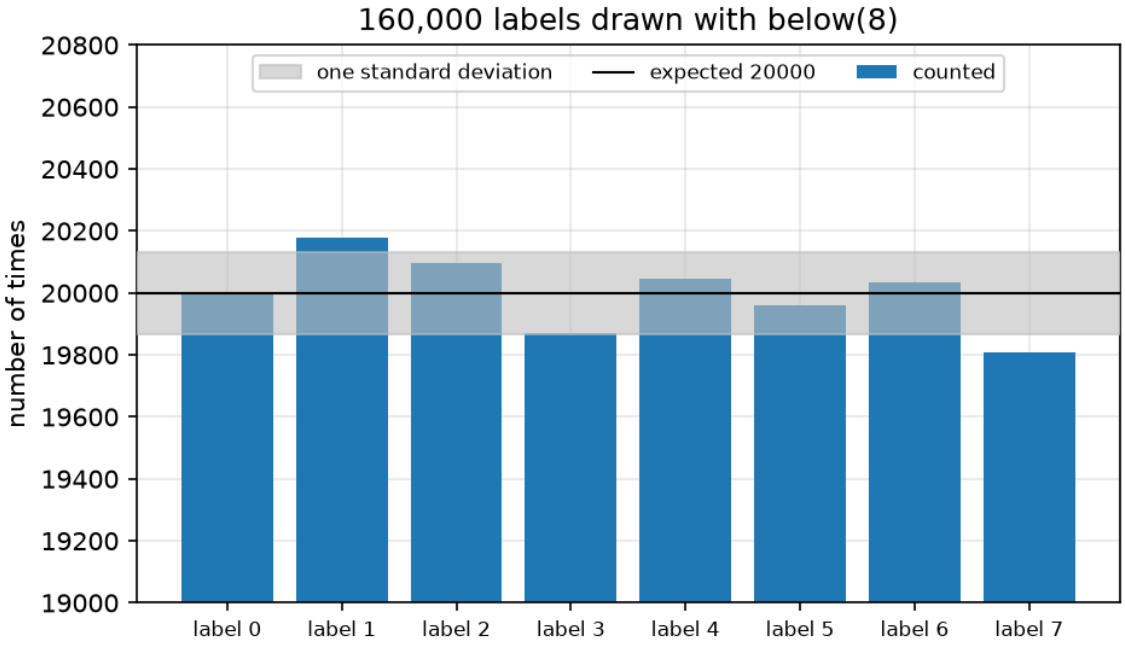

Figure 59: How often each label 0 to 7 came out in 160,000 calls of below(8) of the generator (blue bars), the expected number 20,000 (black line) and the band of one standard deviation, about 132, around it (grey); horizontal axis the label, vertical axis the number of times (the axis starts at 19,000 to make the small differences visible). The counts scatter around 20,000 as a fair random source would. (Notebook 01d, figure 4.)

‘gkdValuesSource‘. Equal fingerprints mean that every one of the 3,161,984 bytes
is the same: the same pairs, in the same order, with the same GKD values. To show
how sensitive the fingerprint is, it also prints the fingerprint after changing
a single byte.

10. Their counts, compared with the record

For each length p the Wolfram report records in ‘measurements.gkdComparison‘: the number of pairs, the number of mismatches between GKD and the author’s determinant, the numbers of values $+1$, -1 and 0, the number of mismatches when the determinant is compared with $-$GKD instead (a *negative control*: a test that must fail, to show that the comparison can fail; it fails exactly where GKD is not zero), and for $p \geq 4$ the number of nonzero values among the 10,000 even samples (all of them, by construction).

The next cell computes the author’s determinant for all 346,304 pairs, with the Leibniz formula applied to many pairs at once as in notebook 01c (‘literal_many‘; for $p = 7$ the formula has $7! = 5040$ terms), builds the same table and compares it, entry by entry, with the record.

In [9]:

11. The Rust self-test for the lengths 5 to 9

The function ‘compare_random(p, 8, 200000, seed)‘ of gkd.rs, called by the self-test with the seed ‘0x2545F4914F6CDD1D XOR p‘, starts the generator at ‘seed OR 1‘ and draws 200,000 samples: for each one p upper labels with ‘below(8)‘; for an even sample the lower list is the upper list re-ordered (for $i = p - 1$ down to 1 swap place i with place ‘below(i + 1)‘), for an odd sample p more labels with ‘below(8)‘. It counts the nonzero GKD values and the mismatches with the Leibniz determinant; gkd-selftest.json records both.

The next cell repeats this. GKD is computed for all samples at once with the sign shortcut of notebook 01c (‘rule_many‘: the sign of the re-ordering is the product of the signs of the two lists), and the determinant with numpy’s elimination (‘np.linalg.det‘, floating point, then rounded; the Leibniz formula would have $9!$ = 362,880 terms per matrix). The cell checks that every determinant is a whole number up to 10^{-6}. It takes 10 to 30 seconds.

In [11]:

Text cell:

```
## 12. Why these numbers: the birthday problem

In the self-test an even sample is nonzero exactly when its $p$ upper labels are
all different (the lower list is then a re-ordering of them). Labels drawn one
```

```
after the other, each with 8 equally likely values, are all different with the
probability

$$P(p) = \frac{8}{8} \cdot \frac{7}{8} \cdots \frac{8 - p + 1}{8}
= \frac{8!/(8-p)!}{8^p},$$

because the second label must avoid the first (7 of 8 values), the third the
first two (6 of 8), and so on. This is the **birthday problem**: the chance that
$p$ people have $p$ different birthdays, with 8 "days" instead of 365. An odd
sample is nonzero with the probability $q(p) = (8!/(8-p)! \cdot p!)/8^{2p}$ (the
counting formula of notebook 01c divided by the number of all pairs).

The next cell computes the expected numbers $100000\,P(p) + 100000\,q(p)$ of
nonzero values in the self-test and their standard deviation
$\sqrt{100000\,P(1 - P) + 100000\,q(1 - q)}$, and checks that every recorded
number lies within 4 standard deviations (and that it is exactly 0 for $p = 9$,
where $P = 0$); "sd" in the printed lines means standard deviation. It does the
same for the odd samples of the Wolfram check
(10,000 per length). Finally it checks the classic birthday problem: among 23
people two share a birthday more often than not.
```

## 13. The last check

The last cell checks that the six figure files of this notebook exist in the
folder Revision/textbook/figures and prints the number of checks that passed.
```

In [14]:

```
figure_names = ["01d_1_binary_counting.png", "01d_2_generator_step.png",
                "01d_3_generator_bits.png", "01d_4_label_histogram.png",
                "01d_5_record_counts.png", "01d_6_birthday_problem.png"]
check(all(output_file(f"{FIGURE_FOLDER}/{name}").is_file() for name in figure_names),
      "all 6 figure files of this notebook exist")
all_checks_passed()
```

Out [14]:

```
PASS all 6 figure files of this notebook exist
ALL 19 CHECKS PASSED (notebook 01d)
```

Text cell:

```
## 14. What this notebook showed

- Whole numbers are strings of bits; a signed byte stores $-1$ as 255; shifts,
  exclusive or and the cut to 64 bits are simple arithmetic on the bits.
- The generator ‘xorshift64*‘ of the Revision programs, written in Python, makes
  outputs that look random but are fixed by the seed; the exporter’s seed is made
  of the hexadecimal digits of $\pi$.
- From the seeds and the recorded source code, the notebook regenerates all
  3,161,984 bytes of GKD values that the Rust exporter gave the Wolfram check;
  their sha256 fingerprint is the one in the record, so every byte is the same.
  Every number of the record’s ‘gkdComparison‘ table (346,304 pairs, the counts
  of $+1$, $-1$ and 0, no mismatch with the author’s determinant, the negative
  control) is reproduced.
- The Rust self-test for the lengths 5 to 9 is reproduced exactly: 200,000 pairs
  each, the nonzero counts 20538, 7812, 1949, 244 and 0, and no mismatch with the
  determinant.
- These counts are what the birthday problem predicts: $p$ labels drawn from 8
  are all different with the probability $8!/((8-p)!\,8^p)$, which is 0 for
  $p = 9$.
- A pseudo-random test is evidence, not a proof; the proof that GKD equals the
  author’s determinant is the four-case argument of notebook 01c. The record’s
  numbers are exactly reproducible, which is what a record must be.
```

1.54 Line-by-line walk-through of Notebook 01d

The notebook has fourteen code cells, In [1] to In [14]. As in Section 1.9, a quoted line `...)` stands for the remaining lines of a figure caption, which Section 1.53 prints in full under its figure.

In [1], the set-up cell. Its comment lines are the run instructions of Section 1.52; its code is the set-up code explained in Section 1.9, with `NOTEBOOK_ID = "01d"`. It prints Set-up of notebook 01d complete: repository folder found, helpers defined.

In [2], binary numbers and bytes.

```
import hashlib  # the sha256 fingerprint
import itertools  # all index lists of a given length
```

```
import json  # reads the JSON reports of the record
import math  # factorials and falling factorials

import mpmath  # numbers with many digits
import numpy as np  # arrays
```

`hashlib` (part of Python) computes fingerprints such as sha256; the other modules as before.

```
number = 2026
bits = format(number, "b")  # the binary digits, a text of 0s and 1s
say(f"{number} in binary: {bits} ({len(bits)} binary digits)")
# The last digit counts 2^0, the one before 2^1, ...: reversed() starts at the end.
by_places = sum(int(digit) * 2 ** place for place, digit in enumerate(reversed(bits)))
check(by_places == number == int(bits, 2), "the binary digits of 2026 give back 2026")
```

`format(number, "b")` writes a whole number in binary. `reversed(bits)` runs through the digits from the last one, and `enumerate` numbers them 0, 1, 2, ..., so the sum adds each digit times its power of 2. `int(bits, 2)` reads a text of binary digits back as a number. Output: 2026 in binary: 11111101010 (11 binary digits), and the PASS line.

```
say(f"the largest number that 64 bits can hold: 2^64 - 1 = {2 ** 64 - 1}")
stored = (-1) & 0xFF  # the 8 bits that a signed byte uses for -1
read_back = int.from_bytes(bytes([stored]), "big", signed=True)
stored_bits = format(stored, "08b")  # 8 binary digits, zeros in front
say(f"-1 in a signed byte: {stored} = {stored_bits}, read back as {read_back}")
check(stored == 255 and read_back == -1, "a signed byte stores -1 as 255 = 11111111")
```

The largest 64-bit number is printed. Python's whole numbers have no fixed number of bits, and `(-1) & 0xFF` keeps the last 8 bits of -1 as a computer stores it, which gives 255. `bytes([stored])` makes a one-byte sequence, and `int.from_bytes(..., "big", signed=True)` reads it back as a signed byte ("big" names the order of the bytes, which does not matter for one byte). `format(stored, "08b")` writes 8 binary digits with zeros in front. Output: -1 in a signed byte: 255 = 11111111, read back as -1. The cell prints two PASS lines.

In [3], counting in binary, as a picture.

```
numbers = np.arange(32)
bit_rows = np.array([(numbers >> k) & 1 for k in range(4, -1, -1)])  # 2^4 ... 2^0
fig, ax = plt.subplots(figsize=(11.0, 2.8))
ax.imshow(bit_rows, cmap="Greys", vmin=0, vmax=1.3, aspect="auto")
ax.grid(False)
```

For the numbers 0 to 31, bit number k is the number shifted right by k places, keeping only its last bit (`& 1`); the rows are made for $k = 4, 3, 2, 1, 0$ (`range(4, -1, -1)` counts down), so the bit worth 2^4 is on top. The table is drawn in grey, dark for 1.

```
ax.set_xticks(range(32), [str(k) for k in range(32)], fontsize=7)
ax.set_yticks(range(5), [f"$2^{k}$" for k in range(4, -1, -1)])
```

```
ax.set_xlabel("the number")
ax.set_ylabel("bit")
ax.set_title("The numbers 0 to 31 in binary (dark = 1)")
save_figure(fig, "binary_counting",
            "The numbers 0 to 31 (columns) written in binary: each row is one bit, "
            ...)
```

What Figure 01d.1 shows: the bottom row alternates with every number, the row above every two numbers, the next every four: binary counting.

In [4], the bit operations.

```
def binary(value, width=8):
    """value in binary with at least width digits (zeros in front)."""
    return format(value, "b").zfill(width)
```

`zfill(width)` adds zeros in front up to the given width.

```
x = 182
say(f"x                 = {binary(x)} = {x}")
say(f"x >> 2            = {binary(x >> 2)} = {x >> 2} = {x} // 4")
say(f"x << 3            = {binary(x << 3, 11)} = {x << 3} = {x} * 8")
say(f"(x << 3) & 0xFF   = {binary((x << 3) & 0xFF)} = {(x << 3) & 0xFF} "
    f"= {x << 3} % 256")
say(f"x ^ 0b11110000    = {binary(x ^ 0b11110000)} = {x ^ 0b11110000}")
```

The example of Section 1.49, printed with the bits of every result (`0b11110000` is Python's spelling of a binary number). The output is

```
x                 = 10110110 = 182
x >> 2            = 00101101 = 45 = 182 // 4
x << 3            = 10110110000 = 1456 = 182 * 8
(x << 3) & 0xFF   = 10110000 = 176 = 1456 % 256
x ^ 0b11110000    = 01000110 = 70
```

```
MASK = 2 ** 64 - 1  # 64 ones: "& MASK" keeps the last 64 bits
generator = np.random.default_rng(12345)
rules_hold = True
for _ in range(1000):
    a = int(generator.integers(0, 2 ** 63)) * 2 + int(generator.integers(0, 2))
    b = int(generator.integers(0, 2 ** 63)) * 2 + int(generator.integers(0, 2))
    k = int(generator.integers(1, 64))
```

The mask of 64 ones, and 1000 random 64-bit numbers `a` and `b` (numpy draws whole numbers below 2^{63}, so a 64-bit number is made as twice such a number plus a random last bit) and a random shift k from 1 to 63 (seed 12345, numpy's generator, not the generator of the record).

```
    rules_hold &= (a >> k) == a // 2 ** k
    rules_hold &= ((a << k) & MASK) == (a * 2 ** k) % 2 ** 64
```

```
    rules_hold &= ((a ^ b) ^ b) == a
check(rules_hold, "shift = division or multiplication by 2^k, & MASK = remainder "
      "modulo 2^64, and XOR twice gives back the number (1000 random 64-bit numbers)")
```

The three rules of Section 1.49: a right shift is whole-number division, a left shift cut to 64 bits is multiplication taken modulo 2^{64}, and an exclusive or done twice is undone. One PASS line.

In [5], the generator `xorshift64*`.

```
MULTIPLIER = 0x2545F4914F6CDD1D  # the constant of xorshift64*
EXPORTER_SEED = 0x243F6A8885A308D3  # the first 16 hexadecimal digits of pi
SELFTEST_SEED = 0x2545F4914F6CDD1D  # the Rust self-test uses the same constant
```

The three constants of the record's programs, in hexadecimal.

```
class XorShift64Star:
    """The pseudo-random generator of the Revision programs."""

    def __init__(self, seed):
        self.state = seed
```

A **class** is a recipe for objects that carry their own data: `XorShift64Star(seed)` makes a generator object, and the function `__init__` (run when the object is made) stores the seed as its state `self.state`.

```
    def below(self, n):
        """One step of the generator; returns its output modulo n (0 ... n-1)."""
        x = self.state
        x ^= x >> 12
        x ^= (x << 25) & MASK
        x ^= x >> 27
        self.state = x
        return ((x * MULTIPLIER) & MASK) % n
```

One step of the generator, exactly as in the Rust code of Section 1.49: the three shift-and-XOR steps (the left shift cut to 64 bits), the new state stored, and the output, the state times the constant cut to 64 bits, reduced modulo n. Called with $n = 2^{64}$ it returns the whole output.

```
say(f"MULTIPLIER = {MULTIPLIER} (decimal), EXPORTER_SEED = {EXPORTER_SEED} (decimal)")
mpmath.mp.dps = 40  # 40 significant digits are plenty for 16 hexadecimal digits
# frac(pi) = 0.14159...; times 16^16 shifts 16 hexadecimal digits before the point
pi_hex = int(mpmath.floor(mpmath.frac(mpmath.pi) * 16 ** 16))
say(f"the first 16 hexadecimal digits of pi after the point: {pi_hex:016X}")
check(pi_hex == EXPORTER_SEED, "the exporter's seed is made of the hexadecimal "
      "digits of pi")
```

The constants in decimal. Then the digits of π: `mpmath.frac` is the part after the point, $0.14159\ldots$; multiplying by 16^{16} moves sixteen hexadecimal digits before the point (as multiplying by 10^{16} moves sixteen decimal digits), and `mpmath.floor` drops the rest. `{pi_hex:016X}` prints the number with 16 hexadecimal digits in capitals: 243F6A8885A308D3, the exporter's seed.

```
first = XorShift64Star(EXPORTER_SEED ^ 4)
again = XorShift64Star(EXPORTER_SEED ^ 4)
other = XorShift64Star(EXPORTER_SEED ^ 5)
numbers_first = [first.below(2 ** 64) for _ in range(1000)]
check(numbers_first == [again.below(2 ** 64) for _ in range(1000)] and
      numbers_first != [other.below(2 ** 64) for _ in range(1000)],
      "the same seed gives the same 1000 outputs, another seed other outputs")
```

Two generators with the same seed (the exporter's seed for length 4) and one with another seed: the first two give the same 1000 outputs, the third different ones. The cell prints two PASS lines.

In [6], one step, bit by bit.

```
def bit_row(value):
    """The 64 bits of value, highest first, as a list of 0s and 1s."""
    return [(value >> k) & 1 for k in range(63, -1, -1)]
```

The 64 bits of a number, from the bit worth 2^{63} down to the bit worth 1.

```
state = EXPORTER_SEED ^ 4
after_1 = state ^ (state >> 12)
after_2 = after_1 ^ ((after_1 << 25) & MASK)
after_3 = after_2 ^ (after_2 >> 27)  # the new state
output = (after_3 * MULTIPLIER) & MASK
check(XorShift64Star(state).below(2 ** 64) == output,
      "the class gives the output computed step by step")
```

The step written out with a name for every intermediate number, starting from the exporter's seed for length 4; the class must give the same output. One PASS line.

```
fig, ax = plt.subplots(figsize=(11.0, 2.9))
ax.imshow([bit_row(v) for v in (state, after_1, after_2, after_3, output)],
          cmap="Greys", vmin=0, vmax=1.3, aspect="auto")
ax.grid(False)
ax.set_yticks(range(5), ["seed", "x ^= x >> 12", "x ^= x << 25", "x ^= x >> 27",
                         "output"])
ax.set_xticks(range(0, 64, 8), [str(63 - k) for k in range(0, 64, 8)])
ax.set_xlabel("bit number (63 = the bit worth $2^{63}$, 0 = the bit worth $2^0$)")
ax.set_title("One step of the generator xorshift64*")
save_figure(fig, "generator_step",
            "The 64 bits (dark = 1) of the exporter's seed for length 4 (top row) "
            ...)
```

The five numbers as five rows of 64 squares, each row labelled with its step; the columns are labelled with the bit number (column 0 holds bit 63). What Figure 01d.2 shows: each shift-and-XOR step leaves some bits untouched and changes the others. The first step cannot change the 12 highest bits (the shifted copy has zeros there), the second the 25 lowest bits, the third the 27 highest bits; compare the rows column by column. The multiplication then mixes all the bits, and the output row shows no trace of the seed.

In [7], do the outputs look random?

```
stream = XorShift64Star(EXPORTER_SEED ^ 4)
outputs = [stream.below(2 ** 64) for _ in range(64)]
fig, ax = plt.subplots(figsize=(7.2, 7.0))
ax.imshow([bit_row(v) for v in outputs], cmap="Greys", vmin=0, vmax=1.3)
ax.grid(False)
# column 0 holds the bit worth 2^63, column 63 the bit worth 2^0: label by bit number
ax.set_xticks(range(0, 64, 8), [str(63 - k) for k in range(0, 64, 8)])
ax.set_xlabel("bit number (63 = the bit worth $2^{63}$, 0 = the bit worth $2^0$)")
ax.set_ylabel("output number")
ax.set_title("The bits of the first 64 outputs")
save_figure(fig, "generator_bits",
            "The 64 bits (columns, dark = 1, the highest bit on the left) of the "
            ...)
```

The first 64 outputs of the generator, one row of 64 bits each. What Figure 01d.3 shows: a square of dark and light squares without any row, column or diagonal pattern.

```
stream = XorShift64Star(EXPORTER_SEED ^ 4)
labels_drawn = np.array([stream.below(8) for _ in range(160000)])
label_counts = np.bincount(labels_drawn, minlength=8)  # how often 0, 1, ..., 7
spread = math.sqrt(160000 * (1 / 8) * (7 / 8))  # the standard deviation
say(f"counts of the labels 0 ... 7: {label_counts.tolist()}")
say(f"largest distance from 20000: {int(np.max(np.abs(label_counts - 20000)))}, "
    f"standard deviation {spread:.1f}")
check(bool(np.all(np.abs(label_counts - 20000) < 5 * spread)),
      "every label comes out within 5 standard deviations of 20000 times")
```

A new generator with the same seed draws 160,000 labels with `below(8)`; `np.bincount` counts how often each label 0 to 7 occurs. Each should occur about $160000/8 = 20000$ times, with the standard deviation $\sqrt{160000 \cdot \frac{1}{8} \cdot \frac{7}{8}} \approx 132.3$. Output:

```
counts of the labels 0 ... 7: [20002, 20179, 20098, 19871, 20045, 19959, 20036, 19810]
largest distance from 20000: 190, standard deviation 132.3
```

The check requires every count within 5 standard deviations of 20000. A single count of a fair source lies further away with a probability of about 0.6 in a million, so with eight counts a fair source fails with a probability of about 5 in a million.

```
fig, ax = plt.subplots(figsize=(7.0, 4.0))
ax.axhspan(20000 - spread, 20000 + spread, color="0.75", alpha=0.6, zorder=3,
           label="one standard deviation")  # drawn over the bars, see-through
ax.bar(range(8), label_counts, color="tab:blue", zorder=2, label="counted")
ax.axhline(20000, color="black", lw=1, zorder=4, label="expected 20000")
ax.set_ylim(19000, 20800)
ax.set_xticks(range(8), [f"label {k}" for k in range(8)], fontsize=8)
ax.set_ylabel("number of times")
ax.set_title("160,000 labels drawn with below(8)")
ax.legend(loc="upper center", ncol=3, fontsize=8);  # above the bars, not on them
save_figure(fig, "label_histogram",
            "How often each label 0 to 7 came out in 160,000 calls of below(8) of "
            ...)
```

The counts as blue bars, a see-through grey band of one standard deviation around 20,000 (`axhspan`; `zorder` decides what is drawn over what: the band over the bars, the black line over the band), and the expected number. The vertical axis starts at 19,000 to make the small differences visible. What Figure 01d.4 shows: the eight bars scatter around 20,000, most of them within or near the grey band. The cell prints one PASS line and two figure lines.

In [8], the exporter's file, regenerated.

```
def inversions(order):
    """The number of pairs of places i < j whose entries stand in the wrong order."""
    return sum(1 for i in range(len(order)) for j in range(i + 1, len(order))
               if order[i] > order[j])
```

Inversions, as in Notebook 01a.

```
def gkd_rule(lower, upper):
    """The program GKD (Revision/gkd_lovelock/code/src/gkd.rs) in Python."""
    place = {}
    for j, u_label in enumerate(upper):
        if u_label in place:  # a repeated upper label: two equal columns
            return 0
        place[u_label] = j
    sigma = []
    for l_label in lower:
        if l_label not in place or place[l_label] in sigma:  # missing or repeated
            return 0
        sigma.append(place[l_label])
    return 1 if inversions(sigma) % 2 == 0 else -1  # the sign of the permutation
```

The fast rule of Notebook 01c, In [5] (Section 1.48), in a shorter form: the cases (c) and (a) are tested in one condition (`or`), and the sign is computed directly.

```
values_bytes = bytearray()  # the regenerated file, byte by byte
pairs_of = {p: ([], []) for p in range(1, 8)}  # p -> (lower lists, upper lists)
for p in (1, 2, 3):  # every pair, in the order of Tuples[Range[0, 7], 2 p]
    for digits in itertools.product(range(8), repeat=2 * p):
        pairs_of[p][0].append(list(digits[:p]))
        pairs_of[p][1].append(list(digits[p:]))
```

A `bytearray` is a list of bytes that can grow. For each length a pair of lists collects the lower and the upper lists. For $p = 1, 2, 3$ the exporter writes every pair in the order of Mathematica's `Tuples[Range[0, 7], 2 p]`, all lists of $2p$ labels in dictionary order, which is the order of `itertools.product(range(8), repeat=2 * p)`; the first p labels are the lower list (`digits[:p]`), the last p the upper list.

```
for p in (4, 5, 6, 7):  # 20000 pseudo-random pairs each
    rng = XorShift64Star(EXPORTER_SEED ^ p)
    for sample in range(20000):
        if sample % 2 == 0:  # p different labels and a re-ordering of them
```

```
            labels = list(range(8))
            for i in range(p):
                j = i + rng.below(8 - i)
                labels[i], labels[j] = labels[j], labels[i]
            upper = labels[:p]
```

For $p = 4$ to 7, a generator with the exporter's seed for that length and 20,000 samples. An even sample takes p different labels: for $i = 0$ to $p - 1$ it exchanges place i of the list $0, \ldots, 7$ with a random place from i to 7 (`i + rng.below(8 - i)`), the first p steps of a shuffle; the first p entries are the upper list.

```
            lower = list(upper)
            for i in range(p - 1, 0, -1):
                j = rng.below(i + 1)
                lower[i], lower[j] = lower[j], lower[i]
        else:  # two arbitrary lists, the upper one drawn first
            upper = [rng.below(8) for _ in range(p)]
            lower = [rng.below(8) for _ in range(p)]
        pairs_of[p][0].append(lower)
        pairs_of[p][1].append(upper)
```

Its lower list is a copy re-ordered by a Fisher-Yates shuffle (for i from $p - 1$ down to 1, exchange place i with a random place from 0 to i). An odd sample draws p upper labels and then p lower labels with `below(8)`. The order of the calls of the generator matters: it is that of the exporter's source code, which the record keeps as text inside the Wolfram check script `Revision/gkd_lovelock/verification/verify_lovelock_gkd.wls`.

```
gkd_values = {}  # p -> array of the GKD values, in the order of the file
for p in range(1, 8):
    values_p = []
    for lower, upper in zip(*pairs_of[p]):
        value = gkd_rule(lower, upper)
        values_p.append(value)
        values_bytes.append(p)
        values_bytes.extend(lower)
        values_bytes.extend(upper)
        values_bytes.append(value & 0xFF)  # -1 is stored as 255
    gkd_values[p] = np.array(values_p)
```

For every pair, in the order of the file, the GKD value and the record of $2p + 2$ bytes: the length, the lower labels, the upper labels (`extend` appends several bytes) and the value as a signed byte (`value & 0xFF` turns -1 into 255). `zip(*pairs_of[p])` pairs the lower and the upper lists.

```
wolfram_path = repository_file("Revision/gkd_lovelock/results/wolfram-gkd-report.json")
wolfram = json.loads(wolfram_path.read_text(encoding="utf-8"))
source = wolfram["gkdValuesSource"]
fingerprint = hashlib.sha256(bytes(values_bytes)).hexdigest()
record_bytes, record_sha256 = source["valuesFileBytes"], source["valuesFileSha256"]
say(f"bytes regenerated {len(values_bytes)}, in the record {record_bytes}")
```

```
say(f"sha256 regenerated:   {fingerprint}")
report("regenerated GKD values (bytes)", len(values_bytes))
report("their sha256, first 16 digits", fingerprint[:16])
say(f"sha256 in the record: {record_sha256}")
```

The Wolfram report and its field `gkdValuesSource`; the fingerprint of the regenerated bytes (`hexdigest` writes it in hexadecimal); the size and fingerprint stated in the record. The output prints both sizes, 3161984, and both fingerprints, which are the same 64 digits:

```
sha256 regenerated:   3ddccfa744b3708bbd3e251852236b0a2d3370e957c67bae8d94168de6d2d695
sha256 in the record: 3ddccfa744b3708bbd3e251852236b0a2d3370e957c67bae8d94168de6d2d695
```

```
check(len(values_bytes) == source["valuesFileBytes"] and
      fingerprint == source["valuesFileSha256"],
      "the regenerated values have the size and the sha256 fingerprint of the record",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, gkdValuesSource")
changed = bytearray(values_bytes)
changed[1000] ^= 1  # change one bit of one byte
say("after changing one bit of byte 1000:")
say(f"sha256 of the changed: {hashlib.sha256(bytes(changed)).hexdigest()}")
```

The check reproduces the record's size and fingerprint: every one of the 3,161,984 bytes is the same. To show how sensitive a fingerprint is, a copy with one bit of byte 1000 flipped gets a completely different fingerprint, beginning 4463b17c1baf0a3e.

```
layout = [len(pairs_of[p][0]) for p in range(1, 8)]
wolfram_checks = {c["name"]: c for c in wolfram["checks"]}
check(layout == [64, 4096, 262144, 20000, 20000, 20000, 20000] and
      wolfram_checks["gkd_values_file_layout"]["verdict"] == "PASS",
      "the layout: 64, 4096, 262144 pairs of length 1, 2, 3 and 20000 of each "
      "length 4 to 7", record="Revision/gkd_lovelock/results/"
      "wolfram-gkd-report.json, check gkd_values_file_layout")
```

The numbers of pairs per length, compared with the layout that the record's check `gkd_valu es_file_layout` states. The cell prints two PASS lines.

In [9], the counts of the Wolfram check.

```
SIGNED = {}  # size n -> list of (permutation, sign)
```

```
def signed_permutations(n):
    if n not in SIGNED:
        SIGNED[n] = [(order, 1 if inversions(order) % 2 == 0 else -1)
                     for order in itertools.permutations(range(n))]
    return SIGNED[n]
```

The permutations with their signs, kept once per size, as in Notebook 01c, In [3].

```
def literal_many(lowers, uppers):
    """Det[Outer[delta, lower, upper]] for many pairs at once (Leibniz formula)."""
    p = lowers.shape[1]
    outer = lowers[:, :, None] == uppers[:, None, :]  # shape (pairs, p, p)
    values = np.zeros(len(lowers), dtype=np.int64)
    rows = np.arange(p)
    for order, order_sign in signed_permutations(p):
        values += order_sign * outer[:, rows, list(order)].all(axis=1)
    return values
```

The literal determinant for many pairs at once, as in Notebook 01c, In [9] (Section 1.48); for $p = 7$ the Leibniz formula has $7! = 5040$ terms.

```
measured = []
for p in range(1, 8):
    lowers = np.array(pairs_of[p][0], dtype=np.int8)
    uppers = np.array(pairs_of[p][1], dtype=np.int8)
    determinant = literal_many(lowers, uppers)
    values_p = gkd_values[p]
    row = {"p": p, "pairs": len(values_p),
           "mismatches": int((determinant != values_p).sum()),
           "plusOne": int((values_p == 1).sum()),
           "minusOne": int((values_p == -1).sum()),
           "zero": int((values_p == 0).sum()),
           "mismatchesAgainstMinusGKD": int((determinant != -values_p).sum())}
```

For each length the author's determinant of all pairs and a row of the table with the same keys as the record's `gkdComparison`: the number of pairs, the mismatches between the determinant and GKD, the counts of $+1$, -1 and 0, and the mismatches against $-$GKD (the negative control).

```
    if p >= 4:  # the even samples are the re-orderings
        row["permutationSamplesNonzero"] = int((values_p[0::2] != 0).sum())
    measured.append(row)
    # format(**row) fills the names in braces with the entries of the dictionary
    say("p = {p}: pairs {pairs:6d}, mismatches {mismatches}, +1 {plusOne:4d}, "
        "-1 {minusOne:4d}, 0 {zero:6d}, against -GKD "
        "{mismatchesAgainstMinusGKD:5d}".format(**row))
```

For $p \geq 4$ the record also counts the nonzero values among the even samples (`values_p[0::2]` takes every second entry, starting with the first), all 10,000 by construction. A text with names in braces is filled from the dictionary by `.format(**row)` (the two stars hand the entries of the dictionary over by name). The output:

```
p = 1: pairs     64, mismatches 0, +1    8, -1    0, 0     56, against -GKD     8
p = 2: pairs   4096, mismatches 0, +1   56, -1   56, 0   3984, against -GKD   112
p = 3: pairs 262144, mismatches 0, +1 1008, -1 1008, 0 260128, against -GKD  2016
p = 4: pairs  20000, mismatches 0, +1 4998, -1 5024, 0   9978, against -GKD 10022
p = 5: pairs  20000, mismatches 0, +1 5024, -1 4981, 0   9995, against -GKD 10005
p = 6: pairs  20000, mismatches 0, +1 4882, -1 5120, 0   9998, against -GKD 10002
p = 7: pairs  20000, mismatches 0, +1 4935, -1 5065, 0  10000, against -GKD 10000
```

```
recorded = wolfram["measurements"]["gkdComparison"]
check(measured == recorded, "every number of the record's gkdComparison table is "
      "reproduced (lengths 1 to 7)",
      record="Revision/gkd_lovelock/results/wolfram-gkd-report.json, measurements "
             "gkdComparison; checks gkd_equals_kdelta_exhaustive_length_1 to 3 and "
             "gkd_equals_kdelta_random_length_4 to 7")
```

The whole table, every key of every row, must equal the record's (two lists of dictionaries are equal when all their entries are). This reproduces the record's table and its seven comparison checks.

```
check(all(r["mismatches"] == 0 for r in measured),
      "the author's determinant equals GKD on all 346304 pairs")
check(all(r["mismatchesAgainstMinusGKD"] == r["plusOne"] + r["minusOne"] > 0
          for r in measured),
      "negative control: compared with -GKD, the test fails exactly at the "
      "nonzero values", record="Revision/gkd_lovelock/results/wolfram-gkd-report"
      ".json, check negative_control_gkd_comparison_detects_a_sign_flip")
```

No mismatch on all 346,304 pairs; and the negative control fails exactly as often as there are nonzero values, and at least once for each length, which reproduces the record's check of the negative control. The cell prints three PASS lines.

In [10], the counts as a picture.

```
fig, ax = plt.subplots(figsize=(9.0, 4.6))
lengths = np.arange(1, 8)
for shift, key, color, name in [(-0.27, "plusOne", "tab:red", "value +1"),
                                (0.0, "minusOne", "tab:blue", "value -1"),
                                (0.27, "zero", "0.6", "value 0")]:
    heights = [max(row[key], 0.8) for row in measured]  # 0.8 marks a count 0
    ax.bar(lengths + shift, heights, width=0.25, color=color, label=name)
    ax.plot(lengths + shift, [max(row[key], 0.8) for row in recorded], "kx", ms=7)
ax.plot([], [], "kx", label="the record's numbers")  # an entry for the legend only
```

For each length three bars, the reproduced counts of $+1$, -1 and 0 (a count 0 drawn as a stub, as in Notebook 01c), and on top of each bar a black cross at the record's number.

```
ax.set_yscale("log")
ax.set_ylim(0.5, 1e6)
ax.set_xticks(lengths)
ax.set_xlabel("length $p$ of the index lists")
ax.set_ylabel("number of pairs (logarithmic scale)")
ax.set_title("The pairs of the Wolfram check: reproduced and recorded")
ax.legend(loc="upper right", ncol=2, fontsize=8);
save_figure(fig, "record_counts",
            "The number of pairs of index lists with the GKD value $+1$ (red), "
            ...)
```

What Figure 01d.5 shows: every cross sits exactly on the top of its bar. For the lengths 1 to 3 the zeros dominate, as counted in Section 1.43; for the lengths 4 to 7 the bars of $+1$ and -1 are about

5,000 each and the bar of 0 about 10,000, because half of the samples are re-orderings (value ± 1) and almost all of the other half give 0. For $p = 1$ the blue bar is a stub: no value -1.

In [11], the Rust self-test for the lengths 5 to 9.

```
def rule_many(lowers, uppers):
    """GKD for many pairs at once: 0, or sign(lower list) times sign(upper list)."""
    p = lowers.shape[1]
    upper_sorted = np.sort(uppers, axis=1)
    upper_distinct = (np.diff(upper_sorted, axis=1) != 0).all(axis=1)
    same_labels = (np.sort(lowers, axis=1) == upper_sorted).all(axis=1)
    first, second = np.triu_indices(p, 1)  # all pairs of places first < second
    parity = ((lowers[:, first] > lowers[:, second]).sum(axis=1)
              + (uppers[:, first] > uppers[:, second]).sum(axis=1)) % 2
    return np.where(upper_distinct & same_labels, np.where(parity == 0, 1, -1), 0)
```

The fast rule for many pairs with the sign shortcut of Section 1.43, as in Notebook 01c, In [9], with the parity of the total number of inversions computed in one line.

```
check(all((rule_many(np.array(pairs_of[p][0], dtype=np.int8),
                     np.array(pairs_of[p][1], dtype=np.int8)) == gkd_values[p]).all()
           for p in range(1, 8)),
      "rule_many equals the plain GKD rule on all 346304 pairs of the exporter")
```

Before it is used, `rule_many` must give the plain values of In [8] on all 346,304 pairs.

```
selftest = json.loads(repository_file("Revision/gkd_lovelock/results/"
                                      "gkd-selftest.json").read_text(encoding="utf-8"))
recorded_random = {e["p"]: e for e in selftest["results"] if e["mode"] == "random"}
selftest_rows = {}
whole_numbers = True
```

The self-test report; its random entries (lengths 5 to 9) by length.

```
for p in (5, 6, 7, 8, 9):
    rng = XorShift64Star((SELFTEST_SEED ^ p) | 1)
    lowers, uppers = [], []
    for sample in range(200000):
        upper = [rng.below(8) for _ in range(p)]
        if sample % 2 == 0:  # a re-ordering of the upper list
            lower = list(upper)
            for i in range(p - 1, 0, -1):
                j = rng.below(i + 1)
                lower[i], lower[j] = lower[j], lower[i]
        else:  # an arbitrary lower list
            lower = [rng.below(8) for _ in range(p)]
        lowers.append(lower)
        uppers.append(upper)
```

The self-test's samples, as the function `compare_random` of `gkd.rs` draws them: the generator starts at (seed XOR p) OR 1 (`|` is Python's OR); every sample draws p upper labels with `below(8)`; an even sample re-orders them by a Fisher-Yates shuffle, an odd sample draws p more labels. (Unlike the exporter, the upper labels of an even sample may repeat; then the value is 0.)

```
    lowers = np.array(lowers, dtype=np.int8)
    uppers = np.array(uppers, dtype=np.int8)
    values_p = rule_many(lowers, uppers)
    determinants = np.concatenate([  # numpy's elimination, in 4 blocks of 50000
        np.linalg.det((lowers[s:s + 50000, :, None]
                       == uppers[s:s + 50000, None, :]).astype(float))
        for s in range(0, 200000, 50000)])
    rounded = np.rint(determinants)  # the nearest whole numbers
    whole_numbers &= bool(np.all(np.abs(determinants - rounded) < 1e-6))
```

GKD for all 200,000 pairs at once, and the determinant of every matrix `Outer` by numpy's elimination (`np.linalg.det` accepts a stack of matrices), in four blocks of 50,000 to save memory; the Leibniz formula would have $9! = 362{,}880$ terms per matrix. The floating-point determinants are rounded to whole numbers, and each must lie within 10^{-6} of its whole number.

```
    selftest_rows[p] = {"pairs": len(values_p), "nonzero": int((values_p != 0).sum()),
                        "mismatches": int((rounded != values_p).sum()),
                        "even": int((values_p[0::2] != 0).sum()),
                        "odd": int((values_p[1::2] != 0).sum())}
    say("p = {p}: {pairs} pairs, nonzero {nonzero:5d}, mismatches {mismatches}"
        .format(p=p, **selftest_rows[p]))
    say("       the record: nonzero {nonzero:5d}, mismatches {mismatches}"
        .format(**recorded_random[p]))
```

For each length: the number of pairs, of nonzero values, of mismatches with the determinant, and of nonzero values among the even and among the odd samples; then a line with these numbers and a line with the record's. The output shows for $p = 5$ to 9 the nonzero counts 20538, 7812, 1949, 244, 0, each equal to the record's, and no mismatch.

```
report("nonzero values of the self-test, p = 5 to 9",
       ", ".join(str(selftest_rows[p]["nonzero"]) for p in (5, 6, 7, 8, 9)))
check(whole_numbers, "every numpy determinant is a whole number up to 1e-6")
check(all(selftest_rows[p][key] == recorded_random[p][key]
          for p in (5, 6, 7, 8, 9) for key in ("pairs", "nonzero", "mismatches")),
      "the self-test for the lengths 5 to 9: the same numbers of pairs, nonzero "
      "values and mismatches", record="Revision/gkd_lovelock/results/"
      "gkd-selftest.json, lengths 5 to 9 (random)")
```

The RESULT line with the five counts, and the checks: whole-number determinants, and the record's numbers of pairs, nonzero values and mismatches reproduced exactly. The cell takes 10 to 30 seconds and prints three PASS lines.

In [12], the birthday problem.

```
def all_different(p, days=8):
    """The probability that p labels drawn at random from days are all different."""
    return math.perm(days, p) / days ** p

def odd_probability(p):
    """The probability that an arbitrary pair of lists of length p is nonzero."""
    return math.perm(8, p) * math.factorial(p) / 8 ** (2 * p)
```

$P(p) = (n!/(n-p)!)/n^p$ for n "days" (8 unless given), and $q(p) = N_{\neq 0}(8,p)/8^{2p}$, the formulas of Section 1.50.

```
selftest_ok = True
for p in (5, 6, 7, 8, 9):
    big_p, small_q = all_different(p), odd_probability(p)
    expected = 100000 * big_p + 100000 * small_q
    spread = math.sqrt(100000 * big_p * (1 - big_p) + 100000 * small_q * (1 - small_q))
    found = recorded_random[p]["nonzero"]
    even, odd = selftest_rows[p]["even"], selftest_rows[p]["odd"]
    say(f"self-test p = {p}: recorded {found:5d}, expected {expected:8.1f}, "
        f"sd {spread:5.1f}; even samples {even}, odd {odd}")
    selftest_ok &= (abs(found - expected) < 4 * spread) if p < 9 else found == 0
check(selftest_ok, "the recorded nonzero counts of the self-test lie within 4 "
      "standard deviations of the birthday-problem expectation (0 exactly for p = 9)")
```

For each length the expected number of nonzero values and its standard deviation (the two kinds of samples are independent, so their variances, the squares of the standard deviations, add), compared with the record's count; for $p = 9$ the count must be exactly 0. The output:

```
self-test p = 5: recorded 20538, expected  20582.9, sd 128.0; even samples 20461, odd 77
self-test p = 6: recorded  7812, expected   7711.6, sd  84.4; even samples 7788, odd 24
self-test p = 7: recorded  1949, expected   1927.2, sd  43.5; even samples 1944, odd 5
self-test p = 8: recorded   244, expected    240.9, sd  15.5; even samples 243, odd 1
self-test p = 9: recorded     0, expected      0.0, sd   0.0; even samples 0, odd 0
```

```
wolfram_ok = True
for row in recorded:
    p = row["p"]
    if p < 4:
        continue
    odd_nonzero = row["plusOne"] + row["minusOne"] - row["permutationSamplesNonzero"]
    expected = 10000 * odd_probability(p)
    spread = math.sqrt(10000 * odd_probability(p) * (1 - odd_probability(p)))
    say(f"Wolfram check p = {p}: nonzero odd samples {odd_nonzero:2d}, expected "
        f"{expected:5.2f}, sd {spread:4.2f}")
    wolfram_ok &= abs(odd_nonzero - expected) < 4 * spread
check(wolfram_ok, "the nonzero odd samples of the Wolfram check lie within 4 "
      "standard deviations of their expectation")
```

The same for the odd samples of the Wolfram check (10,000 per length 4 to 7): the nonzero values minus those of the even samples, compared with $10000\,q(p)$. Output: 22 against 24.03 (standard deviation 4.90), 5 against 7.51, 2 against 2.11 and 0 against 0.46.

```
say(f"birthday problem: 22 people {all_different(22, 365):.4f}, 23 people "
    f"{all_different(23, 365):.4f} all different")
check(all_different(22, 365) > 0.5 > all_different(23, 365),
      "23 is the smallest group in which a shared birthday is more likely than not")
```

The classic case: 22 people have different birthdays with the probability 0.5243, 23 people with 0.4927. Since $P(p)$ only falls as p grows (each new factor is below 1), 23 is the smallest group in which a shared birthday is more likely than not. The cell prints three PASS lines.

In [13], the two birthday problems as a picture.

```
fig, (left, right) = plt.subplots(1, 2, figsize=(11.0, 4.3))
p_values = np.arange(1, 10)
left.plot(p_values, [all_different(int(p)) for p in p_values], "o-", color="tab:blue",
          label="$P(p) = (8!/(8-p)!)/8^p$")
left.plot([5, 6, 7, 8, 9], [selftest_rows[p]["even"] / 100000 for p in (5, 6, 7, 8, 9)],
          "x", color="tab:red", ms=10, mew=2,
          label="self-test: nonzero fraction of the even samples")
left.set_xlabel("number $p$ of labels drawn from 8")
left.set_ylabel("probability that all are different")
left.set_title("8 labels")
left.legend(fontsize=8)
```

On the left $P(p)$ for $p = 1$ to 9, and as red crosses the fractions of nonzero values among the 100,000 even samples of the self-test (`mew=2`: crosses drawn with thick strokes).

```
people = np.arange(1, 61)
right.plot(people, [all_different(int(k), 365) for k in people], color="tab:green")
right.axhline(0.5, color="black", lw=0.8)
right.axvline(23, color="black", ls=":", lw=1)
right.text(24, 0.8, "23 people", fontsize=9)
right.set_xlabel("number of people")
right.set_ylabel("probability of all different birthdays")
right.set_title("365 days")
fig.tight_layout()
save_figure(fig, "birthday_problem",
            "Left: the probability $P(p)$ that $p$ labels drawn at random from 8 "
            ...)
```

On the right the classic case for 1 to 60 people, the line one half and a dotted line at 23 people. What Figure 01d.6 shows: the red crosses lie on the blue curve, which reaches 0 at $p = 9$; the green curve falls below one half at 23 people.

In [14], the last check.

```
figure_names = ["01d_1_binary_counting.png", "01d_2_generator_step.png",
                "01d_3_generator_bits.png", "01d_4_label_histogram.png",

```

The last line is ALL 19 CHECKS PASSED (notebook 01d). The 19 checks are: 2 in In [2], 1 in In [4], 2 in In [5], 1 in In [6], 1 in In [7], 2 in In [8], 3 in In [9], 3 in In [11], 3 in In [12] and 1 in In [14].

1.55 What we proved, what we computed, what we assumed

PROVED in this chapter (by school algebra and the definitions, every derivation written out line by line; every one is also confirmed by a check of a notebook):

- numbers (Sections 1.2 to 1.5): the decimal digits of a fraction p/q end or repeat a block of at most $q-1$ digits; the formula that turns repeating digits back into a fraction; the digits of p/q in lowest terms end exactly when $q = 2^a 5^b$; $\sqrt{2}$ is not a fraction; the fractions made by $p' = p+2q$, $q' = p+q$ have $p^2 - 2q^2 = \pm 1$ and the error $|p/q - \sqrt{2}| \approx 0.35355/q^2$; the step from a floating-point number x to the next is 2^{e-53}, between $\varepsilon x/2$ and εx; $1 - \cos x = 2\sin^2(x/2)$; $\ln(xy) = \ln x + \ln y$; $e - (1+1/n)^n \approx e/(2n)$; the length factors $e^{a_4}\sin^{1/6} z$, 1, $e^{-a_4}\sin^{1/6} z$ and $\cot z$ of the author's metric and their product $\cos z$ for every a_4;

- complex numbers (Sections 1.10 to 1.13): the product rule, $(zw)^* = z^* w^*$, $zz^* = |z|^2$, $|zw| = |z|\,|w|$; Euler's formula and the error bound $e^\theta \theta^{N+1}/(N+1)!$ of its partial sums; the law of exponents $e^{i\alpha}e^{i\beta} = e^{i(\alpha+\beta)}$; multiplication by $re^{i\alpha}$ turns by α and stretches by r; $M(z)M(w) = M(zw)$, $J^2 = -I$, $\det M(z) = |z|^2$, $R(\alpha)R(\beta) = R(\alpha+\beta)$, $\det R = 1$, $R^T R = I$; the roots of unity add up to 0; conjugation leaves real numbers unchanged; $\cosh^2 - \sinh^2 = 1$ and the addition theorems of cosh and sinh; a boost keeps $-t^2 + x^2$, adds rapidities and stretches the light-like directions by $e^{\pm\varphi}$; $e^{-i\varepsilon t}$ has modulus 1 for a real and grows or decays like $e^{\gamma t}$ for an imaginary frequency $\varepsilon = i\gamma$;

- matrices and determinants (Sections 1.18 to 1.21): $(AB)v = A(Bv)$, associativity, $(AB)^T = B^T A^T$, $\mathrm{tr}(AB) = \mathrm{tr}(BA)$; an exchange of two entries flips the sign of a permutation, half of the permutations are even, and a permutation and its inverse have the same sign; the determinants of diagonal, permutation, signed permutation and triangular matrices; the rules 2 to 6 of determinants for every size and rule 1 for 2×2 matrices; the inverse of a 2×2 matrix; the signed area of the image of the unit square is $\det M$; $\det \gamma^a = \pm 1$ for the gamma matrices; $\det g = \cos^2 z$ and $\sqrt{|\det g|} = \sin z \cot z = \cos z$ for the author's metric, for every a_4: the growth of space and the exponential deflation of the extra times cancel;

- index notation (Sections 1.26 to 1.29): the rules of the Kronecker delta, $\delta^a{}_a = 8$; $\eta^{ab}\eta_{bc} = \delta^a{}_c$; lowering changes the signs of the four time-like components; the squared lengths of the examples; in the signature (4,4) exactly half of all random vectors are space-like (with one assumed fact of probability); $S_{ab}A^{ab} = 0$ and its consequence for squared expressions; signed permutation matrices are orthogonal; $(\gamma^a)^T = \eta_{aa}\gamma^a$; $\gamma^a\gamma_a = 8I$, $\gamma^a\gamma^b\gamma_a = -6\gamma^b$, $\mathrm{tr}(\gamma^a\gamma^b) = 16\eta^{ab}$, all from the Clifford relation; the line element $ds^2 = \epsilon^2(\cot^2 z + 3e^{2a_4}s - 1 - 3b_4 e^{-2a_4}s)$ of the step $dx^\mu = \epsilon$, which is $\epsilon^2(6s\sinh(2a_4) - 1 + \cot^2 z)$ at $b_4 = 1$, and the place $a_4^*(z)$ where it then changes from time-like to space-like;

- eigenvalues (Sections 1.34 to 1.37): the eigenvalues add up to the trace and multiply to the determinant; the eigenvalues and eigenvectors of the 2×2 example and the ellipse with half-axes 3 and 1; the eigenvalues $2 - 2\cos(k\pi/(n+1))$ and the sine-wave eigenvectors of the chain matrix; $e^{\pm i\alpha}$ for rotations and $e^{\pm\varphi}$ for boosts; complex eigenvalues of real matrices come in conjugate pairs; symmetric and Hermitian matrices have real eigenvalues, and eigenvectors

with different eigenvalues are perpendicular; the quadratic form in the eigenvector coordinates; Sylvester's law of inertia (with one assumed fact of linear algebra); the signature (4,4) of η and of the author's metric for every a_4 and z; the eigenvalues ± 1 or $\pm i$ of the gamma matrices, eight times each; $\gamma(v)^2 = Q(v)I$, and $\gamma(v)$ is nilpotent but not zero for a light-like v; B is Hermitian exactly when its imaginary part is antisymmetric; the factor $|\lambda_2/\lambda_1|$ of power iteration;

- the generalized Kronecker delta (Sections 1.42 to 1.44): the four cases, so the fast rule of the program GKD equals the author's determinant for every pair of index lists; the two-index formula and the counts 56, 56, 3984; the number $n!/(n-p)! \cdot p!$ of nonzero values; the sign shortcut $\delta^U_L = \mathrm{sign}(L)\,\mathrm{sign}(U)$ (with rule 1 assumed); the vanishing with nine indices in eight dimensions, so the Lovelock sum stops at $k = 3$; the contraction identity with the factor $n - p + 1$ and the factors $8 - 2k = 6, 4, 2$ of the Lovelock trace identities; the Levi-Civita product formula with $(n-p)!$; $\det \eta = +1$;

- binary numbers and the record's tests (Sections 1.49 and 1.50): a right shift is whole-number division by 2^k, a left shift multiplication by 2^k, an exclusive or done twice is undone; the exporter's file has 3,161,984 bytes; the birthday probability $P(p) = (8!/(8-p)!)/8^p$ (with the assumed rule that independent chances multiply).

COMPUTED by the notebooks (each number in the cell named; where a Revision record is reproduced, the record file and its key or check):

- Notebook 01f: the periods of $1/q$ for $q = 2$ to 300, 23 denominators with the full period $q - 1$ (In [4]); the error 1.84×10^{-9} of 19601/13860 and the limit 0.353553 of the error times q^2 (In [5]); $\sqrt{2}$ between two fractions 2^{-60} apart (In [6]); 0.1 stored as $3602879701896397/2^{55}$, $\varepsilon = 2^{-52}$ and the step formula at 2301 numbers (In [7]); the largest relative errors 4.4×10^{-16} and 1.0 of the two formulas for $(1 - \cos x)/x^2$ (In [9]); $e/(2n)$ within 1 per cent and the floating-point error $e - 1$ at $n = 10^{16}$ (In [12]); $\ln 1000 = 6.9078$ (In [12]); the length factors and their product (In [11]; reproduces `Revision/gkd_lovelock/results/curvature.json`, key `sqrtAbsDetG`, and `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `sqrt_abs_det_g`).

- Notebook 01b: the error 4.1×10^{-14} of 21 terms of the series of e^{2i} (In [5]); the factor $\theta/(N+2)$ within 10 per cent (In [6]); $e^{i\pi} = -1$ with a leftover imaginary part of size 1.0×10^{-51} at 50 digits (In [7]); the rotations, roots of unity, boosts and waves in numbers (In [8] to In [14]). It reads no record.

- Notebook 01a: the determinants 2, 15, -35, -24, 730, 15445, 60109 of seven random matrices, three ways (In [10]); $\det M = -192$, $\det N = 128$, $\det(MN) = -24576$ (In [11]); the signed areas of 1000 random matrices (In [12]); $16! = 20922789888000$ (In [13]); the eight gamma matrices are signed permutation matrices with determinant 1 whose squares are $\pm I$ (In [14], In [15]; reproduces `Revision/algebra/reports/python-algebra.json`, checks `reality_signed_permutations` and `clifford_relation`); $\det g = b_4^3 \cos^2 z$ exactly and at 900 points to 2.9×10^{-15} (In [17], In [18]; reproduces `Revision/gkd_lovelock/results/curvature.json`, key `sqrtAbsDetG`, and `Revision/gkd_lovelock/results/python-lovelock-report.json`, check `sqrt_abs_det_g`).

- Notebook 01e: η from the record (In [3]; reproduces `python-algebra.json`, check `coordinate_map`); the fractions 0.5011 and 0.8177 of space-like random vectors in the signatures (4,4) and (3,1) (In [6]); all 64 Clifford relations and the symmetry pattern (In [10]; reproduces the checks `clifford_relation` and `symmetry_pattern` of the same report); the three contractions (In [12]); the metric and its inverse (In [14]; reproduces `curvature.json`, key `metricDiagonal`, and `python-lovelock-report.json`, check `metric_inverse`); the sign of ds^2 on a grid of 301×300 points (In [15]).

- Notebook 01g: the eigenvalues of T_{10} within 8.9×10^{-16} of the formula (In [5]); 200 random 5×5 matrices with conjugate pairs (In [6]); 300 random symmetric matrices with real eigenvalues, and 67.7 per cent complex eigenvalues of 300 non-symmetric ones (In [8]); the signature (4,4) of η (In [10]; reproduces `python-algebra.json`, check `coordinate_map`); Sylvester's law for 2000 random coordinate changes, eigenvalue sizes 1.4×10^{-8} to 37.0 (In [10]); the signature (4,4) of the author's metric at 9150 grid points and the product $b_4^3 \cos^2 z$ (In [11]; reproduces `python-lovelock-report.json`, check `sqrt_abs_det_g`); the eigenvalues of the gamma matrices (In [13]; the checks `clifford_relation` and `symmetry_pattern`); $\gamma(v)^2 = Q(v)I$ for 104 vectors (In [14]); the signature (8,8) of B (In [16]; reproduces `python-algebra.json`, check `B_hermitian_involution_signature`, and `Revision/theory/reports/python-field-theory.json`, check `B_properties`); the power-iteration factors 0.333333 and 0.585786 to 0.585789 (In [18]).

- Notebook 01c, first part: the author's definition, verbatim as in the record's file `PROVENANCE_OF_THE_COMPUTATION.md`, and their cells In[87], In[32] and In[29] as listed in the record's file `notebook-input-cells.txt` (In [2]; both files lie in the folder `Revision/gkd_lovelock/results`, as do the reports named below); the record's examples (In [6]; reproduces the check `gkd_examples` of `python-lovelock-report.json`, the check `definition_unequal_lengths_stay_unevaluated` of `wolfram-gkd-report.json` and the field `gkdSelfCheck` of `lovelock-report.json`).

- Notebook 01c, second part: the literal determinant equals the fast rule on all 266,304 pairs of the lengths 1 to 3, with the record's counts (In [8]; reproduces the checks `gkd_equals_kdelta_exhaustive_length_1`, `_length_2` and `_length_3` of `wolfram-gkd-report.json`, their counts and their 0 mismatches), and on all 16,777,216 pairs of length 4 (In [10]; reproduces `gkd-selftest.json`).

- Notebook 01c, third part: 600 pairs of nine-index lists, all 0 (In [13]; the record's check `gkd_nine_indices_in_eight_dimensions_vanish`); the contraction factors 8 to 1 and 4 to 1 (In [14]); the trace factors 6, 4, 2 (In [15]; reproduces the checks `k1_trace_equals_6_L1`, `k2_trace_equals_4_L2` and `k3_trace_equals_2_L3` of `wolfram-gkd-report.json`); the author's second route, $7!\,\delta_a^b$ (In [17]; with the declaration (4, 4, 0) of the author's cell In[29]).

- Notebook 01d: the 3,161,984 regenerated bytes and their sha256 fingerprint (In [8]; reproduces `wolfram-gkd-report.json`, field `gkdValuesSource`, and check `gkd_values_file_layout`); every number of the table `gkdComparison` and the negative control (In [9]; reproduces `wolfram-gkd-report.json`, field `measurements`, and its checks `gkd_equals_kdelta_exhaustive_length_1` to `_3`, `gkd_equals_kdelta_random_length_4` to `_7` and `negative_control_gkd_comparison_detects_a_sign_flip`); the self-test counts 20538, 7812, 1949, 244, 0 (In [11]; reproduces `gkd-selftest.json`, lengths 5 to 9); all of them within 4 standard deviations of the birthday-problem expectation, and the 23 people of the classic problem (In [12]).

ASSUMED (used, not derived here):

- school algebra and trigonometry: the laws of powers; $\cos^2 + \sin^2 = 1$, the addition theorems, the double-angle formula; the formula for the roots of a quadratic; every point at distance 1 from the origin is $(\cos\theta, \sin\theta)$; Pythagoras; the uniqueness of the factorisation into primes;
- calculus: the series of e^x, cos, sin and $\ln(1+u)$ (Chapter 2 derives the series of e^x from Taylor's theorem, which it also assumes); the triangle inequality for complex numbers;
- linear algebra: $\det(MN) = \det M \det N$ for matrices larger than 2×2; a square matrix can be undone exactly when its determinant is not 0, and $(M - \lambda I)v = 0$ has a solution $v \neq 0$ when $\det(M - \lambda I) = 0$; the fundamental theorem of algebra; the spectral theorem; more than n vectors with n components are linearly dependent; the shoelace formula for signed areas;
- probability: a continuous random quantity takes one exact value with probability 0; independent chances multiply; the expected value Nq and the standard deviation $\sqrt{Nq(1-q)}$ of a count; the fraction $1/2 + 1/\pi$ for the signature (3,1);
- the property of SHA-256 that different files have different fingerprints for all practical purposes;
- tensor calculus: raising all indices of the Levi-Civita tensor of a metric multiplies it by the sign of $\det g$ (Chapter 11);
- taken from the Revision record and derived in later chapters: the gamma matrices, the Clifford relation and the matrices C and B (Chapters 4 and 5; here read from `Revision/algebra/gammas.json` and checked); the meaning of B as the charge density (Chapters 7 and 10); the curvature and the Lovelock tensors (Chapters 3 and 11);
- the author's metric itself, the starting point of the theory. Nothing in this chapter depends on the form of the functions $a_4(x_4)$ and $b_4(x_4)$: every statement holds for every value of a_4 and every positive value of b_4, except where $b_4 = 1$ is said (the line element in the form with sinh, and the pictures drawn at $b_4 = 1$).

HYPOTHESIS and OPEN. No hypothesis enters this chapter, and it leaves no question open. It says nothing about pair creation or about matter and antimatter.

1.56 Exercises

Exercise 1. Find the decimal digits of 3/11 by long division, state the period, and turn the repeating digits back into the fraction with the formula of Section 1.2.

Answer. Start with the remainder 3. $30 = 2 \cdot 11 + 8$: digit 2, remainder 8. $80 = 7 \cdot 11 + 3$: digit 7, remainder 3, the remainder we started with. So $3/11 = 0.(27)$ with the period 2. Back: the block is $C = 27$ with $m = 2$ digits, so $x = C/(10^m - 1) = 27/99$, and dividing numerator and denominator by their greatest common divisor 9 gives 3/11.

Exercise 2. (a) Which of the numbers 0.75 and 0.2 does a computer store exactly, and why? (b) How large is the step from $x = 10^6$ to the next floating-point number, and what is the step divided by x? Compare with $\varepsilon/2$ and ε.

Answer. (a) $0.75 = 3/4$ has the denominator 2^2, a power of 2, so it is stored exactly; $0.2 = 1/5$ has the prime factor 5 in its denominator, so its binary digits do not end (Section 1.4) and it is rounded. (b) $2^{19} = 524288 < 10^6 < 2^{20} = 1048576$, so $10^6 = f \cdot 2^{20}$ with $f = 10^6/2^{20} \approx 0.954$, which lies between $\frac{1}{2}$ and 1; the step is $2^{20-53} = 2^{-33} \approx 1.164 \times 10^{-10}$. Divided by 10^6 it is 1.164×10^{-16}, which lies between $\varepsilon/2 \approx 1.110 \times 10^{-16}$ and $\varepsilon \approx 2.220 \times 10^{-16}$, as Section 1.4 proved.

Exercise 3. (a) Compute $(2 + i)(1 - 3i)$. (b) Write $1/(3 + 4i)$ as real part plus i times imaginary part, and give $|3 + 4i|$. (c) For the complex frequency $\varepsilon = 2 - 0.5i$, what is the size $|e^{-i\varepsilon t}|$ of the wave, and does it grow or decay?

Answer. (a) $(2 + i)(1 - 3i) = 2 - 6i + i - 3i^2 = 2 - 5i + 3 = 5 - 5i$ (multiply out; $i^2 = -1$). (b) $\dfrac{1}{3+4i} = \dfrac{3-4i}{(3+4i)(3-4i)} = \dfrac{3-4i}{9+16} = \dfrac{3}{25} - \dfrac{4}{25}i$, and $|3 + 4i| = \sqrt{9+16} = 5$. (c) $-i\varepsilon t = -i(2 - 0.5i)t = -2it + 0.5i^2t = -2it - 0.5t$, so $e^{-i\varepsilon t} = e^{-0.5t}e^{-2it}$ (Section 1.13); since $|e^{-2it}| = 1$, the size is $e^{-0.5t}$: the wave oscillates and decays.

Exercise 4. For the matrices A with rows $(1, 2), (0, 1)$ and B with rows $(0, 1), (1, 0)$ compute AB, BA, the commutator $[A, B]$, the anticommutator $\{A, B\}$, the traces of AB and BA, and $\det A$, $\det B$, $\det(AB)$.

Answer. Row times column: AB has the rows $(1\cdot0+2\cdot1, 1\cdot1+2\cdot0) = (2, 1)$ and $(0+1, 0+0) = (1, 0)$; BA has the rows $(0 \cdot 1 + 1 \cdot 0, 0 \cdot 2 + 1 \cdot 1) = (0, 1)$ and $(1, 2)$. So $[A, B] = AB - BA$ has the rows $(2, 0)$ and $(0, -2)$, and $\{A, B\} = AB + BA$ has the rows $(2, 2)$ and $(2, 2)$. Both traces are 2 (Section 1.18 proved that they must be equal). $\det A = 1 \cdot 1 - 2 \cdot 0 = 1$, $\det B = 0 - 1 = -1$, $\det(AB) = 2 \cdot 0 - 1 \cdot 1 = -1 = \det A \det B$ (rule 1).

Exercise 5. (a) Find the inversions and the sign of the permutation $(2, 0, 3, 1)$. (b) Compute the determinant of the matrix with the rows $(2, 1, 0)$, $(0, 1, 3)$, $(1, 0, 1)$ with the six-term formula of Section 1.20.

Answer. (a) The pairs of entries in the wrong order are $(2, 0)$, $(2, 1)$ and $(3, 1)$: three inversions, an odd number, so the sign is -1. (b) With $A_{11} = 2$, $A_{12} = 1$, $A_{13} = 0$, $A_{21} = 0$, $A_{22} = 1$, $A_{23} = 3$, $A_{31} = 1$, $A_{32} = 0$, $A_{33} = 1$: $A_{11}A_{22}A_{33} = 2$, $A_{12}A_{23}A_{31} = 3$, $A_{13}A_{21}A_{32} = 0$, $A_{12}A_{21}A_{33} = 0$, $A_{11}A_{23}A_{32} = 0$, $A_{13}A_{22}A_{31} = 0$, so $\det = 2 + 3 + 0 - 0 - 0 - 0 = 5$.

Exercise 6. With the frame metric η of the author's spacetime (Section 1.27): (a) for $v = (0, 1, 0, 0, 0, 1, 0, 0)$ (components in the order $v^0, \ldots, v^7$, so $v^1 = v^5 = 1$) compute $Q(v)$ and the lowered components v_a; (b) for $w = (0, 0, 0, 0, 1, 1, 0, 0)$ compute $Q(w)$; (c) for $u = (1, 1, 1, 1, 1, 1, 0, 0)$ compute $Q(u)$. Classify each vector. (d) Write $\delta^a{}_b\,\delta^b{}_c$ for $a = c = 4$ as an explicit sum and evaluate it.

Answer. (a) $Q(v) = (v^1)^2 - (v^5)^2 = 1 - 1 = 0$: light-like; $v_a = \eta_{aa}v^a = (0, 1, 0, 0, 0, -1, 0, 0)$, because x_5 is time-like. (b) $Q(w) = -(w^4)^2 - (w^5)^2 = -2$: time-like. (c) $Q(u) = 1+1+1+1-1-1 = 2$ (the components along x_0, x_1, x_2, x_3 count $+1$, those along x_4, x_5 count -1): space-like. (d) $\sum_{b=0}^{7} \delta^4{}_b\,\delta^b{}_4$; only $b = 4$ contributes, giving $1 \cdot 1 = 1 = \delta^4{}_4$.

Exercise 7. (a) Check that $\sum_a \sum_b S_{ab}A_{ab} = 0$ for S with the rows $(1, 4), (4, 0)$ and A with the rows $(0, -3), (3, 0)$. (b) Show, with the Clifford relation of the record's gamma matrices, that $\gamma^{(x_1)}\gamma^{(x_4)}\gamma^{(x_1)} = -\gamma^{(x_4)}$.

Answer. (a) The four terms are $1 \cdot 0 + 4 \cdot (-3) + 4 \cdot 3 + 0 \cdot 0 = 0$: the terms $(1, 2)$ and $(2, 1)$ cancel, the diagonal terms are 0 (Section 1.28). (b) $\gamma^{(x_1)}\gamma^{(x_4)} = -\gamma^{(x_4)}\gamma^{(x_1)}$ (different gamma

matrices anticommute), so $\gamma^{(x_1)}\gamma^{(x_4)}\gamma^{(x_1)} = -\gamma^{(x_4)}\gamma^{(x_1)}\gamma^{(x_1)} = -\gamma^{(x_4)}(\gamma^{(x_1)})^2 = -\gamma^{(x_4)}I = -\gamma^{(x_4)}$ (associativity; $(\gamma^{(x_1)})^2 = \eta_{11}I = +I$ for the space-like x_1).

Exercise 8. Let A have the rows $(2, 1-i)$ and $(1+i, 3)$. (a) Show that A is Hermitian. (b) Find its characteristic polynomial and its eigenvalues. (c) Find an eigenvector for each eigenvalue and check that the two are perpendicular ($w^\dagger v = 0$).

Answer. (a) The transpose has the rows $(2, 1+i)$ and $(1-i, 3)$; conjugating every entry gives back A, so $A^\dagger = A$. (b) $\det(A-\lambda I) = (2-\lambda)(3-\lambda)-(1-i)(1+i) = \lambda^2-5\lambda+6-2 = \lambda^2-5\lambda+4 = (\lambda-1)(\lambda-4)$, using $(1-i)(1+i) = 1-i^2 = 2$; the eigenvalues 1 and 4 are real, as Theorem 1 of Section 1.36 requires. (c) For 4: the first row of $(A-4I)v = 0$ reads $-2v_1+(1-i)v_2 = 0$; with $v_2 = 2$, $v = (1-i, 2)$ (second row: $(1+i)(1-i)-2 = 2-2 = 0$). For 1: $v_1+(1-i)v_2 = 0$; with $v_2 = 1$, $w = (-1+i, 1)$ (second row: $(1+i)(-1+i)+2 = (i^2-1)+2 = 0$). Then $w^\dagger v = (-1-i)(1-i)+1\cdot 2 = (-1+i-i+i^2)+2 = -2+2 = 0$.

Exercise 9. Take the author's metric at $a_4 = 0$, $b_4 = 1$ and $z = \pi/4$. (a) Write its eight diagonal entries with $s = \sin^{1/3}(\pi/4)$. (b) Compute the product of the eight entries and compare it with $\cos^2(\pi/4)$. (c) What is its signature, and what happens to its three extra-time entries when a_4 grows to $\ln 2$?

Answer. (a) $\sin(\pi/4) = \cos(\pi/4) = \sqrt{2}/2$ and $\cot(\pi/4) = 1$, so the entries, in the order $x_0, \ldots, x_7$, are $1, s, s, s, -1, -s, -s, -s$ with $s = (\sqrt{2}/2)^{1/3} = 2^{-1/6} \approx 0.8909$ (since $\sqrt{2}/2 = 2^{-1/2}$ and $(2^{-1/2})^{1/3} = 2^{-1/6}$). (b) The product is $1 \cdot s^3 \cdot (-1) \cdot (-s)^3 = s^6 = (2^{-1/6})^6 = 2^{-1} = \frac{1}{2}$, and $\cos^2(\pi/4) = (\sqrt{2}/2)^2 = \frac{1}{2}$: equal, as Section 1.21 proved. (c) Four positive entries (1 and s three times) and four negative ones: the signature (4,4). At $a_4 = \ln 2$ the extra-time entries $-b_4 e^{-2a_4}s$ are multiplied by $e^{-2\ln 2} = \frac{1}{4}$ (and the space entries by 4): they shrink towards 0 but keep their sign, so the signature stays (4,4) (Section 1.36).

Exercise 10. (a) Compute $\delta^{x_2x_3x_1x_4}_{x_1x_2x_3x_4}$ (lower list (x_1, x_2, x_3, x_4), upper list (x_2, x_3, x_1, x_4)) with the four cases of Section 1.42. (b) Compute $\delta^{x_1x_2x_3x_4}_{x_1x_2x_3x_5}$. (c) How many of the 8^{10} pairs of index lists of length 5 over the eight labels have a nonzero value, and how many of them are $+1$?

Answer. (a) No label repeats, and both lists hold $x_1, \ldots, x_4$: case (d). The lower labels stand at the places 3, 1, 2, 4 of the upper list (x_1 is the third upper label, x_2 the first, x_3 the second, x_4 the fourth), so $\sigma = (3, 1, 2, 4)$, with the inversions $(3, 1)$ and $(3, 2)$: even, value $+1$. (b) The lower label x_5 is not among the upper labels: case (c), value 0. (c) $N_{\neq 0}(8, 5) = 8\cdot 7\cdot 6\cdot 5\cdot 4\cdot 5! = 6720\cdot 120 = 806400$, of which half, 403200, are $+1$ (Section 1.43).

Exercise 11. Use the contraction identity of Section 1.44 twice to compute $\sum_c \sum_d \delta^{acd}_{bcd}$ in eight dimensions, and check the result by counting the nonzero terms.

Answer. First contract d in the delta with $p = 3$ indices: $\sum_d \delta^{acd}_{bcd} = (8-3+1)\,\delta^{ac}_{bc} = 6\,\delta^{ac}_{bc}$. Then contract c in the delta with $p = 2$ indices: $\sum_c \delta^{ac}_{bc} = (8-2+1)\,\delta^a_b = 7\,\delta^a_b$. Together $\sum_c \sum_d \delta^{acd}_{bcd} = 42\,\delta^a_b$. Check by counting: for $a \neq b$ every term is 0: if c or d equals a, the upper list repeats a (case (b)); if c or d equals b, the lower list repeats b (case (a)); otherwise c and d differ from a and b, so the lower label b is not among the upper labels a, c, d (case (c)). For $a = b$ the term is $+1$ exactly when c and d differ from a and from each other (equal lists of three different labels) and 0 otherwise; there are 7 choices for c and then 6 for d, so the sum is $7 \cdot 6 = 42$.

Exercise 12. (a) In the record's self-test of length 4, what is the probability that the 4 upper labels of a sample, drawn with `below(8)`, are all different? (b) About how many of 100,000 such samples have four different labels? (c) Why can no sample of length 9 have a nonzero value?

Answer. (a) $P(4) = \frac{8}{8} \cdot \frac{7}{8} \cdot \frac{6}{8} \cdot \frac{5}{8} = \frac{1680}{4096} \approx 0.4102$ (Section 1.50). (b) About $100000 \cdot 0.4102 \approx 41{,}000$ (the expected value NP). (c) Nine labels taken from eight must repeat one (the pigeonhole principle), so case (a) or (b) of Section 1.42 applies and the value is 0; this is why the record's count for $p = 9$ is exactly 0.

2 Mathematics from zero II: several variables, ODEs, Euler and RK4, convergence, the shooting method

This chapter teaches the second half of the mathematics that the book needs: differential equations and how a computer solves them, how to tell how accurate a computed answer is, how to find the special energies of an equation with conditions at both ends of an interval (the shooting method), and how to differentiate a function of several variables. Every idea is built from school algebra and one-variable calculus, and every idea is tried out at once in a notebook. The chapter has four worked examples, Notebooks 02a, 02b, 02c and 02d; the last one rewrites, line by line in Python, the method with which the Rust program of the Revision record solves the Kohn-Sham equations of this book, and reproduces that program's published numbers.

2.1 What this chapter is for

The book's physics lives in equations that say how quantities change. Two places in the book need the tools of this chapter.

First, the author's metric. The metric (introduced from zero in Chapter 3; here we only need its formulas) is a list of eight numbers $g_{00}, \ldots, g_{77}$ that turn small coordinate steps along the eight directions $x_0, \ldots, x_7$ into true lengths. Its entries depend on TWO variables: the time x_4 and the hidden coordinate x_0. Lengths along the three directions of ordinary space, x_1, x_2, x_3, carry the **scale factor** $e^{a_4} \sin^{1/6} z$, and lengths along the three **extra times** x_5, x_6, x_7 carry the scale factor $b_4^{1/2} e^{-a_4} \sin^{1/6} z$, where $a_4(x_4)$ and $b_4(x_4) > 0$ are functions of the time ($b_4 = 1$ in the background of the Revision record) and $z = 6Hx_0$ (with the author's positive constant H) is the author's variable for the hidden direction. When a_4 grows and b_4 stays constant, ordinary space inflates and the three extra times **deflate exponentially**. To say how fast each length changes with x_4 or with x_0 we need **partial derivatives**, the derivatives of a function of several variables (Sections 2.18 and 2.19).

Second, the Kohn-Sham equations of the book (Chapters 14 and 15). They are two coupled first-order differential equations for the two components of an **orbital** (the wave function of one particle of the model) along the hidden coordinate, with one condition at each end of an interval, and they have solutions only for special energies, the **energy levels**. The Rust program of the Revision record solves them by the **shooting method**: it guesses an energy, integrates the equations from one end to the other with the **classical fourth-order Runge-Kutta method (RK4)** in 900 steps, measures by how much the condition at the far end fails, and corrects the energy with Newton's method. Sections 2.2 to 2.7 teach RK4 and the measurement of its accuracy, Sections 2.12 and 2.13 the shooting method, and Section 2.24 the special form of shooting (with the **Prüfer angle**) that the program uses.

The four notebooks of the chapter are:

notebook	what it computes	Revision record it reproduces
02a	Euler, midpoint and RK4 on the deflating extra-time scale factor and on an oscillator; orders 1, 2, 4 on log-log plots; the rounding floor; the predicted error at the step of the Revision solver; Richardson's rule	`Revision/kohn_sham/results/parameters.json` (900 RK4 steps on an interval of length 3; the history constants $A = H = 1$)
02b	the shooting method for a vibrating string and for a quantum well; bisection against the secant rule; exact levels with 30 digits	none (exact formulas only)
02c	partial derivatives, finite differences, the chain rule for $z = 6Hx_0$, the growth and deflation rates of the author's metric, the volume factor, all 25 nonzero Christoffel entries	`Revision/gkd_lovelock/results/curvature.json` and `Revision/field_equations_a4/reports/wolfram-a4-report.json`
02d	the Prüfer-angle shooting and the Newton root finder of the Revision Kohn-Sham solver, rewritten line by line; all 54 levels of its free spectrum	`Revision/kohn_sham/results/spectrum/free-k0-analytic.csv` and two checks of `Revision/kohn_sham/reports/ks-rust-solver.json`

Every statement of the chapter carries one of the five labels of Chapter 0. Most are PROVED here by elementary algebra (and confirmed by a check of a notebook) or COMPUTED by a notebook (with the cell that computes the number and, where it reproduces a Revision record, the record file and its check). A few standard theorems of calculus are quoted without proof; we label them ASSUMED, as the book does for everything it does not derive. Two physical inputs are ASSUMED as well and are named where they enter: the linear history $a_4 = AHx_4$, which is a PRESCRIBED BACKGROUND, and the mirror (brane) conditions of the Kohn-Sham model. No HYPOTHESIS enters this chapter.

2.2 Differential equations

The derivative. For a function $y(t)$ of one variable the derivative is

$$y'(t) = \frac{dy}{dt}(t) = \lim_{h \to 0} \frac{y(t+h) - y(t)}{h},$$

the slope of the graph of y at t, or the rate of change of y per unit of t. We write y'' for the derivative of y' (the second derivative), and $y^{(n)}$ for the n-th derivative.

An ordinary differential equation (ODE) is an equation of the form

$$y'(t) = f(t, y(t))$$

for an unknown function $y(t)$, where f is a known rule that produces a number from t and y, the **right-hand side**. It is "ordinary" because the unknown depends on one variable only. Together with a starting value $y(0) = y_0$ it is an **initial-value problem**. When f is smooth (it has continuous derivatives), the initial-value problem has exactly one solution, at least for some time after the start: this is the theorem of Picard and Lindelöf, which we quote without proof (ASSUMED: a standard theorem of calculus). A computer tries to approximate that one solution.

Systems. Several unknown functions that change together, say a position $x(t)$ and a velocity $v(t)$, form a **system**. We collect them into one list $Y = (x, v)$, a **vector**, and write the system again as $Y' = f(t, Y)$, where now f produces a list of the same length. An equation with a second derivative becomes a system of first-order equations by naming the first derivative: $x'' = -x$ becomes $x' = v$ and $v' = -x$, because $v' = (x')' = x'' = -x$.

Problem A: the deflating extra time. We now derive the first equation of Notebook 02a from the author's metric. The entry of the metric for the extra time x_5 is

$$g_{55} = -e^{-2a_4} \sin^{1/3} z.$$

(This is the author's metric entry, which Notebook 02c reads from the Revision record `Revision /gkd_lovelock/results/curvature.json`, key `metricDiagonal`; its minus sign marks a time-like direction.)

$$s_5 = \sqrt{|g_{55}|} = \sqrt{e^{-2a_4} \sin^{1/3} z}$$

(The scale factor of a direction is defined as the square root of the absolute value of its diagonal metric entry; the absolute value removes the minus sign.)

$$s_5 = e^{-a_4} \sin^{1/6} z$$

(The square root of a product is the product of the square roots; $\sqrt{e^{-2a_4}} = e^{-a_4}$ because $(e^{-a_4})^2 = e^{-2a_4}$, and $\sqrt{\sin^{1/3} z} = \sin^{1/6} z$ because $(\sin^{1/6} z)^2 = \sin^{2/6} z = \sin^{1/3} z$.)

$$s_5(x_4) = e^{-AHx_4} \sin^{1/6} z$$

(We insert the linear history $a_4 = AHx_4$; the number A fixes how fast a_4 grows.)

$$\frac{ds_5}{dx_4} = -AH\, e^{-AHx_4} \sin^{1/6} z$$

(Chain rule: the derivative of e^{cx_4} is $c\, e^{cx_4}$, here with $c = -AH$; at a fixed hidden position $\sin^{1/6} z$ does not depend on x_4 and stays a constant factor.)

$$\frac{ds_5}{dx_4} = -AH\, s_5$$

(The right side of the previous line is $-AH$ times s_5 itself.)

With $A = 1$ and $H = 1$, and after dividing by the constant $\sin^{1/6} z$, the function $b(x_4) = e^{-x_4}$ obeys

$$\frac{db}{dx_4} = -b, \qquad b(0) = 1.$$

This is **Problem A** of Notebook 02a, written with $t = x_4$ and $y = b$: $y' = -y$, $y(0) = 1$, with the exact solution $y(t) = e^{-t}$ (its derivative is $-e^{-t}$ by the chain rule, and $e^0 = 1$). The same steps with $g_{11} = e^{2a_4} \sin^{1/3} z$ give the 3-space factor $a(x_4) = e^{x_4}$ with $da/dx_4 = +a$: ordinary space inflates while the extra time deflates. Their product never changes:

$$a\, b = e^{x_4} e^{-x_4} = e^{x_4 - x_4} = e^0 = 1$$

(the exponential turns sums into products, $e^u e^v = e^{u+v}$).

Status. The algebra above is PROVED. The history $a_4 = AHx_4$ with $A = 1$ is ASSUMED: it is a PRESCRIBED BACKGROUND along which the Revision record computes its Kohn-Sham states (record `Revision/kohn_sham/results/parameters.json`, keys `historyA` $= 1$ and `H` $= 1$, reproduced by Notebook 02a, In [11]); the Revision check `ks_history_is_a_prescribed_backg round` of `Revision/field_equations_a4/reports/ks-source-conditions.json` records that the Kohn-Sham states are not admissible sources of the metric along it, so the history is not derived from the field equations (the equations that determine a_4, Chapter 12): it is put in by hand. The deflation itself is not frozen or static anywhere in this book: b shrinks exponentially as x_4 grows.

Problem B: the oscillator. $x'' = -x$ with $x(0) = 1$ and $x'(0) = 0$. As a system, $x' = v$ and $v' = -x$ with $x(0) = 1$, $v(0) = 0$. The exact solution is $x = \cos t$, $v = -\sin t$: indeed $x' = -\sin t = v$ and $v' = -\cos t = -x$. Its **energy** $E = (x^2 + v^2)/2$ does not change:

$$\frac{dE}{dt} = x\, x' + v\, v'$$

(the derivative of $x^2/2$ is xx' by the chain rule, and likewise for $v^2/2$);

$$\frac{dE}{dt} = x\, v + v\, (-x) = 0$$

(we insert $x' = v$ and $v' = -x$). So $E = (1^2 + 0^2)/2 = 1/2$ at every time, and the point (x, v) runs round the circle $x^2 + v^2 = 1$. A numerical method that does not keep E fixed reveals its error at once; Notebook 02a uses this.

2.3 Taylor's theorem and the exponential series

Taylor's theorem (ASSUMED: a standard theorem of one-variable calculus, quoted without proof). If y has $n + 1$ continuous derivatives, then for every step h

$$y(t + h) = y(t) + h\, y'(t) + \frac{h^2}{2!}\, y''(t) + \cdots + \frac{h^n}{n!}\, y^{(n)}(t) + \frac{h^{n+1}}{(n+1)!}\, y^{(n+1)}(s)$$

for some number s between t and $t+h$. Here $n! = 1 \cdot 2 \cdot 3 \cdots n$ (with $0! = 1$) is the **factorial**. The last term is the **remainder**: it shows that the error of keeping only the terms up to h^n is proportional to h^{n+1} when h is small.

The exponential series. Take $y(t) = e^t$ at $t = 0$ and the step $h = z$. Every derivative of e^t is e^t itself, so every derivative at $t = 0$ is $e^0 = 1$; the term with h^k is therefore $z^k/k!$, and

$$e^z = 1 + z + \frac{z^2}{2} + \frac{z^3}{6} + \frac{z^4}{24} + \frac{z^5}{120} + \dots$$

where the dots stand for the terms with higher powers of z (the remainder goes to zero as more terms are kept, for every z). This series is the yardstick of Sections 2.5 and 2.6.

2.4 Three step rules: Euler, midpoint and RK4

A computer cannot follow a solution continuously. It chooses a **step size** h, the times $t_n = nh$, and computes numbers y_n that approximate $y(t_n)$, one step after the other. N steps of size $h = T/N$ reach the end time T. A **step rule** says how to compute y_{n+1} from y_n.

Euler's method. Taylor's theorem with $n = 1$ says $y(t+h) = y(t) + h\,y'(t) + \frac{h^2}{2}y''(s)$. Dropping the last term and using $y' = f(t, y)$ gives

$$y_{n+1} = y_n + h\,f(t_n, y_n).$$

It follows the slope at the start of the step for the whole step.

The midpoint method. It first uses the starting slope to estimate the value in the middle of the step, and then uses the slope there for the whole step:

$$k_1 = f(t_n, y_n), \qquad k_2 = f(t_n + \tfrac{h}{2},\, y_n + \tfrac{h}{2}k_1), \qquad y_{n+1} = y_n + h\,k_2.$$

The classical fourth-order Runge-Kutta method (RK4). It computes four slopes and averages them with the weights $1 : 2 : 2 : 1$:

$$k_1 = f(t_n, y_n), \quad k_2 = f(t_n + \tfrac{h}{2},\, y_n + \tfrac{h}{2}k_1), \quad k_3 = f(t_n + \tfrac{h}{2},\, y_n + \tfrac{h}{2}k_2), \quad k_4 = f(t_n + h,\, y_n + h\,k_3),$$

$$y_{n+1} = y_n + \frac{h}{6}\,(k_1 + 2k_2 + 2k_3 + k_4).$$

k_1 is the slope at the start, k_2 the slope at the midpoint reached with k_1, k_3 the slope at the midpoint reached with k_2, k_4 the slope at the end reached with k_3. RK4 is the method of the Rust program of the Revision record that solves the Kohn-Sham equations (file `Revision/kohn_sham/solver/src/shoot.rs`). For a system the same formulas hold with y, f and the k's read as vectors.

One step by hand. Take Problem A, $f(t, y) = -y$, from $y_0 = 1$ with the step $h = 1/2$. Euler:

$$y_1 = 1 + \tfrac{1}{2} \cdot (-1) = \tfrac{1}{2}$$

(Euler's rule with $f(0,1) = -1$). The midpoint method:

$$k_1 = f(0,1) = -1$$

(the slope at the start is $-y_0$);

$$k_2 = f\big(\tfrac{1}{4},\, 1 + \tfrac{1}{4} \cdot (-1)\big) = -\big(1 - \tfrac{1}{4}\big) = -\tfrac{3}{4}$$

(half a step is $h/2 = 1/4$; the slope at the estimated midpoint value $3/4$ is minus that value);

$$y_1 = 1 + \tfrac{1}{2} \cdot \big(-\tfrac{3}{4}\big) = 1 - \tfrac{3}{8} = \tfrac{5}{8}$$

(the midpoint rule $y_1 = y_0 + hk_2$). RK4:

$$k_1 = -1, \qquad k_2 = -\big(1 + \tfrac{1}{4} \cdot (-1)\big) = -\tfrac{3}{4}$$

(the same two slopes as in the midpoint method);

$$k_3 = -\big(1 + \tfrac{1}{4} \cdot \big(-\tfrac{3}{4}\big)\big) = -\big(1 - \tfrac{3}{16}\big) = -\tfrac{13}{16}$$

(the midpoint value is now reached with k_2);

$$k_4 = -\big(1 + \tfrac{1}{2} \cdot \big(-\tfrac{13}{16}\big)\big) = -\big(1 - \tfrac{13}{32}\big) = -\tfrac{19}{32}$$

(the end value is reached with the whole step $h = 1/2$ and the slope k_3);

$$k_1 + 2k_2 + 2k_3 + k_4 = -\tfrac{32}{32} - \tfrac{48}{32} - \tfrac{52}{32} - \tfrac{19}{32} = -\tfrac{151}{32}$$

(every term is written over the common denominator 32 and the numerators are added);

$$y_1 = 1 + \tfrac{1/2}{6} \cdot \big(-\tfrac{151}{32}\big) = 1 - \tfrac{151}{384} = \tfrac{233}{384}$$

(the RK4 rule with $h/6 = 1/12$, and $12 \cdot 32 = 384$). The exact value is $e^{-1/2} = 0.6065306597\ldots$; the three methods give 0.5, 0.625 and $233/384 = 0.6067708333\ldots$ (PROVED here; Notebook 02a, In [3], repeats the arithmetic with exact fractions and checks the three results). RK4 is already correct to about four digits after a single large step.

2.5 The amplification factor

To understand the accuracy of a method we apply it to the simplest equation of all, the **test equation**

$$y' = \lambda y$$

with a constant number λ; its exact solution is $y(t) = e^{\lambda t}y(0)$, so one exact step multiplies y by $e^{\lambda h}$. Write $z = \lambda h$. We now show that one step of each method multiplies y_n by a number $R(z)$, its **amplification factor**, and find R.

Euler.

$$y_{n+1} = y_n + h\,\lambda y_n = (1 + z)\,y_n$$

(Euler's rule with $f(t, y) = \lambda y$, then $h\lambda = z$ and y_n taken out as a common factor). So $R(z) = 1 + z$.

Midpoint.

$$k_1 = \lambda y_n$$

(the slope at the start);

$$k_2 = \lambda(y_n + \tfrac{h}{2}\lambda y_n) = \lambda y_n(1 + \tfrac{z}{2})$$

(the slope at the estimated midpoint, with $h\lambda = z$);

$$y_{n+1} = y_n + h\lambda y_n(1 + \tfrac{z}{2}) = (1 + z + \tfrac{z^2}{2})\,y_n$$

(the midpoint rule, then $h\lambda = z$ and the product multiplied out). So $R(z) = 1 + z + z^2/2$.

RK4.

$$k_1 = \lambda y_n, \qquad k_2 = \lambda y_n(1 + \tfrac{z}{2})$$

(as for the midpoint method);

$$k_3 = \lambda(y_n + \tfrac{h}{2}k_2) = \lambda y_n(1 + \tfrac{z}{2} + \tfrac{z^2}{4})$$

(we insert k_2: $\frac{h}{2}k_2 = \frac{z}{2}y_n(1 + \frac{z}{2})$);

$$k_4 = \lambda(y_n + hk_3) = \lambda y_n(1 + z + \tfrac{z^2}{2} + \tfrac{z^3}{4})$$

(we insert k_3: $hk_3 = zy_n(1 + \frac{z}{2} + \frac{z^2}{4})$);

$$k_1 + 2k_2 + 2k_3 + k_4 = \lambda y_n(6 + 3z + z^2 + \tfrac{z^3}{4})$$

(we add the four brackets, the middle two counted twice: the constants $1+2+2+1=6$, the terms with z: $1+1+1=3$, with z^2: $\frac{1}{2}+\frac{1}{2}=1$, with z^3: $\frac{1}{4}$);

$$y_{n+1} = y_n + \frac{h}{6}\lambda y_n(6 + 3z + z^2 + \tfrac{z^3}{4}) = (1 + z + \tfrac{z^2}{2} + \tfrac{z^3}{6} + \tfrac{z^4}{24})\, y_n$$

(the RK4 rule; $h\lambda = z$, and each term of the bracket is multiplied by $z/6$). So

$$R_{\text{Euler}}(z) = 1 + z, \qquad R_{\text{midpoint}}(z) = 1 + z + \frac{z^2}{2}, \qquad R_{\text{RK4}}(z) = 1 + z + \frac{z^2}{2} + \frac{z^3}{6} + \frac{z^4}{24}.$$

Each R is a **polynomial** in z (a sum of powers of z with constant coefficients). Compare with the exponential series of Section 2.3: Euler keeps its first 2 terms, the midpoint method its first 3, RK4 its first 5 (PROVED here; Notebook 02a, In [4], derives the same polynomials with sympy and compares them with the series). The first term that a method misses decides its accuracy, as the next section shows.

2.6 Error, order, the log-log plot, rounding and Richardson's rule

Error and order. The **error** of a computation is the computed value minus the exact value. A method has **order** p when its error at a fixed end time is close to Ch^p for small h, with a number C that does not depend on h. Halving h then divides the error by 2^p:

$$\frac{Ch^p}{C(h/2)^p} = \frac{h^p}{h^p/2^p} = 2^p$$

(the constant C cancels, and $(h/2)^p = h^p/2^p$ because a power of a quotient is the quotient of the powers).

Why Euler has order 1. Taylor's theorem says that one Euler step makes an error of about $\frac{1}{2}h^2|y''|$. To reach the end time T one needs $N = T/h$ steps, and N errors of size about h^2 add up to about $Nh^2 = Th$, which is proportional to h^1.

The exact leading error for Problem A. For Problem A we can do better and compute the error of each method to leading order. Here $\lambda = -1$, so one step multiplies y by $R(-h)$, while the exact factor is e^{-h}. A method of order p keeps the terms of the series of e^{-h} up to the power h^p (Euler $p=1$, midpoint $p=2$, RK4 $p=4$):

$$R(-h) = \sum_{k=0}^{p} \frac{(-h)^k}{k!}, \qquad e^{-h} = \sum_{k=0}^{\infty} \frac{(-h)^k}{k!}$$

(Section 2.5 for R and Section 2.3 for the series of the exponential, both at $z = -h$).

$$R(-h) = e^{-h} - \frac{(-h)^{p+1}}{(p+1)!} - \dots$$

(R is the series minus all the terms it misses; the dots stand for the missed terms with the powers h^{p+2} and higher).

$$R(-h) = e^{-h}(1-q), \qquad q = e^{h}\Big(\frac{(-h)^{p+1}}{(p+1)!} + \dots\Big) = \frac{(-h)^{p+1}}{(p+1)!} + \dots$$

(we take out the factor e^{-h}, which multiplies everything in the bracket by e^{h}; since $e^{h} = 1 + h + \dots$, that changes only the terms with higher powers of h).

$$y_N = R(-h)^N = e^{-Nh}(1-q)^N = e^{-1}(1-q)^N$$

(N steps multiply the start value $y_0 = 1$ by $R(-h)$ N times; a power of a product is the product of the powers; and $Nh = 1$ when we compute up to $t = 1$).

$$(1-q)^N \approx 1 - Nq$$

(the first two terms of the binomial theorem $(1-q)^N = 1 - Nq + \frac{N(N-1)}{2}q^2 - \dots$; the next term is of the size $(Nq)^2$, which is much smaller than Nq when Nq is small).

$$Nq \approx \frac{1}{h} \cdot \frac{(-1)^{p+1}h^{p+1}}{(p+1)!} = \frac{(-1)^{p+1}h^{p}}{(p+1)!}$$

($N = 1/h$, $(-h)^{p+1} = (-1)^{p+1}h^{p+1}$, and one factor h cancels).

$$y_N - e^{-1} \approx -e^{-1}Nq = e^{-1}\,\frac{(-1)^{p}\,h^{p}}{(p+1)!}$$

(we subtract e^{-1} from $y_N \approx e^{-1}(1-Nq)$, and $-(-1)^{p+1} = (-1)^{p}$).

So at $t = 1$ Euler ends too LOW by $e^{-1}h/2$, the midpoint method too HIGH by $e^{-1}h^2/6$, and RK4 too high by $e^{-1}h^4/120$ (PROVED here, to leading order in h). The Rust solver of the Revision record makes $G = 900$ RK4 steps on an interval of length $L = 3$, so its step is $h = L/G = 1/300$ (COMPUTED from the record `Revision/kohn_sham/results/parameters.json`, keys `rk4Steps` and `L_tipCutoff`; Notebook 02a, In [11]). At this step the formula predicts -6.1313×10^{-4} (Euler), $+6.8126 \times 10^{-7}$ (midpoint) and $+3.7848 \times 10^{-13}$ (RK4); Notebook 02a measures -6.1399×10^{-4}, $+6.8296 \times 10^{-7}$ and $+3.7920 \times 10^{-13}$, the ratios 1.0014, 1.0025 and 1.0019 (COMPUTED, In [11]); the small remaining differences are the next terms of the expansion, which the formula leaves out.

The log-log plot. The **logarithm** $\log_{10} x$ is the power to which 10 must be raised to give x; for example $\log_{10} 1000 = 3$ and $\log_{10} 0.001 = -3$. Write $\Delta = Ch^{p}$ for the size of the error and take the logarithm:

$$\log_{10}\Delta = \log_{10} C + p\log_{10} h$$

(the logarithm of a product is the sum of the logarithms, and $\log_{10}(h^{p}) = p\log_{10} h$). As a function of $\log_{10} h$ this is a straight line with **slope** p. A **log-log plot** marks both axes in powers of ten, so

the errors of a method of order p lie on a straight line of slope p, and the order can be read off as a slope. A straight line fitted through measured points by **least squares** (the line that makes the sum of the squared vertical distances smallest) gives the measured order.

Rounding errors. A computer stores a number with about 16 significant decimal digits (53 binary digits). The spacing of the stored numbers near 1 is the **machine epsilon** $\epsilon = 2^{-52} \approx 2.2 \times 10^{-16}$, and every arithmetic operation rounds its result to a relative error of at most about $\epsilon/2$. With N steps about N such rounding errors add up. If all of them had their largest size and the same sign, their total would be about $N\epsilon = \epsilon/h$ times the size of the solution; this is a pessimistic **bound**, the scale of the worst case. In practice the rounding errors have both signs and partly cancel, so their total stays far below the bound; but it still grows with the number of steps, while the truncation error Ch^p falls. A smaller step is therefore not always better: below some step size the rounding errors take over, and the error grows again, slowly. For RK4 on Problem A this **rounding floor** is near 10^{-16}, and with more steps the error grows again but stays 524 to 3709 times below the bound $N\epsilon e^{-1}$ (COMPUTED, Notebook 02a, In [10]).

Richardson's rule. In a real problem the exact answer Y is unknown. Suppose a method of order p gives the value Y_h with the step h and the value $Y_{h/2}$ with half the step, and that both errors are already close to Ch^p:

$$Y_h = Y + Ch^p, \qquad Y_{h/2} = Y + \frac{Ch^p}{2^p}$$

(the order-p error law at the steps h and $h/2$).

$$Y_h - Y_{h/2} = Ch^p\Big(1 - \frac{1}{2^p}\Big) = \frac{Ch^p}{2^p}\,(2^p - 1)$$

(we subtract the second equation from the first; Y cancels; then $1 - 2^{-p} = (2^p - 1)/2^p$).

$$Y_{h/2} - Y = \frac{Ch^p}{2^p} = \frac{Y_h - Y_{h/2}}{2^p - 1}$$

(the error of the finer value, from the second equation, and then divided out of the previous line).

So the difference of two runs, divided by $2^p - 1$, estimates the error of the finer run without knowing Y; for RK4 it is $(Y_h - Y_{h/2})/15$. Subtracting the estimate gives the **extrapolated** value

$$Y_{h/2} - \frac{Y_h - Y_{h/2}}{15} = \frac{16\,Y_{h/2} - Y_h}{15}$$

(both terms written over the denominator 15), which is more accurate than either run (Notebook 02a, In [14]). Richardson's rule is only as good as its assumption: the errors must already follow Ch^p.

2.7 The oscillator and the product of the two scale factors

A complex number turns the oscillator into the test equation. A **complex number** is $w = x + iv$ with real numbers x, v and the number i with $i^2 = -1$ (complex numbers are the subject

of Chapter 1); its **complex conjugate** is $\bar{w} = x - iv$, and $|w|^2 = w\bar{w} = x^2 + v^2$. For the oscillator of Problem B put $w = x + iv$. Then

$$w' = x' + iv' = v - ix$$

(differentiate each part, and insert $x' = v$, $v' = -x$);

$$w' = -i\,(x + iv) = -i\,w$$

(multiply out: $-ix - i^2 v = -ix + v$, which is the previous line). So w obeys the test equation with $\lambda = -i$, and one step of a method multiplies w by $R(-ih)$. The energy is $E = (x^2 + v^2)/2 = |w|^2/2$, so one step multiplies E by

$$|R(-ih)|^2 = R(-ih)\,R(ih)$$

(the conjugate of $R(-ih)$ is $R(ih)$, because the coefficients of the polynomial R are real numbers and the conjugate of $-i$ is i).

Euler.

$$R(-ih)R(ih) = (1 - ih)(1 + ih) = 1 - i^2h^2 = 1 + h^2$$

(the product $(a - b)(a + b) = a^2 - b^2$, and $i^2 = -1$). Every Euler step multiplies the energy by $1 + h^2 > 1$: the computed point spirals outwards.

Midpoint. $R(ih) = 1 + ih + (ih)^2/2 = (1 - \frac{h^2}{2}) + ih$, a complex number with the real part $1 - h^2/2$ and the imaginary part h, so

$$|R(ih)|^2 = \Big(1 - \frac{h^2}{2}\Big)^2 + h^2 = 1 - h^2 + \frac{h^4}{4} + h^2 = 1 + \frac{h^4}{4}$$

($|w|^2 = x^2 + v^2$, then the square multiplied out).

RK4. $R(ih) = 1 + ih - \frac{h^2}{2} - \frac{ih^3}{6} + \frac{h^4}{24}$ (powers of i: $i^2 = -1$, $i^3 = -i$, $i^4 = 1$), with the real part $c = 1 - \frac{h^2}{2} + \frac{h^4}{24}$ and the imaginary part $s = h - \frac{h^3}{6}$.

$$c^2 = 1 - h^2 + \frac{h^4}{4} + \frac{h^4}{12} - \frac{h^6}{24} + \frac{h^8}{576} = 1 - h^2 + \frac{h^4}{3} - \frac{h^6}{24} + \frac{h^8}{576}$$

(the square of a sum of three terms, $(a + b + d)^2 = a^2 + b^2 + d^2 + 2ab + 2ad + 2bd$ with $a = 1$, $b = -h^2/2$, $d = h^4/24$; then $\frac{1}{4} + \frac{1}{12} = \frac{1}{3}$);

$$s^2 = h^2 - \frac{h^4}{3} + \frac{h^6}{36}$$

($(a + b)^2 = a^2 + 2ab + b^2$ with $a = h$, $b = -h^3/6$);

$$c^2 + s^2 = 1 + \Big(-\frac{1}{24} + \frac{1}{36}\Big)h^6 + \frac{h^8}{576} = 1 - \frac{h^6}{72} + \frac{h^8}{576}$$

(we add; the terms with h^2 and h^4 cancel, and $-\frac{3}{72} + \frac{2}{72} = -\frac{1}{72}$).

So one step multiplies the energy by $1 + h^2$ (Euler), $1 + h^4/4$ (midpoint) and $1 - h^6/72 + h^8/576$ (RK4) (PROVED here; Notebook 02a, In [4], derives the same three polynomials with sympy, and In [12] shows that the computed energies follow them to 13 digits). With $h = 0.2$ the factors are 1.04, 1.0004 and 0.99999911.

The product of the scale factors. The 3-space factor obeys $a' = +a$ ($\lambda = +1$) and the extra-time factor $b' = -b$ ($\lambda = -1$), so one step multiplies a by $R(h)$, b by $R(-h)$ and their product, exactly 1 for the true solution, by $R(h)R(-h)$. For Euler

$$R(h)R(-h) = (1 + h)(1 - h) = 1 - h^2$$

(again $(a + b)(a - b) = a^2 - b^2$): the product shrinks by the factor $1 - h^2$ at every step, and the compensation of inflation by deflation is lost. For RK4 split $R(h) = c + s$ into its even part $c = 1 + \frac{h^2}{2} + \frac{h^4}{24}$ and its odd part $s = h + \frac{h^3}{6}$ (the letters c and s now stand for these new polynomials); then $R(-h) = c - s$, because the odd powers change sign, and

$$R(h)R(-h) = (c + s)(c - s) = c^2 - s^2$$

(again $(a + b)(a - b) = a^2 - b^2$).

$$c^2 = 1 + h^2 + \frac{h^4}{4} + \frac{h^4}{12} + \frac{h^6}{24} + \frac{h^8}{576} = 1 + h^2 + \frac{h^4}{3} + \frac{h^6}{24} + \frac{h^8}{576}$$

(the square of a sum of three terms, $(a + b + d)^2 = a^2 + b^2 + d^2 + 2ab + 2ad + 2bd$, now with $a = 1$, $b = +h^2/2$, $d = h^4/24$: $a^2 = 1$, $2ab = h^2$, $b^2 = h^4/4$, $2ad = h^4/12$, $2bd = h^6/24$, $d^2 = h^8/576$; then $\frac{1}{4} + \frac{1}{12} = \frac{1}{3}$);

$$s^2 = h^2 + \frac{h^4}{3} + \frac{h^6}{36}$$

($(a + b)^2 = a^2 + 2ab + b^2$ with $a = h$, $b = +h^3/6$: $a^2 = h^2$, $2ab = h^4/3$, $b^2 = h^6/36$);

$$R(h)R(-h) = c^2 - s^2 = 1 + \Big(\frac{1}{24} - \frac{1}{36}\Big)h^6 + \frac{h^8}{576} = 1 + \frac{h^6}{72} + \frac{h^8}{576}$$

(we subtract; the terms with h^2 and h^4 cancel, and $\frac{1}{24} - \frac{1}{36} = \frac{3}{72} - \frac{2}{72} = \frac{1}{72}$). With $h = 0.25$ and 8 steps, Euler multiplies the product by $0.9375^8 = 0.597$, RK4 by a number within 3×10^{-5} of 1 (PROVED here; COMPUTED in Notebook 02a, In [6]).

2.8 Example: Euler, midpoint and RK4 on the deflating scale factor and the oscillator

Notebook 02a puts Sections 2.2 to 2.7 to work. It makes one step of each method by hand with exact fractions; derives the amplification factors and the energy factors with sympy; solves the inflating and the deflating scale factor with Euler and RK4 and shows what Euler does to their product; measures the errors of the three methods for step sizes from 1/2 down to 1/4096 and reads the orders 1, 2 and 4 from a log-log plot; shows the rounding floor of RK4 with up to 262144 steps; reads the step of the Revision Kohn-Sham solver from its record and checks the predicted errors of Section 2.6 at that step; draws the phase portrait of the oscillator, measures by what angle each method runs ahead of the exact solution and draws the energy drift; and tests Richardson's rule. It ends with the line ALL 29 CHECKS PASSED (notebook 02a).

2.9 How to run Notebook 02a

Step 1. What this notebook does and what it needs.

Notebook 02a (Euler, midpoint and RK4: the order of a method on a log-log plot) is the file `Revision/textbook/notebooks/02a_rk4_convergence.ipynb` of the repository Dirac_claude. It solves two differential equations whose exact solutions are known, the decay equation (the deflation of an extra-time scale factor along a linear history) and the oscillator equation, with the Euler method, the midpoint method and the classical fourth-order Runge-Kutta method (RK4); it derives the exact amplification factor of each method with sympy, measures how the error at a fixed end time shrinks when the step is halved, finds the orders 1, 2 and 4 as slopes on log-log plots, shows where rounding errors stop the improvement, reads the step of the Revision Kohn-Sham solver (900 RK4 steps on an interval of length 3) from its record and predicts the error of each method at that step from the first missed term of the exponential series, predicts the energy drift of the oscillator exactly, and tests the Richardson estimate of the error. It needs a computer with Windows 11, macOS or Linux, an internet connection for the installation, the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

Step 2. Install Git and Python (once per computer).

A terminal is the window in which you type commands: on Windows the app Windows PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any terminal (it runs the shell bash). Type every command of this section into a terminal exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the default choices. Download Python from https://www.python.org/downloads/ and run the installer; in its first window tick the box "Add python.exe to PATH" before you click "Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

```
xcode-select --install
```

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these two commands:

Linux (bash):

```
sudo apt update
sudo apt install git python3 python3-venv
```

Then close the terminal and open a NEW one (a terminal opened before the installation does not know the new programs), and check the version of Python; it must print 3.12 or a higher number:

Windows (PowerShell):

```
py -3 --version
```

macOS (zsh) and Linux (bash):

```
python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type `python3.12` instead of `python3` in the command that creates the environment:

Linux (bash), only when the version is too low:

```
sudo add-apt-repository ppa:deadsnakes/ppa
sudo apt update
sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands `python` and `jupyter` typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run `git pull` in the repository folder after Step 4.

Windows (PowerShell):

```
cd $HOME
git clone https://github.com/once-ere/Dirac_claude.git
```

```
py -3 -m venv "$HOME\dirac-book-env"
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with `Set-ExecutionPolicy` allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Linux (bash):

```
cd ~
git clone https://github.com/once-ere/Dirac_claude.git
python3 -m venv ~/dirac-book-env
source ~/dirac-book-env/bin/activate
python -m pip install --upgrade pip
python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

Step 4. In every new terminal: activate the environment and go into the repository folder.

Every later step starts in the repository folder with the environment active. Run these lines whenever you open a new terminal (they do no harm if the environment is already active):

Windows (PowerShell):

```
Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
& "$HOME\dirac-book-env\Scripts\Activate.ps1"
cd "$HOME\Dirac_claude"
```

macOS (zsh) and Linux (bash):

```
source ~/dirac-book-env/bin/activate
cd ~/Dirac_claude
```

Step 5. Run the notebook in JupyterLab.

In the repository folder, with the environment active, run these two lines (the first one goes into the folder of the notebooks):

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter lab 02a_rk4_convergence.ipynb
```

JupyterLab opens in your web browser and shows the notebook (if no browser window opens, copy the address that starts with `http://localhost:8888/lab` from the terminal into the address bar of your browser). The name at the top right of the notebook must read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its left shows `[*]`; when it has finished, the label shows a number. The notebook has finished when the last code cell shows a number; this takes about 10 seconds on a typical laptop. Scroll to the end and compare the last printed lines with the lines in the step "What the notebook writes and what you must see" below. To keep the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02a_rk4_convergence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with `[NbConvertApp] Writing` and shows no error, every check passed; open the notebook with `jupyter lab 02a_rk4_convergence.ipynb` (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- `Revision/textbook/figures/02a.captions.json`
- `Revision/textbook/figures/02a_1_scale_factors.png`
- `Revision/textbook/figures/02a_2_scale_factor_product.png`
- `Revision/textbook/figures/02a_3_convergence_loglog.png`
- `Revision/textbook/figures/02a_4_error_ratios.png`
- `Revision/textbook/figures/02a_5_rounding_floor.png`
- `Revision/textbook/figures/02a_6_phase_portrait.png`

- `Revision/textbook/figures/02a_7_energy_drift.png`
- `Revision/textbook/figures/02a_8_richardson.png`

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02a exist
ALL 29 CHECKS PASSED (notebook 02a)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

```
python -m ipykernel install --user --name python3
```

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file `Revision/textbook/notebooks/02a_rk4_convergence.ipynb` inside the folder Dirac_claude.
- "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was downloaded before; skip the line with `git clone`.
- Windows: "running scripts is disabled on this system": run the line with `Set-ExecutionPolicy` and then the activation line again. "py is not recognized": use `python` instead of `py -3`; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run `sudo apt install python3-venv` and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (`python -m jupyter` does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what `jupyter lab` does, the second what the headless command does:

```
python -m jupyterlab 02a_rk4_convergence.ipynb
python -m nbconvert --execute --inplace 02a_rk4_convergence.ipynb
```

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

2.10 Notebook 02a: complete text

This section prints the complete text of the notebook file `Revision/textbook/notebooks/02a_rk4_convergence.ipynb`: every cell in order, with the output that the stored, executed notebook holds. A text cell (Jupyter calls it a markdown cell) is printed in a frame after the label Text cell. A code cell is printed after the label In [k], where k is the number that Jupyter gives the cell when it runs it; the text that the cell prints follows after the label Out [k], and every figure that the cell draws follows as a figure with its caption.

Text cell:

```
## 1. What this notebook computes

A differential equation says how fast a quantity changes. A computer solves it by
taking many small *steps*. This notebook compares three ways of making one step,
the **Euler method**, the **midpoint method** and the **classical fourth-order
Runge-Kutta method (RK4)**, on two equations whose exact solutions we know, so
that every error can be measured exactly. It

- makes one step of each method by hand, with exact fractions;
- derives with sympy the exact *amplification factor* of each method, the number
  by which one step multiplies the solution of $y' = \lambda y$;
- solves the growth of the 3-space scale factor and the deflation of an
  extra-time scale factor of the author's metric along a linear history, and
  shows that Euler's method spoils their exact product $1$;
- measures the error at a fixed end time for step sizes from $1/2$ down to
  $1/262144$, finds the *orders* $1$, $2$ and $4$ of the three methods as the
  slopes of straight lines on log-log plots, and shows where rounding errors stop
  the improvement;
- reads from the Revision record Revision/kohn_sham/results/parameters.json the
  step of the Rust program that solves the book's Kohn-Sham equations with RK4,
  and predicts exactly how large the error of each method is at that step;
- solves the oscillator $d^2x/dt^2 = -x$, draws its phase portrait, and predicts the
  drift of its energy exactly from the amplification factors;
- tests Richardson's rule, which estimates the error of a computation without
  knowing the exact answer.

It draws 8 figures and prints a PASS line for every check.
```

Text cell:

```
## 2. How to run this notebook

**Step 1. What this notebook does and what it needs.**

Notebook 02a (Euler, midpoint and RK4: the order of a method on a log-log plot) is the
file ‘Revision/textbook/notebooks/02a_rk4_convergence.ipynb‘ of the repository
Dirac_claude. It solves two differential equations whose exact solutions are known, the
decay equation (the deflation of an extra-time scale factor along a linear history) and
the oscillator equation, with the Euler method, the midpoint method and the classical
fourth-order Runge-Kutta method (RK4); it derives the exact amplification factor of each
method with sympy, measures how the error at a fixed end time shrinks when the step is
halved, finds the orders 1, 2 and 4 as slopes on log-log plots, shows where rounding
errors stop the improvement, reads the step of the Revision Kohn-Sham solver (900 RK4
steps on an interval of length 3) from its record and predicts the error of each method
at that step from the first missed term of the exponential series, predicts the energy
drift of the oscillator exactly, and tests the Richardson estimate of the error. It needs
a computer with Windows 11, macOS or Linux, an internet connection for the installation,
the program Git, and Python 3.12 or newer (the notebooks were built with Python 3.14.5)
with these packages at exactly these versions: numpy 2.4.6, sympy 1.14.0, mpmath 1.3.0,
matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient 0.10.2, ipykernel 7.1.0
and nbconvert 7.16.6. The notebook itself imports numpy, sympy and matplotlib; the other
packages run Jupyter, the program that shows and runs notebooks. It does not need Rust.

**Step 2. Install Git and Python (once per computer).**

A terminal is the window in which you type commands: on Windows the app Windows
PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux any
terminal (it runs the shell bash). Type every command of this section into a terminal
exactly as printed, one line at a time, and press Enter after each line.

Windows: download Git from https://git-scm.com/download/win and install it with the
default choices. Download Python from https://www.python.org/downloads/ and run the
installer; in its first window tick the box "Add python.exe to PATH" before you click
"Install Now".

macOS: download Python from https://www.python.org/downloads/ and run the installer. Then
open the app Terminal and run this command, which installs Git and the compiler tools:

macOS (zsh):

    xcode-select --install

Linux (Debian or Ubuntu; other distributions have packages of the same names): run these
two commands:

Linux (bash):

    sudo apt update
    sudo apt install git python3 python3-venv

Then close the terminal and open a NEW one (a terminal opened before the installation
does not know the new programs), and check the version of Python; it must print 3.12 or a
```

higher number:

Windows (PowerShell):

```
    py -3 --version
```

macOS (zsh) and Linux (bash):

```
    python3 --version
```

If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python 3.12 with the following three commands, and in Step 3 type ‘python3.12‘ instead of ‘python3‘ in the command that creates the environment:

Linux (bash), only when the version is too low:

```
    sudo add-apt-repository ppa:deadsnakes/ppa
    sudo apt update
    sudo apt install python3.12 python3.12-venv
```

Step 3. Get the repository and install the packages (once per computer).

The commands below download the repository (a few hundred megabytes; the folder then needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home folder, create a private Python environment in the folder dirac-book-env inside your home folder (a private environment is a folder with its own copy of Python and of the packages, so that nothing else on your computer is changed), activate it (from then on the commands ‘python‘ and ‘jupyter‘ typed in this terminal are those of the environment, and the prompt starts with (dirac-book-env)), and install the packages at the pinned versions (this downloads about 90 MB and takes a few minutes; the environment takes about 400 MB of disk space). If you have done this step before, for this or for another notebook, skip it and go to Step 4; to get the newest version of the repository, run ‘git pull‘ in the repository folder after Step 4.

Windows (PowerShell):

```
    cd $HOME
    git clone https://github.com/once-ere/Dirac_claude.git
    py -3 -m venv "$HOME\dirac-book-env"
    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
```

The line with ‘Set-ExecutionPolicy‘ allows PowerShell to run the activation script in this one window only; it changes nothing permanently.

macOS (zsh):

```
    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
```

```
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

Linux (bash):

    cd ~
    git clone https://github.com/once-ere/Dirac_claude.git
    python3 -m venv ~/dirac-book-env
    source ~/dirac-book-env/bin/activate
    python -m pip install --upgrade pip
    python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
    python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
    python -m pip install ipykernel==7.1.0 nbconvert==7.16.6

**Step 4. In every new terminal: activate the environment and go into the repository
folder.**

Every later step starts in the repository folder with the environment active. Run these
lines whenever you open a new terminal (they do no harm if the environment is already
active):

Windows (PowerShell):

    Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
    & "$HOME\dirac-book-env\Scripts\Activate.ps1"
    cd "$HOME\Dirac_claude"

macOS (zsh) and Linux (bash):

    source ~/dirac-book-env/bin/activate
    cd ~/Dirac_claude

**Step 5. Run the notebook in JupyterLab.**

In the repository folder, with the environment active, run these two lines (the first one
goes into the folder of the notebooks):

Windows, macOS and Linux:

    cd Revision/textbook/notebooks
    jupyter lab 02a_rk4_convergence.ipynb

JupyterLab opens in your web browser and shows the notebook (if no browser window opens,
copy the address that starts with ‘http://localhost:8888/lab‘ from the terminal into the
address bar of your browser). The name at the top right of the notebook must read Python
3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the label to its
left shows ‘[*]‘; when it has finished, the label shows a number. The notebook has
finished when the last code cell shows a number; this takes about 10 seconds on a typical
laptop. Scroll to the end and compare the last printed lines with the lines in the step
"What the notebook writes and what you must see" below. To keep the results, save the
notebook (menu File > Save Notebook). To stop JupyterLab, choose the menu File > Shut
```

Down, or press Ctrl+C twice in the terminal.

Step 6. Or run the notebook without a browser (headless).

In the repository folder, with the environment active, run:

Windows, macOS and Linux:

```
cd Revision/textbook/notebooks
jupyter nbconvert --to notebook --execute --inplace 02a_rk4_convergence.ipynb
```

This runs every cell from the top to the bottom and saves the results into the notebook file. A failed check stops it with an error message that contains AssertionError and the name of the check. If the command ends with a line that starts with ‘[NbConvertApp] Writing‘ and shows no error, every check passed; open the notebook with ‘jupyter lab 02a_rk4_convergence.ipynb‘ (in the same folder, without running the cells again) to read the printed lines and see the figures.

Step 7. What the notebook writes and what you must see.

The notebook writes (or overwrites) these files:

- ‘Revision/textbook/figures/02a.captions.json‘
- ‘Revision/textbook/figures/02a_1_scale_factors.png‘
- ‘Revision/textbook/figures/02a_2_scale_factor_product.png‘
- ‘Revision/textbook/figures/02a_3_convergence_loglog.png‘
- ‘Revision/textbook/figures/02a_4_error_ratios.png‘
- ‘Revision/textbook/figures/02a_5_rounding_floor.png‘
- ‘Revision/textbook/figures/02a_6_phase_portrait.png‘
- ‘Revision/textbook/figures/02a_7_energy_drift.png‘
- ‘Revision/textbook/figures/02a_8_richardson.png‘

It changes no other file of the repository; running it headless or saving it in JupyterLab also rewrites the notebook file itself. It does not use the internet while it runs. The files it writes are the same files that are stored in the repository (on another computer a figure may differ in a few bytes, which is harmless). To get the stored versions back, run this command in the repository folder (it also undoes every change you made yourself in the folder Revision/textbook):

Windows, macOS and Linux:

```
git checkout -- Revision/textbook
```

Every check of the notebook prints a line that starts with PASS. At the end of the notebook (the output of its last code cell) you must see exactly these lines:

```
PASS all 8 figure files of notebook 02a exist
ALL 29 CHECKS PASSED (notebook 02a)
```

and the notebook must show 8 figures below the cells that draw them.

Step 8. If something goes wrong.

- "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started

without the environment. Stop it (menu File > Shut Down), do Step 4, and start it again. If the error remains, another Python installation has registered its own kernel called python3; with the environment active, run the following command and start JupyterLab again:

    python -m ipykernel install --user --name python3

- "FileNotFoundError: The repository folder was not found": the notebook was opened from a copy outside the repository. Open the file ‘Revision/textbook/notebooks/02a_rk4_convergence.ipynb‘ inside the folder Dirac_claude.
- "fatal: destination path ’Dirac_claude’ already exists" in Step 3: the repository was downloaded before; skip the line with ‘git clone‘.
- Windows: "running scripts is disabled on this system": run the line with ‘Set-ExecutionPolicy‘ and then the activation line again. "py is not recognized": use ‘python‘ instead of ‘py -3‘; "python is not recognized": install Python again and tick "Add python.exe to PATH".
- Linux: "ensurepip is not available" when the environment is created: run ‘sudo apt install python3-venv‘ and repeat Step 3.
- "jupyter is not recognized" or "command not found: jupyter": the environment is not active; do Step 4. If the environment is active and the message stays, the programs jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for programs (‘python -m jupyter‘ does not help then: it has to find the same programs). Start them through Python itself, in the folder of the notebook: the first command below does what ‘jupyter lab‘ does, the second what the headless command does:

    python -m jupyterlab 02a_rk4_convergence.ipynb
    python -m nbconvert --execute --inplace 02a_rk4_convergence.ipynb

- Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event loop" and zmq: this is a message of the package pyzmq, not an error; the run continues normally.
- A red box with "Matplotlib is building the font cache; this may take a moment." in the first run after the installation: this is a message, not an error; the run continues and the message does not come again.
- An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel and Run All Cells; if it fails again, install the packages again with the pip commands of Step 3, because a different package version can change the last digits of a result.

The first code cell below (the set-up cell) repeats these instructions as comments; then it imports the packages, finds the repository folder and defines the helpers ‘save_figure‘ (saves a figure and shows it), ‘check‘ (stops with an AssertionError when a check fails, prints a PASS line when it passes), ‘report‘ (prints a key number as a RESULT line) and ‘all_checks_passed‘ (prints the last line).

In [1]:

```
# HOW TO RUN NOTEBOOK 02a (the complete instructions)
#
# STEP 1. WHAT THIS NOTEBOOK DOES AND WHAT IT NEEDS.
#
# Notebook 02a (Euler, midpoint and RK4: the order of a method on a log-log plot) is the
# file Revision/textbook/notebooks/02a_rk4_convergence.ipynb of the repository
# Dirac_claude. It solves two differential equations whose exact solutions are known, the
```

```
# decay equation (the deflation of an extra-time scale factor along a linear history) and
# the oscillator equation, with the Euler method, the midpoint method and the classical
# fourth-order Runge-Kutta method (RK4); it derives the exact amplification factor of
# each method with sympy, measures how the error at a fixed end time shrinks when the
# step is halved, finds the orders 1, 2 and 4 as slopes on log-log plots, shows where
# rounding errors stop the improvement, reads the step of the Revision Kohn-Sham solver
# (900 RK4 steps on an interval of length 3) from its record and predicts the error of
# each method at that step from the first missed term of the exponential series, predicts
# the energy drift of the oscillator exactly, and tests the Richardson estimate of the
# error. It needs a computer with Windows 11, macOS or Linux, an internet connection for
# the installation, the program Git, and Python 3.12 or newer (the notebooks were built
# with Python 3.14.5) with these packages at exactly these versions: numpy 2.4.6, sympy
# 1.14.0, mpmath 1.3.0, matplotlib 3.11.0, jupyterlab 4.4.10, nbformat 5.10.4, nbclient
# 0.10.2, ipykernel 7.1.0 and nbconvert 7.16.6. The notebook itself imports numpy, sympy
# and matplotlib; the other packages run Jupyter, the program that shows and runs
# notebooks. It does not need Rust.
#
# STEP 2. INSTALL GIT AND PYTHON (ONCE PER COMPUTER).
#
# A terminal is the window in which you type commands: on Windows the app Windows
# PowerShell (or Terminal), on macOS the app Terminal (it runs the shell zsh), on Linux
# any terminal (it runs the shell bash). Type every command of this section into a
# terminal exactly as printed, one line at a time, and press Enter after each line.
#
# Windows: download Git from https://git-scm.com/download/win and install it with the
# default choices. Download Python from https://www.python.org/downloads/ and run the
# installer; in its first window tick the box "Add python.exe to PATH" before you click
# "Install Now".
#
# macOS: download Python from https://www.python.org/downloads/ and run the installer.
# Then open the app Terminal and run this command, which installs Git and the compiler
# tools:
#
# macOS (zsh):
#     xcode-select --install
#
# Linux (Debian or Ubuntu; other distributions have packages of the same names): run
# these two commands:
#
# Linux (bash):
#     sudo apt update
#     sudo apt install git python3 python3-venv
#
# Then close the terminal and open a NEW one (a terminal opened before the installation
# does not know the new programs), and check the version of Python; it must print 3.12 or
# a higher number:
#
# Windows (PowerShell):
#     py -3 --version
#
# macOS (zsh) and Linux (bash):
#     python3 --version
#
# If an older Linux prints a lower number (Ubuntu 22.04 has Python 3.10), install Python
```

```
# 3.12 with the following three commands, and in Step 3 type python3.12 instead of
# python3 in the command that creates the environment:
#
# Linux (bash), only when the version is too low:
#     sudo add-apt-repository ppa:deadsnakes/ppa
#     sudo apt update
#     sudo apt install python3.12 python3.12-venv
#
# STEP 3. GET THE REPOSITORY AND INSTALL THE PACKAGES (ONCE PER COMPUTER).
#
# The commands below download the repository (a few hundred megabytes; the folder then
# needs up to about 1 GB of disk space) into the folder Dirac_claude inside your home
# folder, create a private Python environment in the folder dirac-book-env inside your
# home folder (a private environment is a folder with its own copy of Python and of the
# packages, so that nothing else on your computer is changed), activate it (from then on
# the commands python and jupyter typed in this terminal are those of the environment,
# and the prompt starts with (dirac-book-env)), and install the packages at the pinned
# versions (this downloads about 90 MB and takes a few minutes; the environment takes
# about 400 MB of disk space). If you have done this step before, for this or for another
# notebook, skip it and go to Step 4; to get the newest version of the repository, run
# git pull in the repository folder after Step 4.
#
# Windows (PowerShell):
#     cd $HOME
#     git clone https://github.com/once-ere/Dirac_claude.git
#     py -3 -m venv "$HOME\dirac-book-env"
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# The line with Set-ExecutionPolicy allows PowerShell to run the activation script in
# this one window only; it changes nothing permanently.
#
# macOS (zsh):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# Linux (bash):
#     cd ~
#     git clone https://github.com/once-ere/Dirac_claude.git
#     python3 -m venv ~/dirac-book-env
#     source ~/dirac-book-env/bin/activate
#     python -m pip install --upgrade pip
#     python -m pip install numpy==2.4.6 sympy==1.14.0 mpmath==1.3.0 matplotlib==3.11.0
#     python -m pip install jupyterlab==4.4.10 nbformat==5.10.4 nbclient==0.10.2
```

```
#     python -m pip install ipykernel==7.1.0 nbconvert==7.16.6
#
# STEP 4. IN EVERY NEW TERMINAL: ACTIVATE THE ENVIRONMENT AND GO INTO THE REPOSITORY
# FOLDER.
#
# Every later step starts in the repository folder with the environment active. Run these
# lines whenever you open a new terminal (they do no harm if the environment is already
# active):
#
# Windows (PowerShell):
#     Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope Process -Force
#     & "$HOME\dirac-book-env\Scripts\Activate.ps1"
#     cd "$HOME\Dirac_claude"
#
# macOS (zsh) and Linux (bash):
#     source ~/dirac-book-env/bin/activate
#     cd ~/Dirac_claude
#
# STEP 5. RUN THE NOTEBOOK IN JUPYTERLAB.
#
# In the repository folder, with the environment active, run these two lines (the first
# one goes into the folder of the notebooks):
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter lab 02a_rk4_convergence.ipynb
#
# JupyterLab opens in your web browser and shows the notebook (if no browser window
# opens, copy the address that starts with http://localhost:8888/lab from the terminal
# into the address bar of your browser). The name at the top right of the notebook must
# read Python 3 (ipykernel). Choose the menu Run > Run All Cells. While a cell runs, the
# label to its left shows [*]; when it has finished, the label shows a number. The
# notebook has finished when the last code cell shows a number; this takes about 10
# seconds on a typical laptop. Scroll to the end and compare the last printed lines with
# the lines in the step "What the notebook writes and what you must see" below. To keep
# the results, save the notebook (menu File > Save Notebook). To stop JupyterLab, choose
# the menu File > Shut Down, or press Ctrl+C twice in the terminal.
#
# STEP 6. OR RUN THE NOTEBOOK WITHOUT A BROWSER (HEADLESS).
#
# In the repository folder, with the environment active, run:
#
# Windows, macOS and Linux:
#     cd Revision/textbook/notebooks
#     jupyter nbconvert --to notebook --execute --inplace 02a_rk4_convergence.ipynb
#
# This runs every cell from the top to the bottom and saves the results into the notebook
# file. A failed check stops it with an error message that contains AssertionError and
# the name of the check. If the command ends with a line that starts with [NbConvertApp]
# Writing and shows no error, every check passed; open the notebook with jupyter lab
# 02a_rk4_convergence.ipynb (in the same folder, without running the cells again) to read
# the printed lines and see the figures.
#
# STEP 7. WHAT THE NOTEBOOK WRITES AND WHAT YOU MUST SEE.
```

```
#
# The notebook writes (or overwrites) these files:
#
# - Revision/textbook/figures/02a.captions.json
# - Revision/textbook/figures/02a_1_scale_factors.png
# - Revision/textbook/figures/02a_2_scale_factor_product.png
# - Revision/textbook/figures/02a_3_convergence_loglog.png
# - Revision/textbook/figures/02a_4_error_ratios.png
# - Revision/textbook/figures/02a_5_rounding_floor.png
# - Revision/textbook/figures/02a_6_phase_portrait.png
# - Revision/textbook/figures/02a_7_energy_drift.png
# - Revision/textbook/figures/02a_8_richardson.png
#
# It changes no other file of the repository; running it headless or saving it in
# JupyterLab also rewrites the notebook file itself. It does not use the internet while
# it runs. The files it writes are the same files that are stored in the repository (on
# another computer a figure may differ in a few bytes, which is harmless). To get the
# stored versions back, run this command in the repository folder (it also undoes every
# change you made yourself in the folder Revision/textbook):
#
# Windows, macOS and Linux:
#     git checkout -- Revision/textbook
#
# Every check of the notebook prints a line that starts with PASS. At the end of the
# notebook (the output of its last code cell) you must see exactly these lines:
#
#     PASS all 8 figure files of notebook 02a exist
#     ALL 29 CHECKS PASSED (notebook 02a)
#
# and the notebook must show 8 figures below the cells that draw them.
#
# STEP 8. IF SOMETHING GOES WRONG.
#
# - "ModuleNotFoundError: No module named ..." in the notebook: JupyterLab was started
#   without the environment. Stop it (menu File > Shut Down), do Step 4, and start it
#   again. If the error remains, another Python installation has registered its own
#   kernel called python3; with the environment active, run the following command and
#   start JupyterLab again:
#     python -m ipykernel install --user --name python3
# - "FileNotFoundError: The repository folder was not found": the notebook was opened
#   from a copy outside the repository. Open the file
#   Revision/textbook/notebooks/02a_rk4_convergence.ipynb inside the folder Dirac_claude.
# - "fatal: destination path 'Dirac_claude' already exists" in Step 3: the repository was
#   downloaded before; skip the line with git clone.
# - Windows: "running scripts is disabled on this system": run the line with
#   Set-ExecutionPolicy and then the activation line again. "py is not recognized": use
#   python instead of py -3; "python is not recognized": install Python again and tick
#   "Add python.exe to PATH".
# - Linux: "ensurepip is not available" when the environment is created: run sudo apt
#   install python3-venv and repeat Step 3.
# - "jupyter is not recognized" or "command not found: jupyter": the environment is not
#   active; do Step 4. If the environment is active and the message stays, the programs
#   jupyter-lab and jupyter-nbconvert are not in the folders where the terminal looks for
#   programs (python -m jupyter does not help then: it has to find the same programs).
```

```
#   Start them through Python itself, in the folder of the notebook: the first command
#   below does what jupyter lab does, the second what the headless command does:
#     python -m jupyterlab 02a_rk4_convergence.ipynb
#     python -m nbconvert --execute --inplace 02a_rk4_convergence.ipynb
# - Windows: the headless run prints a RuntimeWarning that mentions the "Proactor event
#   loop" and zmq: this is a message of the package pyzmq, not an error; the run
#   continues normally.
# - A red box with "Matplotlib is building the font cache; this may take a moment." in
#   the first run after the installation: this is a message, not an error; the run
#   continues and the message does not come again.
# - An AssertionError names a check that failed: choose the menu Kernel > Restart Kernel
#   and Run All Cells; if it fails again, install the packages again with the pip
#   commands of Step 3, because a different package version can change the last digits of
#   a result.
#
# ------------------------------------------------------------------------------------

## 3. The words used in this notebook

- **Derivative**: $y'(t) = dy/dt$ is the rate of change of $y$ at time $t$, the
  slope of the graph of $y$.
- **Ordinary differential equation (ODE)**: an equation $y' = f(t, y)$ that gives
  the rate of change of an unknown function $y(t)$ from $t$ and $y$ itself. Here
  $f$ is a known rule, the *right-hand side*.
- **Initial-value problem**: an ODE together with the starting value $y(0)$.
  Exactly one solution belongs to it (for the smooth $f$ of this notebook).
- **System of ODEs**: several unknown functions changing together, for example
  a position $x$ and a velocity $v$; $y$ is then a list (a *vector*) of numbers.
- **Step size** $h$: the time between two computed points; $N$ steps of size
  $h = T/N$ go from $t = 0$ to $t = T$.
- **Euler, midpoint, RK4**: three rules that compute the value after one step
  from the value before it (the formulas are in section 4).
- **Error**: the computed value minus the exact value (we print its size, the
  *absolute value*).
- **Order** $p$: a method has order $p$ when its error at a fixed end time is
```

```
  close to $C h^p$ for small $h$, with a number $C$ that does not depend on $h$.
  Halving $h$ then divides the error by $2^p$.
- **Logarithm, log-log plot**: $\log_{10} x$ is the power to which 10 must be
  raised to give $x$ ($\log_{10} 1000 = 3$). A log-log plot has both axes marked
  in powers of ten, so that $e = C h^p$ becomes the straight line
  $\log e = \log C + p \log h$ whose *slope* is $p$.
- **Rounding error, machine epsilon**: a computer stores about 16 significant
  digits of a number; every operation rounds its result. The spacing of the
  stored numbers near 1 is the machine epsilon $2^{-52} \approx 2.2 \times
  10^{-16}$.
- **Amplification factor** $R(z)$: for the test equation $y' = \lambda y$, one
  step of a method multiplies $y$ by a number $R(z)$ that depends only on
  $z = \lambda h$.
- **Phase portrait**: the curve traced by the point $(x, v)$ (position,
  velocity) as time goes on.
- **Richardson's rule**: an estimate of the error made from two computations with
  the step sizes $h$ and $h/2$.
```

Text cell:

```
## 4. The physical and mathematical situation

**The equations.** We solve two initial-value problems.

*Problem A (decay and growth).* $y' = -y$ with $y(0) = 1$. The exact solution is
$y(t) = e^{-t}$, because the derivative of $e^{-t}$ is $-e^{-t}$ and $e^{0} = 1$.
This equation describes the extra times of the author's metric. Lengths along the
three extra times $x_5, x_6, x_7$ carry the scale factor $e^{-a_4}\sin^{1/6}z$
and lengths along 3-space $x_1, x_2, x_3$ the factor $e^{a_4}\sin^{1/6}z$, where
$a_4(x_4)$ depends on the time $x_4$ and $z = 6 H x_0$ on the hidden coordinate.
Along the linear history $a_4 = A H x_4$, which the book uses as a prescribed
background (here $A = 1$ and $H = 1$), at a fixed hidden position the factor
$\sin^{1/6}z$ does not change with $x_4$, so we leave it out and follow
$b = e^{-x_4}$ and $a = e^{x_4}$. The extra-time factor obeys $db/dx_4 = -b$
(problem A with $t = x_4$: the extra times DEFLATE) and the 3-space factor obeys
$da/dx_4 = +a$ (3-space inflates). Their product $a b = e^{x_4} e^{-x_4} = 1$
never changes.

*Problem B (oscillation).* $d^2x/dt^2 = -x$ with $x(0) = 1$, $x'(0) = 0$. With the
velocity $v = x'$ it becomes a system of two first-order equations, $x' = v$ and
$v' = -x$. The exact solution is $x = \cos t$, $v = -\sin t$, and the energy
$E = (x^2 + v^2)/2$ stays exactly $1/2$, because $\cos^2 t + \sin^2 t = 1$.

**The three methods.** Write $y_n$ for the computed value at $t_n = n h$.

- Euler: $y_{n+1} = y_n + h f(t_n, y_n)$. It follows the slope at the start of
  the step for the whole step.
- Midpoint: $k_1 = f(t_n, y_n)$, $k_2 = f(t_n + h/2, y_n + (h/2) k_1)$,
  $y_{n+1} = y_n + h k_2$. It uses the slope at an estimated midpoint.
- RK4: $k_1 = f(t_n, y_n)$, $k_2 = f(t_n + h/2, y_n + (h/2) k_1)$,
  $k_3 = f(t_n + h/2, y_n + (h/2) k_2)$, $k_4 = f(t_n + h, y_n + h k_3)$,
  $y_{n+1} = y_n + (h/6)(k_1 + 2 k_2 + 2 k_3 + k_4)$. It averages four slopes
  with the weights $1 : 2 : 2 : 1$. RK4 is the method with which the Rust
```

```
  program of the Revision record solves the Kohn-Sham equations of this book
  (file Revision/kohn_sham/solver/src/shoot.rs); section 12 reads its number of
  steps from the record.

**Why Euler has order 1.** Taylor's theorem gives $y(t + h) = y(t) + h y'(t) +
\frac{1}{2} h^2 y''(s)$ for some $s$ between $t$ and $t + h$. Euler keeps the
first two terms, so one step makes an error of size about $\frac{1}{2} h^2
|y''|$. To reach the end time $T$ we need $N = T/h$ steps; $N$ errors of size
$h^2$ add up to about $N h^2 = T h$, proportional to $h^1$. The midpoint method
has order 2 and RK4 order 4; the amplification factors below show why.

**The amplification factor.** For $y' = \lambda y$ the exact solution after one
step is $e^{\lambda h} y_n = e^{z} y_n$, and $e^{z} = 1 + z + z^2/2 + z^3/6 +
z^4/24 + z^5/120 + \dots$ (the Taylor series of the exponential). We shall find
that Euler keeps the first 2 terms of this series, the midpoint method the first
3 and RK4 the first 5. The first term a method misses decides its order.
```

Text cell:

```
## 5. The colours, the three step rules and the solver

The next cell imports the packages, fixes the colours of the plots, and defines
the three step rules exactly as written in section 4. The rules use only
‘+‘, ‘-‘, ‘*‘ and ‘/‘, so the same function works with ordinary numbers, with
exact fractions, with sympy symbols and with numpy vectors. The function ‘solve‘
makes $n$ equal steps from $t = 0$ to $t = T$.
```

In [2]:

## 6. One step by hand, with exact fractions

We make ONE step of size $h = 1/2$ from $y(0) = 1$ for problem A ($y' = -y$).
With exact fractions the results are: Euler $1 - 1/2 = 1/2$; midpoint
$k_1 = -1$, $k_2 = -(1 - 1/4) = -3/4$, so $1 - 3/8 = 5/8$; RK4
$1 - 1/2 + 1/8 - 1/48 + 1/384 = 233/384$. The exact value is
```

```
$e^{-1/2} = 0.6065306597\dots$. The cell lets Python's `Fraction` do the same
arithmetic exactly and checks the three fractions.
```

In [3]:

```
h = Fraction(1, 2)  # the step size 1/2 as an exact fraction
one_step = {name: step(decay, 0, Fraction(1), h) for name, step in METHODS.items()}
for name, value in one_step.items():

midpoint  after one step: 5/8      = 0.6250000000
RK4       after one step: 233/384  = 0.6067708333
exact     e^(-1/2)                 = 0.6065306597
PASS one Euler step of y' = -y gives 1/2
PASS one midpoint step gives 5/8
PASS one RK4 step gives 233/384
```

Text cell:

```
## 7. The exact amplification factors

The next cell applies one step of each method to the test equation $y' = z y$
with the step $h = 1$, starting from $y = 1$, where $z$ is a sympy symbol. The
result is the amplification factor $R(z)$ as a polynomial in $z$. The checks
compare it with the first terms of the Taylor series of $e^{z}$, which sympy
computes with `sp.series`.

The oscillator (problem B) is the same test equation in disguise. Put
$w = x + i v$ with $i^2 = -1$. Then $w' = x' + i v' = v - i x = -i(x + i v) =
-i w$: the test equation with $\lambda = -i$, so one step multiplies $w$ by
$R(-ih)$. The energy is $E = (x^2 + v^2)/2 = |w|^2/2$, so one step multiplies
it by $|R(-ih)|^2 = R(-ih) R(ih)$ (the second factor is the complex conjugate of
the first, because the coefficients of $R$ are real numbers). The cell computes
these three polynomials in $h$ as well; we use them in section 13.
```

In [4]:

```
z = sp.symbols("z")  # z = lambda h
hs = sp.symbols("h", positive=True)  # a positive step size, as a symbol

def linear(t, y):
```

```

## 8. The inflating and the deflating scale factor

The next cell solves $da/dt = a$ (the 3-space factor $a = e^{t}$) and
$db/dt = -b$ (the extra-time factor $b = e^{-t}$) from $t = 0$ to $t = 2$ with
the coarse step $h = 0.25$ (8 steps), by Euler and by RK4, and draws them with
the exact curves. Euler multiplies by $1 + h = 1.25$ and by $1 - h = 0.75$ per
step, so after 8 steps it gives $1.25^8$ and $0.75^8$; the checks confirm this.
```

In [5]:

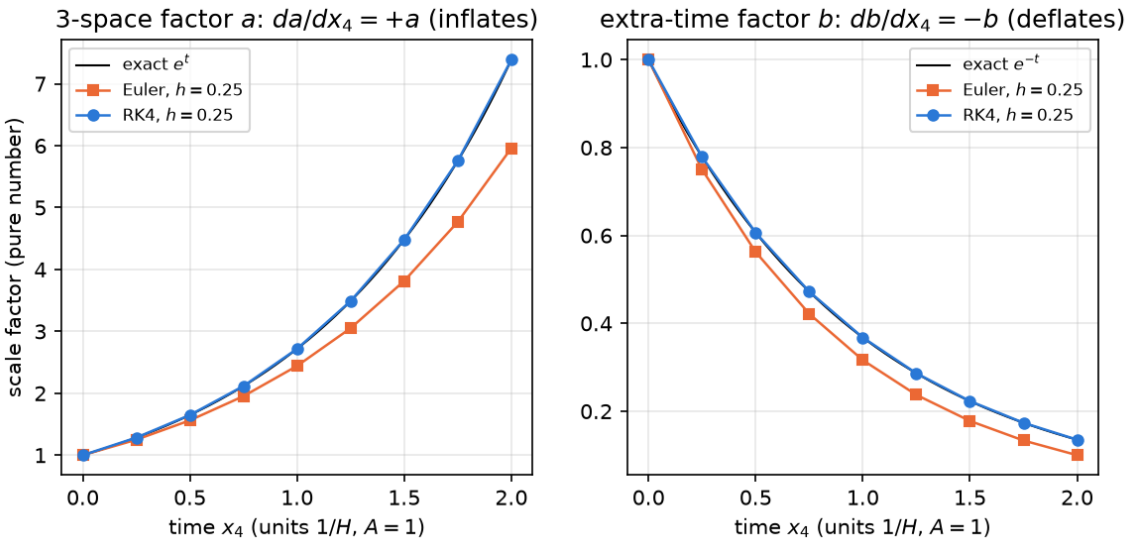

Figure 62: Left: the 3-space scale factor $a = e^{x_4}$, which obeys $da/dx_4 = a$; right: the extra-time scale factor $b = e^{-x_4}$, which obeys $db/dx_4 = -b$, along the linear history $a_4 = AHx_4$ with $A = H = 1$ at a fixed hidden position. Horizontal axis the time x_4 in units of $1/H$, vertical axis the scale factor (a pure number). Black: the exact curves; squares: Euler with the step $h = 0.25$; circles: RK4 with the same step. Euler falls behind the growing curve and decays too fast; RK4 lies on both exact curves. (Notebook 02a, figure 1.)

```
direction. A numerical method multiplies $a$ by $R(h)$ and $b$ by $R(-h)$ per
step, so it multiplies the product by $R(h) R(-h)$. For Euler that is
$(1 + h)(1 - h) = 1 - h^2$: the product shrinks by the factor $1 - h^2$ at every
step, however long we compute. For RK4 the cell lets sympy multiply out
$R(h) R(-h)$: the terms with $h$, $h^2$, $h^3$, $h^4$ and $h^5$ all cancel and
$1 + h^6/72 + h^8/576$ remains, which is much closer to $1$. The left panel of
the figure shows the product itself, the right panel its distance from $1$ on a
logarithmic scale, where both methods can be seen.
```

In [6]:

```
PRODUCT_FACTOR = {name: sp.expand(R[name].subs(z, hs) * R[name].subs(z, -hs))
                  for name in ("euler", "rk4")}
for name, factor in PRODUCT_FACTOR.items():
    say(f"factor of a b per step, {LABELS[name]:5}: {factor}")
check(PRODUCT_FACTOR["euler"] == 1 - hs ** 2
